## Discussion

In a previous Malaysian study on acute diarrhoea, young adults had the highest incidence of acute diarrhoea while children of under five years had a slightly lower incidence <sup>6</sup>. This may be due to their active lifestyle and tendency to be eating outside rather than at home. Meanwhile, in a cross-sectional study among 274 children aged 12–59 months in low socioeconomic city areas of East Jakarta, it was shown that the possibility of getting diarrhoea was amplified in children aged less than 2 years old, and they were more susceptible if they had mothers with poor food hygiene practices, and the risk was extremely high during the weaning period <sup>7</sup> food preparation, cleanliness of utensils, water source and safe drinking water, habits of buying cooked food, child's bottle feeding hygiene, and housing and environmental

condition were collected through home visit interviews and observations by fieldworkers. Thirty-six practices were scored and classified into poor (median and below). The most common age in most diarrhoea studies in children was 6 to 11 months, which can be due to tainted weaning sustenance. Furthermore, crawling begins at this time and the hazard of ingesting tainted materials may cause diarrhoea. However the risk declines after 6 to 11 months; most likely due to strengthened immunity after repeated exposure to pathogens <sup>8</sup>.

There is a high incidence of poverty in rural and urban Sabah as well as in rural Sarawak. Various method for measurement were used, with almost similar findings <sup>9</sup>. In most underdeveloped nations the prevalence of diarrhoea was found to be higher among rural children than among urban children. This could be due to

inadequate access to clean, safe water and sanitation infrastructures in the rural areas<sup>8</sup>. Socioeconomic status and parental care also play a part. Single motherhood is an important risk factor for children's nutritional status and survival before the age of 5 years. It puts a family at disadvantage, especially in terms of the child's health and survival chances but could be reduced when these mothers have access to a better economy, improvements in parental help and healthy behaviour. This could come in the form of welfare benefits and other family-based interventions. Interventions that focuses on single mother families may help reduce under-5 mortality<sup>10</sup>.

Our study findings of Pribumi Sabah as the ethnic group with the highest number of acute diarrhoea cases echoes similar findings from other studies<sup>6</sup>. As we know, sociocultural status does play a part in foodborne illness<sup>11</sup>. In terms of ethnicity, Malaysia is regarded as a diverse, multi-ethnic country. The government is trying to close the gap by relocating the deprived groups to new settlements at the fringe of towns<sup>12</sup>. In other countries like Nepal, ethnicity is found in relation to caste, adding to customary social class categories. Some ethnic groups are usually underprivileged. The underprivileged are at a disadvantage in terms of socioeconomic status<sup>13</sup>. It is important for ethnicity data be included in studies, as this data can contribute to analysis of social and economic disparities. Ethnicity is related to a range of other cultural, demographic, socioeconomic, and ecological variables<sup>14</sup>.

In a cross-sectional study done in Ethiopia on 768 households, it was found that children who were partly receiving breast milk were twice more likely to get diarrhoea compared to those exclusively receiving breast milk. The risk was three times higher for those who received less than 1-year duration of breastfeeding. During this period there is inborn immunity and less exposure to pathogens. Once the child has lost inborn immunity, starts to wean, and is exposed to various pathogens from eating contaminated food, diarrhoeal cases will start to increase<sup>15</sup>. Interventions such as exclusive breastfeeding, continuation of breastfeeding until 24 months of age, complementary feeding to improve nutrition, along with improved sanitation, are positive ways to influence the prevention and outcome of diarrhoea. There is also recommendation for routine zinc supplements in managing childhood diarrhoea, but it is not currently practiced in many countries<sup>16</sup>. Breastfeeding is vital and it should be continued even during diarrhoeal episode<sup>17</sup> the objective of this study

was to examine household management of childhood diarrhoea. A simple random sample of households was selected from the Health and Demographic Surveillance Site-León. Parents or caretakers of children below five years of age, who developed diarrhoea (n = 232. In addition, special health education programs should cater for mothers or caretakers to promote proper feeding practices, in consideration of nutritional status according to standard policies<sup>18</sup>.

Households that are located adjacent to drainage openings are likely to experience diarrhoea because of waste collection that carry diarrhoea pathogens<sup>19</sup>. In managing daily waste, some households either tend to keep their trash bins in the house or around the perimeter of their homes. Trash bins that are not covered tend to draw houseflies. Food may be contaminated by these flies through the action of poor waste handling, and this may thus increase the incidence of diarrhoea in children<sup>20</sup>. Open disposals are also breeding site for insects, which may carry diarrhoea pathogens to water and food<sup>8</sup>.

There is a strong relationship between diarrhoea infections and climate<sup>7</sup> food preparation, cleanliness of utensils, water source and safe drinking water, habits of buying cooked food, child's bottle feeding hygiene, and housing and environmental condition were collected through home visit interviews and observations by fieldworkers. Thirty-six practices were scored and classified into poor (median and below. A study in Congo which used 20 years of historical data on temperature and rainfall found that increased rainfall indirectly promotes an increase in new cholera cases which causes acute diarrhoea. A reduction in cholera cases could be seen when there is an increase in average temperature that promotes a reduction in rainfall<sup>21</sup>.

## Conclusion

The significant factors elicited in this study shows the need to improve the overall hygiene and sanitation in the affected areas. A long-term plan in developing these necessities would surely benefit the population and elevate in general the status of public health in the region.

# Effect of Visfatin on Insulin Resistance in Non-Obese Adolescents

Thidarat Somdee<sup>1</sup>, Suneerat Yangyuen<sup>1</sup>, Suvimol Sungkamanee<sup>2</sup>, Udomsak Mahaweerawat<sup>3</sup>

<sup>1</sup>Assistant Professor, <sup>2</sup>Lecturer, <sup>3</sup>Associate Professor, Faculty of Public Health, Mahasarakham University, Mahasarakham, Thailand

## Abstract

**Background:** Evidence base indicate that insulin resistance (IR) is common among adolescents and related to Diabetes Mellitus (DM). The serum visfatin is adipocytokine derived from visceral fat that may represent a novel IR of metabolic syndrome include DM type II. Therefore, it is necessary to determine the role of serum visfatin and IR in non-obese adolescent. Also this role could help to illustrated more effective early detection for DM type II in non-obese adolescents.

**Objective:** The current study aimed to evaluate serum visfatin and IR in non-obese adolescents and determine its association.

**Method:** In cross-sectional study we recruited 155 normal weights between aged 13-18 years. Laboratory measurements were included triglyceride, fasting blood sugar, insulin and visfatin, also IR index calculated by homeostasis model assessment (HOMA). Anthropometric measurements were included height, weight, bicep and tricep skinfold thickness.

**Results:** Most of subjects were girl 114 (73.55 %). The mean of serum visfatin level was 57.72 ng/ml (range: 0.26-876.2 ng/ml) and HOMA level was 2.26 (range: 0.13-13.4). Non-obese adolescents were found IR. Serum visfatin was not statistical significant with IR ( $OR_{adj} = 3.23$  (95%CI: 0.84–12.45),  $p = 0.098$ ). All lipid profile (bicep, tricep skin fold thickness and triglyceride) were not affected to IR in non-obese adolescent.

**Conclusions:** Serum visfatin in non-obese adolescent is independent to IR. IR usually occurred with obese adolescent, but in this study also occurs with non-obese. The key point is lipid profile does not affect to IR status.

**Keyword:** *Visfatin, insulin resistance, non-obese, adolescent, homeostasis model assessment.*

## Introduction

The increasing of insulin resistance (IR) is an important problem during adolescent. Also, adolescent is associated with decreased sensitivity to insulin.<sup>(1,2)</sup> Furthermore the IR appears to be associated with an increased risk factors of metabolic syndrome especially Diabetes Mellitus (DM) type II.<sup>(1,2)</sup> IR as well as insulin

deficiency have been shown to be strong predictors in the future development of DM type II.<sup>(3-5)</sup> A clear definition of normal physiologic changes in IR that occur during puberty is necessary before an etiologic association between IR and metabolic syndrome can be considered in this age-group.<sup>(6-8)</sup> Hence research about IR in adolescent is paramount importance in preventing DM type II related mortality and morbidity in adults.<sup>(9,10)</sup>

Visfatin, is an adipocytokine that was highly expressed in visceral fat and was originally isolated as a secreted factor that synergizes with interleukin-7.<sup>(11)</sup> Visfatin is proposed as significant pro-inflammatory mediators, which also interfere with the regulation of insulin sensitivity.<sup>(12)</sup> Visfatin directly binds to and stimulates the insulin receptor, exerting insulin-

e-mail: ttoxic@windowlive.com

mimetic affects in vitro and in vivo.<sup>(13)</sup> In addition, some research reported that visfatin is pro-inflammatory in the pathogenesis of beta-thalassemia major and its association with markers of endothelial function.<sup>(14)</sup> So, visfatin may be found in diseases not associated with obesity.

An initial study showed that IR and visfatin, as a significant positive association with total fat mass and body mass index (BMI), especially focus on obesity children and adolescent.<sup>(15,16)</sup> It was found that serum visfatin was markedly elevated in obesity (17), and obesity induces IR by fat tissue.<sup>(18)</sup> Furthermore, some recently research found that IR is high prevalence in South-Asian adolescents with normal BMI.<sup>(19)</sup> Since the hypothesis to describe the pathology of IR can find in normal weight<sup>(20)</sup> In addition, newly identify cutoff points of HOMA established in adolescents for the diagnosis of IR, which use of the HOMA cutoff > 2.5 for both genders.<sup>(21)</sup>

Although, a study between visfatin and metabolic syndrome parameters, such as IR in obese adolescent has recently been undertaken. However the association between visfatin level and IR in normal weight adolescents have not been investigated. In this study, we aimed to evaluate serum visfatin and IR, and associations between serum visfatin and IR in normal weight adolescents.

## Materials and Method

**Design study and sample:** The cross-sectional study in non-obese adolescents aged 13-18 years. The inclusion criteria included adolescent with normal weight as per International Obesity Taskforce (IOTF) criteria.<sup>(22)</sup> The exclusion criteria included subjects with diagnosed diabetes mellitus or taking metformin or any weight reducing drugs, subjects with any known systemic illness or endocrine or metabolic disorders, known to be associated with obesity, or subjects with symptoms to suggest hypothalamic obesity were excluded from the study. A total of 155 non-obese adolescent were recruited from 5 of 18 high schools in Mahasarakham province, Northeast Thailand. Informed consent was obtained from the adolescent and their parents before launching the study. The research protocol was approved by the ethical committee of Mahasarakham University.

**Anthropometry:** The weight of individual dressed in light clothing was measured using a carefully calibrated beam balance (Detecto®). Height measurement was

taken by means of a vertical measuring rod. BMI in kilogram divided by height in square meter was calculated for each subject. Standard techniques were applied in measuring of triceps and biceps skin fold thickness.

**Laboratory determination:** Blood samples were collected about 10 mL from individual subject that was taken in the morning after an overnight fast. All of blood samples were immediately processed in divide into aliquots and stored at -80°C until further determination. For triglycerides levels were determined using a commercially available test kit that obtained from Siemens Healthcare Diagnostic Inc. An enzymatic test was applied for measuring plasma glucose level by a test kit from Dade Behring Inc. Serum insulin was assessed by a commercially available radioimmunoassay test from Linco Research, Inc. The HOMA calculation was applied the formula fasting insulin (mU L<sup>-1</sup>) x fasting glucose (mmol L<sup>-1</sup>) divided by 22.5.<sup>(23, 24)</sup> A commercially available radioimmunoassay test was used to determine serum visfatin levels (LINCO Research, Inc, St., Charles, Missouri, USA). The cut-off point of serum visfatin for DM which was 9.55 ng/ml.<sup>(25)</sup>

**Statistical analysis:** The data were analyzed using Stata version 13.0. Continuous variables were expressed as minimum, maximum, standard deviation (SD) and median. Categorical variables were expressed as number and percentage. The associations of serum visfatin and IR, and the factors associated with IR were using multiple logistic regression analysis. A p-value < 0.05 was considered statistically significant. The classification of IR and non-IR group divided by HOMA cutoff > 2.5.<sup>(21)</sup>

## Results

**Demographic Characteristics:** The 155 subjects non-obese adolescent were recruited in this study. The demographic, anthropometry and laboratory data showed that the ratio of boy and girl are 41/114. The serum levels of visfatin, insulin and fasting blood sugar were 57.72 (0.26-876.2) ng/mL, 19.05 (4.50: 143.9) mU/L and 87.57 (72-126) mg/mL, respectively. As, average value of HOMA was found 2.6 in non-obese adolescent. IR subject was 34.84 percentages and HOMA levels were showed higher than non-IR (1.71 vs. 3.18,  $P < 0.05$ ). The serum visfatin levels were found to be elevated in IR group (15.63 vs. 38.62 ng/mL,  $P < 0.05$ ).

**The effect between visfatin and other variables, with IR in non-obese adolescent:** The variables effected with IR in non-obese adolescent included visfatin,

gender, bicep, tricep skinfold thickness and triglyceride (shown in Table 1). All of 155 subjects found that subject with IR was 34.84%. The effect between visfatin and IR from univariate analysis using simple logistic regression was not statistical significance (OR=3.44 (95%CI: 0.96–12.31), p=0.034).

The results of the multiple logistic regression analysis showed that after controlling for gender, bicep skinfold thickness, tricep skinfold thickness and triglyceride, merely the OR of visfatin (OR<sub>adj</sub>= 3.23 (95%CI: 0.84–12.45), p = 0.098) was not significant. Furthermore the research found that tricep skinfold thickness (OR<sub>adj</sub>= 1.05 (95%CI: 0.99–1.11), p=0.072) was likely to affect with IR. Therefore, serum visfatin is independent to IR in non-obese adoles-cent.

### Discussions

In the present study, it has been reported that 1) serum visfatin is independent to IR in non-obese adolescent 2) all lipid profile are independent to IR in non-obese adolescent and 3) some adolescents with IR are non-obese.

These finding displayed that visfatin is independent with IR in non-obese adolescents. The previous knowledge explained that serum visfatin level which is activated in obesity, is correlated with BMI, and HDL-c in obese adolescents. (15) Visfatin is highly enriched in the visceral fat and bind to insulin receptor.(13) Although, some research reported high visfatin level was occurred with non-obese, it did not found in this study. However,

visfatin was not marker role of metabolic syndrome development in normal weight adolescent that support by Oki *et al.* (26) found that serum visfatin is not correlated with IR and suggested that the serum visfatin are not associated with parameters of body composition or IR.(26) Other results we found that 34.84% of subjects was IR. So indicated that during puberty in children develop a transient state of IR. It is speculated that this physiologic, rather than pathologic, state of IR may allow for the accelerated growth that occurs during pubertal maturation.(16) And new research in 2016 is so interesting they found that low-birth-weight was correlated with insulin resistance at 12 months in non-obese infants. (27) Seem from some review revealed that high and low birth weights and followed by rapid postnatal growth were linked to increased risks of obesity, insulin resistance and high blood pressure in later life. (28) Thus, low-birth-weight may affect to IR status in non-obese adolescent.

Our finding that non-obese adolescent with IR and corresponding with Baba *et al.* (20) found that non-obese adolescents with impaired insulin sensitivity had higher systolic blood pressure and IR is associated with cardiovascular risk factors. However, IR in non-obese adolescent may utility for prevents them from developing real metabolic syndrome in the future.

Some limitations of this study need to be regarded, which we used a cross-sectional study for our design. Cross-sectional study provide information at a single point in time, cannot explain the cause and effect relationship of variables.

**Table 1: Odds ratios (ORs) of having IR and their 95% confidence intervals for visfatin and each factor adjusted for all other factors**

Variable	Number	% IR	Crude OR	Adjust OR	95%CI	p-value

## Conclusions

This study shown that the visfatin in non-obese adolescent is independent to IR, and IR can found in non-obese adolescent. Further investigation is needed to determine tricep skinfold thickness level in non-obese adolescent for approach of clinicians toward prevention IR in future.

# ***Escherichia Coli* in *Musca Domestica* Flies toward the Incidence of Diarrhoea in Children Under Five Years in around the Location of Traditional Fish Processing in the North Jakarta**

Uli Rohati Siregar<sup>1</sup>, Dewi Susanna<sup>2</sup>

<sup>1</sup>Postgraduate Student in Master of Public Health, <sup>2</sup>Lecturer, Department of Environmental Health, Faculty of Public Health, Universitas Indonesia, Depok, Jawa Barat 16424, Indonesia

## **Abstract**

Poor environmental sanitation can cause diarrhoea. Transmission of diarrhoea can occur with faecal to oral transmission. For example, faeces that contain bacteria, viruses, protozoa and worms transferred to food or drinks either with zoonotic or anthroponotic cycles depending on the pathogen. Faecal to oral transmission in infectious diarrhoea carried out by an intermediary zoonotic cycle has considered the insect fly as a potential mechanical agent for the transmission of diarrhoeal disease. This study aims to assess the relationship of *Escherichia coli* (*E. coli*) in *Musca domestica* flies to the incidence of diarrhoea in children under five in a residential area around a traditional fish processing location in North Jakarta. This research used a cross-sectional design; the study conducted from May to June 2019. The study population was children under-fives with a total sample of 97 respondents. Interviews and observations were carried out on mothers of children under-fives as respondents about characteristics of children under-fives, mothers and basic sanitation factors. The study also was done by measuring the density of flies using the Scudder technique with the Fly Grill tool. The existence of *E. coli* measured by examining samples of *Musca domestica* flies caught by the Most Probable Number (MPN) technique. There were significant results by statistical testing for independent variables, which are high levels of fly density, incomplete childhood immunization, maternal education, basic sanitation factors that did not include eligible for clean water supply facilities, household waste disposal, wastewater management, and drinking water sources. Bivariate analysis revealed that there was a significant relationship in positive *E. coli* sample of *Musca domestica* flies to diarrhoea in infants with p-value=0,007. While non-exclusive breastfeeding and family toilet that did not eligible significantly related to the incidence of children under five diarrhoea in the region.

**Keywords:** *Diarrhoea; E. coli; children under five; flies; sanitation, North Jakarta.*

## **Introduction**

Until now, diarrhoea is an environmental-based disease that is still a problem in the world, especially in developing countries. It is the second leading

cause of death in the world after pneumonia<sup>[1][2]</sup>, causing morbidity and mortality in all regions and ages<sup>[3][4][5]</sup>. WHO and UNICEF, say around 2 billion cases of diarrhoea occur worldwide every year, as many as 1.9 million attack children aged younger than five years, even causing death. Developing countries are the countries with the most cases<sup>[1][6]</sup>. In Indonesia, diarrhoeal disease is still a health problem in the community. The spread of diarrhoea can be through contaminated food/drinks, or from person to person as a result of poor sanitation. The magnitude of the number of incidents in infants is due to the vulnerability of infants the immunity that is still weak so it is easier to cause

fluid loss<sup>[8][9][10]</sup>. Poor environmental sanitation can also cause diarrhoea. Transmission of diarrhoea can occur by faecal to oral transmission, where diarrhoea occurs due to contamination of food drinks by poor environmental sanitation, for example, due to faeces containing bacteria, viruses, protozoa and worms transferred to food or drinks both with zoonotic and or anthroponotic cycles depending on the pathogen<sup>[11]</sup>. Faecal to oral transmission in infectious diarrhoea carried out by an intermediary zoonotic cycle has considered the insect fly as a potential mechanical agent for the transmission of diarrhoeal disease.<sup>[12][13][14]</sup>

The location of traditional fish processing in North Jakarta is a place for processing various types of fish that traditionally done. The processing location is not far from residential areas. Based on data from health service facilities in the region the incidence of diarrhoea ranks second out of the ten most extensive types of diseases in the region. Diarrhoea attacks many children under-fives in the area. It suspected that the cause of diarrhoea is due to a large amount of garbage that causes the density of flies. The ability of flies as a mechanical vector can carry pathogenic agents that cause diarrhoea, especially *E. coli*. Based on the above background, researchers are interested in examining the relationship of the presence of *E. coli* in the *Musca domestica* flies to the incidence of children under five diarrhoea in a residential area around a traditional fish processing location in Jakarta. This study aimed to analyze the relationship between the presence of *E. coli* in *Musca domestica* flies and the incidence of children under five diarrhoea around traditional fish processing locations in North Jakarta.

### Method

The study design uses a quantitative approach to a cross-sectional study design. The study population was mothers who have children under five. The sample size of this study obtained through the calculation of the proportion <sup>[15]</sup> binomial formula with the results of 97 mothers. The sample selection uses a multi-stage sampling technique with a simple random sampling method. Interviews and observations were carried out with a questionnaire. The measurement of the density of the respondent’s house flies was done inside the house as many as five points and outside the house of the respondent as many as five points using the Scudder technique using the Fly grill, Thermo hygrometer, hand counter, and stopwatch. The sampling of *Musca domestica* flies carried out after measurements taken. Identification of the presence of *E. coli* in flies was carried out using the Most Probable Number (MPN) technique. Data analysis performed with the chi-square test ( $X^2$ ) with a value of  $p \leq 0.05$ . The interpretation of fly density on the fly grill is 0-2: low and >2: high/dense. The dependent variable of this study is the incidence of diarrhoea in children under five with independent variables of the presence of *E. coli* in *Musca domestica* flies, as well as covariable levels of fly density, children under five factors exclusive breastfeeding and completeness of immunization, maternal factors in the form of education level and basic sanitation factors such as clean water supply facilities, management of household garbage, sewage disposal, faeces disposal and drinking water sources for children under-fives.

### Results

The results of the bivariate analysis can be illustrated in the table below (Table. 1)

**Table 1. Bivariate analysis between Laboratory Results, Flies density, Exclusive breastfeeding, Complete Immunization, Mother’s Education, Water supply facilities, Waste processing facilities, Family toilet facilities, Wastewater disposal facilities, Children under five’s drinking water facilities to *E. coli* in *Musca domestica* flies to the incidence of children under five diarrhoea in a residential area around traditional fish processing locations in North Jakarta**

## Discussion

*E. coli* is known as the lower intestine inhabitants of warm-blooded animal channels, including humans, and often discharged into the environment through faeces<sup>[16][17]</sup>. *E. coli* bacteria in faeces can move to water or food with the help or through animal contact (faecal to oral). Flies can carry *E. coli* obtained from rubbish, household waste and other sources of sewage and then transmitted from the mouth through vomit drops, faeces and other body parts. *E. coli* can be carried by flies on the exoskeleton, legs, in the mouth and the intestinal tract<sup>[18]</sup>. Proboscis and the six feet of the fly equipped with fine hairs and the feet release sticky fluid making the fly easily carry the pathogen *E. coli*<sup>[19]</sup>. The results of laboratory tests conducted of 97 samples of flies from the respondent's house were found as many as 29 samples found positive *E. coli* (29.9%) and 68 negative samples of *E. coli* (70.1%).

The high density of flies has a significant relationship to the occurrence of diarrhoea in infants, has a potential of 26,571 times the risk of causing diarrhoea in infants. This study is in line with the study of Manalu et al. (2012) that there is a significant relationship between high fly density and the incidence of diarrhoea in infants living around the Namo Bintang Garbage Landfill. Flies are one of the Diptera orders that are closed to human settlements and can affect public health<sup>[20]</sup>; the population is very high. The morphology of the body of a small fly the ability to fly away, as well as a short life cycle, and includes omnivorous animals (all-eaters). Besides that, this insect also has high reproductive power and is a multivoltine (several generations in one year)<sup>[20]</sup>. Fly control has been linked to diarrhoea prevention. Efforts to reduce the population of *Musca domestica* is by vector control including physical, chemical and biological control which is carried out comprehensively by improving environmental cleanliness in settlements.

Diarrhoea caused by pathogenic germ transmission is oral-faecal. Risk factors for the spread of this disease are the means of disposal of faeces that do not meet the requirements and the process of washing hands that are not good after defecation and contact with faeces before processing food. Bandages (diapers) thrown directly into the trash, invites the arrival of flies. The habit of flies looking for food in dirty places causes bacterial germs to stick to the body and the hairs of their feet so that germs carried by flies can pollute food and cause pain.

Clean water supply facilities, waste management facilities, wastewater disposal facilities, and drinking water sources have a significant relationship with the incidence of children under five diarrhoea. Wastewater disposal has a significant relationship with the incidence of children under five diarrhoea. This study is in line with Hariyanto (2015) that there is a significant relationship between waste management and the incidence of diarrhoea in Bogor Regency ( $p=0,000$ ). The study is also in line with Wilar (2017) stating that there is a significant relationship between waste disposal facilities and the incidence of diarrhoea in infants in the Banggai Community Health Center in Banggai Lau Regency. Household waste is rubbish generated from daily activities in the household that do not include faeces. Trash is a source of diseases such as breeding grounds for flies, mice and cockroaches. Garbage can invite flies to perch for food and lay eggs in a pile of garbage. The flies then fly and descend the food so that the food can be contaminated with germs carried by flies. Based on the behaviour of flies, at the adult stage the fly chooses a habitat with much organic material that is undergoing decomposition, for example, organic waste that is wet and during the day the fly rests on the edge of the food and electric wire.

The presence of *E. coli* in the *Musca domestica* house fly has a significant relationship with the incidence of children under five diarrhoea. This relationship is in line with research conducted by Venti in Surabaya, which states that *E. coli*, Salmonella, Shigella and Staphylococcus found in *Musca domestica*. Nevertheless, of the three flies, *Musca domestica* is a species that has more potential as a mechanical vector of the disease caused<sup>[21]</sup>. The same thing was also expressed by Putri in her research that, bacteria found in the body of flies divided into six isolates, including genus Salmonella, Providencia, Escherichia and Vibrio<sup>[22]</sup>.

## Conclusion

The variables that show a significant relationship to the incidence of diarrhoea under five years are positive *E. coli* examination results on *Musca domestica* flies, fly density, education, complete immunization status, clean water supply facilities, household waste management facilities, water disposal facilities waste, and sources of drinking water for children under-fives at the location. Efforts made between related agencies jointly carry out inspection and supervision of clean and healthy environmental conditions in the region, especially regarding basic sanitation conditions in addition to increasing public knowledge of the importance of clean and healthy living behaviour by carrying out health promotion activities. It is recommended to collect, sort waste and dispose of garbage every day in a place that does not pollute the environment.

**Funding Information:** This study is funded by International Indexed Publication for Student's Grant (PITTA Grant) University of Indonesia 2019.

**Ethical Clearance:** The number of ethical approval is made by the Ethical Research Committee provided in this study, which is Ethical Research Commission and Community Service Faculty of Public Health University of Indonesia. The number is 461/UN2.F10/PPM.00.02/2019 valid thru April 2020

# Effects of Benzene Exposure on Respiratory Symptoms to Workers in the Informal Footwear Industry

Ummyatul Hajrah<sup>1</sup>, Agustin Kusumayati<sup>2</sup>, Ema Hermawati<sup>2</sup>

<sup>1</sup>Department of Environmental Health, Faculty of Public Health, University of Indonesia, Depok,

<sup>2</sup>Faculty of Public Health, Universitas Indonesia, Depok

## Abstract

**Background:** Benzene is a volatile organic solvent. Benzene has been designated as a carcinogen in humans or a cause of cancer by the International Agency for Research on Cancer. The entry of organic solvent vapors into the body can cause various main reactions in the respiratory tract. The purpose of this study was to determine the relationship between benzene exposure intake and respiratory symptoms. Displace to method, here in abstract.

**Method:** This type of research used cross-sectional design and risk assessment approach. It is conducted in four footwear workshops in Bogor, West Java, during September 2017. This study involved 96 footwear workers.

**Results:** The most symptoms experienced were cough 50% they were quickly tired or tightness during activity 39.6%, sore throat 33.3%, runny nose 31.3%, issued phlegm or reak 18.8%, shortness of breath 14.6%, snorting nouse 6.3%. The result of the risk assessment was 11.5% of workers had real time non-cancer risk as well as 21.9% of workers who had cancer risk.

**Conclusion:** There was no correlation between non-carcinogen intakes, carcinogen intakes and respiratory symptoms ( $p$  value > 0.05). The findings suggest vigilance against the risk of continuous benzene exposure because it can trigger symptoms of carcinogens or non carcinogens.

**Keywords:** *Benzene exposure intake, respiratory symptoms, risk assessment.*

## Introduction

In Indonesia, industrial development is progressing along with the demands of various product needs. To meet these needs, many large and small scale industries have been established, such as the home industry of Small and Medium Enterprises (SMEs). SMEs have

a very important role as a strong and flexible group, and still persist to contribute to the national economy significantly<sup>(1)</sup>. The Ministry of Industry noted the creation of foreign exchange by the footwear industry amounted to USD 4.11 billion or 2.33% of total national exports in 2014, indicating that the footwear industry has the opportunity to continue to increase exports<sup>(2)</sup>. The footwear industry is one of the labor-intensive export commodities where the success of the craftsmen to maintain the presence of the products produced is often not matched by adequate health protection for the risk of their work related to dangerous equipment and materials. Long hours worked and not supported by the required working conditions, often forcing manufacturers to work with fewer ergonomic body positions so they are vulnerable to injury.

---

### Corresponding Author:

Faculty, Universitas Indonesia

e-mail: ema\_her@ui.ac.id

In addition, 70-80% of the workforce engaged in the informal sector generally work in an unfavorable work environment, not organized and the level of welfare is low<sup>(3)</sup>. Studies<sup>(4)(5)(6)</sup> show estimates of carcinogenic and non-carcinogenic health risks due to the exposure of benzene in the process of making primary shoes in the use of glue, because in the process, exposure to organic solvent vapors, especially the benzene contained in the glue can allow health effects if inhaled continuously.

Air pollution in the footwear manufacturing industry has been reported to worsen respiratory and lung function disorders especially in workers who have a long duration of organic solvent exposure<sup>(7)</sup>. The existence of organic solvents which its use is still widespread, especially in the informal sector, is a challenge to public health. There needs to be ongoing monitoring that can be done through a risk assessment to anticipate the effects that can be caused. This study aims to determine the effect of benzene exposure intake on respiratory symptoms.

### Materials and Method

This study was used a cross-sectional study design to describe the effects of individual health due to benzene exposure and risk analysis approaches to obtain benzene exposure intake and risk assessment<sup>(8)(9)(10)</sup>.

This study involved 96 workers and sampling was carried out using a purposive sampling method. The location of the study was conducted in 4 home footwear industry in Bogor, West Java, in September 2017. The data was processed and presented through a descriptive analysis, Chi square analysis was used to identify the association between carcinogen intake, non carcinogen intake and symptoms of respiratory disorder.

Determining the sample of workers was used by purposive sampling method because the study population in general has characteristics, demographics, socio-economic and certain types of activities. Especially workers in the footwear industry. The calculations of the risk assessment was used by microsoft excel application.

### Findings:

**Symptoms of Respiratory Disorder:** The most symptoms experienced were cough (50%), following sequentially according to their presentation they were quickly tired/tightness during activity (39.6%), sore throat (33.3%), runny nose (31.3%), issued phlegm/reak (18.8%), shortness of breath (14.6%), snorting nose (6.3%).

Figure 1. Percentage of Respiratory Symptoms

The entry of organic solvent vapors into the body can cause a variety of reactions, ranging from mild irritation, addiction, kidney disorders, pulmonary edema reactions

and disorders of the central nervous system<sup>(11)</sup>. The main route of exposure is through inhalation, dermal (skin) and oral administration as well as possible<sup>(12)</sup>.

Glue that contains organic solvents in footwear home industry can cause irritation symptoms in the respiratory tract<sup>(13)</sup>, because exposure to volatile organic compound vapors is most important through inhalation<sup>(14)</sup>. In this study the only organic solvent analyzed was benzene. Absorption through breathing and digestion is faster than absorption through the skin, it is because benzene evaporates faster. About 50% of benzene is inhaled and absorbed after 4 hours exposure at a concentration of about 50 ppm benzene in the air. An in vivo study in humans showed that there was an absorption of about 0.05% of the dose of benzene applied to the skin, whereas in an in vitro study of human skin, benzene absorption was consistently as much as 0.2% after exposure to doses between 0.01-520 microliters per square centimeter<sup>(15)</sup>.

The effect of benzene exposure on the respiratory tract was supported by conditions in the workplace in the room that makes the air more polluted if the window circulation of air is inadequate. Indoor air pollution can worsen the condition of the respiratory tract of workers especially those who have a history of diseases such as asthma, allergies etc. because with these working conditions can support the growth of bacteria<sup>(16)</sup>. But the results of the review suggested that dietary or nutritional supplements might be somewhat helpful to protect against water pollution-induced respiratory damage<sup>(17)</sup>

Benzene (C6H6) is a type of chemical that is polycyclic aromatic hydrocarbons (PAH). The nature of benzene which quickly evaporates in the air and is flammable then inhaled through the respiratory tract can irritate the mucous membrane, furthermore it can cause interference with the movement of the cilia so that it cannot clean the airways and due to this irritation also increases mucus production which can cause narrowing of the airways so that respiratory function can be disrupted based on the duration and duration of exposure<sup>(18)</sup>. Benzene with relatively high instability and solubility,

benzene exposure through inhalation poses a greater risk than through skin contact. It has been estimated that size because 60% of the amount inhaled is absorbed in the bloodstream while 1% is absorbed through the skin<sup>(19)</sup> so that the damaged mucosa and submucosa components of the trachea can reflect its function and predispose to lower respiratory tract disease<sup>(20)</sup>.

**Intake of Non Carcinogen and Carcinogen:** In this study the concept of exposure assessment was used to measure the amount of exposure carried out to analyze the amount of exposure, it is by calculating the amount of benzene intake that enters to the body.

The calculation of intake of benzene concentration in the work environment is obtained by using the following equation:

$$I = \frac{C \cdot R \cdot t_e \cdot f_e \cdot D_t}{W_b \cdot t_{avg}}$$

Where, I is intake of benzene exposure the number of risk agents received by an individual per unit of body weight every day (m<sup>3</sup>/kg/day); C is Risk agent concentration, Benzene in the air (mg/m<sup>3</sup>); R is intake rate (m<sup>3</sup>/hour), Normal inhalation rate (EPA, 1997 in Abrianto, 2004)<sup>(21)</sup>:  $y = 5.3 \ln(x) - 6.9$  with  $y = R$  (m<sup>3</sup>/day) and  $x = W_b$  (Kg) the inhalation rate can be estimated according to Indonesian anthropometry characteristics;  $t_e$  is Exposure time per day (hours/day) for inhalation;  $f_e$  is Frequency of annual exposure (days/years (365 days));  $D_t$  is duration of exposure (years), i.e. a long of the respondent lived in the study location until the time of the study, which is stated in real time or 30 years of projected residential default exposure or 25 years for the projected exposure to industrial environment defaults;  $W_b$  is weight (kg);  $t_{avg}$  is average time period, 30 years x 365 days/year (non-carcinogenic) or 70 years x 365 days/year (carcinogenic).

**Table 1. Overview of Workers according to Non-Carcinogen and Carcinogen Intake**

Variable	N	Minimum	Maximum	Median	Std. Dev.
Intake Non karsinogen	96	0,00002	0,40597	0,00048	0,083
Intake Karsinogen	96	0,00001	0,17399	0,0002	0,035

The results was obtained from the intake of benzene exposure in respondents ranging from 0,00001 to 0.40597 mg/kg/day have the potential to have a risk of carcinogens and non-carcinogens, so recommending

risk management by controlling exposure time, duration of exposure and frequency of exposure and the expected ventilation factors in space a risk factor for increasing pollutant exposure. Whereas Habeebullah<sup>(22)</sup> obtained

an average respondent intake of 1.83E-02 with a risk quotient of 3.04E-04 and excess risk cancer of 0.53. Habeebullah has also projected that benzene has been shown to have a greater risk of cancer and suggested to improve the pattern of activities that could be a risk factor for example in the work environment.

Result was obtained from a health risk assessment reveals that there was a significant potential cancer risk by inhaling doses of benzene at the study site because the levels at all locations exceed the acceptable risk then recommend to improve the quality of fuel by reducing the content of benzene<sup>(23)</sup>.

**Risk Characterization:** Risk characteristics was obtained from calculating the estimated risk level with the non-carcinogenic risk calculation equation (RQ)<sup>(9)</sup> as follows:

$$\text{Risk Quotients (RQ)} = \frac{\text{Intake}}{\text{RfC}}$$

The reference concentration (RfC) value for the real time RQ is 8.6 x 10-3 (mg/kg)/day<sup>(24)</sup>

**Excess Cancer Risk (ECR)for Carcinogenic Effects:** The calculation of the level of carcinogenic risk stated by the ECR was calculated by multiplying the Cancer Slope Factor (CSF) with the carcinogenic assumption of each risk agent according to the equation<sup>(9)</sup>:

$$\text{ECR} = \text{Intake}_{\text{Cancer}} \times \text{CSF}$$

Where, ECR is Excess Cancer Risk (Risiko Kanker); Intake<sub>Cancer</sub> is Total chronic intake (lifetime, ie 70 years); CSF is *Cancer Slope Factor*

Cancer Slope Factor is defined as a quantitative relationship between dose and response, which is an estimate (estimation) of the chances of a person (individual) developing into cancer due to exposure (lifetime) by a potential cancer agent. The acceptable cancer risk threshold was adopted from the US-EPA, which is one case of cancer per ten thousand inhabitants<sup>(9)</sup>.

**Table 2. Results of Non-Carcinogen and Carcinogen Risk Assessments for Workers**

Risk	Frequency	Percentage (%)
<b>Non cancer Risk</b>		
RQ > 1	11	11,5
RQ ≤ 1	85	88,5
<b>Cancer Risk</b>		
ECR > 1·10-4	21	21,9
ECR ≤ 1·10-4	75	78,1

The result of the risk assessment 11.5% of workers had real time non-cancer risk as well as 21.9% of workers who had cancer risk. It can be seen that benzene inhalation exposure in the informal footwear industry has described risks that will harm health (cancer and non-cancer) through the calculation of RQ (Risk Quotient) and ECR (Excess Cancer Risk) values that exceed the reference level of benzene exposure. If the value RQ ≤ 1 shows an indication that there is no risk of an adverse effect. While RQ > 1 indicates an indication of possibility of the risk of adverse effect and needs to be controlled<sup>(25)</sup>. Where this value projects a risk of insecurity if exposure continues. Its indications can be assessed by estimating the risk of cancer and non cancer as well as the symptoms of respiratory disorders that will worsen if exposure continues for long periods without risk control.

**Analysis of the Relationship between Non-Carcinogen Intake and Respiratory Symptoms:**

**Table 3. Mann Whitney Test Results between Non-Carcinogen Intake and Respiratory Symptoms in Workers**

	n	Mean Rank	Median (Min-Maks)	p*
Non carcinogenic intake and have symptoms	68	49,68	0,00048(0,00002- 0,40597)	0,519
Non carcinogenic intake and did not have symptoms	28	45,64	0,00052(0,00003 - 0,33706)	
carcinogenic intake and have symptoms	68	49,23	0,000195(0,00001- 0,17399)	0,690
carcinogenic intake and did not have symptoms	28	46,73	0,00022(0,00001- 0,14445)	

\*2-independen sample (significant value : P-Value < 0,05)

Analysis of the relationship of non-carcinogen intake with symptoms of respiratory disorders was analyzed by using the Mann-Whitney test. The results of the analysis obtained was 68 workers who have respiratory symptoms have a median non-carcinogen intake of 0,00048 (mg/kg)/day and 28 workers who did not experience respiratory symptoms have a median value of non-carcinogen intakes of 0,00052 (mg/kg)/day. P value 0.519 (p value > 0.05) which means that statistically there was no relationship between non-carcinogen intake and respiratory symptoms.

The results of the analysis obtained was 68 workers who solved respiratory problems had a mean carcinogen intake of 0,000195 (mg/kg)/day and 28 workers who did not experience respiratory disorders had a carcinogen intake of 0,00022 (mg/kg)/day. Value of p = 0.690 (p value > 0.05) which means that statistically there was no relationship between carcinogenic intakes and respiratory symptoms.

The results of this study indicate that there is no significant association between non-carcinogen intake and respiratory symptoms. The concentration of benzene in the working environment in this study was still below 0.5 ppm as the TLV (Thresold limit value) can be one of the factors supporting the insignificant relationship between benzene intake with respiratory symptoms and can be compared with Avis and Hutton data (1993) recorded in ATSDR (2007)<sup>(12)</sup> that acute exposure of 33 and 59 ppm of benzene vapor which irritates mucous membranes, nose can cause sore throat and cough symptoms. However, previous studies conducted by Kurniawidjaja et al.,<sup>(13)</sup> at 1.40 ppm exposure, have described respiratory complaints in workers associated with benzene exposure in informal footwear workshops where the average value of benzene vapor levels in all workshop sample has more than TLV 0.5 ppm.

### Conclusions

The finding of this study shows no correlation between non-carcinogen intakes and carcinogen intakes with respiratory symptoms. The risk assessment result suggest alertness to the risk of continuous benzene exposure because it can trigger symptoms of disease promoted carcinogenesis and non-carcinogenesis.

# Factors Associated with Limited Level of Health Literacy on Application of Health Information Related to Opioid Use in Kachin State, Myanmar

Ye Htut Oo<sup>1</sup>, Wongs Laohasiriwong<sup>2</sup>

<sup>1</sup>Master of Rural Development Management, Faculty of Graduate School, <sup>2</sup>Dean of Faculty of Public Health, Khon Kaen University, Thailand

## Abstract

**Introduction:** Opioid abuse has caused immense suffering for people in Myanmar especially in Kachin and Shan States. Promoting health literacy relevant to opioid use can lessen those problems but little is known about opioid literacy level of general population. Thus, objectives of this study were to find out the prevalence of literacy level on application of health information relevant to opioid use and the factors affecting the limited level of opioid literacy among adult males in Kachin State, Myanmar.

**Method and Materials:** A total of 327 adult males in Kachin State who had never used illicit drugs were selected for this cross-sectional study. A sub-scale of the European Health Literacy Questionnaire, HLS-EU-Q47, was adapted to assess the level of application on opioid-related health information. Data were collected from July to August 2019 through face to face interview with the participants. Multiple logistic analysis was performed to find out the association.

**Result:** 61.47% of the participants had limited level of literacy in terms of application of opioid-related health information. The findings indicated that not being Bamar (AOR= 3.61, 95% CI = 1.97-6.63,  $p < 0.001$ ), being unemployed (AOR=2.44, 95% CI= 1.38-4.30,  $p < 0.01$ ) and not having siblings who used opioids (AOR=2.47, 95% CI= 1.10-5.56,  $p < 0.05$ ) were more likely to have limited level of literacy in terms of applying opioid-related health information.

**Discussion:** Socioeconomic and environmental factors had influence on health literacy especially application of health information relevant to opioid use. It is important to take appropriate measures to improve opioid-related health literacy particularly among the vulnerable groups to help prevent them from drug use and its problems.

**Keywords:** *Opioids, Health Literacy, Males, Kachin, Myanmar.*

## Introduction

Opioid abuse is a serious public health and safety concern around the world which has significant impact on health and welfare of human<sup>[1]</sup>. Myanmar stood second in producing opium around the world and bore the heavy brunt of opioid abuse<sup>[2]</sup>. Kachin was one of the most opium producing states in Myanmar and had socioeconomic burden of drug use. A qualitative study of Oo and Doe<sup>[3]</sup> stated that not only drug users but also the family members suffered health, socioeconomic and marital problems such as acquiring HIV/AIDS,

discrimination from their communities and domestic violence. Moreover, drug use also caused a real predicament for the whole society<sup>[4]</sup>.

Health literacy is one of the fundamentals for health system where more active role of individuals in decisions and management is required<sup>[5]</sup>. As it is a strong indicator for measuring people's health<sup>[6]</sup>, promoting it relevant to opioid use would be helpful to lessen the drug abuse problems. As stated by Shuja et al<sup>[7]</sup>, an increase in health literacy of people could enhance their knowledge on consequences of illicit drugs which could then resulted

in not using those substances. In fact, health literacy is way beyond being able to read health information and understand them. It empowers people by developing their capacity to apply the information effectively<sup>[8]</sup>.

Until now, little is known about opioid-related health literacy in general population. Therefore, this study aimed to find out the prevalence of literacy level on application of health information relevant to opioid use and the factors affecting the limited level of opioid literacy among adult males in Kachin State, Myanmar. By knowing these factors related to opium literacy, it would be helpful for local authorities and civil society organizations to implement effective interventions to promote health literacy in order to reduce drug use problems.

## Methodology

**Study Design:** This cross-sectional study was conducted to identify factors associated with limited literacy on application of opioid-related health information among adult males in Kachin State, Myanmar. Only adult males were included in this study because it was part of an Independent Study, namely, “a case-control study on risk factors of opioid use”, which was carried out among adult male opioid users and non-drug users.

**Study Subjects:** The sample size in this study was 327 which was estimated from the method of Fleiss with a continuity correction for the above-mentioned case-control study<sup>[9]</sup>. Participants were adult males (18 years or above) who had never used illicit drugs. They were simple randomly selected from general population in Kachin State, Myanmar through local government’s household registration. The exclusion criteria were the people with serious physical and mental problems as well as those who were not able to verbally communicate with interviewers.

**Data collection:** A structured questionnaire which contained socioeconomic and demographic characteristics, opioid-related information (environmental factors) and index of health literacy on applying opioid-related health information was used to collect data from the adult males. Face to face interviews were carried out by the trained interviewers with written guideline. Verbal consent was obtained from the participants before the interview.

**Data analysis:** Data analysis was carried out by using Stata 14.2. The categorical data were described by using frequency and percentage whereas the continuous data were reported as mean and median. For inferential statistics, bivariate analysis was conducted to identify the factors associated with limited level of literacy in terms of applying opioid-related health. The factors with  $p < 0.25$  were continued into the final model or multivariate analysis<sup>[10]</sup>.

**Ethical Approval:** This research was approved by Khon Kean University Ethics Committee in Human research, (Approval number HE622140 4.3.03: 20/2019).

## Results

**Descriptive Analysis:** The study contained 327 adult males who had never used illicit drugs. Most of the participants were between the age of 20 to 39 years (45.57%) with the average age of 35 years. Half of them (50.76%) were single whereas 44.34% were married. Regarding educational level, 57.49% were in secondary education and 30.58% were in university level. Majority of participants were Kachin (70.64%) and Christians (76.76%), and Bamar and Buddhists constituted 19.27% and 21.1% respectively. Most of the participants (85.32%) believed and practised their religions. More than 30% were unemployed and about 14% were unskilled workers. Over half of the respondents earned 100,000 kyats or less monthly. Only about 18% lived in rural areas and about 35% migrated from other places. Alcohol (43.12%) was the most consumed substance for respondents followed by smoking cigarettes or cheroots (30.58%) and chewing betel nuts (10.70%).

**Prevalence of limited health literacy level on applying opioid-related health information:** Opioid-related health literacy on applying the information was assessed by modifying 11 questions of HLS-EU-Q47 (only “apply information” sub-scale). A four-point Likert scale was used for the answers – very difficult, fairly difficult, fairly easy and very easy with the score of 1 to 4 respectively. Recommended scoring system from the formula:  $\text{Index} = (\text{mean} - 1) \times 50/3$  which score ranged from 0 to 50 was utilized<sup>(11)</sup>. According to the score, the participants were categorized into four groups: inadequate (0 to 25), problematic (26 to 33), sufficient (34 to 42) and excellent (43 to 50). To explore the vulnerable group, the first two levels were combined as a group and named as limited health literacy<sup>(11,12,13)</sup>. As shown in Table 1, more than 60% had limited literacy.

**Table 1. Prevalence of Limited Health Literacy Level on Applying Information Relevant to Opioids among the Participants (n = 327)**

Apply information relevant to Opioid-related Health Information	Frequency	Percentage
Limited (0-33)	201	61.47
Sufficient (34-42)	90	27.52
Excellent (43-50)	36	11.01

**Factors associated with limited level of literacy on applying opioid-related health information among adult males: A bivariate analysis:** In the simple logistic regression analysis, eight factors were found to be associated with the limited opioid literacy ( $p < 0.25$ ). They were young and old aged people (COR= 2.27, 95% CI= 1.34 to 3.86), ethnic groups other than Bamar (COR= 4.29, 95% CI= 2.39 to 7.69), not being Buddhists (COR=

3.49, 95% CI= 2.01 to 6.06), being unemployed (COR= 2.90, 95% CI= 1.70 to 4.94), earning inadequate income (COR= 1.62, 95% CI= 1.02 to 2.58), not chewing betel quid (COR= 4.06, 95% CI= 1.91 to 8.63), being born in the study place (COR= 1.61, 95% CI= 1.01 to 2.57) and not having siblings who used drugs (COR= 1.68, 95% CI= 0.79 to 3.56). Table 2 shows the crude association between these variables and limited opioid literacy.

**Table 2. Odds Ratio for each category of factors associated with limited level of literacy on application of health information on opioid use: a bivariate analysis (n= 327)**

Characteristics	Number	% of people with limited health literacy	Crude OR	95%CI	p-value
<b>1. Age</b>					<b>0.0018</b>
Middle age (20-59)	233	56.22	1		
Young and old age	94	74.47	2.27	1.34 to 3.86	
<b>2. Ethnicity</b>					<b>0.0000</b>
Bamar	63	33.33	1		
Other ethnic groups	264	68.18	4.29	2.39 to 7.69	
<b>3. Religion</b>					<b>0.0000</b>
Buddhist	69	37.68	1		
Christian and others	258	67.83	3.49	2.01 to 6.06	
<b>4. Employment Status</b>					<b>0.0000</b>
Employed	225	54.22	1		
Unemployed	102	77.45	2.90	1.70 to 4.94	
<b>5. Financial Situation</b>					<b>0.0391</b>
Enough	195	56.92	1		
Not enough	132	68.18	1.62	1.02 to 2.58	
<b>6. Betel quid</b>					<b>0.0001</b>
Yes	35	31.43	1		
No	292	65.07	4.06	1.91 to 8.63	
<b>7. Migration status</b>					<b>0.0441</b>
Move from other places	113	53.98	1		
Born here	214	65.42	1.61	1.01 to 2.57

Yes	30	50.00	1		
No	297	62.63	1.68	0.79 to 3.56	

**Factors associated with limited level of literacy on applying opioid-related health information among adult males: A multivariate analysis:** Eight variables from bivariate analysis were proceeded to multivariable analysis by using multiple logistic regression with backward elimination. After the analysis, three factors:

being ethnic groups other than Bamar (AOR= 3.61, 95%CI= 1.97-6.63,  $p < 0.001$ ), being unemployed (AOR= 2.44, 95% CI= 1.38-4.30,  $p < 0.01$ ) and not having siblings who used opioids (AOR= 2.47, 95% CI= 1.10-5.56,  $p < 0.05$ ) were significantly associated with the limited opioid literacy, see Table 3.

**Table 3. Odds Ratio for each category of factors associated with limited level of literacy on application of health information on opioid use: a multivariable analysis (n= 327)**

Characteristics	Number	% of people with limited health literacy	Crude OR (95%CI)	Adjusted OR (95%CI)	p-value
<b>1. Ethnicity</b>					<b>&lt; 0.001</b>
Bamar	63	33.33	1

## Discussion

The study observed that limited level of health literacy on application of opioid-related health information was more than 60% which was 10% higher than the finding in a cross-sectional study among 1367 participants from 35 townships<sup>(14)</sup> The latter conducted in different areas but not included Kachin State. Another study reported that limited health literacy in healthcare settings of Southeast Asia countries was found to be higher, with 67.5%<sup>(15)</sup>. Thus, the reason why Kachin State had lower level of satisfactory health literacy may be due to inaccessibility of health services, but it may also be because of the low sample size of the study. The review study in Southeast Asia<sup>(15)</sup> also reported the high discrepancies in showing prevalence of limited literacy by the studies, varied from 1.6% to 99.5%.

The study also found out that socioeconomic (ethnicity, unemployment) and environmental factors (not having siblings who used illicit drugs) had significant associations with the limited level of opium literacy on applying health information. Kachin and other ethnic groups were likelier to have limited health literacy than Bamar (AOR= 3.61, 95%CI= 1.97-6.63,  $p < 0.001$ ). Bamar constituted the most proportion of ethnic groups in the whole country, meaning that ethnic groups

with less proportion had limited literacy. Unemployed persons were more prone to have limited literacy than employed people (AOR= 2.44, 95% CI= 1.38-4.30,  $p < 0.01$ ). A health survey in Catalonia also reported that limited literacy was associated with low socioeconomic status which included unemployment (AOR= 2.11, CI 95%= 1.42–3.15,  $p < 0.001$ )<sup>(16)</sup>. Pedro, Amaral and Escoval<sup>(17)</sup> also mentioned that unemployed people were among vulnerable groups to have limited literacy. As students were also included in unemployed status, they should also be considered in providing health education. The last factor associated with limited application on health information was not having siblings who used opioids (AOR= 2.47, 95% CI= 1.10-5.56,  $p < 0.05$ ). They might not understand well about opioid issues as they may not see the problem around them.

**Limitation of the Study:** This study covers Kachin state only so the similar studies should be conducted in other states such as Shan State where opioid problems are prominent. As general limitation, this cross-sectional study measured exposures and the outcome at the same time and thus, causal relationship between them could not be identified. Moreover, as it included adult males only, other populations such as females, adolescents and the drug users were not represented in this research.

## Conclusion

It was observed that limited level of opium literacy on applying health information was associated with the vulnerable members of the community – ethnic groups rather than Bamar, unemployed people and those who did not have drug user siblings. It is important to take appropriate measures to improve opioid-related health literacy particularly among the vulnerable groups to help prevent them from drug use and its problems. When providing health education, languages that different ethnic groups can understand should be used so that they can understand the drug problems and their adverse effects.

## Conflicting Interest

The authors declare that there is no conflict of interest in this research.

# Evaluation of Serum Lipid Profile after Different Chemotherapeutic Regimens in Iraqi Patients with Breast Cancer

**Zainab Nazar Hasan Anber**

*Lecturer (Ph.D. Clinical Biochemistry), Department of Therapeutics and Clinical pharmacy,  
Baghdad College of Medical Sciences, Baghdad, Iraq*

## Abstract

**Objective:** To investigate the effect of doxorubicin, cyclophosphamide and taxane chemotherapy on the lipid profile in Iraqi patients with breast cancer.

**Method:** This cohort prospective study was carried out at the Biochemistry Department, Baghdad College of Medical Sciences, and at the Oncology Clinic, Oncology Teaching Hospital, Baghdad, Iraq, during the period from May 2019 to October 2019. It included 56 women with regular menstrual cycle (25-45 years) classified into 3 groups: GI: 29 women with primary breast cancer (before starting chemotherapy), GII: the same 29 women of GI who were finished 4 cycles of anthracycline chemotherapy (course 1) and GIII: which involved another 27 women who had finished both courses of chemotherapy, (course 1) and 4 cycles of taxanes (course 2). Serum cholesterol, LDL, HDL and TG were measured using colorimetric method.

**Results:** The results of the present study showed that the (mean±SEM) of the serum cholesterol was decreased significantly ( $p<0.05$ ) in GIII compared to GI and highly significantly ( $p<0.01$ ) compared to GII. While, the serum HDL level was significantly ( $p<0.05$ ) lower in GIII compared to GI. Concerning the serum LDL level, it was increased significantly ( $p<0.05$ ) in GII compared to both GI and GIII. While; the serum TG level shows no significant difference between all groups.

**Conclusion:** Iraqi women with breast cancer had an abnormal state of dyslipidemia that become worsened after chemotherapy.

**Keywords:** Breast cancer, chemotherapy, cholesterol, HDL, LDL, TG.

## Introduction

Carcinoma of breast is a widely common neoplasm among women around the industrialized world. It was increased steadily over the past 40 years. It is considered the second cause of mortality among women ages

between 20-59<sup>(1)</sup>. In Iraq, it is the first in ranking among cancers<sup>(2)</sup>. The cause of the disease is unknown but it could be hormonal, environmental, genetic, radiation, oncogenic viruses and dietary factors<sup>(3)</sup>. Many factors affect the relation of lipid changes with breast cancer and this relationship is still a subject of controversy. Lipids are the major component of membranes integrity in the biological cells, it plays roles in cell growth and development; both for normal and malignant ones. Lipids are richly present in the mammary tissue. Some studies had found that changes of plasma lipids and lipoproteins are associated with the proliferation of malignant cells in the breast tissue. Recently, they had studied the role of both the endogenous and dietary lipids in the etiology and prognosis of cancer<sup>(4)</sup>. The

unbalanced lipid parameters including raised total cholesterol [TCh], low-density lipoprotein-cholesterol (LDL-C) and triglycerides [TG] along with decreased high density lipoprotein-cholesterol [HDL-C] could be a risk factor of cardiovascular diseases<sup>(5)</sup>.

## Subjects and Method

This cross sectional study was conducted at the Department of Biochemistry, Baghdad College of Medical sciences and at the Oncology Hospital, Medical City Hospital, Baghdad, Iraq, during the period from May 2019 to October 2019. It involved 56 Iraqi women diagnosed by Consultant Clinical Oncologist to have had primary carcinoma of breast; their ages range was 25-45 years. The included women were categorized into groups according to their status of treatment: group 1 [G1] included 29 women with primary breast carcinoma who never subjected to chemotherapy treatment, group 2 [G2] consisted of the same 29 women of G1 but after finishing the first course of treatment [4 cycles of anthracycline chemotherapy including Doxorubicin 60mg/m<sup>2</sup> and Cyclophosphamide 600mg/m<sup>2</sup> chemotherapy], and group 3 [G3] which involved different 27 women who completed full regimen of chemotherapy treatment [(course 1) and 4 cycles of Taxane including (Docetaxel) 100mg/m<sup>2</sup>; (course 2)]. Exclusion criteria included pregnant woman, chronic diseases (diabetes mellitus, hypertension), alcoholics, smokers, and women used anti-inflammatory drugs. Formal consent was taken from each woman. Authors obtained ethical approval from the Scientific Committee of the Department of Biochemistry of Baghdad College of Medical sciences. Serum cholesterol, LDL-cholesterol (LDL-C), HDL-cholesterol (HDL-C) and TG were measured using colorimetric method. Five milliliters of blood sample was collected by venipuncture of the peripheral vein from each included woman, transferred into plain tube, allow to clot and the serum was separated immediately by centrifugation at 2500–3000 rpm for a period of 10 min. Investigations included serum measurements of cholesterol, HDL, LDL and TG by colorimetric method. All material kits for the measured parameters were provided from Human GmbH.65205 Wiesbaden, Germany. The statistical analysis including ANOVA

and Student's t-tests were applied to test for significance differences among the studied groups with respect to lipid parameters. Correlation among different studied parameters in each studied group was investigated by linear regression test [r] and the significance of the r-value was examined by related t-test. P-values of less than 0.05 were considered significant.

## Results

The demographic data in table 1 depicts that there was no significant difference in mean values of age between G1 (38.79±0.91 years) and G3 (39.59±0.95 years). Similarly, mean values of BMI were comparable and did not differ significantly between G1 (30.04±0.94 Kg/m<sup>2</sup>) and G3 (31.78±1.24 Kg/m<sup>2</sup>).

**Table 1: Mean (±SEM) Values of Age and Body Mass Index (BMI) in G1 and G3**

Parameters	G1 (n=29)	G3 (n=27)
Age <sup>NS</sup> (Years)	38.79±0.91	39.59±0.95
BMI <sup>NS</sup> (kg/m <sup>2</sup> )	30.04±0.94	31.78±1.24

BMI: body mass index; ANOVA test revealed a non-significant difference between groups (NS)

Table 2 reveals the mean values of the serum measured lipid parameters. It shows that the serum levels of cholesterol was found to be increased in women who finished the first course of chemotherapy treatment [G2; 208.37±8.62 mg/dl] when compared to their levels before treatment [G1; 193.75±6.83 mg/dl], but did not reach the significant level. However, the level of serum cholesterol was then significantly declined in women who had finished complete courses of treatment [G3; 168.30±8.14 mg/dl] when compared to that of G1 [P < 0.05] and G2 [p < 0.01]. Similarly, serum LDL-C was significantly elevated in G2 [125.89±8.88 mg/dl] in comparison with each of G1 [104.24±7.17 mg/dl, p<0.05] and G3 [91.02±7.64 mg/dl, p<0.05]. Regarding serum HDL-C level, it was decreased in post treatment groups compared to that before treatment, but with only significant difference between G3 and G1 [p < 0.05]. Serum TG level showed no significant differences among all groups.

**Table 2: Values of Serum Cholesterol, HDL-C, LDL-C and TG in G1, G2 and G3**

Parameter	G1 (n=29)	G2 (n=29)	G3 (n=27)
Cholesterol mg/dl	193.75±6.83*	208.37±8.62*	168.30±8.14
LDL-C mg/dl	104.24±7.17	125.89±8.88**	91.02±7.64
HDL-C mg/dl	58.60±2.34	52.94±3.71	47.61±1.47***
TG mg/dl <sup>NS</sup>	154.37±7.80	147.68±7.16	148.33±9.55

LDL: low density lipoprotein-cholesterol, HDL: high density lipoprotein-cholesterol, TG: triglycerides. Data are expressed as mean ( $\pm$ SEM). ANOVA and t-test revealed \* significant increase of total cholesterol in G1 [ $p < 0.05$ ] and G2 [ $p < 0.01$ ] than in G3, \*\*significant increase of LDL-C in G2 than in G1 [ $p < 0.05$ ] and G3 [ $p < 0.05$ ], \*\*\*significant decrease of HDL-C in G3 compared to G1 [ $p < 0.05$ ], NS: non- significant differences.

The present study showed that women of G1 exhibited significant direct relationship between serum levels of cholesterol and LDL-C in G1 ( $r=0.95$ ,  $p < 0.01$ ). Also, serum levels of TG and HDL-C showed significant inverse correlation ( $r= -0.394$ ,  $p < 0.05$ ). Furthermore significant negative correlation was observed between serum LDL-C and serum HDL-C ( $r= -0.44$ ,  $p < 0.05$ ) in G1. With respect to G2, there was a significant inverse relationship between age values and serum HDL-C levels ( $r= -0.376$ ,  $p < 0.05$ ) with significant positive relationship between serum levels of cholesterol and LDL-C ( $r= 0.912$ ,  $p < 0.01$ ). Regarding G3; there were a significant direct relationship between BMI and serum TG ( $r= 0.437$ ,  $p < 0.05$ ) and between serum levels of cholesterol and LDL-C ( $r=0.964$ ,  $p < 0.01$ ).

## Discussion

Iso et al. (2009) reported that malignancy was associated with decrease plasma cholesterol levels, and certain types of cancer had a significant effect. The enhanced utilization of cholesterol by carcinoma tissues was culprit in reducing plasma cholesterol<sup>(6)</sup>. One of the important causes in development of breast cancer is increased exposure to estrogen hormone which plays a vital role in metabolism of cholesterol and may reflect the association of breast cancer and increased HDL-C<sup>(7)</sup>. Although adjuvant chemotherapy may improve the survival of breast cancer patients, they had suggested that chemotherapy cause significant changes in the metabolism of lipids in cancer survivors<sup>(8)</sup>.

Alexopoulos et al. (1992); found that breast cancer patients undergoing chemotherapy had a non- significant decrease in both serum total cholesterol and serum LDL. Serum HDL did not show any significance while serum TG showed a significant increase. They had attributed these results to the low number of patients involved

in the study and they had indicated that these lipid disorders could be reversed with the effective treatment of the tumor<sup>(9)</sup>.

Rzymowska et al. (1999) studied 70 women with breast cancer and observed that both types of carrier cholesterol, HDL and LDL levels were declined after treatment of chemotherapy accompanied by significant elevation of triglycerides in women with malignant breast irrespective of being menstruated or menopausal. They had stated that the mechanisms interpreting the chemotherapy associated dyslipidemia could be related to the type of therapy used<sup>(10)</sup>.

Other previous studies reported that HDL-C levels were significantly reduced after chemotherapy and they had found that doxorubicin downregulates the expression PPAR $\gamma$  (peroxisomal proliferator-activated receptor  $\gamma$ ), liver X receptor  $\alpha$  (LXR $\alpha$ ), and ATP binding cassette transporter A1 (ABCA1). While, cyclophosphamide or paclitaxel did not affect the ABCA1 level<sup>(11,12)</sup>

Recent studies reported that taxane-containing chemotherapy has been proven to induce dyslipidemia, which reduces the plasma HDL-C level and increases the plasma hydroperoxide level<sup>(13,14)</sup>.

Alacacioglu et al. (2010) had observed that breast cancer patients treated with taxane, epirubicin and cyclophosphamide showed no significant changes in blood cholesterol, HDL, LDL and TG at baseline and after six cycles of the treatment<sup>(15)</sup>.

Another study examined the metabolic changes in breast cancer patients who received chemotherapy and they had shown significant increases in TC, TG and LDL-C levels<sup>(16)</sup>.

In a study done by Simin et al. (2016) who found

that patients treated with adriamycin, cyclophosphamide and taxane showed no significant changes in the serum lipid profile although slight changes were recorded in each item<sup>(17)</sup>.

Xin et al. (2018) reported certain metabolic abnormalities during adjuvant chemotherapy treatment of women with breast cancer including hypercholesterolemia, hypertriglyceridemia; elevated LDL-C and Apo B along with decrease in HDL-C and Apo A1. They suggested that carcinoma of breast is accompanied by overt dyslipidemia which worsen after chemotherapy<sup>(5)</sup>. These differences in the results may be due to progression of cancer and side effects of the chemotherapeutic agents in addition to genetic, environmental and behavioral differences<sup>(18)</sup>.

The decrease in LDL-C in carcinoma could be attributed to increased uptake of cholesterol by these cells, with consequent elevation in LDL removal through the enhancement of LDL receptor activity. These derangement in lipid metabolism and parameters may be due to release of pro inflammatory cytokines from the inflammatory cells which could be part of an acute-phase reactant against tumor or which may be itself participate in tumor development and also from the tumor itself<sup>(5)</sup>. The significant decrease in the serum HDL in this study was in agreement with that observed by Monika et al. (2016) who concluded that lipid changes that happened with chemotherapy are specific to the chemotherapeutic type used. Doxorubicin lowered HDL-C while paclitaxel increased apoB. In opposite, cyclophosphamide appears to have no significant effect on HDL or apoB metabolism<sup>(19)</sup>. Some hypotheses indicate that chemotherapy may cause dysfunction of the endothelial cells which leads to cytokine alterations, and hence lipids abnormalities<sup>(20,21)</sup>. Other stated that adipocytes associated with cancer will modify the phenotype of the cancer cells<sup>(22)</sup>.

Owiredu et al. (2009); had observed that there was a significant positive correlation between the BMI and both serum total cholesterol and LDL- cholesterol which is more susceptible to lipid peroxidation. They had attributed this to the oxidative stress leading to an increase in cell proliferation of the malignant cells. Also, they had noticed that there was a significant negative correlation between age and serum HDL. All these results were in concordance with the results of the present study<sup>(3)</sup>.

On the other hand; Delgobo et al 2019 found that

Chemotherapy appeared to exert a greater effect on younger breast cancer patients and that lipid metabolism is associated with sex hormones<sup>(23)</sup>.

They had explained that changes in lipid levels after chemotherapy correlate with changes in menstruation. they had concluded that plasma lipid levels are more sensitive to chemotherapy agents since young patients have higher levels of sex hormones and a better lipid metabolism status<sup>(20)</sup>.

## Conclusion

Iraqi women with breast cancer had mild increased in LDL-C which exacerbated during chemotherapy treatment and resolved then after with finishing the complete courses of treatment. These women showed gradual decrease of HDL-C after treatment even its value still within expected level.

# Escherichia Coli as a Biological Model for Reduction of Graphene Oxide

Zina Bakir Al-Hilli<sup>1</sup>, Nawfal Hussein Aldujaili<sup>2</sup>

<sup>1</sup>Department of Microbiology, Faculty of Veterinary Medicine, Al-Qasim Green University, Iraq,

<sup>2</sup>Assit. Prof. Department of Biology, Faculty of Science, University of Kufa, Iraq

## Abstract

The present study was conducted to investigate the ability of bacteria to reduce Graphene Oxide (GO) sheets. Out of 82 bacterial isolates screened, one isolate was selected as a biological model for biosynthesis of reduced graphene oxide (RGO) nanosheets. This isolate was identified by morphological, biochemical tests, VITEK2 System, and 16S rRNA gene sequencing, aligned and submitted to the NCBI, and confirmed as *Escherichia coli* strain E-NO.7 (accession no. MK685205). The UV-vis. absorption peak was around 284 nm. The SEM images revealed thin, wrinkled, closely associated nanosheets. The weight percentage of carbon was 82.00% and oxygen was 18.00%. XRD analysis exhibited a broad diffraction peak at  $2\theta = 26.5^\circ$  corresponding to the interlayer spacing of 0.34 nm. The FTIR spectrum showed decrease in peaks associated to oxygen functional groups, while other peaks vanished completely.

**Keywords:** *Escherichia coli*, Bacterial reduction of Graphene Oxide, Nanobiotechnology.

## Introduction

Graphene is a novel nanomaterial (NM) that has revolutionized the field of nanobiotechnology and emerged as a promising new tool for a variety of applications due to its outstanding physical, chemical, and biological properties as in drug and gene delivery, tissue engineering, biosensing, bioimaging, as well as antibacterial agents<sup>(1)</sup>. Graphene is a monolayer- thick NM composed of carbon atoms arranged in 2D sheet. Each carbon atom is connected to three other carbon atoms in the sheet by covalent bonds resulting in tightly packed honeycomb-like structure<sup>(2)</sup>.

Oxygen functional groups in GO are removed when exposed to reducing conditions. Frequently, GO reduction is carried out to restore the electrical

conductivity, thermal stability, and change many other GO properties<sup>(3)</sup>. Several routes have been reported for reduction of GO nanosheets such as chemical, thermal, electro- chemical and biological method<sup>(4,5)</sup>. Biological reduction of GO has received interest of researchers working on bionanotechnology as such strategy is efficient and eco-friendly in nature thereby decreasing the high cost and risks of toxic chemicals involved in the conventional chemical method. Most of biological reduction method work at moderate conditions like room temperature and atmospheric pressure making them effective, affordable, and easy to handle<sup>(6)</sup>. Different types of biomolecules, microorganisms, and plants can be used as alternatives for reduction of GO. These reducing agents are also called “green reducers” as they are free from corrosion, carcinogenicity, and toxicity<sup>(4)</sup>.

## Experimental Part:

**Screening the bacterial isolates:** A total of 82 bacterial isolates from different sources were screened for ability to reduce GO at concentration of 0.5 mg/ml. Graphene oxide powder was purchased from Graphitene (UK).

**Activation of the isolates:** Each bacterial isolate

e-mail, zinabakir@yahoo.com

was activated according to<sup>(7)</sup> by inoculation of 10ml of BHI broth medium with a single colony and incubated for 24 hr. in shaking incubator at 120 rpm and 37°C. The second preculture was inoculated with the first preculture (1% v/v) and incubated on shaking incubator at 37°C for 24 hr. in 500ml flasks. Cells were harvested by centrifugation of broth culture using large scale centrifuge at 6000 rpm for 25min, 4°C. Cell free supernatant was collected in a sterile flask for use in reduction of GO experiment<sup>(8)</sup>.

**Bacterial reduction of GO:** Reduction experiment was conducted according to the method described by<sup>(9)</sup> with some modification. The GO solution (0.5 mg/ml) was mixed with cell free supernatant in a ratio 1:1 (volume ratio) in 500 ml flask, pH was adjusted to 7, and the mixture was stirred at 37°C for 72 hr. Reduction of GO was checked by visual examination of the solution for change in color of the medium from a clear, brown to black graphene with precipitate. The stable black dispersion centrifuged for 25min at 10,000 rpm, 4°C to remove the supernatant. The supernatant replaced with deionized D.W. and recentrifuged three times at the same speed and time to remove remained supernatant. The black pellet deposited at bottom of tubes then dried in oven at 40°C for 24 hr. The dried powder was collected carefully and stored in sample vials for characterization.

**Identification of the efficient isolate:** The bacterial isolate was identified by morphological and biochemical tests according to<sup>(10)</sup>, VITEK2 System, and by 16S rRNA gene sequencing. Favor Prep Genomic DNA Mini Kit (Geneaid, USA) was used to extract genomic DNA following the manufacturer's protocol. Concentration and purity of DNA was determined using Nanodrop (THERMO, USA). Universal bacterial primers of 16S rRNA gene (F GGAAGTGGACACGGTCCAG) and (R TTAAACCTTGCGGCCGTACT) were provided by (Bioneer, Korea). PCR mixture was prepared by using (Maxime PCR PreMix kit) and was done according to manufacturer's company instructions. DNA sequences were analyzed for sequence similarity to the existing DNA sequences available in the database at National Center for Biotechnology Information (NCBI). The DNA sequences were used to perform BLAST search against sequence database<sup>(11)</sup>.

**Characterization of BRGO:** UV-vis Spectroscopy of the aqueous suspension of BRGO was obtained using Mega 2100 Double Beam UV. visible spectrophotometer (Scinco, Korea). FTIR (ALPHA- BRUKER, Germany)

was used to characterize the functional groups on the surface of the BRGO sample. SEM (FEI NOVA NANOSEM 450I, Netherlands) was used to characterize the surface morphology and thickness of nanosheets. The occurrence of elemental carbon and oxygen was quantified by EDS (BRUKER X FLASH6I 10 (Germany). XRD diffractometer (RIGAKU, Japan) used to recorded  $2\theta$  value in order to characterize the interlayer spacing.

## Results

**Screening the bacterial isolates for biosynthesis of RGO:** Results revealed that one isolate *Z14* was able to reduce GO and selected as a biological model for biosynthesis of RGO. Changing the color of reaction mixture from a clear, brown to black with precipitate represents indicator for biosynthesis of RGO<sup>(12,13)</sup> (Fig. 1).

**Fig. 1- Bacterial reduction of GO. A: Supernatant and GO dispersion, B: BRGO obtained with Z14.**

**Identification of the isolate (Z14):** The bacterial isolate *Z14* was identified and confirmed as *E. coli* by the morphological, biochemical tests, VITEK2 System with probability of 99%. Concentration of extracted genomic DNA checked by Nanodrop was 195.8 ng/ $\mu$ l and the purity was 1.8. From comparison of the 16S rRNA gene sequencing with that in the database in Gene Bank by BLAST program, the microorganism was identified as *Escherichia coli* strain E-NO.7 (accession no. MK685205).

**Characterization of BRGO nanosheets:** After the visibility check, the reduction of GO was proved using UV-vis absorption spectroscopy. The absorption

spectrum showed that the peak of the BRGO suspension was around 284 nm indicating that RGO was successfully synthesized.

The BRGO powder was dropped on double tape and SEM images were taken randomly for the sample. The SEM images revealed that the BRGO material consists of thin, individual sheets closely associated with each other with wrinkled morphology and range of thickness (15-35nm) (Fig. 2) caused by the stacking of individual sheets by various self assembly techniques.

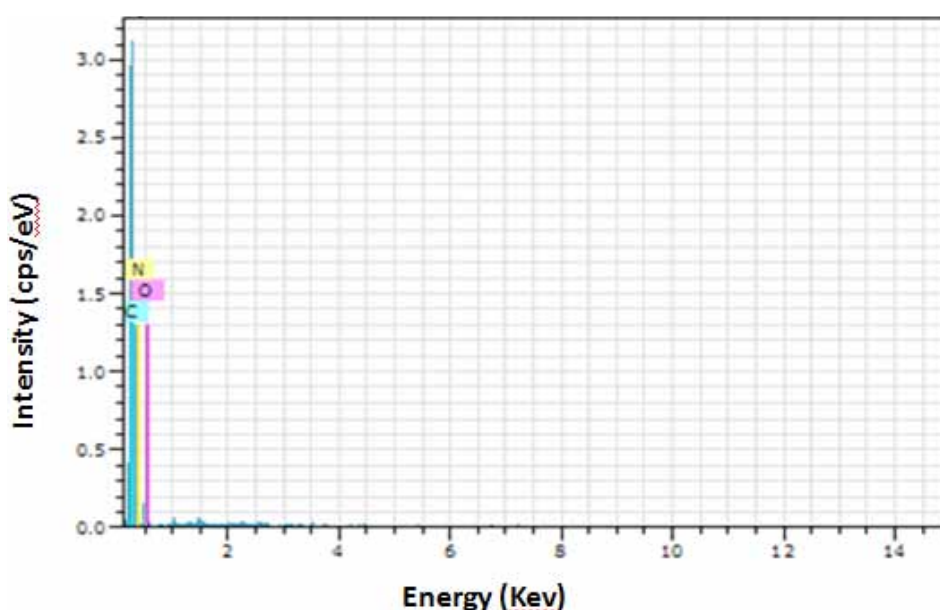

Fig. 2-SEM micrograph of BRGO nanosheets.

Element	Series	Atom (wt. %)
Carbon	K-series	82.00
Oxygen	K-series	18.00

Strong signals from the carbon atoms were observed while medium signals from oxygen and weaker signals from other atoms. The weight percentage of carbon was 82.00% and oxygen was 18.00% which suggesting the partial removal of oxygen containing functional groups as shown in EDS analysis (Fig. 3) and Mapping analysis (Fig. 4).

Fig. 3-EDS analysis of BRGO nanosheets.

Fig. 4-Mapping EDS analysis of BRGO nanosheets shows the distribution of Oxygen (red) and Carbon (green).

The FTIR spectrum showed that the characteristic peaks associated to oxygen functional groups decreased to a great extent, while hydroxyl and alkoxy peaks vanished completely. The absorption peaks were observed at 2915.79  $\text{cm}^{-1}$  (C–H stretching vibrations),

1633.56  $\text{cm}^{-1}$  (C=O stretching vibrations from carbonyl groups), 1526.15  $\text{cm}^{-1}$  (C=C configurable vibrations from the aromatics), and 1035.06  $\text{cm}^{-1}$  (C–O vibrations from epoxy groups, and C–O vibrations from alkoxy groups)(Fig.5).

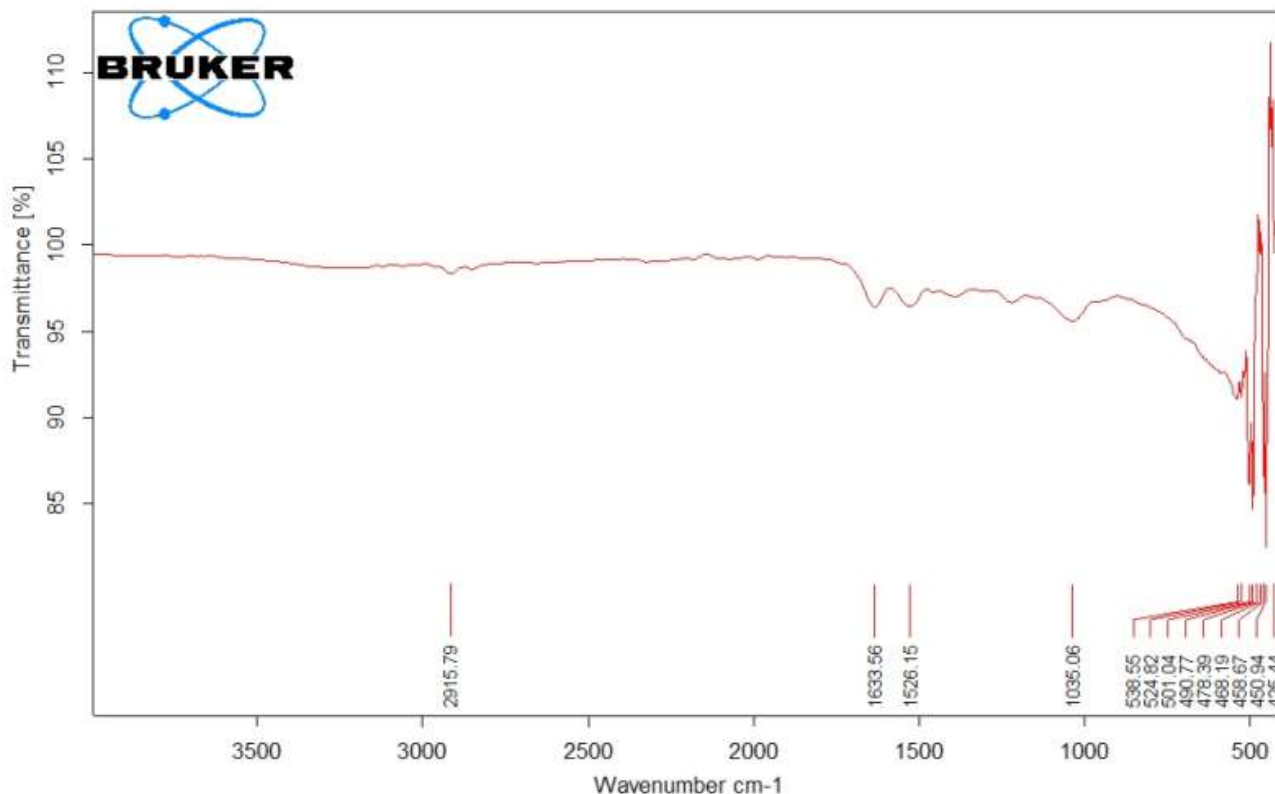

Fig. 5- FTIR spectrum of BRGO.

Results showed that RGO synthesized by *E. coli* strain E-No.7 exhibited a broad diffraction peak at  $2\theta=26.5^\circ$  corresponding to the interlayer spacing of 0.34 nm (Fig. 6).

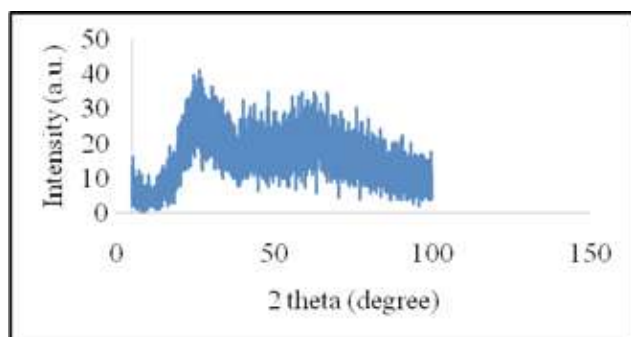

Fig. 6-X-ray diffraction pattern of BRGO.

## Discussion

The interaction between GO sheets and *E. coli* bacteria has been investigated. In previous studies *E. coli* cause reduction of GO and suggested that the GO sheets could act as biocompatible sites for adsorption and proliferation of the bacteria on their surfaces<sup>(9,14)</sup>. The reaction mechanism depends on bacterial cells that have such efficiency directly or indirectly for hydrolyzing acid groups associated with carbon nanosheets specially oxygen atoms. Graphene oxide can serve as the sole electron acceptor by capturing the electrons coming from the respiration process of bacteria<sup>(15)</sup>. For instance, *Shewanella* cells reduce GO via external electron transfer mediated by the outer membrane cytochromes, and by self-secreted electron mediators<sup>(16)</sup>.

The shifting in the peak of BRGO can be attributed to the decrease in oxygen functional groups and an increase in aromatic rings, causing electrons to be easily excited at lower energy<sup>(17)</sup>. So that UV-vis spectrum analysis confirms the restoration of electronic conjugation after the reduction<sup>(3)</sup>. Similar features were observed for the reduction of GO by different phytoextracts, where the peak of RGO is shifted to 268nm and 280 nm<sup>(18,19)</sup>. However, the maximum value observed for the RGO represents the efficiency of the reducing agent used for reduction of GO<sup>(20)</sup>. The SEM images of BRGO showed thin, wrinkled associated individual sheets which can be attributed to the intrinsic properties of graphene<sup>(21)</sup>. Previous studies, confirmed that the RGO exhibited typical wrinkled structure by SEM analysis<sup>(22)</sup>. Using different phytoextracts, SEM images of RGO revealed well separated platelets which are closely associated with each other<sup>(23)</sup>. Using phytoextracts, EDX confirmed the presence of about 71.10% of carbon and 14.2% of oxygen in RGO<sup>(24)</sup> while another study revealed that after reduction of GO by green tea extract, the oxygen was reduced to 28.18%<sup>(19)</sup>.

FTIR spectrum observations of BRGO indicated to the removal most of oxygen functional groups from GO sheet<sup>(25)</sup>. Samples of GO could display a series of different absorption peaks ranging from 900 to 3500  $\text{cm}^{-1}$ , this may be due to different reaction systems and conditions<sup>(4)</sup>. When GO is reduced, the characteristic peaks are gradually weaker over the course of the reaction and some of them vanish completely. This indicates the successful removal of oxygen from the sheets. The spectra of RGO displays a sharp C=C band within the range of 1600  $\text{cm}^{-1}$ <sup>(26,27)</sup>.

In XRD pattern, the diffraction peak at  $2\theta = 26.5^\circ$  indicated the organized crystal structure of BRGO while the interlayer spacing confirmed the removal of oxygen functional groups and water molecules from interlayer during reduction of GO sheets<sup>(9,28)</sup>. Earlier studies revealed that the interlayer distance of RGO decreased significantly after different reduction reactions. After reduction by *Azotobacter chroococcum*, the typical peak near  $2\theta = 11^\circ$  ( $d \sim 0.81 \text{ nm}$ ) for GO vanished while a broad peak appeared in the range of  $17-24^\circ$  indicating parallel stacking of the RGO sheets<sup>(29)</sup>. Upon GO reduction by  $\beta$ -carotene the signal shifted to  $23.13^\circ$  with a d-spacing of  $0.392 \text{ nm}$ <sup>(30)</sup>.

## Conclusion

*Escherichia coli* strain E-NO.7 can be used for the reduction of GO as ecofriendly synthetic protocol. Characterization analyses revealed the successful bacterial synthesis of RGO nanosheets through the removal of oxygen functional groups and water molecules from interlayer during reduction of GO.

# Factors Affecting Pregnant Women Behavior on Antenatal Care (Anc) Examination in Three Health Centers in Jombang Regency

Rahayu Wijayanti<sup>1</sup>, Shrimarti Rukmini Devy<sup>2</sup>, OedojoSoedirham<sup>2</sup>

<sup>1</sup>Health Promotion and Behavioral Sciences, Master Program of Public Health Sciences, <sup>2</sup>Department of Health Promotion and Behavioral Sciences, Faculty of Public Health, Universitas Airlangga, Indonesia

## Abstract

**Background:** The development of health problems that affect the pregnancy of mothers starting from non-communicable diseases and infectious diseases makes the health condition of pregnant women become one of the priority health problems that must be considered. Early detection on pregnant women is a way to find out pregnancy disorders or problems so that they can prevent the severity and even death of the mother. The Integrated ANC at health center is an antenatal care development program with a comprehensive examination conducted comprehensively to find out problems in pregnancy. The purpose of this study was to analyze the factors that influence maternal behavior in the three working areas of Jombang Regency health centers.

**Material and Method:** Research uses a quantitative approach with observational research and is classified as cross sectional. The research sample are 110 pregnant women with 1-5 months gestational age who are permanent residents in 3 regions of Jombang Regency PHC.

**Result:** The factor that influences the behavior of the Integrated ANC examination is the intention to perform the behavior of the mother to do the Integrated ANC examination (Sig = 0.001) and the Saliency of the behavior (Sig = 0,000) the mother has related to the Integrated ANC examination at the health center.

**Conclusion:** Information about the Integrated ANC raises a good understanding of the importance of behavior, so that the mother has a strong intention to make a decision to conduct an Integrated ANC examination.

**Keywords:** *Influence, Behavior, Integrated ANC, Health Center.*

## Introduction

Health problems that affect pregnancy health are directly caused by labor hemorrhage, preeclampsia, and infection. In addition to direct causes, other causes can affect pregnancy health such as non-communicable diseases and infectious diseases. Non-communicable

diseases such as diabetes, hypertension, heart disease and malnutrition while infectious diseases such as malaria, HIV-AIDS, Syphilis, Tuberculosis and hepatitis <sup>1</sup>. In addition, health conditions, mental status and lifestyle can result in complications of pregnancy that can affect the health of pregnant women and results in maternal death<sup>2</sup>.

Early detection on pregnant women is one way to determine pregnancy abnormalities or problems so that they can prevent the severity of even maternal death<sup>3</sup>. The World Health Organization (WHO) recommends antenatal care as a preventive measure for early detection of pregnancy problems<sup>4</sup>. Antenatal care is done to assist in identifying early pregnancy problems and performing treatment complications during pregnancy <sup>3</sup>.

Integrated Antenatal Care (ANC) is a comprehensive program of antenatal care development that is carried out to prevent mothers from experiencing severity and even death. Integrated ANC services cover all basic examinations such as pregnancy examinations, dental examinations, nutritional consultations, laboratory tests such as Hb, blood type, complete blood, complete urine and other supporting examinations such as HIV-AIDS, tuberculosis, syphilis and hepatitis<sup>1,3</sup>.

An integrated ANC examination conducted comprehensively requires the mother to come to the health center. Data on the use of antenatal care services in developing countries shows that the utilization of pregnant women is still low in conducting ANC examinations, which is less than 65%, this is very far compared to developed countries which reached 97%. In Indonesia, the utilization of antenatal care services in health center merely reaches 61.4%<sup>5</sup>.

The low visits of mothers who came to check antenatal care at the health center were influenced by several factors such as age, income, education level, knowledge, social support, quality of care and distance to health facilities<sup>6</sup>. The study of factors that influence the use of antenatal care services in Nigeria explains that knowledge is an important factor so women are aware of their health rights to get appropriate health services. The results also showed that sufficient maternal knowledge of the benefits of ANC and pregnancy-related complications play an important role in the utilization of ANC services<sup>7</sup>.

The Integrated Behavior Model Theory states that behavior is an action that arises due to the intention that someone has. Without motivation, it is not possible for someone to do the recommended behavior. In addition to intentions there are 4 components that directly affect behavior, namely knowledge and skill to perform the behavior, salience of the behavior, environmental constraints and habits<sup>8</sup>.

Based on data from Maternal and Child Health of Jombang District Health Office, the results of the Integrated ANC examination in 2017 amounted to 68.53% and in 2018 it was 79.59%. Based on the existing achievement data, it can be seen that the achievement of the Integrated ANC examination at the Health Center has increased, but it is still far from the national target of 100%. Jombang Regency has 34 Health Centers work areas and three of them have the lowest integrated ANC examination results, namely Jelakombo Health Center

in 2018 of 47.24%, Jabon Health Center in 2018 of 60.72% and Cukir Health Center of 2018 of 66.61%<sup>9</sup>. The purpose of the study was to analyze the factors that influence the behavior of mothers to conduct an integrated ANC examination in the Three Working Areas of the Jombang Regency Health Center with the Theory Integrated Behavior Model approach.

## **Materials and Method**

The study used a quantitative approach with observational analytic type using cross sectional design. The sample in this study were pregnant women with gestational age of 1-5 months and lived in a predetermined health center working area with total of 110 pregnant women. The sampling is done by simple random sampling.

The study was conducted in the three work areas of the Jombang PHC are Jelakombo, Jabon and Cukir. Location selection is based on the lowest achievement of Integrated ANC examination at the health center. The research takes place from January to May 2019.

Measurement scale to see independent variables using Likert scales. Scores are grouped in categories. In the category of Intention to perform behavior (intention) that is weak <9 and Strong  $\geq 9$ . Knowledge and skill to perform the behavior is less <7 and Good  $\geq 7$ . Salience of the behavior is weak <15 and strong  $\geq 15$ . Category of environmental constraints is high <12 and low  $\geq 12$ . Habits is less <11 and good  $\geq 11$ .

The study was analyzed using SPSS 21 software, using a multivariate logistic regression method that was used to see the effects of independent variables, namely by intention to perform behavior, knowledge and skill to perform behavior, salience of the behavior, environmental constraints, and habit towards variables dependent is the mother's behavior to check the Integrated ANC at the health center.

**Findings:** From the data in table 1, it shows that the majority of pregnant women have a strong intention to conduct an Integrated ANC examination at the health center. Other factors that influence the behavior of mothers to check for integrated ANC also show positive results. The knowledge and skills of mothers are mostly in the good category, the importance of behavior in the strong category, barriers for mothers to check the Integrated ANC also in the low category and the habits of pregnant women are included in the good category.

**Table 1. Frequency Distribution of the factors of Intention to perform the behavior, knowledge and skills to perform the behavior, salience of the behavior, environmental constraints and habits**

Variable	N	%
<b>Intention to Perform the Behavior</b>		
Weak	29	26,4
Strong	81	73,6
<b>Knowledge and skills to perform the behavior</b>		
Less	39	35,5
Good	71	64,5
<b>Salience of the behavior</b>		
Weak	49	44,5
Strong	61	55,5
<b>Environmental constraints</b>		
High	31	28,2
Low	79	71,8
<b>Habit</b>		
Less	42	38,2
Good	68	61,8

Behavior is divided into two categories, namely yes and not doing an integrated ANC examination at the health center. Table 2. Indicates that the majority of pregnant women have performed an integrated ANC examination at the health center.

**Table 2. Behavior Distribution of Respondents to Check Integrated ANC**

Behavior	N	%
Yes	51	46,4
No	59	53,6

Factors that influence the behavior of mothers to conduct an integrated ANC examination in the three working areas of the Jombang Regency Health Center are based on the results of the logistic regression test, namely:

**Table 3. Logistic Regression Test Results of Factors Affecting Behavior**

Variable	Sig.	Details
Intention to perform the behavior	0,001	Take effect
Knowledge and skill to perform the behavior	0,465	No effect
Salience of the behavior	0,000	Take effect
Environmental constraints	0,917	No effect
Habit	0,765	No effect

Table 3. shows that there are two factors that influence the behavior of mothers to conduct an ANC examination in the Integrated health center, namely intention to perform the behavior and salience of the behavior.

Intention is a probability or possibility that is subjective, that is someone's estimate of how likely it is to do something. Intention will positively influence the conduct of behavior<sup>10</sup>. The majority of pregnant women have strong intentions in conducting an integrated ANC examination. The results of the same study revealed a strong relationship between women's intention factors in Zambia and the use of maternal health services including antenatal care examinations<sup>11</sup>. The research explained the intentions of pregnant women who were significantly associated with using Maternity Waiting Houses in Jimma City, West Ethiopia. Maternity waiting house is the concept of bringing pregnant women closer to antenatal care services<sup>12</sup>.

Knowledge and skill to perform the behavior is the knowledge of pregnant women about various things related to the Integrated ANC examination at the health center. The majority of pregnant women have good knowledge and skills, this shows that pregnant women understand the Integrated ANC examination that must be done at the health center. The benefits of the Integrated ANC examination and the loss if they do not conduct an Integrated ANC examination at the health center. The study showed 85.3% of pregnant women had a high knowledge score about antenatal care. The level of knowledge in pregnant women has a significant correlation with antenatal care practices in primary health care centers in Benghazi, Libya<sup>13</sup>.

Salience of the behavior is the perception of pregnant women who are important and necessary to carry out various actions that support an integrated ANC examination. The results of the study found that the Salience of the behavior factors influence the behavior of mothers to carry out an integrated ANC examination. The majority of pregnant women have important meanings related to good behavior.

Determining whether an important behavior is performed or not, the mothers must have a good understanding of the behavior of the Integrated ANC examination. Of course understanding is associated with education and knowledge that mothers have. Some studies have found that educated women have a good

examination history and pregnancy outcomes compared to uneducated mothers<sup>14</sup>. Mothers who have knowledge of good antenatal care will find it necessary to carry out antenatal care<sup>15</sup>.

Environmental constraints in this study are various environmental conditions that can hinder or make it difficult for pregnant women to carry out an integrated ANC examination at the health center. The results of the study found that some pregnant women have low/little environmental constraints, which means that mothers with fewer barriers should have a great opportunity to conduct an integrated ANC examination.

Distance to health facilities is one of the most common environmental constraints experienced by pregnant women to get ANC examinations in PHC, especially in rural areas. In general, the impact of distance on users of health facilities increases when combined with a lack of transportation in developing countries. In addition, access to health facilities also affects the frequency of services used<sup>16</sup>. The research shows that the distance to antenatal care is a problem that tends to limit access to antenatal care<sup>7</sup>.

The mother's Habit for conducting an Integrated ANC examination in this study is a variety of actions that consciously have often been carried out by the mother to encourage the mother to conduct an Integrated ANC examination. Mothers who have experience will do a behavior, and then the behavior will become a habit. The study revealed that high parity mothers and older women have fewer antenatal examinations because they have experiences of pregnancy<sup>17</sup>. The habit of mothers getting information about antenatal care also affects the behavior of Integrated ANC examinations at the health center. Research conducted in several developing countries reveals that women who often get information or antenatal care education from doctors or nurses increase the use of ANC examination services<sup>18</sup>.

### **Conclusion**

From this cross sectional study there are several factors studied, namely intention to perform behavior, knowledge and skill to perform, salience of the behavior, environmental constraints and habits. Based on the results of the study, it was found that the factors that influence the behavior of mothers to carry out an integrated ANC examination at the health center in the three working areas of Jombang Regency were Intention to perform the behavior and salience of the behavior. The results of

this study prove that the main determinant of a person's behavior is intention. An important factor in a behavior also contributes to pregnant women to have a decision to do or not conduct ANC Integrated examination at the health center. Information related to the Integrated ANC examination is very necessary to improve good understanding so that mothers have the knowledge and confidence in determining the decision not to carry out or conduct an Integrated ANC examination.

## Abstract

Cervical cancer is one of the most common neoplastic diseases in women in the world. Most of the occurrences of cervical cancer occur in developing countries, so cervical cancer becomes the main cancer for women in developing countries. The presence of cervical cancer results in a decrease in the quality of life in women as sufferers. The research method was case control by looking at the data from the respondent's medical records and analyzed using chi square and logistic regression. The purpose of this study was to identify the relationship between parity and the type of cervical cancer histopathology. Most respondents were aged 36-50 years and the incidence of SCC and adenocarcinoma with parity. Based on the results of univariate analysis between variables obtained  $p = 0.036$ , it can be said that parity with histopathology type is related to the strength of 0.118 and multivariate test found that 2-4 parity is more at risk of cervical cancer with histopa SCC with OR 0.037. Parity with 2-4 is the highest number in this study which suffered from squamous cell carcinoma. Educational efforts related to the program to limit the number of births.

**Keywords:** *Multiparity, histopathology, cervical cancer, adenocarcinoma, squamous cell carcinoma.*

## Introduction

Cervical cancer is one of the most common neoplastic diseases in women in the world. The number of cervical cancer sufferers is almost 500,000 new cases every year and kills 270,000 women every year. About 85% of cervical cancers occur in developing countries, so cervical cancer is the main cancer for women in developing countries. The presence of cervical cancer results in a decrease in the quality of life in women as sufferers. In Indonesia, cervical cancer is also the most common cancer among other gynecologic cancers. The incidence of cervical cancer around 7.9% in the world ranks second in all cancers in women with a 9.3% death incidence rate of all cancers in women in the world<sup>1</sup>.

According to the World health organization, it is estimated that in 2020 there will be an increase in the number of patients reaching 20 million per year. 2014 Hospital Information System data, there were 5,349 cases of cervical cancer in women or 12.8% of total client visits. Meanwhile, in East Java, the number of cervical cancer patients in 2015 was 4,304 and in 2016 there was

an increase to 4,796 cases. The city of Surabaya is one of the biggest contributors to cervical cancer which was reported as many as 877 cases in 2016<sup>2</sup>.

Histopathological type of adenocarcinoma cervical cancer and squamous cell carcinoma is influenced by several factors that are at risk for the occurrence of one of these types of cervical cancer. The risk factors are the number of sexual partners, parity, age too early at first delivery, duration of use of oral contraceptives and smoking, but it is still unclear which direct risk factors can be identified for squamous cell carcinoma which is also for adenocarcinoma<sup>3</sup>. Adenocarcinoma of the cervical uterus has different epidemiological and biological causes than squamous cell carcinoma. HPV infection is the main cause of both types of cervical cancer, several studies show differences between adenocarcinoma and squamous cell carcinoma in relation to other factors, such as smoking, and reproductive factors<sup>4</sup>. A study conducted by Green et al., In the UK found risk factors for adenocarcinoma cervical cancer and squamous cell carcinoma at the age of 20-40 years were increased

parity, age at first birth, oral contraception and duration of smoking..

The aim of this study was to find a relationship between parity and the type of cervical cancer histopathology.

### Method

This research is an analytical survey study with a case control study approach with retrospective analysis. The case group is squamous cell carcinoma and the control group is adenocarcinoma. The sample used in this study was 246 respondents divided into two, namely the control group and the case. Data is obtained by collecting secondary data from medical records. The data collection tool used is the checklist sheet. The data collected was then tabulated and analyzed using the chi square test and logistic regression.

### Result

The results of the study found variables such as age, occupation, education, parity number and type of cervical cancer histopathology

**Table 1 Distribution of respondents by age**

No.	Age	Total	Percent
1	20-35	22	9.0%
2	36-50	128	52.0%
3	>50	96	39.0%
<b>Total</b>		<b>246</b>	<b>100%</b>

Based on the age distribution of the respondents the highest was 36-50 years with a percentage of 52.0%.

Table 2 shows the highest number of respondents based on education level are elementary school graduates, namely 80 respondents or 32.5%.

**Table 2 Distribution of respondents based on education level**

No.	Education Level	Total	Percent
1	Elementary School	80	32.5%
2	Junior High School	64	26.0%
3	Senior High School	74	30.1%
4	College	28	11.4%
<b>Total</b>		<b>246</b>	<b>100.0%</b>

**Table 3 Distribution of respondents based on the amount of parity**

No.	Parity	Total	Percent
1	0	9	3.7%
2	1	47	19.1%
3	2-4	178	72.3%
4	>5	12	4.9%
<b>Total</b>		<b>246</b>	<b>100%</b>

Table 3 shows the number of parity of respondents with the highest parity number, namely 2-4 with 178 respondents or 72.3%.

**Table 4 Distribution of respondents based on the type of histopathology ca cerviks**

No.	Type	Total	Percent
1	Adenocarsinoma	123	50%
2	Squamous cell carcinoma	123	50%
<b>Total</b>		<b>246</b>	<b>100%</b>

Based on table 5 Histopathological types are divided equally because in this study using case control.

Bivariate analysis of variable parity and type of histology Ca Cerviks.

**Table 5 Cross tabulation between parity and histopathology type**

No.	Parity	The Type Of Histopathology		Total	
		Squamous cell carcinoma	Adenocarsinoma	F	%
1	0	15	18	33	13
2	1	34	38	72	29
3	2-4	55	45	100	40
4	≥5	29	12	41	18
<b>Total</b>		<b>123</b>	<b>123</b>	<b>246</b>	<b>100</b>

Chi Square p= 0.036, Contingency Correlation= 0.118

Based on table 5, the highest incidence of parity was found in 2-4 with the type of histopathology of squamosa cell carcinoma as many as 55 respondents. Adenocarcinoma is dominated by 2-4 parity with 45 respondents. Univariate analysis between variables obtained  $p = 0.036$  which can be said that parity with histopathology type is related to the power of 0.118.

Multivariate testing of the relationship between parity and the type of histopathology of cervical cancer using logistic regression

**Table 6. Results of multivariate tests on parity and histopathology relationships**

Parity	P value	OR	CI 95%	
			Upper	Lower
Parity 0	0.054	1	-	-
Parity 1	0.030	0.345	0.132	0.951
Parity 2-4	0.017	0.370	0.164	0.838
Parity $\geq 5$	0.006	0.339	155	738

From the table above, it can be seen that the highest risk of cervical cancer is in parity 2-4 with a value of OR 0.370, meaning the risk of cervical cancer in parity 2-4 is 0.37 times greater than other parities..

### Discussion

**Identification of Parity:** Based on table 4 data collected by classifying parity categories with 0, 1, 2-4, and  $\geq 5$  found the highest parity is 2-4, meaning the respondents have 2-4 children (multipara). High parity is one of the risk factors for cervical cancer. Jensen et al., stated that women who had 4 or more times at risk of having cervical cancer were 1.9 times more than the number of women who gave birth between less than or equal to 3 times, although this was a risk factor but this it should be our attention to detect this group. Pregnancy and childbirth that exceeds 3 people and the distance of pregnancy is too close will increase the incidence of cervical cancer..

The majority of respondents who have children 2-4 are aged 36-50 years. The age of sufferers is between 30-60 years, the most between 45-50 years. This study is also in line with a study conducted by Missaoul which shows that the average age diagnosed with cervical cancer is at most above 40 years of age. The latent period of the prevasive phase to be invasive takes about 10 years. Only 9% of women under 35 years showed invasive cervical cancer at the time of diagnosis, while

53% of KIS (carcinoma in-situ) was found in women over 35 years of age<sup>7</sup>.

According to the theory, the incidence of cervical cancer increases with age and the time it starts to become infected with HPV until it becomes invasive cancer as a multistage carcinogenesis process that requires around 10-20 years. In addition, in old age there is also a decrease in immunity which plays a role in destroying cancer cells, slowing growth and spread.

**Identification of Types of Histopathology of Cervical Cancer:** Based on table 6, the most histopathological type was found in squamosa cell carcinoma with 55 respondents with 2-4 parity. The findings in this study are in line with the research of Chen, Tong, Guo, Lau, & Zhao, who stated that histopathology terminology of cervical cancer is divided into squamous cell carcinoma and adenocarcinoma. The most common type of cervical cancer is found in 80%-85% of squamous cell carcinoma, with the remaining 15% -20% followed by adenocarcinoma or adenoskuamosa carcinoma.

The incidence of squamous cell carcinoma was initially preceded by precancerous lesions, also called cervical intraepithelial neoplasia (CIN), which is the beginning of changes to invasive cervical carcinoma. In these precancerous lesions, cell structure changes become abnormal. Cells change shape and size, cell nucleus enlarges, and cell cytoplasm decreases. High cases of squamous cell carcinoma are often caused by skrinning delay so that it is known that at the time of being squamous cell carcinoma<sup>5</sup>.

However, this is not in accordance with Bonin, Devouassoux-shisheboran, & Gol, who stated that in his research found the most cases of cervical cancer were adenocarcinoma. Adenocarcinoma itself is often found at a young age that is under 35 years. In this study most of the respondents were between 36-50 years old so that the type of adenocarcinoma is more lacey than the type of squamous cell carcinoma

**Relationship of Parity with Types of Histopathology of Cervical Cancer:** Based on the results of the chi square test statistics the value of  $p = 0.036$  and  $\alpha = 0.05$  was obtained. Parity can play a synergistic role with other factors such as HPV to increase the risk of cervical cancer, so that parity can be a cofactor that causes cervical neoplasia. Cervical cancer is most commonly found in women who often give birth. This is presumably due to hormonal changes that occur

during pregnancy and cervical trauma that occur during childbirth. Trauma to the cervix and frequent treatment in the reproductive organs during childbirth can facilitate the entry of HPV as a causative agent for cervical cancer. Changes in the composition of the hormone progesterone and estrogen during pregnancy also cause an influence on HPV and the development of cancer <sup>10</sup>

In this study, women with 2-4 more parity were found as sufferers of cervical cancer. High parity increases trauma to the birth canal. The incidence of cervical adenocarcinoma is often associated with HPV exposure. The development of adenocarcinoma initially originates from epithelial cells that experience genetic mutations that change their behavior <sup>11</sup>. These mutated cells carry out uncontrolled, immortal cell division and invade the stromal tissue below. Circumstances that cause irreversible genetic mutations will cause this cancer to grow. Oncoprotein from E6 will bind and make the tumor suppressor gene (p53) become inactive, while oncoprotein E7 will bind and make the retinoblastoma (pRb) gene product become inactive <sup>12</sup>. This mutation of the tumor suppressor gene causes decreased proliferative and apoptotic activity. High parity can increase the risk of cervical cancer because maintaining a transformation zone is on the ectocervix for a long time (years) so as to facilitate direct exposure to HPV and other cofactors <sup>9</sup>.

Patil, Deshmukh, Rathid, Kotgire, & Chavan found that HPV exposure is possible because of the stimulation of the cervix in the form of trauma and inflammation during labor, which can repeatedly cause excessive responses. Childbirth and abortion play a role in the development of cervical cancer because of the repeated birth process or in other words having many children, the uterine cervix will experience trauma and slow repairs, so this is the way for precancerous conditions. This is in line with research by Zaloudek which states that adenocarcinoma correlates with the presence of HPV invasion. As many as 76% of women with adenocarcinoma are positively infected with HPV with repeated labor history <sup>15</sup>.

Repeated labor takes the form of changes from the ectocervical epithelium, namely the squamous epithelium with the endocervical epithelium, which is a ciliated layer of short cuboid/columnar epithelium. In young SCJ women outside the external uterine os, whereas in women over 35 years SCJ is inside the cervical canal <sup>16</sup>. Therefore in young women, SCJ which is outside the external uterine os is susceptible to external factors such

as mutagens which will trigger dysplasia of the SCJ. In women with high sexual activity, SCJ is located in the external os due to trauma or muscle retraction by prostaglandins. During a woman's life physiological changes occur in the cervical epithelium; the columnar epithelium will be replaced by a squamous epithelium that is thought to originate from a columnar epithelial reserve. Sharma & Pattanshetty found the process of replacing the columnar epithelium into a squamous epithelium called the metaplasia process and occurs due to the influence of low vaginal pH after labor. High metaplasia activity resulting in SCJ hyperactivity leads to squamous cell carcinoma.

This illustrates the increasing number of children the more at risk of developing cervical cancer. Due to injury after childbirth and the distance of labor that is too close will cause the virus that causes cervical cancer to enter. Cervical cancer or cervical cancer is the biggest cause of cancer deaths for women. This cancer occurs in the cervical area, which is the part of the uterus that connects the upper uterus to the vagina. The injury triggers HPV invasion and facilitates abnormalities in cells around the injury. The result will be cervical cancer.

## Conclusion

Based on the results of the study there is a relationship between parity and histo PA with a value of  $p = 0.036$  and the strength of a strong relationship with a value of 0.118. 2-4 parity is 0.370 times higher in squamous cell carcinoma. The need to improve health education programs in the prevention of cervical cancer.

# Stigmatization People Living with HIV AIDS (PLWHA)

Rio Ady Erwanyah<sup>1</sup>, Moecharam<sup>1</sup>, Rizky Asta Pramesti<sup>1</sup>,  
Argo Winoto<sup>1</sup>, Miranti Dea D<sup>1</sup>, Moch Dadang S<sup>1</sup>, Ainur Rusdi<sup>1</sup>

<sup>1</sup>Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

## Abstract

People with HIV AIDS (PLWHA) often experience stigma, the stigma that occurs among them is verbal statement and the act of keeping PLWHA away from social activities, stigma can disrupt the social role of PLWHA. Stigma can come from anyone including health workers. PLWHA need actions to eliminate the stigma that occurs, so that PLWHA can live as other individuals without getting stigma. The purpose of the review literature is to identify the forms and sources of stigma that occur in PLWHA and efforts to eliminate stigma against PLWHA. The author finds journals that are relevant to the problem by using stigma keywords, health workers, HIV AIDS, and people with HIV AIDS. Journals were obtained from the Science Direct, Proquest, SagePub, and Scopus databases with 54 journals and 14 journals fulfilling the criteria for analysis. Journal analysis states that various efforts have been made to solve the problem of stigma against PLWHA, this effort includes the entry of HIV into health care work programs, the source of stigma from health workers requires special attention, because health workers should be promoters to eliminate stigma, necessary increasing the knowledge and expertise of health workers in handling and treating PLWHA. So that officers can become promoters in eliminating stigma against PLWHA

**Keywords:** *HIV, AIDS, People with HIV AIDS (PLWHA), Stigma, Immunology.*

## Introduction

Stigma One of the problems faced in making efforts to control Human Immunodeficiency Virus (HIV) Acquired Immune Deficiency Syndrome (AIDS) in the community, this is due to the fear of being infected and the lack of knowledge about HIV AIDS. Unfair treatment (discrimination) and stigma are not only carried out by the community but also by health workers, stigmatization can be done intentionally or unintentionally. Various efforts have been made to solve the problem of stigma against people with HIV AIDS (PLWHA), these efforts include the inclusion of HIV programs in the Puskesmas work program, but with socialization and health counseling that have not been able to solve the existing problems <sup>1</sup>

Preventive efforts are very necessary because it can reduce the risk of HIV transmission, prevention efforts are considered most effective because they can prevent someone from being exposed to the risk of transmission, research on HIV treatment therapy has been carried out, one of which is Antiretroviral therapy (ART) can increase PLWHA life expectancy <sup>2</sup>

Handling HIV-AIDS problems is not enough only on health aspects, but also refers to social aspects. This is because, HIV-AIDS sufferers not only experience health problems, but also experience social problems. The social problem in question is the presence of stigma on PLWHA and family members, the forms of stigma that are obtained vary among others in the form of verbal statements and discrimination <sup>3</sup>

Stigma occurs not only from people in the surrounding environment, but also often carried out by health workers, who have an important role in advancing in the field of health services. Health workers should provide services to all people in need without distinguishing health and social status. Especially for

---

### Corresponding Author:

**Rio Ady Erwanyah**

Indonesia

e-mail: rio.ady.erwanyah-2017@fkn.unair.ac.id

nurses, they must also have value and self-confidence to provide services including PLWHA. Anxious feelings and worries that the nurse has can do stigmatization without the nurse noticing<sup>4</sup>

The stigma can have an impact on many things starting from the onset of depression, psychological distress, and anxiety which will eventually lead to PLWHA being unable to achieve its independence. Other research shows that PLWHA is reluctant to open an identity because it cannot be accepted by its environment, so that most PLWHA has a disruption of social interaction with the surrounding community<sup>5</sup>. Disparities occur in several places that cause PLWHA to get worse with its health status, which is reflected in the treatment received by PLWHA in the work environment and living environment<sup>6</sup>

The purpose of this study was to conduct a systematic review related to PLWHA's perception of the stigma they experienced. This study is expected to provide ideas for further research related to PLWHA's perception of the stigma experienced and can be used as a reference in efforts to handle PLWHA.

### Method

Study search strategies that are relevant to the topic are carried out using the ScienceDirect, Proquest, and SagePub databases restricted from 2000 to 2018. The keywords used are "stigma", "HIV", "AIDS", fulltext articles and abstracts reviewed to choose studies which matches the criteria. The inclusion criteria in this review are stigma in people with HIV/AIDS. Journal searches using the above keywords get 54 journals and articles that match the inclusion criteria there are 14 journals.

### Result

The journals reviewed in this study are qualitative research journals. The number of articles obtained in this review are 14 journals and all of them use qualitative research. The method used to obtain information is using in-depth interviews and FGD (focus group discussion).

The period of research used in these studies varies from 1 month to 1 year, the longer the time the study and the frequency of interviews on average provide good results for the information obtained. The longer the study, the more information that can be extracted, this is indicated by the frequency of frequent interviews and frequently scheduled group meetings.

The sampling method used in the study was 14 studies that had been carried out qualitatively. The sample in this study varied, for example age, in this study the age of the sample varied from teenagers to late adulthood. So that the data obtained is very diverse and covers all age lines.

Based on the description of 14 studies, it is shown that the handling of HIV-AIDS problems is not enough only on the health aspect, but also refers to the social aspects<sup>7</sup>. This is because, HIV-AIDS sufferers not only experience health problems, but also experience social problems<sup>8</sup>. The social problem in question is the existence of stigma on PLWHA and family members, the forms of stigma that are obtained vary among others in the form of verbal statements and discrimination<sup>9</sup>. Various efforts have been made to solve the problem of stigma against people with HIV AIDS (PLWHA), these efforts include the inclusion of HIV programs in health care work programs, but with the outreach and health counseling that has not been able to solve the existing problems<sup>10</sup>

### Discussion

The results of the review indicate that stigma raises health problems and social activities, 1 of 4 people with HIV are unaware of their HIV diagnosis, and almost half present with a CD4 count <350 cells/microliter<sup>11</sup> 95% of informants reject their health status<sup>12</sup>. Stigma causes negative self-image and the occurrence of discrimination from the community causing interruption social PLWHA<sup>13</sup>. Increasing understanding of social support mechanisms contributes to HIV treatment behaviors from PLWHA and can fill knowledge gaps<sup>14</sup>. Family support and peer group support can increase the level of psychological response<sup>15</sup>.

Stigma and discrimination in health services carried out by health workers is one of the obstacles to the quality of providing health services to patients with HIV and AIDS, which in turn can reduce the health status of patients with HIV and AIDS, the stigma associated with HIV and AIDS is called a big problem and damages family life, social, and individual economics<sup>16</sup>. The stigma associated with HIV and AIDS is also considered a major barrier in the prevention, treatment and treatment of HIV and AIDS<sup>17</sup>

The stigma that occurs is influenced by several factors known as the power factor of the occurrence of stigma<sup>18</sup>. Power factors include four components

including social, political, economic and spiritual factors. Social factors are influenced by weak communication and social contact between health workers and patients. Politically, stigma occurs because there is no policy that regulates the handling of HIV and AIDS patients, and the consequences of stigma and discrimination in patients related to HIV and AIDS. Economic factors, the emergence of stigma and discrimination because of the lack of provision of universal precaution facilities, the absence of rewards and reward services, and no health insurance if contracting HIV and AIDS<sup>19</sup>

### Conclusion

The results of a systematic review of research addressing the problem of HIV-AIDS is not enough only on health aspects, but also refers to social aspects. This is because, HIV-AIDS sufferers not only experience health problems, but also experience social problems. The social problem in question is the existence of stigma on PLWHA and family members, the forms of stigma that are obtained vary among others in the form of verbal statements and discrimination. Various efforts have been made to solve the problem of stigma against people with HIV AIDS (PLWHA), these efforts include the inclusion of HIV programs in health care work programs, but with the outreach and health counseling that has not been able to solve the existing problems.

# Development of Doctors Attire According to Patients Preferences

Rizki Fadillah<sup>1</sup>, Rizma Adlia Syakurah<sup>2</sup>, Riana Sari Puspita Rasyid<sup>3</sup>

<sup>1</sup>Undergraduate Medical Student, Faculty of Medicine, Universitas Sriwijaya, Palembang, <sup>2</sup>Public Health Department, Faculty of Medicine, Universitas Sriwijaya, Palembang, <sup>3</sup>Biochemistry Department, Faculty of Medicine, Universitas Sriwijaya, Palembang

## Abstract

**Background:** Doctor-patient rapport can be built in various ways, and it also includes non-verbal communication. Medical attire is an example of non-verbal communication that affects the patient's comfort and perception of a doctor. Medical attire that suits patient's preferences has a positive effect on the patient's trust and comfort.

**Objective:** This study aims to know about patient's preference towards doctor attire, so it will be a guide for doctor building good rapports in doctor-patient communication.

**Method:** This research is an analytical observational study with cross-sectional approach. Using consecutive sampling method, a sum of 6467 Indonesians was taken as samples. The data acquired from questionnaire via google form include age, sex, level of education, and patient's rate of comfort for doctor apparel. To analyze the data, both Independent T test and One Way Anova were conducted.

**Result:** White coat, basic pants, formal shoes, watch, and glasses are male doctors' garments that patients find very comfortable. On female doctors, the pieces of clothing that patients are very comfortable with are white coat, basic pants, formal shoes, and hijabs. There is a significant result in comparison at each attire ( $p < 0,05$ ).

**Conclusion:** The attire that patients find very comfortable to be worn by doctors are white coat, basic pants, formal shoes, hijabs (on women), watch, and glasses.

**Keywords:** *Medical attire, patient's comfort, white.*

## Introduction

A doctor must provide maximum service in all aspects, including promotive, preventive, curative, and rehabilitative aspects when performing his duties.<sup>1</sup> The important thing for doctors to work effectively is through good doctor-patient relationships.<sup>2</sup> Good relationships can be formed through effective communication, both verbally and nonverbal.<sup>3</sup> Nonverbal communication includes body gestures, facial expressions, eye contact, appearance, especially attire.<sup>4</sup> Nonverbal communication is not only a complement to verbal communication, but also gives meaning to the information conveyed. In fact, 65% of communication is delivered nonverbally.

Appearance is one form of nonverbal communication that plays an important role in shaping the patient's initial perceptions.<sup>4</sup> Doctor's appearance and attire is important in increasing patient trust and satisfaction with health services provided by doctors.<sup>6</sup> This is due to patient trust and satisfaction is not only objectively influenced by medical action, but also subjectively, such as by the good appearance and good attire of the doctor.

Problems regarding the patient's trust in doctors, makes it very important for doctor to improve their quality of service by increasing their nonverbal abilities. Therefore, the research that will be carried out regarding the development of doctor attire according to patient preferences can be beneficial for health practitioners.

This study aims to know about patient’s preference towards doctor attire, so it will be a guide for doctor building good rappers in doctor-patient communication. The benefits obtained are knowing the appearance preferences and how to dress that the patient likes, and make the patient feel more comfortable.

**Method**

This study used a descriptive observational method with a cross sectional design to determine patient preferences in choosing doctor’s clothing. The study was conducted in the span of September 2018 - December 2018 at the Medical Faculty of Sriwijaya University. The population of this study is all Indonesian people. The sample in this study was the population that met the inclusion criteria and was chosen as research subject through sampling process. The method of sampling in this study used a non-probability sampling technique, with a consecutive sampling method.

Consecutive sampling is done by taking all respondents or subjects that meet the research criteria. The inclusion criteria for this study were the Indonesian people who filled out questionnaire data and people who filled out questionnaire is 12 years and above. The exclusion criteria for this study were the questionnaire with unfilled data. The variables in this study were doctor’s attire (tops, bottoms, and accessories) and sociodemographic factors (age, gender and education level).

**Results**

**Table 1. Comparison of the Average Value of the Comfort of Patients Against the Doctor's Tops Attire**

Tops	Mean	p value
<b>Male doctors</b>		
Snelli *	4,32	0,000
Shirt*	3,84	0,000
Batik*	3,21	0,025
Polo shirt	2,28	0,000
Leather jacket	1,86	
<b>Female Doctors</b>		
Snelli*	4,50	0,000
Blouse*	3,55	0,000
Abaya*	3,45	0,000
Batik*	3,39	0,001
T-shirt	2,24	

**Table 2. Comparison of the Average Value of Patient's Comfort Level on Doctor's Bottoms Attire**

Bottoms	Mean	P value
<b>Male doctors</b>		
Basic pants*	4,23	0,000
Cotton pants*	4,13	0,000
Chinos*	2,99	0,000
Jeans	2,7	
<b>Female doctors</b>		
Basic pants*	4,01	0,000
Basic skirt	3,58	0,310
Cullote pants*	3,56	0,000
Short skirt	2,62	

Based on this study, it can be concluded that, patients feel very comfortable when male doctors wear snelli (mean of 4.32), and female doctors wear snelli (mean of 4.50). Snelli is the attire for male and female doctors that is perceived as very comfortable by patient, with significant p value. Meanwhile, patients were very uncomfortable with male doctors who wore leather (mean of 1.86) and female doctors who wore shirts with a (mean of 2.2).

Basic pants are considered very comfortable when worn by male doctors (mean of 4.23). The majority of respondents feel comfortable when female doctors wear basic pants (38.2%) with an average value of 4.01. The comparison of the average value between basic pants and cotton pants on male doctors is 0,000, and the comparison of mean values between basic pants and basic skirts on female doctors also shows the results of 0,000 which means there are significant differences (p <0.05). Most respondents felt uncomfortable seeing male doctors wearing jeans (average score of 2.7) and female doctors wearing short skirts (average score of 2.62).

**Table 3. Comparison of the Average Value of Patient’s Comfort Level on Doctor’s Footwear**

Accessories	Mean	P value
<b>Male doctors</b>		
Watches	4,33	0,094
Glasses*	3,93	0,000
Bracelet*	2,16	0,000
Aqeeq ring*	1,82	0,000
Piercing	1,41	
<b>Female doctors</b>		
Hijab*	4,48	0,003

Accessories	Mean	P value
Watches*	4,21	0,001
Glasses*	3,98	0,000
Socks	3,91	0,175
Make up*	3,84	0,000
Earrings	3,74	0,063
Rings	3,65	0,761
Bracelets*	3,13	0,006
Necklace*	2,94	0,000
Piercing	1,61	

**Table 4. Comparison of Mean between Patients Comfort to Doctor Accessories**

Footwear	Mean	P value
<b>Male doctors</b>		
Dress shoes*	4,23	0,000
Sneakers	3,46	0,729
Flat shoes	3	
<b>Female doctors</b>		
Dress shoes*	3,98	0,000
Sneakers*	3,66	0,000
High Heels*	2,67	0,000
Sandals	2,6	0,111
Boots	2,24	

Most respondents felt very comfortable seeing male doctors wearing dress shoes (mean of 4.23) and feeling comfortable when male doctors wore sneakers (mean of 3.46). Comparison of mean between dress and sneakers yields 0,000 ( $p < 0.05$ ) which indicates that the dress shoes is footwear that the respondent feel at ease with. Regarding, choice of footwear worn by female doctors, most respondents felt very comfortable seeing doctors wearing dress shoes (mean of 3.98) and felt very uncomfortable seeing doctors wearing boots (mean of 2.24). Loafers are the most comfortable women's footwear according to patient preferences ( $p < 0,05$ ).

Male doctor accessories that make patients very comfortable are watches (mean of 4.33) and glasses (mean of 3.93). On bivariate analysis, there were no significant differences ( $p > 0.05$ ), which meant that doctors could wear either one of the accessories, watch, glasses, or both.

Patients are very uncomfortable with male doctors that wear piercings (mean of 1.41). Hijab as accessories for female doctors are considered very comfortable (mean of 4.48,  $p < 0.05$ ), followed by watch (mean of 4.21) and glasses (mean of 3.98). The accessories of

female doctors which are considered very uncomfortable by patients are facial piercing (mean of 1.61).

## Discussion

The results of this study indicate that patients have a high preference for doctors who use snelli. In line with these results, the study of Van Der Merwe and Douse et al. found that patients prefer white coats or snelli as clothes that should be worn by doctors when conducting consultations<sup>5,6</sup>. This is presumably because snelli is an easy way for patients to identify doctors and also increase level of professionalism in the eyes of patients<sup>7,8,9</sup>. White coats are also considered more hygienic as doctors are not directly exposed to patients<sup>1</sup>. Furthermore, doctors who wear conventional clothing such as snelli is preferred by patients because it can increase the trust and desire of patients to share social, sexual, and psychological problems<sup>11</sup>. The most disliked tops attire for male doctors to wear is a leather jacket. In line with this findings, Marriane's research found that in general patients do not like very casual clothes such as leather jackets<sup>12</sup>. Doctors with casual clothing are considered less competent and less trustworthy than doctors with snelli or conventional clothing. Research conducted by Jennings supports this, namely for both male and female respondents, casual clothing is the most disliked clothing worn by doctors<sup>13</sup>. However, casual clothes that are semiformal like shirts are quite preferred by patients. According to Lill and Wilkinson's research, patients prefer doctors to dress semiformally and smile during consultations, makes patients feel more comfortable<sup>14</sup>. Semiformal western clothing such as shirts are also preferred in Saudi Arabia, because they make patients feel more comfortable and want to share more about their social, sexual and psychological problems<sup>15</sup>.

Patients felt least comfortable when female doctors wore t-shirts. Van Der Merwe et al in their research on doctor clothing preferences, found that only a few respondents liked t-shirts as female doctor clothes. This result is somewhat different from Hartmans' research, where t-shirts are female doctor's clothing that make respondents feel more comfortable than snelli or formal clothing<sup>16</sup>. However, Harmants found that doctors who used snelli were considered by patients to be more professional than those who were not<sup>16</sup>. In this study, it was found that the majority of respondents thought basic pants were bottom clothes that were suitable for doctors, both for male and female doctors. Several studies were

found to be in line with these results. Marriane in her research got basic pants as a bottoms that was liked by the majority of respondents, this was because patients considered basic pants to be formal and neat pants so that they could improve patient's comfort<sup>14</sup>. In line with these results, a study conducted by Boyce concluded that material pants as bottoms are the most preferred, because it can increase patients' trust<sup>8</sup>.

On the other end of the spectrum, jeans are bottoms that make the majority of patients feel uncomfortable to wear by male doctors. Marriane's research supports this claim that the preference for jeans for male doctors is low<sup>14</sup>. Chang et al. Sought further patient responses to casual clothing such as jeans, ie people with casual clothing were less competent and less trustworthy than those who dressed conventionally<sup>17</sup>. Short skirts on female doctors are bottomsthat patients feel uncomfortable with. Most respondents prefer female doctors to wear skirts under the knees<sup>13</sup>. Marriane's research also found the same thing, short skirts were felt to be uncomfortable by patients, while more conservative clothing such as long skirts were preferred<sup>14</sup>.

Loafers are footwear for male doctors with the highest rating in patients' comfort. Fox research found that the use of loafers is a characteristic expected by patients to their doctors. Similar to this, Van der Merwe's research found the results of loafers as the most preferred footwear for respondents and most comfortable to use for male doctors and male health service provider<sup>5,18</sup>. On the other hand, flat shoes are footwear for male doctors that are less preferred by patients. Same thing with male doctors, patients prefer female doctors who use footwear in the form of loafers. This result is not in line with Van der Merwe's research which found that patients' preference for female doctor's footwear is flat shoes because it is felt to make patients more comfortable and show the competence of a doctor<sup>5</sup>. Casual doctor's footwear such as sandals, high heels, or boots, in some studies suggest that these items have a low preference level in patients because they are considered to be not very professional and reduce the image of a doctor<sup>5,14</sup>.

Accessories with the highest preference for male doctors are watches. While the accessories that make patients feel very uncomfortable are piercing. Although the norms of society have begun to change with the use of piercings, they are accepted in the community, but this does not seem to apply to health workers. Research conducted by Lill and Wilkinson, states that patients

feel very uncomfortable when male and female doctors wear piercings<sup>14</sup>. According to research conducted by Newman et al, Piercing is considered inappropriate when used by medical workers because it can affect patients' beliefs and their views to the competence of a doctor<sup>19</sup>. For female doctors, the most comfortable accessories are hijab, which is in line with the research conducted by Seeger, which states that there is no difference towards Muslim women who cover themselves with hijab, as long as hijab doesn't limit their work capability<sup>20</sup>. In addition, research conducted by Batais shows that people still like doctors who wear special religious accessories such as turban and long overalls<sup>15</sup>.

**Ethical Clearance:** Taken from research ethics committee of Sriwijaya University Medical Faculty

**Source of Funding:** Taken from Public Health Department, Faculty of Medicine, Universitas Sriwijaya, Palembang, Indonesia

**Conflict of Interest:** The authors would like to deliver grattitude to Sriwijaya University for making this study possible and all parties that supported this study.

## Conclusion

The male doctor's attire patients feel most comfortable is snelli, basic pants, loafers, glasses and watches. Meanwhile, women's doctors attire patients feel most comfortable is snelli, basic pants, loafers, and hijabs.

# Lower Abdominal Pain During Office Hysteroscopy as a Guide in the Assessment of Tubal Patency in Infertile Women

Sally Elattar<sup>1</sup>, Ahmed Maged<sup>2</sup>, Moutaz Elsherbini<sup>3</sup>

<sup>1</sup>Assistant Lecturer of Obs. & Gyn., <sup>2</sup>Professor of Obs. & Gyn., <sup>3</sup>Assistant professor of Obs. & Gyn., Department of Obstetrics and Gynecology, Kasr Al-Ainy Hospital, Faculty of Medicine, Cairo University, Cairo, Egypt

## Abstract

**Objective:** to test the accuracy of pain score measuring on each side of the lower abdomen for diagnosis of tubal patency.

**Material and Method:** 60 patients underwent Office hysteroscopy and pain score on each side of the lower abdomen was measured during hysteroscopy using Visual Analogue Score. Transvaginal ultrasonography was done after hysteroscopy to assess the presence of fluid in Douglas pouch. One week later, laparoscopy was done as a reference test for tubal patency.

**Results:** Pain score was significantly higher on the side of lower abdomen if the respective tube was patent (p value <.001). Area under ROC curve for the pain score test was 0.77 (95%CI: 0.85 to 0.9), p value <0.001 denoting good accuracy. The optimum cutoff for pain score to discriminate tubal patency was >10 with sensitivity and specificity 79.8%and 93.6%, respectively.

**Conclusions:** The pain score during hysteroscopy can be used to diagnose tubal patency. The optimum cutoff score is >10.

**Keywords:** *Hysteroscopy, tubal patency, pain.*

## Introduction

Infertility is a worldwide health problem affecting 12.5% of all couples causing emotional and psychological distress in both men and women.<sup>(1)</sup> Assessment of tubal patency is crucial in tailoring the management strategy of the infertile couple.<sup>(2)</sup>

Laparoscopy is considered the gold standard for diagnosis of tubal patency; however, it is an invasive expensive procedure and carries risks of anesthesia and operative complications.<sup>(3)</sup>

Therefore, worldwide hysterosalpingogram (HSG) is a first step in the evaluation of tubal patency as it is less invasive.<sup>(4)</sup> Nevertheless, it has several risks namely: x-ray exposure, allergy from radio contrast material and infection. Although it is still the first diagnostic test for evaluation of tubal patency, it has a sensitivity of 46% to 65% and a specificity of 68% to 89%.<sup>(5 & 6)</sup>

Over the past few decades, attempts were made to find other method to diagnose tubal patency with comparable or better accuracy than HSG and less invasiveness than laparoscopy. Saline infusion Sonohysterography (SIS) was evaluated to replace HSG but its drawback is that it does not differentiate bilateral tubal patency from unilateral block.<sup>(7)</sup>

To overcome this problem, investigators had introduced hysterosalpingo contrast sonography (HyCoSy) for better delineation & assessment of the tubes than SIS. Nevertheless, the contrast medium is not widely available, expensive and carries the risk

Tel :+201000938439

of anaphylaxis. Moreover, the interpretation of this modality is very dependent on the experience of the sonographer & the whole tube cannot be properly observed due to its tortuosity<sup>(8-10)</sup>.

Hysteroscopy, the gold standard approach to evaluate uterine cavity, was recently investigated for its possible role in the diagnosis of tubal patency especially after progressive advancement in the office hysteroscopy. The first suggested method used during hysteroscopy to evaluate the tubal patency was assessment of fluid in Douglas pouch after hysteroscopy, but this approach has similar problem to SIS. Selective perturbation at hysteroscopy was suggested to diagnose tubal patency, however, this method requires learning and is still less accurate than laparoscopy.<sup>(11 & 12)</sup>

Likeovulatory pain, fluid passing through the patent fallopian tube while doing hysteroscopy may lead to temporary irritation of the local peritoneum resulting in pain at the site of patent tube.<sup>(13)</sup> The current study aimed to evaluate the efficacy of pain level (pain score) at the side of fallopian tube during office hysteroscopy in the differentiation between patent & occluded tube.

## Material and Method

The present study was a prospective interventional diagnostic one in which 60 infertile patients (aged between 20 and 35 years) & candidate for assessment of tubal patency were included. Patients recruitment & data analysis were done at department of Obstetrics and Gynecology, Kasr Al-ainy Hospital, Cairo University from January 2013 to March 2017.

Patients who had lower genital tract infection, chronic medical disorder (e.g., diabetes), chronic pain disorders or contraindications to hysteroscopy or laparoscopy (e.g., multiple previous laparotomies) were excluded from the study. Other exclusion criteria included infertile husband semen, presence of pelvi-abdominal masses, presence of cervical stenosis and appearance of fluid in Douglas pouch by vaginal ultrasound (TVUS) before hysteroscopy. Informed consents were taken from all participants.

For all patients, full history was taken followed by examination and routine preoperative investigations. Hysteroscopy was done for participants in the follicular phase (cycle day 6 or 7). Initial TVUS was done (using 7.5 MHz probe of Voluson E8, GE Healthcare Co., Chicago, IL, USA) to exclude the presence of fluid

in Douglas pouch. Then, Office Hysteroscopy using vaginoscopic approach (4-mm endoscope with 30 degrees camera - Tekno Medical Optik-Chirurgie GmbH & Co., Tuttlingen, Germany) was done. 80 to 100 mmHg pressure and 200 ml of saline were used for all patients to standardize all the conditions before assessment of pain. No anesthesia was given. The procedure time was 6 to 8 minutes in all patients. Analgesia was not given except if needed after completion of the procedure and assessment of pain.

Pain assessment was done during the hysteroscopy procedure using Visual Analogue Scale (VAS). Patients were instructed to report pain on each side of the lower abdomen separately on 2 papers of VAS. Each paper had a line from 0 (no pain) to 100 mm (worst pain). TVUS was repeated 15 minutes after completion of the procedure to assess the presence of fluid in Douglas pouch.

Laparoscopy with methylene blue chromopertubation was done 7 days after hysteroscopy for all patients & the surgeons were blinded for the results of the hysteroscopy. The laparoscopy was done under general anesthesia using classical steps of pneumoperitoneum by CO<sub>2</sub> followed by single port 10 mm trocar insertion subumbilically. The laparoscope (Karl Storz GmbH & Co., Tuttlingen, Germany) was then inserted. Methylene blue was injected through the uterus while visualization of the tubes and the spill was helped by a uterine manipulator.

**Statistical Analysis:** Statistical description of data was done in terms of mean±standard deviation (±SD), median and range, or proportions according to the case. Mean or median value was chosen according to distribution of data. Comparison of medians of variables between the groups was done using Mann Witney test. All hypotheses testing was done two tailed. 95% CIs were calculated for all applicable measurements. ROC analysis was done to assess the diagnostic accuracy of the index test (pain level during hysteroscopy) relative to data of laparoscopy (reference test) results. The area under ROC curve was measured with respective confidence interval (1ry outcome). The ROC analysis was used to calculate accuracy measures (sensitivity, specificity, positive and negative predictive values and positive and negative likelihood ratios) for different pain score cutoff values. Binomial exact test was used to calculate the confidence intervals for the different accuracy measures. A comparison of diagnostic

accuracy between the index test and presence of fluid by ultrasound was done by comparing areas under curves of both tests setting the laparoscopy data as a reference using Delong test (2ry outcome). Alpha error for all tests was set at 0.05. Statistical analyses were done by SPSS software, version 23 (IBM Corp., Armonk, NY, USA, 2015).

### Results

The study included 60 patients. Their characteristics are demonstrated in Table 1. No adverse events happened to study patients related to hysteroscopy or laparoscopy.

Pain score was significantly higher on the side of lower abdomen if the respective tube was patent. Median pain score in case of patent tube 30, range 0 to

60 versus median 0, range 0 to 60 in case of occluded tube, 95%CI of difference between medians: 20 to 30, p value <.001 (Table 2). Area under ROC (receiver operator characteristics) curve for the pain score test was 0.77 (95%CI: 0.85 to 0.9), p value <0.001 denoting good accuracy (primary outcome) (Figure 1). The optimum cutoff for pain score suggested by ROC analysis to discriminate tubal patency was >10. The corresponding sensitivity and specificity for this cutoff were: 79.8% (95%CI: 69.9% to 87.6%) and 93.6% (95%CI: 78.6% to 99.2%) respectively (The areas under curve were similar between the pain test and the presence of fluid after hysteroscopy (0.85 versus 0.86, 95%CI for difference in areas -0.1 to 0.1, p value .78). However, the negative predictive value was much lower in case of fluid assessment test (39% versus 62%) (Table 4 & 5).

Figure 1: ROC curve for diagnostic accuracy of pain score test during hysteroscopy [AUC is 0.85 (95%CI: 0.77 to 0.9), p value: <.001]

Difference in AUCs (95%CI)	0.02 (-0.1 to 0.1)
P value	0.78

**Discussion**

Tubal factor is responsible for 20% of all causes of infertility.<sup>(2)</sup> HSG is the first step for assessing tubal patency. However, it has a sensitivity of 46% to 65% and a specificity of 68% to 89%. Moreover, it has several risks as allergy from the dye and discomfort for the patients.<sup>(6)</sup>

Our study examined the accuracy of pain score on each side of the lower abdomen as a diagnostic test for tubal patency. Pain score was significantly higher on the side of lower abdomen if the respective tube was patent (p value <.001) & the optimum cutoff value to discriminate tubal patency was VAS >10 with a sensitivity and specificity of 79.8% and 93.6%, respectively. Moreover, the AUC for testing the presence of fluid by TVUS (0.86, CI: 0.75 to 0.95) was similar to the AUC of the pain test. However, NPV was much lower in case of fluid test in comparison to the pain test (39% versus 62%). Moreover, the fluid test positivity suggested one or both tubal patency, while the pain score on each side suggested tubal patency specific to that side.

These measures of diagnostic accuracy of pain test are better than measures of accuracy of HSG<sup>(6)</sup> and comparable or better than other tests for tubal patency.<sup>(7-12,14 & 15)</sup> However, some of the new tests (SIS and TVUS assessment of fluid after hysteroscopy) cannot differentiate unilateral tubal block from bilateral patency<sup>(7&11)</sup> while others (HyCoSy or hysteroscopy combined with HyCoSy) have the problems of high cost and complications of the dye.<sup>(10,14&15)</sup> Furthermore, other modalities(i.e. selective perturbation during hysteroscopy and hydrolaparoscopy) require learning and still less accurate than laparoscopy.<sup>(12,16&17)</sup>

To the best of our knowledge this is the first study measuring the pain score for diagnosis of tubal patency. Although we measured pain score as test of tubal patency, the pain was mild to moderate in all patients who felt discomfort. This was in agreement with other

study that found the discomfort felt during hysteroscopy less than that felt during HSG in 70% of patients.<sup>(18)</sup>

Office hysteroscopy has the advantages of low cost and simultaneous assessment of the uterine cavity. No anesthesia or dye are needed. It is less invasive than laparoscopy and better tolerated than hysterosalpingography.

To optimize the internal validity of the present study, we standardized all the conditions (e.g.,Vaginoscopic approach, no anesthesia nor analgesia & the filling pressure was at 80 to 100 mmHg)that might affect the perception of pain during hysteroscopy.<sup>(19)</sup>

However, the limitation of the present study is that it needs external validation in order to rely on its results. This is through replication of the study in different places with different types of patients to validate our results.

**Conclusion**

The pain score measurement on each side of the lower abdomen during office hysteroscopy can be used to diagnose tubal patency with optimal cutoff pain score >10.

**Disclosure:** No conflicts of interest in this work.

**Source of Funding:** Self-funding.

## Abstract

**Introduction:** Lung cancer belongs to the top ten diseases which caused death in the world. World Health Organization (WHO) estimated that there is about 2,09 million cases of lung cancer and 1,76 million death accident due to this disease. Smoking is defined as the most factor that can promote the lung cancer about 80% cases in male and 50% cases in female.

**Aims:** To identify the history of smoking activity in the lung cancer patients in the RSUD Dr. Soetomo, Surabaya.

**Method:** Research was determined as descriptive research with cross-sectional design. Variable in this research smoking status, age on the first time of smoking, duration of smoking, kind of smoke, and smoking level. Lung cancer patients in the RSUD Dr. Soetomo, Surabaya was addressed as subject in this research. Accidental sampling was performed as sampling method to the 53 respondents. Data was collected by distribution of questionnaire which contained risk factor of lung cancer. Data was analyzed by univariate analysis.

**Result:** Result saw that about 31 out of 53 respondents had history of smoking. Most of them had experienced as active smoker (22 respondents, 41,5%), had experience as first-time smoker on the age less than 15 years old (25 respondents, 47,20%), had been smoked for more than 20 years (29 respondents, 54,70%), have preferred to consume smoke with filter (21 responden, 39,60%), and considered as heavy level of smoker (15 respondents, 28,30%).

**Conclusion:** Most of lung cancer patient in the RSUD Dr. Soetomo, Surabaya had history as smoker.

**Keywords:** *Epidemiology, history of smoking, lung cancer, tobacco.*

## Introduction

World Health Organization (WHO) estimates 9.6 million people worldwide deaths caused cancer<sup>(1)</sup>. Lung cancer is the highest cause of death in men in 2018. The

incident Lung cancer amount 22,440 cases Or 14% of all cancer cases<sup>(2)</sup>. The main risk factor for lung cancer is smoking. In general, smoking causes 80% of lung cancer cases in men and 50% of lung cancer cases in women<sup>(3)</sup>.

The Result from Minister of Health Survey 2018 showed that proportion of tobacco consumption in the population aged 15 years and over were 62,9% in men and 33,8% for all. The prevalence of smoking in aged 10-18 years increased from 8.8 in 2016 to 9.1 in 2018<sup>(4)</sup>.

According to Sudoyo<sup>(5)</sup> the definition of smokers is people who have smoked 1 stick or more every day for at least a year. If people were not smoking for a

month, they called people with a history of smoking. The increased risk factors are related to the duration of smoking in a year and the factors when starting smoking (the younger the individual starts smoking, the higher risk of lung cancer). Other factors that can be considered include the types of cigarettes smoked (tar content, filter, and *kretek* cigarettes) (6).

The various research studies found that Lung cancer not only associate with active and passive smoking, but some occupational agents, and indoor or outdoor air pollution(7,8).Lung cancer has most commonly been associated with occupational exposures. Occupational exposures such as Asbestos, Vinyl chloride, Arsenic, Beryllium, Chromium and Nickel(8).

Lung cancer cases in East Java Province calculated about 34,706 cases(9). Based on the recapitulation data for the last 10 months at Dr. Soetomo in 2018, lung cancer morbidity was 733 cases. Lung cancer morbidity is still high in Dr. Hospital Soetomo, it is necessary to conduct research on the description of smoking history as the main risk factor. This research aims to identify the history of smoking activity in the lung cancer patients.

### Methodology

The research was conducted in RSUD Dr. Soetomo, Surabaya on August 2018-January 2019. The

descriptive method obtained from secondary data of research by Dr. Santi Martini, dr., M. Kes about “Risk of diseases caused by smoking”. Cross-sectional was performed in this research. The research sample was about 53 respondents by accidental sampling technic. Moreover, variable in this research were smoking status, age on the first time of smoking, duration of smoking, kind of smoke, and smoking level. However, another risk factor was also included in this research such, for instance, family history, exposure of asbestos, pollutant exposure at home, and pollutant exposure at workplace. The questionnaire of lung cancer risk was used in this research. Then, research was analyzed by univariate analysis and presented frequency distribution by epidemiological approach.

### Results

Distribution of respondents by place and time.East Java consists of 38 districts/cities which consist of 29 districts and 9 cities. Based on the results of the study, it found that the highest lung cancer cases were in Surabaya with 14 respondents (26.41%). It can be due to the location of Dr. Soetomo located in Surabaya. Figure 1. shows that the distribution of respondents based on the year diagnosed was mostly in 2018 as many as 46 respondents (86.79%).

Figure 1. Distribution frequency respondent base on year when diagnose

Distribution of respondents based on people. Characteristics of lung cancer patients based on age showed that the majority of respondents belong to the age of more than 40 years as many as 47 respondents

(88.70%). The characteristics of lung cancer patients based on sex are mostly male about 35 respondents (66.00%) like at Table 1. The characteristics of lung cancer patients based on education are mostly classified

into the basic education category as many as 29 respondents (54.70%) are elementary or equal. More than 50% of lung cancer patients have stage IV as many as 46 respondents (86.8%).

**Table 1. Distribution frequency respondent base on person**

Characteristic	Frequency	Porcentage (%)
Age >40 year	47	88,70
Men	35	66,00
Work	36	67,90
Stage IV	46	86,80
<b>Type of Education</b>		
Basic	29	54,70
Intermediate	18	34,00
High	6	11,30
<b>Total</b>	<b>53</b>	<b>100,0</b>

Distribution of respondents based on smoking history. Based on table 3, the data showed that most lung cancer patients have a history of active smoking as many as 22 respondents (41.50%). Most respondents have a history of smoking by consuming filter cigarettes as many as 21 respondents (39.6%). Most of respondents first time smoking at the age of 15-55 years as many as 25 respondents (47.2%), most respondents had a long history of smoking more than 20 years as many as 29 respondents (54.7%), and most smoking level of respondents is belong to heavy category namely 15 respondents (28.3%).

**Table 2. Distribution Frequency base on history of smoking**

Variable	Frequency	Porcentage (%)
<b>History of Smoking</b>		
Never Smoke	12	22,60
Active Smoker	22	41,50
Passive Smoker	10	18,90
Active and passive smoker	9	17,00
<b>Type of Cigarette</b>		
No Type (Never & Passive smoker)	22	41,50
Filter	21	39,60
Non Filter	10	18,90
<b>Initial Smoking Age</b>		
Never & Passive smoker	22	41,50
1-14 years	6	11,30
15-55 years	25	47,20

Variable	Frequency	Porcentage (%)
<b>Duration Smoking</b>		
Never & Passive smoker	22	41,50
≤20 years	2	3,80
>20 years	29	54,70
<b>Level of Smoking</b>		
Never & Passive smoker	22	41,50
Mild	4	7,50
Middle	12	22,60
Heavy	15	28,3
<b>Total</b>	<b>53</b>	<b>100,0</b>

Distribution of respondents based on other risk factors. Based on Table 2, most respondents did not have a family history of lung cancer about 51 respondents (96.2%), most of the respondents were not exposed to asbestos as many as 40 respondents (75.5%), most respondents were not exposed to pollutants in the residence as many as 49 respondents (92.5%), and the majority of respondents were not exposed to pollutants in the workplace about 44 respondents (83.0%).

**Table 3. Distribution frequency of respondent base on others factor**

Other risk factor	Frequency	Porcentage (%)
<b>History of Family</b>		
Yes	2	3,8
No	51	96,2
<b>Asbestos Exposure</b>		
Exposure	13	24,5
Not Exposure	40	75,5
<b>Pollutant exposure at home</b>		
Exposure	4	7,5
Not Exposure	49	92,5
<b>Pollutant exposure at work place</b>		
Exposure	9	17,0
Not Exposure	44	83,0
<b>Total</b>	<b>53</b>	<b>100,0</b>

### Discussion

Distribution of respondents based on people. Based on the results, it exhibited that the majority of respondents was on the age more than 40 years old. About 95% of lung cancer patients at the age more than 40 years old which conducted by Malhotra as a trend of lung cancer in Delhi, India. Moreover, data showed that most of the respondents were male<sup>(3)</sup>. This study was in line with the research conducted by Neupane<sup>(10)</sup>. It stated that most

lung cancer is suffered by men. Then, based on the results, the respondents had the type of basic education<sup>(10)</sup>. This research is in agreement with the research conducted by Ernawati et al<sup>(11)</sup> which stated that most lung cancer patients have a history of junior high school level. Based on the results, most of the respondents are worker. Furthermore, other data showed that the majority of respondents belonging to stage IV. Some Research performed<sup>(12)</sup>,<sup>(13)</sup> that the stage of lung cancer patients is found in the late stages. Lung detection is generally slow in process. This also can promote patients to have less awareness to see themselves. Most patients are referrals from regional hospitals and health centers, including some services which do not have specialist doctors or supporting tools for diagnosing lung cancer. Another thing considered as a factor is the policy to go to the health center before going to the hospital. There are many reasons for improving the quality of care, evaluation of the cost, and reluctant to do the examination.

Distribution of respondents based on history of smoking. Based on the results, it found that most respondents had a history of active smoking. This research is in line with the research conducted by Hulma, Basyar, and Mulyani<sup>(14)</sup> found that smoking history in most detected in lung cancer patients. Based on the results of the study, it was found that the majority of respondents consumed filter cigarettes. This research is supported by research conducted by Herlina, Rahmalia, and Dewi<sup>(15)</sup>. They stated that lung cancer patients who have a history of smoking more often consume filter cigarettes. Other study found that Smoker have Risk more than 5 times death rate higher than No Smoker for Asian people<sup>(16)</sup>.

Based on the results of the study it was found that the majority of respondents who had a history of smoking, first smoked at the age of less than 15 years with 25 respondents (47.20%). This research is in line with the research conducted by Putera et al<sup>(17)</sup> states that most of lung cancer patients smoke at the age of 17-25 years old. This study is in line with the research conducted by Setyanda et al<sup>(18)</sup> that the average person has a long history of smoking with more than 20 years. The British Doctors' Study found that the relative risk (RR) of smoking for lung cancer have increased over the 20-year, 40- year, and 50-year follow up<sup>(16)</sup>. Based on the results of the study, it was found that most of the respondents were classified as heavy smoking level. This study is similar with Naser, Medison, and Erly<sup>(19)</sup>, that

the highest number of smoking is in the level of heavy smoking. The number of lung cancer patients who have a history of heavy smoking consuming large quantities of cigarettes per day has a greater risk of lung cancer.

Distribution of respondents based on other risk factors. Based on the results of the study, it found that most respondents did not have a family history of lung cancer. This research is in line with the research conducted by Ernawati et al<sup>(11)</sup> stated that most of lung cancer patients do not have a family with a history of cancer. The research by Yoshida et al<sup>(20)</sup> stated that a family history of lung cancer in the close relatives was associated with an increased risk of lung cancer between the sexes. Families who have cancer will increase the risk of lung cancer by 13.8%. First sisters allow a greater risk than brothers<sup>(21)</sup>.

This study was found that the majority of respondents were not exposed to asbestos. This can be seen from the top use (platonik) of occupied houses made of abscesses. Continuous exposure to asbestos and increased amount of exposure will increase the risk of lung cancer. Smokers exposed to asbestos have a higher risk of lung cancer<sup>(22)</sup>. Based on the results of the study, it was found that more than 80% of respondents were not exposed to pollutants in their homes. The pollutants came from the use of wood fuel stoves, the use of kerosene fuel stoves, and mosquito coils. Continuous exposure to the smoke will increase the risk of lung cancer<sup>(23)</sup>.

## Conclusion

Most of lung cancer patient in the RSUD Dr. Soetomo, Surabaya had history as smoker.

**Acknowledgments:** We would like to thank all participants in this study including the patient, patient's family, nurse and doctor. We would like to a big thank you to Dr. Soetomo General Hospital for allowing this research to be carried out.

**Conflict of Interest:** The authors have no conflicts.

**Source of Funding:** It is research and publication of this article funded by Ministry of Research and technology and higher education through Universitas Airlangga 2018.

# Radiographic Evaluation of Two Different Designs for Treatment of Mandibular Bilateral Free End Saddle with Osseo-integrated Implants

Seham Sabra<sup>1</sup>, Gehan Fekry<sup>2</sup>, Emad Agamy<sup>2</sup>

<sup>1</sup>Lecturer, Prosthodontic Department, Al Farabi Colleges for Dentistry and Nursing, KSA,

<sup>2</sup>Professor, Prosthodontic Department, Faculty of Oral and Dental Medicine, Minia University.

## Abstract

**Purpose:** The goal of this study was to evaluate radiographically two different designs for mandibular free end saddle with osseointegrated implants.

**Materials and Method:** Ten lower Kennedy class I partially edentulous patients were selected to receive implant at the second molar area, then patients were divided into 2 groups according to the implant superstructures either (extra-coronal attachment or bar attachment). Patients of both groups receive removable partial denture of the same design. Patients were followed up for 0, 3, 6 and 9 months clinically.

**Results:** Showed statistical difference between the 2 designs.

**Conclusion:** It could be concluded that Tooth-implant supported partial denture may be reasonable and simple solution for Kennedy class I partial denture.

**Keywords:** Lower Kennedy class I, Removal partial denture, implant, extra-coronal, bar attachment.

## Introduction

Free end removable partial dentures were considered the gold standard for missing posterior teeth many years ago, they were originally used to achieve primary stability, restore patient occlusion and prevent tooth migration. But they had a main limitation of gradual ridge resorption due to pressure areas between the tooth-fibro mucosa and support system<sup>(1)</sup>.

The continual resorption of the residual ridge affects the support, stability and retention of RPDs. It also modifies the occlusal conditions by causing premature contacts and uneven occlusal forces on the remaining natural teeth<sup>(2)</sup>.

Bounding of the RPD with implants is a treatment option which combines the advantages of the implants and simplicity of the RPD system, with reducing the drawbacks of invasive attempt and cost of the implants more than two. by placing an implant to the distal extension site of the RPD, enhancement of distribution of the occlusal forces, movement of the posterior rotational axis to a distal position, shortening of the distal extension of the RPD, and reducing potential rotational movement of the RPD can be improved<sup>(3,4)</sup>

Since the common clinical problems of bilateral distal extension RPD are the lack of retention, stability, and esthetics; so, placing bilateral single dental implants in the molar area would effectively change the Kennedy Class I situation to Kennedy Class III which improves retention and stability of the dentures<sup>(5, 6, 7)</sup>

Moreover, implant support decreases the amount of alveolar ridge resorption and the need for relining in the following years.<sup>(7, 8, 9)</sup>

There are different types of connection between

the implants and the acrylic base of the RPD, such as implant cover screws, stress-breaking attachments, and healing caps. Ball, locator or ERA attachments are the different types of stress-breaking attachments that have been applied to the implants in previous studies and some case reports. In addition, placement of only healing caps to function as vertical stopping has previously been reported<sup>(2,5,6,7,9,10,11)</sup>

## Materials and Method

Ten partially edentulous patients indicated for implant installation were selected from Out-patient clinic, Faculty of Oral and Dental Medicine, Minia University. All patients had Kennedy class I lower partially edentulous ridges with completely edentulous maxilla to be restored with complete denture.

**Group I:** Patients received extra-coronal attachment distal to the last natural abutment teeth with construction of metallic removable partial denture.

**Group II:** Patients received bar attachment with construction of metallic removable partial denture.

CBCT was taken before treatment to evaluate bone density and height, presence of any anatomical structures and to determine the appropriate implant angulations.

Reduction of the last 2 abutment teeth on each side was done to receive full veneered porcelain crowns and covered with temporary crowns. Impressions for the upper jaw was done and construction of occlusion blocks to be ready for jaw relation with the lower partial dentures.

Trial setting up of artificial teeth in edentulous areas of mounted upper and lower casts was carried out. Acrylic surgical template was fabricated on edentulous area of lower cast. 2 screw shaped internal hex titanium implants (3.9 mm diameter and 12 mm length) were inserted bilaterally for each patient in the second premolar. Primary stability using Osstell device (*Osstell ISQ, Göteborg, Sweden*) was measured for each implant then a healing collar of suitable length was threaded on the fixture.

3 days after fixture installation, the patients were recalled, and another CBCT were made to confirm the angulation of the implant.

**For group I:** Waxing up for the crowns and extra-coronal attachment distal to the last abutment teeth by the

help of paralellometer was done, the crowns-attachment assembly were sprued, invested and cast, finished and polished.

Try-in was done, porcelain was built-on and porcelain fused to metal restoration was obtained and finally cemented. Rubber base impression was taken for construction of the metal framework (lingual bar, bracing arm on the last abutment tooth and saddle meshwork). Try-in of upper and lower dentures, then delivery with occlusal adjustment.

At this step, direct pick up for the metal housing and retentive cap of the extra-coronal attachment was done Fig. 1:, then finishing for excess resin in the fitting surface was done and dentures were delivered to the patients.

**Fig. 1: Prepared metal surface for direct pick up**

**For group II:** A wax pattern was made for implant abutments and natural abutments with using the bar in its resilient form, spruing, investing and casting. Try in was performed and porcelain was built in and final cementation of the assembly was done. **Fig. 2.** Rubber base impression was taken for construction of the metal framework (lingual bar, bracing arm on the last abutment tooth and saddle meshwork). Then try in was done and jaw relation with the upper occlusion blocks. Try-in of upper and lower dentures, then delivery with occlusal adjustment.

At this step, direct pick-up of the retentive clip was done with self-curing acrylic resin after blocking all undercut. Then excess resin was removed and finished. Dentures were delivered to the patient.

**Fig. 2: Try-in of the finished bar assembly**

**Radiographic Evaluation:**

1. **Pre-Surgical Evaluation:** CBCT was made to determine the bone quantity and quality and an approximation of the implant site with the critical structures.
2. **Follow Up Evaluation:** This phase started just after the prosthesis placement (0-evaluation), then after 3, 6- and 9-month intervals respectively to evaluate

crestal bone height changes of the implant and any peri-implant bone changes with the Digora software (Soredex, Tuusula, Finland)

Standardized digital images were obtained following long cone periapical paralleling technique (Rinn Corporation, XCP instrument for extension cone paralleling technique, USA.) long cone tube (sixteen inch) of X-ray machine, radiographic template, Digital X-ray machine (Kodak 6100, Italy), sensor and personal computer. Bone density and bone height measurements were taken statistically analyzed.

**Results**

- A. Bone height changes around peri-implant bone for both designs:** The results of peri-implant bone height measured for both type of attachments (OT-Strategy and bar attachment) along the follow up intervals (At 0-3, 0-6, and 0-9 months) are shown in fig (3). At all follow up periods the bone level measured showed a significant difference within OT-strategy extra-coronal attachment. While there was no significant difference in the same time intervals for bar attachment design.

**Fig. 3: Effect of time on mean values of peri-implant bone height loss for OT-strategy extracoronary attachment and bar attachment**

**B. Bone height changes around natural abutment for both designs:** The results of abutment bone height measured for both type of attachments (OT-Strategy and bar attachment) along the follow up intervals (At 0-3, 0-6, and 0- 9 months) are shown

in fig(4) At all follow up periods (0-6 and 0-9) the bone level measured showed a significant difference within OT-strategy extra-coronal attachment. While there was no significant difference in the same time intervals for bar attachment design.

Fig. 4: Effect of time on mean values of abutment bone height for OT-strategy extracoronar attachment and bar attachment

Fig. 5: Effect of time on mean values of peri-implant bone density for OT-strategy extracoronar attachment and bar attachment

## Discussion

There was a decrease in bone height for both groups, which coincides with reported studies which explained that crestal bone resorption around implants is a well-known phenomenon occurring mostly as an immediate bone response after implant insertion and after functional implant loading. The amount of bone resorption occurring after loading may be related to many factors as the amount of load, nature of prosthesis, bone quantity and quality, implant related factors (design, number and dimensions), opposing restoration and crown height space<sup>(12,13)</sup>.

It is well known now in the literature that crestal bone resorption is not only unavoidable but also time related. Many studies confirmed this finding<sup>(14)</sup>. All these studies agreed that most of this resorption occurs within the first year from loading with an average of 1.2 mm and the annual bone loss should be < 0.2 mm, which does not contradict with implant success<sup>(15)</sup>.

The bone height changes were significant in the first interval, then insignificant with time, they remain within the clinically permissible range previously mentioned (1.2mm). This may be attributed to many factors. First of all was our careful patient selection that excluded those with previous history of bruxism. This helped to avoid implant overload as much as possible. Second, the type of prosthesis which is an implant-tissues supported prosthesis that shares the load between the ridge and the implant putting into consideration the ability of this prosthesis to protect the implants by the stress breaking action. Also, the screw type 3.9 mm diameter and 12 mm length implant had enough surface area to minimize the stress transmitted to the surrounding bone as supported by many authors<sup>(16)</sup>. Finally, it should be noticed that the opposing restoration was upper complete denture that exerts less load on opposite arch compared to natural dentition or fixed restorations<sup>(17)</sup>.

The significant difference in bone height between both attachments in the 1<sup>st</sup> interval period (0-3 months), showing that bar attachment is better than OT-Strategy, which coincide with Vafaei et al.<sup>(18)</sup>, who examined the effect of overdenture attachment design on the strain distributions and values of both bone and implants. Results from the bar design showed smaller strain magnitudes in both laterotrusive and protrusive motions. Thus, they claimed that, bar design was considered superior than the single standing implants with attachment. Furthermore, Tabata et al.<sup>(19)</sup>, who compared

the stress-strain analysis of splinted versus non-splinted implant overdenture. They found that the use of single standing implants with attachment induced more stress in bony tissues than the bar-clip system.

It is also noticed that splinting of the natural teeth helped in stress distribution in both groups which coincides with Kapur et al.,<sup>(20)</sup> who has suggested that splinted 1<sup>st</sup> and 2<sup>nd</sup> premolars by full coverage crowns, has provided good support and improved the prognosis of cast partial denture. Furthermore, splinting helps in reducing the amount of marginal bone resorption which reduces damaging stresses by efficiently dispersing the load generated during mastication<sup>(21,22,23)</sup>.

**Ethical Clearance:** All patients participated in the study were informed about the nature of the study and its purpose, agreed to take part in it and write an informed consent reviewed and approved by the research ethics committee of the Faculty of Dentistry Minia University.

**Source of Funding:** Self-funding

**Conflict of Interest:** Nil.

# Adaptive Physical Education in Rehabilitation after Injuries Maxillofacial Area

Sergey Petrovich Evseev<sup>1</sup>, Olga Eduardovna Evseeva<sup>1</sup>, Andrey Vladimirovich Aksenov<sup>1</sup>

*1Department of Theory and Method of Adaptive Physical Culture, professor, National State University of Physical Culture, Sport and Health named after PF Lesgaft, st. Decembrists, 35, Saint Petersburg (ex Leningrad), Russia, 190121*

## Abstract

The frequency of damage to the maxillofacial region remains very high. This makes the problem of further improving approaches to the rehabilitation of this category of patients very important for the whole world. The relevance of this problem is due to the large number of patients with fractures of the bones of the facial skeleton and a tendency to worsen these injuries due to the presence of multiple and combined injuries of the head, neck and jaw. The danger of jaw dysfunction and the appearance of a “cosmetic defect” in this category of patients creates a great need to continue improving their rehabilitation. The central place among the rehabilitation approaches used in this pathology is occupied by adaptive physical education. In most cases, it is effectively supplemented by a whole arsenal of physiotherapeutic and psychotherapeutic effects. Their complex application provides in the vast majority of cases the gradual development of a positive persistent effect.

**Keywords:** *Adaptive physical education, injuries, cranial bones, maxillofacial region, rehabilitation.*

## Introduction

In the modern world, the prevalence of various diseases and dysfunctions in people of different ages remains high<sup>1</sup>. Modern medicine does everything possible to restrain the growth of their distribution and reduce their consequences<sup>2</sup>.

However, due to the increase in the frequency and severity of injuries as a result of transport, criminal, sports and domestic accidents, there is a significant increase in the number of patients with acute trauma to the maxillofacial region<sup>3</sup>. Among all patients with

skeletal fractures, patients with facial bone fractures account for about 8%<sup>4</sup>.

Trauma to the maxillofacial region is a complex pathology. Significant changes always occur in the injury zone, which are associated with intoxication with the products of decay and autolysis of necrotic tissues. Its consequences often lead to significant impairment of jaw function. In this case, the appearance of a “cosmetic defect”, which is the reason for the always severe psychological trauma of the injured person, is especially important. Therefore, for the success of treatment and rehabilitation procedures in this category of patients, it is very important to start early and the breadth of the range of recreational activities<sup>5</sup>.

The high frequency of injuries of the maxillofacial area makes the problem of further improving approaches to the rehabilitation of this category of patients very relevant for the whole world. This is due to the large number of victims with fractures of the facial skeleton and a tendency to worsen these injuries due to the presence of multiple and combined injuries of the head, neck and jaw<sup>6</sup>.

e-mail: ilmedv1@yandex.ru

The purpose of the study is to consider existing approaches to the physical rehabilitation of patients with injuries of the maxillofacial region.

**Fundamentals of physical rehabilitation for injuries of the maxillofacial region:** Forced restriction of motor activity, prolonged jaw immobilization, the possibility of cicatricial deformities of soft tissues damaged during a fracture can lead to complications in the form of contractures of the lower jaw and ankylosis of the temporomandibular joint. The severity of these disorders depends on the location of the fracture - with fractures of the condylar process, degenerative changes in both joints are observed more often than with extraarticular fractures<sup>7</sup>.

Initially, these disorders are in the nature of functional insufficiency, which in 2–7 years can develop into degenerative changes. Unilateral arthrosis develops on the side of the lesion after single fractures, and bilateral after double and multiple fractures<sup>8,9</sup>.

The ultimate goal of rehabilitation for jaw fractures is to restore the continuity and anatomical shape of damaged bones with full and early normalization of chewing function<sup>10</sup>.

As a rule, in the first 3-4 days, patients with jaw fractures are recommended a half-bed regimen, and in the future, a free motor regimen. In the first days of treatment in the clinic, a functional rehabilitation program is developed. During it, the patient is engaged in adaptive physical education at home, visiting the clinic once a week to determine the effectiveness of classes and make adjustments to the program<sup>11</sup>. 3-4 days after immobilization, you can assign an adaptive physical culture according to the methodology of the first period of classes. The general serious condition of the patient, fever, fainting, or the presence of an acute inflammatory process in the fracture area or the risk of bleeding are considered temporary contraindications to the use of physical education<sup>12</sup>.

**Adaptive physical education in eliminating the consequences of maxillofacial injuries:** Adaptive physical education contributes to a significant improvement in the general condition of the patient, prevents the development of complications associated with physical inactivity and the immobilization of the temporomandibular joint, accelerates the consolidation of bone fragments, ensures the speedy restoration of the function of this jaw and reduces the patient's disability.

The fulfillment of these tasks largely depends on how timely functional treatment is started and whether it is carried out correctly<sup>13</sup>.

The use of special exercises for facial and chewing muscles depends on the method of immobilization. Promoting the restoration of the coordinated work of the muscles involved in swallowing, chewing and speech is the main task of the gymnastics of the first period<sup>14</sup>.

In connection with an increase in the tone of the masticatory muscles on the side of the fracture and its strengthening under the influence of immobilization, it is necessary to promote the relaxation of facial muscles in every possible way. To this end, exercises are widely used in the form of stroking, rubbing and kneading for the facial muscles, as well as the muscles of the tongue and neck, which contribute to improving blood supply and lymph flow of tissues in the fracture area<sup>15,16</sup>.

If there are no acute inflammatory phenomena in the area of study damage, then on the 7–8 day, you can proceed to massage the face and neck. It should be noted that the muscles and ligaments have their own receptors that respond to contraction: their excitability increases, blood circulation in the muscle fibers is activated, which significantly affects the functional state of the neuromuscular apparatus, pain is quickly stopped and muscles are tightened<sup>17</sup>.

The functional activity of the masticatory muscles is restored faster when the exercises of therapeutic physical culture are included in the treatment of fractures of the lower jaw. With single jaw splinting or osteosynthesis without intermaxillary fixation, patients already on the 2-3 day are allowed careful movements of the lower jaw in various directions, exercises are widely used for facial muscles, tongue and neck muscles, which help to improve local blood circulation and reduce the tonus of chewing muscles during 10-15 minutes<sup>18</sup>.

The functional load for the temporomandibular joint is enhanced by assigning individual tasks to the patient, consisting of several special exercises performed independently by the patient 7-10 times during the day. In case of double jaw splinting, mechanotherapy and passive movements of the lower jaw are not used, as this can lead to the formation of a false joint<sup>19</sup>.

A wide selection of special exercises for chewing muscles (active, active – passive and with resistance, the use of mechanotherapy), performed with a maximum

range of movements (even against a background of moderate pain), eliminates the existing limitations in the function of the temporomandibular joint. Functional load should also be carried out with great care and be supported by the appointment of an appropriate diet<sup>20</sup>.

General strengthening and breathing exercises are prescribed in a dosage that provides increased activity of the cardiorespiratory system, corresponding to the functional capabilities of the patient's body. Against the background of regular motor activity in patients, somatic status changes: microcirculation, the state of the cardiovascular, respiratory, digestive systems improves. The methodology of therapeutic gymnastics provides for an individual selection of general strengthening, breathing and special exercises against the background of the motor regime adequate to the patient's condition<sup>21</sup>.

The alternation of general developmental exercises with special ones in a ratio of 2:3 is recommended. Therapeutic exercises include respiratory and general developmental exercises for all muscle groups in an amount that does not cause an acceleration of the pulse by more than 20-30% compared with the state of rest. Already on the 4th – 5th day, most patients pass from bed rest to free<sup>22</sup>.

At the initial stage, general developmental exercises are performed with gymnastic sticks, dumbbells, in the future, jumping rope, hoop, lunges, push-ups, squats, twisting, morning jogging and so on are gradually added. At first, when performing gymnastic exercises, patients may experience a feeling of fatigue, then, under the influence of regular physical exertion, ease of movement, a surge of strength, increased mood, and improvement of endurance and physical activity appear<sup>23</sup>.

After a trauma, a number of patients develop dysphonia (a qualitative violation of the voice, which is manifested by nasal, hoarseness, hoarseness). In this situation, a correction of phonetics is required. To this end, special tests have been developed with words from complex consonants and vowels. These texts are recommended to be read 3-5 times a day for 20-30 minutes<sup>24</sup>.

**Physiotherapy in the rehabilitation of patients after trauma of the maxillofacial region:** The inclusion of physical treatment method in the rehabilitation complex helps to prevent many consequences of trauma and prolonged immobilization, enhances the restoration of chewing activity after removing tires<sup>25</sup>.

Electrophoresis is a physiotherapeutic procedure in which solutions of drugs are delivered to tissues using electric current. This method of physiotherapy is often used during rehabilitation after injuries and injuries in the face and jaw. In these patients, several types of electrophoresis are used: - on the surface of the tooth; on the gum; into the nasal cavity. This procedure is most often carried out by the Potok-1 apparatus. It includes intraoral and extraoral active electrodes of various sizes and shapes. If necessary, eliminate inflammatory processes, appoint electrophoresis with a solution of ascorbic acid (5%), vitamin P (1%), trypsin solution, 1% nicotinic acid solution<sup>26,27</sup>.

Fluctuorization - treatment is carried out by alternating current. It includes extraoral and intraoral electrodes. This device generates three forms of current: 1 - bipolar symmetric; 2 - partially straightened; 3 - constantly pulsating current<sup>28</sup>. The first and second forms are used to relieve inflammation and pain. The third form is used to administer drug solutions. In inflammation, fluctuation is combined with exposure to ultrahigh-frequency current and microwave therapy<sup>29,30</sup>.

During therapy with alternating current, Darsonval apparatus Spark-1 and Spark-2 are often used. These devices generate high-frequency alternating current of low power and high voltage. As a result, a sharply decaying charge is produced. In the process of such treatment, it is possible to reduce the sensitivity of peripheral nerve receptors, thereby achieving a painkiller effect. Itching in the tissues decreases, vasospasm is relieved, the outflow and movement of leukocytes increases<sup>31,32</sup>.

Ultrahigh-frequency currents as one of the types of electrotherapy for maxillofacial trauma are performed by microwave therapy apparatus-4 and microwave therapy apparatus-66 devices. Under the influence of an ultrasonic field, colloids of molecules change. This is due to thermal and oscillatory effects. Under the influence of ultrahigh-frequency electromagnetic fields, macrophages are activated, edema decreases, metabolism is activated, growth of young connective tissue is enhanced, and sensitivity of nerve receptors decreases.

## Conclusion

Currently, a significant increase in the number of patients with acute trauma of the maxillofacial region is observed in the world. Its consequences often lead

to significant violations of the jaw function and the appearance of a “cosmetic defect”. Modern science and practice have a large arsenal of rehabilitative effects on such patients. The central place among them is adaptive physical education. It is effectively complemented by a whole arsenal of physiotherapeutic and psychotherapeutic effects. Their complex application provides in the vast majority of cases the gradual development of a positive persistent effect.

**Conflict of Interest:** No conflict of interest is declared.

## Abstract

**Objective:** Modulation of autophagy is a promising potential strategy enhancing cancer therapy, especially after development of new autophagy inhibitors. We planned to assess the role of autophagy in Myelodysplastic syndrome (MDS) and Myeloproliferative neoplasms (MPNs).

**Design:** Case controlled single center study.

**Setting:** Internal medicine department, Minia University Hospital, Minia, Egypt.

**Subjects:** A total of 70 subjects divided into two groups: group I: 35 newly diagnosed patients with MDS and MPNs and group II: 35 apparently normal individuals.

**Intervention:** Serum beclin-1 (S.BECN 1) and Serum autophagy protein 7(S. Atg-7) were measured in both groups.

**Main Outcome Measure:** We considered the following parameters: demographic data, bone marrow examination, splenomegaly, hepatomegaly and laboratory investigations in both patients and control group including beclin1 and Atg7.

**Results:** By comparing serum beclin1 level in the two groups: patients group showed that the mean and SD of both S. beclin1 and S. Atg-7 were much higher than the control group. This shows highly significant P value <0.001\*.

**Conclusion:** Measurement of high level of S.BECN 1 and S. Atg 7 in MDS and MPNs indicate that they may be autophagy-dependent markers and it may be modifiable factors through its inhibition or induction.

**Keywords:** *Autophagy, Myelodysplastic syndrome; Myeloproliferative neoplasms.*

## Introduction

The term of Autophagy was firstly described by Christian de duve in 1963, who coined that autophagy is a “self-eating”. He observed that the cell could destroy

its own contents by enclosing it in membranes, forming sack-like vesicles that were transported to a recycling compartment, called lysosome, for degradation. In 2016, Nobel Prize in physiology or medicine was awarded to Yoshinori Oshimi for his discovery of the mechanism of autophagy [1].

Autophagy is a cellular pathway responsible for the sequestration of spent organelles and protein aggregates from the cytoplasm and their delivery into lysosomes for degradation<sup>[2]</sup>. Whereby cellular proteins and organelles are engulfed by autophagosomes, digested in lysosomes, and recycled to sustain cellular metabolism<sup>[3]</sup>.

Autophagy has been shown to play several important roles in cancer [4]. It has a dual role in cancer, acting as both a tumor suppressor by preventing the accumulation of damaged proteins and organelles and as a mechanism of cell survival that can promote the growth of established tumors. Tumor cells activate autophagy in response to cellular stress and/or increased metabolic demands related to rapid cell proliferation. The role of autophagy in cancer has been highly researched and reviewed. There is evidence that emphasizes the role of autophagy both as a tumor suppressor as well as a factor in tumor cell survival. However, recent research has been able to show that autophagy is more likely to be used as a tumor suppressor [5].

Concerning hematological malignancies there is evidence suggests that autophagy defects in hematopoietic stem cells (HSCs) may be implicated in the pathogenesis of Myelodysplastic syndromes (MDS) and myeloproliferative disorders. Bone marrow cells from those patients are characterized by mitochondrial abnormalities and increased cell programmed death [3]. Indeed, multiple autophagic markers, including Beclin 1 and autophagy protein 7 have now been characterized as tumor suppressors [6], through controlling oxidative stress as well as the build-up of potentially DNA damaging wastes [7].

The evolution of autophagy and its relation to hematological malignancies; make it an encouraging field for research. Hoping for further progress in curative management of blood malignancies, so the modulation of autophagy is a promising potential strategy to enhance cancer therapy.

**Ethical Approval:** This study was approved by the Institutional Ethics Committee of School of Medicine, Minia University, Egypt, and all patients gave informed consent before participation in this study. The study conducted in accordance with the ethical guidelines of the 1975 Declaration of Helsinki and International Conference on Harmonization Guidelines for Good Clinical Practice.

### Subjects and Method:

A total of 35 newly diagnosed patients with Myelodysplastic syndrome and myeloproliferative disorders collected in a single center, Minia University Hospital. The diagnosis of Myelodysplastic syndrome and MPNs was based on 2016 WHO criteria.

We excluded the Secondary causes of dysplasia from the MDS group.

During the same period, the serum of 35 apparently healthy individuals collected as a control group.

**Clinical and laboratory assessments:** The diagnosis of MDS is suspected clinically by symptoms and signs of anemia, bleeding tendency or repeated infections, and laboratory by the presence of an abnormal blood count at routine blood test. The assessment of dysplasia on PB and BM smears are the hallmark of the diagnosis of MDS according to the 2016 WHO criteria.

Some additional laboratory tests were done to confirm the diagnosis in MPNs group as detection of JAK II mutation, serum erythropoietin level in polycythemia patients and BCR-ABL gene expression in CML patients.

**Measurement of S. BECLIN-1 and S. Atg-7:** Using commercial kits from ANOVA Company: using Sandwich-ELISA technique. The Microelisa stripplate provided in this kit had been pre-coated with an antibody specific to Beclin 1 and S. Atg-7. Then we calculated the concentration of Beclin 1 and Atg-7 in the samples by comparing the OD of the samples to the standard curve.

**Assay Range:** 30pg/ml- 2000 pg/ml.

**Statistical Analysis:** All analysis was carried out using SPSS software version 20.  $P < 0.05$  was considered statistically significant.

### Results

Out of 35 patients, 19 were males and 16 were females. Their age ranging from 30 to 70 years with 22 of them with no comorbidities but 13 of them had comorbidities. The control group contained 35 apparent normal individuals. Their age were ranging from 46 to 67, 20 of them were males and 15 were females. 31 of them with no comorbidities but 4 had comorbidities.

The patient group subdivided into two groups, 20 patients were MDS and 15 were MPNs. In the MDS: 10 were males and 10 were females. In MPNs: 9 were males and 6 were females. BM examination in MDS: 2 were hypocellular but 18 were hypercellular, while in MPNs: 5 were hypocellular and 10 were hypercellular. In MPNs, 1 case had mild splenomegaly, 4 had moderate splenomegaly and 10 had huge one.

Among the laboratory investigations between two groups: HB level in both groups showed statistically significant difference with P value <0.001\*. Creatinine level, showed statistically significant difference between two groups with P value <0.010\*. By comparing serum beclin1 and Serum Atg 7 in the two groups, there was statistically highly significant difference with P value <0.001

ROC curve for Beclin-1 showed area under curve 0.835, P value <0.001, sensitivity 94.3% and specificity 71.3%. while ROC curve for Atg 7 showed area under curve 0.962, P value <0.001, sensitivity 97.2% and specificity 94.3%. Using Pearson correlation between S. Beclin1 and S. ATG7, there was a moderate association ( $r=0.643$  &  $p<0.001$ ).

## Discussion

Autophagy is included in the regulation of haematopoietic stem cells (HSCs) that are the precursors of normal hematopoiesis<sup>[8,9]</sup>. Dysregulation of autophagy in HSCs is linked to the initiation and progression of blood cancers including: leukemias<sup>[10]</sup>, lymphoproliferative disorders<sup>[11]</sup> and myelodysplastic syndrome<sup>[12]</sup>. Recently, many clinical trials using autophagy inhibitors are being applied to multiple blood cancer types together with chemotherapeutic agents to achieve complete cure. So it is the flavour of the moment to try to understand the relationship between autophagic protein markers and various blood malignancies.

In the present study, 20 newly diagnosed MDS patients and 15 patients of newly diagnosed MPNs, were assessed for autophagy by measuring serum beclin-1 and serum autophagy protein 7. The two groups of patients showed significantly increase in the level of S. BCL-1 and S. ATG-7 which indicating the induction of autophagy in the development of MDS and MPD.

Numerous recent studies suggest that inhibiting autophagy may be an efficient approach to improve the chemotherapeutic antileukemic regimens, but this was not in agreement with Alessio et al.,<sup>[13]</sup> whom suggested that autophagy induction through using autophagy-activating pharmacological or dietary approaches could be utilized as a way to enhance the efficacy of chemotherapeutic agents as well as helping to reduce some of the side effects of anticancer agents.

Our data was agreed with Tan et al.,<sup>[14]</sup> as they proved that hypoxia-induced cell death increased upon knockdown of Beclin-1 or Atg7 as well as with autophagy-deficient cancer cell, were proliferating less in mouse xenograft models.

Folkerts et al.,<sup>[15]</sup> hypothesized that most of blood cancers induce autophagy which contributes to survival in poorly oxygenated tumor areas but, appropriate testing of the efficacy of autophagy inhibition in cancer cells of patients will have to be more developed, with current trials mainly monitoring autophagy in peripheral blood mononuclear cells (PBMCs) as a surrogate marker of response. However, the level of autophagy in PBMCs does not seem to correlate with autophagy inhibition in the tumor microenvironment<sup>[16]</sup>. Therefore, positron emission tomography/computed tomography and magnetic resonance imaging probes for Atg activity are currently being developed.

In our work, the serum BECLIN-1, the key regulator of autophagy showed significantly increase in myeloproliferative group, especially in the CML subtype. These previous data was similar to Xiaoli et al.,<sup>[17]</sup> whom demonstrated that induction of upregulation of Beclin-1 help to augment autophagic cell survival. The levels of miR-93 depression and Beclin-1 upregulation contributed to the levels of Pediatric Leukemias (PL) resistance against chemotherapy. They suggested that strategies which increase miR-93 levels or inhibit cell autophagy may improve the outcome of PL, and this is our aim in the next studies to try the autophagy inhibitors and identify their role in cancer regression in combination with the currently used chemotherapeutic agents. Hoping to come in depth and more detailed informations about the role of autophagy in various blood malignancies, as It is evident that autophagy is more and more emerging as a potential target for cancer therapy.

Also, Vilcassim et al.,<sup>[18]</sup> were agreed with our results of high level of autophagic markers obtained in CML subgroup as they demonstrating that iron chelator Deferasirox (DFX), blocked growth of myeloid leukemia cell lines whilst sparing normal stem cells through its ability to inhibit autophagy, postulating that modulation of intracellular iron levels can be adopted as a tool to elucidate the role of autophagy in this disease.

On the contrary, El-Sharkawy et al.,<sup>[19]</sup> elucidated that beclin-1 dependent autophagy is increased after the beginning of imatinib therapy indicating induction of autophagy in CML patients, along with complete clinical and hematological response, i.e. they supporting the theory of tumor suppression related autophagy and programmed cell death.

However, it is a must to take in our considerations that our study was carried out using serum autophagy markers by ELISA kits instead of gene expression, in a trial to facilitate and simplify the diagnosis and correlation between autophagy and blood malignancies.

However, Chen et al.,<sup>[20]</sup> hypothesized that irregular myeloid proliferation occurred in the bone marrow of autophagy related gene (Atg) 7 knockout mice, which was similar to the process of development of myelodysplastic syndrome (MDS) and this support the theory that the presence of autophagy guard against tumor development.

In the current study, there is significant increase

in both S. Atg 7 and S. BECN-1 in MPNs group compared to the control group that was in accordance with Celso et al.,<sup>[21]</sup> who reported that it was better to combine Ruxolitinib; which is a JAK2 inhibitor used in MPNs with positive JAK2 mutation, with autophagy pharmacological inhibitors, especially chloroquine, may be a promising strategy for improving the outcome of MPN with positive JAK2 mutation. This supports the theory that autophagy promotes blood malignancies.

**Limitations of the present study:** (1) The number of subjects that was small due to financial issues. (2) Future studies are required to further using pharmacological autophagy inhibitors in a larger sample size and assess its role in regression of the blood malignancies either alone or in combination with available chemotherapeutic agents. (3) S. BECN-1 and S. Atg 7 levels were not assessed after initiation of treatment which could provide important information about the relation between autophagy and response to chemotherapy.

### Conclusion

High level of serum BECN-1 and serum Atg 7 in MDS and MPNs indicate that they can be autophagy-dependent markers and it may be a therapeutic window for autophagy inhibition in combination with cancer therapy.

# The Influence of Reward and Communication to Cohesion Team of Tuberculosis Prevention Team in Community Health Centers

Sinta Dewi Lestyoningrum

*Master of Health Administration and Policy, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia*

## Abstract

Tuberculosis is an infectious disease caused by the tuberculosis virus, *Mycobacterium tuberculosis*. Indonesia is the third country after India and China that has 420.994 tuberculosis cases. East Java was ranked in the second among other provinces in Indonesia with more than 20.000 newly cases. Surabaya has the highest number of tuberculosis cases in East Java with the success rate of less than 90%. The key role of a community health center is to support the program of tuberculosis prevention but the organization frequently did not achieve the goal of health program. The study was an observational analytic on the team of tuberculosis prevention in Surabaya's community health centers. The sample was taken using stratified random sampling and chose 43 teams of tuberculosis prevention with simple random sampling. Total of participants was 318 people consisted of a doctors, nurses, and health analysts. The statistical analysis was a linear regression test. The findings showed reward influenced significantly toward team cohesion, while communication variable did not influence to team cohesion. The research concluded there was an influence of intrinsic reward toward cohesion in a team. Team cohesion is one of team process enabling to support team performance to achieve program target of tuberculosis prevention so it suggested paying attention to their staff particularly intrinsic reward by the management.

**Keywords:** *Communication, intrinsic reward, team cohesion, tuberculosis.*

## Introduction

Tuberculosis is a disease caused by anaerobic bacteria living in the lung or any organs that have high oxygen partial pressure<sup>(1)</sup>. Tuberculosis (TB) was caused by *Mycobacterium tuberculosis* that resisted from the acid<sup>(2)</sup>. The incident of TB has been predicted that 10 million in 2017 or 133 cases per 100.000 population have occurred worldwide. There are about 1,3 million mortalities due to tuberculosis and 300.000 mortalities

with HIV<sup>(3)</sup>. Meanwhile, Indonesia's TB incidence was 420.994 cases until May 2018 and the country was positioned in the third after India and China<sup>(4)</sup>. The province positioned second highest incidence of TB in Indonesia was East Java Province with 360.770 cases consisted of positive BTA of 26.152 cases. Surabaya city itself was the highest TB incidence of positive BTA (6.338 cases) among all districts of East Java<sup>(5)</sup>.

The government has made a program of TB prevention and controlling by tracking and finding new cases, treating TB patients and suspect optimally, improving social setting and environment, and implementing BCG immunization<sup>(1)</sup>. The prevention program by the government of Indonesia was launched in Indonesian Ministry of Health Regulation No. 67 the Year 2016 about TB prevention. The program aimed to reduce and to eliminate transmission and prevalence of TB in the society. The primary health facility in Indonesia includes the community health center as the

health facility for prevention and health promotion<sup>(6)</sup>. The community health center must assign doctors, nurses, and health analyst as the responsibility in managing the program of TB prevention<sup>(2)</sup>. Throughout the inter-profession collaboration, the community health center enables to make a team of TB prevention consisted of those three professions. A team was a workgroup consisted of people with equal ability and interact with weach other to actuate the task in a organization<sup>(7)</sup>. The problem faced in a team might be overcome easily compared to an individual problem in an organization<sup>(8)</sup>. However, the problem in a team emerged among the team members. Mcshanedan Von Glinow (2018) stated that one of the supporting factors for a team was team cohesion to obtain effective performance<sup>(10)</sup>. The team cohesion was influenced by reward and effective communication from an organization toward the team. This study aimed to analyze the influence of reward and communication toward team cohesion.

### **Material and Method**

The research was an observational analytic study with a cross-sectional design. It conducted in Surabaya between February and May 2019. The unit of analysis was TB prevention team of each community health center in Surabaya. The study involved 43 teams that were taken using simple random sampling. The sample used proportional stratified random sampling based on success rate (SR) per community health center. The participants were doctors, nurses, and health analyst who work closely with patients who need TB treatment. Total of participants was 318 people from 43 teams of TB prevention. The data collection used a questionnaire that had been validated and tested of its reliability and took from success rate data from Surabaya District Health Office.

The dependent variable was cohesion team, while the independent variable was reward and communication. Cohesion team was defined as the perspective of each member toward his/her interest and motivation to be in a team of TB prevention. A reward was defined as a perspective of every member toward rewarding from an organization because of TB prevention team's result and achievement. Communication was defined as a member's perspective toward effective information from the head of community health center or the leader team of TB prevention.

Cohesion team used GEQ questionnaire consisted

of task cohesion, social cohesion, individual attraction to the group<sup>(9)</sup>. Reward here was intrinsic reward that consisted of trust, responsibility, power, and complimentary. Communication variable consisted of the ability to send information, similar perspective of symbol, language, and abbreviation that occurred in team of TB prevention.

The responses were calculated in mean for team's score. The team score is calculated form average score for all members<sup>(10)</sup>. The statistical analysis used linear regression test and descriptive analysis using mean value, with cut off point of 3.20 from Pareto principle mentioned. The pareto principle explains that 80% of effects occur because of 20% caused. The average score of each team is tested using a linear multivariable regression test, which if the p-value is less than  $\alpha$  value (0,05), it will give significance.

### **Findings and Discussion**

**a. Reward:** Reward is an appreciation form by an organization to staffs or team. The reward not only might come out like money, but also appreciation, giving responsibility, and fully trust to team in decision making<sup>(11)</sup>. The organization offered reward both intrinsic and extrinsic to every staff aiming to improve performance of staffs<sup>(12)</sup>. Intrinsic reward might be a form of an appreciation towards a well-done job and a non-financial way in respect and appreciate the staff's contribution towards quality and consumer service<sup>(13)</sup>. Reward could not affect the successful performance but it made an impact toward motivation of employees<sup>(14)</sup>.

This study focused on intrinsic reward toward the staffs of TB prevention team in a community health center. Intrinsic reward was necessary for the employees besides extrinsic reward. The findings showed the team of TB prevention in all of Surabaya community health centers perceived that the reward they obtained was good (81.4%). Specifically, the indicators of reward variable had high mean value such as getting trust, responsibility delivery, and authority shifting.

The highest mean among those three indicators was responsibility delivery from the head of community health center. Besides, the staffs did not need to be reviewed for the decision they made<sup>(15)</sup>. Meanwhile, responsibility was an obligation for someone to work well according to the procedure and direction

beforehand<sup>(16)</sup>. In this context of the study, responsibility delivery was given according to the ability of each member of TB prevention team.

Responsibility delivery as reward from the head of community health center was perceived as very high reward (44.2%) by the respondents. Responsibility delivery also was suitable for the staff's ability. The ability of employees was a condition indicating maturity which related to insight and skills from education, training, and knowledge<sup>(17)</sup>. Meanwhile, the workability among the staffs was a level of skills, desire, and accomplishing the tasks of their responsibility and authority so they were able to achieve goals and organization's target<sup>(18)</sup>. Giving responsibility based on staff's ability affected to enhance work performance<sup>(19)</sup>.

- b. Communication:** Communication was primary factor for the team to explain its expectation and to coordinate the work that enabling the team to achieve organization's goal in effectively and efficiently way<sup>(11)</sup>. Communication presence in a team described interaction among team members in accomplishing the tasks and owning an important role in transforming input and outcome both cognitive and emotional<sup>(20)</sup>. The condition of communication both organization level and team level had key role in forming the bond among team members<sup>(21)</sup>. Mcshanedan Von Glinow (2018) stated there were three indicators of communication namely information delivery ability, similarity of symbol perception, language, and abbreviations. Another indicator was the understanding of the program of TB prevention. The result indicated that the team members mostly (88.4%), felt effective communication from the leader to them.

The lowest average was the ability to deliver information from the leader to the staffs. The study showed the participants tended to deliver information in a way of face to face or gadget. The result obtained 7% of respondents felt very effective communication in the team of TB prevention from the leader. That finding showed the channel to deliver the message had an impact on team's perception to get information. The team interacted according to the regulation when all members were able to access the visual information. However, that interaction had a limit when the team must be able to adapt dynamically with obstacles of communication channel they used for exchanging information<sup>(22)</sup>.

Another study found the indirect instruction from a leader to the team via voice recording might cause the staffs made more mistakes compared to direct instruction<sup>(23)</sup>.

Also, the mean value of the indicators of the same perception related to symbol, language, and abbreviations among members, and lacking understanding regarding the program was <3.2 like the indicator of information delivery. The communication was potential to improve performance when it presented acquisition and knowledge exchange among team members<sup>(20)</sup>. In addition, low value of same perception on symbol, language, and abbreviations, and program understanding was probably caused by the different professionals in the team. This determination might make different view of knowledge among team members. Different spectrum in the team was planned by Mannixdan Neale. It had six categories which one of them was different knowledge, skills, and abilities (education, functional knowledge, information or expertise, training, experience, and skills)<sup>(24)</sup>. Those low indicators were not complied with another study that found the difference in a team made positive impact on open communication in the team<sup>(20)</sup>.

- c. Team Cohesion:** The team members mostly perceived integrated team cohesion in TB prevention team (93%). The mean value of team cohesion was >3.2 as the variable did not have any indicator. The findings showed low integration among team members. The lowest mean indicator was social cohesion. Cohesion was a process whereby each member shared bond enabling the team to work together<sup>(25)</sup>. Refer to that definition; it was necessary for a team to have integration in order to achieve the goal. The task cohesion was in low mean value so it implied that the team had low perception regarding the unity of team as the social community for the team members. This social cohesion also experienced low mean due to the team needed to collab with other teams of antenatal care, immunization, health promotion, and others. Therefore, the team members did not have high perception of unity due to the collaboration with other teams.

- d. The Influence of Reward, and Communication to Team Cohesion:** The result from statistical analysis test in Table 1 showed variable of reward

influenced team cohesion ( $p=0.007$ ). The value of  $\beta$  coefficient was 0.406 that implied high reward had an opportunity of 40.6% to make integrated team cohesion. Team cohesion needed emotional association among team members based on its definition. Reward given to the team might be able to improve cohesion as rewarding to a team had different qualitative impact compared to rewarding to an individual<sup>(26)</sup>. Torrington, et al. (2011) stated

reward was important for team members in making bonds between each other<sup>(27)</sup>. This finding complied with the situation that the majority respondent as team members of TB prevention had appreciative reward. In detail, there was only one indicator with mean value of  $<3.2$  among four indicators. Meanwhile, it could be described that high reward for the team had an impact of integrated team cohesion.

**Table 1: The Result of Linear Regression Test**

Independent Variable	Dependent Variable	P-value	$\beta$
Reward	Team Cohesion	0.007	0.406
Communication		0.233	-0.211

The variable of communication did not influence team cohesion  $p=0.233$  and it has negative correlation. The result did not comply with other studies that found cohesion correlated with communication between members<sup>(28)</sup>. Another research found effective ways to improve unity in a team by non-verbal communication competency<sup>(29)</sup>. Besides, non-verbal communication was important in interaction among team members to improve nonaccidental messages, and it might lose those fault messages<sup>(30)</sup>. This study defined communication as an ability to deliver information. In detail, the lowest mean was the ability to deliver the information occurred in TB prevention team of Surabaya. This factor probably was the cause of negative correlation and insignificant result of influence of communication variable toward team cohesion. Clark dan Krych (2004) stated that communication ability from a leader to staffs will determine whether the employee will make a mistake or not<sup>(23)</sup>. If communication skill was not good, it would be interpreted in a different way among team members. The different response would make conflict among team members.

**Conclusion**

1. There was significant influence of reward toward cohesion team.
2. There was no influence of communication toward cohesion team.
3. The organization should increase intrinsic reward

for the team in order to improve performance because cohesion team was one of factor affecting the performance. The district health office might enhance intrinsic reward by giving a training of internal positive feedback for the head of community health center.

**Conflict of Interest:** We declared there was no conflict of interest.

**Source of Funding:** Department of Health and Administration Policy, Public Health Faculty, Airlangga University, Surabaya, Indonesia

**Ethical Clearance:** There search has been approved by Ethical Commission of Nursing Faculty, Airlangga University (No. 1316-KEPK). All respondents were given explanation and information including the purposes, method, and also had signed informed consent forms.

# The Effect of Burnout on Employee Satisfaction in 9 Local Health Centers in Surabaya City

Siti Fatimah Hariyati<sup>1</sup>, Ernawaty<sup>1</sup>

<sup>1</sup>Department of Health Policy and Administration, Faculty of Public Health, Airlangga University, Surabaya-60115, East Java, Indonesia

## Abstract

Indonesia took a significant step by using the National Health Insurance which is an integration of various forms of health insurance which have been implemented previously to achieve the target of universal health coverage. The portrait of the use of the National Health Insurance can be seen from the number of visits which increase each year. The increase in patient visits at local health center makes the local health center employees overwhelmed with a lot of tasks. Based on the initial survey at the Keputih Health Center, it was found that the burnout rate of employees in 2018 was 50.9%. The purpose of this study was to analyze the effect of burnout on employee job satisfaction in 9 local health centers in Surabaya. This research is analytical research with quantitative design. Based on the time, the design of this research is cross sectional. The population of this research is all employees of the Surabaya City Health Center who provide services for patients directly every day. The method of sampling uses a stratified non-random side technique. The data collected through survey method with questionnaire as instruments. The results showed that the likelihood of respondents with high burnout would have a higher job satisfaction 5.877 times than the respondents with low burnout. The conclusion is that low burnout will leads to the possibility of higher job satisfaction. The author's suggestion is to calculate the workload of each employee and schedule outbound activities for local health center employees.

**Keywords:** *Burnout, Job Satisfaction, Universal Health Coverage.*

## Introduction

In the Executive Board 144 summit of 2019, the WHO 13th General Program of Work is signed to achieve health target that in 2023 by all WHO member countries, including Indonesia. The target includes one billion people benefiting from Universal Health Coverage (UHC), one billion people are better protected from health emergencies, and one billion people will have a better and healthier life<sup>1</sup>. Indonesia has taken a significant step by using the National Health Insurance which is an amalgamation of various forms of health insurance which have been applied previously. The portrait of the utilization of the National Health Insurance can be seen from the number of visits which increase every year. In 2014 there were 62.3 million visits, while in 2017 there were 219.6 million visits. The implementation of National Health Insurance in all regions, including the remote areas and borders, must be balanced with equitable distribution of human resources

and the fulfillment of the availability of health care facilities<sup>2</sup>.

**Figure 1. Average Monthly Patient Visits in 2016-2018 at Keputih Health Center Surabaya**

The Surabaya city has 63 health centers in total which spread all over the region. The national health

insurance program made the local health center to have a role as gatekeeper. The Gatekeeper means it is the first level of health service facility and place of contact for patients that can be used to reduce the possibility of patient referrals to an advanced health facilities and it is function as an effort to control quality and costs<sup>3</sup>.

Based on Figure 1. it can be seen that the increase in patient visits also occurred at the Keputih health center in Surabaya. The average patient visit of each month back in 2016-2018 is 14.84%. The increase in the average visit of these patients consequently increases the workload of employees in the local health centers which leads to possibility of burnout.

Burnout is a prolonged response to chronic emotional and interpersonal stressors on the job, and is defined by the three dimensions of exhaustion, cynicism, and inefficacy. Exhaustion is the central quality of burnout and the most obvious manifestation of this complex syndrome. Depersonalization is an attempt to put distance between oneself and service recipients by actively ignoring the qualities that make them unique and engaging people. The relationship of inefficacy (reduced personal accomplishment) to the other two aspects of burnout is somewhat more complex, It is difficult to gain a sense of accomplishment when feeling exhausted or when helping people toward whom one is indifferent. However. The lack of efficacy seems to arise more clearly from a lack of relevant resources, whereas exhaustion and cynicism emerge from the presence of work overload and social conflict<sup>4</sup>.

**Table 1. Burnout Perception of Employees at Keputih Health Center Surabaya**

Statement	Disagree		Agree	
	n	%	n	%
Physical exhaustion at the end of the work day.	12	33.3	24	66.7
Overworked.	16	44.4	20	55.6
Boredom due to work.	17	47.2	19	52.8
Stress in working directly with people.	18	50.0	18	50.0
Feeling blamed for the patient's problem.	21	58.3	15	41.7
Feeling reluctant when wake up early because you have to work.	22	61.1	14	38.9
Average		49.1		50.9

Based on table 1. It can also be concluded that the average perception of burnout experienced by the employees in Keputih Health Center is 50.9%. The

employees tend to experience physical fatigue and over worked. Additional workloads should be balanced with the fulfillment of employee's needs hence to maintain employee satisfaction. The term 'job satisfaction' refers to the attitudes and feelings people have about their work. Positive and favourable attitudes towards the job indicate job satisfaction. Negative and unfavourable attitudes towards the job indicate job dissatisfaction<sup>5</sup>. The following is employee satisfaction data at Keputih Health Center..

**Table 2. Employee Satisfaction in Keputih Health Center Surabaya**

Statement	No		Yes	
	n	%	n	%
Praise for work you have done.	10	27.8	26	72.2
Opportunity to improve.	8	22.2	28	77.8
Work system at the Local health center.	8	22.2	28	77.8
Income received.	4	11.1	32	88.9
The way sub ordinates handle complaints.	3	8.3	33	91.7
Interpersonal Relationship.	2	5.6	34	94.4
Average		15.8		83.8

Based on table 2. We can also see that the employees feel dissatisfied with the praise or reward for the work they done; and they also not satisfied with the opportunity offered to improve; and not as well satisfied with the work system at the Local health center. This is indicated by a percentage number that exceeds 20%. Overall, the initial survey at the health center in Keputih resulted in a good level job satisfaction but with a high perception of burnout. Therefore this study was conducted to learn about the effect of burnout on the work satisfaction of employees at the Surabaya city health center.

**Material and Method**

This type of this research is quantitative and the design is observational analytic. The data collection technique is the cross sectional with population of all employees of the Surabaya City Health Center who provide services to patients directly every day. The inclusion criteria in this study are health center employees who provide services for patients directly every day. While the exclusion criteria in this study are employees who provide services indirectly to patients and employees who provide services directly to patients but not every day. Hence the total population is 1890 employees.

The method of sampling in this study uses the stratified non random sampling method with a sample consists of 259 employees. The data was retrieved through survey method with questionnaire instruments. The burnout level was measured through the 1981 Maslach Burnout syndrome Inventory questionnaire<sup>7</sup>. using the Minnesota Satisfaction Questionnaire of 1977<sup>8</sup>. The results of this research are not able to be generalized due to the method of sampling is not random therefore the results of the study will illustrate the extent of its influence but not in its significance.

### Findings And Discussion

**Identification of Employee Burnout Level in 9 Surabaya City Health Centers:** Burnout has 3 dimensions, namely Exhaustion, Depersonalization, and Personal Accomplishment. The following is an identification of employee burnout levels based on 3 dimensions of burnout.

**Table 3. Identification of Employee Burnout Levels in 9 Surabaya City Health Centers**

Questions	Percentage Distribution of Score								Mean	
	1		2		3		4			
	n	%	n	%	n	%	n	%		
<b>Exhaustion</b>										
Emotional drain	26	10.04	129	49.81	89	34.36	15	5.79	2.36	3.07
Physical exhaustion at the end of the work day.	52	20.08	131	50.58	69	26.64	7	2.70	2.12	
Lazy of waking up in the morning	28	10.81	103	39.77	95	36.68	33	12.74	2.51	
Feeling depresses.	5	1.93	54	20.85	116	44.79	84	32.43	3.08	
Feeling bored	12	4.63	115	44.40	86	33.20	46	17.76	2.64

Moral Value	14	5.41	30	11.58	193	74.52	22	8.49	2.86
Sosial Support	16	6.18	41	15.83	185	71.43	17	6.56	2.78
Responsibility	11	4.25	48	18.53	189	72.97	11	4.25	2.77
Supervision-Human Relations	26	10.04	68	26.25	149	57.53	16	6.18	2.60
Supervision-Technical	18	6.95	56	21.62	171	66.02	14	5.41	2.70
Variety	27	10.42	74	28.57	143	55.21	15	5.79	2.56
Working Condition	15	5.79	54	20.85	170	65.64	20	7.72	2.75
<b>Overall average</b>									<b>2.84</b>

Based on table 4. above it can be seen that the job satisfaction assessment resulted in the average value of 2.84. The value is categorized as good as the threshold is with an average value of > 2.5. The average value shows that respondents feel satisfied with their work

both in terms of salary, relationship to superiors and subordinates, work environment conditions and so on.

**Test Result of The Effect of Burnout on Job Satisfaction:** The following is a 3-dimensional relationship of burnout on employee job satisfaction

**Table 5. Correlation between Burnout and Employee’s Job Satisfaction in 9 Surabaya City Health Centers**

Variable	Job Satisfaction				Total	
	Low		High			
	n	%	n	%	n	%
<b>Exhaustion</b>						
Low	54	45.8	64	54.2	118	100
High	73	51.8	68	48.2	141	100
<b>Total</b>	<b>127</b>	<b>49.0</b>	<b>132</b>	<b>51.0</b>	<b>259</b>	<b>100</b>
<b>Depersonalization</b>						
Low	53	42.7	71	57.3	124	100
High	74	54.8	61	45.2	135	100
<b>Total</b>	<b>127</b>	<b>49.0</b>	<b>132</b>	<b>51.0</b>	<b>259</b>	<b>100</b>

Variable	Job Satisfaction				Total	
	Low		High		n	%
	n	%	n	%		
<b>Personal Accomplishment</b>						
Low	53	46.1	62	53.9	115	100
High	74	51.4	70	48.6	144	100
<b>Total</b>	<b>127</b>	<b>49.0</b>	<b>132</b>	<b>51.0</b>	<b>259</b>	<b>100</b>
<b>Total Burnout</b>						
Low	60	47.6	66	52.4	126	100
High	67	50.4	66	49.6	133	100
<b>Total</b>	<b>127</b>	<b>49.0</b>	<b>132</b>	<b>51.0</b>	<b>259</b>	<b>100</b>

Based on table 5. We seen that as many as 64 or 54.2% of the respondents have expericed low exhaustion and higher job satisfaction. There were 71 or 57.3% of the respondents with low depersonalization and high job satisfaction. 62 or 53.9% of respondents have low personal accomplishments and high job satisfaction. And last, 66 or 52.4% of respondents experiencing low total burnout and high job satisfaction.

Hasildariidentifikasi tingkat burnout dan tingkat kepuasan karyawan kemudian di ujimenggunakan aplikasi statistik untuk melihat pengaruh burnout terhadap kepuasan kerja. Besaran pengaruh akan digambarkan dengan nilai OR.

**Table 6. Result of Test for the Effect of Burnout on Employee Job Satisfaction in 9 Surabaya City Health Centers**

Independent Variable (Burnout)	Dependent Variable	OR
Total Burnout	Job Satisfaction	5.877
Personal Accomplishment		0.761
Exhaustion		0.495
Depersonalization		0.228

Based on table 6. It shows that total burnout has the highest OR value of 5.877 means that the likelihood of respondents with high burnout would have a higher job satisfaction 5.877 times than the respondents with low burnout. Based on these results it can be learned that the respondents who have a low total burnout have the possibility experience higher job satisfaction. The respondents who did not feel the boredom or exhaustion of work would work happily and comfortably which could increase the respondents' job satisfaction.

These results are in line with the research conducted by Andarini (2018) where Burnout syndrome has a

negative effect on job satisfaction, which means that with higher burnout syndrome, the more it will reduce job satisfaction<sup>9</sup>. The results are also in line with the research conducted by Rupita (2004) on job satisfaction and burnout in nurses at the DR. Soedarso Pontianak Hospital which resulted that there was a significant negative relationship between job satisfaction and burnout on nurses ( $r = -0.408$  and  $p < 0.05$ ), so when burnout increases, job satisfaction will automatically decrease<sup>6</sup>. The results of this research are also in line with the research of Maslach, Schaufeli, and Leiter (2001) which stated that for people who stay on the job, burnout leads to lower productivity and effectiveness at work. Consequently, it is associated with decreased job satisfaction and a reduced commitment to the job or organization. People are experiencing burnout will have a negative impact on their colleagues, both by causing greater personal conflict and by disrupting job tasks<sup>4</sup>.

Based on table 6. It is proven that depersonalization has the lowest OR value of 0.228. Based on the result it can be learned that respondents with low depersonalization have a high likelihood of better job satisfaction. Respondents tend to be comfortable and able to place themselves as a service provider. Thus the satisfaction perceived by respondents tends to be high.

It is also in line with the research conducted by Nurka et al. (2014) which found that there is a significant correlation between job satisfaction and depersonalization ( $P < 0.001$ ). The multivariate regression analysis showed a significant predictor of depersonalization, namely using knowledge and skills in the workplace<sup>10</sup>.

### Conclusions

Based on the analysis of the effect of burnout on job satisfaction, it is found that when the exhaustion;

depersonalization; and personal accomplishments dimension is low, will leads to the possibility of high job satisfaction. Overall a low burnout level will made the possibility of high job satisfaction.

Based on the results the author recommends that Local health center calculate the workload of each employee so that workload adjustments can be made for employees. Besides, local health center can take the employees for outbound at least once a year to improve interpersonal relations both between employees to superiors and fellow employees and to relieve boredom by the many demands of the work..

**Funding:** Self.

**Conflicts of Interest:** None.

# The Influence of Social and Cultural Factors on the Decision of Selecting a Place for Preeclampsia Mother Giving Birth

Siti Nur Azizah<sup>1</sup>, Ernawaty<sup>2</sup>

<sup>1</sup>Departement of Health Administration and Policy, Public Health Faculty, Airlangga, University, 60115, Surabaya, East Java, Indonesia, <sup>2</sup>Departement of Health Administration and Policy, Public Health Faculty, Airlangga University, 60155, Surabaya, East Java, Indonesia

## Abstract

Maternal Mortality Rate (AKI) is one indicator of state health. AKI in 2017 amounted to 79.4 per 100,000 live births in the city of Surabaya. This number still exceeded the SDGs target sey. While the most common causes of AKI is preeclampsia. Preeclampsia is a specific condition in pregnant women over 20 weeks characterized by placental dysfunction. The main sign of preeclampsia is the presence of hypertension. The case of preeclampsia in Kenjeran Subdistrict Community Health Center (Puskesmas) is one of the highest in Surabaya.

This research is an observational quantitative study. The research design used cross-sectional. The population of this study were all preeclampsia mothers in Kenjeran Subdistrict Puskesmas. The sample in this study were 127 mothers of preeclampsia. Secondary data was used as a reference to determine samples. Primary data was obtained through observation and interviews. The statistical analysis used was multinomial regression.

The results show that there is an influence between social factors (0.024) and the decision to choose the place of delivery and there is no influence between cultural factors (0.831) and the decision to choose the place of delivery.

It is recommended to improve and maintain family support as a social factor for preeclampsia mothers to immediately make a decision to choose a place of delivery. As well as the need for approaches to local customs and culture by health workers to be easily accepted by the community.

**Keywords:** *Mother Gives Birth, Decision Making, Preeclampsia.*

## Introduction

Maternal Mortality Rate (AKI) is one indicator of the health status of a country, because AKI shows the ability and quality of health services<sup>(1)</sup>. This makes an assessment of the health status and performance of

maternal health efforts. There are several provinces with a large number of maternal and neonatal deaths, one of which is East Java.<sup>(2)</sup> AKI in East Java tends to decline in the last three years, but in 2016 it increased again. In 2017, AKI East Java Province reached 91.92 per 100,000 live births. This number increased compared to 2016 which reached 91 per 100,000 live births. One of the areas in East Java that with the highest case of maternal mortality, is Kota Surabaya. AKI in Surabaya in 2017 amounted to 79.40 per 100,000 live births. AKI still exceeds the target of the Sustainable Development Goals (SDGs) of 70 per 100,000 live births. The still high level of AKI has made the government need to make improvements in maternal health services. Based on Surabaya City Health Office in 2017 the highest

cause of death in the city of Surabaya is caused by preeclampsia or eclampsia. Preeclampsia or eclampsia as the leading cause of maternal death in Surabaya City with 29 cases from 2015 to 2017. The risk of maternal death will be high due to risk factors for delays such as late recognition of danger signs, late decision-making, and late arrival at health facilities<sup>(3)</sup>. Decision-making to choose or buy health services is influenced by several factors, namely the characteristic factors, social factors, cultural factors, and psychological factors. Preeclampsia or eclampsia is a condition included in the criteria for obstetric emergencies (4). Therefore, the need for further treatment of mothers with these conditions. Based on the exposure of the problem related to the high maternal mortality rate, it was caused due to complications especially in preeclampsia or eclampsia. Then, considering the background described earlier that the incidence of preeclampsia tends to increase. Then this is the basic reason for knowing the factors that influence the decision making of mothers with cases of preeclampsia in determining the place to give birth.

### Material and Method

This study is a type of analytic research because it analyzes the influence between two independent and dependent variables. This study was an observational study because the researcher did not give treatment to the subject under study and only did data collection. Judging from the time the research was conducted in a certain time or the same period of time when carrying out research.

The population in this study were 328 preeclampsia mothers and used sampling using proportional random sampling. The method used to determine the number of samples was using Leme show formula<sup>(5)</sup>, as shown below:

$$n = \frac{Z^2 \times N \times p \times q}{d^2 \times (N-1) + Z^2 \times p \times q}$$

**Note:**

n = Total sample

N = population

Z = Normal standard deviation for 1,96

d = degree of confidence (0,05)

p = proportion of the target population is 0,12

q = 1-p = 0,88

Then obtained a calculation as follows:

$$n = \frac{1,96^2 \times 328 \times 0,12 \times 0,88}{0,05^2 \times (328-1) + 1,96^2 \times 0,12 \times 0,88}$$

n = 108,78 workers or 109 samples

However, the samples obtained in the field in this study were 127 samples.

The variables in this study were social factors, cultural factors, and decisions on the choice of place of delivery. The instruments in this study used a questionnaire. This study used a multinomial regression test with a confidence level of 95% with a value of  $\alpha = 0.05$ .

**Findings:** Respondents in this study were mothers who were diagnosed with preeclampsia as many as 127 respondents with the following description:

**Based on this research, the distribution of respondents' data is as follows:**

**Table 1. Distribution of Respondents Based on Social Factors and Cultural Factors**

Variable	Category	Frequency	Percentage
Social Factor	Good	105	82,68%
	Not Good	22	17,32%
	<b>Total</b>	127	100%
Cultural Factor	Support	100	78,74%
	Not Supporting	27	21,26%
	<b>Total</b>	127	100%

Based on table 1, it is known that the majority of preeclampsia mothers fall into the category of good social factors as many as 105 respondents or with a percentage of 88.68%. In addition, the majority of preeclampsia mothers is included in the category of supporting cultural factors with a frequency of 100 people or with a percentage of 78.74%.

From the research that has been done, it is known that respondents who decided to choose a hospital as many as 73 people or with a percentage of 57.5%, respondents who decided to choose the practice of independent midwives as many as 40 people with a percentage of 31.5%, and respondents who decided to choose a community health center as many as 14 people with a percentage of 11.0%. This can be seen in table 2.

**Table 2. Distribution of Decisions on the Place of Delivery**

Variable	Category	Frequency	Percentage
Decision on the selection of place of delivery	Hospital	73	57,5
	Practice of Independent Midwives	40	31,5
	Community Health Center	14	11,0

Bivariate analysis produces data relating to the influence between independent variables consisting of social and cultural factors which are then related to the dependent variable, namely the decision to choose the place of delivery. The statistical test used was using a multinomial regression test.

From the results of multinomial regression statistical tests between social factors and the selection of place of delivery found that the significance of 0.024 which means it was smaller than alpha, namely 0.05 so it can be concluded that there was an influence between social factors and the decision to choose the place of delivery. While the results of the test of influence between cultural factors and the decision to choose the place of delivery obtained a significance result of 0.831 with an alpha of 0.05 thus there was no influence between cultural factors and the decision to choose the place of delivery.

**Discussion**

There are several factors that can influence consumers to decide to make a purchase or use services, namely social and cultural factors. Social factors include reference groups, families, roles and status. While cultural factors include culture, subculture, and social class. Every individual must be surrounded by people who can influence his decision<sup>(6)</sup>. Cultural factors are the most fundamental determinant of the desires and behavior of consumers to obtain a value. Culture creates perceptions, values, requests, and behaviors that can be influenced by family, friends, and society<sup>(7)</sup>.

In this study, it shows that 73 people decide to choose hospital as the place of delivery. The results of statistical test show that there was influence between social factors with the decision of selection delivery place. In this study, it was found that social factor of mothers with preeclampsia was included in the category of good. Social factors mentioned as good included is that the mother of preeclampsia had a reference group or figure that used as a role model to influence herself in making

decisions. Then, a preeclamptic woman with the support from her family. This condition can encourage mothers to immediately make decisions because they feel that there is a form of attention given from the family. This research is in accordance with the research conducted by Maleke<sup>(8)</sup> that there is an influence between social factors and decision making.

Someone who is growing and obtaining as et of values, perceptions, and preferences from the surrounding environment due to socialization that occurs will form a behavior habit created for that person. In this study, it was found that the cultural factors of preeclamptic mothers were in the supportive category. The cultural factor in question supports namely that the mother of preeclampsia would not go to shaman, there was no advice on giving birth at home, and did not have to be supported by laborers of the same sex. In this study it was found that there was no influence between cultural factor variables and the decision to choose the place of delivery. In the research conducted by Ruhamak (9), it was found that cultural factors do not significantly influence decision making. This is in line with this study that cultural factors have no influence on maternal decision making.

**Conclusion**

1. The majority of preeclamptic women already have good and supportive social and cultural factors in making decisions.
2. The majority of preeclamptic women decide to choose a hospital as their place of delivery.
3. There is an influence between social factors and the decision to choose the place of delivery. However, there is no influence between cultural factors and the decision to choose the place of delivery.

**Recommendation:**

1. Increase and maintain family support as a social factor for preeclamptic mothers to immediately make a decision to choose a place of delivery
2. There needs to be an approach to local customs and culture by health workers to be easily accepted by the community.

**Conflict of Interest:** All authors have no conflicts of interest to declare

**Source of Funding:** This is an article “The Influence of Social and Cultural Factors on The Decision

of Selecting a Place for Preeclampsia Mother Giving Birth” of Health Administration and Policy Departement that was supported by Faculty of Public Health, Airlangga University

# The Difference of Brain Derivat Neutrophic Factor of Mus Musculus Newborn from Adolescent and Adult Pregnancy

Sri Wahyuni<sup>1</sup>, Widjiati<sup>2</sup>, Muhammad Miftahussurur<sup>3</sup>

<sup>1</sup>Master degree of Reproductive Health Science, Faculty of Medicine Universitas Airlangga Surabaya Indonesia, <sup>2</sup>Departemen of Anatomy Veteriner, Faculty of Veterinary Universitas Airlangga Surabaya Indonesia, <sup>3</sup>Departemen of Internal Medicine, Dr. Seotomo Hospital Surabaya Indonesia

## Abstract

**Background:** The brain is the main organ involved in stress adaptation, while being the target of stress. Stress activates the hypothalamic-pituitary-adrenal (HPA) axis and the system is adrenomedular Simpato thereby increasing the production of corticotropin-releasing hormone (CRH) and arginine-vasopressin (AVP) resulting in lower levels of Brain Derived Neurotrophic Factor (BDNF) in the hippocampus. Objective: The study aims to find out the difference of BDNF of *Mus musculus* newborn brain from adolescents and adults pregnancy. Method: The samples on this study were 32 mice that divided by 2 groups were adolescent pregnancy mice group and adult pregnancy mice group. *Mus musculus* newborn were born by sectio and selected three with the heaviest, medium and lightest of each mothers to sacrificed their brains did decapitated and made immunohypochemical preparations and continued examination of the Immunoreactive Score to calculate Brain Derived Neurotrophic Factor expression. Result: BDNF expression of adolescent pregnancy mice group had higher ( $5.65 \pm 1.044$ ) than adult pregnancy mice group ( $4.15 \pm 1.049$ ). Test results showed that there was differences of BDNF expression in the brain  $p = 0,000$  ( $p < 0.05$ ) with details, there were differences in the cerebrum  $p = 0,015$  and the cerebellum  $p = 0,000$  between adolescent pregnancy mice group and adult pregnancy mice group. Conclusion: BDNF expression in brain of *Mus musculus* newborn from adolescent pregnancy lower than *Mus musculus* newborn from adult pregnancy.

**Keywords:** Stress, adolescent pregnancy, expression Brain Derived Neurotrophic Factor.

## Introduction

Adolescence is defined as the developmental phase in humans whose life cycle lies between childhood and adulthood<sup>1</sup>. According to WHO about teenage pregnancy, an estimated 16 million teenage girls give birth every year, mostly in low and middle income countries<sup>2</sup>. complications from childbirth are the main cause of death among girls between the ages of 15-19 years<sup>3</sup>. Teenage pregnancy has become an issue around the world which needs to be done to reduce the problem

of the birth of adolescent mothers<sup>4,5</sup>. Teenage pregnancy causes a serious impact on physically giving birth at an early age causing high mortality of pregnant women, triggering the emergence of problems with abortion, premature birth, preeclampsia. The psychological impact is the difficulty facing the social environment, experiencing the level of depression, difficulty in accessing to continue higher education, financial difficulties, having weak and unhealthy children<sup>6</sup>

The brain is the main organ involved in stress adaptation, as well as being the target of stress<sup>7</sup>. Stress activates the HPA axis and the adrenomedular sympathetic system thereby increasing the production of corticotropin-releasing hormone (CRH) and arginine-vasopressin (AVP). This increase because of increased secretion of adrenocorticotrophic hormone (ACTH) and glucocorticoid<sup>8</sup>.

Brain Derived Neurothropic Factor as the main factor that plays a role in the survival of nerve cells, as well as being involved in the proliferation, differentiation, and regulation of synapse function in the central nervous system. Acute or chronic stress affects BDNF and TrkB expression in the brain. Chronic stress decreases mRNA and BDNF protein expression in the hippocampus<sup>8</sup>.

The study aims was to find out the difference of BDNF of *Mus musculus* newborn brain from adolescents and adults Pregnancy.

### Material and Method

This was an analytic study and conducted at the Pathology Laboratory of the Faculty of Veterinary Medicine, Universitas Airlangga Surabaya which had been ethically legalized before. **Participants.** Sample size in this study were 32 samples and randomly divided into two groups. There were adolescent pregnant mice (treatment group) and adult pregnant mice (control group) Pregnant *Mus musculus* aged 1,5 months and fulfilled the criteria of study subjects for treatment group were healthy, weighing 15 – 20 grams and age 1,5 month and for control group were healthy, weighing 30-35 grams and age 3 month. *Mus musculus* that were sick or dies during treatment can't be used. **Intervention.** Each sample was given treatment according to the group which were Female mus musculus with 3 months old (Adult mice) and 1.5 months old (Adolescent mice) were impregnated with PMSG dose 5 IU and HCG dose 5 IU injections then mated with male mice aged 5 months. **Outcome.** Brain samples were taken after *Mus musculus* newborn were born then their brains were taken. For one preparat contains 3 brains sample with the heaviest, moderate and lightest. BDNF expression

in each sample was assessed semi-quantitatively according to the modified Remmele method. Data for each sample was observed on ten fields of view (LP) at 400 x magnification. This study was examination used *microscope miconos MCX50LED and camera optilab plus*.

The data was carried out with comparative test using non parametric *Mann Whitney* test.

**Findings:** Pregnant *Mus musculus* randomly grouped and there were 10 mice dead from treatment group and 2 mice dead from control group. *Mus musculus* newborn had 5 mice being reabsorbtion. The Shapiro-Wilk test showed a unnormal distribution ( $p > 0.05$ ) after that using *Mann whitney* test.

**Table 1. Characteristics body weight and gestational age of *Mus musculus* mothers**

		X1		X2	
		n	%	n	%
Body weight	15-20	16	100%	-	-
	21-25	-	-	3	18,75%
	26-30	-	-	10	62,5%
	31-35	-	-	3	18,75%
Gestational Age	20 day	16	100%	16	100%

X1: Adolescent pregnancy mice (Treatment group), X2: Adult pregnancy mice (Control group)

Based on the table 1, all of K1 group samples had body weight 15-20 gram and each three samples of K2 group had body weight 21-25 gram (18,75%) and 31-35 gram (18,75%) meanwhile ten samples K2 group had body weight 26-30 gram (62,5%). All of samples group with gestational age 20 day (100%).

**Table 2: Mean body weight *Mus musculus* mothers and newborn**

Group	BW Mothers			BW newborn	
	Before	After	p	Mean±SD	p
	Mean±SD	Mean±SD			
X1	16,93±1,38	26,00±2,94	0,011	0,31±0,08	0,000
X2	28,00±2,22	41,25±5,88		0,62±0,42	

X1: Adolescent pregnancy mice (Treatment group), X2: Adult pregnancy mice (Control group)

Based on the table 2, The control group (X2) had higher mean of body weight before pregnant (28,00±2,22) than treatment group (X1) (16,93±1,38). Mean of body weight after pregnant of control group (X2) had higher mean (41,25±5,88) than treatment

group (X1) (26,00±2,94).

Mean of body weight *Mus musculus* newborn control group (X2) had higher (0,62±0,42) than treatment group (X1) (0,31±0,08).

**Table 3. Characteristics BDNF expression of Mus musculus newborn.**

Group	Cerebrum			Cerebellum			Brain		
	Mean±SD	Normality	Mann Whitney	Mean±SD	Normality	Mann Whitney	Mean±SD	Normality	Mann Whitney
X1	4,47±1,28	0,019	0,015 <sup>b</sup>	3,82±0,63	0,049	0,000 <sup>b</sup>	4,15±1,049	0,000	0,000 <sup>b</sup>
X2	5,53±1,15	0,054 <sup>a</sup>		5,76±0,95	0,033		5,65±1,044	0,007	

X1: Adolescent pregnancy mice (Treatment group), X2: Adult pregnancy mice (Control group), <sup>a</sup>: Data distribution normal (p>0,05), <sup>b</sup>: significant difference (p<0,05)

**Analysis of the results in cerebrum:** Based on table 3, mean BDNF expression of control group (X2) more high than treatment group (X1) in cerebrum. The results of the normality test showed that unnormal data distribution in treatment group (X1) (p=0,019) so we used *non parametric mann whitney test*. Table 3 shown the results that there was a significant difference of BDNF expression cerebrum between group (p=0,015).

**Analysis of the results in cerebellum:** Table 3 shown that mean BDNF expression of control group (X2) more high than treatment group (X1) in cerebellum. The results of the normality test showed that unnormal data distribution then used *non parametric mann whitney test*. there was a significant difference of BDNF expression cerebellum between groups (p=0,000).

**Analysis of the results in brain:** Based on table 3, mean BDNF expression of control group (X2) more high than treatment group (X1) in brain. The results of the normality test showed that unnormal data distribution and then used *non parametric mann whitney test*. Table 3 shown the results that there was a significant difference of BDNF expression cerebrum and cerebellum (in brain) between group (p=0,000).

**Discussion**

In the adolescent group there were 10 mothers who died during treatment and 2 mothers Mus musculus in the control group who died. The gestational age of the mother mice averaged between 19-20 days, then on the 21<sup>st</sup> day a sectio caesarea was performed. Obtained adolescents pregnancy *Mus musculus* group had 3 mice abortions while the adult pregnancy *Mus musculus* group did not experience abortion. This shows that the gestational age of 1.5 months is not mature enough to reproduction function so that’s difficult to get pregnant and there are many deaths issue related to stress. In accordance with the theory which shown that the age

of productive mice which ready to be impregnated is 30-40 days, this is influenced by the readiness of the reproductive organs<sup>9</sup>. The parent of juvenile mice who experience death, neither pregnancy nor abortion (reabsorption) is the impact of unpreparedness based on the age and reproductive function of mice and the mother of mice experiencing one of the three social stresses namely isolation, new environment or crowding<sup>10,11</sup>.

From the results of the study, it was also explained that there were differences of BDNF expression between Mus musculus both groups in the cerebrum, cerebellum or both (brain). In mice experiments at prepubertal levels and mid-adolescents aged 30-50 days experienced two times longer stress compared to adult aged 70 days<sup>12</sup>. Cortisol in amniotic fluid is closely related to the maternal activity of the HPA system<sup>13</sup>. The placenta enzyme 11β-hydroxystoid dehydrogenase-2 (HSD2) can function as an enzymatic buffer against the effects of maternal glucocorticoid exposure. However, these enzymes can reduce regulation by adverse prenatal history, which is thought to reduce the capacity to protect developing fetuses<sup>14</sup>.

Maternal depression is associated with an increase in the level of glucocorticoid mRNA receptor placenta (GR) allowing placenta GR sensitivity to be changed in stressed mothers<sup>15</sup>. Chronic stress in pregnant mice results in an evaluation of the HPA (hypothalamic pituitary Axis) by measuring plasma levels of ACTH and cortisosterone<sup>16</sup>. In experimental animals, mice undergoing pregnancy can cause differential methylation of the BDNF gene in the blood and brain<sup>16</sup>.

Stress is known to change neuronal structure during development and cause atrophy in the brain<sup>17</sup>. This can jeopardize normal hippocampal connectivity and reduce hippocampal size, reduce cognitive function<sup>18</sup> BDNF is active in the first two weeks of the mice embryo and peaks 10-14 days into the postnatal period, with the

highest levels in the hippocampus. mBDNF maintains cell survival through TrkB binding and downstream paths involving Erk1-2<sup>19</sup>. Prenatal stress changes the conventional pattern of ongoing functions. BDNF genes are clearly regulated by stress and HPA axis activation<sup>20</sup>. It is widely known that chronic stress or high glucocorticoids can reduce mRNA BDNF hippocampus expression<sup>21</sup>. BDNF signals in the hippocampus can follow one of two different signaling pathways that have opposite effects on cells, such as proBDNF, it has a high affinity for p75 receptors, which increases LTD, dendritic atrophy, and cell apoptosis. For proBDNF to be split into mature forms by plasmin, the first plasminogen zymogen must be activated by landfill. After processing, mBDNF can bind to the TrkB receptor either pre or post synaptically. In that dendrite, binding induces Erk 1/2 phosphorylation, which leads to LTP, synaptic plasticity, cell survival and differentiation

Neuroplasticity is a new hypothesis in the etiology of depression. Brain derived neurotrophic factor (BDNF) is the main neurotrophic factor responsible for brain neuroplasticity and neural development. BDNF is responsible for the production, growth and differentiation of immature neurons during the stage of brain development, important for the survival of neurons. BDNF increases the development of noradrenergic and serotonergic neurons, increasing their life span by preventing them from toxic damage<sup>22</sup>. In addition, it is effective in neurogenesis and synaptic plasticity<sup>23</sup> With BDNF gene suppression, deteriorates neuroplasticity, neurons become more susceptible to pressure easily initiate apoptosis and result in atrophy<sup>23</sup>.

Hippocampus is one of the limbic structures which involves emotions and cognition. It also contributes to mood disorders such as depression, and the function of hippocampal formation and regulation of the HPA axis both change in depression<sup>24</sup>. Glucocorticoids have repeatedly been shown to reduce BDNF synthesis, which also applies to pregnancy<sup>25</sup>. Therefore, prenatal maternal HPA stress activation and fetal glucocorticoid exposure are the main mechanisms for modulating BDNF synthesis in pregnancy. Thus, prenatal maternal stress can lead to epigenetic modulation of fetal BDNF regulation, and activation of the maternal HPA system and fetal BDNF. Because free diffusion is bidirectionally between the amniotic fluid and the fetus in the skin of the fetus, placenta, and umbilical cord from 10 to 20 weeks of pregnancy, the composition of amniotic fluid becomes similar to fetal plasma during this period<sup>26</sup>.

## Conclusion

BDNF expression in brain of *Mus musculus* newborn from adolescent pregnancy lower than *Mus musculus* newborn from adult pregnancy in brain.

**Conflict of Interest:** There was no conflict of interest in this study.

**Ethical Clearance:** This study was received ethical approval from the Health Research Ethics Committee, Faculty of Dental Medicine, Universitas Airlangga.

**Source of Funding:** This study was supported by the authors

# The Relationship between Integrated Antenatal Care (ANC) Service and the Transmission Prevention Examination from Mother to Children in Sleman Public Health Centers in 2018

Suci Musvita Ayu<sup>1</sup>, Ana Amalia Rizqi<sup>1</sup>

<sup>1</sup>Faculty of Public Health, Ahmad Dahlan University

## Abstract

**Objectives:** Maternal Mortality Rate (MMR) in Sleman Regency in 2017 amounted to 42.78 per 100.000 live births. It has decreased compared to 2016 which amounted to 56.59 per 100.000 live births. Meanwhile, the Infant Mortality Rate (IMR) was 4.20 per 1.000 live births. It increased compared to 2016 which was 3.11 per 1.000 live births. One of the efforts to reduce maternal and infant mortality is through an integrated antenatal care service program. The purpose of this study is to determine the relationship between integrated Antenatal Care (ANC) services and the Prevention of Mother-to-Child Transmission for Pregnant Women in Sleman Health Center in 2018.

**Method:** This study is analytic observational with a cross-sectional design. The research subjects were pregnant women in Sleman Health Centers. The research samples were 104 people with a purposive sampling technique. The research tools were questionnaires. The data analysis was done with univariate and bivariate.

**Results:** The significant value of 0.001 ( $p < 0.05$ ) was obtained, it means that there was a relationship between integrated Antenatal Care (ANC) services and Mother to Child Transmission Prevention (PPIA) checks on Pregnant Women in Sleman Public Health Centers in 2018, the risk prevalence is 25.71 ( $> 1$ ) and the value of CI is between 3.094 and 213.742 so that it does not exceed the number one, meaning that the variable is a risk factor.

**Conclusions:** There is a relationship between Antenatal Care (ANC) services integrated with Prevention of Transmission from Mother to Child on Pregnant Women in Sleman Health Centers.

**Keywords:** *ANC service, Prevention of Transmission from Mother to Child examination, Pregnant women.*

## Introduction

Maternal Mortality Rate (MMR), Neonatal Mortality Rate (NMR), Infant Mortality Rate (IMR) and Underfive Mortality Rate (UMR) are indicators of the public health

status. The current AKI and AKB in Indonesia are still high compared to other ASEAN countries. Based on the Indonesian Demographic and Health Survey (IDHS) in 2012, MMR was estimated to reach 359 maternal deaths per 100.000 live births. According to the 2012 IDHS, there were IMR 32 deaths per 1000 births, NMR 19 per 1000 live births, UMR 44 per 1000 live births.<sup>(1)</sup>

The direct causes of maternal death are factors associated with complications of pregnancy, childbirth and childbirth such as bleeding, preeclampsia/eclampsia, infection, congestion and abortion. Indirect causes of maternal mortality are factors that aggravate the situation of pregnant women such as four too (too young, too old, too often giving birth and too close to birth distance)

and three late (late recognizing danger signs and making decisions, late reaching health facilities and late in handling emergencies). Other influential factors are pregnant women who suffer from infectious diseases such as malaria, Human Immunodeficiency Virus (HIV)/Acquired Immunodeficiency Syndrome (AIDS), tuberculosis (TB), syphilis, non-communicable diseases such as hypertension, diabetes mellitus, heart disease and mental disorders experiencing malnutrition.<sup>(2)</sup>

Pregnant women who do not take care of pregnancy have a risk of abnormal occurrence 1.6 times higher than women who carry out antenatal care.<sup>(3)</sup> Research of Ariningtyas (2017) state that the implementation of PPIA in maternal and child health services can reduce mortality rates in HIV mothers. The Independent Practice Midwife Service is one of the maternal and child health services in Indonesia.<sup>(4)</sup>

The proportion of HIV/AIDS transmission from mother to baby during the transmission period of pregnancy of 5-10%, the birth delivery of 10-20% and the breastfeeding of 10-15% needs to be anticipated early. One of the efforts to reduce maternal and infant mortality is through an integrated antenatal care (ANC) service program. Integrated ANC services are quality antenatal services provided to all pregnant women in a comprehensive and integrated manner, including promotive, preventive and curative and rehabilitative efforts.<sup>(5)</sup> Clinical review results show that the use of antiretroviral drugs (ARVs) can effectively prevent transmission of HIV from mothers to babies.<sup>(6)</sup>

**Materials and Method**

This study is analytic observational with a cross-sectional design. The research subjects were pregnant women in Sleman Health Centers. The research samples were 104 people with a purposive sampling sampling technique. The research tools were questionnaires. The data analysis was done with univariate and bivariate.

**Result**

The characteristics of the respondents were mostly mothers aged 20-35 years amounted to 89 people (85.6%). Maternal pregnancy is all in the third trimester with 104 people (100.0%), frequency of pregnancy checks > 4 times amounted to 97 (93.3%) and ANC places in health facilities as many as 104 (100.0%) including ANC in Health centers with 58 (55.76%),

ANC in RB of 12 (11.53%), in Midwives for about 24 (23.07%), in the Hospital for about 10 (9.61%).

Status of ANC services for pregnant women with a good category of 90 people (86.5%) and 14 respondents (13.5%) in the bad category. PPIA examination for about 99 respondents (95.2%) of the “did” category and 5 respondents (4.8%) categories of the “did not do”.

There is a relationship between integrated Antenatal Care (ANC) services and Mother to Child Transmission Prevention (PPIA) checks on Pregnant Women in Sleman 2018 Health Center (p=0.001; RP=25.714; CI=3.094-213.742).

## Discussion

### **Integrated Antenatal Care (ANC) Services for Pregnant Women in Sleman Health Centers in 2018:**

The results showed that 90 people (86.5%) pregnant women assessed the quality of integrated Antenatal Care (ANC) services in Sleman Public Health Centers were in good categories.

The actual condition of the integrated Antenatal Care (ANC) service for pregnant women in 2018 has been carried out in Sleman Public Health Centers, namely since the issuance of regulations from the Health Office in the form of 2017 Circular No. 444/9332 on Integrated ANC Services (10T) for pregnant women. Sleman Health Center has provided integrated ANC services to all pregnant women in Sleman Health Center area.

The results of the study are in accordance with the research that shows that the implementation of ANC service standards at Bahu health center according to the category shows that the majority of ANC services in shoulder health centers are in accordance with midwifery service standards compared to services that do not meet midwifery service standards. ANC was good (82.6%) from respondents.

Antenatal services are health services by professionals for mothers during pregnancy, which are carried out in accordance with established standards of antenatal care.<sup>(4)</sup> Quality of service is very close to its relationship to implementation.

The standardized approach of ANC care at Public Health Centers in Sleman is to produce healthy mothers and infants at the end of pregnancy by 1) preventing and handling intercurrent morbidity, 1) hypertension during pregnancy, anemia, malaria, tetanus, sexually

transmitted diseases and 2) detect mothers who have a high risk of complications during childbirth.<sup>(5)</sup>

Based on the results of previous research and the theory, it can be concluded that Antenatal Care (ANC) services for pregnant women in Sleman health centers are in a good category. The application of good service standards in the integrated Antenatal Care (ANC) service at the Sleman Public Health Centers is very useful to protect the community because the process of activities carried out has a clear basis and is able to detect early problems and diseases experienced by pregnant women.

### **Prevention of Mother-to-Child Transmission Prevention (PPIA) for Pregnant Women in Sleman Health Centers in 2018:**

The results showed that 99 people (95.2%) of Pregnant Women conducted a Mother to Child Transmission Prevention (PPIA) Examination in Sleman Health Center 2018. The results of this study supported the PPIA activity component in prong 3 namely prevention of HIV transmission from pregnant women with HIV to the baby they contain.

These results are in accordance with the research that shows that the majority of respondents conducted PITC examinations amounting to 71 respondents (98.6%).<sup>(7)</sup> Other studies in accordance with this study state that mothers who have readiness in carrying out HIV/AIDS tests are mothers who have secondary and high education that influence respondents' knowledge about HIV/AIDS itself.<sup>(8)</sup> The main goal is for babies born to mothers with HIV to be free from HIV, and mothers and babies to stay alive and healthy. PPIA general policy is in line with the national program policies for controlling HIV-AIDS and other STIs, as well as KIA program policies.<sup>(9)</sup>

Knowledge of someone will be the basis of all actions taken. Meanwhile, pregnant women who are

not willing to take part in PPIA and VCT services are mostly due to the negative stigma that exists in the community. With this stigma, people will be reluctant to carry out checks due to shame and fear if known by others.<sup>(10)</sup> Based on the results of previous research and the theory, it can be concluded that 99 people (95.2%) Pregnant women carry out Mother-to-Child Prevention of Transmission Examination (PPIA) at Sleman Health Centers in 2018. Mother's willingness to carry out Preventive Examination from Mother to Child (PPIA) on Pregnant Women in Sleman Public Health Center voluntarily is one form of participation and mothers have knowledge about HIV/AIDS prevention and good behavior.

**The relationship between the integrated Antenatal Care (ANC) service and the Prevention of Transmission from Mother to Child (PPIA) for Pregnant Women in Sleman Health Center:** The results of the study showed a significant value of 0.001 ( $p < 0.05$ ), it can be seen that there is a relationship between integrated Antenatal Care (ANC) services and Mother to Child Transmission Prevention (PPIA) checks on Pregnant Women in Sleman 2018 Health Center, Risk Prevalence 25,714 ( $> 1$ ) and the value of CI between 3,094 and 213,742 so that it does not exceed the number one, meaning that the variable is a risk factor. In this study, it was also found the upper and lower limits in the lower and upper 95% CI too far, this is because the table in the questionnaire answer where the ANC service is 100% is served in health facilities.

The actual condition of integrated Antenatal Care (ANC) services with Prevention of Mother-to-Child Transmission (PPIA) for Pregnant Women in Public Health Center in Sleman in 2018 has a very close relationship, because through this integrated ANC service, pregnant women are given education through speech/counseling about HIV disease, the causes and ways of prevention, so that pregnant women are encouraged to carry out the Prevention of Transmission Examination from Mother to Child (PPIA).

The study was in accordance with a study conducted in Kenya which stated that there was a relationship between integrated ANC services for HIV prevention. The full integration of HIV care into antenatal clinics can significantly increase overall satisfaction with care for mothers in HIV prevention.<sup>(11)</sup>

The results of other studies that are in accordance with this study indicate that there is a significant relationship

of service based on the number of ANC visits ( $p = 0.000$ ) with the participation of pregnant women in HIV testing, where the more number of pregnancy checkup visits, pregnant women tend to take an HIV test Transmission from Mother to Child (PPIA), but also participation in Preventive Examination from Mother to Child (PPIA) is not only influenced by antenatal care services but also other factors such as support by health personnel.<sup>(12)</sup>

Legiati., Et al (2012) said that the knowledge of pregnant women is influenced by the support or role of health workers. Pregnant women who have good knowledge are more likely to take an HIV test compared to pregnant women who have less knowledge.<sup>(13)</sup>

PPIA services have goals, objectives and approaches that are much in common with efforts to prevent congenital syphilis, therefore these two efforts are integrated.<sup>(7)</sup> The success of efforts to prevent HIV transmission from mother to baby is very dependent on various parties, so it does not only affect the active role of health personnel and services in providing education and information about HIV to mothers and their families, but can be done in various ways.

Efforts to successfully prevent HIV transmission can be done by increasing the role of Midwives and Private Practitioners to implement the PPIA program so that it can reach all regions, especially areas far from health centers. This is done in order to increase the knowledge and understanding of the community, especially pregnant women including the family related information about HIV AIDS and the importance of HIV testing.<sup>(14)</sup>

Based on the results of previous research and theory, it can be concluded that there is a relationship between the integrated Antenatal Care (ANC) service and the Prevention of Transmission from Mother to Child (PPIA) in Pregnant Women in Sleman Health Center. This is in line with the results of the study by Setiyawati & Meilani (2014) which showed that the initiation of health care providers or PITC (Provider Initiated Testing and Counseling) in health centers statistically showed a relationship with the behavior of pregnant women in HIV testing. The initiation of a health care provider to take an HIV test has the opportunity to take an HIV test of 21.6 times greater than that of a pregnant woman who does not receive an initiation from a health care provider.<sup>(15)</sup>

The same thing was stated by other researchers who said that by offering mothers for HIV counseling and

testing at the time the mother did ANC, the participation of mothers for counseling and testing was 1.3 times higher (95% CI = 17.3-22.0) compared to mothers not offered HIV counseling and testing.<sup>(16)</sup>

### Conclusion

There is a relationship between the integrated Antenatal Care (ANC) service and the Prevention of Transmission from Mother to Child (PPIA) for Pregnant Women in Sleman Health Center.

**Acknowledgements:** We have the research use personally sourced funding.

**Conflict of Interest:** We declare that there is no conflict of interest.

**Ethical Approval:** The data collected will not be used for at her purposes than this research. This study was discussed by the Ethics Committee of Ahmad Dahlan University, Yogyakarta, Indonesia.

# Correlation of Maternal Education with Parenting and Child Nutritional Status

Sukmawati<sup>1,2</sup>, Bambang Wirjatmadi<sup>3</sup>, Merryana Adriani<sup>3</sup>, Shrimarti Rukmini Devy<sup>4</sup>, Sirajuddin<sup>2</sup>

<sup>1</sup>Doctoral Candidate of Health Sciences, Faculty of Public Health, Airlangga University, Indonesia, <sup>2</sup>Departement of Nutrition, Makassar of Health Polytechnic, Indonesia, <sup>3</sup>Departement of Nutrition, Faculty of Public Health, Airlangga University, Indonesia, <sup>4</sup>Departement of Health Promotion, Faculty of Public Health, Airlangga University, Indonesia

## Abstract

Education levels is the key to childcare. The objective of this study were to analyze the correlation of maternal education by care and nutritional status of children in Maros District in Indonesia.

**Settings and Design:** The sample were under five years old and selected by simple random sampling. Sample size were 156. The design is a cross sectional study. Data analysis by spearman correlation test at 95% confidence level

**Method and Material:** Child weight was measured by electronic SECA scale. Anthropometric data collected in Infants (0–11 mo of age). Three indexes were derived from anthropometric measures, including weight-for-age z score (WHA), length-for-age z score (HAZ), and weight-for-length zscore (WHA). This research was registered with the ethics commission of the Makassar Health Polytechnic.

**Statistical Analysis Used:** The data analyze were used to SPSS 16. Correlations between parenting style and z scores anthropometric were tested by Spearmen correlation at 95% confidence intervals.

**Results:** The Distribution of nutritional status based on WAZ, HAZ and WHZ indexes were normal (within in the basic education level) 67,1%, 53,2% and 74,5% respectively. The nutritional status based on WAZ, HAZ and WHZ indexes were normal (within the continue education level) in 75,7%, 61,4%, and 77,1% respectively. Statistical analysis that education levels were correlated with parenting in the basic educations level group ( $p=0,043$ ).

**Conclusions:** In the group of basic educated mothers, it is known that there is a correlation between the nutritional status of children according to the WAZ index.

**Keywords:** *Education, Parenting and Nutritional Status of Toddlers.*

## Introduction

The increase in the percentage of Stunting in South Sulawesi is that it continued between 2007, 2010 and

2013 which were 29.2%, 39.8% and 40.9% respectively. This percentage is a combination of children under five who are short and short status based on indicators of height for age (HAZ) from the WHO Anthropometric reference. Various factors that affect of stunting. The both the intake and infectious diseases are direct factors. Prevention of stunting is important by overcoming indirect factors, namely parenting. Parenting is intended to care for feeding, child care, seeking treatment and child hygiene care.<sup>1,2,3</sup>

Maternal education tends to have quality care for child feeding, because the reasoning is to work outside in the home. The habit of mothers working outside in the home is entrusting children to caregivers who are also from close families or helpers who are specifically employed.<sup>4-6</sup>

The burden of the mother working outside the home seems to be a factor that correlates with the quality of child feeding care. The length of the mother’s work outside the home, especially during the critical period of growth is an aspect that deserves to be studied. Various underlying reasons include, for ethnic Bugis, whatever type of work the mother still has, she has a total role in responding to childcare.<sup>7,8</sup> Mother’s work should not neglect the care of child feeding, but at the same time sufficient skills and knowledge are needed to carry out parenting roles appropriately and efficiently. If this role is able to be carried out then the suspicion while children will not risk being short. This is what will be tested in this study.

The purpose of this study was to analyze the correlation of maternal education by care and nutritional status of children.

### Subjects and Method

The cross sectional study was conducted in Maros Regency, South Sulawesi, Indonesia, with a sample of

156 people using the random sampling method. Sample size is calculated based on proportional sample formulas.

Data were collected by trained enumerators on interview techniques and anthropometric measurements in April 2018. Questionnaires in this study had gone through trials with good validity and reliability. Question list consists of three parts. Child care patterns were divided into three parts, namely feeding, care, hygiene and medical care and were assessed based on parenting scores. Nutritional status is measured based on anthropometric data of the child’s height and weight. The indicators studied were, weight for age Z scores (WAZ), height for age Z scores (HAZ), weight for height Z scores (WHZ) The measurement uses 0.01 kg accuracy and 0.01 cm. Nutritional status for children for: Underweight: weight for age z scores < -2 standard deviations (SD) of the WHO Child Growth Standards median. Stunting: height for age (HAZ) < -2 SD of the WHO Child Growth Standards median. Wasting: weight for height Z scores (WHZ) < -2 SD of the WHO Child Growth Standards median. Overweight: weight for height Z scores > +2 SD of the WHO Child Growth Standards median. Processing data using SPSS version 16.0 from SPSS Inc. Descriptive data analysis with frequency, proportion, and median distribution. Test statistics with the spearman correlation test at 95% confidence. This study was approved by the Makassar Health Polytechnic Ethics Commission.

### Results:

The results of this study were presented in the following tables:

**Table 1. Distribution of toddlers ‘nutritional status based on parents’ education level**

Index (WAZ)										
Educational Level	Overweight		Normal		Underweight		Severely Underweight		Total	
	n	%	n	%	n	%	N	%	n	%
Basic (N=79)	2	2.5	53	67.1	18	22.8	6	7.6	79	100
Continue (N=70)	0	0.0	53	75.7	11	15.7	6	8.6	70	100
Index (HAZ)										
Educational Level	Hight		Normal		Stunting		Severely Stunting		Total	
	n	%	n	%	n	%	N	%	n	%
Basic (N=79)	2	2.5	42	53.2	28	35.4	7	8.9	79	100
Continue (N=70)	0	0.0	43	61.4	19	27.1	8	11.4	70	100
Index (WHZ)										
Educational Level	Obesity		Normal		Wasting		Severely Wasting		Total	
	n	%	n	%	n	%	n	%	n	%
Basic (N=79)	3	3.8	59	74.7	13	16.5	4	5.1	79	100
Continue (N=70)	3	4.3	54	77.1	12	17.1	1	1.4	70	100

The focus of the spotlight in this table is the percentage of malnutrition and malnutrition in both education, basic education and advanced education groups. The percentage of malnutrition + malnutrition in primary education is 30.4% while in advanced education it is 24.5%.

**Table 2. Distribution of toddler protein energy intake based on parental education level**

Intake Energy												
Energy	Severely Deficit		Heavy Deficit		Light Deficit		Normal		Over		Total	
	n	%	n	%	n	%	n	%	n	%	n	%
Basic (N=79)	47	59.5	7	8.9	2	2.5	13	16.5	10	12.7	79	100
Continue (N=70)	25	35.7	4	5.7	8	11.4	15	21.4	18	25.7	70	100
Intake Protein												
Protein	Severely		Heavy Deficit		Light Deficit		Normal		Over		Total	
	n	%	n	%	n	%	n	%	n	%	n	%
Basic (N=79)	26	32.9	3	3.8	7	8.9	13	16.5	30	38.0	79	100
Continue (N=70)	9	12.9	6	8.6	6	8.6	9	12.9	40	57.1	70	100

Table 2 presents data on energy and protein intake at both levels of basic education and advanced education. Energy very deficit in basic education reached 59.5% while in advanced education it reached 35.7%.

**Table 3. An overview of parenting, knowledge and practice of breastfeeding, in infants under the age of parents**

Parenting	Excellent		Good		Total	
	N	%	n	%	n	%
Basic (N=79)	34	43.0	45	57.0	79	100
Continue (N=70)	24	34.3	46	65.7	70	100
Knowledge of breastfeeding	Excellent		Good		Total	
	N	%	n	%	n	%
Basic (N=79)	15	19.0	64	81.0	79	100
Continue (N=70)	24	34.3	46	65.7	70	100
Breastfeeding Practice	Excellent		Good		Total	
	N	%	n	%	n	%
Basic (N=79)	29	36.7	50	63.3	79	100
Continue (N=70)	19.0	27.1	51	72.9	70	100

Table 3 presents data on parenting, knowledge and practice of breastfeeding for children for both the basic education and further education groups. Good parenting in basic education is 43% while in advanced education it is 34.3%.

**Table 4. Relationship between parenting, knowledge and practice of breastfeeding, with index Body Weight for Age (WAZ) toddlers based on the level of education of parents**

Educational Levels	Value Median		Median WAZ	p-value
Basic	Parenting	66.7	-1.7	0.043 (-0.228)
	Knowledge	54.5		0.475
	Practices	50.0		0.908
Continue	Parenting	66.7	-1.465	0.417
	Knowledge	54.5		0.414
	Practices	40.0		0.122

The results of statistical analysis of the correlation of basic education with parenting, knowledge, and practice of breastfeeding, based on the nutritional status (WAZ) in the basic education group found a negative correlation for parenting ( $p = 0.043$ ) but no correlation with knowledge and practice ( $p > 0.05$ ).

**Table 5. Relationship between parenting, knowledge and practice of breastfeeding, by Height for Age (HAZ) index of toddlers based on the level of education of parents**

Educational Levels	Value Median		Median HAZ	p-value
Basic	Parenting	66.7	-1.7	0.3
	Knowledge	54.5		0.057 (0.215)
	Practice	50.0		0.306
Continue	Parenting	66.7	-1.6	0.026 (-0.267)
	Knowledge	54.5		0.483
	Practice	40.0		0.277

The results of statistical analysis of the correlation of basic education with parenting, knowledge, and practice of breastfeeding, based on nutritional status (HAZ) were in further education found a negative correlation for parenting ( $p = 0.026$ ) but there was no correlation with knowledge and practice ( $p > 0.05$ ) specifically for further education groups

**Table 6. Relationship between parenting, knowledge and practice of breastfeeding, with WHZ index of infants based on the level of education of parents**

Educational Level	Median		Median WHZ	p-value
Basic	Parenting	66.7	-1.1	0.091
	Knowledge	54.5		0.120
	Practices	50.0		0.293
Continue	Parenting	66.7	-1.0	0.857
	Knowledge	54.5		0.657
	Practices	40.0		0.693

The results of the statistical analysis of the correlation of basic education with parenting, knowledge, and practice of breastfeeding, based on the nutritional status (WHZ) in basic education, found no positive correlation to parenting ( $p = 0.091$ ), knowledge ( $p = 0.120$ ) and breastfeeding practice ( $p = 0.293$ ).

### Discussion

Maternal education is directly related to parenting style feeding, care, treatment and personal hygiene.<sup>1</sup> Mothers were known as the main caregivers of children for the composition of roles in Indonesian society in general. Indonesian people, especially urban areas, have applied the concept of gender equality in households. Based on this view, this time the discussion highlighted the point of view of basic education and continue education as the main domain. The main domain to find the point of difference in effects based on nutritional status in all three indexes WAZ, HAZ and WHZ.

This study were found the percentage of malnourished children and combined malnutrition were both basic education group than in continue education group. These results provide shown that children’s opportunities for malnutrition were greater in children whose parents (mothers) have basic education. The parental education is an investment in improving sustainable nutrition in rural communities based on nutritional status at WAZ.<sup>8</sup>

Correlation analysis between parenting and nutritional status of children according to WAZ indicators were significant ( $p = 0.043$ ). This fact that for mothers who have basic education, namely education up to a maximum of 9 years, the actual body weight of a child is influenced by the mother’s education. Especially for basic education in Indonesia, it is divided into two groups, namely the age group of 6-12 years, and the age group 13-16 years, with a duration of 9 years of education. If the mother is only able to complete

education in a group of 6-12 years, then she has the opportunity to work outside the house is limited. If the mother has an education group of 13-16 years, then the opportunity to work outside the home is greater, even if only as an operator worker at small industries. This social phenomenon has an impact on the pattern of mother's care for their children. The value of parenting patterns will be better at a lower level than the higher ones, which is why in this study negative correlation values were found. Whereas specifically parenting knowledge and practice remains a positive and insignificant correlation.

The phenomenon of parenting in the basic education group is different from the continue education group in this study. In the continue education group a positive correlation was found in parenting with BBU nutritional status. The higher the mother's education, the better the parenting style for her child. The upbringing pattern for the mother is further educated, even though she works outside the home but is good, because her education causes her to be able to provide better child care costs, so that the quality and quantity of nutrition is better.

The results found in the above data are consistent with the HAZ indicator. It was found that the percentage of children who were short was higher in the group of children from mothers who had basic education compared to advanced education. Various research reports report that educational factors are strong variables that influence the child's height status. Height is even a good predictor for children's social future. The reported academic potential and economic potential are positively correlated with the education status of both parents. In various countries with low literacy in nutrition science theoretically they will also have low nutritional status. The concept of education as an investment in improving nutrition is found to be positively correlated.<sup>9</sup> Other research has been found that has a strong influence on community nutrition improvement strategies, measurable prevention focus.<sup>10-12</sup>

The next fact that is different based on the WHZ index, it is also found that children whose mothers were only basic education have a higher percentage of children who are thin and very thin compared to children from the advanced education group. The three differences above seem to be very strong reasons that educational factors should be analyzed further towards nutritional status.

Before discussing that, it was also found that the energy and protein intake (Table 2) in the two groups

also tended to be different. This difference can be seen from the percentage of energy deficit children in the group of children from basic educated mothers compared to advanced education. This proves that there are direct factors that cause children different nutritional status in both groups, namely energy and protein intake which is also lower in basic education than education.

# The Correlation Between Social Support and Mental Health among Mothers of Children with Autism Spectrum Disorder

Susi Rosida Simanjutak<sup>1</sup>, Sri Hartini<sup>2</sup>

<sup>1</sup>Student of Magister of Nursing, <sup>2</sup>Department of Nursing, Faculty of Medicine, Public Health, and Nursing, Universitas Gadjah Mada, Yogyakarta, Indonesia

## Abstract

**Background:** The challenges faced by mothers during caring for children with ASD are a risk factor for maternal mental health problems. One effort to maintain the mental health of the mothers who have children with ASD is to ensure the availability of social support.

**Aim:** The aim of this study is to determine the correlation between social support and mental health among mothers of children with ASD.

**Method:** This was a descriptive study with a cross-sectional approach. Eighty (80) mothers of children with ASD were selected as the respondents in this study using purposive sampling method. Bantul and Kulon Progo Regencies were chosen as the research locations. The Multidimensional Scale of Perceived Social Support (MSPSS) and General Health Questionnaire-12 (GHQ-12) were used to measure the social support and maternal mental health. The Spearman test was used to see the correlation between social support and maternal mental health problems.

**Results:** The results show that social support and maternal mental health problems have a significant correlation ( $p=0.03$ ;  $r=-0.23$ ). The univariate test shows that 44% of mothers of children with ASD indicate psychological disorders.

**Conclusion:** There is a correlation between social support and mental health among mothers of children with ASD.

**Keywords:** *Autism Spectrum Disorders (ASD), social support, mental health problems.*

## Introduction

Children with Autism Spectrum Disorder (ASD) have higher behavioral problems than other children. The behavioral problems are hyperactiveness, emotional symptoms, and problems with conduct.<sup>1</sup> A previous research shows that parents of children with ASD

experience higher levels of stress than those of children with other disabilities. This is caused by the unique challenges of caring for children with ASD, who show unpredictable behavior, no interest in an affectional bond, and indifferent attitudes.<sup>2</sup> Meanwhile, caring for children with ASD is a form of long-term commitment that requires responsibility and readiness in facing challenges that increase along with the increasing age of the children.<sup>3</sup>

e-mail: srihartini.psik@ugm.ac.id

Challenges faced by mothers in parenting children with ASD can lead to maternal mental health problems. Mothers of children with ASD have a greater risk of having mental health problems than those of children without a diagnosis of ASD.<sup>4</sup> Estes & Munson (2009) reported that mothers of children with ASD show a

higher parenting stress level than those with children having problems of developmental delay without ASD.<sup>5</sup> Totsika et al. (2011) added that behavioral problems among ASD children are associated with the increasing emotional problems of their mothers.<sup>1</sup> Research by Jose et al., (2017) reported that 76.8% of mothers of children with ASD were depressed, and as many as 60% of them had mild to moderate levels of depression.<sup>6</sup>

JX et al. (2017) stated that the lack of social support for parents of children with ASD will result in mental health problems.<sup>7</sup> Social support is the availability of social networks providing psychological and material resources that can increase an individual's ability to deal with stress (Cohen, 2004).<sup>8</sup> Psychological problems are found to be higher in caregivers of children with disabilities with low social support as stated by Yamaoka et al. (2015).<sup>9</sup>

Based on the statistics of special schools (SLB) issued by the Ministry of Education and Culture (2016), Bantul Regency is one of the districts in Yogyakarta with a large number of children with ASD.<sup>10</sup> Meanwhile, Kulon Progo Regency has an Autism Center (PLA) as one of the therapy centers for children with ASD in the Special Province of Yogyakarta (DIY). The purpose of this study is to determine the correlation between social support and the mental health of mothers who have children with ASD.

## Material and Method

**Research Design and Sample:** This research was a cross-sectional study. It was conducted at Special Schools in Bantul Regency and Autism Center in Kulon Progo in July-September 2018. Eighty mothers of ASD children were selected using purposive sampling method to be the respondents in this study. The inclusion criteria in this study were: (1) mothers of children with ASD (The diagnosis was performed by a pediatrician or clinical psychologist of child development), (2) mothers who lived with a child with ASD and had the main parenting role to help meet the child's primary needs for the past 1 year, and (3) mothers who were willing to become respondents. The exclusion criteria in this study were: (1) mothers of children with ASD accompanied with other disabilities, such as intellectual disabilities, blindness, speechlessness, and deafness, (2) mothers of children with ASD who had a deceased family member in the past month, and (3) mothers who had other children with disabilities.

**Research Instruments:** The Multidimensional Scale of Perceived Social Support (MSPSS) and General Health Questionnaire-12 (GHQ-12) were used to measure social support received by mothers of children with ASD and mental health of mothers of children with ASD. MSPSS was developed by Zimet (1988) containing sources of social support received by mothers in 6 scales.<sup>11</sup> Sources of social support come from family, friends, and someone special when needed. Trifilia (2013) has modified the MSPSS into 4 scales, namely (1) strongly disagree, (2) disagree, (3) agree, (4) strongly agree.<sup>12</sup> The validity and reliability test of the 4 scale of the MSPSS is in the range 0.266-0.617, and the reliability coefficient value is 0.832.<sup>13</sup>

The General Health Questionnaire (GHQ-12) was used to measure the maternal mental health. This instrument was first developed by Goldberg (1970) which consisted of 60 questions.<sup>13</sup> In its development, this questionnaire has been modified several times, namely, version 30, 28, and 12. The GHQ-12 questionnaire focuses on two domains, namely psychological distress and social dysfunction. The mental health questionnaire used in this study was the GHQ-12 questionnaire that had been adapted by Primasari and Hidayat (2016).<sup>14</sup> This questionnaire used Likert scale ranging from 0 (better than usual) to 3 (extremely worse than usual) so that the total scores for this questionnaire were in the range 0-36. The higher the scores, the higher the mental health problems experienced by the mothers. The construct validity test of the GHQ-12 shows that all items in this questionnaire are valid. The results of the reliability test using Cronbach Alpha were in the range 0.670-0.776 with a sensitivity value of 67.80 and a specificity value of 74.75.

**Ethical Considerations:** This research has met the requirements of ethical eligibility from the Ethics Commission of the Faculty of Medicine, Public Health and Nursing (FK-KMK) of UGM (ethic number: KE/FK/0571/EC/2018).

**Data Analysis:** A descriptive statistical analysis was used to determine the description and classification of social support and mental health of the mothers. The social support was classified into 2 categories, namely high social support (36.46) and low social support (<36.46). Furthermore, the maternal mental health problems were grouped into 2 categories, namely without psychological disorders (<10) and with psychological disorders (10). Since the data were not normally distributed ( $p < 0.05$ ),

the Spearman test was used to find out the correlation between the social support and maternal mental health problems.

**Finding:**

**1. The Demographic Characteristics of the Respondents:** The respondents in this study are mothers of children with ASD at SLBs and PLA in Bantul and Kulon Progo Regency. The basic characteristics of the subjects of the research are descriptively presented in Table 1.

**Table 1. Characteristic of Mother of ASD Children (n=80)**

Characteristic	f (%)	Mean±SD
<b>Mothers</b>		
<b>Educational background</b>		
Low	60(75)	
High	20(25)	
<b>Mother's Income</b>		
Low	36(45)	
Adequate	44(55)	
<b>Mother's occupation</b>		
Housewife	52(65)	
Working	28	
Mother's age		40.41±8.14
<b>Marriage Status</b>		
Married and lived together	75(93,75)	
Married and Lived Separately	1(1,25)	
Single parent	4(5)	

Most mothers of children with ASD are married and have a high school diploma. The results show that the

ratio of male and female children with ASD is 1 to 3.70 (table 2).

**Table 2. Characteristic of Children with (n=80)**

Child's Characteristic	f (%)	Mean±SD
<b>Sex</b>		
Male	63(79)	
Female	17(21)	
<b>Children's age (3 – 23 years)</b>		11.35±5.01
<b>Therapy history</b>		
Yes	72(90)	
No	8(10)	

**2. The Social Support and Mental Health:** Most mothers have received high social support, and 44% of mothers have been indicated to have psychological disorders (table 3).

**Table 3. Social Support and Mental Health in Mothers of ASD Children (n=80)**

Variable	f (%)
<b>Social Support</b>	
High	60(75)
Low	20(25)
<b>Mental Health</b>	
Without psychological disorder	45(56)
With psychological disorder	35(44)

The description of mental health shows that 47.5%, 43.8%, and 41.3% of mothers of children with ASD feel extremely bad in terms of feeling useless, unhappy, depressed, and unconfident (table 4).

**Table 4. Mental Health of Mother's of ASD (n=80)**

No	Mental Health	Better than Usual	Same than Usual	Less than Usual	Much less than usual
		f(%)	f(%)	f(%)	f(%)
1	Able to concentrate	16(20)	53(66,30)	10(12,50)	1(1,30)
2	Loss much sleep	1(1,30)	15(18,80)	42(52,50)	22(27,50)
3	Playing useful part	30(37,50)	47(58,80)	2(2,50)	1(1,30)
4	Capable of making decision	21(26,30)	52(65)	5(6,30)	1(1,30)
5	Under stress	1(1,30)	9(11,3)	42(52,50)	28(35)
6	Could not overcome difficulties	1(1,30)	8(10)	41(51,30)	30(37,50)
7	Enjoy normal activities	28(35)	46(57,50)	5(6,30)	1(1,30)
8	Face up to problems	22(27,50)	53(66,30)	4(5)	1(1,30)
9	Feeling unhappy and depressed		4(5)	41(51,30)	35(43,80)
10	Losing confidence	2(2,60)	4(5)	41(51,30)	33(41,30)
11	Thinking of self as worthless	2(2,60)	8(10)	32(40)	38(47,50)
12	Feeling reasonably happy	36(45)	42(52,50)	2(2,50)	

**3. The Correlation between Social Support and Mental Health Problems:** The results show that there is a significant correlation between social support and mental health of mothers of children with ASD ( $p=0.03$ ;  $r=-0.23$ ). The results show a negative correlation and this show that the higher the social support received by mothers, the lower the mental health problems of the mothers.

### Discussion

In this study, the majority of the respondents are married couples and stay at the same house. This condition provides the availability of social support from someone special in life, family, and friends. The availability of social support is one factor that contributes to adaptability.<sup>15</sup> On the contrary, a research with different social support instruments conducted by Obeid and Daou (2015) shows that the perception of mothers of children with ASD on the social support is lower than those of children without developmental problems.<sup>16</sup> Costa et al., (2017) also said that parents of children with ASD have worse mental health than those of children without developmental problems.<sup>17</sup>

Behavioral problems among children with ASD will affect the mental health and the ability of parents to overcome those difficulties.<sup>18</sup> Mental health is important for the individual's development and adaptation processes.<sup>8</sup> Regarding mental health among mothers of children with ASD, the majority of the respondents in this study have no indication of psychological disorders. These results are consonant with a previous study by Zablotsky et al., (2013).<sup>4</sup> They reported that the majority of mothers of children with ASD had good mental health. Vasilopoulou and Nisbet (2016) explained that mental health problems were not found among parents of children with ASD.<sup>19</sup> This is because the increasing spiritual values among parents of children with ASD have helped parents overcome their emotional stress in parenting children with ASD. Different results were found in a study by Jose et al., (2016).<sup>6</sup> The findings showed that 76.8% of mothers of children with ASD were depressed. Costa et al., (2017) also said that parents of children with ASD had worse mental health than those of children without developmental problems.<sup>19</sup> This might be because of the big difference in the size of samples used in the study. Meanwhile, another study with different respondents has found that almost half of the caregivers of children with disabilities have mental health problems.<sup>9</sup>

The analysis show that clinically, there is a significant difference between social support in the group of those with no indication of psychological disorders with that found in the group of those with the indication of psychological disorders. Social support from spouses, families, and close friends for mothers of children with ASD may play a role in maintaining the mental health of mothers of children with ASD. Social support obtained from the environment has a role in maintaining the mental health of mothers of children with ASD.<sup>4</sup> The social support received helps mothers of children with ASD focus on positive aspects, not solely on the difficulties faced while parenting.<sup>20</sup>

Another previous research has explained that social support from families is associated with the increasing optimism, positive feelings, satisfaction with life, and mental health among mothers of children with ASD.<sup>21</sup> Meanwhile, Hsiao (2016) explained that the more social support from neighbors obtained by parents of children with ASD, the better the mental health of parents of children with ASD.<sup>22</sup> A similar research from Zalbotsky et al., (2013) also shows that mothers of children with ASD who have poor mental health are those who lack the sources of emotional and social support from the environment.<sup>4</sup>

Similar results with different respondents have also been found in a study by Yamaoka et al. (2015).<sup>9</sup> The results show that caregivers of children with disabilities who have mental health problems are those lacking the sources of social support. Johnson et al., (2011) reported that parents of children with ASD thought that it was not the behavioral problems of children with ASD that mainly affected their mental health but personal and family problems.<sup>23</sup> Different results have been found in a study by Obeid and Daou (2015). The results show that social support is not correlated with mental health of mothers of children with ASD. This may be influenced by the different number of samples and different social support questionnaires used. Therefore, the availability of social support for mothers of children with ASD is one of the factors that needs to be considered in maintaining and caring for the mental health of mothers of children with ASD.

### Conclusion

Social support in the form of social emotional support received by mothers of children with ASD show a correlation with their mental health condition. This

research encourages health workers to concern with the provision of social support to optimize the mental health of mothers of children with ASD.

**Conflict of Interest:** The authors declared no potential conflict of interest with respect to the research, authorship of this article.

**Acknowledgements:** We were grateful to Universitas Gadjah Mada for supporting funding. We would also like deeply thank to mothers of ASD children for their participating.

# **An Evaluation of Epidemiological Surveillance of Transport Equipment for A Prevention Strategy of Quarantinable Diseases and Pandemic Potential Diseases in the Health Office of First Class Port of Surabaya in the Working Area of Tanjung Perak Port of 2018**

**Syahrial Setia Perdana<sup>1</sup>, Chatarina Umbul<sup>1</sup>**

*<sup>1</sup>Department of Epidemiology, Faculty of Public Health, Universitas Airlangga, Surabaya, East Java, Indonesia*

## **Abstract**

The Epidemiology Surveillance Section has the responsibility for planning, monitoring, evaluating, compiling reports, and coordinating the implementation of epidemiological surveillance of diseases, pandemic potential diseases, new emerging diseases, and re-emerging diseases. One of its programs is Transport Equipment Surveillance. This study is an evaluative descriptive research, conducted in the Port Health Office I of Surabaya in Tanjung Perak Port, Surabaya. This study used total population sampling, with the population of 5 officers of the transport equipment surveillance program. The problem identification of the input found four problems, namely officer compliance in using protective equipment, limited number of officers for local vessels inspection, no printed media for PPE use promotion, the absence of Quarantine Speed Boat facilities for middle sea boarding, and the lack of health communication effort and health promotion media. The top priority problem found in Epidemiological Surveillance of Transport Equipment was the compliance of officers in using Personal Protective Equipment (PPE) and the limited number of officers for local vessels inspection. The analysis result found that the problem were the absence of media, promoting the use of PPE in accordance with Law No. 1 of 1970 and the inconsistency of recruitment policies towards the Minister of Health Decree No. 1116 of 2003. The suggested alternative solutions were supervision and procurement of poster media which promote the use of PPE and opening recruitment for temporary workers to become technical personnel for local vessels inspection.

**Keywords:** *Epidemiological surveillance, transport equipment, prevention, quarantinable diseases, pandemic potential diseases.*

## **Introduction**

The Port Health Office (PHO) is a technical implementation unit within the Ministry of Health that is under and is responsible to the Director General of

Disease Control and Environmental Health. PHO is responsible for preventing and inhibiting the diseases to and from overseas, preventing the potential outbreaks, epidemiological surveillance, quarantine, controlling the impact of environmental health, health services and securing new emerging diseases and re-emerging diseases. One of Divisions in the Port Health Office I of Perak Surabaya is the QCES (Quarantine Control and Epidemiological Surveillance)<sup>(5)</sup>. Under this division is the Epidemiology Surveillance Section, which is responsible for planning, monitoring, evaluating, compiling reports, and coordinating the implementation of epidemiological surveillance of diseases, pandemic potential diseases, new emerging diseases and re-

emerging diseases, and maintaining national and international epidemiological surveillance networks. It is responsible for alertness, assessment, advocacy, and outbreaks management, and disasters and post-disaster management in the health sector with one of its work programs called Transport Equipment Surveillance.

Sanitation in this case is related to the prevention of quarantine diseases and pandemic potential diseases in the PHO. Vessel sanitation is applied to all types of vessels, vessels originating from within and outside the country, and all ship passengers.

Vessels sanitation inspection is intended to certify the vessel health. A sanitation certificate will be issued after the inspection. This certificate is used to obtain Sailing Health Permit (SHP). Two different certificates will be issued after the certification process based on the level of the risk each vessel poses. An SSCC (Ship Sanitation Control Certificate) will be issued for vessels with the inspection result of high risk and an SSCEC (Ship Sanitation Exemption Control Certificate) will be issued for ones with low risk. The examination process is carried out within six months (WHO (2007)<sup>(4)</sup>.

## Material and Method

This study is an evaluative descriptive research. It systematically, factually and accurately describes the phenomenon or the correlation between two studied phenomena<sup>(3)</sup>. Its approach is an evaluation approach, which aims to collect data from policy implementation. It was conducted in the Port Health Office Class I of Surabaya in Tanjung Perak Port, Surabaya. This study used total population sampling, with the population of 5 officers of the transport equipment surveillance program.

Data were collected using two kinds of data, primary and secondary. Primary data was collected using interview to health workers and patients and direct observation on the activities of all officers in Quarantine Control and Epidemiological Surveillance (QCES) in PHO Class I in the working area of Tanjung Perak Port, Surabaya.

**Findings:** The Port Health Office (KKP) has the duty to prevent pandemic potential diseases and outbreaks, epidemiological surveillance, quarantine, safeguarding new emerging diseases and re-emerging diseases. One of the prevention efforts is the issuance of the Certificate of Pratique (CP) and Port Health Quarantine Clearance (PHQC)<sup>(4)</sup>.

The disease threat that arises as a result of increasing global transportation technology is New Emerging Infectious Diseases from other countries. Diseases that have the potential to enter Indonesia include Hanta fever, EBOLA, HFMD, Paragoniasis Pulmonalis, legionnaire's disease, SARS, Avian Influenza, and Nipah Virus.

Some of diseases are in the category of can be overcome. The Law No.1 of 1962 concerning Sea Quarantine and the Law No. 2 of 1962 concerning Air Quarantine only focus on the incoming prevention of 6 quarantine diseases, which later became 3 diseases (PES, Yellow Fever and cholera), not all of quarantine diseases could be overcome<sup>(10) (11)</sup>. Since the enactment of the Revised IHR in 2005, the law has become more irrelevant both in terms of management and law enforcement for violators<sup>(9)</sup>.

Described below is the result of direct observation, document study, and separate interview with the holders of ES of Transport Equipment Program in PHO Class I Surabaya using system approach, consisting of input, process and output. To determine the problem, separate interview was conducted with 5 informants.

Data collection and vessel data recording were carried out by 4 guard officers with two of them are from QCSE section officers while the monthly analysis was carried out by holders of the ES of Transport Equipment program. Field checks, one of the activities of collecting data on Transport Equipment ES and also called boarding activities, was carried out by 4 officers consisting of 1 team leader and doctor, 1 epidemiologist, 1 from the field of Environmental Risk Control and 1 as a member with a flexible role. Each has a specific role in carrying out Epidemiology Surveillance of Transport Equipment in the field. However, in term of human resources, this office (PHO Class I Surabaya) still requires more health workers. From the observation, most workers did not use PPE, especially safety shoes, masks, and gloves.

From the observations in the field, officers or Boarding team members have used personal protective equipment (PPE), in the form of safety helmets, safety shoes, vests and masks. However, sometimes, some officers do not wear masks while boarding to the vessels and the limited number of safety helmet and buoy becomes a barrier to the ship inspection process.

Transportation equipment is available in the form of car boarding so that the team can easily reach the port

location. However, due to the absence of Quarantine Speed Boat facilities, the office needs to rent boats in advance for boarding process in the middle of the sea. For documentation, officers used cellphone camera. The office has 4 computers for ship service, namely computer billing for billing input by agents and 3 operational computers. There were also adequate internet facilities, 2 printer machines and an ATM machine, which is used to print documents along with payment proof for ship administration. There were also printed media in the form of posters showing flowchart of the issuance of health ship letters such as Free Pratique, SSCEC and SSCC, but there is no printed media regarding the obligation to use PPE for officers.

The time needed for a single inspection for overseas vessels is approximately 30 minutes. However, if there is a risk factor for PHEIC, the ship must be quarantined. If it has been proven to be suspected of disease, quarantine and isolation will be carried out for two incubation times. Time for data collection and issuance of domestic ship sailing licenses was approximately 10 minutes for filling online and offline data. It can take longer if the system is experiencing interference.

The team has used the latest technology to facilitate the data collection and administration of Transport Equipment Epidemiological Surveillance, for examples online coordination. The used car boarding transportation is the modern one and is adequate for 5 people. Manual data recap used Microsoft Excel. The documentation tools are quite practical. The testing of samples in the laboratory has also used sophisticated technology where serological tests were carried out at the Surabaya BBKL Laboratory.

Information regarding the arrival of overseas vessels had already been notified by the agent through a notification letter on the arrival of the ship, so that the guard officer could prepare to take a health action check. The manual report on the recapitulation of ship traffic data (using Ms. Excel) is analyzed and presented in the form of monthly written and digital reports, which are input into the SIMKESPEL website and reported monthly to the main office. Every month, online data recapitulation through SIMKESPEL is also conducted so that document concordance can be easily checked, compared with the manual data recaps. The reported data is then disseminated to internal parties (Juanda Port Health Office) and external parties, cross-sector parties, such as the health staff, PT Pelindo, and others.

For the health ranks, this information will form the basis for PHEIC control decision making, planning and program evaluation. The shortcomings in the output process are the absence of reports on the results of the SE Transport Analysis in a period of 1 year so that there is no comparison of performance and findings in the unit of years of performance. These methods met the standards set in the standard operational procedure of Ship Traffic Monitoring Procedure.

The problem identification for the input found 4 problems, namely officer compliance in using Personal Protective Equipment (helmets, masks, gloves and buoys), the limited number of officers for local ships inspection, which makes the inspection is prioritized for foreign ships, no printed media for officers persuading them to use PPE, the absence of Quarantine Speed Boat facilities for boarding purposes in the middle of the sea, and lack of health communication efforts and health promotion media in monitoring ship health and cleanliness.

All stages of surveillance have been carried out by the team, including the implementation of health supervision, the issuance of health documents of vessels arriving and departing from Tanjung Perak Port of Surabaya, conducting analysis which includes calculating the number of vessels and ports of origin and portraying the characteristics of the vessels and its crew, which is proven by the existence of a quick report on the results of the ES of Transport Equipment. In its effort for health communication to the agents, captains and vessel crews, it faced constraints, limited time and no media for promoting ship health.

The determination of problem priority level is used to measure the priority scale of the problem and conclude the problem in the ES of Transport Equipment program. To determine the priority and the problem, the method of ultrasound (Urgency, Seriousness, and Growth) was employed using both quantitative and qualitative approach. The measurements process found that there were 2 top priority problems in the ES of Transport Equipment program, the officer compliance in using personal protective equipment such as helmets, masks, gloves and buoys and the limited number of human resources for local vessel inspection. As the result, checking process was more prioritized for overseas vessels than local ones. After that, problem tree was used (as quantitative results) to analysis the causes of low worker compliance in using PPE. From

the tree problem, it can be seen that there were direct and indirect factors affecting the officer compliance in using Personal Protective Equipment<sup>(1)</sup>. The primary causes were internal and external factors, while the secondary factors were education, knowledge, working years, environmental factors, media, the availability of PPE and supervision of the use of PPE (Sudarmo, Zairin Noor Helmi, 2016)<sup>(7)</sup>.

Article 14 of Law No. 1 of 1970 concerning Occupational Safety stated that there is a need for media in the form of work safety images, work safety requirements and information of law. Those should be displayed in a strategic place, so that workers can continuously read and keep the information in their mind, especially in the preparation process of ship boarding<sup>(12)</sup>. Regular supervision in the use of PPE is certainly needed. In addition, there is also a need to establish policies that obligate workers to use PPE so as to create a safe atmosphere and avoid work risks.

Problem tree was also used, as quantitative results, to analysis the causes of HR-related problems. There were direct and indirect factors in the the problem of limited human resources for local vessels inspection. The primary factor is the recruitment policy for health workers, while the secondary factor is employee qualifications and quota s et by the policies. However, there are also tertiary influencing factors. They are test results, experience, education level, short-term<sup>(8)</sup> quotas and long-term quotas<sup>(6)</sup>.

According to Minister of Health Decree number 1116 concerning Guidelines for the Implementation of Health Epidemiology Surveillance System, in the Health Epidemiology Surveillance System indicator, the required minimum numbers of HR employees and level education for employees in techinal implementation unit of Health Ministry are 2 expert epidemiologist (master degree), 4 expert epidemiologist (undergraduate), 4 skilled epidemiologist and 1 general practitioner<sup>(2)</sup>.

However, at the Health Office of Tanjung Perak Port Class I, the available human resources, especially in the QCES sub-field, are 1 expert epidemiologist (master), 4 expert epidemiology workers (undergraduate) and a general practitioner. So that, it can be concluded that this office have less human resources than the standard s et by the Ministry of Health. As an alternative solution, it is recommended for the office to recruit temporary workers to cover the shortage of skilled epidemiological

workers. The recruits can be assigned as the technical inspectors of local vessel and to maintain coordination and communication with the head office of Juanda PHO in the event of urgency.

## Conclusion

The Port Health Office (PHO) is a technical implementation unit within the Ministry of Health. It is responsible for preventing disease circulation, pandemic potential diseases and epidemiological surveillance. The top priority problem found in Epidemiological Surveillance of Transport Equipment was the compliance of officers in using Personal Protective Equipment (PPE) and the limited number of officers for local vessels inspection. The analysis result found that the problem were the absence of media, promoting the use of PPE in accordance with Law No. 1 of 1970 and the inconsistency of recruitment policies towards the Minister of Health Decree No. 1116 of 2003. The suggested alternative solutions were supervision and procurement of poster media which promote the use of PPE and opening recruitment for temporary worker to become technical personnel for local vessels inspection.

# Does Vertigo Predict Hypertension in Cervical Spondylosis: Clinical Trail Study

**Talib Kadhim Akar**

*Assistant Professor of Internal Medicine, Department of Internal Medicine, College of Medicine,  
University of Basrah, Iraq*

## Abstract

**Background:** Both cervical spondylosis and hypertension are common medical conditions. That is whether spondylosis leads to hypertension and whether vertigo could predict hypertension is not clear.

**Objective:** To identify the relationship between cervical spondylosis & systemic hypertension through identification of probable predictors .

**Patient and Method:** All patients were seen in Al Mowasat outpatient clinic from January 2017 to August 2019 with symptomatic cervical spondylosis .All of them were evaluated for presence of hypertension along with signs and symptoms of cervical spondylosis. Diagnosis of cervical spondylosis was based on clinical criteria and radiological findings.

**Result:** A total of 50 patients(31 males and 19 females) were studied. Hypertension was ascertained in 29(58%). Common signs and symptoms of cervical spondylosis were evaluated including headache in 89.4%, vertigo in 83.7%, chest pain in 55%, shoulder pain in 61.9%, numbness in 65.1%, abnormal reflexes in 44.7%, Babiniski sign in 17% and Body Mass Index  $\geq 30$  in 60.4%). Logistic regression analysis indicated that vertigo is significant independent predictor of hypertension in cervical spondylosis patients.

**Conclusions:** Vertigo was a predictor of hypertension in spondylosis patients.

**Keywords:** *Cervical Spondylosis, Hypertension, Vertigo.*

## Introduction

Cervical spondylosis is a degenerative disease affects intervertebral disc at different levels with osteophytes formation.<sup>1</sup> Symptoms of cervical spondylosis are variable including headache, numbness, weakness of extremities<sup>1</sup> and others but vertigo is most common symptom.<sup>2</sup> Surprisingly cervical spondylosis common among patients complaining of vertigo. <sup>2</sup> but the links between the two conditions are unclear. The disease is

age related disorder increasing with age where it is about 13%, 34%, 58% in the fifth, sixth, and seventh decades in that order<sup>3</sup>, yet many individuals above 30 years, show significant abnormalities on plain x ray<sup>4</sup>. Hypertension is common worldwide problem<sup>5</sup>

About 95% of hypertensive patients have no identifiable causes<sup>5</sup> obesity is one of common cause of secondary hypertension<sup>6</sup>

Hypertension is often asymptomatic<sup>5</sup>, the overall prevalence of hypertension in nearby cities or countries is around 26.5%<sup>7</sup>, 10%<sup>8</sup>, 10.3%<sup>9</sup> and 22%<sup>10</sup> in ThiQar (north of Basrah city), Saudi Arabia, Kuwait & Iran respectively.

The aim of this study is to evaluate the association between cervical spondylosis and systemic hypertension through probable mediators such as vertigo.

**Patients and Method**

This was a cross-sectional study carried out in one major private hospital in Basrah city (Al Mowasat hospital) lasted for twenty months. Patients who met the criteria of having cervical spondylosis both clinically and radiological were included in the study. The study started from January 2018 until August 2019. Diagnosis of cervical spondylosis depended on radiological changes on cervical x-ray and signs and symptoms. Each patient was analyzed for symptoms of cervical spondylosis which including headache, vertigo, numbness shoulder pain, chest pain plus signs like abnormal tendon reflexes, Babinski sign, Lhermitte’s sign. Both compression and traction tests were elicited. Body mass index was evaluated at same time. For each patient, blood pressure was measured with mercurial sphygmomanometer after patients waited for at least five minutes prior to each record. Recorded blood pressure often needed two separated occasions.

Hypertension was defined as blood Pressure  $\geq 140/90$  mmHg<sup>5</sup> or patients on anti-hypertensive medication. Vertigo was defined as rotatory movement either bodily or environmental or according to clinical examination.

Compression tests were performed either by axial compression on the head with neutral head position or rotational movement on extended head, symptoms made worse by these movement indicated a positive test<sup>11</sup> traction test provoked by head traction, symptoms relief signified a positive test<sup>11</sup> diabetes mellitus diagnosed by history of diabetes mellitus, the use of insulin or other hypoglycemic agents or measurement of fasting blood sugar  $\geq 126$ mg/dl or random blood sugar  $\geq 200$ mg/dl.

Body Mass Index (BMI) is the value derived from weight and height as Weight in kg/Height in M<sup>2</sup>). Underweight patients, considered when BMI under 18,5 kg/M<sup>2</sup> while BMI between 18,5 kg/M<sup>2</sup> to 24.9 kg/M<sup>2</sup>

considered as normal, Overweight patients considered when BMI is 25 to 29.9 & BMI  $\geq 30$  is indicating obesity.

Babinski sign defined as dorsiflexion of big toe or fanning of the other toes upon stimulation of lateral planter aspect of the foot<sup>12</sup>

Lhermitte’s sign is a sense of electric shock in extremities provoked by neck flexion<sup>13</sup> radiological finding of cervical spondylosis are including narrowing disc space & marginal osteophytes<sup>14</sup>, opinion of radiologist was obtained in controversial instances.

SPSS version 21 was used, Chi-square with significant value of  $< 0.05$  adapted to assess the predictors of hypertension in cervical spondylosis. In addition logistic regression analysis was used to identify significant predictors of hypertension of the 50 patients with cervical spondylosis, 31 (62%) patients were males, and 19 (38%) were females, thus the male to female ratio was 1.6:1. The mean age was  $51.2 \pm 10.1$  years with a range of 32-72 years.

The hypertensive patients were distributed as 29 males and 9 females. The majority of patients complained of headache which was observed in 42 (89.4%). Others symptoms with relatively higher frequency were vertigo seen in 36 (83.7%). Numbness was seen in 28 (65.1%)

While Chest pain was seen in 22 (55%). BMI analysis showed that Obesity was prevalent in 29 (60.4%).

Evaluations of signs concerning cervical spondylosis were shown also. Abnormal reflexes were observed in 17 (44.7%), Lhermitte’s sign observed in 13 patients, Babinski sign elicited in 7 patients (17%). Diabetes was ascertained in 9 patients.

Logistic regression analysis to predict hypertension shows that only vertigo is independent and significant predictor of hypertension with p value of 0.026 (Table 1).

**Table 1: Logistic regression analysis predicting the hypertension in Cervical spondylosis**

Variable	B	S.E.	WALD	DF	SIG	EXP (B)
Sex	1.027	1.748	.345	1	0.557	2.793

Constant	-20.990-	11.848	3.139	1	0.076	.000

## Discussion

The correlation between cervical spondylosis and hypertension had been studied since few decades in different aspects.

50 years ago Al Badran et al, reported that headache in hypertensive patients if not relieved by reduction of elevated blood pressure, is likely attributable to cervical spondylosis<sup>15</sup>

Liu & Ploumis in study published in 2012 reported that cervical spondylosis could be a possible cause of hypertension, they found more than one third of hypertensive patients are no longer need antihypertensive medicine after decompressive cervical surgery and created a term cervicogenic hypertension<sup>16</sup>

A Chinese study<sup>17</sup> by Peng B et al (2015) described some association between hypertension and cervical spondylosis, they found also that surgical treatment of cervical spondylosis had successfully controlled hypertension, This study was, however, with limited number of patients(two patients only) but, interestingly they reported important point, which is,surgical decompression of degenerative disc that contributing to cervical spondylosis is relieving hypertension as well as vertigo. In these two patients.

Our observations showed vertigo is independent predictor for hypertension .but vertigo is commonly seen in patients with cervical spondylosis<sup>2</sup>. On the other hand, studies of vertigo in hypertensive patients did not indicate that elevated blood pressure was causing vertigo,(but if existed together) it commonly attributable to other concomitant causes like central nervous system or vestibular diseases.<sup>18</sup>

MarchioriL,et al found that incidence of vertigo in hypertensive and non hypertensive patients were similar and concluded that no correlation of vertigo with hypertension could be ascertained.<sup>19</sup> In the present study and according to the logistic regression analysis to predict hypertension, vertigo was the only significant (P=0.021) and independent predictor .in spondylotic patients. Such results clearly denoted that vertigo carried significant impacts in hypertensive patients in complex mechanism need further evaluation or indeed the presence of vertigo could be accidental or possible explanations are the hypotension provoked by antihypertensive medications<sup>18</sup> or concomitant vertebrobasilar insufficiency due to atherosclerosis in hypertensive patients . It remains

plausible however to conclude that the presence of vertigo in cervical spondylosis patients strongly suggests coexistent hypertension.

## Conclusions

The presence of vertigo was strongly predict the systemic hypertension in patients with cervical spondylosis.

# Maternal Death Model Induced Neuron Cells Apoptosis in *Rattus Norvegicus* Newborn

Tri Yunita Fitria Damayanti<sup>1</sup>, Hermanto Tri Joewono<sup>2</sup>, Widjiati<sup>3</sup>

<sup>1</sup>Postgraduate Students in Reproductive Health Sciences, <sup>2</sup>Department of Obstetrics and Gynecology, <sup>3</sup>Prof. Department of Embryology, Airlangga University, Surabaya, Indonesia

## Abstract

The loss of bonding attachments to maternal deaths as a cause of neonatal stress had an impact on brain growth and development in early life. HPA axis activation responded to secrete corticotropin releasing hormone which stimulated adrenocorticotrophic hormones secretion. These hormones induced the adrenal gland cortex to secrete glucocorticoids. Excessive release of glucocorticoids would suppress BDNF expression resulting in BDNF hypofunction resulting in neuronal cell apoptosis which was characterized by an increase in neuronal cell apoptosis index. This study aimed to analyze the apoptosis index of neuron cells in the cerebrum and cerebellum of newborn *Rattus norvegicus* that were not separated from the mother until 3 days old as the control group (K1) and the cerebrum and cerebellum of newborn *Rattus norvegicus* that were separated from the mother by giving animal milk as replacement nutrition until 3 days old as a group treatment (K2). 3 *Rattus norvegicus* newborn with heaviest, medium, and lowest weights were taken from each mother then sacrificed for the brain histochemical preparations. Imonohistochemical examination was carried out to calculate the neuronal apoptosis index. The analysis results showed that the apoptotic index of neuron cells in the cerebellum and cerebrum of newborn *Rattus norvegicus* which separated from the mother were higher than those not separated from the mother.

**Keywords:** *Maternal death model, apoptosis index, neuron cells.*

## Introduction

Maternal mortality was maternal death while in pregnant or 42 days after the end of pregnancy, regardless of place or age of pregnancy.<sup>8,9,10</sup> Maternal Mortality Rate (MMR) was the number of maternal deaths during pregnancy, childbirth, and childbirth caused by pregnancy, childbirth, and childbirth, or management, and not for other reasons such as accidents or falls in every 100,000 births life.<sup>4,5,6</sup> Based on Indonesian health profile data, MMR showed 305 maternal deaths per 100,000 live births in 2015. This number had not

met Indonesia's MMR target for 2015 Millennium Development Goals (MDGs), which was 102 per live birth.<sup>4,5,6</sup>

The of maternal deaths was the direct contact loss between the baby and the mother. The loss of the baby's chance to get breast milk would dramatically affected the baby's health throughout his/her life.<sup>10</sup> Bonding attachments contributed to the baby development, such as emotions, cognition, and overall mental health. Stimulation of the baby's sensory system could directly affected brain development and stress in infants.<sup>11</sup>

Stressors at the beginning of life would caused glucocorticoid enhancement. Glucocorticoid played an important role in the BDNF regulation. Glucocorticoid function were (1) decreased activator protein-1 (AP-1) and CREB activity required in BDNF gene transcription; (2) affected the cascade of the BDNF signal via the TrkB and p75NTR receptors; (3) reduced the influx of Ca<sup>2+</sup> ions on the postsynaptic membrane; (4) inhibiting the

signal cascade mediated by TrkB and a decrease in phospho-TrkB (pTrkB) expression; and (5) influenced the regulation of the PLC- $\gamma$  signal cascade by BDNF and inhibit the PI3K-Akt pathway thereby increasing the proapoptosis pathway of neuron cells in the brain.<sup>15,16</sup>

Physiological apoptosis played an important role in maintaining homeostasis in brain growth and development. However, apoptosis could be pathological when triggered by excessive hormonal conditions, for example in chronic stress which increased glucocorticoid levels and resulted in decreased BDNF function resulting in high neuronal cell death.<sup>15</sup> Separation of the postnatal mother from day 2-14 decreased BDNF expression in the ventral hippocampus and ventromedial prefrontal cortex. Significant reduction in BDNF expression occurred in the separation with the mother in postnatal days 3-15.<sup>11</sup>

The acceleration of neuronal apoptosis in infants would interfere with the neurons function, namely processing information in the brain and the control center. Growth and development of baby neurons disorders resulted in impaired cognitive, motor, and language development.<sup>13</sup> Based on the impact of increasing the neuron cells apoptosis index in infants as a stress response during maternal death, babies from maternal deaths needed special attention for the growth and development of their brain, especially in the first 1,000 days of life in preparation for future survival. Therefore, a study to analyze maternal mortality models that induced apoptosis of newborn *Rattus norvegicus* neuronal cells needed to be done.

## Materials and Method

This study was a true laboratory experiment with a randomized post-test only control group design study design. The study was conducted from March to May 2019 at the Experimental Animal Cage and Laboratory of the Faculty of Medicine, Airlangga University. The maternal mortality study model consisted of two groups, namely the newborn *Rattus norvegicus* which was not separated from the mother until 3 days old as the control group (K1) and the newborn *Rattus norvegicus* which was separated from the mother by giving animal milk as replacement nutrition until 3 days old as the treatment group (K2).

The prospective mother of *Rattus norvegicus* was impregnated through superovulation by injecting 10 IU of Pregnant mare serum gonadotropin (PMSG) hormone. 48 hours later, the prospective mother was injected with HCG 10 IU and mated by monomating. Vaginal plug examination was carried out 17 hours after monomating to ensure pregnancy. Pregnant female *Rattus norvegicus* was taken randomly. After the mother gave birth, the newborn *Rattus norvegicus* of control group remained with the mother, while the newborn *Rattus norvegicus* of treatment group was separated from the mother and given animal milk as a substitute nutrient. Care and observation were carried out for 3 days. After 3 days, 3 *Rattus norvegicus* children from each mother were taken with the heaviest, medium, and lowest weights according to the number of samples needed with the Federer formula along with a 10% correction, which was 18 per group. Samples were sacrificed and the brain was put into 10% formalin for organ preservation. Histochemical preparations were made to calculate the apoptosis index of neuron cells by immunohistochemical examination.

The expression of the Apoptosis Index in each sample was assessed semi-quantitatively using the TUNEL Assay method. The number of neuron cells that undergo apoptosis in 10 view fields was seen by magnifying a microscope 400 times and calculated per 100 cells divided by the total number of cells and multiplied by 1,000. Apoptotic cells would stain dark brown to blackish.

Normality of the data was tested using the Shapiro Wilk test to determine the required analysis. If the data was normally distributed, then the analysis carried out next was parametric analysis. Nonparametric analysis was carried out if the data was not normally distributed. Normal distributed data was continued by T test 2 samples, while data not normally distributed were followed by Mann Whitney test. This study uses a significance level of 0.05 with a confidence level of 95%.

**Findings:** The results showed that the mean of neuron cell apoptosis index in the 3-days-old *Rattus norvegicus* cerebrum in the control group (K1) was  $2.89 \pm 1.28$ , whereas the mean of neuron cell apoptosis index in the 3-days-old *Rattus norvegicus* cerebrum in the treatment group (K2) amounting to  $4.68 \pm 1.67$  (Table 1).

\*Significantly different p<0,05

**Discussion**

The results showed that the mean of neuron cells apoptosis index in the 3-days-old *Rattus norvegicus* cerebrum which was separated from the mother was higher than the mean index of neuronal apoptosis in the 3-days-old *Rattus norvegicus* cerebrum which was not separated from the mother. The results also showed an average apoptotic index of neuron cells in the 3-days-old *Rattus norvegicus* cerebellum separated from the mother higher than the average apoptotic index of neuron cells

in the 3-days-old *Rattus norvegicus* cerebellum which were not separated from the mother.

This study was conducted by separating the newly born *Rattus norvegicus* from its mother for 3 days as a model of maternal death. The impact of maternal death was the direct contact loss between the baby and the mother. The loss of the baby’s chance to get breast milk would dramatically affected the baby’s health throughout his life.<sup>10</sup> Bonding attachments contributed to the development of the baby, such as emotions, cognition, and overall mental health. Stimulation of the baby’s sensory system could directly affected brain development.<sup>12</sup>

The stress system in infants without attachment bonding coordinated brain activity with emotional and physical stressors and controled the release of stress hormones or cortisol (in humans) from the adrenal gland. Stress hormones modulated brain activity to produce behavioral responses, adjust homeostasis, and produce an adaptive response to survival.<sup>13</sup>

Maternal mortality initiated stress in newborns due to the attachments loss that played a role in the growth and development of newborns. Stressors would activated the HPA axis which began with the paraventricular hypothalamus to secrete CRH and then stimulated ACTH secretion by the pituitary gland. ACTH induced the adrenal gland cortex to secrete glucocorticoids (GC), namely cortisol which was an indicator of stress. Glucocorticoid bound to the glucocorticoid receptor (GR) in the cerebrum and cerebellum in the baby’s brain. In chronic stress, BDNF expression decreased. BDNF consists of two forms, namely mature BDNF and proBDNF which had receptors, namely TrK B and p75NTR. Mature BDNF would be more tied to TrK B, then activate cell survival pathways and cell growth through protein kinase B (Akt) and through activation of Ras would activate MEK/MAPK/ERK. The proBDNF bond to the p75NTR receptor activated the apoptotic pathway through co-receptor bonds, namely sortilin. Sortilin would activate jun-N terminal kinase (JNK) which would phosphorylate C-Jun. C-Jun activated proapoptotic proteins such as p53, Bad, BIM, and BAX so that it stimulated mitochondria to release cytochrome-C and finally activated caspase 3,6,9 which initiated the apoptosis process via the intrinsic pathway.<sup>7,15,16</sup>

Administration of DEX (Dexamethasone) in male rats (22-26g) was carried out for 7, 14, 21, 28 days

at a dose of 5 mg/kg/day. DEX was synthetic from glucocorticoid, a hormone that affected the stress system in the body. Giving glucocorticoids (DEX) significantly ( $p = 0.01$ ) increased the apoptosis of neuron cells in the brain to cause injury and damage to brain tissue.<sup>19</sup>

Chronic stress increased neuronal cell apoptosis. Chronic stress increases the susceptibility of neurons in the cortex of mice by using chronic unpredictable mild stress (CMS) for 5 weeks. The results showed an increase in corticosterone levels. These effects were accompanied by a detectable increase in caspase-3 positive neurons in the cerebral cortex. This showed that apoptosis occurs in neuron cells.<sup>1</sup>

### Conclusion

The apoptotic index of neuron cells in the cerebellum and the 3-days-old *Rattus norvegicus* cerebellum separated from the mother was higher than the apoptotic index of neuron cells in the cerebellum and *Rattus norvegicus* cerebellum which were not separated from the mother.

# Behavioral Based Nutrition Education Intervention to Increase Fish Consumption among School Children Using Raised Bed Pool Media: Protocol for a Randomized Control Trial

Trias Mahmudiono<sup>1,2</sup>, Triska Susila Nindya<sup>1</sup>, Qonita Rachmah<sup>1</sup>, Luh Ade Wiradnyani<sup>2</sup>

<sup>1</sup>Departement of Nutrition–Faculty of Public Health, Universitas Airlangga, Jl. Mulyorejo Kampus C, Surabaya 60115, Indonesia, <sup>2</sup>Departement of Nutrition–SEAMEO Regional Centre for Food and Nutrition, Universitas Indonesia, Jl. Salemba Raya No.6, Jakarta 10430, Indonesia

## Abstract

**Objective:** The aim of the study is to analyze the effectiveness of behavioral based nutrition education to increase fish consumption among school children using raised bed pool media.

**Method:** This is a randomized control trial involving 104 elementary school children to increase their fish consumption. Children in the intervention group will be given six-sessions nutrition education intervention for 3 months with additional raised bed pool media for education. General Linear Modeling Repeated Measure will be used to assess difference in the increase of fish consumption.

**Discussion:** Raised bed pool will serve as visual reminder to the children that magnify the effect of nutrition education. The strength of the study is that evidence on the effectiveness of nutrition education intervention using raised bed pool was scarce relatively to the abundance body of knowledge related to raised bed garden. Raised bed pool is unique as it provide potential protein source from the fish in the RBP that are lacking from the raised bed garden. The intervention offers the advantage of potentially active ingredients to support behavioral change, such as improved knowledge, attitude, perceived behavioral control and intention.

**Keywords:** *Nutrition education, fish consumption, school children, raised bed pool.*

## Introduction

Hidden hunger, a micronutrient deficiency such as iron, iodine, vitamin A, or calcium, is one of nutrition problem that still exist in developing country including Indonesia. Prevalence of anaemia in schoolchildren globally reached 37% in which found to be higher in Asian children than African<sup>(1)</sup>. Based on the IFLS

survey, the prevalence of anaemia in children aged 5-12 years declined from 36.4% in 2000 to 20.6% in 2008<sup>(2)</sup>. The latest report on Basic Health Research 2013 shows that the prevalence of anaemia in children aged 5 - 14 years is 26.4% and count as public health problem<sup>(3)</sup>. A study in one primary school in Surabaya found the anaemia prevalence in schoolchild reached 13.2%<sup>(4)</sup>.

In the short term, anaemia in schoolchildren affects the level of learning concentration due to reduced oxygen supply to the brain causes lack of haemoglobin<sup>(5)</sup>. The results of the study in Makassar showed a positive relationship between the intakes of heme protein with the incidence of anaemia in school children. School children who only occasionally consume heme protein sources (2-3 times/week) are more at risk of anaemia than those who frequently consume (4-7 times/week)<sup>(6)</sup>. Studies conducted on children in Brazil also found that children

triasmahmudiono@gmail.com

with protein intake <28.8 g/day had an increased risk of anaemia than children with a protein intake >44.6 g/day<sup>(7)</sup>. Similar results were also demonstrated by a study in North Boolang Mongondow, Indonesia in which children who consumed protein less than RDI were more at risk of anaemia than children with protein intake more than RDI<sup>(8)</sup>.

Fish is one source of heme protein that has good iron absorption rate. Protein content in fish reaches 18% and consists of essential amino acids. According to the Indonesian Food Exchange List, one serving of fresh fish (50 g) contains 10 grams of protein. The Total Diet Study in 2014 reported the average consumption of fish and processed fish meat. In the children group (aged 5-12 years) was 70.7 grams per person per day, with the most percentage derived from marine fish as much as 37.9 grams per person per day or equivalent to 54% of the total consumption of fish then continued by the intake of freshwater fish that accounts for 38% of total fish consumption or about 26.9 grams per person per day<sup>(9)</sup>. The annual report of the Ministry of Marine Affairs and Fisheries shows that fish consumption per capita per year has increased from 2010 to 2014. In 2010, fish consumption was still 30.48 kg/capita/year and increase to 38.14 kg/capita/year in 2014 with the highest growth reaching 8.32% per year. Fish consumption in East Java in 2010 was only 19.01 kg/capita/year up to 27.89 kg/capita/year with 46% growth level in the last 4 years<sup>(7)</sup>. In 2019, fish consumption is targeted to reach 54.49 kg/capita/year<sup>(8)</sup>.

Surabaya is included as the second largest metropolitan city in Indonesia with approximately 2.8 million people<sup>(10)</sup>. Public health issues in metropolitan city such as anaemia require a comprehensive policy approach, although in developing countries, resource limitations are often becoming a constraint<sup>(11)</sup>. However, given the magnitude of the impact of anaemia on the quality of Indonesian human resources, efforts should be made to overcome the problem with the improvement of intervention method. Nutrition education is one of the most cost-effective interventions and resulting a long-lasting impact<sup>(12)</sup>.

One of behaviour change theory that is widely used in nutrition education is *Theory of Planned Behaviour* (TPB)<sup>(13)</sup>. Behaviour is strongly influenced by intention, which is jointly influenced by attitudes, subjective norms, and perceived behavioural control. The youth garden program based on the Theory of

Planned Behaviour succeeded in improving the attitude in boys (p-value<0.001) and girls (p-value<0.001), and increased of perceived behaviour control in consuming vegetables and fruits in girls (p-value=0.014)<sup>(14)</sup>. Nutrition education interventions based on school gardens succeeded in increasing the desire and intention to try eating vegetables and fruits in children, increasing children's knowledge of the importance of eating vegetables and fruits, as well as improving children's attitudes and skills to increase vegetable and fruit consumption<sup>(15,16)</sup> also fruit and vegetable asking behaviour at home<sup>(17)</sup>.

RBP media in nutrition education serve as instant reminder for schoolchildren is expected to increase school children intention to love eating fish. The RBP Project also targets variables to increase school children perceived behaviour control to eat fish with a weekly fishmeal program, fish-game cards, and catfish-based food menu making. School gardening and raised bed pool equally prioritize the concept of mastery experience for children to be actively involved in the management of gardening programs or cultivating freshwater fish. Compared to the raised bed garden, the raised bed pool program produces an animal food source of heme-iron protein that is relatively easily absorbed by the body than non-heme iron. School children characteristics are more interested in interacting with moving objects rather than stationary objects. We hypothesize that RBP have a higher appeal to actively involve the school children than the raised bed garden. Therefore this study aimed to evaluate the effectiveness of RBP as media of nutrition education to improve protein intake and prevent anaemia among school-children.

## Method/Design

This research is a randomized control trial (RCT) with intervention in the form of nutrition education for 3 months to elementary school children 4<sup>th</sup> and 5<sup>th</sup> grade. Intervention in this study consists of a combination of 6 nutritional education sessions based on Theory of Planned Behavior by utilizing the raised bed pool in the school environment. The study will be using a parallel assignment with the two groups of samples experiencing different interventions during the same period of time.

**Setting:** The school was chosen purposively by considering the location of Sidotopo Subdistrict; the majority of the population is in the economic status of medium to low income. Selection of Sidotopo Wetan I

and II elementary school is based on easy accessibility, there is no raised bed pool, and there is no similar research before.

**Sample Size:** The sample size in this study was determined using formula of sample size for compare the mean of a continuous measurement in two samples, using a z-statistic to approximate the t-statistic with the effect size calculated from the results of McAleese, et al.<sup>(18)</sup> on increased consumption of vegetables per serving in nutritional education interventions based on school gardening (n=45, SD=1.7, ES=1.2) compared with control group. By using 80% power and alpha of 0.05, the minimum samples obtained without cluster correction were 32 subjects for each group. Then, taking into account the design effect  $1 + (p(m+1))$  using cluster size 30 and Inter-cluster Correlation Coefficient (ICC)=0.043 based on manual diabetic research<sup>(19)</sup>, the minimum sample required was 46 primary school children in each group with the consideration of 10% drop out, the sample in this study was 52 school children in each group. Based on preliminary survey conducted in both elementary schools, the total number of grade 4 and 5 students recorded is 900 children (research population). A screening then performed based on several criteria and 400 eligible subjects were retrieved. Assuming 10% of refusal to follow the study, then 104 children were eligible and willing to become research subject.

**Inclusion and exclusion criteria:** Inclusion criteria required participants to be aged 10-12 years, not allergic to fish, and not on a special diet. While the dropout criteria are the subject missing out from >50% or more than 3 times intervention sessions. The subjects were chosen because of the good literacy in 4<sup>th</sup> and 5<sup>th</sup> grade of elementary school at baseline.

**Intervention:** The RBP will be built at the school environment upon permission from the principal. Each consented participant in the intervention group will be given six sets of educational materials in the form of comic, recipe book, and info graphic. The comic describes benefit of catfish in increasing student's concentration during school hours. In addition, stationeries worth USD \$1 or about IDR 15,000 provided each participant after consenting to involve the whole study. Six education sessions for RBP group will be given once every two weeks for three months. During the nutrition education sessions, hands-on activities will be provided to help children improve their self-efficacy

toward fish consumption. The comparison group will not receive any nutrition education or exposure to raised bed pool in their school environment.

**Outcome:** Primary outcome is measured at the beginning and at the end of the study or after three months' education. The primary outcome is the change in fish consumption (gram/day). Fish consumption will be measured using food diary record. A total of three-days food diary records will be collected in a week. Dietary data will be analyzed using food processor software drawing from a database of Indonesian Food updated yearly by the Department of Nutrition, Universitas Airlangga – Indonesia. Secondary outcomes for the study are: anthropometric and body composition data, parent's characteristics, child's nutrition knowledge, and psychological variables.

**Anthropometric and body composition data:** Data will be collected including age, weight, and height of the children. Weight is going to be measured using Omron HBP-317 digital scale with 0.01 kg correction and will be measured in light clothing without shoes. Height is going to be measured to the nearest 0.1 cm using a stadiometer (SECA 213). Both weight and height is going to be measured twice to ensure the result's validity. Another measurement to assess the nutritional status of the children is body composition including body fat and body muscle percentage, as well as resting metabolic rate. These indicators are going to be measured using Omron HBF-317 that validated with SECA digital weight scale.

**Characteristics:** A general questionnaire is developed to obtain parent's characteristic data that includes parent's educational background, employment, and number of family member, literacy level, family income, and food expense. Child's nutrition knowledge is measured using previously validated questionnaire. The questionnaire consists of three parts; the first part focus on the nutrition and health knowledge with total of six questions and the second part focus on household serving size to measure how well children know about the portion, and the last part consist of questions related to MyPlate Indonesia.

**Psychological data:** All of the psychological data questionnaires were developed as Likert scale answers based on Bandura's guide for constructing attitude, subjective norm, perceived behavioral control, behavior, and intention scales. Children attitude to consume fish

as the source of animal protein will be measured using a three items questionnaire. Perceived behavioral control, behavior and intention to consume fish are going to be measured using three questions.

**Statistical analysis plan:** To analyze the difference in outcomes of control and intervention groups, a paired t-test will be used for normally distributed data and Kruskal Wallis test will be employed to data that is not normally distributed. In order to have more robust conclusion, the results will be adjusted for possible confounders such as school children characteristics, SES and household characteristics using General Linear Modeling Repeated Measure (GLM-RM). All data analyzes were performed at IBM SPSS Statistics 22.

## Discussion

This study will compare the effectiveness of six-session nutrition education intervention using RBP with control receiving only printed educational materials about the benefit of fish consumption. The study setting is in low to middle income elementary school in Surabaya City, Indonesia. It is hypothesized that participants in the intervention group (RBP) will benefit from the six sessions nutrition education developed based on the theory of planned behavior. Theraised bed pool will be served as visual reminder to the children that believed will magnify the effect of the 6 sessions of behaviorally oriented nutrition education.

One of the strengths of the study is that evidence on the effectiveness of nutrition education intervention using raised bed pool was scare relatively to the abundance body of knowledge related to raised bed garden. Raised bed pool is unique as it provides potential protein source from the fish in the RBP that are lacking from the raised bed garden. Both elementary schools involved in this study were drawn from public schools located in the low to middle income population. Generalization of the results of the intervention could be limited due to the present setting of the sample.

The intervention offers the advantage of potentially active ingredients to support behavioral change, such as improved knowledge, attitude, perceived behavioral control and intention. We will employ 2 times anthropometric measurement of the elementary school children during recruitment to reduce measurement bias. Selection bias will be reduced by random allocation of consented participants. Due to the nature of the intervention, blinding participants as well as nutrition

educators and research assistants delivering the intervention are not possible. In order to limit potential bias, all measurements were performed through standardized protocol, and all enumerators were trained prior to data collection.

## Declarations

**Competing interests:** We have no conflict of interest to report for this study.

**Funding:** The Ministry of Education and Culture of Republic of Indonesia funded this study through a contractual research between Universitas Airlangga and the Southeast Asian Minister of Education Organization Regional Center for Food and Nutrition (SEAMEO RECFON).

**Ethical Clearance:** Ethics approval for this study was received from the Institutional Review Board (IRB) at Faculty of Public Health Universitas Airlangga. This study was given Universal Trial Number (UTN=U1111-1199-992) and was registered in the Thai Clinical Trials Registry (TCTR20171207002).

# The Actions to Control the Blood Pressure among a Community Hypertensive Elder in Denpasar City

Triyana P.D.<sup>1</sup>, Budi U.<sup>2</sup>, Zaenal A.<sup>1</sup>, Riny P.<sup>1</sup>, Lis T.<sup>1</sup>, Antonia H.H.<sup>1</sup>

<sup>1</sup>Faculty of Nursing, Universitas Airlangga, Surabaya, <sup>2</sup>Faculty of Medicine, Universitas Airlangga, Surabaya

## Abstract

**Objectives:** To evaluate the actions of hypertensive elders in Primary Health Care among Denpasar City in maintaining blood pressure.

**Method:** The population is patients aged  $\geq 60$  years who were admitted to the Integrated Health Care for elders between 13 March to 20 May 2019. The proportional random sampling was used, remaining the selected of 210 elders from four PHC separated by four different districts. The actions were evaluated by questionnaire that used to assess what the elders do as awareness to maintain blood pressure.

**Results:** The total of 210 elders were reviewed (mean age, 67.2 years) with 120 participants (57.1%) were female. Amount 187 participants (89.04%) were categorized into elderly and the rest were old. The mean of systolic and diastolic blood pressure was 148.6/88.9. There are six kinds of medicine that have been given to elders. Elders also have other condition which contribute to illness such as diabetic, hyperlipidemia, hyperuricemia and arthritis (10%). Regular control schedule and morning blood pressure monitoring as the critical points which are need attention.

**Conclusion:** The elders have to concern with control schedule arrangement and morning blood pressure measurement to achieve BP target.

**Keywords:** *Hypertensive elders, blood pressure control.*

## Introduction

The health condition of elders, especially uncontrolled blood pressure, it still exist, contributes to the increase of cardiovascular disease. In South East Asia, low obedience of hypertensive elders in treatment was reported as factor that lead the rising number of death. A research was conducted in China in 2017 reported that degradation of medication proportion and blood pressure control need patient compliance and awareness to control hypertension (HTN) and minimize the risk of complication.<sup>1</sup>HTN in the age group  $\geq 65$ , mostly in woman, known as one of trigger factors of worldwide premature death.<sup>2</sup>

Viridis, et al. describes the aging process with arterial stiffness and changing of inner wall arteries mainly on aorta and proximal branch. Thickening of the intima cause loosing of elasticity and affect haemodynamic. When the stiffness attack large arteries, the cushioning

function was damaged, then an ejection function of the ventricle and recoil elasticity will decline. Continuity of this situation potentially increase the risk of stroke and heart failure.<sup>3</sup>

The 4th most populated country in the world based on the United Nations report in 2015, Indonesia, has an elders population that increased about two times during 50 years. At 2018, the percentage of the elder population reached 24,49 million (9.27%). It reveals that Indonesia is in transition to ageing population due to the percentage of persons aged, upper 60 years is more than 7% which is dominated by group of aged 60-69 years (63.39%). The Indonesian Central Bureau of Statistics in 2018 reported that five provinces in Indonesia as the most populated of elders, included Bali. This is a challenge of Indonesia to achieve independent and high quality elders and reduce the burden of the national development.<sup>4,5</sup>

The report of Basic Health Result in Indonesia, year

2018, was reported that the HTN of elders upper 75 years as the highest percentage in 2018 reached 69.5%. Based on this case, 13.3% have not taken any medicine and 32% irregularly medicated.<sup>6</sup> In Bali, HTN has been the second position from the 10 highest illness admission in Primary Health Care (PHC) and more than 2000 patients had been referred to hospital.<sup>7</sup>

The preliminary study was conducted in Denpasar, Central City of Bali, by counting the hypertensive elder visitation to PHC during September to December 2018, was 4088 during four months from eleven PHC.

Based on all studies, the continual study needs to perform to explore more about the awareness of hypertensive elders in controlling blood pressure. This study was involved hypertensive elders to describe the applied behavior during HTN program.

### Method

This study was approved by the Committee of Ethical Approval in the Faculty of Nursing Universitas Airlangga by number 1321-KEPK. We conducted a cross sectional study which involved hypertensive elders as a participant. Cluster sampling was used to determine four PHC in Denpasar City that separated by four different sub-districts.

The total population from average visits reached 596 patients from the selected PHC, then 210 participants was chosen by using proportional random sampling. There are PHC 1 North Denpasar (41 participants), PHC 1 East Denpasar (53 participants), PHC 1 West Denpasar (88 participants) and PHC 3 South Denpasar (33 participants). To be included in this study, elders needed to be diagnosed as having HTN with 1 year minimum duration of taking medication; have history of (BP) records with Systolic Blood Pressure (SBP)  $\geq 140$  mmHg and Diastolic Blood Pressure (DBP)  $\geq 90$  mmHg for the past two months on the health record book of elderly. Each elder has been given an explanation that involved elder's family without any force to write on the inform consent.

Data collection was started from 13 March to 20 May 2019. Information collected included demographic data, BP measurement, medication, duration of diagnosed and the actions to control HTN. The elders were asked about the actions to control BP that concern to 9 points of the control schedule, morning blood pressure measurements, consultation, physical activity,

diet, sleep, stress distraction, desire to look for health information and willingness to apply the advice from health care provider.

Researchers have a responsibility to ensure participants comfort and stop the process if the elderly need health services and help them to receive the treatment. The study was conducted with respect of the total confidentiality of data. Therefore, anonymous data were analyzed using SPSS 17 with descriptive analysis.

### Results

Hypertensive elders with the total number amounted 210 participants aged 60 to 80 (mean,  $67.24 \pm 5.096$ ) years were included and categorized into elderly (<75 years, 89%) and old ( $\geq 75$  years, 11%). Gender distribution was dominated by female (n=120, 57.14%). In this study, Omron series HEM-7121 blood pressure monitor were used to measure the BP. From 210 elders, the blood pressure was recorded for systolic with a minimum level of 120 mmHg, maximum level of 210 mmHg with mean  $146.61 \pm 13.75$ . Systolic blood pressure was categorized into  $\leq 160$  mmHg (n=170, 81.0%) and  $> 160$  mmHg (n=40, 19%). Furthermore, diastolic with result  $\leq 100$  mmHg was recorded on 174 participants (82.9%) and the rest was  $> 100$  mmHg with mean  $88.92 \pm 8.95$ .

There are 17 participants (8.09%) were used more than one kind of medicine. Five kinds of medicine that the elders consumed to control blood pressure which are calcium channel blocker (amlodipine), ace inhibitor (captopril, lisinopril, ramipril), angiotensin II receptor blocker (valsartan, candesartan, telmisartan, irbesartan), beta blocker (bisoprolol), diuretic (spironolactone), and platelet antiaggregation (cilostazol, aspilet, clopidogrel). The most of the participants used calcium channel blocker such as amlodipine (75.71%). This medicine is included in health insurance from BPJS Kesehatan (Social Insurance Administration Agency of Indonesia) as the first treatment from PHC for HTN. Another medicine is an ace inhibitor (captopril). The patients who need the other medicines, mostly are specialists referred patients in hospitals, internist or cardiologist. Every 2 weeks the patients need to check the blood pressure and receive a referral form to meet the specialist.

From all participants, 9 elders (4.28%) also have diabetes mellitus, 5 elders (2.38%) with hyperlipidemia, arthritis and hyperuricemia (2 elders, 0.95%), and history of stroke or heart attack amounted 5 elders (2.38%). Based on duration of HTN diagnosed, the participants

were categorized into three groups, 128 elders (60.95%) with duration of HTN around 1 to 5 years, 70 elders (33.33%) were diagnosed 6 to 10 years, and the rest (5.71%) is the participants who diagnosed more than 10 years.

The results of 9 aspects that describe the action of elders to control HTN are described on the table below.

**Table 1. The number of hypertensive elders in action to control HTN**

Elders action	Perform		Not perform	
	n	%	n	%
Regular control schedule	52	24.8	158	75.2
Morning BP measurement	16	7.6	194	92.4
Consul to doctor	156	74.3	54	25.7
Regular activity	138	65.7	72	34.3
Diet (sodium restriction)	192	91.4	18	91.4
Sleep duration (7-8hours/day)	169	80.5	41	19.5
Stress distraction	205	97.6	5	2.4
Willingness to learn	153	72.9	57	27.1
Willingness to apply the suggestion	174	82.9	36	17.1

Table 1 illustrates some interesting facts about what the hypertensive elders do to control BP. It allows the percentage of participants who do and do not perform that action.

- 1. Regular control schedule:** The number of elders who have arranged control schedule to PHC is only 52 persons (24.8%). It means not all elders control the health condition. Actually, the health care provider gives medicine for 2 weeks only and suggest the patient to control before the last medicine is taken. It means 1-2 days before the last tablet, the patient should come to PHC to check BP, body weight and other conditions related to HTN and receive the treatment as needed. The recommendation for hypertensive elders with ischemia is they should lower the blood pressure around <135/85 or <130/80 for elders who have diabetes mellitus or chronic kidney disease.<sup>8</sup>If the patients able to seek PHC, it beneficially helps them to perform appropriate self-management in controlling blood pressure.
- 2. Morning blood pressure measurement:** The second action only perform with less than 10%. It reveals that low awareness to BP monitoring, while it is the skill that they should have because the BP usually peaks also in the morning. Morning

BP measurement should be improved with due to both ischemic stroke and coronary events often occur.<sup>9</sup>The trained elderly to measure and interpret BP result are beneficent to prevent complications of asymptomatic high BP.

- 3. Consultation with the doctor:** From the third point, consult to doctor, counted 156 (74.3%) pay attention to seek a medical doctor if the sign and symptom of high BP still exist even though the medicine have been taken. The others were ignored and have been chosen only stay at home and take a rest. This poorly condition needs high attention, especially for the elders with complication while they should be referred to Advance Health Facilities as a recommendation from Ministry of Health Republic of Indonesia.<sup>10</sup>
- 4. Regular activity:** The total number of 138 elders perform 30 minutes activity per day. Recommendation about regular activity included walking, jogging, swimming or cycling.<sup>2</sup> Based on *American Heart Association (AHA)* recommendation, the appropriate activity for elder is 30 minutes slow walking/day or 150 minutes/week as a minimal duration to increase fitness.<sup>11</sup>
- 5. Diet (sodium restriction):** Almost elders have paid attention to sodium restriction, more than 90%. Diet restriction based on *The Dietary Approaches to Stop Hypertension (DASH)* was proven to reduce BP by increasing the consumption of fruits, vegetables, wheat, poultry meat and fish with restriction of sweetener and red meat with sodium consumption less than 5g/day.<sup>2</sup>
- 6. Sleep duration (7-8hours/day):** Only 41 participants have problems with sleep duration when 80.5% of all were sleeping for 7-8 hours/day. The research was proven that afternoon sleep >30 minutes or a night sleep >9 hours potentially increase the risk of death.<sup>12</sup> The National Sleep Foundation suggests the appropriate duration around 7 to 8 hours/day.<sup>13</sup> It will help the elders still have enough time to act in daily activities.
- 7. Stress distraction:** Almost all participants have no matter about stress distraction. They will do some hobbies like fishing, cycling or gardening to reduce the level of stress. Stress has close linkages to BP level. Stress consistently affects the systolic and diastolic blood pressure.<sup>14</sup> Therefore, the elders need more activity to help them distract from the trigger of stress.

**8. Willingness to learn:** Amounted 72.9% (153) elders are active to seek information about HTN and what they have to do to achieve normal BP. The learning process is related to the increase of knowledge and experience. The elders who aware to seek information to achieve a healthy life in consequence will have more confidence and adherence to the treatment program.<sup>15</sup> The health care provider also has responsibility to give education as Minimal Standard of Health Services based on The Law of Ministry of Health Republic of Indonesia number 43 year 2016.<sup>10</sup>

**9. Willingness to apply the suggestion:** Most of the elders (n=174, 82.9%) are aware and have desire to adhere healthy life style. The important point of willingness is how to achieve elder independence to perform self-management as the key role of successful treatment.<sup>16</sup> This is proof that the elders have willingness to prevent the deteriorate health conditions in HTN as chronic illness.<sup>17</sup> It is beneficially for elders to stay healthy after received any suggestion from a health care provider.

### Discussion

This study demonstrates the actions which are performed by community hypertensive elder to control BP. In contrast with self-management of HTN, two points that required the attention of elders to increase are regular control schedule and morning blood pressure measurement. Less than a quarter off total participants have low attention to these points. It might be the consideration of health care provider to remind and support them to be treated hypertensive elders and aware with complication reduction. The other risk factors of HTN such as low intensity of activity, diet, sleep and stress are the causes that can be controlled. Confident and adherence to the treatment program will increase when the elders aware to seek information to achieve meaningful healthy life. It is related to self-care behavior about how to preserve normal BP.<sup>15</sup>

The patient who visits irregularly or out of schedule, is potentially a loss of HTN control, while the hypertensive elders need to consume the medicine regularly and control the body weight to reduce the ischemic heart attack event. They need complex treatment because it requires continuity of caring about cardiovascular, activity and more information to achieve the target of BP.<sup>18</sup>

There are several limitations of the present study. The BP only documented at the moment of data collection without compared to the last 2 months BP. The patients who has another diagnosis beside HTN also included in this study, which might require more attention to detect more serious complication that may occur.

### Conclusion

The seven actions that have been performed by the most of hypertensive elders included awareness in consultation based on untreatable signs and symptoms, regular activity, sodium restriction, sleep duration, stress relief, willingness to learn and apply health recommendation. However, not only less than a quarter of participants do not concern to make and follow the regular control schedule to PHC, but also less than 10% elders did not perform morning blood pressure monitoring.

# Internal Constraints and Policy Constraints on Conventional X-Rays

Ulfa Munta Ati<sup>1</sup>, Annis Dwi Trisnawati<sup>1</sup>

<sup>1</sup>Departement of Administration and Health Policy, Faculty of Public Health, Airlangga University, Indonesia

## Abstract

Every organization has obstacles in every work process carried out. Existing constraints can be an obstacle to organizations to improve service quality. This research was conducted to analyze internal constraints and policies constraints on conventional X-ray at the Radiology Unit at Bhakti Dharma Husada Hospital (BDH) in Surabaya. It is an analytic observational study with an applied cross-sectional design. The measurement technique in this study uses Likert measurement scale techniques. The population in this study is the workforce in the radiology unit at BDH Hospital in Surabaya which is directly related to the production process. The results of this study indicate that internal constraint variables on sub-variable resources constraints are not constraints (273) and knowledge constraints (34) become constraints on conventional X-ray stages. Variable policy constraints with internal sub-variables policy constraints (224) are not a constraint in the conventional X-ray photo-taking stage. Limitations of knowledge are constraints on the radiology unit when making conventional X-rays. This is because there are no radiology officers so officers have low competence. To improve the quality of services in the radiology unit, it is necessary to have policies that govern directly on knowledge management.

**Keywords:** *Internal constraints, policy constraints, x-rays.*

## Introduction

Hospitals that do not improve service quality will not be able to win the competition to get to the market. According to Ferencikova<sup>1</sup>, Companies have to react to dynamic market conditions and rising customers' requirements for shorter delivery times, lower prices, and better quality and services. Service quality is an important element in customer satisfaction as product quality. After managers try to go beyond product and process conformity (or quality), they move up from process improvement to system-level improvement<sup>2</sup>.

The process of improving service quality also needs

to be measured to find out the increase that occurred. According to Kristiyanti<sup>3</sup>, an organization needs measurement to find out the quality of service that is the goal of the organization. In order to measure the level of success of an organization, there is a need for clear indicators by stakeholders. Performance indicators are quantitative and/or qualitative measures that describe the level of achievement of a predetermined goal or goal. organizations have inhibiting factors for measuring performance<sup>4</sup>. Services offer major room for improvement by applying the theory of constraints concepts and tools<sup>5</sup>.

According to Ministry of Health of Indonesia, the incidence of damage to conventional X-rays is X-rays that cannot be read by the executor<sup>6</sup>. Conventional photodamage events have increased and decreased in number every month from 2012 to 2013 in the Radiology Unit of the Bhakti Dharma Husada Regional General Hospital, Surabaya City (BDH Hospital). In 2012, the number of conventional X-ray damage in the Radiology Unit of BDH Hospital in Surabaya from January to

Indonesia

e-mail: ulfiamuntaati1@gmail.com

December was still at 3.15% to 5.78%. Based on this it can be seen that in 2012 the number of X-ray damage in the Radiology Unit of BDH Hospital in Surabaya City has not reached hospital Minimum Service Standards (MSS) of  $\leq 2\%$ . In 2013, the incidence of conventional X-ray damage in the Radiology Unit of BDH Hospital in Surabaya City has decreased but has not yet reached MSS. The average number of X-ray damage from January 2012 to September 2013 was 2.71%.

The quarterly report on the Radiology Unit of BDH City Hospital in Surabaya in 2013 stated that the causes of conventional X-ray damage were thought to have come from human error and damage to the machine, which resulted in the film being refused to be read. Based on the causes of damage to conventional X-rays, the Radiology Unit of BDH Hospital in Surabaya added CR (Computed Radiography) machines in July, but the decline in the incidence of conventional X-rays did not occur. It can be seen that the addition of a new tool in the Radiology Unit of BDH Hospital in Surabaya is not a solution to the problem of conventional X-ray damage.

This study aims to analyze the internal constraints and policy constraints at the conventional X-rays in the Radiology Unit of BDH Hospital in Surabaya.

### Method

This research is an analytic research with an observational approach. The research variable is measured cross-sectionally so that it is obtained an overview of the conditions and activities at that time. The measurement technique in this study uses a Likert scale measurement technique<sup>7</sup>. The unit of analysis in this study was the Radiology Unit in BDH Hospital Surabaya City. The population in this study is the radiology workforce at the BDH Hospital in Surabaya City which deals directly with the production process and supplier of conventional X-ray photo production materials. The research subjects consisted of 9 respondents consisting of 6 radiographers, 2 darkroom officers, and 1 procurement officer.

Variable constraints at the conventional X-ray taking stage are identified by combining the Theory of Constraints proposed by Goldratt and Cox<sup>4</sup>, types of constraints based on Fogarty, Blackstone, and Hoffman; Schragenhim and Dettmer<sup>8,9</sup>. This research identifies constraints only limited to internal constraints and policy constraints in accordance with Goldratt and Cox<sup>4</sup>. Internal variables constraints are measured using sub-variable resources constraints and knowledge constraints.

Variable policy constraints are measured using sub-variable internal policy constraints. Measurement results from variable internal constraints and policy constraints are in the form of categories instead of constraints and constraints.

## Result and Discussion

### Resources Constraints on Conventional X-ray:

Resources constraints are defined as constraints derived from human resources (HR) and machines owned by the organization. This constraint can be in the form of the ability of production input factors such as raw materials, labor, and machinery<sup>10</sup>. The results showed that sub-variables resources constraints in the conventional X-ray photo-taking stage were included in the categories, not constraints (such as: "Table 1"). This is in line with research Lusthaus *et al.*,<sup>11</sup>, organizational performance is influenced by three main factors and one of them is organizational capacity.

Limits that prevent the system from achieving its objectives can be physical or non-physical. Physical constraints in the form of resources, raw materials, or supplies, they are relatively easy to identify by carrying out capacity analysis. However, if the constraints are non-physical, such as policies, behavior, or actions, they will be more difficult to identify<sup>12</sup>. According to Robbin<sup>13</sup>, there are 3 factors that support HR to achieve high performance, namely motivation, ability, and opportunity.

Table 1 shows the radiographer's motivation at BDH Hospital in Surabaya City is not a constraint at the conventional X-ray photo-taking stage. The results of the assessment agree with Hakim and Wuryanto<sup>14</sup>, who stated that employees with low motivation to work will also have a low commitment to do work. Employee Performance Improvement can be done by stimulating aspects that make him want to take more action to increase work productivity. However, in contrast to the results of Akbar<sup>15</sup>, motivation is the only variable that has a significance for weak influences. This shows that motivation does not play a strong role in explaining the increase or decrease in the performance of civil servants who work in the Tambaksari Subdistrict, Surabaya.

One factor that influences employee performance in a company is the development of a career in the company<sup>16</sup>. Career development will make employees happy at work so that the impact on performance improvement. The results of this study indicate that the

guarantee of the development of a radiographer's career at BDH Hospital in Surabaya City is not a constraint at the stage of conventional X-ray imaging.

According to Toha<sup>17</sup>, ability is one element in individual maturity that is related to knowledge or skills that can be obtained from education, training and an experience. The results of this study indicate that the radiographer's ability in BDH Hospital in Surabaya City is not a constraint at the conventional X-ray photo-taking the stage (as shown in Table 1). The results of this study are supported by an of Akbar<sup>15</sup>, that there is a strong influence between the level of ability level on the performance of civil servants in Tambaksari Subdistrict, Surabaya.

Basically, the organization does not only need capable and skilled workers but workers who can work harder and want to achieve optimal results and are in line with organizational goals. The ability to work for employees is an expertise that employees have when doing their work<sup>18</sup>. Table 1 shows the respondent's assessment of the dimension of opportunity at the X-ray taking stage obtained a total of 36 points and did not become a constraint on the organization.

To measure the effectiveness of production equipment companies often use overall equipment effectiveness (OEE)<sup>19</sup>. Assessment of the dimensions of the machine obtains the number of values 4 (as shown in Table 1). This is based on the calculation of the value of  $OEE = Availability \times Performance\ rate \times Quality\ rate$  is obtained by 92.9%. Based on the results of the research, it can be seen that the measurement of the effectiveness of conventional X-ray machines using the OEE method has exceeded the ideal standard of OEE JIPM (Japan Institute of Plant Maintenance), which is 84%.

The results of the study, it was found that the conventional X-ray machine in the Radiology Unit at BDH Hospital in Surabaya City did not become a constraint in the conventional X-rays. The results differ from the opinion of Goldratt<sup>20</sup>, which states that machines are one source that limits the flow of production. The machine can limit product flow due to the possibility of production flow imbalance which causes the bottleneck machine.

#### **Knowledge Constraints on Conventional X-rays:**

The results showed that the sub-variables of knowledge constraints in the conventional X-rays were included in the constraints category at the conventional X-ray

photo-taking stage (such as: "Table 1"). This results are supported by the statements of Schragenhim and Dettmer<sup>9</sup>, that constraints resources, knowledge constraints, and policy constraints have the potential to become constraints on all types of organizations.

Based on the results of the study it can be seen that the low total value in the sub-variable knowledge constraints in the Radiology Unit of BDH City Hospital of Surabaya due to the absence of policies that directly regulate knowledge management. The results of this study are in line with the research conducted by Tian, Cai, and Jiang<sup>21</sup>, the support of knowledge management organizations, knowledge management of organizational learning, and organizational support for organizational learning can significantly have a positive effect.

Table 1 shows that the lowest total value of knowledge constraints sub-variable in the conventional X-ray photo taking is competency indicator. This is because there is no training directly related to knowledge management in the Radiology Unit of BDH Hospital in Surabaya City. Knowledge management is the process of developing the knowledge and skills of each individual in an organization<sup>22</sup>. Hospital management must improve education and training programs, because with higher levels of education and training able to improve the performance of employees who will have a very positive influence on improving service quality. Education and training have a significant influence on performance<sup>23</sup>.

#### **Internal Policy Constraints on Conventional X-rays:**

According to Fogarty, Blackstone and Hoffman<sup>8</sup>, Policies constraints are defined as constraints originating from within or outside which limit organizational performance to work processes. These constraints can take the form of laws, rules, or work procedures. Table 1 shows that the results of this study indicate that the sub-variable internal policy constraints in the conventional X-ray photo-taking phase are not constraints. The results of these studies differ from opinion Dettmer<sup>2</sup>, which states that policy constraints are more often a constraint to the organization to work processes when compared with other constraints.

Based on the results of the study, it was shown that the preparation of operational procedure standards (SOP) in the Radiology Unit of BDH Hospital in Surabaya City had paid attention to important criteria for improving performance results. The results of this study support

the opinion of Natasia, Loekqijanan and Kurniawati<sup>24</sup>, the Standard Operational Procedure (SOP) is defined as a standard that must be used as a reference in providing each service. This standard operating procedure can be used to assess the performance of each agency. A good

quality management system always uses SOP as a basis that will be socialized in advance to all competent parties to implement it. SOP is an instruction set that has the power as an instruction or directive that must be done to carry out the work process.

**Table 1. Assessment of Respondents Against Internal and Policy Constraints Variables at the X-ray Photograph Stage in the Radiology Unit of BDH Hospital Surabaya City 2014**

**Source:** Primary Data Results of the Research Questionnaire Process.

### Conclusion

Variable internal constraints do not become constraints in the conventional X-ray photo-taking stage. Sub variable resources constraints support service performance in the radiology unit. Motivation, opportunity, ability, and machine in the radiology unit support for the achievement of service performance. Whereas, sub-variable knowledge constraints become constraints at the stage of conventional X-rays. The absence of training for radiology officers to support low officer competency values. A policy related to knowledge management is needed by the management of BDH Hospital in Surabaya to support the process of developing knowledge and skills in the radiology unit. Knowledge management policies in the radiology unit are expected to improve service performance. Variable policy constraints with sub-variables internal policy constraints do not become constraints at the stage

of conventional X-rays. The preparation of standard operational procedures (SOP) in the Radiology Unit of BDH Hospital in Surabaya City has considered important criteria to be a support to improve performance results.

# Effects of Hyaluronic Acid and Silver Sulfadiazine in Laceration Wound on Wistar Rats

Vannes C.P. Sapan<sup>1</sup>, Jufri Latief<sup>2</sup>, Prihantono<sup>1</sup>, Arifin Seweng<sup>4</sup>

<sup>1</sup>Department of Surgery, <sup>2</sup>Orthopaedic Surgery Department, Faculty of Medicine, Hasanuddin University, Makassar, Indonesia

## Abstract

This study aimed to determine the effect of giving hyaluronic acid and silver sulfadiazine to the wound healing in Wistar rats. This research was an experimental study using post-test design with a control group consisting of 3 treatments groups, in which each group consisted of 3 male wistar (*Rattus norvegicus*) rats which were modeled for back incision of 3 cm and a depth 5 mm. Statistic test used Kruskal-Wallis test. All collected data were processed and analyzed using Statistical Package for the Social Sciences (SPSS) program version 22 with a significant statistic test result if P value was  $< 0.05$ . The results of the research indicate that PMN increased more rapidly in wounds given hyaluronic acid and silver sulfadiazine compared to treatment which is only given silver sulfadiazine on day 0 and day 6. The statistic results on day 0 showed a significant difference with a P-value = 0.027 and on day 6 with a P value = 0.027. In wound given hyaluronic acid and silver sulfadiazine, an increase in the number of fibroblasts is faster than that of treated with silver sulfadiazine and treatment of open wound without treatment on days 6 and 14. Statistic result on day 6 (P = 0.027) and day 14 (P = 0.027) indicates a significant difference. Granulation thickness that occurs in laceration wounds given hyaluronic acid and silver sulfadiazine and only silver sulfadiazine are still not formed on day 0 for all samples (3 samples). Granulation thickness is formed and thick on day 6 in each group compared to those treated with open treatment without treatment. Statistic results on day 6 (P = 0.027) indicates a significant difference and on day 14 (P = 0.051) all groups indicate a thin granulation which indicates a significant differences.

**Keywords:** *Hyaluronic Acid, Silver Sulfadiazine, Laceration Wounds.*

## Introduction

Definition of wound healing is a repair process of organ or tissue damage, especially skin. In wound healing, there were systemic processes that exceeded the damage itself. Previous research showed that there were stem cells and other progenitor cells involved in wound healing, so a wound healing process requires a broader perspective than only local organ damage. Wound healing is best to understand as a whole as organisms

respond to damage, without considering the location whether it is on skin, liver, or heart.<sup>1,2</sup>

There were 2 different processes related to wound healing to cause homeostasis remodeling process. The first one is various cellular matrix replacements as a patch to rearrange physical and physiological continuance of damaged organ. This process caused scar formation. The second process is a recap of the damaged organ reformation. Initial organ architecture was rebuild/reformed again by reactivating cell formation. This process was called regeneration. Wound healing can be divided into 3 phase, which is the inflammation phase, proliferation, and remodeling phase.<sup>1,3</sup> Some researchers also divide wound healing into 4 steps.<sup>4,5,6</sup>

Wound healing is a complex biological cascade consist of several sequential events aimed to restore

damaged tissues. Extracellular matrix component plays an important role in the regulation of all the tissue repairing phase including cellular migration, inflammation, angiogenesis, remodeling, and scar/connective tissue formation. Researches have shown that extracellular matrix not only provides microenvironment for a wound but also involved in several signaling pathway activities that occurred on wound bed during the healing process. Hyaluronic acid is an extracellular matrix component with several unique characteristics which have an important role in tissue regeneration.<sup>7,8</sup>

Hyaluronic acid is a major component in the extracellular matrix and has been shown to have a positive effect in wound healing. On the other side, silver sulfadiazine is an anti-microbial agent that's very effective for most type of bacteria and has been used widely as the main component in dressings for burn injury.<sup>9</sup>

Silver sulfadiazine is a sulfonamide based ointment with antibacterial and anti-fungal activity. Silver sulfadiazine work by combined activities of silver and sulfonamide. If these chemicals interact with body fluid that contains sodium chloride, the silver ion will be released gradually and sustained on the wound area.<sup>3</sup>

Hyaluronic acid and silver sulfadiazine are extracellular matrix component that plays a role in the wound healing process. Based on those facts, the researcher was interested to do a study which aimed to assess the effects of silver sulfadiazine plus hyaluronic acid ointment to wound healing in Wistar rats.

## Materials and Method

This research is an experimental study. It was done on 2 April – 26 April 2019, using 2 laboratories which are Hasanuddin University Animal Laboratory to nurture and experiment on the animal model, and Hasanuddin University Hospital Pathology Anatomy Laboratory to make histopathology slides. Subjects are

male albino Wistar (*Rattus Norvegicus*) rat, aged 2-3 months that weights 150-250 grams. Twenty-seven rats were acquired from Hasanuddin University Animal Laboratory, which allocated to 2 treatment groups and 1 control group, each consists of 9 rats.

**Inclusion criteria:** Male albino Wistar (*Rattus Norvegicus*) rat, aged 2-3 months, weights 150-250 grams, and in healthy condition.

**Exclusion Criteria:** Biopsy sample damaged, wound infection, and subjects died before the research period is over.

Assessing the effect of timing to give topical hyaluronic acid and silver sulfadiazine ointment or topical silver sulfadiazine ointment only was done using histopathological examination to evaluate changes on damaged skin tissue structure after burn injury. Histopathological examination was carried on day 0, day 6, and day 14.

**Data Analysis:** All data were collected and analyzed using Statistical Package for the Social Sciences (SPSS) program version 22 with P value < 0.05 in statistic analysis was considered statistically significant. The measurement result will be presented in narration, graphics, tables, and figures. Data analysis was done using Kruskal-Wallis test.

## Results

**Sample Characteristics:** Research subjects were 27 rats which allocated to 2 treatment groups and 1 control group, each consists of 9 rats. Subjects' wound in group 1 was treated with a topical agent containing hyaluronic acid and silver sulfadiazine. Subjects' wound in group 2 was treated with a topical agent containing silver sulfadiazine. The wound in group 3 (control) was kept open without any treatment. Each group will then be assessed on day 0, day 6, and day 14 after treatment, as seen in Table 1.

**Table 1. Sample Distribution**

		Group			Total
		Silver Sulfadiazine	Hyaluronic Acid + Silver Sulfadiazine	Control	
Time (Day)	0	3	3	3	9
	6	3	3	3	9
	14	3	3	3	9
<b>Total</b>		<b>9</b>	<b>9</b>	<b>9</b>	<b>27</b>

Comparison of PMN amount based on group and treatment time toward wound healing shows that an initial assessment, PMN number was found significantly higher in HA + SS group (55.7) and lowest in control group (25). Post hoc test shows that mean PMN amount in the HA + SS group was significantly higher compared to SS group and control group, and mean PMN amount in the SS group was significantly higher compared to the control group. On day 6 assessment, mean PMN amount was significantly higher in the HA + SS group and lowest in the control group. Post hoc test shows that mean PMN amount in the HA + SS group was significantly higher compared to SS group and control group, and mean PMN amount in the SS group was significantly higher compared to the control group. On day 14 assessment, mean PMN amount was significantly higher in the HA + SS group and lowest in the control group. Post hoc test shows that mean PMN amount in HA + SS group was significantly higher compared to SS group and control group, and mean PMN amount in SS group was significantly higher compared to control group, as seen in Table 2.

**Table 2. PMN comparison based on Group**

Variable	Group	n	Mean	SD	P
PMN 0	SS	3	42,0	4,4	0,027
	HA + SS	3	55,7	5,1	
	Control	3	25,0	2,0	
PMN 6	SS	3	93,3	3,2	0,027
	HA + SS	3	117,3	6,1	
	Control	3	59,7	1,5	
PMN 14	SS	3	52,3	4,0	0,027
	HA + SS	3	81,0	3,6	
	Control	3	31,7	1,5	

Comparison of fibroblast amount based on group and treatment time shows that an initial assessment, fibroblast number was found significantly higher in HA + SS group (25.0) and lowest in the SS group (9.3). Post hoc test shows that mean fibroblast amount in HA + SS group was significantly higher compared to the SS group and control group, while the mean fibroblast amount in SS group was similar to the control group. On day 6 assessment, mean fibroblast amount was significantly higher in the HA + SS group and lowest in control group. Post hoc test shows that mean fibroblast amount in the HA + SS group was significantly higher compared to the SS group and control group, and mean fibroblast amount in the SS group was significantly higher compared to control group. On day 14 assessment, mean fibroblast

amount was significantly higher in HA + SS group and lowest in control group. Post hoc test shows that mean fibroblast amount in HA + SS group was significantly higher compared to SS group and control group, and mean fibroblast amount in SS group was significantly higher compared to control group, as seen in Table 3.

**Table 3. Fibroblast comparison based on group**

Variable	Group	n	Mean	SD	P
Fibroblast 0	SS	3	9,3	2,1	0,044
	HA + SS	3	25,0	6,2	
	Control	3	12,0	2,0	
Fibroblast 6	SS	3	52,7	2,5	0,027
	HA + SS	3	89,7	2,5	
	Control	3	32,7	2,1	
Fibroblast 14	SS	3	61,7	3,5	0,027
	HA + SS	3	107,0	6,0	
	Control	3	50,0	4,6	

Comparison of granulation thickness based on group and treatment time shows that an initial assessment, there hasn't been any granulation tissue on every group. On day 6 assessment, granulation thickness was significantly higher in the HA + SS group (3.5) and lowest in the control group (1.5). Post hoc test shows that granulation thickness in the HA + SS group was significantly higher compared to the SS group and control group, and granulation thickness in SS group (2.9) was significantly higher compared to control group. On day 14 assessment, there was no significant difference in granulation thickness for HA + SS group and SS group. Post hoc test shows that granulation thickness in HA + SS group was significantly higher compared to control, and granulation thickness in the SS group was significantly higher compared to the control group, as seen in Table 4.

**Table 4. Granulation thickness comparison based on group**

Variable	Group	n	Mean	SD	P
Granulation 0	SS	3	0,0	0,0	-
	HA + SS	3	0,0	0,0	
	Control	3	0,0	0,0	
Granulation 6	SS	3	2,9	0,2	0,027
	HA + SS	3	3,5	0,2	
	Control	3	1,5	0,2	
Granulation 14	SS	3	2,2	0,3	0,051
	HA + SS	3	2,2	0,3	
	Control	3	1,2	0,2	

## Discussion

In this research, subjects were 27 rats which allocated to 2 treatment groups and 1 control group, each consists of 9 rats. Results show that PMN amount in wound treated with hyaluronic acid and silver sulfadiazine were higher on day 0 (mean 55.7) and day 6 (mean 117.3) compared to the wound treated with silver sulfadiazine only on day 0 (mean 42.0) and day 6 (mean 93.3). Statistic result on day 0 showed significant difference with P value 0.027 and on day 6 with P value 0.027.

Polymorphonuclear (PMN) is the first cell to migrate to wound site. The amount will increase dramatically and reach its peak in 24-48 hours. Its main function is for bacterial phagocytosis. Increased blood vessels permeability, local prostaglandin production, and presence of chemotactil component such as complementary factor, interleukin-1 (IL-1), tumor necrosis factor- $\alpha$  (TNF- $\alpha$ ), TNF- $\beta$ , platelet factor 4, or bacterial byproducts will all stimulate neutrophil migration.<sup>3</sup>

As we all know, wound healing was divided into 3 phases which is inflammation, proliferation, and remodeling phase. Inflammation phase starts since the beginning of wound until day 5. Ruptured blood vessels in wound will cause bleeding and body will react/try to stop the bleeding by the haemostatic process. Haemostatic happened due to released thrombocytes that make blood vessels glued to each other. Thrombocytes will then adhere and degranulate, and then attracting inflammatory cells such as polymorphonuclear leucocytes (PMNs, neutrophil), and monocytes. Polymorphonuclear (PMN) cells are the first cell to migrate to the wound site. The amount will increase dramatically and reach its peak in 24-48 hours.<sup>3</sup>

Fibroblast was originated from undifferentiated mesenchymal cells, releasing mucopolysaccharide, glysin amino acid, and proline which were the main component of collagen fibers that held wound edge together. This research shows that the number of fibroblast in wound treated with hyaluronic acid and silver sulfadiazine will be higher in day 6 and day 14 (mean 89.7 and 107.0) respectively, compared to wound treated with silver sulfadiazine only in day 6 and day 14 (mean 52.7 and 61.7) respectively. While wound that was kept open without any treatment in day 6 and day 14 have each (mean 32.7 and 50.0). A statistical result from day 6 shows significant difference with P value 0.027, and on day 14 with P value 0.027.

This research shows that in all samples, granulation thickness in laceration wound treated with hyaluronic acid and silver sulfadiazine or with silver sulfadiazine only during day 0 haven't been formed yet (3 samples in each treatment group). Granulation will start to form and thickened during day 6 in each group compared to wound without any treatment. Statistical results from day 6 shows significant difference with P value 0.027, and on day 14 each group shows thin granulation which has significant difference with P value 0.051.

Angiogenesis is the basic steps in wound healing in which new blood vessels will be formed from the existing one. The new blood vessels will be involved in granulation tissue formation, providing tissues with oxygen and nutrients to grow. Angiogenesis happened at the existing blood vessels. In this type of angiogenesis, there were vasodilatation process and increased permeability from existing blood vessels tissue, ECM degradation, and endothelial cells migration.<sup>1,10</sup>

Hyaluronic acid has different properties, depends on its molecule size. It has been well documented that high molecular weight hyaluronic acid will show anti-inflammation and immunosuppressive properties, while low molecular weight hyaluronic acid have pro-inflammation properties.

Researches have shown that smaller hyaluronic fragment will increase expression and induction of several chemoattractant cytokines which will increase inflammation cells inside the wound.

Hyaluronic acid will fasten fibroblast growth inside the collagen matrix, estimated by tubulin synthesis, a very important substance in fibroblast differentiation inside matrix collagen. Hyaluronic acid was also a substrate that facilitates fibroblast migration inside the extracellular matrix.

All of the things mentioned above were consistent with previous research which stated that the combination of topical hyaluronic acid and silver sulfadiazine will increase PMN and fibroblast number, as well as reinforce granulation tissues. It was also consistent with the research stated that PMN amount was higher in day 6 compared to day 14, when in early inflammation phase high molecular weight hyaluronic acid was dominant, giving anti-inflammation effect.

Silver sulfadiazine can reduce bacterial density on wound edge and inhibit negative gram bacteria

colonization, so silver sulfadiazine supplementation to wound was believed to be able to reduce wound infection expected to fasten wound healing without any obstruction, appropriate with its phase.

### Conclusion

The combination of hyaluronic acid and silver sulfadiazine topical was better in the wound healing process compared to silver sulfadiazine alone and untreated wound care by triggering the inflammatory and proliferative processes and increasing granulation.

## Abstract

**Background:** Breast cancer is the commonly diagnosed cancer among women globally and the major reason of deaths related to cancer in developing world, although breast cancer in young women is less common and often overlooked, it is still considered a major health concern. This study aimed to study breast cancer among young Iraqi women.

**Methodology:** A retrospective study done on 50 diagnosed breast cancer cases below 40 years during period of 2017 and 2018 among women records of attendees to women health center in AL-ELWYIA maternity teaching hospital.

**Result:** Out of total diagnosed breast cancer case during period of 2017 and 2018 (264), 50(18.9%) patients were below 40 years. the peak age at presentation ranged from 35-39 years (50%), family history was detected in 24% of cases, early menarche before age of 12 years was detected in 26% of cases, 68% of patients presented with painless palpable mass, stage 2 disease were recognized in 76% of the studied sample and 86% were ductal in origin.

**Conclusion:** The breast cancer among young Iraqi women under 40 years had high incidence rate but might be less aggressive than what was reported in western countries.

**Keywords:** Breast cancer, incidence, young age, Baghdad, Iraq.

## Introduction

Breast cancer is the most common malignancy among the Iraqi population constituting one third of the registered female cancer and 17.8% are diagnosed in patients under 40 years<sup>(1)</sup> Although the diagnosis of breast cancer is much less common in women under the age of 40 years, it remains a great challenge to patients, families and health care providers and it can have a

greater impact than in older women<sup>(2,3)</sup>. In woman under 40 years of age, delay breast cancer diagnosis is a common problem due to various factors such as a lack of information about the disease and consequent delay in seeking medical care, lack of screening programs in this age group, and fast tumor growth and pattern of breast parenchyma, which can hinder the identification of lesions both on clinical examination and on certain imaging method<sup>(4,5)</sup> so the Knowledge of the clinical and imaging forms of breast cancer in young woman and correlation with the pathological finding of these cancers is important for improving the detection of mammary lesions in this group<sup>(6)</sup>. Tumors in young women are more likely to be of a higher histological grade<sup>(7)</sup> and to be classified as estrogen receptor and progesterone receptor negative<sup>(8,9)</sup>. In addition, young women are more likely to have local recurrences, to be diagnosed

---

Senior Resident, AL-Alwiyaa Maternity Teaching Hospital, Women Health Center  
e-mail: Venusaltaie@gmail.com

at a more advanced stage, and to have an inferior 5 year survival compared to their older premenopausal counterparts<sup>(9,10)</sup>.

The differences in tumor characteristics and clinical outcomes suggest that breast cancer arising in young women may be a distinct clinical entity. A study by Anders and colleagues<sup>(8)</sup> looked at tumor gene expression between two age specific cohorts (young, ≤ 45 years; and older, ≥ 65 years), and identified 367 gene sets that could differentiate tumors in young women from tumors in older women. This suggests that breast cancer in young women may be distinct with a unique underlying biology<sup>(11)</sup>.

**Objectives:** To describe the clinical profile, image findings and pathological aspects of breast cancer in young women, to enhance early detection of cancer in young Iraqi women.

### Patients and Method

A retrospective study done among women records of attendees to women health center in AL-ELwya maternity teaching hospital. The required data obtained from the information system data base during a 2-years period starting from January 2017 and December 2018. 50 patients were enrolled in this study, patients proved to have breast cancer by histo-pathological study. The evaluated variables included age at diagnosis, marital status, age of menarche, number of parity, history of lactation, and first degree family history of the breast cancer, clinical presentation, clinical and radiological diagnosis were also recorded. Statistical analysis was performed and different variables were analyzed.

### Result

A total of 50 breast cancer patients below 40 years were enrolled in this study, the mean age of patients was 33.8(±3.7) years, 50%(25) of patients were between 35-39 years, figure 1.

**Figure 1: Age distribution of studied patients.**

Study of some risk factors showed, 76%(38) were married and from those 12%(6) had one or two child and 76%(38) had three or more children, only 4%(2) of patients had age of menarche more than 14 years. 24% (12) had positive first degree family history and 86%(43) of patients had lactation history more than 6 months, table -1.

**Table 1: Risk factors for studied group.**

Variable	Number (%)	
Marital Status	Married	38(76%)
	Divorced	5(10%)
	Single	4(8%)
	Widow	3(6%)

Variable	Number (%)	
Parity	Nil	6(12%)
	≤2	6(12%)
	≥3	38(76%)
Menarche Age	≤11 years	13(26%)
	12 or 13 years	35(70%)
	≥14 years	2(4%)
Family History	+ve	12(24%)
	-ve	38(76%)
Lactation History	+ve	43(86%)
	-ve	7(14%)

The ultrasound finding of those patients revealed that 76%(38) of patients had only mass, the mass was

in UOQ among 70%(35) of patients and no one patients had lesion in both breast, table -2-

**Table 2: Ultrasound finding of studied patients.**

Variable	NO (%)	
Ultrasound finding	Mass	38(76%)
	Mass with associated features	12(24%)
Site of tumor	UOQ	35(70%)
	UIQ	7(14%)
	LOQ	0
	LIQ	1(2%)
	Retroareolar	6(12%)
	More	1(2%)
	Laterality	Right breast
	Left breast	14(28%)
	Both	0

Majority of patients had stage II breast cancer (76%) and only one patient had stage IV and I. Grade

2 represent 78%(39) of studied patients and invasive ductal carcinoma found in 86%(43) of patients, table -3-

**Table 3: Histopathological finding of studied patients.**

Variable	NO(%)	
Tumor stage	Stage I	1(2%)
	Stage II	38(76%)
	Stage III	10(20%)
	Stage IV	1(2%)
Tumor grade	Grade 1	1(2%)
	Grade 2	39(78%)
	Grade 3	10(20%)
Histopathological type	Invasive Ductal carcinoma	43(86%)
	Invasive Lobular carcinoma	7(14%)
	Other	0

The clinical presentation of studied patients was showed that 68% (34) of patients had lump and 42%(21) of patients had pain, other showed in figure 2.

**Figure 2: Clinical presentation of studied patients.**

**Discussion**

Breast cancer incidence increases with age with vast majority of women being diagnosed after age of 40 years<sup>(11)</sup>, the comparison of clinic-pathological and radiological features of breast cancer arising in young women with those older ones has been the subject of discussion in several studies<sup>(12)</sup>. In the present study we have chosen to define early onset breast cancer when

diagnosed at age of 40 years and younger, breast cancer is described as young women disease in Arab World and other developing countries<sup>(13,14)</sup> compared to that observed in Western countries in which the median age for breast cancer is a decade younger and approximately two third of patients are aged under 50 years<sup>(15)</sup> this may be due to clear social, economic and population differences. A total of 264 breast cancer patients were

enrolled in this study 81.1% were 40 years and above while 18.9% were below 40 years. The latter is slightly lower than other Asian countries such as Korea<sup>(16)</sup>, Iran<sup>(17)</sup> and Saudi Arabia<sup>(18)</sup> but is significantly higher than that of western population<sup>(19)</sup>. This suggest the possibility that certain differences in pathogenesis of breast cancer may exist between young Iraqi patients and women in western population these differences may be related to race, social background factors, dietary habits, economic development level and environmental exposure among other. In this study 76% of our patients were married or had married. Married women were more likely to receive a breast examination within the last years than single (never married) or no longer married women<sup>(20)</sup>. 76% of those below 40 years had 3 or more child, Rodriquez et al found that women aged less than 35 years with early child bearing and multiparty are risk factors probably due to short term elevation in breast cancer risk for several months immediately following a birth<sup>(21)</sup>. In this study 26% of those below 40 years had early menarche before age of 12 years in compare to Najmeh et al who found that 17.6% of patients had early menarche which is considered one of the possible risk factors of breast cancer<sup>(22)</sup>. Presence of familial background has been identified as an important risk factor for developing breast cancer at an early age and to be suggestive of hereditary syndrome<sup>(23)</sup>. In this study 23.5% of those below 40 years had positive family history of breast cancer in accordance with previously reported data from sidoni et al study who found that (24%) of patients below 40 years had positive family history<sup>(24)</sup>, larger series have reported much higher proportions up to 48%<sup>(25)</sup>, while McAree et al study reveals only 13.4% had a positive family history<sup>(26)</sup>. Antoniou et al found that breast cancer at an early age is more likely to be associated with an increased familial risk, especially in women harboring a BRCA1 mutation<sup>(27)</sup>, however BRCA1 analysis was not available in our center at time of study there for the relationship between a positive family history and a positive BRCA1 mutation not properly assessed, the genetic component should be more explored, since genetic studies including young women are very scarce nationwide and there is insufficient data to provide conclusive evidence. Currently, there no routine screening program in Iraq for women less than 40 years of age for that reason most women in this age group are symptomatic and presented mostly with palpable lump. The examination finding in this study were palpable lump in 68%, axillary node, skin changes no breast cancer diagnosed in a

symptomatic women which in agreement with Agnese et al that reported that young patients under 40 years were much more likely to present with palpable lump 70%<sup>(28)</sup>. Ultrasound study reveals that 76% of patients presented with mass. Histo-pathological review of the sample of the study revealed that 86% of breast cancer were ductal (invasive ductal carcinoma) in compare to Cj Fisher et al. who found that 88% of those aged below 40 years were ductal<sup>(29)</sup> and McAree et al. found that 85.5% of breast cancer were invasive ductal type<sup>(26)</sup>. In this study 20% of patients are diagnosed at grade 3 which is lower than the result of Abdullateef et al. who found that 32.8% of patients below 40 years were grade 3<sup>(1)</sup> and also lower than the result obtained by fernandopulle et al. study that identified that 60% of patients are grade 3 in young Asian women<sup>(30)</sup> the later tumor grade at diagnosis might be related to delay diagnosis in young patients, which can be explained by work pressure or low index of suspicion by the patients and primary physician. **Conclusion:** The breast cancer among young Iraqi women under 40 years had high incidence rate. Larger studies are warranted to confirm our findings. We have to increase awareness of women regarding this disease and start screening to high risk patients in this age group.

**Ethical Clearance:** Taken from the Arabic Board of Health Specialization.

# How Do School Nurse Programs Influence Premarital Sexual behavior In Adolescents?

Wenny Artanty Nisman<sup>1</sup>, Yayi Suryo Prabandari<sup>2</sup>, Ova Emilia<sup>3</sup>, Elsi Dwi Hapsari<sup>1</sup>

<sup>1</sup>Lecturer, Pediatric and Maternity Nursing Department, Faculty of Medicine, UGM, Yogyakarta, <sup>2</sup>Lecturer, Health Behavior, Social Medicine, and Environment Health Department, Faculty of Medicine, UGM, Yogyakarta, <sup>3</sup>Lecturer, Obstetric Gynecology Department, Faculty of Medicine, UGM, Yogyakarta

## Abstract

**Background:** Teens are very vulnerable to premarital sexual behavior. The impact includes unwanted teen pregnancy and sexually transmitted infections. Prevention efforts need to be done effectively and one important way is through school nurse programs.

**Objective:** This study aimed to identify the effects of school nurse programs on prevention premarital sexual behavior.

**Method:** This research was a quantitative, quasi-experimental study with a nonequivalent (pretest and posttest) control group design. This research was conducted in two schools from January to February 2017. Schools were determined based on preliminary studies with predetermined criteria. Determination of School A as the intervention group and School B for the control group used a simple random sampling method. The purposive sampling method was used to select 68 students for the intervention group and 66 students for the control group. The data were analyzed by paired t-tests. Ethical approval was given with permit number Ref: KE/FK950/EC/2015.

**Results:** After the school nurse program, the values of healthy dating behavior, behavior of saying no to premarital sex and behavioral decision-making ability in the intervention group were higher than in the control group:  $0.200 \pm 0.42$  vs.  $-0.203 \pm 0.20$ ,  $p = 0.000$ ;  $0.193 \pm 0.40$  vs.  $0.032 \pm 0.43$ ,  $p = 0.029$ ; and  $0.032 \pm 0.18$  vs.  $-0.251 \pm 0.23$ ,  $p = 0.000$  which were significantly difference ( $p < 0.05$ ). Meanwhile, there was also an increase in the value of self-efficacy in adolescents in both the intervention and the control groups:  $0.017 \pm 0.22$  vs.  $0.053 \pm 0.19$ ,  $p = 0.315$ , but the differences in the two groups were not significant.

**Conclusion:** School nurse programs can effectively reduce premarital sexual behavior, especially by increasing healthy dating behaviors, the behavior of saying no to premarital sex and behavioral decision-making abilities in adolescents.

**Keywords:** *Adolescents, premarital sexual behavior, school nurse program, self-efficacy, dating behavior.*

## Introduction

Premarital sexual behavior has a bad impact on adolescents. The number of adolescents who died from pregnancy and childbirth reached as many as 70,000 deaths<sup>1</sup>. Pregnancy and childbirth can cause teens to experience serious pregnancy complications. Complication rates will increase in gestational ages less than 15 years<sup>2</sup>. Adolescents are also at risk of unsafe abortion and 65% of adolescents have fistulas in their reproductive organs due to childbirth complications<sup>3</sup>.

Adolescents are also at risk of having sexually transmitted infections due to premarital sexual behavior. The number of sexually transmitted infections in female adolescents have a higher prevalence than male adolescents<sup>4</sup>. Adolescents are also a very vulnerable population to contract Human Immunodeficiency Virus/ Acquired Immune Deficiency Syndrome (HIV/AIDS). Very few teenagers who access and get services from health services for the prevention of these diseases. Adolescent knowledge of STD and HIV-AIDS is very

low, and adolescents who receive examinations for these diseases are extremely rare<sup>5</sup>.

The most important interventions for the prevention of pregnancy in adolescents are mostly done in schools, particularly in teenage classes. Several studies in the review reported that the intervention was also integrated with the school curriculum they received at school<sup>6</sup>. Kirby<sup>7</sup> state, there is a positive effect of school characteristics and school-specific programs on the prevention of risky sexual behavior.

School nurse programs have not been prevalent in Indonesia. School nurse as a nursing professional practitioner in charge of facilitating a positive response of child or adolescent development<sup>8</sup>. This study aimed to identify the effects of school nurse programs on preventing premarital sexual behavior as indicated by self-efficacy to prevent premarital sexual behavior, healthy dating behavior, saying no to premarital sex and decision-making behavior.

### **Material and Method**

This research was a quasi-experimental study with nonequivalent (pretest and posttest) control group design. This research design included an experimental group, that is group A and a control group, that is group B, in which both groups were selected without randomization. In both groups, pretest and posttest measurements were performed.

The sample of research was determined by School A in Jetis Subdistrict and School B in Tegalrejo Subdistrict because the number of teenage births in those sub districts were considered high in 2013. Both schools were selected based on preliminary studies conducted by researchers. Simple random sampling was conducted to determine which school would act as the intervention group and which school would be the control group.

The sample population for the research included students of the senior high school class X and XI in School A and School B. The inclusion criteria: the

students enrolled in School A and School B, still in class X and XI, who had dating experience, willing to be research respondents and attend personal and social skills training. Exclusion criteria: students who did not follow and complete the full range of personal and social skills training. Based on the results of the sample calculation with  $\alpha$  95% and  $\beta$  90%, the obtained minimum result of the sample size was 29.05. To anticipate the dropout sample, 10% of the total was added to a minimum of 32 samples per group. However, the implementation of this study included all students in class X, and XI who met the inclusion criteria<sup>9</sup>.

Students in the intervention group received school nurse programs, which contain adolescent reproductive health education through training in personal and social skills<sup>10</sup> provided by school nurses. The students in the control group received routine interventions from the public health center in the form of reproductive health education. School nurses are generalist nurses who have received special training on adolescent reproductive health education conducted by psychologists. The psychologists have had clinical experience in handling youth and are certified as trainers.

The instruments used in this study consisted of 4 instruments: 1) self-efficacy questionnaire to prevent premarital sexual behavior, 2) rubric for measuring healthy dating behavior, 3) observation checklist for measuring behavior of saying no to premarital sex, and 4) questionnaire to measure the ability to make decisions related to premarital sex. All measuring instruments have passed the tests of validity and reliability, tested in SMK C of Jetis Sub district which has similar characteristics with 145 respondents of the research, so the instruments were considered valid and reliable. Data were analyzed by unpaired t-tests to compare scores in each unpaired group and paired t-tests to compare scores in the paired groups. This research received approval from the Medical and Health Research Ethics Committee of the Faculty of Medicine Universitas Gadjah Mada with certificate number Ref: KE/FK/950/EC/2017.

**Discussion**

School nurse programs in the intervention group was not been able to provide meaningful improvement in self-efficacy compared with those who did not receive school nurse program. This result is possible because of unpredictable factors not seen by previous researchers. Factors that may affect adolescent self-beliefs include religiosity. The control group with a religious background at school makes the program activities of the students more religiously oriented. Provision of religious learning and learning on how to behave well individually and socially can affect the behavior of the students. Religious learning and behavioral learning in the control school involve socio-cultural factors that influence adolescent behavior. There is a relationship between religiosity with sexual activity<sup>11</sup>.

According to the theory of social learning, self-efficacy is a contributing factor that encourages behavior change. The self-efficacy theory explains that psychological intervention can change maladaptive behavior<sup>12</sup>. Self-efficacy is also associated with a desire to test for HIV and STD<sup>13</sup>. Similar studies also observed the effectiveness of HIV-AIDS peer education programs to improve adolescent knowledge and self-efficacy<sup>14</sup>. Health education concerning sexuality helps nursing students to increase their knowledge, and explore their values and feelings about sexuality<sup>15</sup>.

The intervention group experienced an increase in healthy dating behavior, while the control group actually decreased. Dating for teenagers is also a time for recreation and a chance to have fun<sup>16</sup>. Dating is often associated with both positive and negative outcomes<sup>17</sup>. For healthy dating behavior, the most desirable outcomes are non-sexual intercourse or interventions for preventable teenage pregnancy.

The results showed an increase in the behavior of saying no to premarital sex in the intervention group, while in the control group this behavior actually decreased. The behavior of saying no to premarital sex is a change in individual behavior that will occur after being given special stimulation of the environment. This environment also enables teenagers to practice their behavior, as provided in personal and social skills training. Personal and social skills trainings also support special competencies for adolescent reproductive health, increasing adolescent self-efficacy and self-belief<sup>18</sup>.

The development of life skills helps teens to translate knowledge, attitudes and values into healthy behaviors, such as reducing health risks and adopting health behaviors that improve their quality of life in general<sup>19</sup>. The behavior of saying no to premarital sex or refusal skills according to Mellanby et al<sup>20</sup>. is one of the innovative intervention programs developed from social learning theory, where the goal is to create an

environment that can change behaviors that can stimulate changes in individual behavior. Tortorelo et al<sup>21</sup> study provides intervention in the form of safer choices where one of the outcomes is self-efficacy to declare no to premarital sex.

The provision of school nurse programs can improve two to three items of decision-making behavior more in the group who received the intervention compared with the group who did not. Behavioral decision-making ability is one component of life skills that is included in cognitive skills. Behavioral component of decision-making ability is very important in engaging in healthy activities<sup>22</sup>. Teens become capable of making complex decisions involving many factors. Some examples of factors involved in decision-making are the current desires and long-term goals, the desires of oneself and the desires of others<sup>23</sup>.

The results of this study indicated that the comparison of the average difference in the behavior of decision-making ability showed a significant difference between the intervention group and the control group. The interventions in nursing services in schools aimed to train adolescents to be able to make decisions appropriately. The situational context given in the stimulation is quite diverse from experiences with friends at school, at home, dating experience, relationships with friends, teachers and parents.

Based on the theory of cognitive control in adolescents, it is explained that the presence of cognitive control enhances the behavior of decision-making ability with long-term effects affecting the academic achievement of adolescents<sup>22</sup>. The effectiveness of the influence of an intervention on the behavior of adolescent decision-making ability can be seen in previous research by Knight et al<sup>23</sup>. The behavior of decision-making involves three tasks that relate to each other: first the normative analysis is to identify the influence that might be involved in a decision. Second is descriptive studies, i.e. individual characteristics associated with the decision can be compared with normative analysis. Third, prescriptive intervention will help someone to bridge the gap of differences in understanding.<sup>24</sup>

### Conclusions

School nurse programs involving personal and social skills training, can change the value of healthy dating behavior, behavior say no to premarital sex and behavioral decision making about premarital sex in the

intervention group is higher than the control group, with significant differences in values statistics.

# Women's Involvement in Decision Making and Unmet Need for Contraception In Indonesia

Yunita Amraeni<sup>1,2</sup>, Sudijanto Kamso<sup>3</sup>, Sabarinah B. Prasetyo<sup>3</sup>

<sup>1</sup>Higher Education Institution of Health Mandala Waluya, Kendari, <sup>2</sup>Doctorate Student, Faculty of Public Health, Universitas Indonesia, <sup>3</sup>Department of Biostatistics and Population Studies, Faculty of Public Health, Universitas Indonesia

## Abstract

**Background:** The issue of gender inequality in reproductive health has a role in determining contraceptive use in women. Gender issues related to inequality in decision making are the main context in family planning interventions. The purpose of this study is to assess women's participation in decision making and its relation to unmet need.

**Method:** A cross-sectional study was conducted using IDHS data in 2012. The study involved 1516 women of childbearing age (15-49 years) with married categories in areas with high unmet need (West Papua) and the lowest unmet need area (Bangka Belitung).

**Results:** Married women in the Bangka Belitung region have more power in decision making than married women in West Papua. Involvement in economic matters and the decision to use contraception as the most dominant factor and involvement in the household have a significant relationship with the occurrence of unmet need, as well as education, wealth, and experience in using contraception related to unmet need. While age, fertility preference, husband's desire to have children, and involvement in health and mobility were not directly related to unmet need.

**Conclusions:** Better participation in decision making is higher for women in the Bangka Belitung region than in Papua. Empowerment of women in terms of the economy and the use of contraception needs to be improved so that they have power in decision making.

**Keywords:** *Unmet Need, Modern Contraception, Decision Making, Involvement.*

## Introduction

Contraceptive use is one of the government's policies to reduce the total fertility rate. Decline in TFR was not followed by a decrease in unmet need. Based on the 2012 IDHS data, the unmet need figure is still stagnant at 11%. Unmet need disparities still occur in every province in Indonesia. The highest unmet need reached 23.7% in the West Papua region while the lowest unmet need was in Bangka Belitung with a figure of 5.6%<sup>6</sup>. This is thought to have social and cultural influences that influence decisions in family planning.

Unmet need is associated with client needs that have not been fulfilled regarding the expectation of being able to delay pregnancy or the desire to be able to limit

pregnancy. The desire to fulfill these needs is based on the desire/unwillingness to have children, determine the ideal number of children and use contraception<sup>21</sup>. Related to the existence of gender issues, it shows the occurrence of inequality in terms of equality of reproductive rights. This can be seen in the differences in the desire/unwillingness to have children, the determination of the ideal number of children and contraceptive use between men and women as couples who should have a joint decision on this matter<sup>14,15</sup>.

Based on the desire to have children, almost 50% of married women say they do not want to have more children (including those who have been sterilized). But around 15% of women show the fact of pregnancy

when they don't/don't want children<sup>6</sup>. The desire to have children and determine the ideal number of children greatly affects the subject of contraceptive use. To achieve this desire, men and women must have a decision to use contraception or not to use<sup>11</sup>.

Indonesia is one of the developing countries that is still influenced by social and culture which places women in a position below men<sup>14</sup>. This affects women's participation in making decisions in all aspects. Indonesia is a patriarchal society that believes that women are inferior to men<sup>23</sup>.

This is supported by The Conference on Population and Development (ICPD) in Cairo 1994, a testament to the commitment of the international community on issues of gender, population and development with a new perspective. Decisions in contraceptive use and fertility are thought to be the influence of gender inequality especially in patriarchal societies<sup>1</sup>. Studies in Ethiopia show male dominance of women leads to an increase in the number of children<sup>20</sup>. Studies in sub-Saharan Africa also illustrate that there are indications of decision-making problems that affect contraceptive use by women without their partners knowing<sup>3</sup>.

The disparity in the number of unmet need may be caused by the existence of a strong patriarchal system in several regions. Therefore, the aim of this study is to assess women's participation in decision making and its relation to unmet need in regions with high and low unmet need in Indonesia.

## Method

**Study area and setting:** The cross-sectional study was conducted using IDHS data in 2012. Data measurements were carried out in two regions, namely Bangka Belitung as the area with the lowest unmet need numbers and West Papua as the highest unmet need number.

**Sampling:** This study involved 1516 women of childbearing age (15-49 years) with married categories. Using data from the Indonesian Demographic and Health Survey (IDHS) in 2012, the research design used was cross sectional.

**Measurement:** Participation in decisions is an

independent variable measured using the autonomy index obtained based on the literature<sup>4,9,12,22</sup>. Questions related to participation followed the questionnaire in the Indonesian IDHS survey which included women's participation in decision making in terms of economy, household, mobility and health. Questions related to decision making are categorized as having high autonomy in decisions if women are involved in all aspects of decision making. Moderate autonomy if there is  $\leq 2$  decision aspect involvement and does not have autonomy in the decision if there is  $\leq 1$  decision aspect involvement. Contraceptive use is a dependent variable with unmet need categories and not unmet need. Unmet need is indicated if women have the desire to postpone pregnancy or do not want to have more children, but do not use any contraception to prevent pregnancy. Other variables that are indirectly related to women's decision participation will also be measured such as age, employment, education, resident, fertility preference, and wealth.

**Statistic Analysis:** Data was processed using Statistical Package for the Social Sciences (SPSS) software version 15.0. Univariable, bivariable and multivariable analysis was carried out. Chi square will be used to see the closeness of the relationship between variables and logistic regression test to identify the most significant of variable.

## Result

**Socio demographic characteristics:** Most of the respondents in the two regions were in the age group 25-29. The majority of married women have education at the primary and secondary levels in both regions. But in West Papua more women with higher education than in Bangka Belitung. While the economic level in West Papua is lower than Bangka Belitung (see table 1).

**Reproductive Health Characteristic:** Regarding contraceptive use, it turned out that the dominant women used traditional method to delay pregnancy in both groups. About 27.2% of women in Bangka no longer want children, while 22.8% still plan to become pregnant. In contrast, in West Papua, there are fewer women who do not want children (17%) compared to women who still want to add children (20.1%). For more details can be seen in table 1.

**Table 1. Socio demographic variabls of married women (N= 1516)**

	Bangka Belitung (%)	West Papua (%)	Total (%)
<b>Age Group</b>			
15-19	23(1,5)	33(2,2)	56(3,7)

Don't know	90(6,3)	220(15,4)	310(21,7)

**Decision making power in both area:** Overall, the power of decision making in the West Papua region is lower than Bangka Belitung. There were no significant differences in decision making in the aspects of health services, household and mobility in both groups. But in the economic aspect, the involvement of women in West Papua was lower (39.6%) compared to Babel (48.1%).

Likewise with the decision in contraception, as many as 27.8% of women in West Papua and 19.7% of women in Babylon were not involved in the decision.

**Factor Related unmet need of contraception:**

**Unmet need and socio demographic:**

Figure 1. Power of Decision Making on Married women in Bangka Belitung and West Papua, Indonesia 2012

**Unmet need and decision making:** Involvement in health service, household and mobility aspects in both groups showed that women without cases of unmet need had better involvement than unmet need groups. Similar to the low number of women’s involvement in these three aspects, there were more women who did not experience unmet need. There are 13.9% of women in the group without unmet need involved in economic matters while in the unmet need group only around 9%. And as much as 7.5% of women without unmet need have better involvement in contraception compared to 5.2% of the unmet need group.

Table 3. Unmet need and involvement decision making of married women (N= 1516)

Decision Making	No Unmet need	Unmet need	p value

Better involvement	0,007	1,90(1,19-3,03)
<b>Involvement in Contraception</b>		
Low involvement	0,000	1
Better involvement	0,000	1,80(1,30-2,48)

The results in this study to prove the assumption of participation or involvement of women in decision

making in all aspects are closely related to the incidence of unmet need.

The results of this study indicate that the dominant factor affecting the unmet need is the involvement of women in decisions in the economy and contraception. This is consistent with the research conducted by another research that Decision-making was found to be positively associated with contraceptive use and not having unmet need for contraception<sup>5,18</sup>.

Decisions in terms of economics influence decisions in contraceptive use, allegedly because finance affects authority. This is consistent with the study of Palamulenithat employment status factors influence contraceptive use in women<sup>19</sup>. This research is also found that there were no significant differences between the two regions in terms of decision making in health services and mobility. This is presumably because the government has been maximal in its efforts to equalize health both in terms of facilities and officers. While for decisions in terms of mobility, now it may have become a thing that is not rigid and taboo to do, so that cases of mobility related to visits to relatives and friends are not the dominant thing to discuss.

This study also found that low involvement in household-related decision making, economy and contraception was more dominant in the West Papua region. This is allegedly related to economic growth. This study found that the middle to upper class people based on wealth index were more dominant in the Bangka Belitung region. The situation of economic growth affects the economic level of the family. Possibly in the West Papua region, the status of work is more for men than women<sup>15</sup>. So that women in the region depend on their husband/partner's livelihood. This is also affects household decisions and contraceptive use.

Contraceptive use can be influenced by external factors related to the position of women in social life<sup>9,10</sup>. The assessment of women's position has been assessed by gender differences that place women and men in accordance with their functions and their respective roles<sup>2</sup>. Problems arise when there are gender inequalities that limit each other's rights<sup>13</sup>. Gender-based power inequalities can limit open communication between partners about reproductive health decisions and women's access to reproductive health services, which contributing to poor health outcomes The importance of partner communication is often emphasized in family

planning and research programs, this is the first step in making rational fertility decision processes<sup>17</sup>. In developing countries some women have low bargaining positions. In fact, women who are either under collective decision making with their partners or completely dependent on the decisions of male partners on the issue affect their reproductive lives<sup>8</sup>.

## Conclusion

The findings indicate that creating conditions for women who can improve their financial status by increasing women's empowerment in terms of economy can increase autonomy in maintaining the right to reproductive health itself. This research is limited by data available to measure women's empowerment. Other limitations of this study are uses cross sectional which cannot determine the temporal relationship between two variables.

**Source of Funding:** Ministry of Finance's research fund management agency.

**Conflict of Interest:** None declared

**Ethical Clearance:** Obtained from institutional ethical committee of Indonesia University.

## Abstract

Stroke is a major cause of long-term disability. It causes the patient to be family-dependent. Caring stroke patients is a burden for the family caregivers. They must adapt to the patient's condition and be able to handle the patient. Meanwhile, the stroke incidence is unpredictable so the family does not have time to prepare themselves in caring the patient. Thus, the hospital must be able to meet the educational needs of the family in caring stroke patients at home. This study aims to explore the educational needs of family caregivers in caring stroke patients at home. This study applies a qualitative approach and data analysis using Collaizi. This research was conducted through in-depth interviews on fifteen stroke family caregivers at Haji General Hospital, Surabaya. The results of this study indicated that the needs of stroke family caregiver education are: physical education (education about medical rehabilitation training at home, mobilization and transfer of patients, training of handling patients' ADL, signs, symptoms and risk of recurrent stroke); for psychological education and structured discharge planning education.

Keywords: *Stroke family caregiver, education, needs.*

## Introduction

The World Health Organization (WHO) defines stroke as rapidly developing clinical signs of focal (global) disturbance of cerebral function, lasting more than 24 hours or leading to death, with no apparent cause other than that of vascular origin. According to the World Stroke Organization, strokes have now become an epidemic in the world. Worldwide, stroke is the second leading cause of death. The current trend shows that the annual number of deaths will increase to 6.7 million in 2015 if no appropriate action are taken. Aside

from being a cause of death, stroke is a major cause of long-term disability.

Disability (physical disability) results in sufferers experiencing difficulties on their daily activities, therefore they need assistance<sup>1</sup>. Family support is expected to help patients optimize the rehabilitation phase of patients so that they can improve the quality of life for post-stroke patients<sup>[1]</sup>. However, family members carry the burden of continuous treatment for the stroke patients<sup>[2]</sup>. Stroke patients and their families often report that they have not been given enough information about strokes and feel unprepared for life after returning from the hospital. The results of a study conducted by Shyu et al (2008)<sup>[3]</sup> found that families of stroke patients often felt they were not prepared enough to meet the physical, cognitive, and emotional needs of stroke patients. The patient's family only received little informations in caring the patient at home. Nurses provide less information about things that relate to patients' daily needs and how families can overcome problems that arise. Therefore, researchers are interested to explore the educational needs of stroke family caregivers.

## Method

**Research Design:** The type of this research includes descriptive research with qualitative method, phenomenological approach. This phenomenological approach is to understand, explain and give deep meaning to the educational needs of the family caregiver about post-acute care for stroke patients at Hospital based on their perspective at the time this research was conducted. The study data was collected through in-depth interviews. The researcher also made field notes to comprehensively better ensure the completeness of the data.

**Sample:** This research was conducted in a hospital of East Java provincial government. Total of 15 stroke family care givers participated in this study. The participants consisted of fourteen women and one male. The age of participants varied from 25 to 68 years. The final education of participants in this study varied from high school to Bachelor's Degree.

**Data Analysis:** Data analysis was carried out using the Collaizi method. The order of data analysis were performing verbatim transcription, identifying the keywords, categorizing, determining sub-themes, conducting validation to participants and determining the final theme of the study.

## Result

One of the effects of stroke is the existence of limitations in carrying out daily activities. This is a burden for the family caregiver, as they have to help the patient's daily activities. Meanwhile, family caregivers have limitations in physical, knowledge and skills. Therefore, providing the family caregiver a proper education is very important. The results of the study found three themes, which were physical, psychological and structured discharge planning education needs.

**Physical Education Needs:** Education related to the patient's physical condition is the most needed requirement by the family caregiver. The physical education needed by family caregivers including: education about medical rehabilitation training at home, mobilization and transfer of patients, training of handling patients' ADL, signs, symptoms and risk of recurrent stroke.

**1. Medical rehabilitation training at home:** The majority of informants mentioned that they needed education about medical rehabilitation, i.e. how

to do the proper therapy on the legs, arms and communication for the patient. The excerpts from the interview are as follows:

"I want to get some information on how to practice lifting hands, they are heavy, right? So, how?" [Ik2, child]

"So, you know, it feels stiff to stand up. What do I have to do to make it easier to walk?" [Ik5, child]

"How to recover the way (the patient) talk? Is there a cure or exerciset to be back like normal?" [Ik11, wife]

### 2. Mobilization and transfer of patients:

Mobilization is assumed to be one of the things that health workers need to provide. Some informants said that they wanted to know how to practice walking and using a cane during walking exercises. The result of the interviews were as follows:

"My husband can already take a step, but I'm still afraid if he ask me to train him to walk. He uses a walking stick, so how to use it?" [Ik7, wife]

"She asked for a walk using a wheelchair later at home. I'm afraid she would fall when I put her on the wheelchair. I want someone to teach me how." [Ik9, husband]

"Usually, I just tilt (the patient) to the right because the left hand hurts. Of course I'm afraid when doing it. I want to be taught on how to tilt the body" [Ik4, child]

**3. Training and handling of patient's ADL:** Some informants complained about how to help assist patient's ADL. This is because patients were unable to carry out their own activities. An education about ADL assistance needed were how to help patients wearing clothes, how to bathe and how to feed the patients without making them choke.

"It's hard to help him wearing clothes because his hand can't move. What is the proper way to do it? Can I pull his hand? Because I'm afraid to do it and leaving him naked is quite impossible." [Ik8, wife]

"When I bathe him, it confuses me. It's too heavy to lift the hand, but is it okay to wipe (the hand)? I want to learn the right way to wipe the hand, how to tilt the body, and what if bathing him once a week? I want to ask about the treatment. I still find it difficult." [Ik7, wife]

"The patient sometimes choke when eating. Why is it? [...] how to avoid that?" [Ik2, child]

One participant stated that it is essential to provide the education on feeding the patients properly using nasogastric tube, the side effects, recommended lying positions during feeding, how to regulate food menus, and how to prepare food for feeding through a nasogastric tube, as expressed by one participant the following :

"How to feed (the patient) in lying position. Is it okay to feed (the patient) with this position? And if (the patient) must sit, how is the right way to sit? And then what is the side effect? I just want to know." (Ik3, child)

"How to put on diapers? Because it's hard to lift the body. I'll be doing it by myself at home later." [Ik13, child]

#### **4. Signs, symptoms and efforts to prevent the risk of recurrent stroke. The majority of informants stated that they wanted to know how to prevent recurrent stroke.**

"I once heard the stories of those people, they said don't let (the patient) fall down, or else it will worsen the condition. It's so scary. Is that true? If so, they should've told us so we would be careful" [Ik1. Wife]

"The doctor explained yesterday, said there was a golden period or something. So if (the patient) have another stroke, we must help in hours. How do you do it? This would freak me out. I would like to ask this again to the doctor again because it is quite important." [Ik2, child]

**Psychological Education Needs:** Educational needs about how to deal with patients' psychological changes are also important for the informants. They complained that they were their confused about the patient's psychological changes and how to deal with their condition who became easy to get angry, be offended, and be sad. They sometimes became emotional when dealing with angry patients. Some interview quotes were as follows:

I am so confused, why does my husband become quiet, sometimes he suddenly cries, he wasn't like that before. He just wants to talk to his child. What should I do? Who can explain this to me? [IK1, wife]

"Father gets angry easily now. When his children visit him, it seems like he wants to start a fight with them [...] How do I make him calm? That's what I want to know." [Ik2, child]

When my father gets angry, sometimes I'm so exasperated, I feel like pinching him. But sometimes I feel sorry for him too. What is the solution when it comes like this? I myself am also tired of taking care of everything [...] I want to learn how to handle this kind of situation [Ik4, child]

Moreover, education on how to motivate and encourage patients is also needed for by the caregivers. According to them, some patients feel sad and despair in experiencing their condition. The excerpt of the interview is as follows:

For me, I want to know how to get back the patient's spirit to live again. It's sad when he can only cry and doesn't want to do anything [Ik6, wife]

I don't know what to do. Please teach me to make the patient to stay motivated [I4, child]

**Structured Discharge Planning Needs:** The discharge planning given to the family caregivers has not been structured so far. All informants stated that the provision of education by the PPA (professional caregivers) related to planning the return of stroke patients was very important. The majority of informants stated that education is needed as their guide in caring their affected family members at home. This was revealed by several participants:

"Yes, I want to be told that at home, about what to do for the (muscles and joints) exercise, and what's not, so I can take care of my parent" (Ik14, child)

"Yes, about taking care of the sick, for example, taking care of the diet, bathing, the exercise for walk" (Ik 13, child)

## **Discussion**

Family caregiver requires education from caregiving professionals so that they are able to treat patients properly at home. The required information is related to physical education needs (medical rehabilitation training at home training, mobilization and transfer of patients, handling patients' ADL and early symptoms of stroke). Whereas the need for psychological education is related to the patients' psychological changes and how to handle them. All informants stated that they needed education about how to perform medical rehabilitation at home. Changes in patients' neurological deficits caused them to experience limitations and became dependent on the family caregiver. In order to avoid the long term impact

of the neurological deficit, the family caregiver must learn about the rehabilitation techniques [4].

Organ dysfunction in stroke patients causes them to depend on the family caregiver to carry out daily activities. In handling ADL (Activity Daily Living), the family must have the skills so that the patient's ADL can be handled properly and to minimize the occurrence of complications. For example, bathing the patient must be done as clean as possible to avoid the risk of decubitus, improper feeding can increase the risk of pneumonia and improper way of wearing clothes will make it difficult for the process. Safe transfer techniques are important to prevent injury. Therefore families need to get education about safety and prevention of falling down.

The majority of informants also needed education regarding explanations about the introduction of stroke symptoms and prevention of complications. This is important to provide proper and fast handling and prevent recurrent strokes. Not only that, an education about how to manage risk factors such as hypertension, heart disease, diabetes, high cholesterol, and smoking is important to prevent recurrent stroke [4].

Based on the results of the study, psychological education is also a necessity for stroke patients. This is due to the fact that stroke patients generally experience dysfunction of mental and psychological activity that is manifested by emotional lability that shows the reaction easily or inappropriately [5]. Moreover, stroke patients usually show loss of self-control, so they tend to become easily angry and offended.

Hospitals need to assess the needs of education for the family caregiver. By doing so, the education provided will be in accordance with their needs. Education needs to be given in the form of knowledge and skills improvement to obtain the ideal result.

Discharge planning is a component of an ongoing treatment system for clients and helps families to find a way to solve the problems [4]. Discharge planning aims to help patients and families achieve optimal levels of health. Discharge planning starts on the day the patient is hospitalized, followed by scheduled update according to the patient's condition. The results of the study showed that the return planning was not structured. Most participants said they had been given an explanation of how to treat stroke patients. However, it seems not quite enough because the informants do not directly practice the procedure. Moreover, there was no evaluation to

see the extent to which the informants understood the education provided. This was expressed by most participants, where they said that nurses had told them what to do, but were limited to giving information and without providing explanations on how to perform correctly. Meanwhile, some of other participants said they knew various ways to do treatment, by seeing nurses working.

The role of nurses besides providing nursing care directly, they also provide information, education and skills needed by the family caregiver. In providing the information, education and skills, their goal is to aim for families to understand about stroke and to know the proper treatment [6]. Good knowledge, attitudes and behavior of the family will encourage patient gradually become independent. Health treatment at home as part of the nursing process at the hospital. Medical surgical specialist nurses have a great role in appropriate discharge planing to the patient's condition [7]. Warhola (1980) [8] mentioned that specialist nurses play a role to planning and coordinating nursing care according to the needs of patients and families. As the executors of nursing care, specialist nurses provide and evaluate nursing care. Structured discharge planning application is very necessary to make family caregivers be independent. In order do Structured discharge planning, it is necessary to have social support from various parties such as nurses, hospital management and family caregivers. The existence of social support from various parties will make the program run smoothly [9].

## Conclusion

The results of this study indicated that the family caregiver requires education from caregiving professionals for caring stroke patients at home. This education is their provision in caring patients at home. Assessment on educational needs is important in order to meet the educational needs of stroke family caregivers. Education is given in accordance with the needs of the results of the assessment in the form of knowledge and skills. To see the extent to which family caregivers can learn about the education provided, an evaluation is needed. Hospitals are expected to be able to meet the educational needs for stroke family caregivers so that they are ready to for caring patients at home.

**Conflict of Interest:** The researcher stated that there was no conflict of interest in this study

## Abstract

Anxiety is one of the psychological responses experienced by clients with diabetic ulcers that can affect glycemic control, serious complications, foot self-care behavior and slow the wound healing process. This research used to find out the factors that influence anxiety in clients with diabetic ulcers. This study was a retrospective analysis using medical records and diagnostic results of diabetic ulcers at Haji General Hospital, Surabaya, Indonesia. The sample was 951 people suffering from diabetic ulcers between January 2014 - December 2018. Samples were diagnosed with anxiety based on nursing diagnoses and fulfilling inclusion and exclusion criteria. The multivariable model of diabetic ulcer client anxiety was generated using stepwise logistic regression. There were independent variables affecting the anxiety of diabetic ulcer clients namely wound type ( $p < 0.015$ ; OR = 0.91), health insurance ( $p < 0.001$ ; OR = 0.77) and gender ( $p < 0.040$ ; OR = 0.98) with the contribution of the four independent variables at 31% and the prediction accuracy of 86.6%. Gender of patients have a risk of 0.98 times experiencing anxiety, male contribute 0.64 times compared to female, so nursing interventions can be focused on wound care.

**Keyword:** Predictive, Risk Factor, Diabetic foot ulcer, Anxiety.

## Introduction

In 2030, it is estimated that DM ranks 7th in the cause of death in the world<sup>1,2</sup>. The World Health Organization states that the prevalence of DM worldwide is estimated at 9%. One of complication of DM is diabetic foot ulcer (DFU). In Indonesia patients with chronic diseases such as DFU tend to experience anxiety because the stigma associated with DFU in society is bad. The stigma of DFU in Indonesia is associated with incurable diseases, possible amputation and death. Anxiety is one of the psychological responses experienced by DFU sufferers because of changes in health, loss of function, and non-intact conditions in the body such as injuries, amputations and affect foot self-care behavior then slow healing process in DFU and a decrease in quality of life<sup>3,4,5</sup>.

One of the effects of anxiety is the length of the wound healing process. Research conducted by Razjouyan, et al, found an association between anxiety and wound healing. DFU people with anxiety experience delays in healing wounds. Pedras, et al, found a significant relationship to anxiety and quality of life of people with DFU. Anxiety that occurs shows that they experience ineffective psychosocial adaptations<sup>6</sup>.

People with chronic diseases, such as DFU, who can adapt well will be able to accept the reality of their illness, rearrange and restructure the environment so that there is meaning and purpose in quality of life that exceeds the limitations posed by the disease<sup>7</sup>. Dealing with anxiety is the responsibility of the health care provider who, of course, includes nurses. Efforts that have been made in the treatment room to deal with anxiety are health education, pharmacological therapy, non-pharmacology and stress management but have not been optimal in reducing anxiety in clients<sup>8</sup>.

Fear, anxiety, and dread may affect a person's relationship to his or her sense of safety, whether in term of diabetes or in relation to other chronic conditions. These emotions are causal factors that influence whether or not people with symptoms seek treatment in a timely manner. Some of the most informative responses in the research presented here involve avoidance of health care visits because of the fear of being told they have developed DFU. It is important to study related causes of anxiety in patients with diabetic ulcers. Factors that can influence are individual patient factors or hospital service systems. Individual patient factors including

demographics, age, gender, education and others. service system factors are from insurance to the referral system. All hospitals in Indonesia are required to accept patients with BPJS insurance. Failure in management anxiety is due to a mismatch between the anxiety experienced with the therapy provided, so it is very important to study related anxiety itself. Nurses as one of the health professions are required to be able to facilitate the basic needs of clients, one of which is psychological needs with a nursing process that views humans as a whole and uniquely puts forward a holistic approach that includes bio-psycho-socio-spiritual and cultural <sup>9</sup>. Previous studies have been carried out and only analyze anxiety in DM patients not DFU. This study aims to find factors that influence anxiety that occur in clients with diabetic ulcers.

### Method

This research used to find out the factors that influence anxiety in clients with diabetic ulcers. This study design was a retrospective analysis.

**Ethical Clearance:** Ethical clearance was obtained from The Ethics Committee of the Hajj General Hospital, Surabaya (ethics approval number 073/13/KOM.ETIK/2019).

**Partisipant:** Data were collected by a medical record and diagnostic results of diabetic ulcers at Haji General Hospital, Surabaya. The sample were 951 people suffering from diabetic ulcer between January 2014 - Desember 2018. The inclusion criteria determined in this study were patients over 40 years old, had foot ulcers, HbA1c values above 6.5% and diagnosed with anxiety based on nursing diagnoses. The specified exclusion criteria are having a mental disorder.

**Variables:** Data collected as variables in this study were gender, duration of diabetic ulcers, use of health insurance, type of injury, length of stay and complications. Data is collected using a checklist sheet consisting of these items. The collected data then categorized based on the provisions set.

**Statistical Analysis:** The Statistical Analysis using SPSS 25 generated using stepwise logistic regression. The first step is to classify the entire data obtained by categorical 1 and 2. The next step is to crosstab the data and choose the chi-square that serves to make variable selection. Variables that have a value of  $p < 0.25$  will be

included in the multivariate logistic regression analysis with the provisions  $p < 0.05$ . The results of logistic regression are then interpreted and presented.

### Result

**Participant Characteristics:** Participant characteristics can be seen in table 1. Based on the table, there are 742 men and 209 women. BPJS users are more dominant than non BPJS. The type of infection wound is the most type and the duration of treatment more than 3 days is also dominant. Duration of diabetic ulcers more than 7 months and complication more than 1 also dominant. Of the 951 participant there are differences regarding anxiety status. Participants who experience anxiety are more around 824 and are not anxious 127

**Table 1. Characteristics of Participant**

Variabel	N = 951	N%	Mean	SD
Gender			0.78	0.41
Women	209	22		
Men	742	78		
Duration of diabetic ulcers			0.62	0.48
Less than 7 months	359	37.7		
More than 7 months	592	62.3		
Length of stay			0.78	0.42
Less than 3 days	212	22.3		
More than 3 days	739	77.7		
Health insurance			0.75	0.43
Non BPJS	242	25.4

Risk Factor For Anxiety On Clients With Diabetic Foot Ulcer in bivariate analyses

Bivariate tests use chi square by displaying crosstab on each variable analyzed.

**Table 2. Bivariat analyze Risk Factor For Anxiety On Clients With Diabetic Foot Ulcer**

Variablel	Anxiety (N=951)	Non Anxiety (N=951)	OR	CI (95%)	P value
Gender			1.55	1.02 - 2.36	0.048
Women	172	37	1.39	1.03 - 1.88	
Men	652	90	0.89	0.79 - 1.00	
Duration of diabetic ulcers			1.51	1.04 - 2.20	0.038
Less than 7 months	300	59	1.27	1.03 - 1.57	
More than 7 months	524	68	0.82	0.71 - 0.99	
Length of stay			0.98	0.62 - 1.54	1.00
Less than 3 days	184	28	0.98	0.69 - 1.40	
More than 3 days	640	99	1.00	0.90 - 1.10	
Health insurance			1.89	1.27 - 2.81	0.002
Non BPJS	195	47	1.56	1.20 - 2.02	
BPJS	629	80	0.82	0.71 - 0.94	
Wound type			1.66	1.13 - 2.45	0.012
Non Infectious	231	50	1.40	1.10 - 1.78	
Infectious	593	77	0.84	0.72 - 0.97	
Complication			1.25	0.86 - 1.83	0.278
Only 1	299	53	1.15	0.91 - 1.44	
More than 1	525	74	0.91	0.78 - 1.06	

CI : Confidence Interval ; OR: Odds Ratio; BPJS : Social Security Administrator

From table 2 there are 4 independent variables that fit significant criteria. The chi-square test found a wound type (p <0.012; OR = 2.4), duration of illness (p <0.038; OR = 1.03), health insurance (p <0.002; OR = 0.82) and gender (p <0.048; OR = 0.99). The type of wound is the most dominant factor in this test. Variables that have p

value <0.25 will then be made covariate variables in the next multivariate test.

Risk Factor For Anxiety On Clients With Diabetic Foot Ulcer with Multivariat analyze.

**Table 3. Multivariat analyze Risk Factor For Anxiety On Clients With Diabetic Foot Ulcer.**

Variables	OR	CI 95%	p value	Nagelkelke R Square
Gender			0.040	0.31
Women	1			
Men	0.64	0.42 – 0.98		
Wound type			0.015	
Non Infectious	1			
Infectious	0.61	0.41 – 0.91		
Health insurance			0.001	
Non BPJS	1			
BPJS	0.52	0.35 – 0.77		

CI : Confidence Interval ; OR: Odds Ratio; BPJS : Social Security Administrator

Based on table 3, the multivariate test results obtained using logistic regression and found three significant variables namely wound type ( $p < 0.015$ ; OR = 0.91), health insurance ( $p < 0.001$ ; OR = 0.77) and gender ( $p < 0.040$ ; OR = 0.98) with the contribution of the four independent variables at 31% and the prediction accuracy of 86.6%. One variable is Duration of diabetic ulcers not significant in the second model of the logistic regression test so it needs to be eliminated.

## Discussion

In this study in controlling confounding factors researchers used the restriction method by including all respondents who had the same confounding factors. This means that each respondent has the same characteristics as others so that other confounding factors can be minimized beyond the factors studied. In this study 3 variables were found which affected the anxiety of patients with diabetic foot ulcers. These variables are gender, type of injury, and health insurance. Wound type is the second dominant factor triggering anxiety in patients with foot ulcers. This can be seen from a high OR value that is 0.91 with a  $p$  value  $< 0.015$ . Wound conditions that occur in clients with diabetes can increase the incidence of depression and anxiety<sup>10</sup>. The bigger the wound will cause psychological stress, causing negative thoughts on the client. the client will feel that the wound cannot heal. The study found a correlation between wounds with depression and anxiety with measurements of HARDS and CES-D scale<sup>11</sup>. In this study it was found that infectious contributes 0.61 times greater than non-infectious conditions. Wounds experienced by diabetics often result in gangrene which is an infectious complication. This condition results in patients having difficulty doing activities and work. The study by Charalambous, Vassilopoulos, & Koulouri, found a correlation between the condition of diabetic wounds with the psychological patient. Anxiety that occurs in patients with chronic wounds is caused by bad stigma, previous injury experience, lack of support from both the family and the health care system, the presence of pain and long-term treatment that he experiences<sup>12</sup>. Research conducted by Razjouyan et al found an association between anxiety and wound healing. DFU people with anxiety experience delays in healing wounds<sup>13</sup>.

Gender is the dominant factor with OR = 0.98, between male and female is one of the factors that influence the occurrence of anxiety in patients with

diabetic ulcers with  $p$  value  $< 0.040$ . In the results of the study found differences in anxiety on the sexes. Men tend to experience anxiety 0.64 times greater than women. Sex difference is one of the determinants of anxiety conditions. Reisner et al, found a difference in anxiety response in men and women. Men tend to experience anxiety because of their role as the main support in the family<sup>14</sup>. The condition of the illness results in the inability to fulfill the duties and responsibilities in the family<sup>15</sup>. According form the research find indicate that gender selectively modulates the influence of anxiety on ambiguous decision-making, but not risk decision-making<sup>16</sup>. Niles et al found that there is a relationship between gender and psychological responses to inflammation. In cases of inflammation, a person's tendency to experience symptoms of depression and anxiety. Men are more prone to symptoms of depression but less respond to anxiety<sup>17</sup>. The whole participant is over 40 years old and has worked so that the tendency to be unable to meet the needs in the family results in anxiety. While the high proportion of male respondents in the current study is in line with other studies of diabetic foot disease affected populations, reasons for this asymmetrical gender distribution remain unclear as the prevalence of diabetes in the age group surveyed is almost the same for men and women.

Multivariate models found the effect of health insurance on the anxiety of patients with diabetic ulcers ( $p < 0.001$ ; OR = 0.77). Health insurance is one of the guarantees needed to cover all patient medical expenses. In Indonesia there is health insurance provided by the government, namely BPJS. Most hospitals in Indonesia receive services with BPJS but patients using BPJS must fulfill the entire set of administrations. The complicated process makes patients easily experience stress due to feeling that they have not been taken action by health personnel. BPJS users experience a tendency to experience anxiety 0.52 times greater than patients without health insurance. Chronic ulcers present a substantial economic burden to the health care system. Health care decision makers are encouraged to consider additional resources to preventative interventions for chronic ulcers to reduce downstream costs<sup>18</sup>. Low-cost DFU primary prevention efforts producing even small decreases in DFU incidence may provide the best opportunity for cost-savings, especially if focused on patients with neuropathy and/or PAD. Mobile phone-based reminders, self-identification of risk factors, and written brochures may be among such low-cost

interventions that should be investigated for cost-savings potential<sup>19</sup>.

All of these aspects make the patient feel frustrated, dissatisfied, insecure, fearful, helpless and uncontrolled. Individuals with injuries feel unable to carry out daily activities, and often consider themselves unable to play their role in society<sup>20</sup>. The weakness in this study is that there are still 69% of factors that contribute to increasing anxiety in patients with unknown diabetic ulcers, so further research is needed to examine all aspects of patients and other research method in revealing the results.

### Conclusion

The most dominant factor found in this study was the type of wound types of wounds that are infection have a risk of 1.65 times experiencing anxiety compared to non-infection, so nursing interventions can be focused on wound care.

**Conflict of Interest:** None.

# Cyclic Fatigue Resistance of Wave One Gold, F6 SkyTaper, One Curve, and AF Blue R3 NiTi Rotary Instrumentation Systems

Zainab M. Abdul- Ameer<sup>1</sup>, Samar Abdul Hamed<sup>2</sup>, Rasha H. Jehad<sup>1</sup>, Jacob Al-Hashemi<sup>3</sup>

<sup>1</sup>Assist. Prof., <sup>2</sup>Lecturer, Department of Conservative Dentistry, College of Dentistry, University of Baghdad, Baghdad, Iraq, <sup>3</sup>Assist. Lecturer, Department of Conservative Dentistry, College of Dentistry, Al-Mustansiriyah University, Baghdad, Iraq

## Abstract

**Objective:** This in vitro study is aimed to compare and evaluate the cyclic fatigue of four varying NiTi rotary instrumentation systems.

**Method:** Four types of rotary files were used in four groups (10 files for each group). Group A: Wave One Gold; Group B: AF Blue R3; Group C: One Curve; Group D: F6 SkyTaper. These groups were evaluated by a cyclic fatigue apparatus to measure cyclic fatigue resistance within the artificial metallic simulating canal. All the files were rotated in artificial canals until they fracture. The resistance to cyclic fatigue was determined by counting the number of cycles to fracture, and the time to failure was recorded in seconds then transformed to minutes.

**Results:** One-way analysis of variance test showed a significant difference ( $P < 0.001$ ) in the average values of cycle number and time needed for file fracture.

The t-test results indicate a significant difference ( $P < 0.001$ ) among all groups.

**Conclusions:** The study concluded that with an apical curvature of an artificial canal with an angle curvature of  $60^\circ$ , AF Blue R3 and F6 SkyTaper instruments exhibit a higher resistance to cyclic fatigue than One Curve and Wave One Gold files most possibly due to surface and alloy feature variation.

**Keywords:** Endodontics, instrumentation, cyclic fatigue.

## Introduction

Rotary instruments for root canal systems made from nickel-titanium (NiTi) alloy exhibit more elasticity than stainless steel instruments, which are rigid and unsuitable for large apical enlargement in thin-curved canals<sup>[1]</sup>. Specifically, the elastic flexibility of NiTi instruments is approximately 2–3 times greater than that of stainless-steel instruments<sup>[2&3]</sup>.

NiTi instruments feature a risk for fracture owing to cyclic fatigue and torsional shear; this condition is an important disadvantage of rotary files when rotate freely in a curved canal<sup>[4-6]</sup>. In order to increase the easiness and speed of root canal preparation procedure for practitioners, a single file NiTi rotary systems with

either complete rotation or reciprocation motion were introduced<sup>[7]</sup>. Wave One Gold files manufactured by Dentsply Maillefer in Switzerland are a new version of Wave One files. The geometry, dimensions, and cross-section are modified while maintaining reciprocation motion. The files are made by gold, which is heated at first and then slowly cooled for file production; these files also exhibit two cutting edges with a parallelogram cross-section, which may increase file flexibility as claimed by the manufacturer<sup>[8]</sup>.

The F6 SkyTaper manufactured by Komet, Brasseler GmbH & Co. in Germany is a new generation of single-file, one-use NiTi system comprising one available instrument with five diverse sizes (20, 25, 30, 35, and 40) and showing a constant taper of 0.06, which

is critical for shaping of the root canal. These files are distinguished by their cross-sectional design, which is a unique double-S cross-section. The F6 SkyTaper instrument is produced for use in a continuous clockwise rotation motion [9].

One Curve file manufactured by MICRO MEGA in France is a heat-treated C-wire with a regulated memory of NiTi and a potential to prebending to facilitate access to the root canal. It's also a single-use, single instrument rotary file employed in continuous rotation. The variable cross-section ensures excellent cutting efficiency and debris removal up to the medium and coronal parts of the canal with a perfectly centered trajectory [10 & 11].

AF Blue R3 manufactured by Fanta Dental Materials Co.,Ltd. in Shanghai is a special heat-treated wire used for producing endodontic rotary files. However, NiTi files display a high possibility of unnoticed fracture inside root canals, different from the stainless-steel files, which are most likely to show plastic deformation signs. AFTM-Wire is a developed NiTi alloy and features excellent mechanical strength properties. The flexibility of AFTM-Wire avoids canal transportation. Meanwhile, its hardness is large enough to allow for good cutting efficacy. Fanta AFTM-Wire offers three levels of flexibility depending on the crystallographic phases present in the alloy and rectangular cross-section of AF BLUE R3 [12].

The null hypothesis indicates that the tested rotary NiTi instruments show no differences in their cyclic fatigue resistances.

This in vitro study is aimed for comparison and evaluation the cyclic fatigues of Wave One Gold, F6

SkyTaper, One Curve, and AF Blue R3 NiTi rotary instrumentation systems.

### Materials and Method

Figure 1: The artificial simulating canal

Figure 2: Cyclic fatigue testing device.

Figure 3: Time in seconds and number of cycles to fracture among groups

Four different rotary instruments were used, and 10 instruments for each type were investigated in the four groups.

**Group A:** Wave One Gold (primary, #25.07), 25 mm length, and NiTi rotary instruments (350 rpm/5 N cm).

**Group B:** AF Blue R3 (#25.06), 25 mm length, and NiTi rotary instruments (300 rpm/2.6 N cm).

**Group C:** One Curve (#25.06), 25 mm length, and NiTi rotary instruments (300 rpm/2.5 N cm).

**Group D:** F6 SkyTaper (#25.06), 25 mm length, and NiTi rotary instruments (300 rpm/2.2 N cm).

The instruments were tested within an artificial simulating canal (angle curvature: 60°; Figure 1). The curvature radius was 5 mm, whereas canal width was 1.5 mm. The simulated canal constructed within stainless-steel blocks covered by a swiveling glass allowed for observation of files rotating in the canal and discard of broken instruments after each test<sup>[13]</sup>.

To eliminate binding in the simulating canal, the files were created to be slightly wider than those used in the test (0.3 mm wider than the instruments used), granting a modest lateral movement inside the canal<sup>[14&15]</sup>.

The cyclic fatigue testing apparatus utilized in this study, as shown in Figure 2. The apparatus consists of a wood main frame attached with an electric hand piece and a simulating canal carved in a stainless-steel block. The electric hand piece is supported to a movable apparatus, allowing accurate and repeated placement of each instrument inside the simulating canal<sup>[16]</sup>.

The testing canal was filled with a lubrication medium (3-In-One Multi-Purpose Oil manufactured by WD-40, USA) to minimize the friction produced by the tested file with the canal walls<sup>[17]</sup>. A glass cover was

fixed by the clipper to facilitate file insertion inside the canal and to prevent the instrument from slipping out, thus also providing a clear view of the instruments.

A button on the electric motor was pressed to initiate rotation. Meanwhile, a digital stop watch was also operated. Instrument rotation was monitored by the operator until the file fractured, the corresponding time was recorded. The electric motor button was pressed again once to stop rotation during fracture of the instrument. The slide was opened, and the fractured file was replaced by a new one.

The time needed for instrument fracture from the beginning of the rotation was recorded in seconds then transformed into minutes. Afterward, time (T) in minutes was multiplied by revolutions per minute (RPM) to conclude the number of cycles needed for each instrument to fracture (NCF) as in the following equation:

$$NFC = RPM \times T$$

Statistics, including maximum, mean, minimum, and standard deviation(S.D.), calculated for the cycle numbers needed to fracture each file. The data were obtained and noted using SPSS (program version 18) and used in statistical analysis.

One-way analysis of variance (ANOVA) was utilized to determine any statistical difference between the mean cycles needed for fracture occurrence for the different rotary instruments. A separate t-test was performed to assess the significance of variance between a pair of instruments. P values of more than 0.05 were considered statistically non-significant, whereas P values equal or less than 0.05 were regarded as significant. On the other hand, P values less than 0.01 were regarded as highly significant

## Results

**Table (1): Descriptive Statistical analysis for the time (Seconds) and number of cycles to fracture**

Groups	Type of test	Min	Max.	Mean	±SD
A	Time	108.42	113.13	110.94	1.870
	No. of cycles	632.45	659.92	647.18	10.908
B	Time	190.79	214.89	207.66	10.105
	No. of cycles	953.95	1074.45	1038.31	50.527
C	Time	114.14	121.82	118.91	2.900
	No. of cycles	570.7	609.1	594.59	14.500
D	Time	152.13	164.21	159.06	5.189
	No. of cycles	760.65	821.05	795.3	25.946

**Table (2): ANOVA test for the time and number of cycles to fracture**

Type of test	S. O. V.	SS	Df	MS	F-test	P-value
Time	Between	47166	3	15722	715.67	0.000
	Within	615	28	21.968		HS
	Total	47781	31			
Number of cycles	Between	947894.2	3	315964.7	568.61	0.000
	Within	15558.9	28	555.67		HS
	Total	963453.1	31			

**Table (3): t-test for the difference in time and number of cycles to fracture between each two groups**

Comparison Groups	t-test time	p-value	t-test number of cycles	p-value
A & B	19.240	0.000	15.280	0.000
A & C	5.165	0.007	6.480	0.003
A & D	16.821	0.000	9.996	0.001
B & C	19.884	0.000	19.884	0.000
B & D	13.546	0.000	13.546	0.000
C & D	13.616	0.000	13.616	0.000

Table 1 summarizes the descriptive statistics for each system. The average cycle-to-fracture values of the AF Blue R3 group were the highest among all groups, whereas the lowest was observed in the Wave One Gold group.

The data inspected by one-way ANOVA demonstrated significant difference (P<0.001) in the NCF mean values among all groups (Table 2).

Using t-test, further comparisons among groups were conducted to determine where the significant difference occurred (Table 3). The t-test results reveal a significant difference among all groups (P<0.01), except for Group A (Wave One Gold) and Group C (One Curve) (P< 0.05), where is not a statistically significant differences in variation were reached (P=0.05).

**Discussion:**

The fracture of rotating NiTi instrument is one of the most critical complications that develop during canal preparation [18]. Diverse classes of rotary NiTi instruments show variation in resistance to fatigue failure owing to differences in numerous factors, such as their manufacture [19&20].

In this study, the resistance of rotary files to cyclic fatigue was tested under simulating conditions to reduce the effect of other failure mechanisms, e.g., canal diameter and length. As other studies, the test was

evaluated using stimulating canals made of stainless steel [21 & 22]. Considering that this study aimed to examine the physical properties of NiTi rotary files, the extracted teeth were unsuitable models as no two root canals are exactly identical [23]. One operator has examined the files, whereas the other has operated the stopwatch [24]. The Wave One Gold, AF Blue R3, One Curve, and F6 SkyTaper NiTi rotary instrumentations were selected given their differing cross-sections, processing metallurgic alteration, and rotation axes. Comparisons were conducted with files of similar curvature and diameter to minimize the *confounding variables*. The Blue R3 files were the most resistant to cyclic fatigue, followed by F6 SkyTaper, One Curve, and Wave One Gold files. The t-test results showed a significant difference among all groups (P<0.01). However, the difference between Wave One Gold and One Curve (P<0.05) groups showed no statistical significance. In the AF Blue R3 files, the cyclic resistance may be related to a more metal mass and a larger cross-sectional area due to its rectangular cross-section in addition to the AF-R Wire Technique, which depend on the crystallographic phases present in the alloy. The files are manufactured with NiTi, which undergoes an innovative heat treatment, altering its molecular structure, to achieve an increase in cyclic fatigue resistance; surface treatment of the file involves chemical polishing, and additional flexibility and a distinct blue color are also added [12]. However, no data were published until the date of evaluation of the

cyclic fatigue resistance of the roots by using AF Blue R3 files. Therefore, comparison of our results with other studies is impossible. The F6 SkyTaper instruments showed more cyclic fatigue resistance compared with the One Curve and Wave One Gold instruments. This observation may be related to the decreased cross-sectional area associated with the unique double S-shaped cross-section design of F6 SkyTaper. Plotino *et al.* noted an inverse relation between cyclic fatigue resistance and cross-section metal mass of NiTi files [25]. This result agrees with that of a study concluding that Wave One Gold shows low resistance to cyclic fatigue [26&27]. This difference in the cross-section between files might also contribute to their cyclic fatigue resistance.

Wave One Gold instruments were less resistant to cyclic fatigue and were fractured within a short period possibly due to their cross-section design (parallelogram-shaped cross-section), which should be regarded for conclusions of this study. The thermal processing increased the temperature of austenitic transformation of nickel-titanium alloy and improved its crystal structure arrangement [28 & 29]. These factors may improve instrument performance. One Curve files are manufactured with a C-wire by applying controlled heat treatment with the property of regulated memory, thus improving file resistance to cyclic fatigue. Parashos *et al.* noted that small core diameter enhances instrument resistance to cyclic fatigue [30]. One Curve features a low core diameter (approximately 48.327  $\mu\text{m}^2$ ). All these findings explain the enhanced fatigue resistance of One Curve files.

### Conclusion:

Considering the outcomes in this article, we can conclude that AF Blue R3 file exhibits the highest resistance to cyclic fatigue in comparison with F6, One Curve, and Wave One Gold files. Further research is advised to assess the resistance to cyclic fatigue of these files by using different canal lengths and curvatures. The clinical performance of these new files should also be evaluated.

## Abstract

The purpose of this study is to investigate dietary habits in retired athletes in Saudi Arabia. Seventy (70) former athletes, aged between 20-60 years old, who had participated in international and national competitions, and had since stopped competitive sport were recruited for this study. Sports history, age, height, and weight, dietary habits were collected using an online questionnaire. The study results showed that 47.14% of the participants are overweight and 22.86% are obese. It also indicated that 84.29% of the former athletes were eating fast food, whereas, the prevalence of drinking fizzy drinks was 71.43%. Also, the results of this study found out that there is no significant relationship between eating fast food and drinking fizzy drinks and obesity.

**Keywords:** Former athletes; obesity; dietary habits; fizzy drinks.

## Introduction

The dietary habits and lifestyle behaviours among individuals in developing countries has been changed due to the adoption of the western lifestyle, which is making them becoming overweight and obese and consequently more prone to develop cardiovascular disease (CVD), type 2 (T2D), high cholesterol, and hypertension, which all together are the main cause of mortality over the world<sup>(1,2)</sup>. According to Mohammad H. Al-Qahtani (2016), the type and amount of the diet constitute a main role in the process of pathogenesis of the previous diseases.

Health and eating behaviours in any society may be a good indication for the public health and the level of

their risks to have the lifestyle disease such as T2D and high BP<sup>(2)</sup>. Saudi Arabia is one of those countries that have very high prevalence of overweight and obesity<sup>(2,3)</sup>. Furthermore, the trend of consuming western food is very popular among Saudi people, and they are very much prone to eating burgers, pizzas, and sweets with increased drinking of soft drinks and low level of physical activity is prevalent among them.

It has been reported that there is a significant association between unhealthy diet consumption (fast food) and sedentary lifestyle<sup>(1)</sup>. However, a findings of study in Brazil have shown there is a positive relationship between physical activity (PA) and increased intake of healthy diet such as fruits and vegetables, whereas sedentary behaviours was associated with an increase in the intake of unhealthy diet such fat food<sup>(1)</sup>. According to Khabaz et al., (2017) who stated that the mixture of intake of an unhealthy diet and sedentary behaviour might lead to overweight and obesity, independent of decreased physical activity. Khabaz and his colleagues also showed that overweight and obesity was widespread among people who consume too much offast food and unhealthy food. Fast food is described as food that is made and served in very quickly<sup>(4,5)</sup>. Fast Food generally consists of a big size of portion and high energy density

from fat and saturated fat, moreover, it contains high amount of salt, sugar, and low amount of fibres which increase the risk for overweight, obesity, and high BP<sup>(4-6)</sup>.

Former athletes are more likely to eat unhealthy foods than they were in competitive years. Eating high energy foods are considered as a health-risk habits among former athletes and the increase in body weight might goes hand in hand with shifting from active lifestyle to retirement phase<sup>(7,8)</sup>. A recent results of several studies revealed that the prevalence of obesity and overweight in former athletes is high and all these may involve in the development of many disease<sup>(7-9)</sup>.

Several studies have reported the prevalence and impact of dietary behaviours of people in Saudi Arabia, the majority of these studies reported that the dietary behaviours in people is unhealthy and people generally are not following the international recommendation requirement<sup>(2,5)</sup>. However, in literature, the dietary behaviours of former athletes are seldom studied, equally, at international level, the dietary behaviour of former athletes are not critically studied, also in Saudi Arabia, to the best of our knowledge, we do not found any research on the dietary behaviours among former athletes.

Thus, there is need for a comprehensive evaluation of dietary behaviors in former athletes that could help to diagnose such problems earlier so that preventive measures can be taken to avoid adverse effects. Therefore, this study was designed to find out dietary habits among former athletes.

## Method

An online questionnaire was administered to participants. The link to the questionnaire was sent to the Saudi Athletics Federation, asking them to send a request to former athletes to participate in this research. This study was approved by a panel of experts who were considered to be an ethical committee for the school of education at the University Technology Malaysia (UTM). All participants provided informed consent electronically before participation in this study. Subsequently, seventy (70) individuals agreed to participate. The research participants were former male athletes who had participated in international and national competitions and had ceased participating in

competitive sport. The inclusion criteria was that the participant must be 20 years old or above. The online, self-administered questionnaire collected data on sports history, age, height, weight, and dietary behaviours. BMI was defined as weight (in kilograms) divided by the square of the height (in meters). For the comparisons between our groups and data from the World Health Organization (WHO), overweight was defined as a BMI of 25-29.9, and obesity was defined as a BMI  $\geq 30$  kg/m<sup>2</sup>.

**Statistical Analysis:** Statistical analysis was performed using software SPSS version 23. P-values of  $<0.05$  were considered to be statistically significant. The Data are reported as mean, standard deviations, or number (percentage, %). A chi-square test was performed to analysed categorical variables. Chi-square was also applied for testing relationships between categorical variables.

## Results

The results are derived from the data obtained from the online self-reported questionnaire. The total number of participants in this study was 70, all of whom were former athletes from Saudi Arabia. Table 1 presents the demographic variables, and Figure 1, 2 & 3 show the percentage of fast food, fizzy drinks, and smoking status among former athletes. As shown Table 1, the mean height and weight of the participants were 174.61 cm (SD = 7.605) and 83.99 kg (SD = 14.568), respectively. The mean age of the participants was 39.73 years old (SD = 7.75) and ranged from 24 to 59 years old. The majority of the participants were track & field players (34.3%), footballers (24.3%), and Karate practitioners (20.0%). The prevalence of overweight was 47.14% and obesity was 22.86%.

The findings, as shown in Figure 1, demonstrate that the majority of the former athletes were eating fast food (84.29%), whereas, the prevalence of drinking fizzy drinks was 71.43%. The study found no relationship between eating fast food and drinking fizzy drinks.

**Table 1. Physical Variables**

Demographic Variable	Mean $\pm$ SD
Age (Years)	39.73 $\pm$ 7.75 (24; 59)
Height (cm)	174.61 $\pm$ 7.605 (157; 194)
Weight (kg)	83.99 $\pm$ 14.568 (62; 130)
BMI (kg/m <sup>2</sup> )	27.6244 $\pm$ 58630 (17.17; 43.94)

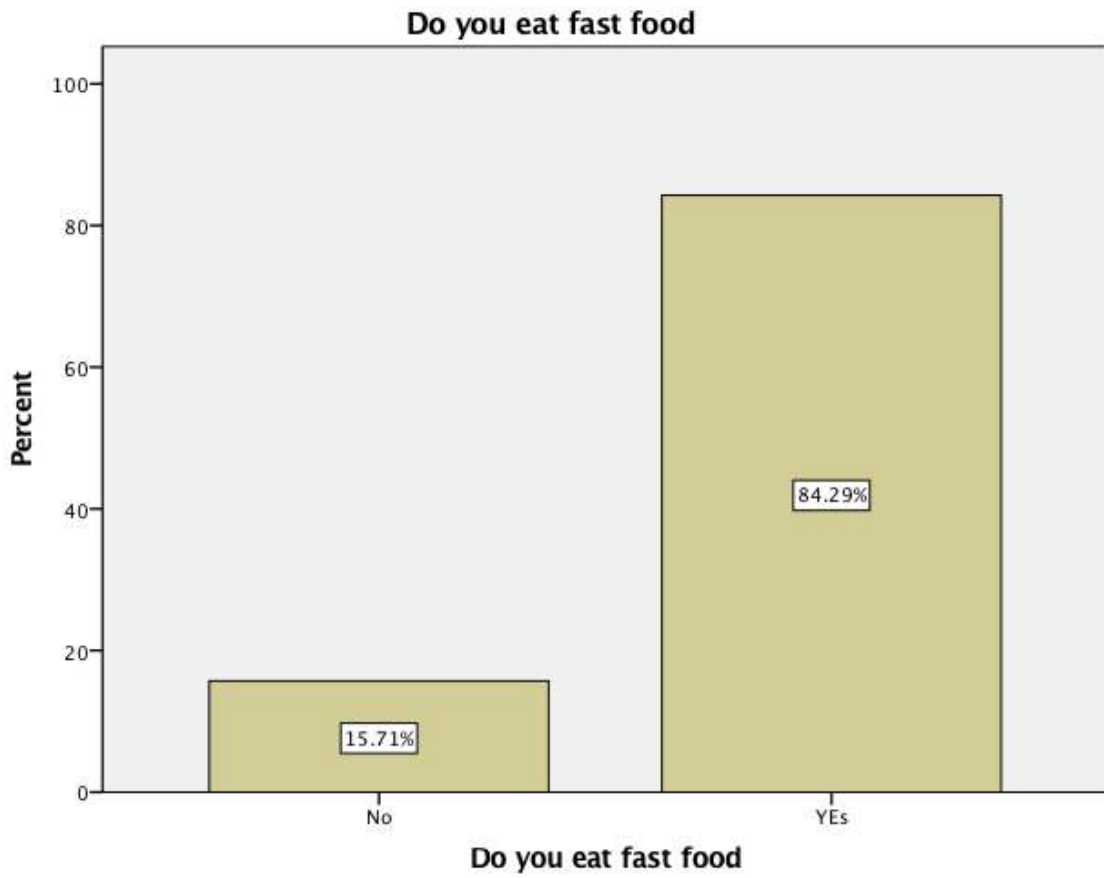

Fig. 1: Percentages of former athletes who eat fast food

Fig. 2 Percentages of former athletes who drink fizzy drinks

## Discussion

It is accepted that engagement in regular physical activity can lead to a better health and a long life<sup>(8,10–12)</sup>. However, several studies have reported that the risk of long-term diseases increase when the athletes adopted a sedentary lifestyle after ceasing to participate in competitive sport<sup>(9,13)</sup>.

It has been reported that former athletes generally keep active and live a healthier lifestyle when they get older<sup>(10,12–14)</sup>. However, several studies have indicated that a significant number of former athletes reduce their level of physical activity and or engage in sedentary behaviours after ceasing to participate in competitive sport<sup>(8,13)</sup>. It has been reported that there are several reasons why former athletes do not participate in physical activities: for example, long-term injuries might prevent former athletes from carrying out physical activity<sup>(8)</sup>. Furthermore, the process of ageing may play a significant role in increasing the body composition and reducing the cardiorespiratory functions<sup>(11,15,16)</sup>.

Although many studies have focused on the current health of former athletes<sup>(9,14,17)</sup>, there is a lack of research associated with athletes who had engaged in regular exercise before they had retired. The findings, which used a group of seventy (70) former athletes that included men from 13 different sports, found that the percentages of overweight and obese individuals in the study sample were high, similar to those of the general Saudi population<sup>(3,18–22)</sup>.

According to the study findings, a significant number of former athletes are now eating fast food and drinking fizzy drinks (Figure 1 & 2), which may contribute to increasing the prevalence of overweight and obesity among former athletes.

The study findings are consistent with results from several studies conducted in Saudi Arabia<sup>(1,2,5,23)</sup>, which shows that the percentage of fast food and drinking fizzy drinks is high. According to Najlaa Mandoura et al., (2018), about 86% of participants were eating fast food. A recent study also stated that former professional footballers had higher body weight and BMI scores<sup>(8)</sup>. It is accepted that unhealthy diet is a risk factor for several long-term illness, such as CVD, T2D, hypertension, and some cancers<sup>(9,16)</sup>. It has been reported that high BMI often occurs as a result of a lack of physical activity or high intake of foods<sup>(8)</sup>.

Although this is a small study, it is in fact the first study to determine the prevalence of fast food and fizzy drinks in former athletes in Saudi Arabia, and therefore the outcomes are of great importance, in spite of the small number of participants.

**Limitations:** This study depended on self-reported survey via the former athletes which may result in reporting bias. The study sample size is relatively small. Moreover, the study assessed only the prevalence of consuming fast food without assessing the frequency of use and the portions size, which might give more information about the fast food behaviours among former athletes. Despite these limitations, the study provided a clear evidence on the high prevalence of fast food and fizzy drinks consumption among former athletes.

## Conclusion

The outcomes of this research revealed that the majority of former athletes are consuming fast food and drinking fizzy drinks. Also, the study indicated that the majority of overweight and obese people are consuming fast food. Additionally, the study reported that there is no significant relationship between eating fast food and BMI.

**Acknowledgements:** We are grateful to all participants in the study for their active cooperation. We also express our admiration to the Saudi Athletic Federation for their collaboration.

**Competing Interests:** The authors declare that they have no competing interests.

**Funding:** No funding has been received for this manuscript.

## Abstract

**Context:** The present study was performed to evaluate the Efficacy of Diode Laser in maturogenesis of Immature Teeth with Necrotic Pulps in comparison to conventional technique of revascularization using triple antibiotic mix. Immature necrotic permanent maxillary anterior teeth of medically free patients 8-16years old were used to perform regenerative endodontic procedures (revascularization) and divided into 3 groups (n = 10) : group I: Ten teeth were disinfected by triple antibiotic paste then Revascularization was done using the standard method. Group II: Ten teeth were Laser disinfected; Revascularization was done using the standard method. Group III: Ten teeth were disinfected by triple antibiotic paste then Revascularization was done using the standard method followed by diode laser bio-stimulation. Follow-up was done at 3, 6, 9 and 12 months intervals and included clinical examination for signs and symptoms and radiographic evaluation for increase in root length, increase in root thickness, a decrease in apical diameter, and a decrease in lesion size, and the antibacterial efficacy of the Diode laser (980) nm and triple antibiotic disinfection method on the colony forming units. It was resulted that, the colony forming unit's results revealed non-significant difference in percent change after treatment between triple antibiotic paste and laser disinfection. It was concluded that: Diode laser irradiation seems to be a valuable tool in the eradication of polymicrobial nature of root canal infection. Diode laser could be used instead of triple antibiotic paste for disinfection of root canals in revascularization. Diode laser decontamination showed no teeth discoloration as opposed by the triple antibiotic paste.

**Keywords:** Diode Laser, Triple Antibiotic Paste, Revascularization, Canal Disinfection, Immature Necrotic Teeth.

## Introduction

The treatment of immature permanent teeth with necrotic pulp constitutes a challenging situation facing

endodontists. Such conditions present difficulty in root canal debridement and obturation because of the open apex. Moreover, they are more prone to fracture because of thin weak dentinal root canal walls. Such cases were traditionally treated by apexification procedures using calcium hydroxide<sup>(1)</sup>. Such management requires long-term placement of calcium hydroxide inside the root canal to induce the formation of an apical hard tissue barrier. Recently, many authors advocated the placement of an ortho-grade apical plug<sup>(2)</sup>. Mineral trioxide aggregate (MTA) proved to be an excellent candidate; however,

apical plugs do not solve the problem of the thin and weak dentinal root canal walls<sup>(3)</sup>.

Periapical tissues in immature teeth are rich in blood supply and contain stem cells that have the potentiality for tissue regeneration<sup>(4)</sup>. Under suitable conditions, stem cells can be programmed for self-regeneration to restore the lost part. Hence, the concept of regeneration of immature non-vital teeth was advocated. Eradication of bacteria from the canal space is mandatory for successful regenerative endodontic procedures. Research with topical antibiotics showed that a combination of metronidazole, minocycline, and ciprofloxacin could be effective against common endodontic pathogens in vitro and in vivo<sup>(5)</sup>. However, a disinfected empty canal space cannot support the ingrowth of new regenerated tissues on its own so a scaffold is needed for support. Advances in tissue engineering research focused on three key elements for tissue regeneration<sup>(6)</sup>: stem cells that have the ability for proliferation and differentiation; scaffold, which is a three, dimensional structure that supports the regenerated tissue integrity; and growth factors, which are secreted signals governing morphogenesis and differentiation.

Laser is an acronym for light amplification by stimulated emission of radiation. It is classified according to power into low power lasers (LPL) which is also called low intensity lasers (LIL) and low level laser therapy (LLL) which is used in bio-modulation, stimulation of healing, decreasing inflammation, decontamination and pain relief<sup>(7)</sup>.

The beneficial effect of (LLL) on bone was proved by many authors. It was observed that the collagen production, osteoblastic activity and increased bone mineral density, also it was found that (LLL) promotes bone regeneration and improves bone density in several studies<sup>(8)</sup>.

The aim of the study was to evaluate the Efficacy of Diode Laser in maturogenesis of Immature Teeth with Necrotic Pulp in comparison to conventional technique of revascularization using triple antibiotic mix.

## Methodology

**Group I: Triple antibiotic paste disinfection then revascularization using the standard method:**

**The disinfection visit:** Swab for bacterial culture were taken and sent to the bacteriology lab. The root

canals were copiously and slowly irrigated with 20 ml of 1.5%<sup>(9)</sup> sodium hypochlorite (NaOCl) solution for 5 minutes alternatively with 20 ml of 17% ethylene diamine tetra acetic acid (E.D.T.A) solution for 5 minutes with intermediated rinse of distilled water with paper point dryness in between irrigations.<sup>(10)</sup> The triple antibiotic paste was prepared using metronidazole, ciprofloxacin and doxycycline. The doxycycline capsule content was evacuated in a sterile mortar; a tablet of metronidazole and a tablet of ciprofloxacin were crushed and ground into homogenous powder in the same mortar using a pestle. Saline drops were added and mixed using the pestle until a creamy paste was achieved<sup>(9)</sup>. The canals were dried with paper points and medicated with triple antibiotic paste; the access cavity was sealed with intermediate restorative material (I.R.M).

**The revascularization visit:** The revascularization visit was scheduled when the tooth was asymptomatic with no signs of discharge. The tooth was isolated, and then the I.R.M was removed. Local anesthesia without a vasoconstrictor (Scandonest 3% plain) was administered. The antibiotic paste was washed out with saline with gently agitation of small file to remove the antimicrobial medicament. Swab for bacterial culture were taken and sent to the bacteriology lab, the blood initiation and MT placement was done, and the cavity was finally restored with light cure composite resin.

**Group II: Laser disinfection with revascularization using the standard method:**

**The disinfection visit:** Preoperative radiograph, access cavity, and irrigation were performed in a similar way as previously described during Group I disinfection visit then, the diode laser decontamination and disinfection was applied with the parameter of Power: 1.5 watt, Mode: pulse: SP:  $T_{on}=10ms$ ;  $T_{off}=10ms$  50Hz (50% pulse mode), for 5 seconds in spiral movement in apical to coronal direction no stop with non-initiated endodontic tip 200 micron diameter and 15 mm length three times. Irrigation with NaOCl, irradiation with the laser, then irrigation with E.D.T.A and irradiation with the laser, followed again by NaOCl irrigation and laser irradiation.<sup>(11)</sup> final irrigation with E.D.T.A followed by final rinse of distilled water with paper point dryness in between irrigations.. Swab for bacterial culture were taken and sent to the bacteriology lab, the access cavity was sealed with I.R.M.

**The revascularization visit:** The revascularization

visit was performed in a similar way as previously described in Group I.

**Group III: Triple antibiotic paste disinfection then Revascularization using the standard method followed by diode laser bio-stimulation:**

**The disinfection visit:** The disinfection visit was performed in a similar way as previously described during Group I.

**The revascularization visit:** The revascularization visit was performed in a similar way as previously described in Group I then, the diode laser bio-stimulation was applied using Wiser Diode Laser.

**Bacterial sampling “culture”:**

**Pretreatment bacteriologic sampling, colony forming units (CFU /ml):** Canals were swapped with sterile paper point. A sterile paper point #40 was placed in the root canal to the working length, allowed to saturate and transformed into sterile tubes containing 1 ml of sterile saline solution. Before placing the paper point into the tubes, the mouth of each tube was heated on the flame to prevent contamination. Each sample was carefully homogenized by being vortexed for 10 seconds.

**Serial dilution agar plat count technique:** Antibacterial activity of the different swaps was evaluated by using serial dilution agar plate technique. The media was prepared by dissolving the following in 1 Liter of distilled water; (tryptone 5.0 gm, yeast extract 2.5 gm, glucose 1.0 gm, agar bios LL 15.0 gm, pH 7.0 +/- 0.2) was weighed on a piece of aluminum foil using an electronic sensitive balance. The pH was adjusted to 7.2 and brought to boil to be dissolved completely then sterilized in autoclave at 121°C.

After vibrating the samples in a vortex to get a homogenous mix and transfer the bacteria from the swap to the solution. For the pour plate technique, the agar was liquefied by autoclaving, and then the bottle of molten agar was placed in a 50°C water bath and allowed to cool. The required details were marked on the base of sterile agar plates (Petri dishes); about 20 mL of molten agar was poured into each of the plates. 1 mL of each of the diluted swap was poured into the base of the labeled plates using a separate pipette to avoid carryover errors, gently swirling each plate to mix the 1 mL of diluted sample into the agar.

The test was performed in triplicates. Single sterile channel micropipette tip was used to add 1 ml of the standard microbial media to each plate. All the procedures were carried out under aseptic condition in a laminar flow cabinet in an area of no more than 10 cm away from a glowing torch to avoid any contamination during the procedure.

The plates were left without moving for at least 15 minutes to allow the agar to solidify. When the agar was set, it was inverted and incubated at 37 °C temperature and 100% relative humidity, for 48 hours. The endpoint for evaluation was the mean number of colony-forming units (CFUs) per mL.

After 48 hours, petri dishes were examined for bacterial growth by colony counter apparatus and the colony forming units (CFU) per ml were counted. Visible colonies were counted in each plate and then transformed into actual counts based on the known dilution factors (x10). The total colony forming units (CFU) considered as a baseline pretreatment count.

**Post treatment bacteriologic sampling and bacterial count:** When root canal disinfection procedure was completed, post treatment bacteriologic sampling and count were performed in a similar way as previously described during the Pretreatment bacteriologic sampling.

**Results**

**Comparison of bacterial count in different groups:** Comparison of mean bacterial count (log 10) in groups I & II is presented in Fig. (1) & Table (1)

Pre-treatment, the highest mean value (4.89±0.79) was recorded in triple antibiotic group. Independent t test revealed a highly significant difference between both groups (p=0.0056).

Post-treatment, the highest mean value (1.71±0.85) was recorded in triple antibiotic group. Independent t test revealed a highly significant difference between both groups (p=0.004).

The percent change in bacterial count after treatment was calculated and compared between the 2 groups. A greater percent decrease (-84.7±20.66) was recorded in triple antibiotic group. Independent t test revealed non-significant difference in percent change after treatment between both groups (p=0.635), (Table 1).

**Table 1: Comparison between groups I & II regarding mean bacterial count (log 10) and percent change after treatment (independent t test)**

	Triple antibiotic	Laser	t	P
Pre (log10)	4.888±0.793	3.049±1.671	3.144	0.0056*
Post (log10)	1.712±0.848	0.552±0.097	4.298	0.0004*
Percent change (%)	-84.70±20.66	-79.94±23.30	0.483	0.635ns

Significance level P<0.05, \*significant, ns=non-significant

**Fig. (1):**Column chart showing mean bacterial count (log 10) in triple antibiotic and laser groups

**V-b-Comparison of bacterial count before and after treatment within the same group:** Comparison of mean bacterial count (log 10) before and after treatment within the same group is presented in (Table 2).

Both groups revealed a highly lower mean bacterial count after treatment (p=0.00, p=0.0002 in in triple antibiotic and laser groups respectively).

**Table 2: Comparison of mean bacterial count (log 10) before and after treatment within the same group (paired t test)**

	Triple antibiotic	Laser
Pre (log10)	4.888±0.793	3.049±1.671
Post (log10)	1.712±0.848	0.552±0.097
T	8.67	4.72
P	0.000*	0.0002*

Significance level P<0.05, \*significant

### Discussion

The colony forming unit’s results revealed non-significant difference in percent change after treatment

between triple antibiotic paste and laser disinfection (Fig 1, Table 1). Unfortunately, there were no available studies comparing the antibacterial efficiency of both disinfection method used, however several studies revealed the antibacterial effect of the triple antibiotic paste (12-15). The effects of the triple antibiotic were discussed earlier in this discussion. *Moritz et al (1997)* (16) showed the bactericidal effect of a diode laser (810 nm) at 3 W during 5 x 5 s against intracanal *Escherichia coli* and *Enterococcus faecalis* in extracted teeth. Irradiation at 4 W was even more effective although associated with a temperature rise of 6°C. The same result with a diode laser (810 nm) at 3 W during 30 s was reported by *Gutknecht et al (2000)* (16) against intracanal *Enterococcus faecalis*. While our results disagreed with *Bago et al (2012)* (17) who found that Photo-activated disinfection and EndoActivator were significantly more effective than diode irradiation and single NaOCl irrigation in reducing CFUs, this result could be attributed to the protocol used with the pulsed diode laser group, in which the disinfection was done in dry field Root canals were irradiated with a pulsed diode laser For 20 s, repeated three times at intervals of 10 s

between each one, which contradict the protocol used in this study and proposed by (*Benedicenti et al 2008*)<sup>(11)</sup> in which the 980 diode laser decontamination and disinfection was applied with the parameter of Power: 1.5 watt, Mode: pulse: SP: T<sub>on</sub>=10ms; T<sub>off</sub>10ms 50Hz (50% pulse mode), for 5 seconds in spiral movement in apical to coronal direction no stop with non-initiated endodontic tip 200 micron diameter and 15 mm length three times. irrigation with NaOCl, irradiation with the laser, then irrigation with EDTA and irradiation with the laser, followed again by NaOCl irrigation and laser irradiation, final irrigation with E.D.T.A followed by final rinse of distilled water.<sup>(11)</sup>

Thus, it's worth mentioning that the known drawbacks of the triple antibiotic paste such as toxicity to the Dental pulp stem cells, discoloration of the tooth and development of the bacterial resistance can be eluded by using lasers in disinfection for regenerative purpose.

### Conclusion

1. Diode laser irradiation seems to be a valuable tool in the eradication of polymicrobial nature of root canal infection.
2. Diode laser could be used instead of triple antibiotic paste for disinfection of root canals in revascularization.
3. Diode laser decontamination showed no teeth discoloration as opposed by the triple antibiotic paste.

**Conflict of Interest:** No

**Source of Funding:** Self-funding.

**Ethical Clearance:** every patient in this study had given their informed consent for inclusion before their participation. Which is conducted in accordance with the declaration of Helsinki, it was approved by the ethics committee of minya university number (133).

## Abstract

**Background:** The epidural infusion of local anesthetic and opioid achieves effective postoperative analgesia in thoracic surgery patients. Nevertheless, high dose of opioids may induce dose-dependent undesired effects. Recent reports showed that adjuvant epidural magnesium administration significantly improve intra and postoperative analgesic outcomes. The present randomized trial aimed to assess the intra and postoperative analgesic effect of continuous epidural infusion of magnesium sulphate in patients undergoing elective cancer thoracic surgery.

**Method:** Sixty ASA III patients undergoing elective cancer thoracic surgery were randomized in 1:1 ratio to receive adjuvant epidural magnesium sulphate or 0.9% sodium chloride solution. The primary outcomes in the present study were intra and postoperative analgesic requirements, and postoperative pain score.

**Results:** The magnesium sulphate group showed a statistically significant lower number of required fentanyl doses than the control group (74.3% needed two or more doses in magnesium sulphate group versus 94.4% in the control group,  $p = 0.026$ ). A similar finding was observed for need for ketorolac 30mg ( $p = 0.017$ ). The postoperative VAS was significantly lower in magnesium sulphate group from the 12<sup>th</sup> hour ( $p = 0.033$ ) to the 48<sup>th</sup> hour postoperatively ( $p < 0.001$ ). The magnesium sulphate group showed more stable hemodynamics. No major side-effects were observed in any of the study groups.

**Conclusion:** Epidural magnesium sulphate is a potent adjuvant analgesic that reduced opioid consumption and postoperative pain in patients undergoing thoracic surgery.

**Keywords:** Thoracic Surgery; Epidural Analgesia; Magnesium Sulphate

## Introduction

Lung cancer is the second most common cancer type in both gender with reported 220,000 new cases and 158,080 deaths in 2016 in United States alone<sup>1</sup>. Up to 25% of the lung cancer patients are diagnosed during early stages (stage I or II) which is usually treated by anatomical surgical resection. For longtime, open

thoracotomy was the surgical approach of choice for surgical resection of lung cancer, with acceptable five-year overall survival<sup>2</sup>. However, postoperative pain is a major challenge in patients undergoing thoracotomy, it was reported that thoracotomy is commonly associated with postoperative, sometimes severe, pain that can impair respiratory functions with subsequent hypoventilation and respiratory failure<sup>3,4</sup>. Moreover, ineffective management of immediate postoperative pain may lead to chronic pain syndrome in a considerable proportion of the patients undergoing thoracotomy<sup>5</sup>. The occurrence of postoperative pain following thoracic surgery was proposed to be a consequence of tissue damage and neuroplastic changes; thus, preemptive analgesia is one of the main management options to avoid the occurrence of such neuroplastic changes<sup>6</sup>.

However, the management of postoperative pain is particularly difficult in patients undergoing thoracic surgery, the majority of those patients are classified as American Society of Anesthesiology (ASA) class III due to associated comorbidities, impaired pulmonary function, and old age<sup>7,8</sup>. Multimodal regimens and narcotic-based patient controlled analgesia (PCA) are not effective options in many cases due to technical complexity –in high risk patients- and serious side-effects<sup>9</sup>. To date, epidural analgesia is the gold standard for postoperative pain relief after thoracic surgery<sup>10</sup> local anesthetic wound infiltration, systemic N-methyl-D-aspartic acid (NMDA). The epidural infusion of local anesthetic and opioid achieves effective postoperative analgesia with low rates of central nervous system (CNS) and respiratory complications<sup>11</sup> and therefore regional analgesia has been intensively studied in this procedure. Thoracic epidural analgesia is commonly considered the “gold standard” in this setting; however, evaluation of the evidence is needed to assess the comparative benefits of alternative techniques, guide clinical practice and identify areas requiring further research. **Method:** In this systematic review of randomized trials we evaluated thoracic epidural, paravertebral, intrathecal, intercostal, and interpleural analgesic techniques, compared to each other and to systemic opioid analgesia, in adult thoracotomy. Postoperative pain, analgesic use, and complications were analyzed. **Results:** Continuous paravertebral block was as effective as thoracic epidural analgesia with local anesthetic (LA). Nevertheless, high dose of opioids may lead to dose-dependent adverse events such as nausea, vomiting, impaired intestinal motility, and respiratory depression<sup>8</sup>.

Recently, a growing body of evidence has proposed that magnesium is an effective, adjuvant, local and systemic analgesic due to its blockade of N-methyl-D-aspartate (NMDA) receptors and calcium channels<sup>12</sup>. Epidural magnesium sulphate showed better analgesic and reduced the need for rescue analgesics when added to epidural fentanyl in surgical patients<sup>13</sup> including intravenous, intrathecal, and epidural in different dosage regimens. The effect of single bolus dose of magnesium as an adjuvant to fentanyl for postoperative analgesia has not been studied. This prospective randomized controlled trial was done to evaluate the efficacy of single bolus administration of magnesium epidurally as an adjuvant to epidural fentanyl for postoperative analgesia in patients undergoing total hip replacement under combined spinal epidural anesthesia. **Method:** Sixty patients received combined spinal-epidural anesthesia with 2 mL of 0.5% hyperbaric bupivacaine intrathecally. After the surgery, patients were randomized into Group F [epidural fentanyl (1 µg/kg). However, there is a scarcity in the published literature that assessed the analgesic effect of epidural magnesium sulphate, as adjuvant to epidural fentanyl in patients undergoing thoracic surgery. The present randomized controlled trial aimed to assess the intra and postoperative analgesic effect of epidural infusion of magnesium sulphate in patients undergoing elective open thoracotomy.

## Material and Method

We confirm that the present trial run in concordance with international ethical standards and applicable local regulatory rules. The Ethical Committee of Cairo University National Cancer Institute, Institutional Review Board, provided ethical approval for this study (Ethical Committee No. 201617007.3- IRB00004025-FWA00007284). A written informed consent was obtained from every patient prior to study enrollment. We followed Consolidated Standards of Reporting Trials (CONSORT) guidelines during the preparation of this randomized controlled trial<sup>14</sup>.

**Study Design and Patients:** Adult, ASA III, lung cancer patients, who were scheduled to undergo elective open thoracotomy and agreed to sign the informed consents, were included in the present trial. Patients with major liver or kidney impairment, neuromuscular disease, second or third degree atrioventricular block, extreme obesity were excluded. We excluded patients exposed to opioids and/or calcium channel blockers before surgery as well.

The present study was a phase II, randomized, controlled trial that was conducted at the operating theatre of Anaesthesia, ICU and pain management department of Cairo University National Cancer Institute. Eligible patients were randomized in 1:1 ratio to receive either epidural magnesium sulfate or sodium chloride using computerized randomization schedule. Pre operatively, patients underwent routine assessment and were made familiar with the use of the visual analogue scale (VAS).

**Technique:** In all patients, cardiovascular function was monitored by electrocardiography and invasive blood pressure measurement, oxygenation by pulse oximeter, ventilation by capnography, level of neuromuscular blockade by a Train of Four (TOF) Guard neuro stimulator (Organon, Tehnika), and level of hypnosis by bispectral index (BIS) determination on a BIS monitor (Datex-Ohmeda).

In magnesium sulphate group, patients were injected with 25 mg 0.5% levobupivacaine and 50 mg 10% MgSO<sub>4</sub> via epidural catheter (Th 4-Th 6) 15 minutes before induction of general anesthesia. In the control group, patients were injected with 25 mg 0.5% levobupivacaine via epidural catheter (Th 4- th5 or th5 Th 6) 15 minutes before induction of general anesthesia. Anesthesia was induced with midazolam at a dose of 0.03 mg/kg, fentanyl 0.3-0.6 µg/kg, and propofol 1 mg/kg. After the induction of anesthesia, magnesium sulphate group received continuous epidural infusion of 10% MgSO<sub>4</sub> at a dose of 50 mg/h, whereas the control received the same volume of epidural 0.9% NaCl.

In all patients, neuromuscular blockade achieved with muscle relaxant rocuronium at a dose of 0.7 mg/kg to facilitate endotracheal intubation. All patients mechanically ventilated with 1:1 air/oxygen mixture. Hypnosis was maintained by continuous sevofluran according to BIS values 40-60, and myorelaxation according to TOF = 1 by continuous rocuronium infusion. Intraoperative elevation of the mean blood pressure and pulse by  $\geq 20\%$  of the initial values was defined as inadequate analgesia. These patients received a fentanyl bolus dose of 0.2 µg/kg. At the end of the operation, sevofluran discontinued on skin closure and neuromuscular blockade was antagonized by the administration of sugammadex. The patients were extubated when the BIS values reached 80 and the TOF ratio was  $> 0.8$ .

Postoperatively, during the first 48 hours,

magnesium sulphate group received the 50 mg/ hour magnesium sulfate in addition to levobupivacain 2.5mg /hour continuous epidural infusion and systemic opioid fentanyl 0.3-0.6 µg/kg, whereas control group received epidural the same volume 0.9 % Na Cl and local anesthetic levobupivacain 2.5mg /hour and systemic opioid (fentanyl). The value of VAS  $\leq 4$  was maintained by adjusting the rate of infusion in both groups. Hemodynamic parameters (central venous pressure, non-invasive systolic and diastolic blood pressure, heart rate) urine output and respiratory rate were recorded 48 hours postoperatively.

**Efficacy Measures:** The primary outcomes in the present study was to determine cumulative doses of intraoperative administered fentanyl and cumulative doses of fentanyl administered during 48 hours postoperatively. The secondary outcomes were VAS score for rest and movement every 4 hours, level of sedation, cardiovascular, respiratory and neurological complications, incidence of postoperative shivering, nausea and vomiting, and global patient satisfaction.

**Statistical Analysis:** Recorded data were analyzed using the statistical package for social sciences, version 20.0 (SPSS Inc., Chicago, Illinois, USA). Quantitative data were expressed as mean  $\pm$  standard deviation (SD). Qualitative data were expressed as frequency and percentage. Independent-samples t-test of significance was used to compare between quantitative data, while Chi-square test of significance was used in order to compare proportions between qualitative parameters. The confidence interval was set to 95% and the margin of error accepted was set to 5%. So, the p-value was considered significant  $< 0.05$ .

## Results

The present study included seventy patients who were assigned in 1:1 ratio to either magnesium sulphate group or control group. Both groups were comparable regarding the demographic data. There was no statistically significant difference between the two groups in baseline MAP and heart rate.

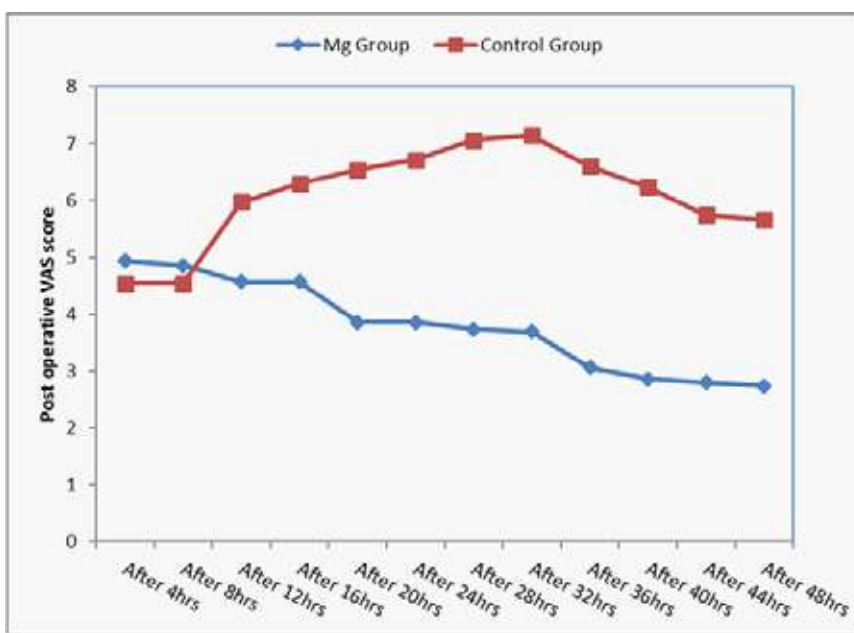

With regard to our primary outcomes, the total dose of fentanyl was significantly higher in control group than the magnesium sulphate group (2575 versus 1850 doses, respectively,  $p = 0.0265$ ). The magnesium sulphate group showed a statistically significant lower number of required fentanyl doses than the control group (74.3% needed two or more doses in magnesium sulphate group

versus 94.4% in the control group,  $p=0.026$ ). A similar findings was observed for need for ketorolac 30mg ( $p=0.017$ ; **Table 1**).

**Table 1: Comparison between groups according to needs for analgesic**

Needs for analgesic	Mg Group (n=35)	Control Group (n=35)	x2	p-value
<b>NSAID doses ()</b>				
1	13 (37.1%)	4 (11.4%)	12.029	0.017*
2	13 (37.1%)	10 (28.6%)		
3	6 (17.1%)	9 (25.7%)		
4	3 (8.6%)	8 (22.9%)		
5	0 (0.0%)	4 (11.4%)		
Total Dose	3450	5150		
<b>Fenanyl doses (0.3 m/kg)</b>				
1	9 (25.7%)	2 (5.7%)	11.045	0.026*
2	16 (45.7%)	12 (34.3%)		
3	7 (20.0%)	9 (25.7%)		
4	3 (8.6%)	10 (28.6%)		
5	0 (0.0%)	2 (5.7%)		
Total Dose	1850	2575		

The postoperative VAS was significantly lower in magnesium sulphate group from the 12th hour ( $4.57\pm 0.50$  versus  $5.97\pm 1.18$ , respectively;  $p=0.033$ ) to the 48th hour postoperatively ( $2.74\pm 0.66$  versus  $5.66\pm 1.03$ , respectively;  $p<0.001$ ; **Figure 1**). A statistically significant higher proportion of patients were satisfied in magnesium sulphate group than control group (80% versus 22.9%, respectively,  $p<0.001$ ).

**Figure (1): Line chart between groups according to postoperative VAS score.**

The MAP was significantly lower in magnesium sulphate group than control group 12 hours postoperatively ( $80\pm 2.1$  versus  $96.29\pm 7.89$ , respectively;  $p=0.012$ ; **Figure.2**); these finding was stable till 48 hours postoperatively. Six hours after the operation, the

heart rate was significantly lower in magnesium sulphate group than control group ( $81.77\pm 9.39$  vs.  $96.86\pm 8.95$ , respectively;  $p=0.023$ ), and the trend was consistent till 48 hours after the operation ( $p<0.001$ ; **Figure 3**).

Figure (2): Line chart between groups according to mean arterial blood pressure (mmHg).

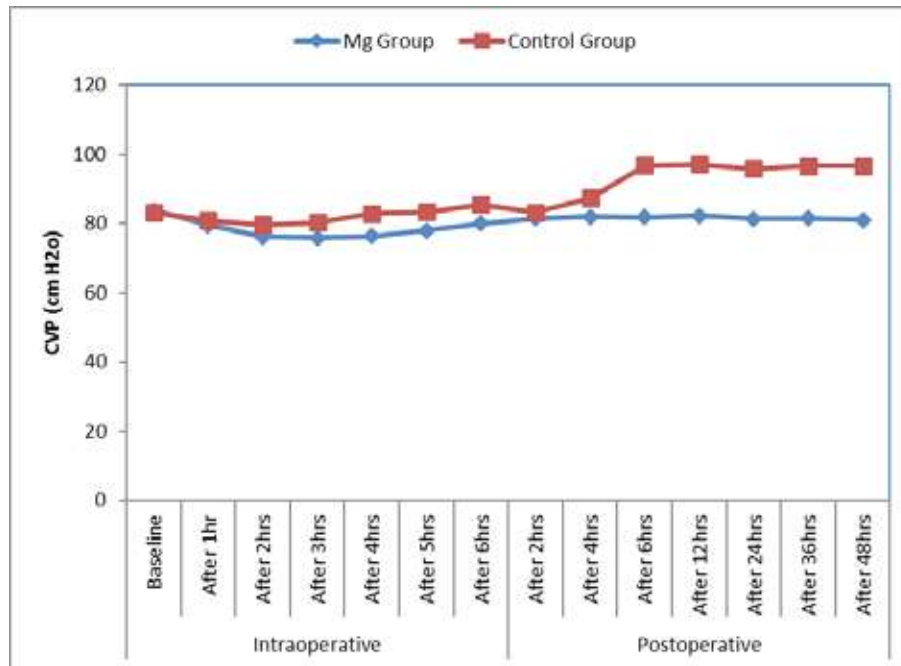

Figure (3): Line chart between groups according to heart rate (Beat/min).

The incidence of nausea and vomiting was significantly higher in the control group than the magnesium sulphate group ( $p < 0.001$ ; Table 2). No major adverse events were observed in both groups.

Table 2: Comparison between groups according to side effects

Side effects	Mg Group (n=35)	Control Group (n=35)	$\chi^2$	p-value
Nausea & Vomiting	5 (14.3%)	24 (68.6%)	21.253	<0.001**
Cardiovascular	5 (14.3%)	28 (80.0%)	30.328	<0.001**
Increase respiratory	6 (17.1%)	9 (25.7%)	0.343	0.558
CNS	4 (11.4%)	5 (14.3%)	0.128	0.721

## Discussion

The present study randomized, controlled, trial assessed the analgesic effect of epidural magnesium sulphate as adjuvant to the conventional combination of local anesthetic and opioid in patients undergoing thoracic surgery. Our randomized controlled trial showed that epidural magnesium sulphate significantly reduced the cumulative doses of intraoperative administered fentanyl and cumulative doses of fentanyl administered during 48 hours postoperatively; as well as the need for rescue analgesic. In addition, epidural magnesium sulphate led to statistically significant lower postoperative pain scores. Moreover, magnesium sulphate group showed more stable hemodynamics than control group, although the difference was clinically subtle. We did not observe any major adverse events in both groups, however, the incidence of nausea and vomiting was significantly higher in the control group than the magnesium sulphate group.

Over the past decades, a growing body of evidence has suggested a significant role of glutamate receptors on peripheral nociceptive sensation; thus, an effective blockade of glutamate receptors, such as N-methyl-D-aspartate (NMDA) receptor, can alleviate different type of pain including postoperative pain<sup>15</sup>. Magnesium sulphate has emerged as an effective, adjuvant, local and systemic analgesic due to its effective blockade of NMDA receptors and calcium channels after systemic absorption<sup>12</sup>. It also increases the number of nerve fibers affected by bupivacaine and therefore potentiates its conduction block<sup>16</sup>. Thus, we proposed that adjuvant infusion of epidural magnesium sulphate to the standard combination of epidural infusion of local anesthetic and opioid can lead to better opioid consumption and postoperative analgesia. Our trial confirmed this hypothesis by showing that the epidural magnesium sulphate significantly reduced the cumulative doses of administered fentanyl and postoperative pain scores. In concordance with our findings,

However, we acknowledge that the present trial has some limitations. The reduced pain scores and reduced requirements for postoperative analgesia in the magnesium group could be a result of the longer block, rather than a reduction in nociception. The study did not allow a separation of the longer spinal blockade versus the potential analgesic effect of magnesium.

In conclusion, the present randomized trial showed that epidural magnesium sulphate is a potent

adjuvant analgesic that reduced opioid consumption and postoperative pain in patients undergoing thoracic surgery. For patients undergoing elective lung cancer resection, it is recommended to have a magnesium sulphate as adjuvant because this improves the quality and duration of postoperative analgesia. Further trials are required to validate these findings.

## Abstract

**Background:** This study is designed to study factors associated with tuberculosis in marshlands of Iraq

**Method:** This is a case control study conducted in three governorates containing marshlands in the south of Iraq. Cases were new pulmonary TB case aged over 14 years and Control were age, sex and district matched other than TB patients seeking for health care in primary health care centers. Analysis used the following tests: Chi-square, T-test and Mann-Whitney tests.

**Findings:** The study sample composed of 455 new TB cases and 444 controls. Males constituted 47% of both study groups. Mean age was 41.1±17.4 year for TB cases and 40.4±14.3 year for control group. Underweight was found more among TB cases (19% in cases and 6.9% in control group) ( $P < 0.05$ ). Employment rate in cases was half that of control and housewives were more among cases (43.4% in cases and 28.2% among control) ( $P < 0.05$ ). Duration of smoking was significantly longer in TB cases (18.6±13.7 year) than in control group (12.8±9.6 year) ( $P < 0.05$ ). Diabetes rate was significantly higher among cases (16.6%) than in control (10.2%) ( $P < 0.05$ ). Length of Dexamethasone use was significantly higher in TB patients ( $P < 0.05$ ). It was significant to find TB cases more to have rooms without windows. Family size was higher in cases ( $P < 0.05$ )

**Conclusion:** Main factors associated with TB in south of Iraq were underweight, unemployment, period of smoking, diabetes, period of Dexamethasone use, living in rooms devoid of windows and large family size. Poverty related factors are likely behind having TB in marshlands.

**Keywords:** Tuberculosis, Marshlands, diabetes, smoking, poverty

## Introduction

Tuberculosis (TB) is contagious and airborne. It ranks as the second leading cause of death from a single infectious agent [1]. In Iraq, WHO estimates 45 new and relapsed TB cases and more than 3000 death annually [2].

Three Iraqisouthern governorates have marshland areas (Misan, Thiqr, and Basrah) with a population exceeds five million (20% living in Marshlands).

---

e-mail: laythalsalihi@yahoo.com

Marshlands in south Iraq experience poor health services, poor infrastructure development and population living near polluted sites and industrial plants. Extensive ecological damage to this area, with the accompanying displacement of much of the indigenous population, was identified as one of Iraq's major environmental and humanitarian disasters in post-conflict assessments by international organizations<sup>[3]</sup>.

Factors lead to causation of TB anywhere include low education level<sup>[4, 5]</sup>, income<sup>[5]</sup>, employment<sup>[4]</sup>, malnutrition<sup>[5]</sup>, smoking<sup>[2,8]</sup>, diabetes<sup>[4,5, 6]</sup>, HIV<sup>[7]</sup>, household contact<sup>[7]</sup>, living and working conditions<sup>[8, 9]</sup>, crowding<sup>[4, 7]</sup>, poverty<sup>[4,9]</sup>, poor ventilation<sup>[9]</sup>, use of solid fuel for cooking<sup>[10]</sup>

However, little is known about many other risk factors within marshlands in Iraq. This study is designed to study the factors associated with TB with a specific focus on marshlands area.

### Subjects and Method

This study conducted in three southern governorates of Iraq (Basrah, Thiqr and Misan). Out of 18 districts, six of them are marshland areas containing marshland population and number of TB management units (TBMUs), PHCCs and TB cases registered during 2011.

This is Case Control Study that cases (new TB cases) registered in NTP registered during time of data collection from the three governorates and control (non-TB patients and non-TB suspects attending PHCCs belong to same three governorates during the time of data collection)

**Case:** All TB cases older than 14 years who were newly registered in National TB Control Program in southern governorates from the day of the implementation of the study, not a case of TB relapse or retreatment

Controls were chosen in a way they match cases in age (not more than five years older or younger than TB cases), sex, and locality (nearest PHCC to the cases locality).

#### Data were collected during 2013:

**Statistical Analysis:** A statistical package SPSS20 was used for data analysis. Chi-square, T-test and Mann-Whitney test were used in analysis. Level of significance was set at 0.05.

**Findings:** Study sample composed of 455 new cases of TB and 444 controls. Males constituted 47% of both study groups ( $P > 0.05$ ).

Mean age for TB cases group was  $41.1 \pm 17.4$  year and for control group was  $40.4 \pm 14.3$  year. Mean **Body Mass Index** (BMI) was  $23.0 \pm 5.9 \text{ kg/m}^2$  for cases and it was significantly lower than mean BMI in control group which was  $25.9 \pm 7.8 \text{ kg/m}^2$  ( $P < 0.05$ ). **Underweight** condition was found more among TB cases (19% in cases and 6.9% in control group) and overweight and obesity observed more among control (70% in control and 30.5%) and this distribution is found significant in this study ( $P < 0.05$ ).

Regarding occupation; interesting findings were **employed** people were double among control compared to cases (24.6% in control and 11.9% in cases), and **housewives** were much more among cases compared to control group (43.4% in cases and 28.2% among control) ( $P < 0.05$ ).

Smoking status was not significantly associated with tuberculosis ( $P > 0.05$ ) while **the duration of smoking cigarettes** was significantly longer in TB cases ( $18.6 \pm 13.7$  year) than in control group ( $12.8 \pm 9.6$  year) ( $P < 0.05$ ).

**Family history of TB** is significantly associated with recent TB disease (22.4% of cases have a positive family history for TB compared to 12.7% in control group) ( $P < 0.05$ , table 1).

Finding BCG scar was significantly found less frequent in cases ( $P < 0.05$ , table 1).

This study found **allergic bronchitis** is less frequent in TB cases than in control ( $P < 0.05$ , table 1).

Regarding having positive history for tumors; there was no significant association between tumors and TB disease ( $P > 0.05$ , table 1).

**Diabetes Mellitus** disease was significantly higher among cases (16.6%) than in control (10.2%) ( $P < 0.05$ , table 1).

History of anemia showed no significant association with TB ( $P > 0.05$ , table 1).

History of cortisone or steroid therapy was not significant with TB disease ( $P > 0.05$ , table 3) but the longer duration of Dexamethasone use was significantly related to TB disease ( $P < 0.05$ , table 1).

**Table 1: Distribution of participants according to study group and to related medical history:**

Variables	Study Group				P Value
	Case		Control		
	N	100.0%	N	100.0%	
Family history of TB	101/451	22.4%	56/441	12.7%	<0.001
Scar of BCG	266/450	59.1%	303/441	68.7%	0.003
Allergic Bronchitis	91/446	20.4%	126/437	28.8%	0.004
Tumors	9/448	2.0%	8/437	1.8%	0.847
Diabetes	75/452	16.6%	45/442	10.2%	0.005
History of Anemia	113/445	25.4%	100/442	22.6%	0.471
History of Cortisone or steroid treatment	39/451	8.6%	52/442	11.8%	0.224
History of use of Dexon	65/442	14.7%	78/438	17.8%	0.454
Months of Dexon use; M±SD	13.2±21.3		4.1±6.1		<0.001

TB patients were significantly more frequently residing near to health facilities than control ( $P < 0.05$ , table 2).

It was significant to find TB cases more to have rooms without windows than control ( $P < 0.05$ , table 2).

Family size found to be higher in cases group ( $P < 0.05$ , table 2).

Frequency of drinking non-sterile milk was significantly higher among TB cases (19.0%) than in control (5.7%) ( $P < 0.05$ , table 2).

Tuberculosis patients at southern governorates in Iraq are less likely to work in polluted environment ( $P < 0.05$ , table 2).

**Table 2: Distribution of environmental factors for each study group:**

Variables	Study Group				P Value
	Case		Control		
	N	100.0%	N	100.0%	
Home is built from					0.055
• Reeds & papyrus	4/452	0.9%	1/440	0.2%	
• Clay	50/452	11.1%	31/440	7.0%	
• Plates	5/452	1.1%	2/440	0.5%	
• Bricks	393/452	86.9%	406/440	92.3%	
Windows per room					0.031
• No windows	25/453	5.5%	12/443	2.7%	
• Only one	292/453	64.5%	315/443	71.1%	
• More than one	136/453	30.0%	116/443	26.2%	
Family size	8.8±4.3		8.3±3.5		0.048
Crowding Index	2.9±1.3		3.0±1.4		0.049
Drink non-sterile milk	86/452	19.0%	25/442	5.7%	<0.001
Pollution at workplace					0.002
• Dust and sands	118/449	26.2%	159/436	36.3%	
• Smoke	29/449	6.4%	19/436	4.3%	
• Exposure to animals	29/449	6.4%	14/436	3.2%	
• No pollution	273/449	60.7%	244/436	55.7%	

## Discussion

TB cases distribution in this study characterized by the significant dominance of the younger age group (15-45 year) which is consistent with TB epidemiology in high growth population [12]. Compared to this young age group, risk for TB occurrence is more than double after the age of 65 which is consistent with the vulnerability to develop active disease at such ages [12].

Generally speaking; TB patients have lower BMI compared to control this could be attributed to the fact tuberculosis patients are more likely to be poor and malnourished. These findings are consistent with previous literatures that underweight is a risk factor for TB [4,5,11].

Single people are twice at risk to develop TB than others a finding shared by another study in Croatia [4]

Education level less than intermediate education increases the risk of TB around two times or more [11] and high education protects from TB [5].

Regarding occupation; hard work/farming, student status and unemployment are more prone to develop TB compared to other occupations [4,11].

According to this study; tobacco smoking and duration of smoking were not significant predictors of TB disease. A study in Northern India did not find this association is significant [10], while other studies found Tobacco smoking a risk factor for TB [4, 11].

Family history of TB is associated with TB. Contacts of TB cases are prone to infection and disease development [4].

This study found a protective effect for allergic bronchitis (asthma) from tuberculosis. Community control were found less frequent to have asthma than TB patients, this finding was encountered in a study included three countries in West Africa [13]. In addition, a putative link between exposure to mycobacteria and a decreased risk of atopic disease was suggested by a Japanese study [14]

Tumors or malignancies showed no significant association with TB disease despite the risk of low immune status brought by its treatment [4]. Tumors have low public importance due to low prevalence despite strong evidence for causal association [11].

Diabetes Mellitus increases the risk of developing

TB according to some literatures [4, 6, and 11]. This study found a significant association of diabetes with TB.

Taking into consideration that steroid therapy suppresses immunity and increase the risk for developing active TB [15, 16], systemic steroids therapy over long periods causes a significant increase in TB incidence [17-19]. Related findings in this study were not significant apart from increased risk with longer use of Dexamethasone medications.

Homes with no windows i.e. with improper ventilation with fresh air and poor sun-light illumination, is a significant predictor for TB [8]

Unlike a study [5] found no significant association between house hold size and TB; in this study “family size” including “number of family members older than 15” slightly significantly increased the risk of TB occurrence. Crowding increases risk of TB transmission and there are no good data on strength of association with developing TB disease [11].

Workplace environment polluted with dust or sands decrease the risk of TB occurrence in this study while workplace environments polluted with smoke, exposure to animals, or other pollutants which showed no significant risk for TB in this study. Literatures states that indoor air pollution (smoking [20], fuel combustion – solid biomass fuel [20] or kerosene [21]) and outdoor air pollution risks for lung tissue damage and increased susceptibility to develop TB disease [22].

Taking into consideration among the key correlates of poverty and under the category of household and individual characteristics; among the most important are [23, 24] demographic (household size, age structure, dependency ratio, gender of head), economic (employment status, hours worked, property owned) and social (health and nutritional status, education, shelter).

This study found some factors that are shared between TB and poverty, including:

**Under weight:** it is an indicator of poor nutritional status.

**Low education level:** Literacy and schooling are key determinants of poor people’s ability to take advantage of income-earning opportunities [23].

**Unemployment:** The overall unemployment rate in Iraq is high [25].

**Living environment:** living in non-urban residence, homes built from mud and homes not provided with windows.

Living in such conditions questions the availability and the use of drinking water, communications services, electricity, and other energy sources, the level of sanitation, the degree of isolation (availability of roads and paths which are usable at all times, length of time and availability of transportation to get to work) and the degree of personal safety<sup>[23]</sup>.

**Large family size:** A possible correlation between household size and level of poverty<sup>[23]</sup>. The poor tend to live in larger households<sup>[24]</sup>.

This study illustrated the link between poverty and TB, a link which is already known for many years<sup>[25]</sup>, and as a disease of poverty, Tuberculosis is responsible for the loss of many years of healthy life<sup>[26]</sup>; Effort cut this vicious cycle between poverty and TB are needed to alleviate both of them in a country where poverty level continues to remain high (23% of the population living under the national poverty line of US\$ 2.20 per day)<sup>[27]</sup>.

### Conclusion

Main factors associated with TB in south of Iraq were underweight, unemployment, period of smoking, diabetes, period of Dexamethasone use, living in rooms devoid of windows and large family size. Poverty related factors are likely behind having TB in marshlands.

**Conflict of Interest:** there is no conflict of interest

**Funding:** This study was partially funded by WHO through 2011-2013 Operational Research grants.

**Ethical Clearance:** was obtained prior to conduct of the study.

# Relationship Antenatalcare (ANC) with Neonatal Death in Indonesia (Data Analysis 2017 IDHS)

Ade Mulya Nasrun<sup>1</sup>, Helda<sup>2</sup>

<sup>1</sup>Master of Epidemiology Study Program, Faculty of Public Health, Universitas Indonesia, Depok,

<sup>2</sup>Department Epidemiology, Faculty of Public Health, Universitas Indonesia, Depok

## Abstract

**Background:** The results of the Indonesian Demographic and Health Survey (IDHS) in 2017 show an NMR of 15 per 1.000 live births. These figures are still lower than the Sustainable Development Goals (SDG's) Sustainable Development Goals target, with the target that in 2030 neonatal mortality rate (NMR) no more than 12 per 1.000 live births by 2030. Neonatal mortality comes from poor maternal health, inadequate care during pregnancy, management of improper complications during pregnancy and childbirth. The purpose of this study was to see the relationship between history of antenatal care (ANC) visits and neonatal death in Indonesia.

**Method:** This study used a case control design with female respondents aged 15-49 years. Multiple Logistic Regression is used to see the variables most related with the 95% Confident Interval. Data was analyzed using SPSS 24 for windows.

**Results:** The final model shows that there is a significant relationship between the history of ANC and neonatal death after controlled variables for labor complications. OR value = 2.449 (95% CI: 1.358-4.417).

**Conclusion:** The implementation of Antenatal Care (ANC) for pregnant women is a step to detect problems or complications that may arise during pregnancy. Problems or complications during pregnancy can affect the safety of the mother and baby. Implementing ANC in accordance with the standards recommended by the government is a solution in reducing maternal and newborn mortality.

**Keywords:** Neonatal Death, Antenatal Care, Indonesian Health Demographic Survey

## Introduction

Neonates are newborns up to the age of 28 days. During this time there is a huge change in life in the womb and organ maturation occurs in almost all systems. Infants aged less than one month are age groups who have the highest risk of health problems and various health problems can arise.<sup>(1)</sup>

In the current trend, more than 60 countries will lose the target of Sustainable Development Goals (SDG's) to

reduce neonatal deaths to the lowest 12 deaths per 1.000 live births by 2030. About half of them will not reach the target by 2050. This countries brings about 80% of the burden of neonatal death in 2016.<sup>(2)</sup>

In 2016 there were 5.6 million children died before their fifth birthday, of which around 2.6 million (46%) died in the first month of life of all under-five deaths have ben occured during this period. This means that there are 7.000 newborn deaths every day. The majority of neonatal deaths are concentrated in the first day and week, with around 1 million death on the first day and almost one million dying in the next six days.<sup>(2)</sup>

The results of the Indonesian Demographic and Health Survey (IDHS) in 2017 show an NMR of 15 per

---

Master of Epidemiology Study Program, Faculty of Public Health, Universitas Indonesia, Depok

1,000 live births. This implies that 1 in 67 babies die in the first month of life. As many as 75% of all deaths in the first 5 years occur between birth and first birthday and 63% of infant deaths occur within one month after birth.<sup>(3)</sup> In infant mortality the results of the 2017 IDHS show lower rates compared to the results of the 2012 IDHS.<sup>(4)</sup> These figures are still low from the targets of the Sustainable Development Goals (SDG's), with the target that in the year 2030 NMR no more than 12 per 1,000 live births.<sup>(5)</sup>

Neonatal mortality comes from poor maternal health, inadequate care during pregnancy, management of improper complications during pregnancy and childbirth, poor hygiene during childbirth and the first critical hours after birth, and lack of care for newborns.<sup>(6)</sup> All of these risk factors can be minimized or prevented through Antenatal care (ANC) interventions.

Antenatal Care (ANC) is a pregnancy checkup to optimize the mental and physical health of pregnant women, so that they are able to face childbirth, puerperium, preparation for breast feeding and the normal return of reproductive health.<sup>(7)</sup> During pregnancy, ANC is very important for early detection of risks. High rates of pregnancy and childbirth can also reduce maternal mortality and monitor the condition of the fetus.<sup>(8)</sup>

Based on the 2017 IDHS report, mothers with a history of getting ANC at least 4 times were 77%. This percentage is slightly higher than the target of the Ministry of Health in 2015 of 72%. Based on these data, coverage of ANC at least 4 times nationally shows that there are still around 28% of mothers who have not received ANC at least 4 times.<sup>(3)</sup>

Research by Tufa Kolola found that mothers who received an ANC less than 4 times had a risk of 3.48 times for death in babies born.<sup>(9)</sup> Other studies by Monica PL in Ghana used data from the Demographic and Health Survey (DHS) in Ghana as well found a decrease in the risk of neonatal death in mothers who received ANC more than 4 times.<sup>(10)</sup> Research by Imelda (2019) found that there was a relationship between ANC and neonatal deaths in the Mentawai Islands.<sup>(11)</sup> Research conducted by Desy (2013) also found that there was a relationship between ANC and neonatal death.<sup>(12)</sup>

Research on the relationship between antenatal care (ANC) history and neonatal mortality using IDHS data is still rare. Antenatal care (ANC) can prevent various risk factors for neonatal death. Therefore researchers are interested in further analyzing how much influence

the risk of Antenatal care (ANC) on neonatal deaths in Indonesia.

## Research Method

**Study Design:** This study is an analytical study using a case control design to determine the relationship between the history of ANC as an independent variable and neonatal death as the dependent variable.

**Population and Samples:** The population in this study were all female individuals who participated in the 2017 IDHS survey interview, which amounted to 17,848 people who were willing to become respondents. The study population were mothers who gave birth to babies who died at the age of 0 to 28 days and the comparison population was mothers who gave birth to live babies. The inclusion criteria in this study were women who had live babies, infants died at less than 29 days of age and exclusion criteria were variables with incomplete data. The total eligible population is 8,349 respondents. There are 95 cases of neonatal deaths. The comparison of cases and controls used is 1: 4. Case samples are 95 and the controls chosen are 380.

**Variable:** The dependent variable is neonatal mortality, the independent variable is the history of ANC and the covariate variables are residence, maternal age, maternal education, parity, tetanus toxoid (TT) immunization, pregnancy complications, complications of labor, place of delivery, twin births, ANC (antenatal care). This study uses data from the 2017 Indonesian Health Demographic Survey.

**Data Collection:** The 2017 IDHS data contains comprehensive information about population and maternal and child health in Indonesia. The 2017 IDHS sample covers 1,970 census blocks covering urban and rural areas in all provinces in Indonesia, including women of childbearing age aged 15-49 years. The sample frame of the 2017 IDHS uses the Master Census Block Sample from the 2010 Population Census results.

**Data Analysis:** Univariate analysis to see the frequency distribution of respondents' characteristics. Bivariate analysis is used to see the relationship of the independent variable with the dependent variable is to use the Logistic Regression test. Multivariate analysis using the Multiple Logistic Regression test by entering all candidate variables with criteria  $p < 0.25$  to see the relationship between the ANC history of neonatal mortality after control of the covariate variable. Data analysis using SPSS.24 software.

ANC > 4	73	76,8	333	87,6		

**Table 2: Final Model of Multivariate Antenatalcare Relationship (ANC) with Neonatal Death in Indonesia**

Variabel	P value	OR	95% CI	
			Lower	Upper
ANC	0,003	2,449	1,358	4,417
Labor Complications	0,074	1,629	0,954	2,784

The proportion of infants dying in urban areas is higher (51.6%) compared to rural areas (48.4%). In the maternal age group, the proportion of infants who died in mothers aged <20 years and > 35 years was lower (35.8%) compared to mothers aged 20-35 years (64.2%). The proportion of infants who died in mothers with

secondary education was higher (86.3 %) compared to higher education mothers (13.7%). The proportion of babies who die in mothers with more than 4 children is smaller (9.5%) than mothers who have children less than 4 (90.5.1%). The proportion of infants dying was higher in mothers who did not get tetanus injections (60%) than mothers who received tetanus injections (40%). The proportion of infants who died in mothers with a history of pregnancy complications was higher (80%) than mothers who did not experience pregnancy complications (20%). The proportion of infants dying in mothers who experienced labor complications was higher (74.7%) than mothers who did not experience labor complications (25.3%). The proportion of infants who were born in non-health facilities was lower (29.5%) than babies born in health facilities (70.5%). The proportion of infants who died in twin births was lower (5.3%) compared to single-born babies (94.7%). In mothers with a history of ANC visits, the proportion of infants dying was higher in mothers with a history of ANC > 4 (76.8%) than mothers with ANC > 4 (23.2%).

Independent variables that meet candidate requirements for multivariate models (p value <0.25) are the age of the mother, complications of pregnancy, complications of labor, place of delivery, multiple births and ANC (antenatal care). The final model shows that there is a significant relationship between the history of ANC and neonatal death after controlled variables for labor complications.

## Discussion

The results of this study also showed that there is a relationship between ANC and neonatal deaths in Indonesia. Mothers who received ANC <4 times during pregnancy had a risk of 2,449 times to get neonatal death compared to mothers who received ANC > 4 times during pregnancy, after being controlled by variables of labor complications.

Research in Kenya using Kenya's Demographic and Health Survey (DHS) data found that mothers with a history of small ANC visits from 4 had a high chance of risk of death in babies born.<sup>(13)</sup> The study used basic survey data on maternal and newborn intervention in Eastern Uganda found that there was a reduction in the risk of neonatal death in women with a history of ANC visits more than 4 times.<sup>(14)</sup> Other studies by Monica PL in Ghana using the Demographic and Health Survey (DHS) in Ghana also found a reduced risk of neonatal

death in mothers who get ANC more than 4 times.<sup>(10)</sup> In many Sub-Saharan Africa (SSA) countries, many risk factors can be minimized or prevented through Antenatalcare interventions (ANC). Recommendations from WHO through effective ANC services are a minimum of four or more ANC visits.<sup>(13)</sup>

Ministerial Regulation number 97 of 2014 mandates that maternal health services during pregnancy be carried out through comprehensive and good quality antenatalcare services to prepare clean, safe and healthy deliveries. Health care for pregnant women is given to pregnant women by health workers in health care facilities. This process is carried out during the maternal gestational age range grouped according to gestational age into the first trimester, second trimester, and third trimester. The standard of service time is recommended to ensure the protection of pregnant women and or the fetus in the form of early detection of risk factors, prevention, and early treatment of pregnancy complications which if not handled properly can lead to death.<sup>(15)</sup>

## Conclusion

Antenatal care (ANC) is a step taken to detect problems or complications that may arise during pregnancy. Problems or complications during pregnancy can affect the safety of the mother and baby. One of the main indicators in reducing maternal and neonatal mortality is to implement ANC in accordance with the standards recommended by the government.

**Limitation of Study:** This study used secondary data analysis and not all variables can be included because there are variables whose data is missing. Potential information bias that can occur in this study is non-differential misclassification, including recall bias. At the time of data collection, respondents were asked to recall events in the past 5 (five) years regarding their health condition during pregnancy and childbirth. Information about the variables of neonatal death, TT immunization, the presence or absence of pregnancy complications and labor complications, the history of ANC and PNC were obtained based solely on the respondent's memory, not from medical records that could result in underestimated risk values.

**Conflict of Interest:** The authors declare that they have no conflict of interest.

**Acknowledgement:** We thank the Indonesian National Population and Family Planning Board for providing survey data.

**Ethical Clearance:** Ethical approval was granted by the Institutional Review Board of ICF International and ORC Macro (ICF IRB FWA00000845).

**Source of Funding:** Self funding.

# The Effect of Mind Fullness Therapy on Psych on Euro Immunology: A Systematic Review

Agus Yulianto<sup>1</sup>, Zaenal Abidin<sup>1</sup>, Abdul Fauzi<sup>1</sup>, Anita Dewi A.<sup>1</sup>, Ika Endah K.<sup>1</sup>,  
Dady Zharfan H.<sup>1</sup>, M. Hendri Haryono<sup>1</sup>

## Abstract

**Context:** Psych on euro immunology (PNI) is a link between psychological factors that affect the immune system and physical health through neural and endocrinological pathways. Mindfulness as an exercise is aware of the conditions experienced by the body, mind, feeling, current situation and conscious thinking to make a feeling or situation calm. The purpose of this study was to find the effect of mindfulness therapy on psychoneuroimmunology by using a systematic review based on the PRISMA guidelines. Database Scopus, ScienceDirect, Proquest, Pubmed, and Springerlink which have been published in the limits of January 2013-November 2018. Articles were identified using the keywords “Mindfulness” AND “Psychoneuroimmunology” OR “Psycho” OR “Neuro” OR “Immunology” . The article used is intervention research. Twenty eight of the 307 articles found were used in this systematic review. The article reviewed mentions that mindfulness therapy has positive benefits for psychoneuroimmunology. Mindfulness therapy can be used as a non farmacological intervention to overcome health problems related to psychoneuroimmunology.

**Keyword:** *Mindfullness, Psychology, Neurology, Immunology, Psychoneuroimmunology, PNI*

## Introduction

Psych on euro immunology (PNI) discusses about how psychological factors affect the immune system and physical health through neural and endocrinological pathways. This relationship is very relevant for immunological mediated health problems, including infectious diseases, cancer, autoimmunity, allergies, and wound healing. Psychosocial characteristics associated with changes in immune function indicate that psychological interventions such as, relaxation and hypnotherapy and mindfulness to improve mood, coping and social support in an effort to modulate immune function<sup>1</sup> and incidences of depression, fatigue, and anxiety are elevated. We examined effects of a mindfulness-based intervention (MBI).

In this systematic review, we will discuss the effectiveness of mindfulness on psychoneuro immunology. Mindfulness also refers to practices or techniques such as meditation practice, based on the contemplative Buddhist tradition<sup>2</sup> during and following the stressor. Results We found that PMAA reduced psycho-physiological dysregulation in response to an anxiogenic stressor, as well as moderated the anxiogenic effect of distress intolerance on psychological but not physiological responding to the stressor among smokers pre-disposed to experience distress via deprivation. Conclusions The present study findings have a number of theoretical and clinical implications for work on mindfulness mechanisms, distress tolerance, emotion regulation, and smoking cessation interventions.

2. There is a great deal of interest in research on mindfulness including Mindfulness-Based Cognitive Therapy (MBCT), Mindfulness-Based Cancer Recovery (MBCR) and Mindfulness-Based Stress Reduction (MBSR).

Mindfulness-Based Stress Reduction (MBSR) is a treatment program to relieve stress and overcome chronic

e-mail : agus22yulian@gmail.com.

diseases as an inflammatory biomarker<sup>345</sup> health status, coping capacity, mindfulness, posttraumatic growth, and immune status. This RTC assigned 166 women with breast cancer to one of three groups: MBSR (8 weekly group sessions of MBSR. Certified Mindfulness-Based Cognitive Therapy (MBCT) 8- The weekly skill-based skills training group program was originally designed to prevent recurrence of depression and recurrence formed as a basis for empirical research to test predictors of relapsing depression<sup>6,7,8</sup> most of the available studies suffer from important methodological shortcomings, including the lack of adequate control groups. The present study aims to compare MBCT with a psycho-educational control group designed to be structurally equivalent to the MBCT program but excluding the main putative "active ingredient" of MBCT (i.e., mindfulness meditation practice<sup>9,10</sup>. With Mindfulness-Based Cancer Recovery (MBCR) there is a greater decrease in mood disorders (especially fatigue, anxiety and confusion) and stress symptoms including tension, sympathetic stimulation and cognitive symptoms in cancer patients<sup>11</sup>.

The purpose of this study was to find the effect of mindfulness therapy on psychoneuroimmunology.

## Method

This Systematic review uses a guide based on the Preferred Reporting Item for Systematic Review and Meta-Analysis (PRISMA)<sup>12</sup>.

**Literature Search Strategy:** The literature used in this Systematic Review uses tracing through 5 electronic databases, namely: Scopus, ScienceDirect, Proquest, Pubmed, and Springerlink which have been published within the limits of January 2013-November 2018 with keywords "Mindfulness" AND "Psych on euro immunology" OR "Psycho" OR "Neuro" OR "Immunology".

### Criteria for Inclusion and Exclusion:

**Desain Studi:** The study design being the inclusion criteria in this Systematic Review is a Randomized Controlled Trial (RCT) design that is published using English

**Populasi:** The population in this systematic review is, All studies that describe patients who get Mindfulness Training interventions with or without a control group, Men and women > 17 years old and Seeing the effect of

Mindfulness on Psychoneuroimmunology on patients.

**Intervention:** Various types of mindfulness interventions that affect psychological, neurological and immunological effects on various types of diseases.

**Clinical Results:** The main outcome of this systematic review is to look at the influence of mindfulness interventions on psychological, neuro and immunology.

**Study Selection:** Standard protocol for selecting studies as suggested in the systematic review method guide, PRISMA. The steps taken are removal of duplication, examination independently for titles, abstracts and keywords and delete citations that are not relevant according to the inclusion criteria, if the title and abstract seem to meet the inclusion criteria and according to the purpose of the systematic review, the next step is the selection of journals with full text, the final step is the selection of articles using the RCT approach to reduce the risk of bias.

**Data Extraction:** Data is extracted from each study that meets the requirements. The extracted data includes the characteristics of the study, characteristics of mindfulness, characteristics of the results and summary of results.

**Analysis of Data:** Studies are grouped according to the effects of mindfulness on psychology, neurology and immunology. If possible, the research was then grouped based on the time of follow-up and the type of control group

## Result

**Literature search and study selection:** Search results and the selection of studies following the PRISMA guidelines<sup>12</sup>. The selection of journals based on the keywords used produces 307 articles. 256 articles found after duplication screening. 201 is eliminated due to irrelevant studies based on titles and abstracts. A total of 56 articles with full text were taken with 33 studies excluded. So that 23 studies were selected which will be carried out systematic reviews.

**Population:** The sample size of the 23 studies used is that the least systematic review is 23 people divided into two groups, namely the control and intervention groups, with the age range 18-51 years, and the characteristics of patients are female patients with Multiple Sclerosis, while the highest number of samples was 271 people,

divided into three (3) treatment groups as well as female patients with stage I, II and III Breast Cancer conditions with age > 18 years.

The conditions of patients sampled in this study included patients with conditions: Breast Cancer, Multiple Sclerosis, Cardiovascular Disease, Sleep Disorders, HIV Infection, Major Depression Disorder, Patients after undergoing Hematopoietic Stem Cell Transplantation (HSCT), patients with stressful conditions/have a high stressor, patients with lung injury/ lung problems, and smoker patients.

**Characteristics of Intervention:** There are several types of mindfulness interventions including Mindfulness-Based Cognitive Therapy (MBCT), Mindfulness-Based Cancer Recovery (MBCR), Mindfulness-based intervention (MBI), Mindfulness Meditation (MM). The intervention was carried out with different duration and frequency with the shortest time being 3 days with a duration of 25 minutes per day and the longest time was 8 weeks with a duration of 45 minutes per day.

**Size of Clinical Outcomes:** Research reports the outcome measures used to measure psychology, neurology and immunology. Outcome measures are used to measure the psychological symptoms of stress inventory (SOSI), the profile of mood states (POMS), the Beck Depression Inventory-2 (BDI-II), the Hamilton Rating Scale for Depression (HAM-D). Measurement of neurological results using salivary cortisol, neurological inflammation. Whereas to measure Immunology results using the Lymphocyte Proliferation Test (LTT), ELISA (Cytokine Assays), Flow Cytometric Analysis (FACS), CD4, c-reactive protein, IL-6, and d-dimer

**Intervention Efficacy Analysis:** For each RCT intervention it was explained they evaluated the effect of mindfulness on treatment separately. Some journals continue to follow up up to 12 months after the intervention so that they can assess the long-term influence of the intervention that has been done.

### Effect of mindfulness on psych on euro immunology

#### Psychological:

a. **Stress:** Kingston et al., reported that the Mindfulness-based cognitive therapy (MBCT) group experienced a significant increase in awareness and a decrease in anxiety levels. The most preferred program is

Mindfulness-Based Cancer Recovery (MBCR) (55%) compared to management stress<sup>13</sup>.

- b. **Depression:** Chiesa et al., most of the available studies suffer from important methodological shortcomings, including the lack of adequate control groups. The present study aims to compare MBCT with a psycho-educational control group designed to be structurally equivalent to the MBCT program but excluding the main putative "active ingredient" of MBCT (i.e., mindfulness meditation practice showed a decrease in the level of depression measured using the proven HAM-D and BDI scores over the long-term period in the MBCT group than in the psycho-education group. Kenne Sarenmalm et al., health status, coping capacity, mindfulness, posttraumatic growth, and immune status. This RTC assigned 166 women with breast cancer to one of three groups: MBSR (8 weekly group sessions of MBSR stated that the MBSR group experienced a significant increase in depression scores, with a pre-MBSR average using a HAD-score of 4.3 and a post-MBSR score of 3.3 (P = 0.001), and compared with non-MBSR (P = 0.015).
- c. **Fatigue:** Fatigue decreased significantly in the Ambulance Activity Feedback (AAF) therapy and Web-based mindfulness-based cognitive therapy (eMBCT) group compared to the psycho-education group<sup>14</sup>. Relevant clinical changes in fatigue severity were observed in 66% (41/62) of patients receiving AAF therapy, 49% (27/55) patients received eMBCT, and 12% (6/50) patients received psycho-education.

**Neurology:** Research shows that the increase in posterior cingulate cortex rsFC with left dlPFC (p = 0.05). Mindfulness meditation training statistically changes in IL-6 so mindfulness has been shown to increase the marker of risk of inflammatory diseases<sup>15</sup>.

**Immunology:** Research shows that MBSR therapy carried out for 45 minutes / day for 8 weeks causes a decrease in CRP and IL-6 levels<sup>16</sup>. Frederick et al, in their study found a decrease in CD4 + T-cells in the MBSR group of 49.6 cells / µl and the control group 54.2 cells / µl difference from 4.6 cells (p = 0.85)

### Discussion

There are several important findings regarding the effect or effectiveness of mindfulness that will now be discussed in detail.

## Psychology:

**Stress:** The program most favored by patients with stage I, II, III breast cancer is MBSR (55%) compared to management stress. The mindfulness group has been shown to improve mood disorders, stress, quality of life<sup>13</sup> and weight loss by relieving stress<sup>17</sup>, improving sleep quality<sup>18</sup>. There were no significant effects MM and general interventions because they were equally effective in reducing stress and related symptoms<sup>19</sup> therefore the need for stress-reducing method is great. This randomized controlled trial compared the efficacy of self-help physical activity (PA).

MBSR intervention showed that there were no significant improvements in physical symptoms and mental health ( $p > 0.05$ ). However, a significant increase was observed in patients' quality of life ( $p > 0.05$ ) in patients with Multiple sclerosis<sup>20</sup>.

**Depression:** Based on the MBCT intervention in patients diagnosed with dysthymia at least 2 years and experiencing depression during treatment experienced a significant increase in improving depression symptoms and mindfulness skills in patients compared to the control group<sup>7</sup>. Electro-cortical clinical work pathways with MBCT in multi-leveled depression are nonlinear and interdependent mechanisms, represented by dynamics of mediated EEG synchronization<sup>6</sup>.

Based on HAM-D and BDI scores, as well as quality of life scores and awareness, showed a higher increase, which was especially evident over the long-term period in the MBCT group than in the psycho-education group<sup>8</sup> most of the available studies suffer from important methodological shortcomings, including the lack of adequate control groups. The present study aims to compare MBCT with a psycho-educational control group designed to be structurally equivalent to the MBCT program but excluding the main putative "active ingredient" of MBCT (i.e., mindfulness meditation practice<sup>9</sup>). Patients with breast cancer who took MBSR for 8 weeks experienced a significant increase in depression scores, with an average pre-MBSR HAD score of 4.3 and post-MBSR scores of 3.3 ( $P = 0.001$ ), and compared with non-MBSR ( $P = 0.015$ )<sup>5</sup> health status, coping capacity, mindfulness, posttraumatic growth, and immune status. This RTC assigned 166 women with breast cancer to one of three groups: MBSR (8 weekly group sessions of MBSR. Multiple sclerosis patients with mindfulness interventions result in a greater reduction in the rate of

depression than psycho-educational interventions, up to 6 months of follow-up<sup>21,22</sup>.

**Fatigue:** Fatigue decreased significantly in the AAF and eMBCT groups compared to the psycho-education group. Relevant clinical changes in fatigue severity were observed in 66% (41/62) of patients receiving AAF therapy, 49% (27/55) patients received eMBCT, and 12% (6/50) patients received psycho-education<sup>14</sup>.

**Neurology:** Mindfulness carried out for 3 days with a duration of 2.5 hours / day can reduce salivary cortisol reactivity and reactivity to psychological stress after doing cognitive therapy. Mindfulness meditation training causes an increase in the posterior cingulate cortex rsFC with dlPFC ( $p = 0.05$ ) and statistically changes in IL-6.

**Immunology:** There was a significant effect on the MBSR group on mental health and quality of life compared to the control group and there was a significant increase of lymphocyte proliferation with phytohemagglutinin (PHA) and peripheral blood IL-17, but did not significantly affect lymphocyte (CD4 +, CD8 + and NK-cell)<sup>3</sup>.

HIV patients who take MBSR for 8 minutes with 1x meeting / week duration of 2.5 hours. Follow-up 12 months after MBSR and a decrease in the average number of CD4 T cells was 49.6 cells /  $\mu$ l compared to 54.2 cells /  $\mu$ l in the control group, a difference of 4.6 cells supporting the MBSR group (95% CI, -44.6, 53.7,  $p = 0.85$ ). Differences between groups in other immunological related outcomes (c reactive protein, IL-6, HIV-1 viral load, and d-dimer) were not statistically significant at each time point (3, 6 and 12 months after intervention)<sup>23</sup>.

There are several potential limitations associated with this systematic review, namely (1) the risk of publication bias, (2) the main outcome is not always the same as in other studies.

## Conclusion

There are several types of mindfulness and their effects on psychoneuroimmunology but this cannot determine the most effective type of mindfulness. Mindfulness as a whole has an influence on psychoneuroimmunology especially on the psychological. Further randomized research must be carried out by including more objective steps to explain the mechanism of mindfulness to psycho-

neuro and immunology simultaneously.

**Conflict of Interest:** None

**Financial Support and Sponsorship:** Author

**Ethical Clearance:** Taken from The Ethics Committee of the General Hospital Hajj, Surabaya (ethics approval number 079/13/K.E/2019)

# Long Term Outcome of Laparoscopic Assisted Anorectoplasty in Management of High Anorectal Malformations in Males

Ahmed Akoula<sup>1</sup>, Ahmed Wishahy<sup>2</sup>, Gamal Eltagy<sup>3</sup>, Omar Nagy<sup>4</sup>, Mohammed Abdelrahman<sup>5</sup>

<sup>1</sup>*Pediatric Surgery Department, Cairo University Specialized Pediatric Hospital, Cairo, Egypt*

## Abstract

**Aim of the Study:** The purpose of this study is to evaluate the long term outcome of laparoscopic-assisted anorectoplasty (LAARP) in management of male children with high-type anorectal malformation (ARM).

**Method:** Forty patients with high ARM were operated between January 2005 and January 2014 were reviewed. All of them underwent LAARP. Age at operation, type of fistula, associated anomalies, complications and degree of continence were evaluated. Bowel functions were assessed using the Cleveland Clinic Incontinence Score. Ethical procedures including obtaining informed consent were conducted in accordance with the ethical standards of the Committee on Human Experimentation of Cairo University.

**Main Results:** The mean follow up period was (6.4±2 years). The type of fistulae were recto-bladder neck and recto-vesical (45% and 55% respectively). Rectal mucosal prolapse occurred in 40% of patients. The rates of normal continence (score 0:4) (25%), mild incontinence (score 5:9) (30%), moderate incontinence (score 10:14) (30%) and severe incontinence (score 15:20) (15%). None of our patients included in the study suffered from constipation.

**Conclusion:** The long term functional outcomes after LAARP was satisfactory apart from rectal mucosal prolapse, however LAARP is a suitable method for management of ARM patients with higher type fistulae.

**Keywords:** LAARP, PSARP, male imperforate anus, high anorectal malformation.

## Introduction

Since laparoscopically assisted anorectoplasty (LAARP) was first described by Georgeson et al<sup>1</sup> as an alternative to posterior sagittal anorectoplasty (PSARP), it has gained popularity for the management of patients with high anorectal malformations (ARMs). Surgeons adopting this approach believe that it offers advantages in terms of a better cosmetic outcome, in addition to accurate placement of the pull-through rectum within

the muscle complex without division<sup>2-6</sup>. However, to the best of our knowledge, there is a paucity of articles comparing the functional outcomes of the two approaches<sup>2, 6-12</sup>. The aim of this study was to evaluate the long-term outcomes and complications of LAARP for high types of imperforate anus in males.

## Materials and Method

**Patient Demographics:** We reviewed the data of male patients of imperforate anus with high fistulae who underwent surgery in our institution from January 2005 to January 2014. Forty Five patients were operated on during this period and were asked to attend our paediatric colorectal clinic for assessment. All of them were managed by LAARP. Closure of colostomy was done for all patients after reaching the desired size of anal dilatation. Five patients were either lost to follow-up or refused to participate in our study. Patients with

sacral anomalies were excluded from the study.

The median ages of the patients at the time of assessment were 7.5 (range: 4-11) years. Operations were performed by a single surgeon. LAARP was performed as described by Georgeson et al<sup>1</sup>. Types of malformations were identified according to colostogram findings and were confirmed by operative findings (Fig. 1). 22 patients had recto-vesical fistulae, while 18 patients had recto-bladder neck fistulae.

Patients were reviewed retrospectively. The age at operation, associated anomalies and complications were compared.

**Fig 1: Distal colostogram showing Rectobladder neck fistula**

**Complications:** The postoperative complications were evaluated. We examined anal stenosis, rectal prolapse and malposition of the rectum. The colon position within the muscle complex was assessed by MRI for patients suffering from any degree of incontinence. Malposition was defined as misplacement of the rectum outside the muscle complex along any length of the tunnel<sup>10</sup>.

### Functional Results

Bowel control for patients older than 3 years was assessed. Functional assessment was performed using the Cleveland Clinic Incontinence (CCI) score<sup>13</sup>. In this scoring system, the frequency of incontinence, in addition to the extent to which a person's life is altered, is evaluated using 5 questions assessing the type of incontinence (solid, liquid, gas, wears pad, lifestyle alteration). The frequency with which each type of incontinence occurs is rated on a scale from 0 (never)

to 4 (always or 1/day). The frequencies are added to yield a total score, which can range from 0 to 20, with higher scores indicating higher levels of incontinence. A good outcome was considered when the patient was continent (score 0-4) or had mild incontinence (score 5-9). Poor outcome patients were those presenting with moderate (score 10-14) or severe (score 15-20) incontinence. Sphincter squeezing was assessed using Kelly's score<sup>14</sup>. Pena's criteria were used for assessment of constipation<sup>15</sup>.

**Statistical Analysis:** Data were analysed using SPSS version 23. Student's t test was used to compare the mean age at operation, type of fistula and associated anomalies. The chi-square test was applied to compare the postoperative complications and the functional outcome. A value of  $P < 0.05$  was considered statistically significant.

**Findings:** No statistically significant difference was observed for the age at the time of operation. Also no statistically significant difference was found between the types of fistulae included in our study, 22 patients had recto-vesical fistulae while 18 cases had recto-bladder neck fistula (55% vs 45% respectively).

All patients were followed up for more than 3 years; the median follow-up period was  $6.4 \pm 2$  years. Regarding anal stenosis occurred only in 2 cases (5%) while rectal prolapse was significantly more in our patients (Fig. 2). It occurred in 16 cases by a rate of 40% which is a high percentage.

Malposition of the rectum was found only in 2 cases (5%) while centrally positioned rectum was found in 95% of patients (Fig. 3A, 3B). If MRI failed to show a centrally placed rectum within the muscle complex, we termed it malposition of the rectum. The rate of strong sphincter squeezing (score 2) was found in 25% patients (10 cases). However, patients with weak squeezing (score 1) were (10%) 4 cases. Significantly more patients had no squeezing (score 0) (65%) 26 cases. None of our patients experienced recurrent fistula or rectal retraction.

The rates of voluntary bowel control (score 0-4) was found in 25% of patients, mild incontinence (score 5-9) was found in 30% of patients, moderate incontinence (score 10-14) was found in 30% of patients and severe incontinence (score 15-20) was found in 15% of our patients. Furthermore, none of our patients complaining of constipation.

**Fig 2: Rectal mucosal prolapse post LAARP**

**Fig 3A : MRI coronal section with centrally positioned rectum**

**Fig 3B: MRI sagittal section with centrally positioned rectum**

## Conclusions

We concluded that LAARP has satisfactory long-term outcomes. LAARP might even offer an advantage for patients with high recto-urinary fistulae presenting as recto-bladder neck and recto-vesical fistulae. LAARP is associated with a higher incidence of rectal prolapse. We recommend modification of this technique by performing application of an anchoring stitch on the rectum to the presacral fascia. Nevertheless, performing a study with a larger sample size and longer follow-up period is recommended to obtain more reliable results.

**Level of Evidence:** Level III.

## Discussion

Although PSARP is the classic approach for cases of recto-prostatic and recto-bulbar fistulae<sup>16,17</sup>, LAARP has been gaining popularity for treating patients with recto-bladder neck and recto-vesical fistulae. Indeed, the advantages of LAARP outweigh those of PSARP in terms of limited pelvic dissection, precise centralization of the rectum within the muscle complex and puborectalis muscle without division, preservation of the levator ani and muscle complex, accurate assessment of the fistula site, and reduced pain and wound complications, in addition to improved cosmesis<sup>18</sup>. However, no consensus exists on either approach in terms of long-term bowel control<sup>19</sup>. To the best of our knowledge, only a limited number of research studies that assess the long-term results of both approaches have been performed.

Rectal prolapse occurred in 40% (16/40) of our patients after LAARP. The rate of rectal prolapse post-LAARP ranged between 8.8% and 46%<sup>3,20,21</sup>. Jung et al<sup>22</sup>, similar to our results, found rectal prolapse after LAARP in as many as 52% of patients. There are two possible explanations for this finding: the more rectal dissection associated with LAARP as well as a lack of rectal fixation within the muscle complex might contribute to this increased incidence. Therefore, some authors recommend the application of an anchoring stitch between the rectum and presacral fascia to avoid such complications during LAARP<sup>23</sup>. Bischoff et al reported a higher incidence in patients with recto-bladder neck and recto-vesical fistulae as a result of poor sacral and pelvic musculature<sup>21</sup>. Hence, securing the rectum to the presacral fascia, in addition to limiting rectal dissection, is essential to avoid such morbidity<sup>21</sup>.

MRI was used to assess the position of the rectum

within the muscle complex in all cases. Only two patients (5%) had their rectum pulled away from the midline, despite that all patients were operated on by experienced paediatric surgeon. Patients with deviation from the midline and suffering from faecal soiling underwent redo anorectoplasty through a posterior sagittal approach. These results were similar to Tong QS et al<sup>4</sup>, who reported a lower incidence of malposition of the rectum after LAARP. In contrast, Elbarbary MM et al<sup>24</sup> reported a higher incidence of malposition with LAARP. They assessed the centralization of the rectum at three transverse levels (levator ani, muscle complex and external anal sphincter); non centralized cases were either anterior in relation to the external anal sphincter or deviated to the right side of the muscle complex.

Anal stenosis occurred only in 5% (n=2) of patients. No patients experienced rectal retraction or recurrent fistula.

Regarding constipation, none of our patients suffered from constipation. A proposed explanation is that the preserved muscle complex in LAARP decreases the incidence of postoperative scarring, hence avoiding the associated decreased rectal sensation and subsequent recto-sigmoid dilatation with constipation and overflow soiling.

Concerning bowel function and soiling, LAARP appears to result in better long term outcomes. Kudou S et al<sup>3</sup> and Ming AX et al<sup>12</sup> found that LAARP and PSARP patients had similar bowel habits, despite that the age at the time of evaluation of faecal continence was younger in the LAARP group in both studies, suggesting that anorectal function in the LAARP group would improve over the long term. Additionally, in a Japanese multicentre study<sup>7</sup>, faecal continence was evaluated using two types of scoring systems: the Kelly score and a newly developed system, the Japanese Study Group of Anorectal Anomalies Follow-up Project (JASGAP), which compared PSARP and LAARP and found no statistically significant difference.

**Source of Funding:** Self funding

**Conflict of Interest:** Age of pull-through and time at which bowel continuity was restored were relatively greater than those of other studies. This is due to the lack of specialized paediatric colorectal centres in the country and a large case load in our institution, in addition to reluctance of some caregivers as a result of low educational standards. Also, we used only the Cleveland

Clinic scoring system to assess the functional outcome, which lacks objective parameters such as manometry. However, we believe that the history given by parents is the most important parameter to assess bowel control, rather than dependence on numerical values that may not reflect the patient's lifestyle

# Regionalization Referral System of the Hospital National Health Insurance

Amir Mahmud Hafsa<sup>1</sup>, Alimin Maidin<sup>2</sup>, Sukri Palutturi<sup>3</sup>, Stang<sup>4</sup>

<sup>1</sup>Doctoral Student Program, Faculty of Public Health, Universitas Hasanuddin, Makassar, Indonesia, <sup>1</sup>Dentistry Department, Faculty of Dentistry, Universitas Hasanuddin, Makassar, Indonesia, <sup>2</sup>Hospital Management Department, Faculty of Public Health, Universitas Hasanuddin, Makassar, Indonesia, <sup>3</sup>Health Administration and Policy Department, Faculty of Public Health, Universitas Hasanuddin, Makassar, Indonesia, <sup>4</sup>Health Biostatistic Department, Faculty of Public Health, Universitas Hasanuddin, Makassar, Indonesia

## Abstract

**Context:** A reference system in Indonesia is not running effectively and efficiently which cause cumulation of patient in advance health facility, with the result that there is utilization of skilled workers and advance equipment unwisely and quality deterioration of health. This matter is needed rationalization of health service more than devolution and decentralization of public services by the government of south Celebes include consolidation of take holder and local institution and also other services centralization. The purpose of this research is analyzing the rationalization of the referral system which integrated to national health assurance in South Celebes seen from several knowledge factors and social community value. This research used qualitative approach of phenomenology design, with analyzing method which used content analysis base on triangulation method, source triangulation and data triangulation. The result is gotten that there was information and communication bias among policy, provider, as a result from receiver variety in social community, made society not obey the rationalization of the referral system. This research can be concluded that understanding and awareness between policy and provider, social security administration is needed to give better health services. Affecting the sustain ability of health service negatively can cause lack of patient satisfaction. Furthermore, lacking of facility in family practice center can increase the high of reference.

**Keywords:** *Regionalization of The Referral System, Health Service, Health Social Value*

## Introduction

Socio-cultural development of society, life style, demands of the time and advance technology development which cannot be balanced with knowledge development, information access becomes one of factors or variables that influence in implementation of community social live policy very varied. The education failure to

policy and provider, caused community obedience to regionalization of the referral system policy<sup>(1)</sup>. Health social security provider, they have not fulfilled equity principle appropriate with constitution of national social health insurance required health equal service base on medical needs which is not bound by amount of participant contributions<sup>(2)</sup>. The benefit obtained before the era of social health insurance also vary based on the provider, for instance there are some nit guaranteed services, limitation to services, and there is an obligation in paying deviation bill and also difference in accessing payment claim in accordance with segmentation of providers of health insurance participation. This case shows that uncomprehensive membership, the service we get always have discrimination between one to another in health service<sup>(3,4)</sup>.

Regionalization of the referral system is a form of health reference management in hospital of province/district/city which cannot be separated from health service system in South Celebes Province and this system becomes flagship program of the governance of South Celebes which implemented in giving quality referral health services, equal, and affordable, and also quality for all societies of South Celebes. One of main concerns is lack of standard procedures and protocol for reference patients among various service levels start from reference service in the first level until reference center, the prediction of patient referral waiting time from premier level to higher level and the quality of information which is reflected in reference form and reference system service have continuous positive effects<sup>(5)</sup>. this research intends to create a new system that integrated with National Health Insurance Referral System in South Celebes Province.

### Research Method

This research is done in Daya Hospital as the second level reference, Wahidin hospital as tertiary hospital or the last level of reference and health department of South Celebes as an originator, program executor, at a time as supervisor of implementation of regionalization of the referral system. For almost two years interview research to the hospital's directors and vice directors, health of medical nurse, head of reference system, head of emergency room and staffs, head of medical colleague, and ten patients from two hospitals and head of health department, head of medical service, the head of reference and also exp tiem 9 free health. The research with qualitative method of phenomenology approach which analysis used content analysis based on method triangulation, source triangulation, and data triangulation.

### Results and Discussion

**Society's Knowledge to Regionalization of Health Reference System:** Society as a main basic for government in making policy. It Is understandable that society in every district is not balance in various aspects of life. Not only financial, knowledge, social structure, in South Celebes one district is different with another, so as the health policy is appropriate with evidence based, a regional characteristic, the current policy cannot top down anymore. Such us information from R1, and other 12 informants which is almost same with assumed related to regionalization of the referral system about

social cultural understanding which still need handling comprehensively and continuously and also need deep understanding to be able to evaluate the extent to which the program runs, to foster, to educate society about implementation of health service in order to run in accordance with the realm of the BPJS, so that the same thing did not happen again which was expressed by the informant as follows:

“Kegagalan edukasi pada receiver, policy mengakibatkan tidak patuhnya masyarakat terhadap aturan regionalisasi sistem rujukan....”

*(R1, 59 Years Old)*

While according to informant R3 and other information, they confirmed about a riot of the regionalization of the referral system nowadays which is sometimes the society assume as strange and confusing policy. Especially the receiver and society who have done health service because the ill they suffered does not heal plus complicated BPJS rules. Sometimes make them give up. Like living in the stone age as expressed by informant R3 and other informants:

“Regionalisasi sistem rujukan waktu kesehatan gratis itu is the best tapi begitu berintegrasi ke JKN semua amburadul itu sebabkan karena bias informasi, kita semua tidak bekerja maksima.” *(R3,44 Years Old)*

While informant R2 argue no less interesting than the previous informant as authentic fact that is expressed as follows:

“Kegagalan edukasi pada dokter yang bekerja di rumah sakit daerah .....di rumah sakit swasta di kota hingga ada pasien yang mau dirujuk saat dikonfirmasi oleh dokter yang petugas .... ok langsung saja ke RS tempat saya kerja” *(R2, 45 Years Old)*

Government and profession must sit together, make policy about doctor's practice license related to domicile and the distance between work place and practice place and also notice a region to make health policy because in certain condition will happen the same case as was revealed by informant R2, an example expressed by the informant that Daya Region Hospital became an option of referral in that time. Same as informant R6, as vice director of Daya Hospital who has experiences when doing doctor's job in PKM that there was something wrong nowadays because need to know that 2 other informants said:

“Pada awalnya masyarakat patuh terhadap sistem rujukan berjenjang namun tidak lama, masyarakat enggan berobat di puskesmas karena selalu .... akhirnya masyarakat berpendapat buat apa ke PKM mending langsung aja ke rumah sakit” (R6, 40 Years Old)

Informant R10, and 6 are informants who stated that almost all receiver failed in education and there was unbalance in society in term of utilization of BPJS health service facilitation. Some certain patients misuse BPJS to get direct reference to the hospital whereas their ill can be cured in health center. But for the society, sometimes the health center just become a stepping stone to get reference letter of advance health facility. This matter will become a problem when there is society who really need hospital service, delay or even cannot be served because the hospital is full. We need strict rules, precise to give discipline in health service especially referral system, there must be a reward and punishment so that the society get the right health service base on indication. Failed education to the society, provider and receiver is a collaboration that need a special handling, in the future, should be form special team or own department to give clear and bright information so that the society can do health service well, effectively and efficiently. Information bias not happen again.

According to informant R15 (40 years old, emergency room team) (FGD UGD) ever misunderstood and confused because an extraordinary thing happened when the family of patient suddenly rampage with unknown cause. Whereas doctors and emergency team have tried maximally and also based on vision of WHO 2020 <sup>(5)</sup> the feasibility of transferring information and skills as well as the availability of resources that service in emergency unit is and emergency unit that is considered the most vital or is assumed to be a little more valuable than an infinite asset as the following statement:

“Idealnya seorang tenaga medis harus mampu mengedukasi pasien..... sehingga bisa dihindari seperti yang pernah terjadi di UGD Wahidin .... Telah ditindaki segera dengan baik berdasarkan SOP tapi entah apa yang terjadi tiba-tiba keluarga pasien ngamuk dan minta keluar paksa” (R15, 40 Years Old)

According to informant R14 that patient must understand about referral rule regarding to BPJS because if they do not understand so that misunderstanding happen and can make service process become complicated so maximum benchmark as the following statement:

“Seorang pasien harus paham alur rujukan dari Faskes mana berasal dan mau kemana, ini terkait dengan sistem informasi rujukan bila pasien misalnya dari rumah sakit Siloam dia akan mengikuti rujukan dapat diliat melalui memonitoring di UGD, dan dari mana mau kemana atau bahkan keluar paksa pak itu ... ada format khusus” (R14, 50 Years Old)

According to informant R17 is more strange and considered do not understand to the regionalization of the referral system of National Health Insurance (JKN) assumed that the society must obey to follow the government rules no matter you far or near that is your personal business. This is one of the saddest and heartbreaking evidences when he was interviewed and never imagined about his statement because he is a senior doctor, head department, the head of health center as the following expression:

“Saya tinggal di perbatasan desa A, dengan Desa B kabupaten lain, kalau .... berobat di desa A jaraknya jauh sekali, lalu ke desa B tapi sebagai pasien umum, ....maka pemerintah bilang ya apa mau na pemerintah pasti bilang janganko tinggal disitu, kasi pindah rumahmu” (R17, 44Years Old)

**Social Value View To The Regionalization Of The Referral System:** Kuswinarti (2016) said that social structure is placement of socio-cultural and organs of the society in position which is considered suitable with organism function as an entirety<sup>(6)</sup>. Social value which is meant is region teaching, ideology, principle, morality, and also politeness rules which have by society, while organs of the society is social groups, institute, social institution that efforts embodiment of certain value becomes real and use in fulfilling needs<sup>(7)</sup>. We believe that all society in the whole world without exception to Indonesia have a right of equal chance to enjoy health service with the best quality that can be achieved, patient as a core pushes us with not discriminative approach to health service policy which uphold health right for all<sup>(8)</sup>. The government has not able yet to make national health insurance (JKN) model which membership based on social value, ability to pay, differentiate the classification of national health insurance member base on society life level<sup>(9)</sup>. Furthermore, health service level to patient is differentiated and not given freedom to choose health facility that suitable with what he wants. Informant R2 stated that:

*“Sebagaimana prinsip orang jeneponto telah dibuktikan sesuai pernyataannya” bajikangngangi mate acceraka na mate ammokki mokki” (sikap semangat juang yang tinggi, usaha keras, tidak menyerah, janganakan harta nyawa sekalipun diberikan) rela membayar asalkan mendapatkan pelayanan yang bisa memberikan jaminan, keamanan dan kenyamanan terhadap keluarga atau si buah hatinya yang sakit”*

*(R26, 43 Years Old)*

A high spirit to sacrifice his family's health interest, commitment and principle, istiqomah as stated by informant R26 is one of patriotism attitude that worthy of imitation by all people, committed to work together in developing inclusion solution, innovative and continuously to increase integration between the regionalization of the referral system policy with holistic approach to access health service easy, safe, comfort because availability, adequacy, accessibility, suitability of health service needs:

*“Sebenarnya JKN sudah bagus namun banyak masalah di faskes seperti kasus yang terjadi disebuah paskes yaitu ada oknum hanya jerawat didiagnosa tumor, akhirnya dirujuk, bahkan kasus di kabupaten tertentu di rumah sakit bersalin normal oleh bidan dimalam hari. Besok dokternya visit disuruh kuret celakanya terjadi pendarahan akhirnya pasien meninggal”*

*(R2, 45 Years Old)*

The informant invoked astonishing facts, do beyond healthy reason, when a program is become as inhumane business field. Acne was diagnosed as tumor and patient of normal delivery was given another action that caused the patient dead become an example that tarnishing the good name of medical. Seeing this thing is very important to make a health program which is able to solve it as following statement of R22:

*“Data jaminan kesehatan di sulsel sudah 70% memiliki KIS, kalau 80% berarti zona hijau dan 4 kabupaten di Sulawesi Selatan Zona hijau dengan asumsi 20 % termaksud golongan yang mampu dan terdaftar di asuransi lain, pemerintah fokus pada masyarakat miskin dan tidak mampu, anehnya banyak masyarakat miskin yang tidak memiliki jaminan kesehatan”*

*(R22, 45 Years Old)*

Health insurance in South Celebes has increased from year to year, but the society has not able yet to place himself right suitable with economic ability or his live level. There are still many poor societies who do not

have KIS (Indonesia Healthy Card) whereas the level of affordability (registered) as member of BPJS and have KIS reached 90%, it is caused because the society is not all the poor. But many rich people who get and enjoy the facility of KIS which should only be for poor people if refer to the statement of informant R22, A statement from a doctor and BPJS staff as following stated:

*“Saya dokter melakukan riset bahwa kalau pasien bpjs rawat jalan hampir tidak ada puas tapi kalau betul-betul sakit, baru puas, dan berkata bayangkan saya dirawat 2 minggu tidak ada saya bayar sama sekali”*

*(R13, 45 Years Old)*

**Same as stated by Informant R11 that:**

*“Sebenarnya regulasinya sudah jalan misalnya dari RS tipe C ke RS Wahidin itu langsung di tolak, cuman dari puskesmas ke RS tipe B belum misalnya dari puskesmas ke RS Daya, belum pernah menolak pasien karena saya sudah arahkan ke RS Jala-ammari TNI AL sebagai RS tipe C tapi tidak mau banyak permintaannya juga paham rumahnya dekat sini”*

*(R11, 44 Years Old)*

About the responsibility, this doctor is always take unpopular policy, sometimes make informant take steps that contradict with higher policy made him got warning several times by his boss meant BPJS that life must have principle sometimes the rules are violated for the principle as following statement:

*“Pada dasarnya persoalan rujuk – merujuk tidak ada masalah, saya pernah ditegur kenapa dirujuk ... bisa ditangani, dengan alasan yang jelas, RS penuh ke berkompeten dan fasilitasnya lebih bagus”*

*(R14, 50 Years Old)*

**Conclusion**

The research result stated that health service especially the regionalization of the referral system has not running effectively and efficiently which caused by bias information to policy and provider, failed education by policy and provider that caused the society or receiver is not obey the regionalization of the referral system. the regionalization of the referral system nowadays needs to be revised or joint policy among regions, region must fit the needs of society with various perspective about health service access with the spirit of understanding each other. Regionalization must be updated so as achieve quality health service and stand for society so that society's social value become meaningful, be believed in team work, as the best tools to identify

challenge, to transfer knowledge, and avoid overlap in effort to overcome access gaps in Indonesia especially South Celebes.

**Funding Sources:** Used during this study were sourced from personal funds.

**Internal Conflict:** The author (s) declare that they have no conflict of interest.

# Relationship of Knowledge and Experience with Perception of the Level of Emergency in Patient's Family at Emergency Room

Ani Sutriningsih<sup>1</sup>, Setya Haksama<sup>2</sup>, Firman Suryadi Rahman<sup>3</sup>

<sup>1,3</sup> Student at Doctoral Program of Public Health, Universitas Airlangga, Indonesia,

<sup>2</sup> Faculty of Public Health, Universitas Airlangga, Indonesia

## Abstract

**Context:** Handling in Emergency Room (ER) is often considered late by the patient's family. Public perception in this case the patient's family about the condition of the emergency is based on knowledge about the clinical condition of the emergency and psychosocial and the experience of bringing patients to the ER. The goal of this study is to find the relationship between knowledge and experience with perceptions of the level of emergency of patient's family in ER. The research design is a cross sectional approach. The population covers the families of traffic accident patients in the ER with the total of 100 people using purposive sampling. The results showed that more than half (55%) of respondents had good knowledge (55%), more than half (66%) of respondents had experience delivering patients to ER, and almost all (94%) had a severe perception of the condition of patients on ER. The results of the research used Spearman Rank test to know the relationship between knowledge and experience with perceptions of the level of emergency of patients family in ER. The p value obtained was 0.043(significancy of 0.05) which means there is a relationship between knowledge with perceptions of the level of emergency and the p value obtained was 0.176(no significancy of 0.05) which means there is no relationship between experience with perceived level of emergency. It is expected that the next researcher will examine the factors that influence the patient's family knowledge about the level of emergency of patients in the ER.

**Keywords:** *knowledge, experience, perception, family of patients, level of emergency*

## Introduction

Handling in Emergency Room (ER) is often considered late by the patient's family. Internal and external factors that affect the delay in handling emergency cases include the character of the patient, staffing, availability of stretchers and health workers, time of arrival of patients, implementation of management and selected examination and treatment strategies.

The highest gap in the communication process occurs in the patient's priority scaling process, where ER users do not obtain information verbally about the priority scale and response time set in the ER of the Dr. Saiful Anwar Malang General Hospital<sup>1</sup>. Based on the observations of researchers at one of the Malang City Hospital ER found the complaints of families of patients who took patients to the emergency room about the slow handling of patients and the absence of information about the condition of the patient because the family was not allowed to enter the emergency room. The results of interviews of researchers with the patient's family stated that the reason for bringing traffic accident patients to the emergency room was falling pain, broken bones, torn wounds, bleeding, and getting treatment as soon as possible.

The elements that form perceptions in general are the existence of objects that are a concern, stimulus, and influencing factors such as stereotypes, experiences, intelligence, circumstances, needs, and emotions <sup>2</sup>. In this study perceptions arise due to the stimulus of the object that is the concern of the patient's family, namely traffic accidents. Public perception in this case the patient's family about the condition of the emergency is based on knowledge about the clinical condition of the emergency and psychosocial and the experience of bringing the patient to the emergency room <sup>3,4</sup>. The knowledge of the patient's family about the level of emergency based on the reason for coming to the emergency room is due to pain, injury and trauma and the availability of skilled human resources and emergency facilities such as laboratory and x-ray examinations, health insurance status and barriers to primary health care providers <sup>5,6,7,8</sup>. Based on research as much as 58% - 82% of visits in the emergency department for pediatric cases are unfortunate conditions. The reason parents take patients to the emergency room is because the emergency department has skilled workers who will provide immediate treatment <sup>5</sup>.

Differences in perceptions of the level of emergency between nurses who deal with patients and the families of patients who deliver patients to the emergency room can trigger conflict between the two parties. Elder et al. in 2004 reported a significant gap in patient knowledge about perceptions of triage in the ER<sup>9</sup>. This is in accordance with the study of Ekwall et al. in 2008 who reported irregularities regarding the relationship between nurses' perceptions and patients about emergency <sup>10</sup>. In this study the nurse assessed the patient's problems as being less severe but not in accordance with the patient's perceptions causing psychological effects. Based on the above background, it is necessary to conduct research on the relationship of knowledge and experience with perceptions of the level of emergency in the family of patients in the emergency department.

## Materials and Method

This research was a correlation study with a cross sectional approach where data retrieval of independent and bound variables is measured at the same time and there is no follow-up <sup>11</sup>. At the time of the study, there were 100 people who are families of traffic accident patients in the ER at the Dr. Saiful Anwar Malang General Hospital using purposive sampling. The inclusion criteria of respondents in this study included being willing to

be respondents, male and female, in a state of calm and not experiencing severe anxiety (based on the Hamilton Anxiety Rating Scale (HARS) questionnaire, as well as parents, husbands, wives, or children of traffic accident patients who know the condition and take patients to the emergency room at Dr. Saiful Anwar Malang General Hospital.

The independent variable in this study is the patient's family knowledge compiled by the researcher based on a literature review consisting of 10 items that have been tested for its validity and reliability with results in the range 0.667–0.885 meaning the patient's family knowledge questionnaire is valid because the value is greater than 0.632 and obtained  $r$  value = 0.661 where  $r > r$  table value (0.632), then this instrument is said to be reliable with high classification. The parameters in the patient's family knowledge questionnaire can be seen in Table 1. While the instrument for measuring dependent variables uses an observation sheet to record the results of the patient's family perception of the level of emergency. Data was analyzed using the Spearman Rank test with the help of SPSS at the significance level obtained  $p$  value  $0.001 < (\alpha 0.05)$ . Research ethics by applying the respect for person principle (respecting human dignity), minimizing maleficence, maximizing beneficial results (beneficence), explaining research procedures and paying attention to honesty and accuracy. Ethical Clearance was obtained from The Ethical Committee Medical Research, Medicine Faculty, Brawijaya University where in collaboration in Dr. Saiful Anwar Malang General Hospital.

## Results and Discussion

Dr. Saiful Anwar Malang General Hospital is a Class A General Hospital owned by the Regional Government of East Java Province. RSUD dr. Saiful Anwar Malang is located in the middle of Malang city, precisely on Jalan Jaksa Agung Suprpto 2 Malang, which is a strategic location that is easily accessible to the community both by surrounding communities and from outside the city. The Emergency Room (ER) is located at the northern front door of RSUD dr. Saiful Anwar Malang. ER has a triage room, Resuscitation / Priority 1 room, Priority 2 general cases, Priority 2 cases of Neonates, Priority 2 cases of Obstetrics and Priority 3. In addition, ER also has a nurse room, doctor's room, operating room, Information and Education Room (KIE), Decontamination Room, Administration Room, pharmacy depot, X-Ray room, CT Scan and toilet.

Based on the results of the study, respondents' characteristics according to age, sex, education, and family relationships with patients who were sent to the emergency room can be seen in Table 2. Based on Table 2, it was obtained that respondents have an average age of 36 years (SD = 8.27) where age at this time is of productive age. More than half (59%) of respondents were female, almost half (45%) of respondents had junior secondary education where high enough education would be easier to receive information and more than a quarter (31%) of respondents had family relations as wives. Based on the results of the study found the characteristics of knowledge and experience on perceptions of the level of emergency of the respondents (Table 3). Based on Table 3, it is known that more than half of the respondents have severe perceptions (94%) and good knowledge (55%), and more than half of the respondents (66%) have experience delivering patients to the ER. Good knowledge will make it easier to perceive the patient's condition.

Based on the results of the study, it was found that more than half of the respondents had good knowledge and had the experience of delivering patients to the emergency room. Factors that affect knowledge include age, education, and experience. Nearly half (45%) of respondents have senior secondary education where a high level of education will be easier to receive information. In addition to the level of education, Vallejo et al. (2011) reported 70% of patients considered that their health problems were not serious, but they thought this situation must be resolved immediately, meaning the patient's family took the patient to the ER in the hope of getting immediate treatment even though airway conditions, breathing function (breathing) and circulation of patients is not severe<sup>12</sup>.

Based on Table 3, it was obtained that more than half of respondents had good knowledge (55%), almost all perceptions were severe (54%), who had sufficient knowledge (38%), most perceptions were severe (34%), who had less knowledge (5%) all perceptions are severe (5%), and those who have bad knowledge (2%) are perceived to be insecure and not critical at 1% each. At 95% confidence level using the Spearman Rank Test, p value  $0.043 < (\alpha 0.05)$  was obtained, meaning that  $H_0$  is rejected so that there is a relationship between knowledge and perceptions of the level of emergency. The results of this study are in accordance with the theory of Notoatmodjo that knowledge is very close to education

both obtained through formal and informal education<sup>11</sup>. In this study, respondents had ages between 18 and 67 with an average age of 36.34 years and almost half (45%) of respondents had senior secondary education (45%). A high level of education will be easier to receive information. The results of this study are in accordance with Notoatmodjo which states that with increasing age a person will experience changes in physical and psychological (mental) aspects, where the psychological aspect of a person's thinking level is more mature and mature<sup>11</sup>.

Based on Table 3, it was obtained that more than half (66%) of respondents had experience and had severe perceptions (64%). At 95% confidence level using the Spearman Rank Test, p value  $0.176 > (\alpha 0.05)$  was obtained, meaning that  $H_0$  is accepted so that there is no relationship between experience and perceptions of the level of emergency. The results of this study are not in accordance with the Fellows' statement which states that the experience of bringing patients to the emergency room beforehand causes patients and those who take it to feel that the patient's condition is severe but is better prepared to deal with a dense situation in the ER<sup>4</sup>. The family of patients who had previously taken patients to the emergency room assumed that the pain complaints felt by patients were one reason that patients were in a severe category and had to get treatment as soon as possible even though the airway, respiratory function, and circulation were adequate. The results of this study are in accordance with Rachmat, Krech and Crutchfield in Sobur (2003) who explained that one of the factors that influence perception is a personal factor consisting of experience, motivation and personality. Experience will help a person improve perceptual abilities<sup>13,14</sup>.

<b>Total (%)</b>		<b>94</b>	<b>6</b>	<b>100</b>	

### Conclusion

In conclusion, the better the patient's family knowledge, the more likely it is to perceive the patient's condition in the direction of emergency in the ER of the Dr. Saiful Anwar Malang General Hospital. There is no relationship between experience with perceptions of the level of emergency in the family of patients in the ER at the Dr. Saiful Anwar Malang General Hospital ( $p = 0.176$ ). Suggestions for hospitals to increase the patient's family knowledge through Communication, Information and Education (KIE) to the patient's family about the level of emergency when the patient is on the ER both verbally and in writing. For the next researcher, it is expected to examine the factors that can improve the patient's family knowledge about the level of emergency.

## Abstract

**Introduction:** Poor nutritional status is a major nutritional problem in infants and has an impact on growth disorders and is a problem that needs to be addressed seriously, age 6-18 months is a very important period as well as a critical period in the process of growth and development both physically and intellectually. Therefore, every baby at this time must obtain nutritional intake according to their needs. Aim; to prove the relationship between enabling factors and infant nutritional status.

**Method:** Type of research used analytical survey with a cross-sectional study approach. This research was carried out in Maccini Sawah Sub-District, Makassar Sub-District, Makassar City. The sample of this study was infants with exhaustive sampling with 62 samples.

**Results:** The study found that the age of starting complementary food for breast milk was related to the nutritional status of the baby with a p-value (0,000), the type of complementary foods for breast milk related to the nutritional status of the baby with a p-value (0,015), the frequency of complementary foods for breast milk related to nutritional status with p-value 0.004), and the variation of complementary foods for breast milk administration is related to nutritional status with p-value (0.001).

**Conclusion:** It was found that there was a strong relationship between age, starting, giving, type, frequency, and variation of complementary feeding with infant nutritional status.

**Keywords:** *Nutritional Status, Complementary Food, Breast Milk, Enabling Factors*

## Introduction

Nutritional status in children is very important for their lives, growing and developing into healthy, productive adults who benefit the community, this is an

international priority to improve children's nutritional status<sup>(1)</sup>. The World Child Association (UNICEF) and the World Health Organization (WHO) state that good nutrition practices in children include the initiation of early breastfeeding, exclusive breastfeeding ages 0-6 months, the addition of adequate, safe nutrition, and complementary foods according to the breastfeeding period for 1 year<sup>(2,3)</sup>. The prevalence of malnutrition in Indonesia is still high. One potential factor that contributes to the high prevalence of malnutrition is the inappropriate complementary diet and practice of breastfeeding<sup>(4)</sup>.

e-mail: antoarunraja@gmail.com

Malnutrition during breastfeeding, especially the practice of exclusive breast milk for 6 months after birth is a risk factor for infant and child morbidity and mortality that can be corrected by providing complementary food (5). One intervention to prevent a more effective way to reduce 13-15% of child deaths is to apply exclusive breastfeeding supplemented with complementary foods that will prevent 19% of children’s deaths (6). The impact during the child learning process is inactivity, intellectual disruption, decreased productivity, and development of social behavior(5).

Improvement of maternal nutrition carried out before and during exclusive breastfeeding is one of the efforts to improve infant nutrition 0-6 months. This problem is very important and needs to be addressed seriously. The age of 6-18 months is a critical period due to malnutrition at the age of under two years, has an impact on decreasing brain development, physical growth, intellectual, and productivity, the impact of malnutrition is largely irreversible. Malnutrition in infants and children occur because of the food given is low in nutrition or energy. Additional food for babies in developing countries generally made of cereals or tubers tends to be powdery. At the age of one year, the proper administration of complementary foods for breast milk is expected to meet the nutritional needs of the baby, but it can also stimulate the baby’s eating behavior which is usually liquid and then adapt to the types of porridge and biscuits (7). Premature babies are at high risk and really need adequate nutrition to increase proper growth (8). The complimentary food program of breast milk is very important to give to babies in overcoming high nutrient deficiencies, based on the description above the authors

feel interested in conducting research on the relationship of enabling factors for complementary food for breast milk with the nutritional status of infants. Aim; to prove the relationship between enabling factors and infant nutritional status.

**Method**

This research was conducted in 2017 with samples in the study, namely infants aged 6-11 months, using exhaustive sampling techniques as many as 62 infants. The type of research used is an analytical survey with the approach cross sectional study. The source of complementary food data is derived from the results of interviews with mothers and caregivers using questionnaires, nutritional status data obtained from weighing the baby’s weight using Baby Scale the GEA brand with measurement accuracy of 0.05 Kg to 0.1 Kg followed by calculation of standard deviation using anthropometric method (WHO Anthro Plus) and referring to the NCHS table. Data analysis using univariate, bivariate and multivariate analysis.

**Results**

**Sample Characteristics:** Table 1 shows a description of the sex of the baby, the age of the baby, the level of education and the type of work the mother has on the case of infant nutritional status. The homogeneity test results between cases of abnormal nutritional status and normal nutritional status in the baby sex obtained a value of p = 0.77, the average age of the baby obtained a value of p = 0.87, the maternal education level obtained a value of p = 0.44 and work mother obtained p value = 0.73.

**Table 1: Analysis of Sample**

n: Number of Samples, \* Homogeneity Test

**Factors Enabling Complementary Foods:** relationship between enabling factors and infant nutritional status is presented in Table 2. Based on table 2, age suitability in supplementary feeding does not have a significant relationship with infant nutritional status, age suitability in the process of providing complementary food for breast milk in cases of abnormal nutritional status is more  $37.5 \pm 22.7$  compared with age suitability in the case of normal nutritional status  $62.5 \pm 77.3$ . Chi-square test between the two variables obtained p value = 0.23. There is a significant relationship between the consistency of the type of complementary food

given with the nutritional status of the baby, where the consistency in the case of abnormal nutritional status is more  $55.6 \pm 14.3$  compared to the consistency of food types in the case of normal nutritional status  $44.3 \pm 85.7$ . The chi-square test between the two variables obtained p = 0.001. there is a significant relationship between the frequency of complementary feeding and the nutritional status of infants, where the frequency in cases of abnormal nutritional status is more  $45.2 \pm 19.4$  compared to the frequency in cases of normal nutritional status  $54.8 \pm 80.6$ . The chi-square test between the two variables obtained a value of p = 0.03.

**Table 2: Correlation Factors Enabling Food Complementary foods for breast milk with Infant Nutritional Status**

**Multivariate Analysis:** Requirements fulfilled in multivariate analysis, namely all variables related to p value <0.05 entered which are then analyzed include variable consistency the type of complementary food,

the frequency of supplementary feeding, using the statistical ratio method to see the riskier and most related variables. It is indicated that the consistency of food types and frequency can improve nutritional status (Table 3).

**Table 3: Multiple Logistic Regression**

Variable	B	Sig (p-value)	Exp (B)	OR	95% CI
* Consistency type	2.186	0.001	8.903	7.500	2.384 to 33.054

### Discussion

**Giving Age Suitability:** Provision of complementary foods for breast milk should be started at the age of 6 months because the digestive system of the body has started to be perfect and ready to receive food other than breast milk. When babies enter the age of 6 months and above, some nutritional elements such as protein, carbohydrates and some vitamins and minerals contained in breast milk are no longer sufficient. Based on the results of this study that the suitability of the age of the first time giving is not related to nutritional status. Important findings in this study, supplementary feeding was first given in the first 6 months, but more were given formula milk at the age of under 6 months. Similarly, Lakshman’s research is more focused and specific in the provision of bottled milk and obesogenic foods<sup>(9)</sup>.

The results of this study are in contrast to Alzaheb’s research in Saudi Arabia (2015) stating that the practice of giving is very useful as a complement to infant malnutrition obtained from breast milk<sup>(10)</sup>. The introduction of earlier complementary foods before a six-month-old baby has a negative effect as a substitute for breast milk and can stop breastfeeding practices at an early stage<sup>(11,12)</sup>. Baby’s nutritional needs increase along with increasing age and reduced breast milk production and duration of breastfeeding<sup>(10)</sup>. In the first year of life, the method of feeding babies on time is one way of intervention carried out in the community to support optimal baby growth and development<sup>(13)</sup>.

**Consistency of Food Types:** important finding in this research is that the type of complementary food has an influence on the nutritional status of infants and children. Research found and explained more specifically

the age conformity with the type of quality food consumed has an influence on the absorption of nutrients that have an impact on nutritional status. Various kinds of complementary foods for breast milk are given to each day according to age development. Complementary foods cannot match breast milk in its nutritional content, enzymes, hormones, and immunological substances and antibodies. Modified food ingredients or mixtures of various types of food ingredients that are specially made as complementary foods for breast milk so that these foods contain complete nutrients needed by babies because this period includes the period of growth.

This study is not in line with stating that the average food supplement studied cannot meet the needs of calcium, iron and zinc every day as a nutritional source of complementary foods for infants in developing countries<sup>(14)</sup>. This study is in line with that conducted in Tanzania in the 6-23 month age group (2010) which states that the main determinant that can affect a baby’s health, development and growth is the proper consumption of complementary foods<sup>(15)</sup>. Giving baby food is a modification factor that can reduce mortality and disability caused by preterm birth<sup>(16)</sup>. The growth and development of premature babies is in accordance with types of food such as breast milk or fortified formula<sup>(17)</sup>.

**Giving Frequency:** Quantity of complementary food is very important for brain growth and intelligence development. The fulfillment of infant and family nutrition is closely related to the frequency of food provided. The frequency of breastfeeding must be adjusted to the age and ability to produce breast milk. Increasing age needs are also increasing and the ability

to produce breast milk decreases so that the frequency of supplementary food supply is increasing and added some types of snack foods.

The frequency of eating children is also influenced by several factors such as the family's socio-economic status and the number of family members. According to the theory, the proportion of adults more than children in the family can result in less food availability for children. Low-income communities increase the attention and focus on breastfeeding and supplementary food for babies<sup>(1)</sup>. The results of this study are similar to research conducted in Krakow and Silesia (2014) stating that regular feeding is very important, adequate daily nutrient intake is useful for physical development and and it is necessary to introduce healthy eating patterns for health during the growth period<sup>(18)</sup>. Perceptions about breast milk and feeding given complementary breast milk can be improved by health education<sup>(13)</sup>.

### Conclusion

Provision of complementary breast milk food is related to the nutritional status of the baby. The consistency of food types has a greater relationship with nutritional status compared to frequency. The age match for starting complementary foods performed by mothers starts at 6 months of age. The practice of giving complementary foods for breast milk is influenced by the mother's knowledge which has an impact on the mother's skills in serving complementary foods.

**Significant Statement:** Results of this study found that babies need complementary food as they age to cover malnutrition from the intake of breast milk for growth and development. The practice of providing good complementary foods can be seen from the suitability and consistency in providing complementary foods caused by knowledge of maternal nutrition.

**Funding Sources:** Used during this study were sourced from personal funds.

**Acknowledgments:** The authors wish to thank all the Public Health students who helped in the collection of the data. The Makassar City Government, the Health Office, the Head of the community health center which has given research permission. Respondents who have been willing to spend time in the interview process.

**Internal Conflict:** The author (s) declare that they have no conflict of interest.

**Ethical Clearance:** Ethical approval has been obtained from Ethical Commission of Health Research, Faculty of Public Health, with protocol number UH910183006.

# Urinary Tract Stones Cases Profile at a B-type General Hospital, Gresik, East Java in March: May 2018

Ardito Ario Willy Goller<sup>1</sup>, Rochmad Yasin<sup>2</sup>

<sup>1</sup>General Practitioner, Ibnu Sina General Hospital, Gresik, East Java, Indonesia, <sup>2</sup>General Urologist, Ibnu Sina General Hospital, Gresik, East Java, Indonesia

## Abstract

**Introduction & objectives:** Urinary tract stones are associated with various risk factors, both endogenous and exogenous risk factors. The aim of this study is to investigate the demographic data of the outpatient clinic in Ibnu Sina General Hospital, a B-type hospital located in Gresik, East Java, Indonesia.

**Patients and Method:** This research was a descriptive study from medical records and questionnaires. A total of 118 patients was admitted to this research during March - May 2018. The variables used in this study were age group, sex, family history, water intake, and location of stones.

**Results:** The research show obtained result that the age group with the highest number of urinary tract stone cases is the age group of 45-64 years old (63,6%). Most of the patients were male (58,5%). The majority of the patients denied to having familial history of urinary tract stones (79,7%). The largest part of the patients didn't take >2,5L per-day (82,2%). Most of the stones were found in Upper Urinary Tract (81,4%).

**Conclusion:** From the results of the research the highest number of cases in each group was found to be in the age group of 45-64 years, male group, patients without any family history of urinary tract stone group, patients with water intake < 2.5L/day group, and patients whose stone located in the upper urinary tract group.

**Keywords:** *Urolithiasis, urinary tract stones, epidemiology, risk factor, east java, indonesia*

## Introduction

Urinary tract stones are a pathological condition because of the presence of hard masses such as stones that form along the urethra and can cause pain, bleeding, or infections of the urinary tract. If not treated properly, this obstruction can cause malfunction and permanent kidney structure damage, such as obstructive nephropathy, and if you have a urinary tract infection can cause urosepsis.<sup>1</sup>

Urinary tract stones are associated with various risk factors that must be recognized by everyone, both endogenous or exogenous risk factors. Usually there is a combination of endogenous and exogenous factors that lead to stone formation. Endogenous risk factors include age, sex, and family history. While exogenous risk factors include climatic conditions, nutrition, obesity, fluid intake, work, and medication.<sup>2</sup>

In Indonesia, the prevalence of urinary tract stone disease increases with age. The prevalence of urinary tract stones is 0.6%. The highest was in the age group of 55-64 years (1.3%) and it was higher in male (0.8%) compared to female (0.4%).<sup>3</sup>

## Materials and Method

This is a descriptive research. Retrieval of patient

data was obtained from medical record and questionnaire filled by patients with urinary tract stones at the Outpatient Clinic of Ibnu Sina General Hospital during March - May 2018. All patients who fit the inclusion criteria were included in this study, the variables of this study were age, sex, history of stones in the family, amount of fluid intake, and location of the stone. From the inclusion criteria, 118 cases of patients with urinary tract stones were obtained.

### Results

This study is a retrospective study of patients with urinary tract stones in the Outpatient Installation of Ibnu Sina Gresik Hospital during March-May 2018. The patient’s diagnosis is based on medical records.

The results showed that the age group with the

highest number of cases of urinary tract stones was the age group of 45-64 years, as many as 76 patients (63.6%) and the group with the least number was the age group 1-4 years and 5-14 years with 1 patient (0.8%) in each group. Based on the sex group (69 male patients and 49 female patients), the ratio of male compared to female was 1.4: 1 (58.5%: 41.5%). Patients who had family history of urinary tract stones were reported as many as 24 patients (20.3%), while 94 patients (79.7%) denied for having it. The group of patients with fluid intake > 2.5L per day was 21 patients (17.8%) and the remaining 97 patients consumed < 2.5L water per day. A total of 96 patients (81.4%) had urinary tract stones located in the upper urinary tract, 20 patients (16.9%) in the lower urinary tract, and 2 patients (1.7%) had stones both in the upper and lower urinary tract. The data is presented in Table 1.

**Table 1: Characteristic of Research Subject**

Criteria		Amount	Percentage (%)
Age (Year)	< 1	0	0
	1 – 4	1	0,8
	5 – 14	1	0,8
	15-24	2	1,7
	25-44	23	19,5
	45-64	76	63,6
	≥65	16	13,6
Sex	Male	69	58,5
	Female	49	41,5
History of Urinary Tract Stone within Family	Yes	24	20,3
	No	94	79,7
Fluid Intake ≥2,5 L/day	Yes	21	17,8
	No	97	82,2
Stone Location	Upper	96	81,4
	Both	2	1,7
	Lower	20	16,9

### Discussion

Based on age group, the most cases were found in the 45-64 year age group as many as 76 patients (63.6%). the age group with the highest number of urinary tract stone cases in this study accordance with the study that was published in 2017 which states that the majority of cases of urinary tract stones are in the age group 40 years to 60 years and the number of cases which is rare in children.<sup>4</sup>

As in adults, the factors involved in the metabolic syndrome such as obesity also pose a risk of urinary tract stone formation in children.<sup>5</sup>

Changes in stone composition have also been reported, this may occur as a result of lifestyle changes according to age development. The choice of lifestyle and food involved in the metabolic syndrome complex is an important factor that contributes to this development.<sup>6</sup>

In terms of sex, the majority of cases were found in male as many as 69 patients (58.5%). This is consistent with many studies in developed and developing countries.<sup>7</sup>

It has been observed that women show a bimodal distribution of stone disease, demonstrating a second peak in the sixth decade of life corresponding to the onset of menopause and a fall in estrogen level. This finding and the lower incidence of stone disease in woman compared with men have been attributed to the protective effect of estrogen against stone formation in premenopause women, owing to enhanced renal calcium absorption and reduced bone resorption.<sup>8</sup>

Lower urinary saturation of calcium oxalate and brushite was identified in women compared with men. Moreover, urinary calcium was lower in women than in men until beyond age 50, when it reached equivalence in the two groups.<sup>9</sup>

Patients who had family history of urinary kidney stone as many as 24 patient (20,3%). Urolithiasis was significantly associated with a positive family history of urinary tract stones.<sup>10</sup> Another study found that first-degree relatives of those with stones have twice as high a chance of stone disease.<sup>11</sup> Defects in urine acidification can be inherited and polygenic factors, as well as household diet and environmental factors, can play a role.<sup>12</sup>

Although the data above supports that there is a significant relationship between urinary tract stone patients and the history of this in the family, there is a discrepancy in the results of this study. This may be due to a recall bias by the patient, where the patient may be wrong in mentioning the presence or absence of a family history due to limited knowledge and memory of the patient.

Based on the amount of fluid intake, patients with fluid intake > 2,5L per day in cases of urinary tract stones were 21 patients (17,8%). The cut off figure 2,5L was adapted from EAU 11th edition as a measure of prevention of urinary tract stones in general. In another study of the 21.000 patients who were expected to be obedient to drink 2L / day of fluid, 11572 patients were found to be able to avoid first incidence of urinary tract stones.<sup>13</sup>

Dehydration is not only caused by fluid intake, but a balance between intake and output. Eventhough

the patient has been drinking enough fluid according to the recommended limits, the needs of each patient are different, varies according to individual's activity, exposure of sunlight, infection, diet, medication consumption, etc.<sup>14</sup>

Dehydration is a very important thing because higher temperatures are positively associated with stone prevalence.<sup>10</sup> Because the concentration of the amount of the crystallized solute is the most important matter which finally forms stone, thus the reduction in urine volume will strengthen the saturation of all solutes and increase the risk of all stone formation. In addition, oliguria also increases urinary stasis.<sup>15</sup>

Viewed from the location, urinary tract stones appeared to be located in upper, lower or both. The majority of stones' location were found at the upper urinary tract as many as 96 patients (81.4%). The results of this study are in accordance with the study that was published in 2015, with the results of the study that the upper urinary tract stones as the location of the most stones with 286 patients (82.4%) of a total of 347 patients. On the other hand, the location of the stone changes with age where the proportion of bladder stones increases, while the proportion of kidney stones decreases.<sup>16</sup>

Supersaturation which plays an important role in calcium oxalate stones, is deposition of stone material in a renal papillary calcium phosphate nidus. The calcium phosphate precipitate on the base of the thin membrane loop of Henle, erodes into the interstitium, and then accumulates in the subepithelial space of the renal papilla. A deposit from a subepithelial known as Randall's plaques eventually erodes through papillary urothelium. Calcium phosphate and calcium oxalate gradually deposit on the substrate to create a urinary tract stones.<sup>17</sup>

Benign prostate hyperplasia in the elderly causes a tendency towards obstruction. This might be a possible explanation for the high incidence of stones in the bladder in older people. Another thing that makes women at risk for lower urinary tract stones is the presence of other risk factors, such as changes in bladder function associated with relaxation of smooth muscle tone in the elderly, with reduced bladder emptying efficiency that supports urinary stagnation and stone.<sup>18</sup>

## Conclusions

From the results of the research the highest number

of cases in each group was found to be in the age group of 45-64 years, male group, patients without any family history of urinary tract stone group, patients with water intake < 2.5L/day group, and patients whose stone located in the upper urinary tract group.

**Acknowledgments:** We thanked dr. Endang Puspitowati, Sp.THT – KL as President of Ibnu Sina General Hospital. Thank you for all staff who provide the medical record. We also thank the respondents of the study for their contribution. There is no funding association in this research.

# Performance of Immunization Program Managers Based on Malcolm Baldrige Criteria for Performance Excellence (MBCFPE) in Puskesmas Tangerang District in 2019

Asruddin<sup>1</sup>, Dian Ayubi<sup>2</sup>, Pujiyanto<sup>3</sup>

<sup>1</sup>Masters in Public Health, Faculty of Public Health, Universitas Indonesia, <sup>2</sup>Department of Health and Behavioral Education Faculty of Public Health, Universitas Indonesia, <sup>3</sup>Department of Administration and Health Policy, Faculty of Public Health, Universitas Indonesia

## Abstract

**Background:** Coverage of basic immunization to infants In Tangerang Regency, the last three years of 2014-2016 rose 2% - 7% every year, it always increases every year and immunization coverage nationally exceeds the national target of 90% 93.83%. This is different from the incidence of diphtheria in Tangerang Regency. The implementation of an immunization program provides an important role in the outbreak of vaccines by health workers who can preserve people's perceptions regarding unwanted reactions due to vaccination, causing re-emergence of diseases in the form (KLB). This event can also occur because a damaged vaccine cannot be repaired and cannot cause immunity. As a result, outbreaks of immunization-preventable diseases will continue to occur so that this study will know the description and relationship of program management performance based on Malcolm Baldrige.

**Method:** it used is quantitative and qualitative method using questionnaires and in-depth interviews.

**Results:** The results of the performance of immunization managers based on *Malcolm Baldrige* were obtained that strategic planning had the highest yield of 85.02. The lowest variable is to focus on the team with a value of 78.02. Multivariate showed that the correlation results of performance has a strong correlation with the variable Leadership Strategic Planning, Customer Focus, Measurement, Analysis and Knowledge Management, Focus on Team and Focus on Process Rated determinant coefficient ( $R^2 = 0.793$ ) where the variable most The high effect on the results with (B) = 0.429 or 42.9% while the focus variable on the team is the smallest variable which has an effect on the performance results with (B) = 0.003 or 0.3%.

**Conclusion:** So that better measurement, analysis and knowledge management, strategic planning, customer focus, leadership, focus on the process and focus on the team will improve the performance results.

**Keywords:** *Malcolm Baldrige, Performance, Program Managers, immunization*

## Introduction

Routine Immunization Coverage in infants in Tangerang District in the last three years of 2014-2016

always increases every year and immunization coverage nationally exceeds the national target of 90% to 93.83%<sup>(1)</sup> This is different from the Extraordinary Events (KLB) Diphtheria Tangerang Regency 73 cases reported up to January 2018 covering eight sub-districts<sup>(2)</sup>

Faculty of Public Health, Universitas Indonesia.

e-mail: dian\_ayb@Ui.Ac.Id

Puskesmas as the frontline in public health services have a very large role. The quality and quantity of human resources it must be improved so that the quality of health services can be felt by all communities. The use of damaged vaccines will give false recipients of the

vaccine recipients and this can also affect the program’s credibility to be negative. As a result, epidemics that can be prevented by immunization will continue to occur. (3), (4).

Determinants of complete basic immunization status in infants are the support of health workers after family support, access to health services and knowledge of mothers (5). The important role of puskesmas as the spearhead of government health services that provide health services to the wider community has various challenges as an organization to maintain electability as a public servant compared to similar organizations(6) because the success of a program is determined by the quality of health care on improving the quality of life of the community

Malcolm Baldrige criteria is a collection that is integrated with the instructions for excellence and continuity of performance in the health center immunization program in Tangerang Regency. (7). This research is expected to portray the implementation of immunization programs with the Malcolm Baldrige approach in health centers in Tangerang Regency

**Research and Method**

**Design Study:** The research method is *Mix method*, which is a quantitative method using questionnaires and qualitative using in-depth interviews and observations.

**Population Study:** Population is the entire person in charge of managing immunization organizer programs in Tangerang District Puskesmas, amounting to 43 officers. The sample used was the whole population (*Total Sampling*) with  $\alpha = 5\%$

**Data Collection:** obtained from primary sources from questionnaires with 56 statements, in-depth interviews with 15 questions and observations with 13 documents that referred to the criteria *Malcolm Baldrige*. Data collection of respondents using questionnaires that have been tested for validity and reliability in Depok City. Analysis of data used in quantitative analysis using multiple linear regression method with a scale of 100 on the SPSS 16.

**Research Results**

**Table 1. Description of Dependent Variables**

Size (Scala 100)	Value
	Variable Results
Minimum	40
Maximum	100
Mean	83,25
SD	11,40

Average values of 83.25 with standard deviation 11.40 on a scale of 100 Table.

**Table 2: Description of Independent Variables**

Size (Scala 100)	Value					
	Leadership	Strategic planning	Focus patients	Measurement, analysis, Knowledge Management	Focus teams	, Focus Process
Minimum	55	40	50	42,22	55	50
Maximum	100	100	97,5	100	100	100
Mean	82,05	85,02	79,65	83,00	78,02	80,31
SD	9,72	10,48	8,25	9,04	8,69	9,19

Strategic planning variable has the highest yield of 85.02 with a standard deviation of 10.48. The lowest variable is the focus of the team with a value of 78.02 with a standard deviation of 8.69.

**Table 3: Multivariate correlation of independent variables with Results**

Variabel	r	R <sup>2</sup>	p-value
Leadership, Strategic planning, Focus patients, Measurement, analysis and knowledge management, Focus teams, Focus process	0.759	0,793	0,001

Multivariate analysis of the dependent variable and independent r value = 0.759 which shows that the two variables have a strong and positive pattern. This means that the better the independent variable, the better the performance results. R<sup>2</sup> = 0.793 indicates that 79.32% of the variation of performance results can be explained by the independent variable.

Multivariate analysis of independent with dependent variables shows that the measurement variables, analysis and knowledge management are the highest variables that influence the results with the value (B) = 0.429 or 42.9% while the focus variable on the team is the smallest variable that influences the performance results with a value (B) = 0.003 or 0.3%.

**Table 4: Contributions influence of independent variables on the results**

Variabel	Standardized Coefficients (B)
Leadership	0,053
Strategic planning	0,199
Focus patients	0,190
Measurement, analysis and knowledge management	0,429
Focus teams	0,003
Focus process	0,158

**Table 5: Items of priority variabel**

Items of improved priority variabel	Items of Maintainable priority variabel
<b>Leadership</b>	
Efforts in program manager regeneration	Intense communication with all officers
<b>Strategic planning</b>	
Involvement of officers determining strategic plans	Preparation of activity plans
<b>Focus patients</b>	
Acceptance complaints in the implementation of customer	patient-oriented services
<b>Measurement, analysis and knowledge management</b>	
Ability to analyze performance in efforts to improve	Reporting and recording systems are used for IEC
<b>Team focus</b>	
Award or punishment for program managers	Training in conducting immunization
<b>Focus process</b>	
Development of new procedures according to needs	Implement tasks in accordance with work guidelines
<b>Results</b>	
Evaluate the implementation of immunizations with instruments carried out regularly is carried out	Logistics storageit is well implemented which includes maintained vaccine quality

**Discussion**

**Results:** Puskesmas carries out tasks in accordance with annual planning, the existence of health promotion activities prior to service. The documentation of the implementation of the report on the implementation of activities has been made and the implementation has been in accordance with the established Standard Operating Procedure which is a prerequisite in the accreditation of puskesmas. This is in accordance with previous research. Service can be achieved in good categories if there is commitment of human resources, which is good and right, in accordance with standard

operating procedures <sup>(8)</sup>.

Independent variables have a correlation and are positively patterned towards the dependent variable. This means that the better the independent variable will improve results. The highest value (R) is measurement, analysis and knowledge management (R<sup>2</sup>= 0.753) illustrating that these variables have the most influence on performance. The focus variable on the team (R<sup>2</sup>= 0.292) is the smallest variable. due to involving all employees in the puskesmas without seeing their competencies and developing the competency of the officers, they have not been *updated*.

**Leadership:** Efforts to prepare the regeneration of program managers are still low. Because of the lack of resources and workload, communication is intense with officers and basic socialization of policies to officers is the highest thing, because the health center is able to conduct two-way communication by involving all parties. This is in line with research that good and effective communication between all parts is a strength for organizational sustainability<sup>(9),(10)</sup>

The results of bivariate leadership variables with the results of performance obtained the value of  $r = 0.621$  which shows that both variables have strong and positive patterns of relationships. Value ( $R^2 = 0.386$ ) shows that 38.6% variation in performance results can be explained by leadership variables.  $p$  value 0.001 ( $<0.05$ ), meaning that there is a relationship between leadership and performance results. While the multivariate results of the *Standardized Coefficients* ( $B$ ) = 0.053 showed that 5.3% of the leadership variables contributed to the performance results simultaneously with other variables. The better the leadership, the better the performance results of the puskesmas, this is in line with previous studies<sup>(11)</sup>.

**Strategic Planning:** Strategic planning involves specific plans, strategic determination, strategic program policies needed to achieve organizational goals. This can arise because of input in the form of requests, support, and the environment, from the outside to the policy owner<sup>(12)</sup>.

Bivariate strategic planning variables with results obtained by the value of  $r = 0.801$  which shows both variables have a strong and positive pattern of relationships. Value ( $R^2 = 0.641$ ) showed that 64.1% of the variation of performance results can be explained by the strategic planning. The statistical test results obtained  $p$  value 0.001 ( $<0.05$ ), meaning that there is a relationship between strategic planning and performance results.

The better the strategic planning will improve results, according to the research that strategic planning, customer focus and measurement will not affect leadership<sup>(11)</sup>.

**Focus Customers:** Satisfaction is a fulfillment response that is considered satisfactory in the form of an overall attitude directed at consumers of goods or services after they obtain and use it<sup>(13)</sup>. Expectations are directly proportional to the patient's desire to enjoy

service satisfactorily. If the services provided are as expected, the quality is interpreted well and satisfactorily as well as it should.<sup>(14)</sup>

Customer satisfaction and loyalty will increase if puskesmas is able to handle complaints effectively at the first contact, customer information can be obtained through regular customer satisfaction surveys by placing voice boxes, centers complaints conducting immunization. in line with the research that service quality contributes of patient satisfaction for puskesmas services<sup>(15)</sup>

The results of the variable bivariate focus patients with results obtained a value of  $r = 0.718$  which shows both of these variables have a strong and positive pattern. ( $R^2 = 0.516$ ) shows that 51.6% variation in results can be explained by variable focus patients.  $p$  value 0.001 ( $<0.05$ ), meaning that there is a relationship between focus patients and results.

The better focus patients will improve puskesmas performance. Reception and search for complaints is still not optimal. Puskesmas use social media as a means of complaint (suggestion box, *call center*, telephone, sms, or whatsapp) in obtaining complaints. This shows that the organization has involved puskesmas with an effective, systematic and responsive approach even though there are still parts that need to be systematically evaluated<sup>(16)</sup>

**Knowledge Measurement, Analysis and Management:** This variable explains how the puskesmas collects, selects, analyzes, manages and improves data, information and knowledge assets and how the health center uses the findings of the review results to improve its performance.<sup>(17)</sup> Organizations must use data or information in decision making, this is very necessary in identifying patient needs and patient expectations.<sup>(18)</sup>

The results of variable bivariate analysis focusing on the team with performance results obtained a value of  $r = 0.54$  which shows the two variables has a strong and positive relationship. The value ( $R^2 = 0.292$ ) shows that 29.2% variation in performance results can be explained by the focus variable on the team.  $p$  value 0.001 ( $<0.05$ ), meaning that there is a relationship between the focus on the team and the performance results.

**Focus Team:** Organizational culture, work stress and staff job satisfaction have a positive effect on employee performance<sup>(19)</sup>. Job stress causes employees to feel the need to mobilize all their abilities to achieve

high performance and to complete tasks well.

Bivariate analysis of variables focus teams with performance results obtained value  $r = 0.54$  which shows that both variables have a strong and positive pattern. Value ( $R^2 = 0.292$ ) shows 29.2% variation in performance results can be explained by variable focus on the team.  $p$  value 0.001 ( $<0.05$ ), meaning that there is a relationship between the focus on the team and the results of the performance

The better the focus team will improve performance. Reward or punishment in assignments on the focus variable on the team gets the lowest score. Rewards is one of the controlling tools used to motivate personnel, while *punishment* is something that produces a deterrent effect. If *reward and punishment* is carried out appropriately and wisely, the puskesmas will have more qualified staff who can improve performance. <sup>(20)</sup>

**Focus process:** Management is the process of planning, organizing, leaders, controlling the efforts of members of the organization and the process of using all, organizational resources to achieve established organizational goals while the process is a systematic way to carry out a job <sup>(21)</sup>

Results of variable bivariate focus process with the results of performance obtained a value of  $r = 0.568$  which shows both variables have a strong and positive pattern relationship. The value ( $R^2 = 0.322$ ) shows that 32.2% of the variation in performance results can be explained by the variable focus on the process.  $p$  value 0.001 ( $<0.05$ ), meaning that there is a relationship between the focus on the process and the performance results. The better the management process will improve results of its performance.

### Conclusion

Strategic planning variables have the highest value while the variable focuses on the lowest team. All variables have a strong and positive pattern. Measurement variables, analysis and knowledge management are the variables that have the strongest relationship. The better independent variabel will improve performance results of program management in Tangerang Regency

**Conflicts of Interest:** During this study there was no conflict of interests

**Source of Funding:** Self funding.

# The Impact of Primary Dysmenorrhea on the Level of Physical Activity among College age Students

Ayat M. Omar Masoud<sup>1</sup>, Heba A. Bahey El-Deen<sup>2</sup>, Samya M. Hegazy<sup>3a&b</sup>

<sup>1</sup>Assistant Professor, Department of Nursing, College of Applied Medical Sciences, Jouf University, Kingdom of Saudi Arabia, <sup>2</sup>Associate Professor, Department of Physical Therapy and Health Rehabilitation, College of Applied Medical Sciences, Jouf University, Kingdom of Saudi Arabia, <sup>3a</sup>Assistant Professor, Department of Nursing, College of Applied Medical Sciences, Jouf University, Kingdom of Saudi Arabia, <sup>3b</sup>Lecturer, Department of Pediatric Nursing, Faculty of Nursing, Tanta University, Egypt.

## Abstract

**Background:** Dysmenorrhea is one of the most prevalent adolescent health problems. Aim . This study aimed to evaluate the impact of primary dysmenorrhea on the level of physical activity among female students at the College of Applied Medical Sciences, Jouf University.

**Method:** A cross-sectional study was conducted in this study. Purposive sampling technique was used to enroll seventy-nine female students who reported moderate to severe pain and recruited from Physiotherapy and Health Rehabilitation Department from the middle of April to the end of August. A self-administered questionnaire, was designed to collect required data in this research.

**Results:** from the present study showed that there was a significant impact of pain on the absenteeism, low concentration, poor academic performance, and reduced physical activity. All those effects were accompanied by higher pain rating scale ( $p$ -value 0.0001, 0, 0001, 0.011 and 0.023 respectively).

**Conclusion:** Most of the female students had experienced a variety of dysmenorrhea degrees that may have an adverse effect on the number of physical activity limitations and other variables such as absenteeism, low concentration, and poor academic performance.

**Keywords:** *dysmenorrhea, physical exercise, young adult .*

## Introduction

Primary dysmenorrhea (PD) is defined as the menstrual cycle's painful discomfort. It is very common among adolescent females. It is usually accompanied by abdominal and pelvic pain, nausea, diarrhea, vomiting, headaches, dizziness, lower limb, and lower back pain [1]. Dysmenorrhea is classified into two discrete types. The

primary type is the menstrual pain with the absence of any underlying pathological cause. While the secondary one is usually associated with a well-defined pelvic disease [2]. The predominance of PD was measured in many countries of the world and was confirmed that it differs from one place to another according to the geographical location. Predominance of PD in Arab countries such as Iraq, Lebanon, Egypt and Saudi Arabia, the was 89.4%, 74.3%, 84.01%, and 60.9%, respectively [3-5].

In a study conducted by Ismaile, 2016 [6] concluded that the rate of dysmenorrhea prevalence was ranging from 50% to 90% in adult girls. Persistent PD pain has a direct impact on the everyday activities and performance of adult females. For instance, previous study by Abu Helwa., 2018 [7] stated that menstrual pain is the major

leading factor forcing female students out of school and college for the short-term, which negatively affects their academic activities. The academic performance of females who experienced dysmenorrhea varies during their menstrual cycle. [8]. Therefore this research was aimed to evaluate the impact of dysmenorrhea on the physical activity and academic performance of female students.

**Subject and Method:**

**Study Design:** This study was a descriptive, cross-sectional study using.

**Setting:** This study conducted in the faculty of Applied Medical Sciences, Jouf University. From the middle of April to the end of August 2018.

**Sample:** A purposive sample of seventy-nine female students from all academic years who reported moderate to severe pain, All students were recruited according to the following criteria:

**Inclusion Criteria:** Female students ages ranged between 18-22 years, All participants were single and belonged to the same homogeneous group.

**Exclusion Criteria:** Female students with diagnosed secondary dysmenorrhea, any other systemic diseases or endocrinal disorders or who undergo major abdominal surgery. Furthermore, students with pre-existing gynecological conditions, students who were taken oral pills for contraception due to any hormonal problem or other reasons.

**Tool of the Study:** A structured self-administrative questionnaire prepared based on prior researches in the literature, it was composed of three distinct parts. Part one explored the demographic data related to the personal characteristics of the study participants Moreover, part two asked about the effects and symptoms related to dysmenorrhea such as measuring pain intensity through a numerical rating pain scale starting from 0 to 10 (No pain to worst pain), McCaffery M., and Beeb A., (1999) [9] and supported by a smiley face illustration. In this part, premenstrual symptoms such as abdominal pain, leg cramps, nausea and vomiting, were also included in addition to absenteeism, low concentration, poor academic performance, and reduced physical activity included.

Part three was derived from the international physical activity questionnaire (IPAQ) (Craig et al.,

2003) [10] that was designed to investigate both type and level of physical activities practiced daily.

**Data Collection and Procedure:**

- Once the questionnaire was distributed to college students, they were told as, to how and when (during menstruation) the questionnaires to be filled. All questionnaire items were explained to each participant. The questionnaire was allowed to be taken at home to be accomplished and returned on the next day then they were handed the questionnaire to be filled which most probably after the first day of their menses by one week.
- All participants received consent form and information sheet before filling the questionnaire, also allowed to withdraw freely. Hence, no cases have been reported.

**Data Analysis:** For descriptive statistics, for qualitative variables, quantitative variables For analytical statistics, t-test, Pearson correlation and ANOVA test was used to study the relation between levels of pain rating scale and duration of physical activities.

**Results**

Table 1: the mean age 22.4 (1.1) years old while their menarche age was 12.2 (1.8) years old and they had normal BMI 23.4 (5.5) Kg/m2. Fifty-two (65.8%) subjects had regular menstruation with a mean duration of menstruation 5.7 (1.2) days.

**Table 1: Characteristics of The Study Sample (n=79)**

Variable		M ± SD
Age(years)		22.40 ± 1.14
Weight(kg)		60.51 ± 12.00
Height(cm.)		158.21 ± 4.71
BMI		23.48 ± 5.57
Age at menarche(years)		12.22 ± 1.87
Duration of menstruation(days)		5.74 ± 1.25
Variable	Values	n. (%)
Regularity	Yes	52 (65.8)
	No	27 (34.2)
Family history	Yes	63 (79.7)
	No	16 (19.3)
Marital status	Married	20 (25.3)
	Single	59 (74.7)

**Table 2:** demonstrated that 41.8% of the students complained from moderate pain and 49.4% complained from severe pain according to pain rating scale (4-6 & 7-10) during menstruation respectively while only 8.9% reported a mild level of pain (0-3) with mean value 6.3 ±2.2.

**Table 2: Pain Rating Scale of The Sample (n=79)**

Variable	Values	n (%)
Pain scale	0-3	7 (8.9)
	4-6	33 (41.8)
	7-10	39 (49.4)
	Mean ± SD 6.37 ± 2.21	

Note. n = number; % = percent; SD = Standard deviation.

According to the impact of dysmenorrhea on participated students, the most common types of associated symptoms were abdominal pain followed by fatigue and leg cramps representing (91.1%, 72.2% and 40.5%) respectively. Additionally, the academic performance was affected by menstruation in different ways, nearly half of students reported a high percentage of absenteeism 46.8% during menstruation and the majority of them complained from low concentration 78.5% and poor academic performance 77.2% while 87.3% demonstrated reduced in their physical activity. Furthermore, the results showed a significant impact of pain intensity on absenteeism, low concentration, poor academic performance, and reduced physical activity in which all accompanied by higher pain rating scale as

(p-value 0.0001, 0.0001, 0.011 and 0.023 respectively). Moreover regarding to physical activities that done by students during menstruation, present study showed that the mean value of duration of vigorous activities was 1.2±2.1 days and 25.2±5.9 minutes (mins), while for moderate activities was 3.2±2 days and 116.9±106.6 mins meanwhile the mean value of duration of mild activities in the form of walking was 3.9±1.8 hours, 78.8±58 mins, while for sitting were 6.1±3mins.

As regards to the relation between levels of pain rating scale and duration of physical activities study revealed that there was a significant relation between levels of the pain rating scale and days of mild activities in form of a walk. The days mean number for pain scale 0-3 was 1.9 days while the mean number of days for pain scale 4-6 was 4.3 days and for pain scale 7-10 was 4 days which means that a higher pain scale was associated with longer days of mild activities in the form of walking. Moreover, reported that there was a positive direct relation between duration of menstruation and time of walk.(p-value 0.01). Also, there is a positive direct relation between a number of symptoms and days and time of vigorous activities only (0.42 & 0.37 respectively).

Table 3. Showed a significant direct impact of duration of menstruation on time of walking. Duration of menstruation was a significant predictor of walking duration.

**Table 3: Regression Analysis For Impact Of Duration Of Menstruation On Duration Of Physical Activities**

Variable	Duration of menstruation			
	β	SE	t-value	p-value
Days of vigorous activities	.02	.19	.01	.991
Time of vigorous activities(min.)	2.34	5.01	.46	.640
Days of moderate activities	.11	.18	.54	.583
Time of moderate activities(min.)	16.40	9.40	1.73	.080
Days of mild activities in form of walk	.18	.17	1.05	.290
Time of mild activities in the form of walking (min.)	12.34	5.08	2.42	.010*
Time of sitting(hours)	0.03	0.27	0.01	0.991

\*p< .001 Note.SE= standard error; min= minutes.

### Discussion

A high prevalence of the PD (91.2%) among college-aged females in the North Province of KSA was

reported in the results of the current study. Other studies reported different PD prevalence in different regions of KSA such as 60.9% in Jeddah, 56% in Eastern Province, 61.7% in Hail, and 77.0% in Taif [1- 4].

Moreover, a study by Alaettin et al. [11] stated in their study that 72.7% of dysmenorrhea reported among female students; this estimate is congruent with the percentages observed in the prior study between 28% and 89.5% Unsal et al [12] and Wong [13].

From our opinion explanation for this variance in these figures can be due to the use of selected groups of women and the lack of a universally accepted criterion for identifying dysmenorrhea, which was likely as highly responsible for the difference as data collection method, the research meanings of dysmenorrhea and pain, and the sample populations themselves.

The current study demonstrated that academic performance was affected by menstruation in different ways, nearly half of students reported a high percentage of absenteeism 46.8% during menstruation and the majority of them complained from low concentration 78.5% and poor of academic performance 77.2% also 87.3% demonstrated reduced in their physical activity. This comes in agreement with study done by Dalia et al. [4] who stated that the intensity of the pain experienced by students coincided to their lack of concentration and recent also to their class.

Recently Orhan et al [14] concluded that the results of the present study present that primary dysmenorrhea affects adversely on academic performance and sharing in sports and social activities. In addition, we found that dysmenorrhea participants are 3.2 times more likely to lose concentration in the workplace compared to girls who never experienced loss of concentration in their menstrual cycle. Dysmenorrhea has been shown to have a noticeable effect on daily activities, thus affects on QoL, contributing to absenteeism, diminished physical activity, concentration, and social relations as stated by Joshi et al. [15] while he studied the Primary dysmenorrhea and its effect on quality of life in young girls

Also our study results demonstrated that nearly more than one third of studied students (41.8% & 49.4%) reported that they complained from moderate to severe pain according to pain rating scale (4-6 & 7-10) during menstruation as well as the study by Esimai [14] reported that the levels of menstrual pain are classified as 3-4 as mild 5-6 and 7-10 as severe. In this report, the highest score between nursing students had menstrual pain listed from 5 to 6 as a score of menstrual pain with an average of 27%. These variations in pain intensity may be related to cultural differences in pain perception

and pain tolerance variability.

Our study showed that a higher pain scale was associated with longer days of mild activities in the form of walking. This may be attributed to the sedation effect of activities like walking that forming an alternative movement of lower limbs in reducing pain-related dysmenorrhea.

In the line with this findings study by Joshi et al [15] documented that dysmenorrhea was significantly affect on day-to-day activities, as decreased physical activity, loss of concentration and poor social relationships. Various studies also have been shown that the more physically active female students are shown to have less signs of dysmenorrhea relative to their sedentary peers. Physical activity plays a crucial role in the homeostasis of the body, including hormonal regulation and menstrual cycle control [16].

In a study performed by Joshi [15] revealed that there was no clear correlation between physical activity and dysmenorrhea and the most common type of activities was walking in (76.1%) of the participated females. Another study also revealed the same results. Nonetheless, some epidemiological studies have identified a decrease in the prevalence of dysmenorrhea [17].

Current data indicate that most exercise treatments have fewer side effects and were favored for pain reduction over pharmacological or herbal therapies [18].

Lastly, concerning the physical activity, our study revealed that medical students who represented our study sample and have primary dysmenorrhea are commonly affected by adverse effects of dysmenorrhea due to their prolonged duration of practical requirements during their attending a variety of their studies inside their college.

## Conclusion

The findings of this study concluded that most of the female students have experienced dysmenorrhea that may be having number of physical activity limitations. So that further studies will be needed in multicenter and specialties with a larger and more varied sample population. Moreover, collaborative efforts may be needed from health care providers.

**Funding:** Self-funding.

**Conflicts of Interest:** There is no conflict of interest.

**Acknowledgment:** The researchers are grateful to thank the College authorities and all the participants for their cooperation and contribution toward this study. ## Abstract

**Context:** The direct causes of accidents often involved human error, organizational and management factors in all industries incidents. The old paradigm of domino theory which emphasizes that accidents were always rooted in management errors began to slowly changed. Human factors such as behavior, motivation, psychology began to be considered, as enabling factor to improve safety compliance; reduce the potential for accidents in the workplace.

This study was to determine the factors associated to safety compliance at feed poultry industry workers in Sidoarjo. This research is a quantitative study with a cross sectional approach. Method used to measure safety compliance was the questionnaire filling. The population in this study were 150 people and the samples obtained using a simple random sampling technique were 108 workers. The results showed that there was no relationship with age (0.563), experience (1.000), level of education (1.000), and training (1.000). There was a relationship between safety concern (0.008), and appreciation (0.012). To improve safety compliance, a leader who focused on fulfilling work safety aspects both at the supervisors and managers level as well as giving appreciation to workers who worked safely is needed.

**Keywords:** *Appreciation, Safety Concern, Safety Compliance*

## Introduction

Safety performance was one of the company's achievement in safety management systems and occupational health implementation. A good safety performance showed that a company was committed to prevent accidents, occupational diseases, and increase productivity. A terrible implementation of safety

management system and occupational health was one of the causes of accidents. According to working accident report launched by<sup>5</sup>, in every 15 seconds, there were 153 workers suffered occupational accidents and 317 million accidents annually. The accident resulted 6,300 workers died, increased the rate of absenteeism, loss of working hours, and expenses 4% of the *Gross Domestic Product* each year.

The causes of accidents happen due to human factor and occupational factor. It took a precaution to ensure a safe working environment, so that workers could work safely. The role of a leader was expected to be able to minimize the occurrence of accidents and to improve the safety performance of personal and company.

Feed Poultry Industry at Sidoarjo, ran business activities as producing animal feed. According to

e-mail: denny.ardyanto@fkm.unair.ac.id .

observations of potential hazards of organic dust, addictive materials, working climate, noise of workplace, the hazards of unnatural working attitude, Forklift vehicle passing road, there found a worker who worked with unsafe work like working at high place without a safety equipment, working without any protective equipment, and ignorance of the danger in the workplace. Therefore, it is a need to raise leadership skill which enable to change employee unsafety behavior become employee with awareness of safety environment. Through this awareness, employee is expected to improve their safety performance personally and globally in the company.

<sup>2</sup>explained that safety leadership was a social interaction with members or employees. In this interaction, a growing mutual trust and the exchange of attention of the leaders for occupational safety and health were existed. The interaction process would encourage leaders to pay attention towards occupational health and safety aspects. Safety leadership could be defined as the process of interaction between leaders and followers. Leaders could use their influence to achieve safety goals of an organization under the state organization and individual factors.<sup>15</sup>

The factors that determined the safety leadership role with *motivation safety*, *safety policy*, and *safety concerns* approach would be able to improve the implementation of management system of occupational safety and health performance.<sup>7</sup>

*Safety concerns* referred to the extent to which leaders emphasize the importance of safety equipment and their interest in behaving based on the safety rules, emphasizing the increased security, and having a coordination with other departments to solve the safety problem of employee.<sup>9</sup>

According to,<sup>4</sup> internally, motivation was everything that lied in a work and profession. If things in a work built a level of motivation that could produce optimal adherence, then one indicator is recognition. Recognition was a form of appreciation and attention. Differences might occur between the situations where the tangible rewards that have been granted by the recognition were compared with the absence of any recognition.

<sup>3</sup>saw the safety performance aspects of job performance and safety performance of the model proposed by the theory of job performance.<sup>1</sup>They identified two components of the safety performance,

namely 1) the safety compliance; and 2) the safety participation. Safety compliance refers to the core safety activities that must be performed by employees to maintain safety in the workplace, such as following the rules and safety procedures, and the use of personal protective equipment (PPE) correctly.<sup>3</sup> Fulfillment of the safety covers employee behavior that improves their health and personal safety. This could be considered as part of the employee's role.

Contextual performance could be understood as the efforts made by individuals who were indirectly related to the main job, but it played an important role in shaping the organization, social environment, and the psychology of employees.<sup>8</sup>The following was an explanation of the safety performance dimensions:

- a. **Safety Compliance:** Safety compliance referred to the performance task components used to describe the core safety activities implemented by the individual to maintain safety in the workplace. Behavioral safety compliance included compliance with existing safety regulations, the use of personal protective equipment (PPE), and the efforts of individuals behave safely at work.<sup>3</sup>

## Materials and Method

This research was conducted in January 2019 in Feed Poultry Industry at Sidoarjo. This research was observational research with the cross-sectional approach. The population of this study were 150 workers who later became 108 workers as sample using random sampling technique. The independent variables in this study were safety concern and recognition. Besides, the surveyed respondents' characteristics involved age, length of work, safety training, and education level. The dependent variable used was safety compliance.

This method was carried out using a questionnaire to determine the age, length of work, education, training, safety concern, recognition, and safety compliance. To fill the questionnaire, the researchers read out the questionnaire to the respondents, and filled the questionnaire for the respondents.

According to,<sup>6</sup> a questionnaire was a tool for data collection that contained written questions. The questionnaire in this study was based on a Likert scale developed by Renis Likert in 1932. In this study, the questionnaires consisted of:

- a. **Safety Compliance:** Safety compliance was

measured using a questionnaire measuring instrument that was made under safety compliance with safety regulations set by the company itself.<sup>3</sup>In this study, the questionnaire consisted of five items that used a Likert scale with some options as “Always”, “Often”, “Sometimes” and “Never”.

**b. Safety Concern:** Safety concern was measured using a questionnaire to measure instruments and to collect information related to the role of supervisor on the implementation of safety at work based on the perception of workers.<sup>7</sup> This questionnaire was developed by the researchers, and consisted of six items that used a Likert scale with some options as “Strongly Agree,” “Agree”, “Disagree” and “Strongly Disagree”.

**c. Recognition:** Recognition was measured using

a questionnaire to dig and overview the role of supervisors in his appreciation to workers who adhered the safety rules set by the company. In this study, the questionnaire consisted of five items that used a Likert scale with some options as “Always”, “often”, “Sometimes” and “Never”.

The data obtained were presented descriptively, and was expected to provide an overview of the characteristics of respondents, safety concerns and safety compliance. The analysis of the variables was used to determine the presence or absence of relationship between the variables. The bivariate analysis of this study’s variables used Chi-Square test with SPSS version 17.<sup>11</sup>

**Finding:** 1. The Analysis of Factors that Correlated with Safety Compliance

**Table 1: Distribution of Statistical Analysis Result**

Variable	Safety Compliance				P (Value)	PR
	Low		High			
	N	%	n	%		
<b>Age</b>						
< 38 years	30	55.5	26	48.2	0.563	1.161
≥ 38 years	24	44.5	28	51.8		
Total	54	100	54	100		
<b>Length of Work</b>						
< 6 years	8	14.8	9	16.7	1.000	0.931
≥ 6 years	46	85.2	45	83.3		
Total	54	100	54	100		
<b>SHE Training</b>						
Has not participated in K3 training	10	18.5	11	20.4	1.000	0.942
Has participated in K3 training	44	81.5	43	79.6		
Total	54	100	54	100		
<b>Education Level</b>						
Vocational High School	51	94.4	50	92.6	1.000	1.178
College/University	3	5.6	4	7.4		
Total	54	100	54	100		
<b>Safety Concern</b>						
Low	43	79.6	29	53.7	0.008	1.955
High	11	20.4	25	46.3		
Total	54	100	54	100		
<b>Recognition</b>						
Low	35	64.8	21	38.9	0.012	1.711
High	19	35.2	33	61.1		
Total	54	100	54	100		

Table 2 explained that the category of  $\geq 38$  years have safety compliance with the high category of 51.8%, while the category of  $<38$  years have safety compliance with the lower category of 55.5%. The result of  $X^2$  test showed that the relationship between age and safety compliance were not significant. It was indicated by p-value as 0.563. These results differed from a research<sup>12</sup> that showed the older workers were more likely vulnerable to injury, but they had good safety performance. The younger workers were not vulnerable to injury, but their safety performance was not optimal. The age and experience of the workers ran hand-in-hand in determining the condition and safety status. Therefore, companies must be careful in managing its human resources.

Based on the theory of Gibson,<sup>10</sup> one of the factors that affected person's performance was age, the more increased the person's age and the longer he worked; the more adept he was at his job. At that age, a person tended to start to master the work, selected the job he liked, and being critical of his work.

Based on the results of this study, 83.3% of workers who had tenure  $\geq 6$  years had high safety compliance. The sufficient working experience made the workers understand the hazards in the workplace, and was able to raise their awareness in the workplace. The result of  $X^2$  test against years of service and safety compliance, showed no significant with p-value magnitude of 1,000.

According to,<sup>13</sup> the classification of work period was divided into two, namely 1) the new working period ( $<6$  years); and 2) a longer working period ( $\geq 6$  years). The dominating working period was  $\geq 6$  years. It could be ascertained that there was no additional employees that supported the jobs, and they were classified as workers with long working lives. In another sense, the work period was the length of the workers worked in the workplace. The period of work could affect workers' performance (positive and negative).

The Safety and Health Environment (SHE) training delivery has not been able to improve safety compliance. The  $X^2$  test showed no significant results with a p-value of 1.000. The results of interview with K3L worker training program section has been presented, and it included basic health and safety, first aid (P3K), fire management, housekeeping (5R), and ISO.

Morrison,<sup>3</sup> have called safety knowledge as an influence on safety performance by increasing employee

participation in activities such as training. The training that was held by the company would provide knowledge and skills of the employees to be able to work effectively and efficiently and to motivate employees to behave safely in executing their job.

The results of interview on K3L worker, training programs that have been provided included basic safety, first aid (P3K), fire management, housekeeping (5R), and quality standards. Based on the interview, the trainings were less supportive to improve worker safety compliance. Safety compliance (in this study) emphasized on compliance with safety regulations in the workplace and on how to identify and control workplace hazards that has been set by the company.

Most of the educational levels of Livestock Feed Industry workers at Sidoarjo were vocational high school (SMK). The total respondents with vocational education level were 101 respondents as the following classifications: 1) 45 respondents have a low safety performance; and 2) 56 respondents have a high safety performance. Fisher's test results showed the relationship between the levels of education with safety performance was not significant as the magnitude of the significant value was 0.697 (more than 0.05).

Furthermore, the relationship between safety concerns and safety compliance was significant. It was proven by 0008  $X^2$  test with the prevalence ratio (PR) 1.735. It meant that the role of supervisors on working safety unit could improve worker safety compliance in the animal feed industry at Sidoarjo.

This results was consistent with a study,<sup>7</sup> which explained that leaders would set a priority occupational safety workplace behavior according to the rules of the company, so it would make employees change their mindset and behavior in their work gradually. Thus, the awareness on safety performance would become the culture of the company. As an illustration, person would have difficulty in working without any safety gear that has been set by the company.<sup>15</sup>

On the other hand, the significant relationship between the recognition and safety compliance was proven by the test result of  $X^2$  0.012 with prevalence ratio (PR) 1.831. It has the intention that the urge to give recognition and appreciation towards workers who applied the rules of working safety was factually able to increase fodder workers' safety compliance at Sidoarjo.

According to,<sup>14</sup> there were two things to improve motivation as: 1) the individual inputs; and 2) the context of the work. The context of work could influence working motivation. In this case, a worker would be motivated when their performance was appreciated verbally or non-verbally. With the appreciation given, the worker could improve safety compliance safety that has been set by the company.

### Conclusion

The factors that were associated with the increased safety compliance were safety concern and shape recognition/appreciation. Supervisor who gave appreciation and attention to safety at work would focus on the dangers that arose in the workplace. The supervisor also provided safety equipment and being responsive towards the issue of workers' safety. This action would make its members imitate the behavior of supervisors. Besides, the compliance of workers against safety compliance would increase.

# Public Perceptions About Immunization in Indonesia: National Online Survey

Celcius Butandy<sup>1</sup>, Muhammad Auzan Ridho<sup>1</sup>, Klara Sinta<sup>1</sup>, Rizma Adlia Syakurah<sup>2</sup>

<sup>1</sup>Faculty of Medicine, Universitas Sriwijaya, Palembang, Indonesia, <sup>2</sup>Public Health Department, Faculty of Medicine, Universitas Sriwijaya, Palembang, Indonesia

## Abstract

**Background:** Immunization is one of the ways to build an immunity to a child by injecting vaccines to prevent certain disease. Nationally, immunization coverage continued to increase but the coverage gap in some areas in Indonesia due to the negative perceptions of immunization that affect to the arising outbreaks of certain diseases.

**Objective:** The study is aimed to identify and to analyze the perceptions of Indonesian society (aged  $\geq 18$  years) about the importance of immunization and the sources of information about vaccines using Likert scale.

**Method:** The method is a descriptive-analytic, applying cross-sectional survey using online questionnaire instruments.

**Results:** The results of the study from 2050 respondents showed that 1184 respondents (57.8%) received information sources on vaccines from health workers, overall respondents believed (86.4%) of immunization and the factors which are related significantly to vaccination perception were age, gender, education, income, and job with p value  $< 0.05$ .

**Conclusion:** Vaccination is an important activity for early childhood. Factors that significantly affect public perception of vaccination in general are age, gender, education level, income, number of children, and occupation

**Keyword:** Perception, Immunization, Vaccination, Childhood, Indonesia.

## Introduction

More than 1.4 million children in the world die annually from diseases that can be prevented by immunization. Immunization is also proven to be the most cost-effective solution to public health problems caused by infectious diseases<sup>1</sup>. Some of the infectious diseases that belong to immunized-preventable diseases

(PD3I) include: Diphtheria, Tetanus, Hepatitis B, meningitis, pneumonia -post, pertussis, and polio<sup>2</sup>.

In Indonesia, the coverage of national immunization increases continuously. Evaluation of Immunization Programs for 2015-2016 reported to the Office of the Presidential Secretariat that the coverage of complete primary immunization in infants reached 86.9% in 2015 with the target of 91% that year and 91.6% in 2016 with the target of 91.5% coverage. According to WHO/UNICEF in 2015, almost one million Indonesian children are not immunized or completely immunized<sup>3</sup>.

Vaccine concerns are a global issue in many countries, especially in developing countries included

Indonesia<sup>4</sup>. Many misconceptions about immunization are rumored in the community such as that immunization causes fever and even danger children that can cause illness moreover death<sup>5</sup>.

Based on the facts, low immunization coverage causes the trend of its morbidity and mortality in infants and toddlers increases. To increase the coverage of this immunization, the knowledge about community perception related to immunization is necessary. Therefore, a study is needed to identify how the perception of Indonesian society aged  $\geq 18$  years about the importance of immunization and source of information about vaccine.

### Method

This study is a national online survey conducted in January-March 2018 with the method of cross-sectional among Indonesian population aged  $\geq 18$  years. This study used questionnaires which are developed from national and international standard surveys of New South Wales Child Health Survey, New South Wales Health Adult Health Survey, Queensland Health Survey, US National Immunization Healthcare and UK Wave Survey<sup>6-8</sup>.

The questionnaire that was distributed to all Indonesian people was represented by 2050 samples through online google form. Then the basic demographics of all respondents, sources of information about vaccination, and public perception of vaccination are identified.

All respondents who responded the questionnaire according to the criteria participated in the study without being excluded by any criteria. All respondents received an indirect explanation of the research at the time of filling out the questionnaire and given the voluntary consent directly. Assessment of respondent perceptions uses Likert Scale in the form of statement Strongly Agree, Agree, Neutral, Disagree, and Strongly Disagree. The data was processed using IBM SPSS 22 and analyzed descriptively and analytically by Pearson chi-square test.

### Results

This study is an online cross-sectional survey conducted from January 27 to March 18, 2018. Among 2050 respondents, 984 of them have children while the rest do not have yet. The respondents was 29 years old as average, with the oldest age of 69 years and the youngest

age of 17 years. Based on the survey, most respondents got information about the vaccine from health workers as much as 1184 respondents (57.8%), while 506 respondents (24.7%) from internet/social media and 287 respondents (14.0%) from their families.

The distribution of respondents shows the most frequent characteristic of them which was aged 25-34 years as many as 837 (40.8%) with the gender of women which reached 1291 respondents (63%). Most of respondents' latest educations was bachelor degree (S1) as much as 1331 respondents (64.9%). Islam was the most frequent religion as many as 1884 respondents (91.9%). The number of respondents who did not have children was estimated 984 respondents (48%), private worker as many as 732 (35.7%), and the income category <PMW (Provincial Minimum Wage) as many as 862 respondents (42%) as the highest class of each category.

The majority of respondents assumed that the purpose of vaccination is to protect their children (90.4%). Most respondents believe that vaccination is safe (86.4%) and be able to protect the community (77.9%). However, a small percentage reported perceiving that vaccine could not prevent the disease (20.7%), could cause autism (12.0%) and even religiously forbidden to do (7.2%).

Based on Pearson chi-square analysis in table 1, the general community concerns towards vaccination was correlated ( $p < 0.05$ ) with respondents' demographics of age, gender, education level, number of children, and occupation. In this study, religion view becomes a factor which does not have a significant relationship with the general community concerns towards vaccination with the various p-values ( $p > 0.05$ ). Religion has a significant relationship only to a concern statement about the forbidden law of vaccine in Islam ( $p = 0.000$ ). Based on Pearson chi-square analysis shown, demographic characteristics other than religion including age, gender, education level, income, number of children and occupation, have a correlation with the positive community perceptions about vaccination. This represents that religion has no significant relationship to some statements leading to a positive perception of vaccination. In general, the highest community groups which signifies strong positive support for vaccination were the class of age 45-54 years (26.9%), female gender (24.0%), education level of doctorate (52.9%), had income <PMW 24.0%, having no children (30.30%), and students (35.6%).

Represents the group of age, gender, education, income, number of children and occupations, have a negative public perception of vaccination. This suggests that religion has no significant relationship to some of the statements leading to a negative perception of vaccination. In general, most community agreeing on the counter-vaccination statements are group of 35-44 years old (23%), male gender (17.7%), junior high school as the education level (65.4%), have the equivalent to UMP income (23.9%), has 2 children or more (25%), and working as civil servants (20.4%). The following is a bivariate analysis of the demographic characteristics of each of the statements describing the perception of vaccination in Indonesia.

**Table 1: Community concerns towards vaccination.**

<b>n = 2050</b>	<b>Strongly Agree or Agree (%)</b>
I vaccinate my child to protect him/her	90,4
I believe that vaccinations are safe for children in general	86,4
I am confident in information provided by healthcare professional	83,6
I vaccinate my child to help protect the wide community	77,9
I am satisfied with amount of information provided by healthcare professional	74,9
Behavior of not vaccinating children causes harm	61,7
I am concerned that vaccines are not tested enough for safety	36,9
I am concerned about the increasing number of vaccines recommended for children	32,3
I am concerned about the distress to children of the injection itself	32,0
I am concerned that children get too many vaccines during the first two years of life	28,5
I am concerned that a child's immunity system could be weakened by vaccinations	22,9
I prefer children to get natural immunity from the diseases rather than immunity from the vaccines	21,3
I am concerned that vaccines are given to children to prevent diseases that they are not likely to get	21,0
I am concerned that vaccines are given to children to prevent diseases that are not serious	20,7
Vaccination is not needed because others have vaccinated their children and diseases have been controlled	15,8
I am concerned that vaccines can cause autism in healthy children	12,0
I hesitate to get my child vaccinated because it is forbidden in my religion	7,2

## Discussion

This study was conducted to determine about the public perceptions about vaccination for children. An individual's confidence about the vaccine will affect health behaviors to vaccinate as an attempt to prevent some diseases. In a study of six European countries, the role of physicians, pharmacists and nearby hospitals were regarded as the most reliable source of information about medicine and as the reminders about health hazards<sup>9</sup>. This is positively aligned with the results of this study in which information provided by health workers is trusted by most communities<sup>10</sup>. The health literacy on vaccination is not limited to discover some evidences that the vaccine is safe, people who have good health literacy also should be able to understand the dangers if vaccines are not given and do not hesitate for getting vaccinated without the odd rationalization related to the community that has been fully immunized and the disease had disappeared<sup>11</sup>.

In Indonesia, it is allowed the circulation of vaccines with thimerosal levels of 0.005-0.01% because it is still under its threshold according to WHO<sup>12,13</sup>. In this study, for the age group  $\geq 55$  years, none believes the vaccine can cause autism in healthy children. They often highlight the rare occasions in which a child suffers from the unexpected side effects of the vaccine<sup>14</sup>.

Although religion factor does not relate significantly with the positive and negative perceptions of vaccines in general, the Muslim group still affects specific views of the vaccine law<sup>15</sup>. The education from health workers are also necessary to improve vaccine perceptions related to the false long-term effects of the vaccine, one of them is that the child's immune system is assumed being weakened by vaccination<sup>16</sup>. Respondents concerns that the vaccine is given to children can not prevent the disease illustrates public concerns about vaccination-related attitudes<sup>17</sup>.

In this study, young-aged group is the most often strongly disagree about this concern. The strongest predictor of one's health is health literacy<sup>18</sup>. Where the value of health literacy in young people is higher than older people. This is because young people, especially in this case adolescents, they can more easily access health information when compared to older people<sup>19</sup>. In one study showing the total number of pediatric patients had admitted with a febrile seizure event, none of the children who had febrile seizures caused from vaccination<sup>20</sup>. Remember that perception is the cognitive

aspect of attitudes, then measuring perceptions can be used as the instruments of disclosure of attitude<sup>21,22</sup>. Economic factors affect a person's ability to obtain education and health services, thereby affecting the level of ability to access, understand, assess and apply health information<sup>23</sup>.

Most of the respondents were satisfied with the information provided by health personnel<sup>24</sup>. Studies show that lack of information and knowledge about disease causes they don't to vaccinate their children so that it is necessary to optimize health promotion media to increase parental participation in vaccinating their children<sup>25</sup>. According to Becker, the concept of healthy behavior is the development of the concept of behavior developed by Bloom<sup>26</sup>. In the five most important reasons for vaccinations promoted by the CDC, immunization can save a child's life in the first place<sup>27</sup>.

In this study, the group that agreed on the perception of vaccination as protection against their children increased by age. Ages affect a person shown by the higher level of knowledge and the stronger consistency of an individual, this will build the more mature in thinking and receiving information<sup>28</sup>.

In this study, the public's belief of that the prevention of disease for the wide community is important is strongly influenced by the latest education level compared to the age, gender, income, number of children, or occupational age. A research showed that promoting vaccination activities conducted by health workers with the good communication can help the community in revising negative issues about vaccination<sup>29</sup>. Therefore, promotional programs on vaccination should be held more frequent in purpose that the community knowledge about vaccination is improved. This hopefully change their perceptions towards vaccination and willingness to vaccinate<sup>30</sup>.

### Conclusion

Vaccination aims to prepare a person's immune response to be active to encounter the disease. Vaccination is an important activity for early childhood. Factors that significantly affect public perception of vaccination in general are age, gender, education level, income, number of children, and occupation.

# The Effect of Metal Nanoparticle on LH, FSH and Testosterone in Male Rats

Dalya K. Naser<sup>1</sup>, Kadhim A. Aadim<sup>2</sup>, Ahmed K. Abbas<sup>1</sup>, Salah M.M. AL-Chalabi<sup>3</sup>

<sup>1</sup>Assistant lecturer, and Professor Dr, University of Wasit, College of Science, Department of Physics, <sup>2</sup>Professor Dr, University of Baghdad, College of Science, Department of physics, <sup>3</sup>Assistant Professor Dr, University of Al-Nahrin the Research Center of Biotechnology

## Abstract

**Context:** In our study, metal nanoparticles Ag, Cu, ZnO, CdO, and Sn NPs were prepared by pulse laser ablation in liquid and characterized for investigation of reproductive toxicity in adult male rats. Thirty six healthy rats, two month age old and the rats weighing from 250-300 g, divided into six groups of six animals each (GAg, GCu, GZnO, GCdO and Sn) group which receive oral 0.3 ml dose of metal nanoparticles for 30 day. Blood samples were collected via cardiac puncture for serum collection. The formation Ag NPs, Cu NPs, ZnO NPs, CdO NPs, Sn NPs were shown through the x-ray diffraction pattern. AFM indicate to formation metal nanoparticles with diameter 61.36, 70.44, 66.82, 74.87 and 67.34 nm of Ag, Cu, ZnO, CdO, and Sn NPs respectively. The results showed significant ( $P < 0.05$ ) elevation of luteinizing hormone (LH) for each metal nanoparticles except AgNPs non-significant. Each metal nanoparticle significant ( $P < 0.05$  and  $** p \leq 0.01$ ) of follicle-stimulating hormone (FSH), whereas in testosterone only Cu and Sn NPs significant ( $P < 0.05$ ).

**Keywords:** Metal nanoparticles, pulse laser ablation, testosterone, LH, FSH.

## Introduction:

The application of nanomedicine is wide-ranging. One of nano-medicine's most significant problems is to comprehend its environmental efficacy and also to determine the possible toxicity of nano-scale materials. [1] The metallic nanoparticles (NPs) show distinct characteristics than they found at larger bulk size. These characteristics are accredited according to their smaller size and bigger area by volume ratio. [2] Nanoparticles of metal and metal oxide such as silver, zinc, gold, or titanium dioxide have been used as antimicrobial agents for over a century. The conduct of nanometals against pathogenic organisms at nanometric dimensions is currently being studied. [3]

The particle size is a significant nanomaterial characteristic that plays a main part in the characteristics of unique nanoparticles. The particle size may represent its physicochemical characteristics and enhance the ability to sorb and interact with biological tissues. [4,5] In reality, more research has been done on the size of nanoparticles than on other nano-scale properties. [6] Up to now, results have shown that the use of nanomaterials increases biological activity as their size decreases. Today, multi-industry uses this science [7].

Nanoparticles and other cellular reactions toxicity relies on the nature of the material and doses were used. This showed that liver parenchyma cells play a significant part in eliminating nanoparticles from the blood. [8] Theoretically, nanoparticles may have some adverse effects on human health and the environment and their obvious effects on male reproductive function have not yet been clarified.

There are currently many techniques for generating suspended nanoparticles in aqueous solutions. Chemical

techniques are the most frequently used because they are comparatively economical and the particle size can be easily controlled. Nevertheless, laser ablation in liquids has lately been shown to be a promising new method for obtaining metal colloids.<sup>[9-11]</sup>The aim of present study was to investigate the effects of metal nanoparticles toxicity on luteinizing hormone (LH), follicle-stimulating hormone (FSH) and testosterone.

### Experimental Part:

**1. Preparation of Metal Nanoparticles:** Metal nanoparticles (Ag, Cu, Sn, ZnO and CdO) were produced by laser ablation of (Ag, Cu, Zn and Cd) targets (diameter = 1.5 mm, thickness = 0.6 mm, 99.99% immersed in a vessel filled with 3 mL of deionized water (DI) with power 500mJ and .The target irradiated vertically by a Q-switched Nd-YAG laser (DIAMOND-288 pattern EPLS), with wavelength ( $\lambda = 1064$  nm) duration time at 6 Hz. The laser beam was focused by a focal length 10cm), subsequently, we placed the pure metal solution and the pulsed Nd-YAG laser re-irradiates, the concentrated laser beam spot diameter was 4 mm.

**2. Experimental Model:** Suspensions of metal nanoparticles were administered to rats with 0.3 ml doses via oral gavage. Thirty six healthy rats and two months of age and rats weighing 250-300 g are all permitted to acclimatize in animal house conditions for one week ( $25 \pm 3^\circ\text{C}$ , 50-55 percent relative humidity, and 12 hours light/dark cycle). The rats were divided into 6 groups in 6-rat capability cages made of plastic and sprinkled ground with sawdust, replaced every three days. The rats were fed a normal nutritionally balanced diet.

**3. Experimental Design:** Wistar male rats were divided into six groups of six individual animals.

1. Control - Animals got (deionized water) only
2. Ag- Animals got 0.3 ml/ day of oral Ag NPs for 30 day.
3. Cu- Animals got 0.3 ml/ day of oral Cu NPs for 30 day.
4. Sn- Animals got 0.3 ml/ day of oral Sn NPs for 30 day.

5. ZnO- Animals got 0.3 ml/ day of oral ZnO NPs for 30 day.

6. CdO- Animals got 0.3 ml/ day of oral CdO NPs for 30 day.

**4. Blood Collection and Serum Separation:** At the end of the experimental period, blood collection 3ml per group was collected by heart puncture, Blood was gathered from each rat in the eppendorf tube. At  $30^\circ\text{C}$  and 3000 rpm for 15 min, eppendorf pipes were centrifuged. The blood sample was divided into two layers, the upper serum layer and the lower rejected layer, and then Pasteur pipette pulled it. Till blood measurements, the serum layer from each rat was placed in freezing condition.

**5. Statistical Analysis:** Data is shown as the mean  $\pm$  SD. With Graphpad Prism 6.0 software, statistical analyzes were carried out using ANOVA one way. Means were used to compare untreated rats with distinct treated groups ( $*P \leq 0.05$ ,  $**P \leq 0.01$ ,  $***P \leq 0.001$ ,  $****P \leq 0.0001$ ).

## Result & Discussion

### 1- Structural and Topography of Nanoparticles:

Metal and oxide nanoparticle (Ag NPs, Cu NPs, ZnO NPs, CdO NPs) are formed by examining the x-ray, this is mentioned in my other paper.<sup>[12]</sup>

AFM imaging of metal nanoparticles was conducted on a smooth glass slide substrates by drop casting at heat  $60^\circ\text{C}$ . Film surface morphology was explored using AFM pictures, which at very elevated magnification generates topological surface pictures. AFM pictures as commonly recognized provide a helpful tool for unambiguously characterizing the order of magnitude and nanoparticle size distribution.

Figure (1) shows the morphology of dried colloids for Ag, Cu, Sn, ZnO and CdO NPs, 500 mJ / pulse and 500 pulses prepared by PLAL in DI. The images indicate that the MNPs have semi-sphere forms and we can see from graphic (2D) that the number and particle distribution of MNPs, note that the lowest size is Ag NPs and the bigger size is CdO NPs. Table (1) shows the average roughness value in DI at 500 laser energy and 500 pulses.

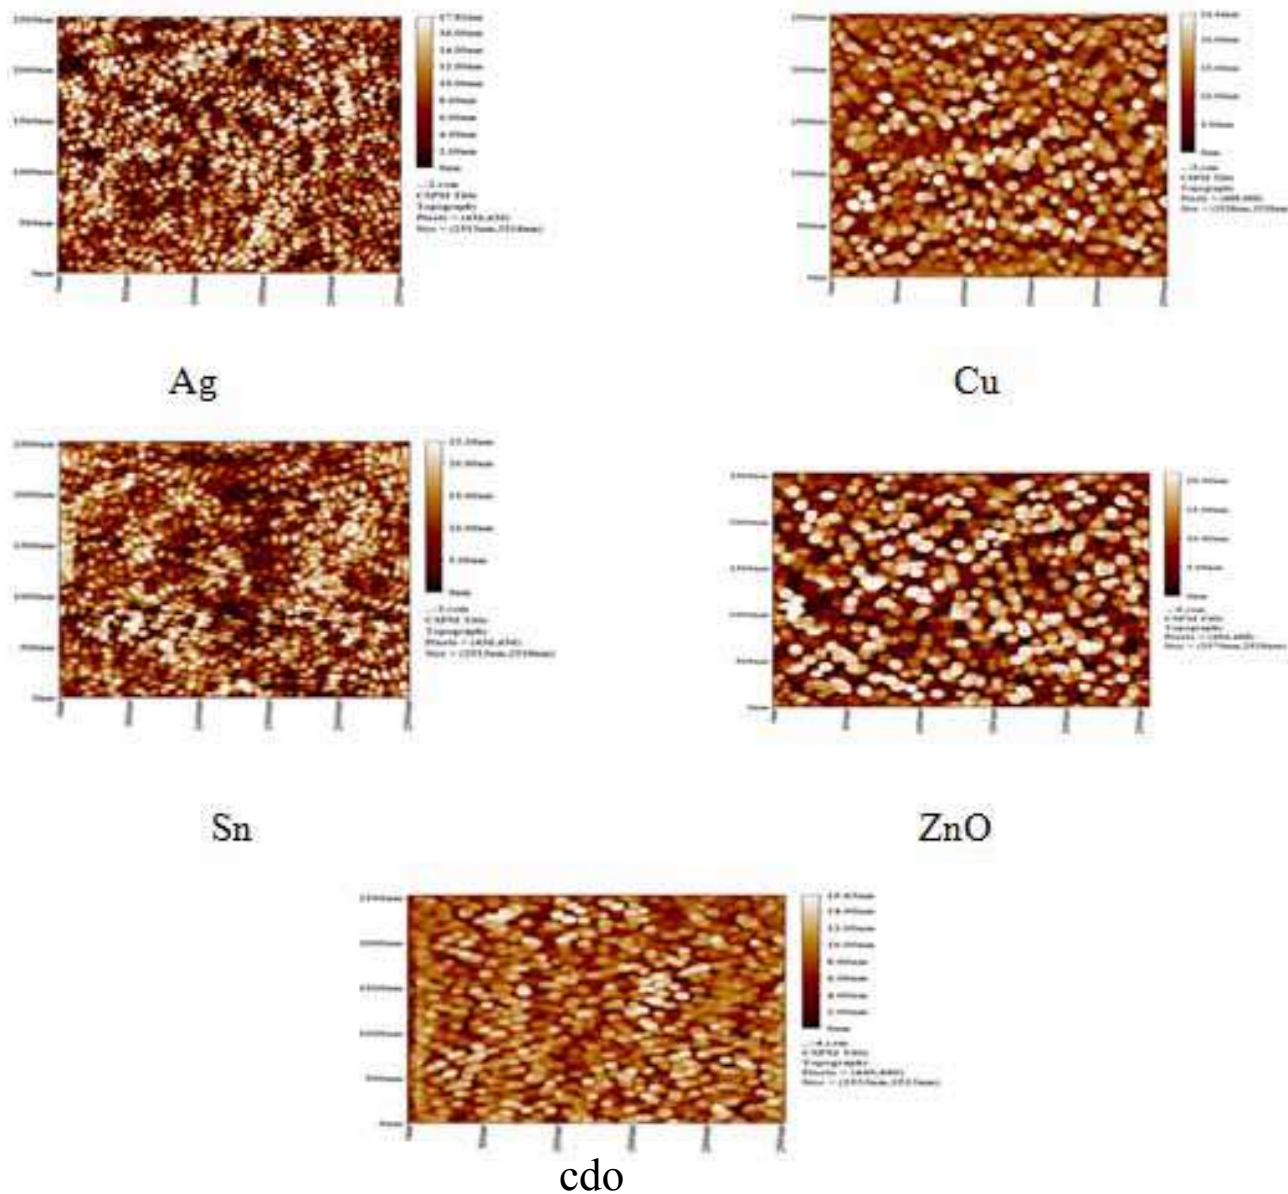

Figure 1: Typical 2DAFM image of Ag, Cu, Sn, ZnO and CdO nanoparticles prepared by PLAL by ablation of Sn target immersed in DI at 500 pulses constant, at 500mJ/pulse.

Table 1: shows the values of roughness average and average diameter for MNPs in DI.

MNPs	Roughness Average (nm)	Average Diameter (nm)
Ag	4.23	61.36
Cu	4.44	70.44
ZnO	5.09	66.82
CdO	2.24	74.87
Sn	5.2	67.34

2. Atomic Absorption Spectrometer Analysis (AAS): The concentration of Ag, Cu, ZnO, CdO

and Sn respectively, as in the table (2), prepared in PLAL has been determined by atomic absorption spectrometry.

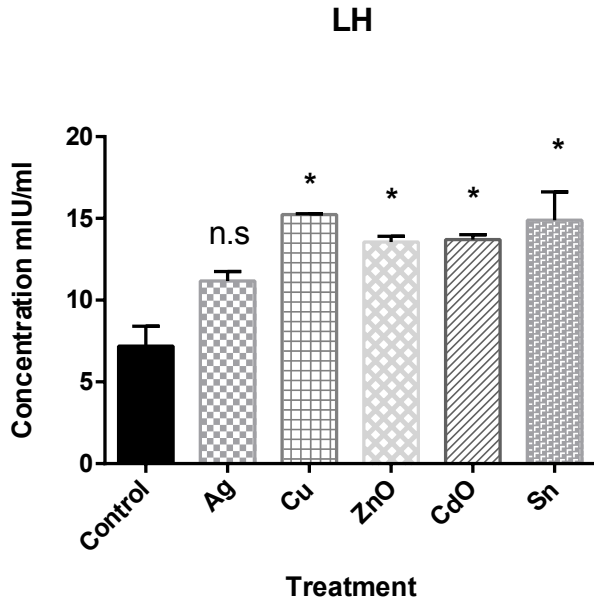

Table 2: Shows the concentration of MNPs with 500 mJ and 500 pulses.

Metal Nanoparticles	Concentration (ppm)
Ag	40.4081
Cu	10.3758
ZnO	24.0768
CdO	0.027
Sn	53.45

**3. Effect Metal Nanoparticles on Sexual Hormones:**

Figure (2) indicate that the level of serum leutinizing hormone(LH) in male rats dosed with MNPs showed a significant rise ( $p \leq 0.05$ ) over control. High LH shows an original testis failure and may happen as a result of chromosomal disorders. With the exception of group Ag NPs, the non-significant note ( $p > 0.05$ ) in the LH corresponds to<sup>[13]</sup>.

**Figure 2: The effect of MNPs on blood serum LH in male rats.**

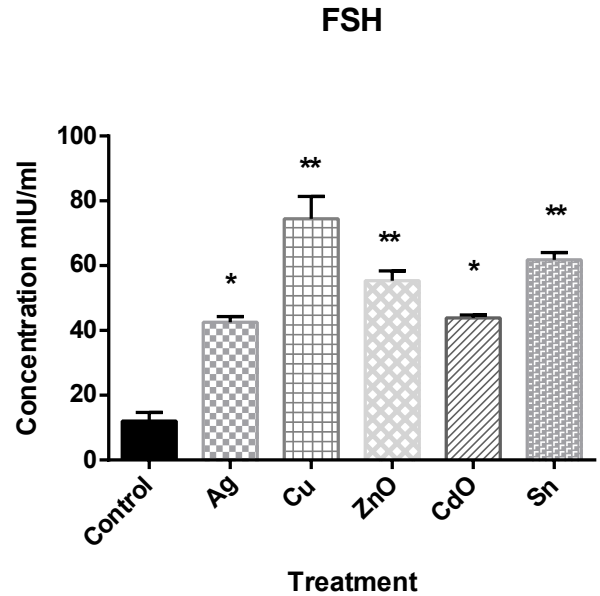

\* $p \leq 0.05$  and non-significant n.s

Figure (3) indicate that the concentration of the Serum follicular stimulating hormone (FSH) showed a significant rise (\* $p \leq 0.05$  and \*\* $p \leq 0.01$ ) in masculine rats dosed with MNPs compared to control, corresponding to.<sup>[14]</sup> This implies pituitary gland dysfunction, which can trigger reproduction of weaknesses.

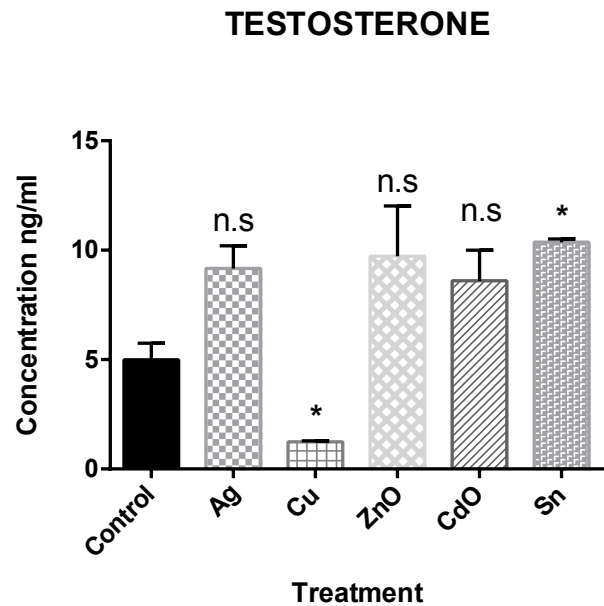

Figure (4) indicate that the level of serum testosterone hormone in male rats dosed with Ag, ZnO and CdO is non-significant ( $p > 0.05$ ) This outcome corresponds to.<sup>[14,15]</sup>for male rats dosed with Ag, ZnO and CdO as opposed to control at this dose. In Cu NPs this outcome corresponds to<sup>[16]</sup>, low testosterone concentration suggests a hypothalamic issue, adrenal disease, pituitary disease, or liver disease, indicating that copper nanoparticles can be regarded a reproductive toxicant. Sn NPs demonstrate a significant rise in the concentration of serum testosterone hormone ( $p \leq 0.05$ ) elevated testosterone concentrations may indicate enlarged testis or adrenal glands.

**Figure 3: The effect of MNPs on blood serum FSH in male rats.**

(\* $p \leq 0.05$  and \*\* $p \leq 0.01$ )

**Figure 4: The effect of MNPs on blood serum testosterone in male rats.**

\* $p \leq 0.05$  and non-significant n.s

**Conclusions**

In summary, oral administration of Ag, Cu, ZnO, CdO, and Sn NPs prepared by PLAL in 500 mJ and 500 pulses, Zn and Cd metals transformation to ZnO and CdO nanoparticles prepared by PLAL. Indicate some of

this metal (especially Cu and Sn NPs) have reproductive toxicity on male rats.

**Conflict of Interest:** There are no conflict of interest.

**Source of Funding:** Self Source funding.

**Ethical Clearance:** It is no behalf of authors certify the research conducted after being got official ethics clearance.

# Association of Exclusive Breast Feeding Practice and Physical Activities in Reducing of Postpartum Maternal Weight

Dede Wulanita Sari<sup>1</sup>, Luluk Mutmainnah<sup>1</sup>, Sri Sumarmi<sup>1</sup>

<sup>1</sup>Department of Nutrition, Faculty of Public Health, Airlangga University

## Abstract

**Context:** Weight gain experienced by pregnant women needs to be monitored to ensure the ideal body weight nutrition. It can be reduced by monitoring body weight during pregnancy and encouraging mothers to provide exclusive breast feeding and physical training after 6 weeks of postpartum care. The study was conducted in the Keputih Health Center catchment in Surabaya because coverage of high exclusive breast feeding practice. The study aimed to prove whether exclusive breast feeding is a dominant factor in naturally decreasing postpartum maternal weight. The were all mothers who had babies aged 6-7 months. That a sample of 25 mothers is obtained. Data analysis using descriptive analysis, chi-square analysis and using logistic regression analysis. The results showed that 84.6% of postpartum mothers had a weight loss of 0.5-12 kg and 11.5% had increased. There is a significant relationship between exclusive breast feeding with the decreasing of in maternal postpartum weight with a value of  $C = 0.432$  and OR 1.0, which means that mothers who give exclusive breast feeding have the opportunity to experience weight loss from mothers who give breast feeding un exclusively. And there is a weak relationship between variables of physical activity with a decrease in maternal postpartum weight with a value of  $C = 0.275$ . So the variable that has a significant relationship in postpartum maternal weight loss is exclusive breast feeding, so the importance of the postpartum mother to give exclusive breast feeding during the first 6 months is supported by high physical activity.

**Keyword:** *Weight loss, postpartum mothers, exclusive breastfeeding, physical activity, Keputih health center.*

## Introduction

Pregnancy is the reproductive stage where a pregnant woman will gain weight naturally and quickly<sup>1</sup>. According to IOM, the range of weight gain during pregnancy is 12.5-18 kg for women with a BMI <18.5 kg / m<sup>2</sup> (underweight) with an average weight gain of 0.51 kg / week, women with a BMI of 18, 5-24.9 kg / m<sup>2</sup> (normal) is 11.5-16 kg with an average weight gain of 0.42 kg / week, women with a BMI of 25-29.9 kg / m<sup>2</sup>(overweight) gain weight recommended is 7-11.5 kg

range of weight gain 5-9 kg with an average weight gain of 0.28 kg / week, for women with a BMI of  $\geq 30$  kg / m<sup>2</sup> (obese) with an average weight gain of 0, 22 kg / week. The average weight gain during pregnancy occurs in the second and third trimesters<sup>2</sup>.

Weight gain caused by the weight of the fetus reached 3 kg placenta 0.5 kg, amniotic fluid 1 kg. The normal uterine weight is 30 gr, which increases to 1 kg, besides accumulating fat such as the buttocks, breasts and others reaches 1.5 kg, the accumulation of 2 kg egg white and 1.5 kg water retention. Excessive body weight during pregnancy is a risk factor for a number of chronic diseases, such as type 2 diabetes, dyslipidemia, and cardiovascular disease and increases morbidity and mortality.

This can be a determining factor for obesity<sup>3</sup>Rio Grande do Sul, Brazil, aged 19 to 45 years, between

---

Airlangga University.

e-mail: wulanitasari78@gmail.com

weeks 38 and 42 of pregnancy. The patients were evaluated at one month, three months, and six months after delivery. Student's t-test or one-way analysis of variance (ANOVA. Research conducted by Zahabi revealed that normal weight during pregnancy can reduce the number of infant deaths, and babies born with an average body weight<sup>4</sup> each for 6 weeks and a washout period for 20 days. Subjects in the soy bread diet were asked to replace 120 grams of their daily usual bread intake with equal amount of soy bread. No significant effects of soy bread on serum lipid, systolic blood pressure and anthropometric indices were observed compared to the regular diet ( $p > 0.05$ ). The identification of this study included an increase in gestational weight, and body weight before delivery, which explained 34.5% experienced a decrease in postpartum weight by recognizing various determinants so as to reduce overweight and the emergence of diseases associated with excess weight. According to research conducted by Olson, et al, the results show that postpartum maternal weight retention is one of the causes of obesity<sup>5</sup>. This can be reduced by monitoring body weight during pregnancy and encouraging mothers to give exclusive breastfeeding and physical exercise after 6 weeks of postpartum visits.

In addition, according to a study conducted by Shobeiri et al, in Hamadan Health Centers, between physical exercise variables, pre-pregnancy weight, and exclusive breastfeeding, the most influential factor in postpartum weight loss was exclusive breastfeeding<sup>6</sup>. Decreasing postpartum maternal weight can reach 2.95 kg to 6.24 kg. Exclusive breastfeeding can reduce postpartum maternal weight because the energy released to produce breast milk is around 500-650 kcal / day. In a day of 850 cc ASI requires 750 kcal of energy while the intake of food consumed can contribute energy of 500 kcal / day so that 250 kcal is deficient. Weakness will be taken from fat reserves so that it can lose weight.

Another way to maintain energy balance is to increase energy expenditure. In theory, increasing energy expenditure in physical exercise can result in rapid weight loss. Lovelady, states that heavy exercise can increase total energy expenditure in nursing mothers<sup>7</sup>. This research was conducted in the work area of Keputih Health Center, Surabaya due to the high coverage of exclusive breastfeeding which reached 69.70% or a number of 169. This study aims to prove whether exclusive breastfeeding is a dominant factor in naturally decreasing maternal weight for 6 months postpartum or there are other factors.

## Material and Method

The type of research used is descriptive research. Descriptive research method was carried out with cross sectional approach. The study was conducted in the working area of Keputih Health Center in Sukolilo District, Surabaya City. The population in this study were all mothers who had babies aged 6-7 months and were recorded in the work area to the Keputih Health Center in Sukolilo District, Surabaya City. This study has obtained the approval and feasibility of the research from the Ethics Committee of the Faculty of Public Health, Airlangga University on April 19, 2017 No: 135-KEPK

The sampling technique in this study was total sampling. The samples taken in this study were 25 mothers. Dependent variable is a decrease in postpartum maternal weight and independent variables, namely exclusive breastfeeding, and physical activity. In addition, the data taken in this study is the general data of respondents.

The decrease in maternal weight 6 months postpartum was measured by calculating the difference in BB before giving birth minus 5 kg with maternal weight when infants aged 6/7 months<sup>8</sup>. Exclusive breastfeeding by interview with the help of exclusively categorized questionnaires, breastfeeding predominance, or not exclusive. Physical activity with interviews using the Gopal Physical Activity Questionnaire (GPAQ) Form and classified based on the MET developed by WHO consists of 16 simple questions about activities everyday which is then categorized into 3 categories: high activity, moderate activity, light activity. Identity data of respondents was conducted by interview with the help of a questionnaire. Data analysis consisted of Descriptive Analysis, Chi-Square Analysis and Logistic Regression Analysis

### Findings:

**Characteristics of Postpartum Mothers in the Work Area of Keputih Health Center:** Respondents who experienced weight loss of more than kg5kg were 10 (76.9%) of people aged 20-29 years. Respondents who gave the most exclusive breastfeeding, namely in the age range of 20-29 years, amounted to 6 respondents, while respondents with the age range of 30-40 years amounted to 5 respondents. Based on the chi-square test obtained (value  $p > 0.502 > \alpha$  value of 0.05). This means that there is no significant relationship between age and exclusive breastfeeding at Keputih Health Center.

This is in line with the research conducted by Qatrunnada, Soraya due to the influence of other factors, one of which is maternal health conditions such as nipple blisters or engorgement<sup>9</sup>. Even though the mother's age is more than 35 years and has good breastfeeding experience if the mother is breastfeeding, both exclusive breastfeeding and non-exclusive breastfeeding will continue to affect the behavior of the mother to continue giving exclusive breastfeeding or not. However this research is not in line with the research conducted by Puswati which states that there is a significant relationship between age and exclusive breastfeeding<sup>10</sup>. The findings of this study support the theory that age greatly determines maternal health related to the condition of pregnancy, childbirth, childbirth and how to care for and breastfeed her baby. Mothers less than 20 years old are still immature and not physically ready both during pregnancy and childbirth<sup>11</sup>. Different from mothers aged 20-30 years and over who have an increasingly mature mindset certainly has a variety of experiences both from themselves and from others<sup>9</sup>.

Educational level variables from 25 respondents as many as 12 high school graduating mothers, graduated from junior high school and D1 / D3 / S1 each from 4 mothers, and graduated from elementary school as many as 5 mothers. Of the 12 mothers who graduated from high school, 5 mothers gave exclusive breastfeeding, and 3 D1 / D3 / S1 graduates included exclusive breastfeeding.

Based on the chi-square test obtained (p value  $0.523 > \alpha$  value of 0.05). This means that there is no significant relationship between the level of education and exclusive breastfeeding in the work area of Keputih Health Center. The results of the study are in line with the Qatrunnada, Soraya study, this is due to the misunderstanding of breastfeeding and breastfeeding in mothers who give non-exclusive breastfeeding, even though they have gone through the level of education to college<sup>9</sup>. Informants who are less precise and accurate can be the trigger. However, this study is not in line with the research of Hikmawati which states that there is a significant relationship between the education status of mothers and exclusive breastfeeding<sup>12</sup>. Formal education plays an important role but the lack of true support and information can be an inhibiting factor for exclusive breastfeeding even though the mother has high formal education<sup>13</sup>.

Working status variables, respondents who gave the most exclusive breastfeeding were respondents

who did not work as many as 7 respondents, more than respondents who worked, only 5 respondents. Based on the chi-square test obtained (p value = 0.181 greater than the value of  $\alpha = 0.05$ ) means that there is no significant relationship between mothers who work with exclusive breastfeeding status in the work area of Keputih Health Center. This is because some mothers in the Keputih Health Center work area as housewives. The type of work a mother has is related to the daily activities of the mother. Housewives have more time to give exclusive breastfeeding to children.

**Table 1: Characteristics of Respondents**

Variable	N	%
<b>Age (years)</b>		
<20	3	12
20-29	13	52
30-39	8	32
≥40	1	4
<b>Education</b>

Graduated from junior high school	4	16
Finish high school / vocational school	12	48
D1 / D3 / S1 graduate	4	16
<b>Working status</b>		
Work	11	44
Don't work	14	56
<b>Changes in postpartum weight (kg)</b>		
<b>Increase</b>		
≥ 5	0	0
<5	3	12
<b>Downhill</b>		
≥ 5	10	40
<5	12	48
<b>Giving Breast Milk</b>		
Exclusive	12	48
Predominant Breastfeeding	3	12
Not Exclusive	10	40
<b>Physical Activity</b>		
High	4	16
Is being	13	52
Low	8	32

**Relationship between Giving Breast Milk and Postpartum Maternal Weight Loss:** The results of the analysis of the relationship of breastfeeding with a decrease in maternal postpartum weight in the work area of Keputih Health Center showed a contingency coefficient value of 0.432 and the results of the OR

logistic regression showed a value of 1.0 which meant that postpartum mothers who gave exclusive breastfeeding had a risk of 1.0 times weight loss. The results of this study are in line with the research of Mahera, rifki et al., in the work area of the Tenayan Raya Pekanbaru Health Center<sup>14</sup>. After giving birth the mother will experience weight loss during pregnancy around 5-6 kg due to the expenditure of the baby, placenta, amniotic fluid and blood<sup>14</sup>. But there are some mothers who still experience weight around 1.4-2 kg. Mothers will also experience changes or weight loss between 5-11 kg due to the birth process and exclusive breastfeeding<sup>15</sup>. Mothers who give exclusive breastfeeding experience rapid weight loss due to breastfeeding mothers need a large amount of energy, which is around 250 kcal / day which will

be taken from the mother’s calorie reserves, namely fat stores during pregnancy. If for 4 months the mother is breastfeeding exclusive breastfeeding, she will lose 250 kcal x 3 x 4 = 45,000 kcal which is equivalent to 5 kg of fat<sup>14</sup>.

However, this study is not in line with findings published by “The International Breastfeeding Journal” which said, during the first 4 weeks after giving birth mothers who during breastfeeding combine breast milk with formula milk had a greater weight loss compared to mothers who gave exclusive breastfeeding<sup>16</sup>. This study shows that not all postpartum mothers who give exclusive breastfeeding experience weight loss.

**Table 2: Relationship Between Breastfeeding and Postpartum Maternal Weight Loss**

Giving Breast Milk	Weight Loss				Weight Gain		Total		Contingency Coefficient (C)	OR
	< 5 kg		≥ 5 kg		< 5 kg					
	n	%	n	%	n	%	n	%		
a. Exclusive	3	25	7	58,3	2	16,7	12	100	0,432	1,0000
b. Predominant Breastfeeding	0	0	2	67	1	33	3	100		
c. Not exclusive breastfeeding	7	70	3	30	0	0	10	100		

**Relation of Physical Activity to Postpartum Maternal Weight Loss:** The results of the analysis of the relationship between physical activity and decreased maternal weight in the work area of the Keputih

Community Health Center indicate that the correlation coefficient is 0.275 means that there is a weak relationship between physical activity and a decrease in postpartum maternal weight in the Keputih Health Center work area.

**Table 3: Relation of Physical Activity to Postpartum Maternal Weight Loss**

Physical Activity	Weight Loss				Weight Gain		Total		Contingency Coefficient (C)
	< 5 kg		≥ 5 kg		< 5 kg				
	n	%	n	%	n	%	N	%	
a. Low	3	37,5	4	50	1	12,5	8	100	0,275
b. Is Being	4	30,7	7	53,8	2	15,5	13	100	
c. High	3	75	1	35	0	0	4	100	

The results of this study are in line with the research conducted by Kinnuen, et all., (2009) if postpartum mothers engage in moderate physical activity for 30 minutes over a period of 5 days and harder physical activity for 3 times a week postpartum. In research that carried out high physical activity only amounted to 4 people according to the research conducted by Ramadhani (2012), showing that the higher the physical

activity carried out, the higher the weight loss of postpartum mothers

**Conclusion**

The characteristics of the respondents mostly had an age range of 20-29 years totaling 13 (52%), graduating from high school / vocational school amounting to 12 (48%) and 14 (56%) mothers who did not work

or housewives (IRT). There was no relationship at all between the variables of mothers breastfeeding exclusive breastfeeding with maternal age ( $p$  value  $0.502 > \alpha$  value  $0.05$ ), maternal education level ( $p$  value  $0.523 > \alpha$  value  $0.05$ ) and maternal employment status ( $p$  value  $0.181 > \alpha$  value of  $0.05$ ) in the working area of Keputih Health Center. There is a sufficient relationship between exclusive breastfeeding and a decrease in postpartum maternal weight in the work area of Keputih Health Center. Postpartum mothers who give exclusive breastfeeding are at a risk of 1.0 times losing weight from mothers who give breastfeeding non-exclusively. The variable physical activity did not have a relationship with a decrease in postpartum maternal weight in the work area of Keputih Health Center.

**Funding:** Self-funding

**Conflict of Interest:** There are not any of conflicts amongst the authors

# Short-term Survival of Stroke Patients According to Hemorrhagic and Ischemic Stroke Type in National Brain Center Hospital Jakarta

Desvina Della<sup>1</sup>, Helda<sup>2</sup>

<sup>1</sup>Master of Epidemiology, Faculty of Public Health, Universitas Indonesia, <sup>2</sup>Department of Epidemiology, Faculty of Public Health, Universitas Indonesia

## Abstract

**Background & Objectives:** Stroke is the second leading cause of death in the world. The aim of this study was to identify a short-term (30 days) survival of stroke patients according to hemorrhagic (HS) and ischemic (IS) stroke type in National Brain Center Hospital Jakarta.

**Method:** A cohort retrospective study. Acute first-ever stroke inpatients were included in this study. The sample consists of 134 HS and 134 IS and recorded in medical record from January 1 to November 30, 2018. All study patients were followed-up from diagnosis time to event (death). The Kaplan-Meier method was used to estimate the survival probability and Cox Regression to investigate the effect of variables.

**Results:** Survival at 30 days was higher for IS (91,8%) than HS (78,3%) of the first-ever stroke ( $p < 0,05$ ). Mean survival time of IS (27 days) was longer than HS (23 days). The risk of death for HS was (HR = 2,78; 95% CI 1,385 – 5,591) times greater than the risk of death for IS in National Brain Center Hospital Jakarta ( $p < 0,05$ ).

**Conclusions:** Survival probability IS was higher than HS within 30 days of the first-ever stroke ( $p < 0,05$ ).

**Keywords:** *Survival, Stroke, Hemorrhagic, Ischemic.*

## Introduction

Stroke is the second leading cause of death in the world.<sup>(1)</sup> According to American Heart Association (AHA) estimates, 795.000 strokes occur in The United State and 610.000 of these are first attacks. Stroke kill nearly 130,000 people a year and on average, every 4 minutes someone dies of a stroke,<sup>(2)</sup> while in United Kingdom there are more than 100,000 strokes each year, that is around one stroke every five minutes.<sup>(3)</sup> In Asia, the highest mortality rates are observed in

Mongolia 222,6/100.000 person-years and Indonesia 193,3/100.000 person-years by the age-and sex-standardized.<sup>(4)</sup>

World Health Organization definition (WHO) of stroke: rapidly developing signs of focal (or global) disturbance of cerebral function with symptoms lasting over 24 h or leading to death with no apparent cause other than vascular.<sup>(5)</sup> Stroke can be divided into two main types; hemorrhagic (HS) and ischemic (IS). Hemorrhagic stroke occurs when a weakened blood vessel ruptures.<sup>(6)</sup> It's caused by a weakened vessel that ruptures and bleeds into the surrounding brain. The blood accumulates and compresses the surrounding brain tissue.<sup>(7)</sup> Ischemic stroke occurs when an artery to the brain is blocked. This is most often caused by atherosclerosis, or gradual cholesterol deposition. If the arteries become too narrow, blood cells may collect and form blood clots. These blood clots can block the artery

e-mail: heldanazar1@gmail.com

where they are formed (thrombosis), or can dislodge and become trapped in arteries closer to the brain (embolism).<sup>(8,9)</sup>

Globally, stroke incidence according to stroke type is 15% - 30% for HS and 70% - 85% for IS. In Asia, 30% for HS and 70% for IS. HS cases are lower than IS, but HS cause death more often than IS.<sup>(9)</sup> In earlier study, found that stroke type was a dominant factor for stroke survival in 1 year. Survival probability for IS (63,7%) was higher than HS (22,9%). The risk of HS was 3 times greater than the risk of IS.<sup>(10)</sup>

National Brain Center Hospital Jakarta is a vertical hospital owned by the Ministry of Health which is one of the centers for handling stroke. Stroke incidence has increased in the last 3 years in this hospital. This study was to identify a short-term (30 days) survival of stroke patients according to hemorrhagic (HS) and ischemic (IS) stroke type in National Brain Center Hospital Jakarta. Estimate stroke survival according to stroke type is essential to understanding stroke treatment in order to achieve optimal health outcome. The intervention in

secondary prevention may improve patient’s condition to decrease mortality rate of stroke.

**Method**

This is a cohort retrospective study. All study patients were followed-up for 30 days from diagnosis time to event (death). The sample consists of 134 HS and 134 IS. Simple random sampling technique was used to select the sample. The inclusion criteria; inpatients with acute first-ever stroke that recorded in medical record from January 1 to November 30,2018. The exclusion criteria; medical records were not available or not stored in the medical records department during the study. The Kaplan-Meier method was used to estimate the survival probability and Cox Regression to investigate the effect of variables.

**Results**

There were 268 patients included in this study. Of them, 134 were HS and 134 were IS. Table 1 shows characteristic of stroke patients;status, age, and gender.

**Table 1: Characteristics of Stroke Patients**

Variables	Total	HS	IS
No. of patients (%)	268 (100,0)	134 (50,0)	134 (50,0)
<b>Stroke patients status</b>			
Censor	229 (85,4)	106 (39,5)	123 (45,9)
Event (death)	39 (14,6)	28 (10,5)	11 (4,1)
<b>Age (years)</b>			
< 60	143 (53,4)	85 (31,7)	58 (21,7)
≥ 60	125 (46,6)	49 (18,3)	76 (28,3)
<b>Gender</b>			
Female	104 (38,8)	47 (17,5)	57 (21,3)
Male	164 (61,2)	87 (32,5)	77 (28,7)

Among 268 patients, 14,6% were died for 30 days. Event (death) of HS (10,5%) was higher than IS (4,1%). The mean age of patients was 37 years old for HS and 57 years old for IS. The age of HS patients were higher

at < 60 years old, while IS patients were higher at ≥ 60 years old. Male (61,2%) was higher than female (38,8%) in this study.

**Figure 1: Cumulative Survival Probability**

The Kaplan-Meier method was used to estimate the survival probability within 30 days of the first-ever stroke. (Figure 1.) shows cumulative survival probability curve of stroke patients. Among 268 patients, 98,5% survived for 1 day, 90,3% survived for 1 week, and 85,1% survived for 1 month.

**Figure 2: Survival Probability according to HS and IS**

Survival at 30 days was higher for IS than HS of the first-ever stroke ( $p < 0,05$ ). (Figure 2.) shows survival probability curve according to HS and IS. Among 134 HS patients, 97,0% survived for 1 day, 86,6% survived for 1 week, and 78,3% survived for 1 month. While, among 134 IS patients, 100,0% survived for 1 day, 94,0% survived for 1 week, and 91,8% survived for 1 month.

Overall mean survival time of patients stroke were 25 days. Mean survival time of IS (27 days) was longer than HS (23 days). The risk of death for HS was (HR = 2,78; 95% CI 1,385 – 5,591) times greater than the risk of death for IS in National Brain Center Hospital Jakarta ( $p < 0,05$ ).

## Discussion

We identified 268 inpatients with acute first-ever stroke from January 1 to November 30, 2018. Of those, 134 were HS and 134 were IS. The mean age of patients was 37 years old for HS and 57 years old for IS. The age of HS patients were higher at  $< 60$  years old, while IS patients were higher at  $\geq 60$  years old. This suggests that HS may occur more often among younger people as reported in other studies.<sup>(11,16,17)</sup> Male (61,2%) was higher than female (38,8%) in this study.

In our study, 39 patients (14,6%) died in 30 days. The Kaplan-Meier estimates the cumulative survival probability within 30 days were 98,5% survived for 1 day, 90,3% survived for 1 week, and 85,1% survived for 1 month. Event (death) of HS (10,5%) was higher than IS (4,1%). In previous studies, Butsing et al. found that 26% of stroke patients died within 30 days<sup>(11)</sup> and also study in Australia, found about 24% patients died in 28 days after stroke.<sup>(10,14)</sup>

The number of HS cases are lower than IS, but HS cause death more often than IS.<sup>(9)</sup> In earlier study, found that stroke type was a dominant factor for stroke survival.<sup>(10)</sup> Our findings on Kaplan Meier analysis showed, the short-term survival probability was higher among IS than HS patients. All IS patients survived for 1 day, while HS patients had decreased survival (97,0%). For 1 month, 91,8% survived for IS, while 78,3% for HS. Consistent with other studies, Butsing et al. revealed the short-term survival probability for HS was shorter than for IS within 30 days of the first stroke.<sup>(11)</sup> Study by Lee et al. found that survival among patients admitted to hospital for HS was lower than among patients hospitalised for IS and TIA in the first 28 days after the index stroke.<sup>(12)</sup>

The Perth Community Stroke Study similarly observed higher 30-day case fatalities for HS than for IS.<sup>(12,13)</sup> Study in Japan, showed the 30-day case fatality rate was substantially greater in patients with cerebral hemorrhage (63.3%) or subarachnoid hemorrhage (58.6%) than in patients with cerebral infarction (9.0%).<sup>(15)</sup>

Those who suffer IS have a much better chance for survival than those who experience HS, as HS not only damages brain cells but also may lead to increased pressure on the brain or spasms in the blood vessels.<sup>(18,19)</sup> We found that overall survival time of patients stroke were 25 days. Mean survival time of IS (27 days) was longer than HS (23 days). The risk of death for HS was (HR = 2,78; 95% CI 1,385 – 5,591) times greater than the risk of death for IS in National Brain Center Hospital Jakarta ( $p < 0,05$ ). Similar to another study by Mulyani et al. the risk HS was 3 times greater than the risk of IS.<sup>(10)</sup>

There are limitations to our study. First, we have not identified risk factors for death. Second, we couldn't do long-term follow-up because the patient's identity is confidential, so we couldn't call patients by phone to find out their status after discharged from the hospital.

## Conclusions

Survival at 30 days was higher for IS than HS of the first-ever stroke ( $p < 0,05$ ). Mean survival time of IS (27 days) was longer than HS (23 days). The risk of death for HS is (HR = 2,78; 95% CI 1,385 – 5,591) times greater than the risk of death for IS in National Brain Center Hospital Jakarta ( $p < 0,05$ ).

**Ethical Considerations:** This study was approved by the National Brain Center Hospital Jakarta Ethics Committee (No: UM.01.05/12/004/2019) and Faculty of Public Health Universitas Indonesia Ethics Committee (No.443/UN2.F.10/PPM.00.02/2019).

# Factors Affecting Nurse Performance in Medical Ward

Desy Puspa Sari<sup>1</sup>, Bayu Saputera<sup>2</sup>, Muhammad Saleh<sup>2</sup>,  
Qomariyatus Sholihah<sup>3</sup>, Ibrahim Daud<sup>4</sup>

<sup>1</sup>Resbaharti Clinic, Tanah Bumbu, South Borneo, Indonesia; <sup>2</sup>Dr. H. Andi Abdurrahman Noor General Hospital, Tanah Bumbu, South Borneo, Indonesia; <sup>3</sup> Faculty of Engineering, Brawijaya University, Malang City, East Java, Indonesia; <sup>4</sup>Graduate Programs, Indonesian School of Economics, Banjarmasin, South Borneo, Indonesia.

## Abstract

**Context:** Nurses are the world's fastest-growing professions. The number of registered nurses increases every year. Nurse performance becomes the determinant of a hospital's accountability. Factors affecting performance were divided based on their perspectives: individual differences, situational, and regulation. This research was analytic descriptive study with cross-sectional approach. The study was conducted in dr. H. Andi Abdurrahman Noor General Hospital, Indonesia from September to October 2017. The sample consisted of 24 nurses in the medical ward. An open-ended structured questionnaire was used as an instrument of data collection. Design the questionnaire based on observations of the literature that has been presented. Data were analyzed using a cumulative percentage system and presented in tables. Some respondents were dissatisfied with his personal appearance. This was influenced by eleven factors, with the most important factors were overwork, lack of facilities, and inability to control stress. From a situational perspective, some factors affecting nurse performance were workload (83.3%), facilities (66.7%), cooperation (29.1%), and work environment (12.5%). Supervision (45.8), salaries (37.5%), service fee (45.8%), and rewards (12.5%) were grouped according to the regulation perspective. While the ability (54.1%), skills (12.5%), and motivation (8.3%) had an individual impact.

**Keywords:** Factor, hospital management, nurse, performance.

## Introduction

Nurses are the world's fastest-growing professions. The number of registered nurses increases every year. In 2003, there were 2,449,000s and became 2,888,000s in 2014 (18 percent increase).<sup>1</sup> In Indonesia, nurses are the largest health professions (compared to general practitioners, specialists, midwives, pharmacists and dentists) with 296,876 members (49%) in 2016. The national nurses ratio is 113.40 per 100,000 population

in the same year, which is far from the target of 180 per 100,000 population in 2009.<sup>2</sup> In these circumstances, the nurses - who is the first line in health care - is required to always do the best. So the assumption that the nurses are an important factor in determining the accountability of the hospital is not wrong.

Nurse performance in patient care is influenced by various factors. Study by Adatara et al (2016) found that optimal nursing performance was influenced by ability, mutualism, motivation, professionalism, clear assignment and target, availability of equipment, and functional feedback systems.<sup>3</sup> While based on Yaghoubi et al study (2013) was found that the nurse performance correlated significantly with work environment, legality of work, continuous work evaluation, incentives, assistance from management to achieve work goals, clarity of main tasks and functions, and individual capability.<sup>4</sup>

---

### Correspondence:

Dr. H. Andi Abdurrahman Noor General Hospital, H. M. Amin Street, Sepunggur, Tanah Bumbu District, South Borneo Province, Indonesia.

Te: +62 821 5698 8281

e-mail: blacklecture@yahoo.com

Previous study was conducted by Kamati et al (2014) at a national referral hospital in Namibia. The study was conducted on 48 nurses from a 284 total population, using a questionnaire. The results showed that there was negative correlation between the nurses performance with short working mad, bad feedback, low remuneration, poor work environment, and poor training. Limitations in this study were the absence of control that elements and the results were done in one hospital due to lack of resources.<sup>5</sup>

The large number of factors that affecting nurse performance as employees makes Sonnentag and Frese divide them into three parts according to their perspectives: individual differences, situational, and regulation.<sup>6</sup>

**Individual Differences Perspective:** Many studies illustrate how individual differences perspective affects to their performance. To get a well-performing of nurses, the hospital must select individuals based on their abilities, work experience, and motivation and personality.<sup>3,5,6</sup>

**Situational Perspective:** This perspective refers to environmental factors that could support the improvement of nurse performance. The most basic question in this perspective: *“In what situations could the individual perform the best performance?”* Some factors in this perspective are job characteristics, capabilities/circumstances that allow for stress control, and forced situations.<sup>4,5,6</sup>

**Regulation Perspective:** This perspective focuses on performance processes and concepts as a result of work. The most important question in this perspective: *“How is performance generated?”* And *“What happens when a person works?”* This regulation could be either financial or non-financial (feedback, social reward) interventions.<sup>3,4,5,6</sup>

Despite the numerous studies conducted, in its development, nurse performance remains an important point in hospital marketing. Therefore, strengthening the theory about the factors that affecting nurse performance should continue to be done, as an effort to improve service to patients and build a good hospital image.

**Material and Method**

This research was analytical descriptive study with cross-sectional approach. The place this study was dr.

H. Andi Abdurrahman Noor General Hospital, located in Tanah Bumbu District, South Borneo Province, Indonesia. Data is collected between September and October 2017. The population of this study was all nurses who numbered 165 people. Form total population, there were 24 samples of nurses who served in medical ward.

An open-ended structured questionnaire was used as an instrument of data collection. Design the questionnaire based on observations of the literature that has been presented. Open-ended questions allow respondents to be spontaneous in conveying and focusing opinions in their own words. Respondents were asked questions about the factors that according to their perspectives had the highest effect on nurse performance in the first order, to the last sequence they thought had the least influence.

Data were analyzed using a cumulative percentage system. Demographic characteristics, performance satisfaction levels, and factors that impact the nurses performance were analyzed with descriptive statistics and presented in tables.

**Results**

Respondents consisted of 54.2% of female, with 16 respondents aged between 21-30 years, one respondent aged between 41-50 years, and the rest in middle age. More than half of the respondents had a diploma in nursing. More than 70% of respondents are non-permanent employees/contracts with varying work experiences, dominantly respondents worked less than four years as a nurse in this hospital.

Based on personal assessment of respondents, 66.7% were satisfied with his personal appearance. Most respondents felt that they had made the best effort to serve patients even though the equipment available at the hospital was not yet complete. While the rest felt not able to perform maximum service to patients (see Table 1).

**Table 1: Level of satisfaction with personal performance**

Level of Satisfaction	Frequency	Percent
Not Satisfied	8	33.3
Satisfied	16	66.7

Factors affecting nurse performance were ranked from the most-mentioned to the least. The most frequently mentioned factor in this case was the excessive workload (83.3% of the total respondents). This was influenced by

the ratio between the nurses and the bed in medical ward (only about 1:12) and the documentation on the medical record which time-consuming for the nurses. Lack of facilities became the second largest factor (66.7%). The facilities include medical and non-medical equipment, such as diagnostic equipment, emergency equipment and personal protective equipment. The inability to control stress in the workplace is the third largest factor (54.2%). This stress was mainly due to pressure from supervisors and leaders (see **Table 2**).

**Table 2: Factors that result in poor of nurse performance**

Factors	Frequency	Rank
Excessive workload	20	1 <sup>st</sup>
Lack of facilities	16	2 <sup>nd</sup>
Inability to control stress	13	3 <sup>rd</sup>
Lack of supervision	11	4 <sup>th</sup>
Non-compliance of service fee with workload	11	5 <sup>th</sup>
Salary incompatibility with minimum wage	9	6 <sup>th</sup>
Poor cooperation between different profession of employees	7	7 <sup>th</sup>
Lack of non-financial rewards	3	8 <sup>th</sup>
Inconvenience work environment	3	9 <sup>th</sup>
Unavailability of continuing education	3	10 <sup>th</sup>
Status as a non-permanent employee/ contract	2	11 <sup>th</sup>

### Discussion

One that affects the workload of the nurses was the ratio between the patient and the nurses. According to the California Nurse Association (CNA), the number of patients supervised by the nurses varies according to the work unit, but does not exceed six patients.<sup>7</sup> While, at the hospital where the research was conducted, the fact was still far from the ideal situation, where the average ratio was only 1:12. Document overload also results in excessive workload of nurses. When viewed from the Hospital Accreditation Standard of Indonesia 2012, there were still many overlapping forms on the medical record so that the time to complete the document becomes longer.<sup>8</sup> This will impact on shorter nursing services and lead to limited nurse-patient interactions. In 2015, Muhammadi et al studied the factors that affecting nurse performance who work in intensive care unit (ICU). There were many things that cause poor of the nurse performance, including difficulty sitting down to work on documentation, unfriendly workplaces, poor

workplace settings and inventory space, poor equipment conditions, drug delays, unpredictable situations, and poor cooperation.<sup>9</sup>

Inadequate facilities were the second most mentioned factor. This was in accordance with study conducted by Adatara et al (2016) who found that the availability of equipment affects the poor performance of 28% of respondents.<sup>4</sup> While stress and ability to control it is the third largest factor affecting the nurses performance. Simanjorang et al (2015) found a significant relationship between job stress and the nurses performance.<sup>10</sup> It was also found in this study, in which the ability to control stress has been mentioned by more than half the number of respondents.

Other studies had also shown that organizational factors, interpersonal cooperation, nurses cooperation with other professions, and relationships with leaders or supervision had an impact on the nurses performance. Good relationships and regular supervisory supervision with various parties in the workplace will improve nurses ability and motivation to perform their duties better.<sup>11,12,13</sup> Despite other influencing factors such as motivation, salary in accordance with regional minimum wages, and non-financial rewards. This was in accordance with James et al (2015) study, in which financial and non-financial rewards had a positive impact on the performance of health workers. Non-financial rewards can be promoted or candidates for specialized training.<sup>14</sup>

The work environment was also an important factor, although it was ranked ninth from eleven factors that affecting nurse performance.<sup>15</sup> While, the least-mentioned factor was the employment status. There was no evidence-base showing the relationship between employment status and nurse performance, but it was assumed that the status of government employees has higher income than contract workers, with the same workload. This clearly impacts financially for the nurses.

### Conclusion

From this research, there were eleven factors that influence nurse performance. If grouped according to Sonnentag and Frese theories, then the situational perspective had a great impact on nurse performance, followed by individual differences and regulation perspectives. Factors of the situational perspective in this study were the workload (83.3%), facilities (66.7%), cooperation (29.1%), and work environment (12.5%).

Supervision (45.8), salaries (37.5%), service fee (45.8%), and rewards (12.5%) were grouped according to the regulation perspective. While the ability (54.1%), skills (12.5%), and motivation (8.3%) have an individual impact. It was important to know by the hospital management, because if they improve the nurses performance means simultaneously they also improve the image of the hospital in a community perspective.

# Maternal Death Model Decreases the Expression of BDNF in *Rattus Norvegicus* Newborns' Cerebrum and Cerebellum

Duhita Dyah Apsari<sup>1</sup>, Hermanto Tri Joewono<sup>2</sup>, Widjiati<sup>3</sup>

<sup>1</sup>Postgraduate Student of Reproductive Health Sciences, Faculty of Medicine, Airlangga University, Surabaya, Indonesia, <sup>2</sup>Department of Obstetrics and Gynecology, Airlangga University, Surabaya, Indonesia, <sup>3</sup>Prof., Department of Embryology, Faculty of Veterinary Medicine, Airlangga University, Surabaya, Indonesia

## Abstract

**Context:** Maternal death occurred in pregnancy period up to 42 days after giving birth. Maternal death could cause early life stress in newborns which activated HPA axis and glucocorticoid secretion as stress hormone marker. The developing brain was very sensitive to the initial exposure to stressors that would affect the Brain Derived Neurotrophic Factor (BDNF) expression, which was one of the most important endogenous mediators of stress responses in the brain. This study aimed to analyze BDNF expression in the cerebrum and cerebellum of *Rattus norvegicus* newborn with maternal death model. The control group (K1) consisted of newborns *Rattus norvegicus* which were not separated from the mother until 3 days old and the treatment group (K2) is maternal death model consisted of newborns *Rattus norvegicus* which were separated immediately from the mother after birth until 3 days old and fed with animal milk as a substitute nutrient. After 3 days treatments, 3 newborns with heaviest, medium, and lowest weights were taken from each mother to sacrifice. The BDNF expression examination was carried out on cerebrum and cerebellum by immunohistochemical method. The results showed that the mean BDNF expression in the cerebrum and cerebellum of 3 days old *Rattus norvegicus* with maternal death model which separated from the mother were lower than the mean BDNF expression of control group though there were no significant difference based on statistical analysis.

**Keywords:** *BDNF expression, separation from mother, maternal death model*

## Introduction

Maternal death is the death of a woman during pregnancy, childbirth, or within 42 days after the end of pregnancy. Maternal death did not depend on the length and location of the pregnancy. This death could be caused by anything related to pregnancy, childbirth, or medical handling. Maternal and infant death rates were a benchmark in assessing the health status of a country.<sup>17,27</sup>

Maternal death could affect the children's survival, especially in the first 1,000 days of life for children. The main impact of maternal death was the direct loss of the relationship between the mother and the newborn baby, causing by the absence of bonding and attachment between mother and baby and the immediate cessation of breast milk intake. Mothers also played an important role in giving and responding to communicative signals from babies after birth. The absence of bonding and attachment was one of the causes of neonatal stress. Neonatal stress is an early life stress occurred in neonatal period (birth to 1 month).<sup>1,10</sup>

In early life, babies were prone to experiencing pain and stress. When a baby faced a particular stressor, the hypothalamic-pituitary-adrenal axis would

---

be activated and the paraventricular hypothalamus secretes Corticotropin-releasing hormone (CRH) which then stimulated the secretion of Adrenocorticotropic hormone (ACTH) by the pituitary gland. This hormone would induce the adrenal gland cortex to secrete glucocorticoids (GC), namely cortisol, which was considered a stress indicator hormone. Neonatal stress in newborns was associated with cortisol hormone responses and baby behavior. Neonatal stress caused glucocorticoid increasing which could had an impact on the baby's brain development. In addition, the socio-emotional stress reactivity during the early period of neonatal life would affected the brain development.<sup>10,11</sup>

The part of the brain that had cognitive function was the cerebral cortex, but recent research showed that the cerebellum contained more neurons than the cerebral cortex that allowed it to be involved in cognitive function.<sup>2</sup> The cerebrum and cerebellum were interconnected through polysynaptics and form a system associated with cognitive function and interference neuropsychiatry.<sup>7</sup>

Brain Derived Neurotrophic Factor (BDNF) is a neurotrophic factor that played an important role in brain development because of its ability to protect brain cells from various pathological conditions. BDNF also

functioned to maintain neuron survival and regulate synaptic plasticity by increasing the number of dendritic spines and synapse formation. This molecular mechanism underlies cognitive function and brain development which was influenced by BDNF regulation.<sup>14</sup> BDNF was also one of the most important endogenous mediators of stress response in the brain. The developing brain was very sensitive to the initial exposure to stressors which would also affected BDNF expression.<sup>9</sup> Based on this background, this study was conducted to analyze the differences in BDNF expression in the cerebrum and cerebellum of 3 days old *Rattus norvegicus* newborns with maternal death model.

## Material and Method

This research was true laboratory experimental with randomized post-test only control group design. The 3-day-old *Rattus norvegicus* as sample unit. Female rats were pregnant through the superovulation technique by giving a 10 IU injection of the hormone Pregnant mare serum gonadotropin (PMSG). After 48 hours, they were given 10 IU injection of HCG hormone and later continued to monomating. Pregnant rat diagnosis was seen at 17 hours after mating with the presence of a vaginal plug.<sup>26</sup> The pregnant rats were cared until aterm and gave birth naturally.

### Findings:

**Figure 1. BDNF expression in the 3 days old *Rattus norvegicus* cerebrum between control group and treatment group. BDNF expression represented by brown color chromogen. Yellow arrow indicated the area was the maximum expression. (Immunohistochemical staining, 400x magnification; Miconos microscope MCX50LED; Optilab Plus camera)**

Experimental animal samples were divided randomly into 2 groups, namely the control group (K1) consisting of newborn rats which were not separated from the mother until 3 days old and the treatment group (K2) is maternal death model consisting of newborn rats which were separated from the mother immediately after birth until 3 days old and fed with animal milk as a substitute nutrient. After 3 days treatments, 3 newborns with the heaviest, medium, and lowest weights were taken from each mother to be sacrificed and the head decapitation was performed. The head part was separated and then put into 10% formalin. Imonohistochemical examination of BDNF expression was carried out on histochemical cerebrum and cerebellum preparations.

**Table 1: Mean and standard deviation of BDNF expression cerebrum**

**Table 3: Mean and standard deviation of BDNF expression cerebellum**

Group	n	BDNF Expression (IRS)
		Mean ± Standard Deviation
K1	18	3.06 ± 1.48
K2	18	2.39 ± 1.01

**Table 4: Analysis of BDNF expression cerebellum**

Group		p Value	Differences Test Analysis
K1	K2	0.392*	Mann Whitney

The results showed that BDNF expression mean in cerebrum of treatment group was lower than control group (Table 1) and by Mann Whitney test result showed

that not significant differences in the BDNF expression in cerebrum between control group and treatment group with a p value = 0.348 (significantly different need p value <0.05) (Table 2) which mean that the decrease of BDNF expression were not happened drastically based on statistical analysis. Similar results also showed in cerebellum that the BDNF expression mean of treatment group was lower than control group (Table 3) with no significant different (p value = 0.392) (Table 4).

## Discussion

In this research, the maternal death model was carried out by separation of newborns from the mother from day 0 to day 3. The full separation immediately after birth and examination of BDNF cerebrum and cerebellum expression of 3 days old newborn had never been done before. The separation treatment from day 0 to day 3 early in newborn rats would be the same as the human baby separation immediately after birth from the mother for approximately 1 month. This was included in the criteria for maternal death (42 days after birth).

This research showed that BDNF expression mean of 3 days old *Rattus norvegicus* cerebrum and cerebellum with maternal death model was lower than control group (Table 1; Table 3). The decrease of BDNF expression could caused by several things.

In early life, babies were prone to experiencing pain and stress. Research by Shi *et al* (2010) states that chronic stress could reduce mRNA expression and BDNF protein expression in hippocampus. The study by Calabrese *et al* (2015) also showed that the separation of rat's pups from the mother in the postnatal day 2 to day 14 had reduced BDNF expression in the ventral hippocampus and ventromedial prefrontal cortex. However, the separation in the study was only carried out 3 hours every day then returned to the mother after the treatment. In another study, Binggio *et al* (2014) showed that a decrease in BDNF expression occurred in the postnatal separation from the 3rd to the 15th day postnatal.<sup>4,8,22</sup>

Brain-Derived Neurotrophic Factor (BDNF) was a protein that played an important role in the development, maintenance, and synaptic plasticity.<sup>16</sup> This protein was expressed in the brain, which included the frontal cortex, parietal, cingulatus, temporal, retrospenial, prirhinal, hippocampal, entorhinal cortex, brain stem, cerebrum, and cerebellum. Each area in the brain had different BDNF concentrations.<sup>5</sup> The BDNF gene expression

in the brain was influenced by many stimuli, both in physiological and pathological conditions. BDNF regulation was influenced by activation of NMDA receptors (NMDAR), calcium influx ( $Ca^{2+}$ ), and through activation of CREB.<sup>10</sup> BDNF was one of the most important endogenous mediators of stress response in the human and mammalian brains. The developing brain was very sensitive to the initial exposure to stressors, especially because of the reprogramming number of stress-sensitive gene pathways.<sup>9</sup>

Stressor at early of life would cause glucocorticoid to increase. Glucocorticoid played an important role in the BDNF regulation. Glucocorticoid decreased the activity of activator protein-1 (AP-1) and CREB needed in transcription of BDNF genes, influenced the cascade of BDNF signals via TrkB and p75NTR receptors, decreases the infusion of  $Ca^{2+}$  ions in postsynapsed membranes, inhibits trkB-mediated signal cascades, and decreases expression phospho-TrkB (pTrkB), and influence the PLC- $\gamma$  signal cascade regulation by BDNF and inhibit the PI3K-Akt pathway.<sup>23,24</sup>

With the BDNF presence, the TrkB receptor homodimerizes and initiates several signaling pathways and would support neuron survival, growth, and differentiation. Glucocorticoid(GC) passed through the plasma membrane and entered the cytosol to bind to glucocorticoid receptor (GR), and induces homodimerization (GR-GC complex). The GR-GC complex would target BDNF promoters. Increased glucocorticoid levels caused relocation of nucleus CREB regulated transcription coactivator 2 (CRTC2) to the cytosol. This could decreased the transcription activity of CREB which would caused a decrease in BDNF expression.<sup>12</sup>

In addition, regulation of BDNF expression by glucocorticoid was also related to DNA methylation and histone modification. BDNF transcripts containing exons I, II, IV, and VI were mostly expressed in transcript neurons so that they display different subcellular localization and could showed that protein was translated by different efficiency in soma or dendritic which would produce local effects. Decreasing BDNF expression was also often associated with increased DNA methylation in BDNF promoters. DNA methylation was one of the contributing factors to long-term epigenetic reprogramming and gene activity in the developing brain. Methylation of BDNF genes was often considered a key mechanism of early life stress and influenced brain

function.<sup>13,25</sup> Research by Roth *et al* (2009) and Blaze *et al* (2013) showed that early life stress in children caused changes in DNA methylation in BDNF accompanied by reduced expression in BDNF.<sup>6,18</sup>

Stress also could caused the glucocorticoid receptor translocation from the cytoplasm to the nucleus that would result in the imbalance of mitochondria and the production of NADPH oxidase (NOX). Some stress signaling pathways would follow NOX stimulation and would led to cell damage and lower BDNF expression.<sup>19</sup>

Changes in BDNF expression indicated a dependence on the time period, that was on direct or long-term effects, acute or chronic. A recent analysis of hippocampal transcriptomics showed that the stress effects on children on BDNF expression were very dependent on age and could vary over the lifetime.<sup>25</sup>

The mean BDNF expression of cerebrum and cerebellum with maternal death model were lower than control group but there were no significant different. Acute stress could increased BDNF level but with longer stress exposure it would led to chronic stress that decreased BDNF level.<sup>21</sup> The 3 days separation and the decrease of BDNF in this research showed chronic stress but the decreasing of BDNF not significant might be caused by chronic stress that not happened in long period and not severe.

### Conclusion

The results showed that the mean BDNF expression of 3 days old *Rattus norvegicus* cerebrum and cerebellum with maternal death model which newborns separated from the mother after birth until 3 days were lower than control group which not separated from the mother though there were no significant different.

**Ethical Clearance:** This study had obtained an ethical feasibility permit based from Research Ethics Commission of the Faculty of Veterinary Medicine, Airlangga University.

# Is it a Common Oral Lichen Planus or a Part of Grinspan's Syndrome?

Dwi Ariani<sup>1</sup>, Harum Sasanti<sup>2</sup>, Taufan Bramantoro<sup>3</sup>

<sup>1</sup>Department of Oral Medicine, Faculty of Dentistry, Universitas Prof. Dr. Moestopo, Indonesia, <sup>2</sup>Department of Oral Medicine, Faculty of Dentistry, Universitas Indonesia, Indonesia, <sup>3</sup>Department of Public Health, Faculty of Dental Medicine, Universitas Airlangga, Indonesia

## Abstract

**Introduction:** Grinspan's syndrome has triad of clinical symptoms: Oral Lichen Planus (OLP), diabetes mellitus, and hypertension. OLP is a disorder commonly found in oral mucosa. The symptoms and clinical features are often misdiagnosed which potentially harm the patients.

**Discussion:** A 74-year-old female had chief complaint of ulcers on the lower lip for 2 years. She had history of diabetes mellitus and hypertension for years. Previously, she went to dentist with an alleged herpes simplex virus infection and was treated with antiviral for a week but no improvement. The patient is diagnosed with erosive type OLP. Exploration was necessary to find out whether it was OLP or part of Grinspan Syndrome.

**Conclusion:** The diagnosis was Grinspan's Syndrome. Dentists must be familiar with medical management of hypertension and diabetes mellitus to take a role in the diagnosis and treatment of oral lesion with both of diseases in order to maintain optimum health.

**Keywords:** Grinspan's syndrome, oral lichen planus, diabetes mellitus, hypertension.

## Introduction

Lichen Planus (LP) is a mucocutaneous disorder present in the chronic squamous epithelium that may affect the mucosal, genital, and skin, including scalp and nails. Oral Lichen Planus (OLP) is the most commonly found oral disease and often found in the buccal mucosa, tongue, palate, mole, gingiva, and lips. The clinical features of OLP have one or more of six classical appearances: reticular, erosive, atrophic, plaque, papulla, bullous. The erosive form has a symptom relation ranging from mild discomfort to pain or burning sensation, especially when consuming hot or spicy foods.<sup>1-3</sup> The diagnosis of

OLP is obtained from clinical examination and mucosal biopsy of the oral cavity if there is no doubt of a clinical diagnosis. The criteria used for histological diagnosis are abnormal keratinization, the presence of stratum granulosum, basal cell degeneration, and inflammatory cell infiltration, such as ribbons dominated by lymphocyte cells, which are present in connective tissue.<sup>4-9</sup> Grinspan et al found an interesting association between OLP and diabetes mellitus (DM) and vascular hypertension which is then called Grinspan Syndrome.<sup>10-12</sup> This case report is unique because presenting rare case of Grinspan's Syndrome, especially in geriatric.

**Case History:** A 74-year-old female came with chief complaint of ulcers on lower lip for 2 years. History of fever was denied. A couple months ago patients went to Mecca to perform the pilgrimage. While being there, she could not eat regularly and drink enough. Ulcers on the lips progressively worsened until a week ago when she came to hospital. In the previous treatment, the patient's complaint was diagnosed from herpes simplex

virus infection. She had taken acyclovir for 2 weeks. Her lower lips feel drier, sometimes the brown liquid would come out from the wound. Communication with the patient was constrained by age, she had a limited hearing and memory disorientation. She also suffered from diabetes mellitus and hypertension for years. Blood pressure was 150/90 mmHg and she claimed for taking antihypertensive medication, such as 5 mg Amlodipine twice daily. The patient's blood glucose was above 300mg/dl, and she took Metformin twice daily before and Glimperide after eating. Even though she regularly consumed drugs for hypertension and diabetes mellitus, blood pressure and blood sugar levels remained above normal. The patient used removable dentures in the upper and lower jaws for 5 years. Since the ulcers on her lips appeared, she felt uncomfortable using her dentures. She had less appetite and sleepless nights. On extra-oral examination, the lower lip border of the vermilion contained brown crust surrounded by erosive areas with white striae. On intraoral examination, there was atrophy and fissure in the dorsal portion of the tongue and all the teeth in the upper and lower jaws have disappeared. Laboratory results of blood tests obtained a rate of sedimentation of blood above the reference value and hemoglobin at the lower limit of the reference value. The possibility was iron deficiency anemia. From the results of clinical examination, the diagnosis of work suspected Lichen Planus Oral erosion type with systemic factors diabetes mellitus and hypertension was found. This case was about the Grinspan's Syndrome.

Management for erosive-type OLPs is by using topical corticosteroids on the red lip margin and the use of triamcinolone acetinoid cream ointment 4 times daily on thin lips. Patients were administered with an iron-deficiency anemia by taking multivitamins containing folic acid and ferrous fumarate twice daily for 2 weeks and supportive therapy using Zinc, B, and E once daily. Communication, instruction, and education were emphasized in patients to consume foods high in iron, such as red meat, red beans, red fruits, such as beet, and vegetables. She was also advised to replace her dentures.

After a week of treatment, the patient came back for visit. Patients felt several improvements, especially on the bottom lip. After extra-oral examination, the wound and crust on the lower lip were healed with marked thin red areas on the lower lip, better hygiene of the mouth, and comfort in the mouth was increasing. She used triamcinolone acetinoid cream ointment on her lower lip according to the doctor's instructions, and she felt

the lower lip was softer. She took vitamins according to each dose before breakfast and dinner. She continued to take diabetes and hypertension drugs according to the dose. In general, she felt better than last week and more comfortable when eating.

### Discussion

Lichen planus is common in patients over 50, and more in women than men. With changes in daily diet, patients with OLP consumed too few fresh vegetables and fruits. Stress and emotions can be considered as contributing factors, especially in the exacerbation phase of OLP.<sup>5,13-16</sup>

Patients with OLP lesions and using drugs related to reactions in the oral mucosa are also a possible implication of the drugs. The patients will experience symptoms described as Grinspan's Syndrome with a wide variety of drugs which now is known as oral

lichenoid reactions. The clinical picture will look like a phenomenon of drug reactions and is no longer referred to Grinspan's Syndrome.<sup>10</sup> Clinical manifestations of OLP and medical history suggest that drug consumption may lead to lichenoid changes. It is important to note that the lichenoid response appears as an agent response that amplifies the presence of drug-induced abnormalities rather than the induction of a disease. Clinical response to OLP management is done such as by removing suspected drugs in amplifying OLP or by using topical steroids in OLP lesions.<sup>6,17-20</sup> The main goal of OLP therapy is to reduce the symptoms of pain, remove oral lesions, reduce the risk of oral cancer, and maintain oral hygiene.<sup>21</sup>

Circumstances in the oral cavity reflect the health of the body and systemic diseases. Good dental and oral hygiene are partially dependent on the patients' mental health status. A state of stress, depression, and excessive anxiety lead to the cleanliness of the oral cavity which will be neglected. When experiencing stress, the body releases adrenaline and noradrenaline so that it not only leads to a decrease in blood circulation, but there is the possibility of altering the blood elements needed to maintain the body's resistance to disease.<sup>22,23</sup>

In this article, the patient was diagnosed as having Grinspan's Syndrome, which is associated with erosive lichen planus, diabetes mellitus, hypertension. Dentists must be familiar with medical management of hypertension and diabetes mellitus patients by taking important role in the diagnosis and treatment of oral lesion with both of diseases in order to contribute to maintain optimum health.

### Conclusion

**Acknowledgements:** All the listed authors contributed to patient's treatment and writing the article, and hereby stated that the manuscript has never been presented as part at a meeting.

**Conflict of Interest:** All authors reported no conflict of interest of this work

**Source of Funding:** This study was conducted with individual funding

**Ethical Principle:** This study is original and accordance with the ethical principle of non maleficence and confidentiality. This article has never been published and is not under consideration in other publications.

## Abstract

**Context:** Lead exposure can have a harmful effect on the body, one of which is the reproduction system. Lead can increase oxidative stress that can cause damage to organ. This research aims to prove the effect of chitosan in reducing MDA levels and increasing 17 $\beta$  estradiol level and VEGF expression due to lead exposure. This study was a true experimental in vivostudy using apost-test only group control design. This study used female wistar strain rats as the experimental animals that were divided into a negative control group, a positive control group (dose of lead 175 mg/kg/BW) and treatment groups (dose of chitosan 16, 32, and 64 mg/kg/BW) for 30 days. Surgery was carried out during the proestrus phase. The MDA level was measured using a microplate reader, 17 $\beta$  Estradiol level using ELISA, and the VEGF expression using IHC. This study used One Way ANOVA test and LSD test. The dose of chitosan that was considered capable of reducing uterine MDA level was treatment group 2 (dose of 32 mg/Kg/BW). Administration of chitosan at dose 3 (dose of 64 mg/Kg/BW) was able to increase Estradiol 17 $\beta$  levels and VEGF expression optimally. Chitosan can quantitatively reduce MDA level and increase 17 $\beta$  estradiol. In addition, chitosan administration can significantly increase VEGF expression.

**Keywords:** *Reproduction, Lead, chitosan, Malondialdehyde, 17 $\beta$  Estradiol, VEGF.*

## Introduction

Lead is highly found in the environment because it is difficult to degrade and can come from exhaust fumes, industrial waste, batteries, etc. Its toxicity can adversely affect the reproductive system.<sup>[1]</sup> Lead can induce oxidative stress.<sup>[2]</sup> Cadmium, mercury and arsenic Oxidative stress is caused by high free radicals because of the mechanism in reducing levels of antioxidant enzymes (SOD, CAT, and GSH).<sup>[1]</sup> Lead can deactivate ALAD (Amino Laevulinic Acid Dehydrase) which is an enzyme in heme biosynthesis resulting in an increase

in ALA (Aminolaevulinic Acid) that stimulates the production of ROS.<sup>[2]</sup> Cadmium, mercury and arsenic

Oxidative stress can cause damage to membrane lipids, proteins, and DNA.<sup>[3]</sup> Lipid peroxidation is a chain reaction during oxidative stress derived from unstable and easily decomposed Poly Unsaturated Fatty Acid (PUFA), and also forms a complex set of compounds consisting of Malondialdehyde (MDA). MDA is an important indicator of lipid peroxidation.<sup>[4]</sup>

In addition, lead is able to pass through the Brain Brain Blood (BBB) because it has a high affinity in binding to CaM compared to Ca<sup>2+</sup> which is the second messenger at the cellular level.<sup>[5]</sup> This change can affect the biosynthesis of sex hormones by damaging the hypothalamus function, so GnRH stimulation is disrupted.<sup>[6]</sup> Lead in the blood results in decreased production of LH, FSH, and 17 $\beta$  estradiol.<sup>[7]</sup> A high level of 17 $\beta$  estradiol plays an important role in fertility

Phone: 082158619686 .

because it can increase LH in the ovulation process and stimulate folliculogenesis.<sup>[8]</sup>

17 $\beta$  estradiol is also involved in angiogenic factors in the endometrium, including Vascular Endothelial Growth Factor (VEGF) that is the main regulator of angiogenesis in various tissues including endometrium.<sup>[9]</sup> VEGF imbalance can trigger abnormal bleeding during menstruation.<sup>[10]</sup>

Antioxidant administration can reduce the toxic effects of lead. One of the antioxidants that can be used is chitosan. Chitosan is a modification of a chitin compound found in the outer shells of Crustacean species such as shrimp. Chitosan has an antioxidant mechanism through its ability to stabilize free radicals (Scavenging) and bind metal ions (Chelating). The interaction between chitosan and heavy metals includes absorption, ion exchange, and chelation. The hydroxyl (OH) and amino groups (NH<sub>2</sub>) are key chitosan groups as antioxidant agents that can prevent free radicals.<sup>[11]</sup>

This study aimed to determine the effect of oral chitosan administration on MDA level, 17 $\beta$  estradiol level, and VEGF expression on the endometrium rats exposed to lead acetate.

## Material and Method

**Research Description:** This *in vivo* study is true experimental with a post-test only control group design. The experimental animal was wistar strain rats (*Rattus norvegicus*) exposed to lead and given an chitosan. Observations were carried out on utery MDA level, blood serum 17 $\beta$  estradiol level, and endometrium VEGF expression.

**Experimental Animal:** The inclusion criteria were wistar strain rats, female, healthy (clean white fur, active), not pregnant, aged 8 weeks old, and 125-175 gr of body weight. The exclusion criteria were rats that appeared sick before being treated. This research has gone through the ethical feasibility step (Ethical Clearance) at the Ethics Commission of Faculty of

Medicine, University of Brawijaya.

**Experimental Design:** The number of samples used in this study was 25 white female wistar strainrats. After acclimatization, the random sampling technique was carried out. Rats were divided into five groups, two control groups (negative and positive controls), and three treatment groups (given chitosan doses of 16, 32, and 64 mg/kg/BW). All groups were given a lead at a dose of 175 mg/kg/BW/day, except for the negative control group. The administration of lead acetate (dissolved with aquades) and chitosan (dissolved with asetat acid) was carried out orally. Surgery was done after a 30 day treatment and in the proestrus phase by vagina swab.

**Measurement of MDA, 17 $\beta$  Estradiol, and IHC Staining:** The bloods then centrifuged to obtain the serum, ELISA method was carried to measure 17 $\beta$  estradiol level using ELISA Kit (from the Elabscience trademark catalog no.E-EL-0152). The left endometrial tissues were crushed and centrifuged to obtain a supernatant then using a microplate reader to obtain the MDA level using MDA Assay Kit (from the Elabscience trademark catalog no.E-BC-K142). The right endometrium was stained using IHC used antibodies from Santa Cruz trademark sc-57496 to observe the VEGF expression.

**Statistical Analysis:** Statistical analysis was begun with the data normality test and homogeneity test with a significance level of  $p > 0.05$ . One Way ANOVA Test was used to compare more than two sample groups. LSD test was used to determine the most effective chitosan dosage.

## Result

**Effect of Chitosan Administration on Uterine MDA Level after Induced by Lead:** One Way ANOVA test results on uterine MDA levels obtained a P-Value of 0.309 ( $> 0.05$ ), which means that there were no significant differences, then there was no need to do LSD test.

**Table 1: One Way ANOVA Test Results for MDA leve**

Research Group	N	Mean±SD(nmol/gr)	P-Value
Negative Control	5	15,354±4,676	0,309
Positive Control (lead 175 mg/kg/BW)	5	21,259±18,139	
Treatment 1(lead 175+chitosan 16 mg/kg/BW)	5	10,475±5,165	
Treatment 2(lead 175+chitosan 32 mg/kg/BW)	5	10,114±4,372	
Treatment 3(lead 175+chitosan 64 mg/kg/BW)	5	20,279±11,831	

Table 1 shows that the comparison of the positive control group (21,259±18,139) to the negative control group (15,354±4,676) shows a difference in the mean of the uterine MDA levels quantitatively. In the treatment group 1 (10,475±5,165) compared to the group of treatment group 2 (10,114±4,372), there was a quantitative decrease. However, in the treatment group 3, there was an upward trend of uterine MDA levels. This

shows that the group 2 given chitosan dose of 32 mg/kg/BW was capable of reducing uterine MDA levels.

**Effect of Chitosan Administration to 17β Estradiol after Lead Exposure:** One Way ANOVA test results on 17β estradiol levels obtained P-Value of 0.968 (>0.05), which means that there no significant difference, then there was no need to do the LSD test.

**Table 2: One Way ANOVA Test Results of 17β Estradiol Levels**

Research Groups	N	Mean±SD (pg/dl)	P-Value
Negative Control (without treatment)	5	36,614±18,32 <sup>a</sup>	0,968
Positive Control (lead 175 mg/kg/BW)	5	33,817±14,28 <sup>a</sup>	
Treatment 1(lead 175+chitosan 16 mg/kg/BW)	5	34,804±15,22 <sup>a</sup>	
Treatment 2(lead 175+chitosan 32 mg/kg/BW)	5	36,328±26,29 <sup>a</sup>	
Treatment 3(lead 175+chitosan 64 mg/kg/BW)	5	41,554±14,44 <sup>a</sup>	

Table 2 shows that the comparison of the negative control group (36.614±18.32<sup>a</sup>) to the positive control group (33,817±14,28<sup>a</sup>) revealed a difference in the mean level of 17β estradiol quantitatively. From the comparison of treatment group 1 (34.804±15.22<sup>a</sup>), treatment group 2 (36.382±26.29<sup>a</sup>), and treatment group 3 (41.554±14.44<sup>a</sup>), there was a quantitative difference through the consecutive increases in the three treatment groups. The administration of chitosan at a dose of 64 mg/kg/BW showed the most effective dose in increasing 17β estradiol level.

**Effect of Chitosan Administration on Uterine VEGF Expression after Lead Exposure:** VEGF expression scan results are seen in the cytoplasm of endometrial glandular epithelial cells in brown color (Figure 1).

**Figure 1. Expression of VEGF in the cytoplasm of endometrial glandular epithelial cells in brown color**

The following table is the One-Way ANOVA test results of VEGF:

**Table 3: One Way ANOVA Test Results of Uterine VEGF (%)**

Research Groups	Mean±SD	P-Value
Negative Control (without treatment)	75.18±4.142 <sup>c</sup>	0.000<
Positive Control (lead 175 mg/kg/BW)	61.10±3.89 <sup>a</sup>	
Treatment 1 (lead 175+chitosan 16 mg/kg/BW)	67.16±3.97 <sup>b</sup>	
Treatment 2 (lead 175+chitosan 32 mg/kg/BW)	72.28±1.66 <sup>c</sup>	
Treatment 3 (lead 175+chitosan 64 mg/kg/BW)	75.26±3.94 <sup>c</sup>	

**Description:** The mean±sd shows the Duncan test results, if carrying different letters means that there is a significant difference (P-Value<0.05).

One Way ANOVA test on the mean of uterine VEGF expression obtained p-value=0,000<0,05, which showed significant differences, then test on LSD was conducted.

Table 3 shows that there are significant differences in the mean of VEGF expression (61.10±3.89<sup>a</sup>%) of the positive control with treatment group 1 (67.16±3.97<sup>b</sup>%). In the positive control group (61.10±3.89<sup>a</sup>%) with treatment group 2 (72.28±1.66<sup>c</sup>%), there were significant differences. Also, in the positive control group (61.10±3.89<sup>a</sup>%) with the treatment group 3 (75.26±3.94<sup>c</sup>%), there were significant differences. The chitosan dose which is considered the fastest to increase VEGF is 64 mg/kg/BW.

## Discussion

Lead toxicity mechanism is oxidative stress because of ROS production and decreased antioxidants.<sup>[1]</sup> Lead causes ALAD inhibition that increases ALA substrate that produces hydroxyl radical generation.<sup>[2]</sup> cadmium, mercury and arsenic. All of these mechanisms cause cells to be susceptible to oxidative stress.

Lipid peroxidation is another biomarker of oxidative stress. MDA is a lipid peroxidation product formed from the reaction of oxygen radicals with PUFA in phospholipid membrane and shows the damage of cells.<sup>[4]</sup>

In this study, the differences present in the positive and negative control groups were in accordance with the studies conducted on male rabbits that showed a difference in MDA levels between the control group and the treatment groups exposed to lead acetate.<sup>[12]</sup>

However, the study of lead acetate administration to male rats for four weeks explained that there was no statistically significant increase in plasma MDA levels in dose of 5,10,20,40, and 80 mg/kg/BW compared to the control group.<sup>[13]</sup> The differences in the results of MDA levels in these studies were thought to be caused by different length of exposure time.

In the brain, lead can substitute calcium as the second messenger and disrupt the hypothalamus and pituitary gland, thus causes disruption of GnRH stimulation. So, it can reduce FSH and LH production and reduce the 17β estradiol in serum.<sup>[14]</sup>

In this study, a dose of 175 mg/kg/BW lead acetate was able to reduce the 17β estradiol level. This is in line with the research by Dhir and Dhan (2010) that there will be a decrease in steroidogenesis activity in lead-exposed rats.<sup>[15]</sup> Estrogen functions as a growth hormone in the reproductive system, ovulation triggers, and oocyte development.<sup>[8]</sup>

In this study, the mean of 17β estradiol levels in positive controls was decreased compared to negative controls, but not significant. The treatment groups 1, 2, and 3 also increase the 17β estradiol level but were not significant. The dose and length of exposure are some possible mechanisms that might occur so that they are not significant.<sup>[16]</sup> This study used 30 days of exposure with a lead dose of 175 mg/kg, which was considered in the subchronic category. Decision making was based on previous research by Sari et al. (2018) who conducted lead exposure in rats for 30 days at a dose of 175 mg/kg to obtain subchronic categories.<sup>[17]</sup> Several other studies had a longer time, such as 15 weeks.<sup>[18]</sup> Many factors that cause lead exposure in this study were not significant. This is consistent with the research of Iavicoli et al. (2004), that lead exposure in rats with eight different doses showed an increase in 17β estradiol levels but was not significant.<sup>[19]</sup>

The estrogen and progesterone hormones play a role in forming a new layer of blood vessels in the endometrium. New blood vessels develop during each menstrual cycle through angiogenesis and vascular remodeling originating from pre-existing blood vessels in the endometrial basal zone.<sup>[20]</sup> In addition to progesterone and estrogen, many factors play a role in angiogenesis, one of which is VEGF. VEGF is a key compound of angiogenesis.<sup>[21]</sup> In this study, VEGF expression in positive controls decreased compared

to negative controls that were significant. VEGF expression and its receptors on human and mammalian endometrium, throughout the menstrual cycle, increase during the final proliferation and luteal phase, a period which is consistent with angiogenesis.<sup>[22]</sup> whose specific receptors have not been examined in detail thus far. We conducted the present study to determine, by immunocytochemistry and computerized image analysis of the functional is, the expression and modulation of the receptors Flk-1/KDR and Flt-1, which mediate VEGF effects on endothelial mitogenicity, chemotaxis, and capillary permeability. VEGF receptors are expressed mainly in endometrial endothelial cells, with variations of intensity and number of stained capillaries related to the phase of the cycle. The number of capillaries immunostained for Flk-1/KDR was maximal in the proliferative phase (ratio Flk-1/CD34: 1

Previous studies in rats and rabbits showed that VEGF and its receptors participated in increased angiogenesis and vascular permeability needed in the implantation process. Lack of VEGF expression and its receptors in rats leads to the development of poor blood vessel tissue in the endometrium that can lead to implantation failure and abortion.<sup>[23]</sup> In addition, a decrease in VEGF can have an impact on abnormal angiogenesis. Disrupted angiogenesis will disrupt blood vessel function such as abnormalities of menstruation.<sup>[24]</sup> which have been linked to the activation of both of these transcription factors. Therefore, the involvement of these pathways in estrogen-induced VEGF expression was investigated. Inhibitors of the MAPK (U0126

Chitosan can prevent oxidative stress through its reaction with free radicals so that it is not reactive, stabilizes free radicals, and inhibits the free radical chain reactions. Chitosan has an amino group that is able to bind to metals (including lead), so lead acetate is stable and can reduce toxic properties in lead.<sup>[25]</sup>

The greater the dose of chitosan given, the more amino groups that bind to lead, so it can reduce uterine MDA level, increase 17 $\beta$  estradiol level, and increase VEGF expression. However, in treatment group 3 on examination of uterine MDA levels, the treatment of lead acetate exposure and chitosan at a dose of 64 mg/kg/BW was not much different from the positive control group. The authors suspect that the chitosan dose 64 mg/kg/BW/day was not appropriate because it can increase the risk of changes in antioxidants to be prooxidants in MDA level. It was thought to produce more superoxide anion radicals.<sup>[26]</sup>

## Conclusion

A dose of 32 mg/Kg/BW chitosan can quantitatively reduce MDA level and a dose of 64 mg/Kg/BW chitosan can increase 17 $\beta$  estradiol. In addition, a dose of 64 mg/Kg/BW chitosan administration can significantly increase VEGF expression.

## Author

**Context:** It is known that the increase in chronological age itself is a serious risk factor for the development of cardiovascular disease, especially in men. In men over the age of 50 who have several risk factors for cardiovascular disease, the risk of starting coronary heart disease or hypertension is very high. Therefore, it becomes necessary to develop affordable and safe programs to minimize this danger, based on the physical recovery of men older than 50 years, through the use of dosed and acceptable physical activity complexes for this age. Their effectiveness will be based on the possibilities of regular physical exertion in terms of toning up the cardiovascular system, enhancing metabolism and increasing the general endurance of the body. The study showed that the use of a set of physical activities for 1 year, including classes on the simulators “SPIRIT Medical Systems MU100 vertical ergometer” and “Finnlo”, with the addition of classes at “Finnlo MAXIMUM-S” from the second half of the year provides a more pronounced overall health the effect and greater increase in the level of physical fitness than the annual physical activity, including classes on the “Finnlo MAXIMUM-S elliptic” trainers with the addition of physical training in the second half of the year on the “ SPIRIT Medical Systems MU100 vertical ergometer”.

**Keywords:** Dosed physical activity, exercise equipment, men, pre-retirement and retirement age, cardiovascular diseases.

## Introduction

The relationship between low levels of physical activity and the development of cardiovascular diseases with age has long been observed<sup>1</sup>. The danger of physical inactivity is associated with the risk of development of

a number of negative changes against its background, including in the heart and blood vessels<sup>2</sup>. Even the reports of the World Health Organization officially indicated that more than 20% of cases of the development of cardiovascular diseases in the developed countries of the world occur due to the low level of physical activity in the population<sup>3</sup>. To fill the body's need for motor activity, comprehensive cardiorehabilitation programs are regularly developed, which necessarily include physical exercises<sup>4,5</sup>.

Among the positive effects of physical training in middle-aged and elderly people there is a decrease in overall mortality by 20% (primarily mortality from

cardiovascular diseases), a modification of risk factors for the development of cardiovascular pathology, and an increase in the general functional capabilities of the body<sup>6</sup>. However, despite the continuous methodological improvement of the process of rehabilitation of cardiological patients, the prevention of premature aging of the cardiovascular system in people older than 50 years, as a rule, is limited to general recommendations for increasing motor activity<sup>7</sup>.

In Russia, serious attention is traditionally paid to solving age-related health problems in the male population. As a rule, this is done by restoring the traditions of maintaining athletic form, for which age norms of the general functional capabilities of the human body were introduced into the practice of healthcare<sup>8</sup>. However, the majority of able-bodied men over 50, obeying the contradictory behavioral stereotypes that have formed in Russian society, independently organize their leisure in the field of recovery, which is very far from a healthy lifestyle<sup>9</sup>.

Due to the fact that the relationship between walking distance per day and the possibility of reducing early mortality of men from cardiovascular causes was previously found, it was of great interest to create complexes of physical exercises that could provide not only an increase in their general physical fitness, but also improvement of their cardiovascular system with minimizing the risk of early cardiovascular death<sup>10</sup>. In this regard, it becomes necessary to develop affordable and safe programs for physical recovery of men over 50 years of age, based on dosed and acceptable for this age complexes of physical activity, which is convenient to dose.

In this regard, the goal is set to develop and test a comprehensive program for their general improvement for able-bodied men of pre-retirement and retirement age.

## Materials and Method

The study was conducted at the Faculty of Physical Education of the Russian State Social University. It was approved by the local ethics committee of the Russian State Social University (protocol №10 of 2017.11.10). The study involved 57 men aged 52-63 years (mean age  $58.3 \pm 0.78$  years). All men were randomly divided into two equal comparable groups - observation group 1 (28 people) and observation group 2 (29 people). All men were clinically healthy and had not previously

been physically trained. They did not have metabolic, oncological diseases and diseases of the cardiovascular system. All examined had risk factors for the development of cardiovascular pathology: they all smoked at least a pack of cigarettes a day, were overweight (weight index  $27.7 \pm 0.5$  kg/m<sup>2</sup>), and were regularly tested for various reasons, emotional stresses and had a blood cholesterol level above the normal level ( $5.8 \pm 0.7$  mmol/l). All men noted regular vague discomfort in the heart and episodes of destabilization of blood pressure.

To improve the health of the examined men, the authors have developed two programs of fitness training and evaluated their effectiveness.

Program №1 (developing) included daily exercises on simulators, the structure of which included the following:

- Preparatory part (6 min) with breathing exercises and the use of walking.
- The main part in the first six months of classes included special exercises for the muscles of the pelvic floor, perineum, and thighs on a “Finnlo MAXIMUM-S elliptic” (figure 1) (20 min). Due to the smooth increase in resistance during training, the muscles of the legs and abdominal muscles are trained and the functions of the cardiovascular system are dosed.

**Figure 1: Simulator “Finnlo MAXIMUM-S elliptic”**

After six months of classes, classes (10 min) were added to the main part of the classes on the simulator “SPIRIT Medical Systems MU100 vertical ergometer” (figure 2). A feature of this simulator is the ability to change the direction of the impact of an uneven load

on the limbs with alternating isokinetic muscle tension, which stimulates the blood circulation throughout the body (figure 2).

**Figure 2: Simulator “SPIRIT Medical Systems MU100 vertical ergometer”**

The final part of the lesson (4 minutes) included standard gymnastic and breathing exercises. In addition to training on simulators, the developing program included daily walking for 4 km at a measured pace.

Program №2 (training) included daily training on simulators, the structure of which included the following:

- Preparatory part (6 min) from dosed walking and breathing exercises;
- The main part included special exercises on the simulator “SPIRIT Medical Systems MU100 vertical ergometer” (20 min) (figure 2) and 10 minutes on the simulator “ Finnlo EllypsisSX1” (figure 3). The use of these simulators made it possible to activate all the large muscle groups of the body, primarily the thigh muscles.

**Figure 3: Simulator “Finnlo EllypsisSX1”**

Six months later, classes were added on the simulator “Finnlo MAXIMUM-S” (10 minutes) (figure 4). During the classes, resistance to the work of the legs and abdominal press sets in, which additionally trains the cardiovascular system (figure 4).

**Figure 4: Simulator “Finnlo MAXIMUM-S”**

The final part of the lesson (6 minutes) included standard gymnastic and breathing exercises. In addition to training on simulators, the training program included daily walking for 6 km at an accelerated pace.

In order to achieve the goal set in the work, the examined motor activity by the number of steps per day, conducted a 12-minute Cooper test, recorded the heart rate during exercise, determined the endurance coefficient, and the values of systolic and diastolic blood

pressure. Men who made up both observation groups were examined twice - at the end and after a year of daily training according to the schemes proposed by him. The obtained digital values of the considered indicators were processed using Student's t-test (t).

## Results

Obtained during the examination of all men included in the study, the digital values of the examination are presented in table 1.

**Table 1: Dynamics of the considered indicators in the observation groups**

Parameters	Study time	Observation group 1 (n=28), M±m	Observation group 2 (n=29), M±m
Physical activity, thousand steps / day	Initially	6.5±0.10	6.3±0.07
	At the end of the observation	7.5±0.16 p<0.05	9.2±0.13 p<0.01 p <sub>1</sub> <0.01
The results of the 12-minute Cooper test, km	Initially	1.6±0.03	1.6±0.02
	At the end of the observation	1.7±0.07	1.9±0.04 p<0.01 p <sub>1</sub> <0.01
Heart rate during class, beats / minute	Initially	119.0±0.29	118.4 ±0.34
	At the end of the observation	109.0±0.28	101.0±0.30 p<0.05 p <sub>1</sub> <0.05
Endurance ratio	Initially	19.8 ±0.09	20.0±0.11
	At the end of the observation	21.3±0.16	23.8±0.12 p<0.05 p <sub>1</sub> <0.05
Systolic blood pressure, mmHg	Initially	138.6±0.39	136.6±0.29
	At the end of the observation	132.5±0.27	120.6±0.18 p<0.05 p <sub>1</sub> <0.05
Diastolic blood pressure, mmHg	Initially	94.6±0.27	93.5±0.25
	At the end of the observation	90.2±0.20	82.2±0.14 p<0.05 p <sub>1</sub> <0.05

**Legend:** pre liability of dynamics in groups, p<sub>1</sub> - significance of differences in results by the end of observation in groups.

The initially low physical activity of the examined increased among them as a result of the application of both fitness programs. However, the application of program №2 (training) provided a more pronounced increase in this indicator in the second observation group. By the

end of the observation in her, this indicator exceeded that in the first group of men by 22.7%. When assessing both groups using the 12-minute Cooper test, initially the same indicators improved also more pronounced in the second group. By the end of the observation, they exceeded the results in the first group by 11.7%. In the process of classes in both groups there was a decrease in the value of heart rate, more pronounced in the second group by 17.2% versus 9.4% in the first. This was accompanied

by an increase in the coefficient of endurance, which by the time the observation was completed in the second observation group exceeded that in the first group by 11.7%. As a result of regular physical exertion, the observed men managed to lower their blood pressure by transferring it from a zone of high normal to a zone of normal blood pressure. At the same time, the results in the second group of observations were preferable due to the fact that they were inferior to those in the first group: in systolic blood pressure by 9.9%, in diastolic blood pressure by 9.7%.

## Discussion

Rational feasible muscle activity at any age contributes to the increase in adaptation to it of all organs, systems and the body as a whole<sup>11</sup>. A prominent role in the adequate adaptation of the body to the effects of physical activity belongs to the strengthening of the cardiovascular system, which largely limits the severity of the oxygen supply of the working organs<sup>12</sup>. Already against the background of a single physical load, the volume and speed of blood flow increases, vascular resistance is optimized, rheological properties of blood change, which affects the level of oxygen delivery to tissues. With prolonged, regular and feasible physical exertion at any age, an increase in the level of training of the heart muscle is noted and the activity of hemostasis decreases, which reduces the risk of thrombosis<sup>13</sup>.

It is known that in men older than 50 years, the vascular wall often experiences a tendency to spasm. In addition, several risk factors for the formation of cardiovascular diseases very often accumulate in this population group. They are, without a doubt, based on functionally unfavorable changes in the metabolism and in the state of the heart and blood vessels. Under conditions of low physical activity and minimal functional reserves, they can accelerate the formation of dysfunctions, and then pathologies in the circulatory system<sup>14</sup>.

In this work, two effective approaches to the recovery of men older than 50 years who have a risk of cardiovascular pathology were developed and tested. The trainees managed to achieve more pronounced results according to the program based on more intensive regular physical activities. Against their background, it was possible to achieve not only a pronounced optimization of the considered indicators of the cardiovascular system, but also an increase in

its reserve capabilities, which exceeded the effect of the application of a developing program of physical activity. The achieved effect on program №2 in men starting to age is more effective, as it provides a more pronounced healing effect on their organs. So, against the background of the daily execution of program № 2, men over 50 were able to significantly develop strength and endurance, which helps to optimize their state of the heart and blood vessels<sup>15</sup>.

The achieved beneficial effect on the body of both physical activity programs was largely realized due to the strengthening of metabolic processes. During physical exertion, there was a “soft” increase in the level of fitness of the male organism as a whole, strengthening their cardiovascular system, revealing the reserves of their respiratory system and thereby stimulating the work of the hormonal system and the central and autonomic parts of the nervous system<sup>16</sup>.

Obviously, from the early stages of the implementation of both recovery programs, the phenomena of muscle elasticity and endurance, as well as the flexibility of the spine, increase. It is known that regular exercise, especially on simulators, normalizes the production of neurotransmitters (acetylcholine, catecholamines and histamine), which provide a balance of functional processes in the brain.

When comparing the results in both observation groups, it became clear that program №2 has significant advantages over program №1, since only it allowed the indicators available for students to reach the optimal level. This gives grounds to consider it highly effective and promising for wide testing, including for various forms of dysfunctions and the beginning pathology in the heart of people of mature and old age, even if they have any concomitant compensated diseases.

## Conclusion

If men over the age of 50 have several risk factors for cardiovascular disease at once, the risk of coronary heart disease or hypertension becomes quite high. It is known that regular physical activity can tone up the cardiovascular system, enhance metabolism and increase the overall stamina of the body. The study showed that the use of a set of physical activities for 1 year, including classes on the simulators “ SPIRIT Medical Systems MU100 vertical ergometer “ and “Finnlo EllypsisSX1”, with the addition of classes at “Finnlo MAXIMUM-S” from the second half of the year provides a more

pronounced overall health the effect and greater increase in the level of physical fitness than the annual physical activity, including classes on the “Finnlo MAXIMUM-S elliptic” trainers with the addition of physical training in the second half of the year on the simulator “SPIRIT Medical Systems MU100 vertical ergometer”.

## Abstract

**Background:** Improve the human resource requires good brain quality since the phase of conception. Offering stimulus with classical music and regional music (gamelan) which is believed can help to boost the brain cells and intellectual intelligence. Exposure to Mozart's music, Javanese, Sundanese and Balinese gamelan affects the number of neuron cells.

**Objective:** Analyze the different of the number of neuronal cells on cerebrum and cerebellum offsprings *Rattus norvegicus* from mothers were exposed with Mozart music, Javanese Gamelan, Sundanese, Balinese and not exposed to music during pregnancy.

**Method:** This study was a experimental study with post test only control group design. The samples were divided randomly into 5 groups. The treatments were given the 10th day of pregnancy, for one hour in soundproof box with an intensity 65 db. On the 20th day of pregnancy, The *Rattus norvegicus* offsprings were born by sectio and selected three with the heaviest, medium and lightest of each mothers to sacrificed their brains were decapitated and dissection and counted the number of neuron cells using Hematosicline-Eosin stainin and analyzed using comparison test, with significancy  $p < 0,05$ .

**Results:** There were significant differences from the number of neuron cells of offspring *Rattus norvegicus* on cerebrum between groups with  $p = 0.001$  and on cerebellum with  $p = 0.001$ .

**Conclusion:** There are differences the number of neuron cells on cerebrum and cerebellum between offsprings *Rattus norvegicus* were not exposed to music and those exposed to music.

**Keywords:** Balinese Gamelan, Javanese Gamelan, Mozart, Number of Neuronal cells, Sundanese Gamelan.

## Introduction

The one of the efforts to improving the national development is improve the human resource requires

good brain quality since the phase of conception<sup>1</sup>. Intelligence is the biopsychosocial potential used to find a idea, solve a problem and process information quickly<sup>2</sup>. Information and stimulus are processed through interwoven between nerve cells or synapses, the more the number of neuron cells, the more synapses are formed so that the apoptosis also reduced and the brain will process information<sup>3</sup>.

The brain starts to grow and develop from 8 weeks of gestation and cell proliferation will stop when the

e-mail: putrielfridakusuma@gmail.com

pregnancy is  $\pm 20$  weeks with stages of proliferation, migration, differentiation, myelinisation and synaptogenesis. The brain that grows by getting stimulus will increase brain capacity due to fewer cell apoptosis<sup>4</sup>. Stimulus can be given after  $\pm 20$  weeks pregnancy because at this time axons arising from neurons have reached the target organ and form a network (neural network). The fetus begins to be able to hear voices from outside because at this phase the fetal ear has been fully formed and begins to function<sup>4</sup>. Recent research has shown the Cerebellum to be associated with the contralateral cerebrum via the polysynaptic circuit. The input stimulus is captured by the pond then crosses to the cerebellum profundus nucleus to the thalamus then to the cerebrum cortex<sup>5</sup>.

Music is one of effective stimulus that can improve fetal intelligence<sup>6</sup>. Music that can be used as a stimulus is classical music from Mozart. Study in mice that received Mozart’s music exposure, the number of neuron cells was higher than group with Beethoven and Chopin’s exposure<sup>6</sup>. Mozart’s music with a frequency of 75-10,000 Hz and intensity of 70-130 dB provides a lower apoptotic index than other music<sup>7</sup>. Gamelan musics are the original music from Indonesia and divided into big three gamelan according to the area of origin, that are Javanese, Balinese and Sundanese.

The aim of the study is differences of the number of neuron cells in the *cerebrum and cerebellum Rattus norvegicus* offspring between those exposed to Mozart music, Javanese gamelan, Sundanese gamelan, Balinese gamelan and not exposed to music during pregnancy.

**Material and Method**

This was an analytic study with post test only control group design and conducted at the Pathology Laboratory of the Faculty of Veterinary Medicine, Universitas Airlangga Surabaya which had been ethically legalized before. **Participants.** Sample size in this study were five sample in each group that randomly divided into five groups. Total sample were 25 rats. Pregnant *Rattus norvegicus* aged 2-3 months and fulfilled the criteria of study subjects were healthy, weighing 110-130 grams and gestational age 19-20 days. *Rattus norvegicus* mothers that was sick or dies during treatment and the *Rattus norvegicus* offspring dies or born before the gestational age 19th day can’t be used. **Intervention.** Each sample was given treatment

according to the group which were given Mozart music exposure, Javanese Gamelan exposure, Sundanese gamelan exposure, Balinese Gamelan exposure and not given music exposure from the gestational age 10th until 19th day for one hour in a soundproof box to anticipate maybe *Rattus norvegicus* can hear any voices from outside. Music was presented by using Windows media player program with 65 dB intensity using Sound level meter. **Outcome.** Brain samples were taken after *Rattus norvegicus* offsprings were born by *sectio caesar* on the 20<sup>th</sup>-day pregnancy, then their brains were taken. For one preparat contains 3 brains sample. Using *Hematosicline-Eosin (H-E)* staining with dark blue nuclei and viewed with 5x visual field with 400 magnification after that, samples counted the number of neuron cells. The data was carried out a comparative test using ANOVA test and LSD (Least Significant Difference) to see the differences in each group.

**Findings:** Pregnant *Rattus norvegicus* were randomly grouped and no rats deaths were found in pregnant *Rattus norvegicus*. the three heaviest, medium and lightest of offspring *Rattus norvegicus each group* were did decapitation, made into one preparation and stained. The Shapiro-Wilk test showed a normal distribution of *Rattus norvegicus* weight data ( $p > 0.05$ ).

Pregnant *Rattus norvegicus* were randomly grouped and no rats deaths were found in pregnant *Rattus norvegicus*. the three heaviest, medium and lightest of offspring *Rattus norvegicus each group* were did decapitation, made into one preparation and stained. The Shapiro-Wilk test showed a normal distribution of *Rattus norvegicus* weight data ( $p > 0,05$ ).

**Table 1: Mean body weight Rattus norvegicus mothers and offspring.**

Group	BW Mothers			BW offspring		
	Mean	SD	p	Mean	SD	p
Control	119,8	3,34	0,211	0,49	0,03	0,561
Mozart	121,8	3,49		1,74	0,82	
Java	121,2	4,65		1,56	0,92	
Sunda	121,2	4,08		1,51	0,97	
Bali	120,2	4,14		1,30	0,66	

Based on the table 1, The highest mean *Rattus norvegicus* body weight was Mozart exposure group ( $121.8 \pm 3.49$ ) and the highest mean body weight offspring was the Mozart group ( $1.74 \pm 0.82$ ).

**Table 2: Characteristics numbers of neurons cells of *Rattus norvegicus* offsprings.**

Group	cerebrum			cerebellum		
	Mean	SD	p	Mean	SD	p
Control	12,56	0,97	0,896	8,68	0,72	0,858
Mozart	22,08	2,21	0,399	13,08	1,15	0,721
Java	18,24	1,49	0,951	10,76	1,73	0,697
Sunda	17,84	3,2	0,394	10,64	1,99	0,892
Bali	17,2	4,21	0,403	9,16	0,63	0,884

Based on table 2, The number of neuron cells of Mozart group was the group with the highest average on cerebrum (22.08 ± 2.21) and cerebellum (13.08 ± 1.15).

**Analysis of the Results on Cerebrum:** The results of the normality test showed that normal data distribution so we used ANOVA and *Post Hoc LSD* for difference each group. Table 3 shown the results of the that there was a significant difference of numbers of neuron cells between all group (p<0,005).

**Table 3: Anova and post hoc LSD test result**

Group	P			
	Mozart	Java	Sunda	Bali
Control	0,000*	0,003*	0,016*	0,013*
Mozart		0,036*	0,022*	0,010*
Java			0,818	0,550
Sunda				0,712
Anova*	0,001			

Table 3 shown that the number of neuron cells from *Rattus norvegicus* offspring on cerebrum have significant differences between control group and all of groups study and Mozart’s music exposure group has also significant differences with all groups.

**Analysis of the Results on Cerebellum:** Table 4 shown the results that indicate there is a significant differences of numbers of neuron cells between all group p=0,001.

**Table 4: Anova and post hoc LSD test result**

Group	p			
	Mozart	Java	Sunda	Bali
Control	0,000*	0,025*	0,034*	0,583
Mozart		0,014	0,010*	0,000*
Java			0,891	0,078
Sunda				0,101
Anova*	0,001			

Table 4 shown that number of neuron cells of *Rattus norvegicus* offspring on cerebellum have significant differences between control group and all groups of music exposure except Balinese gamelan music exposure (p = 583). Mozart’s music exposure group also has significant.

### Discussion

Classical music has proven to have a good stimulating effect to improve brain function. *Rattus norvegicus* with Mozart’s music exposure have higher a number of neuron cells than Beethoven and Chopin’s music exposed<sup>7</sup>. The study of Mozart’s composition in humans proves that the provision of Mozart’s composition affects the fetal biophysical profile where there was increased in the rate of acceleration, the length of acceleration, increased fetal heart rate during acceleration, and the amount of fetal motion due to exposure to Mozart composition during the day<sup>10</sup>.

The musical component consists of intensity, frequency, beats and major-minor tones. Mozart’s music has high rhythms, melodies and frequencies that can stimulate creative areas and motivate the brain, so as to be able to calm listeners, improve concentration, memory and spatial perception<sup>11</sup>. This study was found that there were differences on the number of cerebrum and cerebellum neuron cells of *Rattus norvegicus* offsprings whose parents were exposed to Mozart’s music with those who were not exposed to music during pregnancy. the results had been supported by of a previous study that Mozart’s music exposure increased the number of neuron cells compared to without music exposure<sup>12</sup>. Other studies mentioned that more stimuli from the environment, then more synapses form and then more number of neuron cells that survive not to be apoptosis<sup>13</sup>.

Mozart was music which best combination of sounds with frequency, intensity, rhythm, timbre and melody<sup>4</sup>. The theory was suitable with the results of our study and the application of Mozart’s music also affects the average expression of higher BDNF where BDNF has defense capabilities and the potential to activate the growth of neurons<sup>14,15</sup>. In this study the only modifiable musical element was the intensity. So for all types of music exposed have been adjusted to the intensity of 65 db using a sound level meter. Noise exposure (95 dB supersonic for 1 hour) in experimental animals resulting in impaired growth, decreased neurogenesis in the

hippocampus and impaired spatial ability<sup>16</sup>. Whereas, experimental animals with music exposure (65 dB for 1 hour) found increased neurogenesis and higher spatial ability.

Another result of this study was there were differences on the number of neuron cells in the cerebrum and cerebellum between those exposed to Javanese and Sundanese gamelans music with those not exposed to music. The brain that grows in an environment with rich stimulus has a thicker cortex, a larger nucleus of neuron cells and more glia cells and also have more dendritic sites that allow more synapses to be formed so that brain capacity will be increased. Javanese gamelan is a gamelan music originates from Java island, Indonesia. This music have slow harmony, consistent tone color, and low pitch while Sundanese gamelan music was original music from the Sunda region, West Java<sup>17,23</sup>. This music also has the characteristics of a slow harmony, lively and dominated by musical instruments such as flutes, degung and lutes<sup>17,23</sup>.

Slow tempo gamelan music like Javanese and Sundanese gamelan has a beat which almost same as Mozart's music, which is approximately 60 beats/minute<sup>9</sup>. Where the beat is in accordance with the mother's heart rate. Gamelan music was music which using the Pelog and Slendro scales (*laras*). Slendro was group of pentatonic scales (*laras*) which are usually cheerful, lively and joyful and the Pelog scales was exactly the same as the major pentatonic scales (5 tones). Generally it is played with a state of calm, respect, noble and whole<sup>18</sup>. Javanese and Sundanese gamelans pelogone usually played using a major base tone and the majority of major notes are same as Mozart which is dominated by major tones<sup>19</sup>.

The Javanese and Sundanese gamelan exposure groups have difference number of neuron cells on cerebellum with not music exposure group but there was no difference between Balinese gamelan exposure group and the control group. Balinese gamelan was original music from Bali island which having a strong character and most fast rhythm because Balinese gamelan has a lot of music equipments that was shaped like a small cymbal called Ceng-Ceng that was made sounds loud and played quickly<sup>20</sup>. Javanese and Sundanese gamelans has a softer tone compared to Balinese Gamelan with harder and faster tone<sup>21</sup>. Balinese gamelan also has pelog and slendro scales. The pelog scales were played using a minor basic tone<sup>22,25</sup>. This is different which different

with classical music which dominated by major tones.

Mozart's music exposure group has higher numbers of cerebrum and cerebellum neurons than all gamelan exposure group. Previous study explained that the sensitivity of the basilar membrane at the base of the chinchilla cochlea obtained sensitivity at a frequency of around 8000 Hz which is useful for charging brain cells<sup>23</sup>. The music used in this study has been analyzed using the cool edit pro 2.0 software which Mozart has a range of 8,000 Hz, while Javanese, Sundanese and Balinese gamelan music have range 15,000 Hz. This frequency is higher than Mozart's music. This difference of frequency will be captured differently by cochlear photocopying, so the response to the brain will be different. Mozart's music has the best combination to be stimulation during pregnancy.

## Conclusion

The exposure of Mozart's music during pregnancy has an effect on number neurons in the cerebrum and cerebellum of *Rattus norvegicus* offsprings and exposure compared to the Javanese gamelan, Sundanese gamelan and Balinese gamelan. For the next study can be added from other brains composition like glia cells, sinapsin or bdnf.

**Conflict of Interest:** There was no conflict of interest in this study.

**Ethical Clearance:** This study was received ethical approval from the Health Research Ethics Committee, Faculty of Dental Medicine, Universitas Airlangga.

# Correlation the Components of Health Belief Model and the Intensity of Blood Tablets Consumption in Pre-Conception Mother

Evita Kumala Dewi<sup>1</sup>, Sri Umijati<sup>2</sup>, Aditiawarman<sup>3</sup>

<sup>1</sup>Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia, <sup>2</sup>Department of Public Health - Preventive Medicine, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia, <sup>3</sup>Department of Obstetrics and Gynecology, Faculty of Medicine, Universitas Airlangga, Dr. Soetomo Hospital, Surabaya, Indonesia

## Abstract

**Introduction and Objective:** The high number of prevalence of anemia in women of childbearing age has reached 22.7%. Anemia causes complication which increase maternal mortality rate, low birth weight, and stunting. Government efforts to tackle anemia through the blood tablets program have not reduced the prevalence of anemia. The coverage of blood tablets in pre-conception mothers in Tambakrejo Public Health Center is still at a low level with 64.22%. The side effects of blood tablets such as nausea, vomiting, constipation, and black defecation often make the consumers feel uncomfortable. Pre-conception mother perceptions can be figured out by measuring instruments in the form of Health Belief Model (HBM). This study was conducted to analyze the correlation the components of HBM and the intensity of blood tablet in pre-conception mothers.

**Material and Method:** This study used an observational analytic method with a cross-sectional study design. The samples were 37 pre-conception mothers were collected through random sampling technique. The independent variables consisted of perceived susceptibility, severity, threats, benefits, barriers, and self-efficacy. Meanwhile, the dependent variable was the intensity of blood tablets in pre-conception mothers. This study also used questionnaires as an instrument. As for the data analysis, it was done using the Mc-Nemar test.

**Findings:** Most pre-conception mothers have sufficient perceived of susceptibility (62.2%), severity (54.1%), and threats (56.8%) of anemia as well as the benefits, barriers, and self-efficacy to consume blood tablets (54.1%). Besides that, most of the pre-conception mothers (35.1%) have a low intensity in consuming blood tablets. The Mc-Nemar test showed a p-value by <0.05.

**Conclusion:** There is a correlation the perceived of susceptibility, severity, threats, benefits, barriers, and self-efficacy and the intensity of blood tablets in pre-conception mothers.

**Keywords:** *Health Belief Model, intensity, blood tablets, pre-conception mothers*

## Introduction

A pre-conception mother is a married woman of fertile age and is planning for a pregnancy.<sup>(1)</sup> Pre-conceptions or periods of pregnancy preparation are efficiently run for at least 2-6 months before pregnancy.<sup>(2)</sup> Women with good pre-conception preparation can reduce the occurrence of maternal and

infant pregnancy complications.<sup>(3)</sup> Nutritional adequacy during the pre-conception period will have an impact on nutritional adequacy during pregnancy and can affect fetal growth during the first 8 weeks of life in the intrauterine phase.<sup>(4)</sup> Anemia is a nutritional problem which is prone to children and women. The prevalence of anemia in Indonesia has not been decreased, anemia is found in women of fertile age has reached 22.7% and will increase in pregnancy by 37.1%.<sup>(5)(6)</sup> Anemia in developing countries can be caused by conditions of blood disorders such as thalassemia, malaria, worm infections, and most often due to iron deficiency and folic acid during the preparation of pregnancy to delivery.<sup>(7)</sup> The Centers Disease Control and Prevention (CDC), recommends all women of childbearing age to consume iron supplements of 60 mg and folic acid of 0.4 mg per day.<sup>(5)</sup> TTD for preconception mothers is consumed once a week for 1-2 months. The Minister of Health Regulation (Permenkes) Number 75 of 2013 concerning Nutritional Adequacy recommended for the Indonesian recommends that the need for Fe(iron) for women in childbearing age is 26 mg per day.<sup>(8)</sup> Oral of TTD may cause side effects on the gastrointestinal tract in some people, such as heartburn, nausea, vomiting, diarrhea, constipation, and black defecation.<sup>(9)</sup> Iron needs for pre-conception are crucial to avoid iron deficiency or anemia which can lead to complications in pregnancy such as miscarriage, Intrauterine Growth Restriction (IUGR), neonatal asphyxia, and postpartum bleeding.<sup>(10)</sup> Folic acid is important to support fetal growth early in pregnancy.<sup>(7)(10)</sup> Adequate consumption of folic acid can reduce the risk of disability in the fetus such as spina bifida.<sup>(11)</sup>

The Health Belief Models (HBM) is a concept of individual perceptions which able to influence feedback behavior in decision making regarding their health conditions.<sup>(12)</sup> The HBM theory according to Rosenstock consists of several types of perceptual models, including perceived susceptibility, severity, threats, benefits, barriers, and self-efficacy. The concept of HBM theory states that perceived susceptibility and severity of an illness can affect the perceived of threats. This means that when an individual feels that the disease might be prone to her and is a serious illness, the person will tend to perceived threats posed as a health disorder. Perceived of benefits and barriers obtained may influence each other in the prevention and treatment behavior of an illness. Individuals tend to make decisions if the benefits obtained will outweigh the problems. The

benefits of prevention and treatment are more decisive than the possible problems.<sup>(12)(13)</sup> Perceptions of have a direct influence on an individual perceived of self-efficacy. Individuals will perform health behaviors if the individual believes that the effort he or she is doing is useful and believes that they can overcome the problems.<sup>(12)</sup> Factors of individual awareness about the importance of maintaining balanced nutrition and the low nutritional adequacy of the pre-conception period need to be addressed in order to improve the health of the mothers and children. The low consumption of blood tablets is still low due to its side effects that are perceived as barriers by individuals. However, these individuals still have a low awareness of the benefits obtained, which can prevent complications of anemia. Individuals with low awareness also tend to feel that anemia is not a serious disease and can threaten health. This study was conducted to analyze the correlation components of HBM and the intensity of blood tablets consumption in pre-conception mothers.

## Material and Method

This research was conducted in the working area of the Tambakrejo Public Health Center. The design of this study is an observational analytic with cross sectional design. The sampling was done through random sampling technique with the number of samples as many as 37 pre-conception mothers who meet the inclusion criteria, namely married and planning a pregnancy. The sample exclusion criteria were mothers with reproductive organ disorders and contra indications to the consumption of blood tablet. The independent variable consists of perceived of susceptibility, severity, threats, benefits, barriers, and self-efficacy. The dependent variable is the intensity of blood tablets consumption. The instrument for this research is in the form of a questionnaire consisting of 27 parameters. The respondent's perception indicator uses the calculation of T score formula and standard deviation to avoid the bias value. The scale of the perception data is divided into three categories, adequate ( $T\text{-score} > \text{mean} + \text{sd}$ ), sufficient ( $\text{mean} - \text{sd} < T\text{-score} < \text{mean} + \text{sd}$ ), and deficient ( $T\text{-score} < \text{mean} - \text{sd}$ ).<sup>(14)</sup> As for the indicators of the intensity of blood tablet consumption, the researcher used assumptions, namely, high ( $>6$ ), moderate (3-6), and low ( $<3$ ) times over the past two months. The data was analyzed through the Mc-Nemar test in the SPSS program.

**Findings:** Based on the respondents characteristics data, the highest amount of respondents was in the age

category of 20-25 year old category with 15 people (40.5%). The lowest age of respondents was 22 years old and the highest with 44 years old and the average age of respondents was 29 years old with a standard deviation of 1,300. The respondents with senior high school education of 26 (70.3%), while respondents who worked as a private company employees as many as 19 (51.4%).

**Table 1: Correlation of Perceived Threats with Intensity of Blood Tablets Consumption**

Perceived Threats	Intensity Consumption of Blood Tablets					
	High		Moderate		Low	
	N	%	N	%	N	%
Adequate	3	25	0	0	0	0
Sufficient	8	66,7	12	100	1	7,7
Deficient	1	8,3	0	0	12	92,3
Total	12	100	12	100	13	100

Individuals who believe that they are susceptible will perceived anemia as a serious disease, and pose a health threats, which they will tend to try to prevent or treat the illness.<sup>(12)(13)</sup>The results showed that the majority of respondents had low intensity of consumption, most of them were respondents with perceived susceptibility categories with 11 respondents (84.6%), and lower severity degrees with 12 respondents (92.3%).The Mc-Nemar test data analysis on the three components of HBM obtained p values of 0.004, 0.029, and 0.019 or  $p < \alpha$  (0.05) respectively, which means that there is a correlation between the perceived susceptibility and consumption intensity of blood tablets for anemia prevention. Respondents who have perceived of susceptibility, severity, and sufficient threats to anemia should feel that anemia may have a bad impact, thus the individual must increase the intensity of consumption of the blood tablets. However, in this study respondents with perceived of susceptibility, severity, and threats are quite likely to ignore and assume that anemia is not a disease that will cause adverse effects, which made them tends to have weak intensity of consumption. This also happens because according to respondents, they do not feel susceptible to anemia, do not think anemia is a serious disease, and poses a health threat therefore they will not try to prevent or treat it. This research is in line with the research conducted by Aryanti (2018) who stated that perceptions of susceptibility and threats are related to compliance with HIV testing in pregnant women.<sup>(15)</sup>Based on the cross tabulation test analysis, it

is found that the respondent felt that they are susceptible and threatened by anemia, thus they will tend to try to prevent or threats it by taking blood tablets during the pre-conception period. Although, this study is inversely proportional to the research conducted by Annisa (2017) who found that there was no correlation between perceived susceptibility and threats with the intention of young women to take blood tablets.<sup>(16)</sup>This happens because the young women are reluctant to discuss anemia, which made them tend not to know that anemia is prone to women and should be avoided to prevent complications.

**Table 2: Correlation of Perceived Benefits with Intensity of Blood Tablets Consumption**

Perceived Benefits	Intensity Consumption of Blood Tablets					
	High		Moderate		Low	
	N	%	N	%	N	%

Sufficient	8	66,7	11	91,7	1	7,7
Deficient	4	33,3	1	8,3	0	0
Total	12	100	12	100	13	100

**Table 4: Correlation of Perceived Self Efficacy with Intensity of Blood Tablets Consumption**

Perceived Self Efficacy	Intensity Consumption of Blood Tablets					
	High		Moderate		Low	
	N	%	N	%	N	%
Adequate	4	33,3	0	0	0	0
Sufficient	8	66,7	11	91,7	0	0
Deficient	0	0	1	8,3	13	100
Total	12	100	12	100	13	100

A person will take into account the susceptibility and degree of risk of an illness, then the person will consider the benefits and barriers that will be received so as to affect the self-efficacy to attempt health behaviors.<sup>(13)(17)</sup>

Based on the results of the data analysis with the McNemar test which obtained p value in the perceived barriers of 0.007, the benefits and self-efficacy with 0.011 or  $<\alpha$  (0.05) respectively, which means there is a correlation between perceived benefits, barriers, and self-efficacy, with the intensity of blood tablets consumption in pre-conception mothers to prevent anemia. Most pre-conception mothers who claim to receive good benefit or have good perceived of benefits have assessed various risks of anemia. But the results of these considerations may vary according to the information and the process of managing the information which leads to perception that will be applied as health behavior. Respondents who have perceptions of sufficient benefits in consuming the blood tablets should be able to consider these benefits to increase their intensity of consumption. But in this study, the respondents with perceived of benefits were quite likely to still consider their barriers in consuming the blood tablets, therefore they tended to have low intensity of consumption. This also happened because according to the respondents, they felt that the barriers which they experienced were greater, thus they refuse to prevent or treat them. These findings are in line with the research conducted by Afifah (2018) which stated that there is a correlation between the perceived of benefits, barriers, and self-efficacy with efforts to prevent TB disease in adolescents.<sup>(18)</sup> On the other hand, Hendrastuti's research (2018) says there is no relationship between perceived of benefits, barriers, and self-efficacy perceived by mothers towards basic immunization status in their children.<sup>(19)</sup> This happens due to the respondents still consider negative obstacles or impacts caused by prevention and treatment efforts. Based on the HBM theory, although the benefits of action are more decisive than the barriers, if these barriers are massive, they will certainly hinder and inhibit the health behavior.<sup>(20)</sup>

### Conclusion

The Health Belief Model consists of six interrelated components. The perceived of susceptibility and severity can affect perceptions of threats. While the perception of benefits and barriers tends to be a consideration for decision making. The perceived of susceptibility, severity, threats, benefits, and constraints that may affect perceived of self-efficacy. This study shows that there is a correlation between perceived of susceptibility, severity, threats, benefits, barriers, and self-efficacy with the intensity of blood tablets consumption in preconception mothers.

# Factors Affecting the Survival of Antiretroviral (Arv) Therapy Patients in One of the Hospitals in Jakarta 2007-2017

Fauziyah Hasani<sup>1</sup>, Nuning Maria Kiptiyah<sup>2</sup>,  
Mondastri Korib Sudaryo<sup>3</sup>, Elisabeth SL Handayani<sup>4</sup>

<sup>1</sup>Masters Epidemiology Program, Faculty of Public Health, University of Indonesia, <sup>2</sup>Department of Epidemiology, Indonesian Faculty of Public Health, University of Indonesia, <sup>3</sup>Department of Epidemiology, Indonesian Faculty of Public Health, University of Indonesia, <sup>4</sup>RSPAD Gatot Soebroto Jakarta

## Abstract

**Context:** Antiretroviral therapy (ARV) is a revolution in the treatment of HIV/AIDS patients. Some prognosis factors that are known to affect the survival of ARV patients are age, gender, education level, marital status, clinical stage, functional status, initial CD4 level, transmission of HIV, opportunistic infections, type of ARV used, and adherence. This study aims to determine prognosis factors that influence the survival of ARV therapy patients at the Central Army Hospital (RSPAD) GatotSoebroto Jakarta in 2007-2017. The design of this study was a retrospective cohort using medical record data on ARV therapy patients at GatotSoebroto Hospital in Jakarta. The study sample was a naive ARV patient as many 812 patients. This study found the probability of survival of antiretroviral therapy patients during the 11 years of observation was 66.5%. The results of the analysis with Extended Cox show that the most significant prognosis factor affecting the survival of ARV therapy patients is opportunistic infections, where patients who have opportunistic infections have a risk of death 9.5 times compared to those who do not have opportunistic infections.

**Keywords:** Survival, antiretroviral therapy, prognosis factors.

## Introduction

The revolution in the treatment of people with HIV/AIDS has occurred since 1996, where since that year Antiretroviral (ARV) therapy has been carried out on PLWHA. Some prognosis factors that affect the survival of antiretroviral therapy are transmission of HIV<sup>(4-6)</sup>, CD4 levels<sup>(4,7,8)</sup>, opportunistic infections<sup>(7,9)</sup>, nutritional status<sup>(10)</sup>, age and sex<sup>(11,12)</sup>, marital status<sup>(4)</sup>, type of work<sup>(5,12)</sup>, education level<sup>(5,9)</sup> and adherence<sup>(13)</sup>.

GatotSubroto Hospital in Jakarta is one of the referral hospitals in DKI Jakarta for ARV treatment. The

GatotSubroto Jakarta Army Hospital not only serves patients with military (TNI) backgrounds but is also one of the hospitals that is accessed by the general public. This study aims to determine the prognosis factors that affect the survival of ARV therapy patients at GatotSoebroto Army Hospital in Jakarta in the period 2007 - 2017. The outcome of this outcome is the probability of survival of ARV therapy patients based on the prognostic factors that influence it and the contribution of independent variables together.

## Material and Method

The study design used was a retrospective cohort study using a dynamic cohort population system. This study took data from medical record data from GatotSoebroto Jakarta Army Hospital in 2007-2017 for HIV/AIDS patients who received ARV therapy.

The source population of this study was all HIV/AIDS patients who received ARV therapy. Eligible populations are determined based on inclusion and

---

e-mail: fauziyah.hasani03@gmail.com

exclusion criteria. The inclusion criteria were HIV/AIDS patients who started the first ARV therapy (naive) based on medical records dynamically (during the observation period January 2007 - December 2017), adults >15 years old, starting treatment maximum 31 December 2016. While the exclusion criteria are incomplete patient data for research. The minimum sample size of the study was obtained from the sample calculation formula hypothesis test two different rates for survival analysis, that is equal to 352 subjects. The sampling technique in this study was exhaustive sampling which means that all members of the population can be taken as samples in the study, which collected 812 data.

The outcome of this study was the time of death, within the time of observation until 2017. The dependent variable produced was the survival of ARV therapy patients in units of days and the survival status of ARV therapy patients. The independent variables studied included age, gender, education level, marital status, clinical stage, functional status, initial CD4 level, opportunistic infections, types of antiretroviral drugs used, HIV transmission, and adherence.

Analysis of the data used Kaplan Meier, Log Rank Test, and Proportional Hazard (PH) Assumption with the Goodness Of Fit (GOF) test. There were one independent variables that did not fulfill the PH Assumption so that the multivariate analysis used Extended Cox.

## Result

Most ARV therapy patients are seen as male patients in productive age. Age variables use the cut off point based on the ROC curve, with a sensitivity of 52.4% and specificity of 46.6%.

The clinical stage categorization is in line with the categorization of CD4 levels, and seen in 2007 - 2017 more HIV/AIDS patients started therapy after the disease reached stage III or IV or with CD4 levels reaching <200 cells/mm<sup>3</sup>. Categorization of adherence to taking medication using indicators is negligent in scheduling drug taking with variations in the number of drugs.

**Picture 1. Cumulative Probability of Survival of Patients on ARV Therapy at GatotSoebroto Army Hospital in 2007 - 2017**

From the graph, there were 166 patients (20.4%) as event and 646 patients (79.6%) as sensor. From observations for 11 years (4007 days) from January 2007 - December 2017, the last event occurred on the 3550th day, and obtained a cumulative survival probability of 66.5% with a standard error of 0.043.

The results of observations from 2007 to 2017 in this study showed that about 79.6% of patients categorized as censors, 35.7% of patients still continued treatment until the observation was completed, 19.6% of patients

were loss to follow-up and 24.3% of patients moved hospital (refer out) before the observation is complete.

The final model of Extended Cox showed that the factor that significantly affected the survival of other ARV therapy patients was the level of education (HR = 2,69; 95% CI: 1,64 - 4,42), clinical stage (HR = 2,02; 95% CI: 1,43 - 2,84), functional status (HR = 5,07; 95% CI: 3,38 - 7,60), transmission of HIV (HR = 1,77; 95% CI: 1,29 - 2,42), and opportunistic infections (HR = 9,49; 95% CI: 1,31 - 68,64).

**Table 2. Final Model of Extended Cox Analysis Factors Affecting the Survival of ARV Therapy Patients at GatotSoebroto Hospital in 2007-2017**

Variable	Coef (B)	SE	P	HR <sub>Adj</sub>	95%CI
<b>Education Level</b>					
College				1	
≤ High School	0,991	0,253	0,000	2,69	1,64 – 4,42
<b>Clinical Stage</b>					
I-III				1	
IV	0,701	0,174	0,000	2,02	1,43 – 2,84
<b>Functional Status</b>

<b>Opportunistic Infection</b>					
No				1	
Yes	2,251	1,009	0,026	9,49	1,31 – 68, 64

\*Multivariate analysis was performed using the backward method. Variables that are released in stages are step 1: adherence, step 2: age, step 3: gender, and step 4: initial CD4 level.

## Discussion

This study uses a retrospective cohort design with survival analysis so that all subjects can be taken into account the time contribution given until the observation ends. The causal effect that results from this study can be justified because the prognosis factors for survival of ARV therapy patients precede the consequences (death). Selection bias in cohort studies can occur due to lost to follow-up or loss of subjects of observation before the observation period ends. However, because the percentage of lost to follow-up is less than 20% so it can still be tolerated. Information bias that might occur in this study is information about medication compliance which is only based on adherence to the promise of taking the drug, but not based on compliance with taking the drug. However, the possibility of this bias occurs in both groups, so that the bias that occurs is categorized as non-differential misclassification.

The probability of survival for 11 years obtained from this study was 66.5%. This result lower than the study conducted by Lela Amelia (2007) in Fatmawati General Hospital who found a 33-month survival probability of ARV therapy patients at 78.2%, but higher than the Sri Rami (2008) study that had a 3-year survival probability at RSKO Jakarta at 40.60%. What needs to be noted was the number of patients referred out. Judging from the

adherence factor, the patients referred out, which almost all belonged to the obedient category, so we can assume the patients who referred out were still alive until the end of the observation period. Based on the results of multivariate analysis, several prognosis factors affecting the survival of ARV therapy patients are education level, clinical stage, functional status, transmission of HIV, and opportunistic infections.

From the survival curve it was found that the cumulative survival probability of patients with tertiary education was 78.5%, while patients with education ≤ high school amounted to 62.6%. Variables of education level statistically influenced the survival of ARV therapy patients with P 0,000 (HR 2,69, 95% CI: 1,64 - 4,42), in other words patients with ≤high school educational levels equivalent had 2.7 times greater risk of death than college education level. This is in line with the Apidechkul (2011) study which states that the survival of ARV therapy patients is lower in people with lower levels of education because they are far from health information and health services caused by poverty. However, this result is different from the results of the research by Guerreiroet. al (2002) which states that highly educated ARV therapy patients have a risk of death of 15.58 times than those of low-educated ARV therapy.

The division of clinical stadium categories was divided into groups starting ARV therapy at clinical stages I, II, III and in clinical stage IV. The division of this category is based on the data of the patients studied starting from 2007 where in the range of 2007-2011 the policy of ARV therapy began after the patient had a CD4 level <200 cells / mm<sup>3</sup> or had entered stage IV, whereas from 2012 onwards the policy changed where the patient can start ARV therapy with CD4 levels <350 cells / mm<sup>3</sup> or at clinical stages I, II and III. Clinical stage variables were statistically influencing the survival of ARV therapy patients with P 0,000 (HR 2,02, 95% CI: 1,43 - 2,84), in other words patients who started ARV therapy at IV clinical stage had twice the risk of death compared to patients who start ARV therapy at clinical stages I, II and III.

Functional status variables statistically affected the survival of ARV therapy patients with P 0,000 (HR = 2,74; 95% CI: 1,81 - 4,14) (HR = 5,07; 95% CI: 3,38 - 7,60) in other words the group of patients with ambulance functional status has a risk of death 2.7 times compared to the group of patients with functional status of work, while the group of patients with lie down functional status has a risk of death 5.1 times compared to the group of patients with functional status of work. From the results of the study, it was found that there was a dose response relationship in functional status variables.

Transmission of HIV variable were statistically significant for the survival of ARV therapy patients with P 0,000 (HR 1,77; 95% CI: 1,29 - 2,42), in other words patients who contracted HIV because IDU use had a 1.8 times greater risk of death than because of sexual intercourse. This is in line with the research of Mahdi (2005) which states that survival in patients with IDU transmission is shorter than non IDU. Michael Carter reports, people with HIV from heterosexual, or homosexual risk groups were more likely to survive longer than five years after taking ARVs than those who contracted HIV through injecting drug use (97% vs. 97% vs. 83%). Injecting drug use in people with HIV / AIDS has a risk of death (HR of 8.81 times compared to non-injecting drug users as in sexual behavior (Gorgoset. Al, 2006). Injection drug use will more easily spread intravenously to poison the whole blood flow so as to facilitate infection with the HIV virus which will gradually reduce immunity (Apidechkul 2011).

Opportunistic infection variables significantly

affected the survival of ARV therapy patients with P 0.026 (HR 9.49; 95% CI: 1.31 - 68.64), in other words patients who had opportunistic infections had a 9.5 times greater risk of death than patients who did not have opportunistic infection. The results of this study are in line with the research of Nastiet. al (2003) who stated in the results of his research that HIV / AIDS sufferers who had diseases due to opportunistic infections had a 2.8 times the risk of death (HR) to die compared with patients without opportunistic infections. Whereas from the results of the research Guerreiroet. al (2001) stated that HIV / AIDS sufferers with opportunistic infections had a risk of death (HR) of 3.03 times compared to patients without opportunistic infections. The relationship between opportunistic infections and the survival of ARV therapy patients in the study showed a significant relationship, but the range of HR confidence intervals obtained was quite wide. This is probably due to the low number of respondents who did not have opportunistic infections and only 1 (one) event occurred in this group.

## Conclusion

The probability of surviving ARV patients at the GatotSoebroto Army Hospital in Jakarta from 2017 to 2017 is 66.5%. Factors affecting the survival of ARV therapy patients include education level, clinical stage, functional status, transmission of HIV and opportunistic infections. The most dominant factor affecting the survival of ARV therapy patients is opportunistic infections, where patients who have opportunistic infections have a risk of death 9.5 times compared to those who do not have opportunistic infections.

<sup>1</sup>Student of Bachelor Program, Health Policy and Administration Departement, Faculty of Public Health Universitas Airlangga, <sup>2</sup>Lecturer of Faculty of Public Health Universitas Airlangga

## Abstract

**Background:** In the last 3 years outpatient installations have not been able to reach the specified patient satisfaction standard. The existence of a tiered BPJS system made the visit of the Medical Rehabilitation Poly to be poly with the most number of visits among other poly. After conducting the data survey at the beginning it was known that the patient's satisfaction was still low at the Medical Rehabilitation Poly with 70% of patients stating that they were not satisfied with the facilities and services available.

**Objective:** The purpose of this study was to analyze the respondents' assessment of service convenience at the Medical Rehabilitation Center.

**Method:** This study was analytic observational with a cross sectional approach. The population in this study were all patients at the Medical Rehabilitation Poly in 2017. The samples used were 333 respondents. The study was conducted using a questionnaire by asking questions directly to the respondents.

**Result:** Based on service convenience dimensions, respondents rated decision convenience as good, very good access convenience, good transaction convenience, and good benefit convenience. There is only one variable that is poorly assessed, namely service waiting time in transaction convenience.

**Conclusion:** The conclusion of this study is that respondents considered that service convenience in the Medical Rehabilitation Poly of Rumah Sakit Islam A. Yani Surabaya was good.

**Keywords:** *Assessment, Satisfaction, Service Convenience.*

## Introduction

Health is a basic need for society. Today people are becoming increasingly aware of the quality or quality of health services that are able to provide satisfaction to the community itself. Satisfaction is closely related to the expected service and the reality of the service that has been provided. Satisfaction will be fulfilled if the service provided in a hospital is felt to be in line with expectations.

Consumers or patients in choosing to utilize health services from a hospital prioritizing comfort is one of the most important things<sup>2</sup>. It is very important to understand the concept of comfort that consumers want (the target market) of a hospital because the increasing technology

that facilitates public access to various hospitals with competitive prices causes consumers to have many choices and increasingly want comfort<sup>7</sup>. Convenience of consumers needs to be evaluated or measured in order to improve the quality of health services. Five types of customer convenience that can be identified, namely (1) Decision Convenience, consumer perceptions of deciding to use a service, (2) Access Convenience, ease of access to service places, (3) Transaction Convenience, ease of transaction when serving, (4) Benefit Convenience, ease in obtaining conformity between benefits obtained with the sacrifices made, (5) Post Benefit Convenience, reuse of these services.

In 2018 patient satisfaction for the Outpatient Installation of the Rumah Sakit Islam A. Yani Surabaya

with a satisfaction score of 76.23% still did not meet the patient satisfaction standard of  $\geq 90\%$ . During the last 3 years based on data from the medical record unit, outpatient units experienced a rapid increase in visits. This is also due to the existence of a tiered referral system from BPJS. Among all work units, the Medical Rehabilitation Poly is a work unit with the highest number of visits in 2017.

After conducting the initial data survey and interviewing 30 patients at the Medical Rehabilitation Police, they said they were not satisfied with the facilities and services available. So the problem raised in this study is the low patient satisfaction at the Medical Rehabilitation Poly in 2018.

The purpose of this study was to analyze the respondents' assessment of service convenience at the Medical Clinic of the Yogyakarta Yani Islamic Rehabilitation Hospital.

### Material and Method

This study is an observational analytical study, in which data and information are collected without intervention or treatment in the population. The research design was reviewed in terms of the time of the study, this study used a cross sectional research approach, namely data collection and research subjects were only observed once at a certain time or time.

The population in this study were all patients in the Medical Rehabilitation Poly of the Y Yani Hospital in Surabaya in 2017. The number of patient visits in 2017 was 29761. The sample criteria in this study were respondents who had received service, respondents were aware and were able to communicate with well, the respondent is willing and agrees to fill out the questionnaire. The sample for this study was 333 patients.

This research was carried out at the Medical Rehabilitation Clinic of the Islamic Hospital of A. Yani Surabaya during April - May 2019. The research was conducted by asking respondents directly about questions related to their assessment of service convenience.

### Result

**Service Convenience:** Convenience services are consumer perceptions of time and effort in using services<sup>1</sup>. This conceptualization uses the dimensions of time and effort as convenience (saving time or effort)

or costs or the burden of inconvenience (waste of time and or effort). There are five types of identification, namely decision convenience, access convenience, transaction convenience, convenience benefits and post benefit convenience. Each type of convenience reflects the stages of consumer activity related to the purchase or use of services<sup>1</sup>.

- a. **Decision Convenience:** Consumer perceptions of the cost of time and effort to make a purchase decision or service use. Decisions include consumers who will do themselves or buy services, choose service suppliers and determine the specific services to be purchased<sup>5</sup>.
- b. **Access Convenience:** Consumer perceptions of the cost of time and effort to initiate service delivery. Consumers do when deciding to use one service, access is needed to reach or receive these services such as actions that must be taken by customers to order or request services / services, for example consumers must come directly, order with telephone, internet and fax)
- c. **Transaction Convenience:** Customer perception of the cost of time and effort to enter into a transaction. This is done when the consumer has decided and accesses the services, then the consumer participates in receiving services<sup>6</sup>. This type of convenience focuses on the actions that consumers must take in obtaining the right to use services<sup>4</sup>.
- d. **Benefit Convenience:** Customer perceptions of the cost of time and effort to experience the core benefits or services<sup>5</sup>. Consumers can estimate the fairness between the direct and indirect costs spent with the core benefits obtained. Consumers who have a negative perception of benefit convenience will have a worse effect on overall service convenience. This is due to the cumulative negative perceptions of decision, access and transaction convenience<sup>1</sup>.
- e. **Post-Benefit Convenience:** Customer perception of the cost of time and effort when contacting the service provider again after the benefit stage. This stage is felt by consumers after getting the core benefits of consumer services. This type of convenience relates to consumer needs for product repairs, maintenance and exchange. This also includes situations where a postoperative patient must follow up<sup>5</sup>.

Service quality starts from customer needs and ends at the customer's perception. This means that the

image of good quality is not based on the point of view or perception of the service provider, but based on the customer's point of view or perception. Customers are consumers who consume and enjoy company services, so customers are the ones who should determine the quality of services<sup>4</sup>.

**Respondent's Assessment of Service Convenience in the Medical Rehabilitation Poly of the Rumah Sakit Islam A. Yani Surabaya:** Respondents' assessment of service convenience at the Medical Rehabilitation Poly of Rumah Sakit Islam A. Yani Surabaya, which included decision convenience variables, access convenience, transaction convenience, and convenience benefits performed by scoring and then calculated the total score and mean. Comparison of the average results of each

service convenience variable is explained in table 1 below.

Mean 1,00 – 1,75 : Very Bad

Mean >1,75 – 2,50 : Bad

Mean >2,50 – 3,25 : Good

Mean >3,25 : Very Good

**Explanation:**

1 = very dissatisfied

2 = dissatisfied

3 = satisfied

4 = very satisfied

**Table 1: Respondent's Assessment of Service Convenience in the Medical Rehabilitation Poly of the Rumah Sakit Islam A. Yani Surabaya in 2019**

No.	Service Convenience	Score				Total Score	N	Mean	Exp.
		1	2	3	4				
<b>I. Decision Convenience</b>									
1.	Ease of information in decision making	0	7	279	47	1039	333	3,12	Good
<b>Average Assesment Decision Convenience</b>								<b>3,12</b>	<b>Good</b>
<b>II. Access Coveniencie</b>									
2,	Distance between hospital and respondent's house	7	40	160	126	1071	333	3,21	Good
3.	Costs incurred to go to hospital	0	7	159	167	1159	333	3,48	Very Good
<b>Average Assessment Access Convenience</b>								<b>3,34</b>	<b>Very Good</b>
<b>III. Transaction Convenience</b>									
4.	Presence of a doctor	0	33	210	90	1056	333	3,17	Good
5.	The existence of nurses	0	12	161	160	1147	333	3,44	Very Good
6.	Doctor's skills	0	0	209	124	1123	333	3,37	Very Good
7.	Nurse skills	0	21	271	41	1019	333	3,06	Good
8.	Doctor's modesty	0	6	228	99	1092	333	3,27	Very Good
9.	Courtesy nurses	0	7	234	92	1084	333	3,25	Good
10.	Ease of administrative procedures	7	34	258	34	985	333	2,95	Good
11.	Waiting time before receiving service	67	114	152	0	751	333	2,25	Bad
12.	Sophisticated medical devices	0	27	258	48	1020	333	3,06	Good
13.	Cleanliness of the waiting room	0	0	227	106	1105	333	3,31	Good
14.	Cleanliness of service space	0	0	141	192	1191	333	3,57	Very Good
15.	Security during service	0	14	223	96	1081	333	3,24	Good
<b>Average Assessment Transaction Convenience</b>								<b>3,16</b>	<b>Good</b>
<b>IV. Benefit Convenience</b>									
16.	Benefits obtained after service	0	25	207	101	1075	333	3,23	Good
<b>Average Assessment Benefit Convenience</b>								<b>3,23</b>	<b>Good</b>
<b>Average Assessment Service Convenience</b>								<b>3,21</b>	<b>Good</b>

As ed on table 1, it can be learned that the decision convenience dimension is considered good by the respondents. In the dimension of access convenience, the average value of the results shows a very good category. In the transaction convenience dimension, the average respondent judges good. However, on transaction convenience, the item waiting time before receiving service is considered bad by the respondent. While on the benefits convenience dimension, respondents were considered good. Overall, respondents' assessment of service convenience is good with a mean overall dimension of 3.21.

## Discussion

**Respondents' Assessment Analysis of Convenience Service at the Medical Rehabilitation Poly of the Rumah Sakit Islam A. Yani Surabaya:** At this time the patient's comfort factor is very important. The comfort felt by patients when obtaining health services will have an influence on the utilization of health services. The variables used to measure patients' convenience (satisfaction) with satisfaction in this study are decision convenience, access convenience, transaction convenience and benefit convenience<sup>1</sup>.

**Decision Convenience:** Decision convenience is a patient's perception of the time and effort that must be sacrificed in making a decision to utilize health services<sup>1</sup>. Based on the research results of the respondents at the A. Yani Surabaya Islamic Hospital Medical Rehabilitation Poly, the decision-making process and speed of decision-making to carry out medical rehabilitation services at the A. Yani Islamic Hospital in Surabaya were carried out quickly because 100% of the respondents came from BPJS, they are bound by health insurance regulations so that the decision-making process and speed of decision making are carried out very easily and quickly<sup>4</sup>.

**Access Convenience:** Access Convenience is the patient's perception of the costs, time and effort that must be sacrificed in order to be able to start to obtain health services<sup>1</sup>. Access means that health services are not hindered by geographical, social, economic, cultural, organizational or language barriers. Geographical access can be measured by the type of transportation distance, travel time and other physical barriers that can prevent a person from obtaining health services.

Based on the results of the study, access convenience at the Poli of Medical Rehabilitation of the Islamic Hospital of A. Yani Surabaya has been very good and

needs to be maintained. According to respondents' comments regarding the costs incurred in obtaining services they did not burden them. Likewise with regard to distance, the position of the A. Yani Surabaya Islamic Hospital is near shopping centers, stations, and major roads making the respondents' assessment of the distance very good because it is easily accessible.

**Transaction Convenience:** Transaction convenience is a patient's perception of the costs, time and effort that must be sacrificed to make a transaction<sup>1</sup>. The comfort type focuses on the actions that must be taken by the customer to obtain the right to use the service. The greater the effort made by respondents to get health services, the smaller the value of the convenience of transactions obtained<sup>8</sup>. Customer assessment of a service can also be influenced by the personal interaction of respondents to health workers in health services.

Based on the research results of transaction convenience at the A. Yani Hospital Surabaya Medical Rehabilitation Polyclinic, the variable presence of nurses, doctor's courtesy, and cleanliness of the service room were considered very good, while nurses 'skill variables, nurses' courtesy, administrative procedures, sophistication medical devices, cleanliness of the waiting room, and security during service are considered good. But there is one variable that is considered bad, namely the waiting time before service. According to respondents' comments, the waiting time is still too long but has increased from the previous year from the old poly room.

**Benefit Convenience:** Convenience benefit is the fourth type of convenience examined in this study<sup>1</sup>. Benefit convenience is the consumer's perception of the cost of time and effort to get the core benefits of services. This type of comfort is comfort while getting or utilizing health services<sup>7</sup>.

Based on the results of the benefits convenience study at the Medical Rehabilitation Poly of the Rumah Sakit Islam A. Yani Surabaya, respondents were considered good.

## Conclusion

he conclusion of this study is that the service convenience model is that respondents consider that service convenience in the Medical Rehabilitation Center of the Islamic Hospital of A. Yani Surabaya is good. This can be seen from the results of the study, from

the decision convenience it was considered good, access convenience was considered very good, transaction convenience was considered good, and benefit convenience was considered good. But in transaction convenience, the waiting time variable is considered bad by the respondent. This is due to the high number of patient visits in one year. So that the advice that can be given to the management of the Medical Unit of the Medical Rehabilitation Center of the Islamic Hospital of A. Yani Surabaya is to maintain the existing facilities and services because the respondents consider that the service convenience is good.

# Relationship Between Safety Promotion and Perception of the Use of Personal Protective Equipment (PPE) on Workers at Pt Aneka Gas Industri Region V East Java

I Komang Indra Irmawan<sup>1</sup>, Hario Megatsari<sup>1</sup>

<sup>1</sup>Department of Health Promotion and Behavioral Sciences, Faculty of Public Health, Universitas Airlangga Surabaya, East Java, Indonesia

## Abstract

**Context:** The behavior of not using personal protective equipment (PPE) is an unsafe decision that can increase the number of work accidents and work-related illnesses in the industrial environment. One of the factors that can influence the behavior of using PPE is individuals' perception. Perception can be analyzed using a theory called as the Health Belief Model (HBM). Cues to action according to the safety promotion is one component of HBM, which is an external factor that can influence individual's perception. Hence, this study aims to analyze the relationship between safety promotion and worker's perception about the use of PPE.

This research is a quantitative descriptive study with a cross-sectional design. The samples were chosen based on the slovinformula and obtained a total sample of 87 operating unit workers of various departments at PT. Aneka Gas Industri Region V, East Java. The independent variable in this study is the effectiveness of Safety Promotion. While the dependent variable in this study is the perception of the use of PPE. The data was analyzed using the Chi-Square correlation test.

The results show that there is a relationship between the effectiveness of safety promotion and the perception of PPE ( $p = 0.013$ ). This study concludes that there is a relationship between the effectiveness of safety promotion with the perception of the use of PPE.

**Keywords:** *Safety Promotion, Personal Protective Equipment (PPE), Health Belief Model (HBM).*

## Introduction

The rapid development of industrial sector may be affected by increased potential hazards in the workplace. If industries do not controlled their application of good occupational safety and health, it will cause increase the

number of work accidents and occupational diseases. Data from the International Labor Organization (ILO) in 2018 states that 2.78 million workers die each year due to workplace accidents and occupational diseases<sup>(1)</sup>. Heinrich's research (1959) shows that 88% of work accidents are generally caused by unsafe behavior<sup>(2)</sup>. One example of workers' unsafe behavior that has a high risk of work accidents and occupational diseases is non-compliance in the use of Personal Protective Equipment (PPE).

Non-compliance behavior using PPE can be influenced by several factors and one of them is workers' perception on the use of PPE during work. A research by Ristia (2017) revealed that perceived risk and knowledge influenced workers compliance in using PPE<sup>(3)</sup>. One

method for understanding workers perceptions is by analyzing it through the Health Belief Model (HBM) theory. There are four main types of perceptions within the HBM theory, namely the perceived susceptibility, perceived severity, perceived benefits, and perceived barriers. In its development, the HBM model is expanded by adding a couple of variables, namely self-efficacy and cues to action<sup>(4)</sup>.

According to Rosenstock (1966), cues to action was added to the HBM model based on the assumption that it would stimulate individual perceptions<sup>(5)</sup>. Thus, programs in the workplace are capable of forming or changing worker's perceptions, especially in regard to information and messages related to the use of PPE, one of which is by implementing safety promotions. According to WHO (1998), Safety promotion is a process applied at a local, national and international level by individuals, communities, governments and others, including enterprises and non-government organizations, to maintain and develop safety<sup>(6)</sup>. A research by Saragih *et al.* (2016) shows that most workers have positive perception about the use of PPE due to the exposure of safety talk carried out every morning before they start to work<sup>(7)</sup>.

As one of the leading companies in the industrial gas processing sector in Indonesia, PT. Aneka Gas Industri Region V still encounter some issues related to the use of PPE. No studies have analyzed the workers' perceptions about using PPE and the association with safety promotion that has been taken by the company. Therefore, this study aims to analyze the relationship between the company's effort to perform safety promotion with the workers' perception of the use of PPE at PT. Aneka Gas Industri Region V based on the theory of HBM.

## Material and Method

This study is based on a framework of HBM theoretical concepts that was developed by Glanz *et al.* (2015). This framework explains that cues to action can affect individual healthy behaviour, both directly and indirectly, through its influence on individual perceptions which consist of perceived risk (perceived susceptibility & severity), perceived benefits, perceived barriers, and perceived self-efficacy<sup>(8)</sup>.

This research is a quantitative descriptive research with a Cross-Sectional study. This research was conducted at PT. Aneka Gas Industri Region V, East Java, Indonesia in February-May 2019. The sample of this study includes 87 operational unit workers from various departments; the number sample was determined by Slovin formula from a total of 105 worker populations. The primary data is obtained by distributing questionnaire to the respondents. Meanwhile, the secondary data was obtained by analyzing data owned by the company, including a general description of the company and safety programs. All data that obtained are displayed in the form of narratives, tables of frequency distribution and cross tabulation using the Chi-Square correlation test.

## Result

PT. Aneka Gas Industri Region V East Java is a company that produces different types of gases that are needed for the production of other industries. The company has a Safety Health and Environment (SHE) Department who is responsible for identifying and mapping potential hazards, as well as making ideas related to the safety program. One of the safety programs that has been implemented is Safety Promotion, which includes having safety talk, safety induction, safety sign & safety training.

The majority of respondents in this study were >35 years old male workers. The majority of respondents are high school graduates and the majority of respondents are classified as workers who have work in the company for, at least, 3 years.

**1. Effectiveness of Safety Promotion:** The effectiveness of the safety promotion is measured through a questionnaire containing 14 statements that represent 5 main components of safety promotion effectiveness measurement. The measurements consists of the content of the message, types of media used, the goal target, target involvement and leader involvement. Frequency distribution effectiveness of safety promotion for each statement can be seen in **Table 1**.

**Table 1: Frequency distribution effectiveness of safety promotion**

Component of effectiveness of safety promotion	Answer	N	%
<b>Message Content</b>			
1. There is information about using PPE on Safety Promotion	Yes	79	90,8
	No	8	9,2
2. The messages on Safety Promotion are informative or explains in detail	Yes	66	75,9
	No	21	24,1
3. The messages on Safety Promotion are persuasive or invites	Yes	77	88,5
	No	10	11,5
4. The messages on Safety Promotion are emotional or has the effect of fear and deterrence	Yes	16	18,4
	No	71	81,6
<b>Media</b>			
5. The Safety Promotion is delivered using media that are easily seen and understand	Yes	84	96,6
	No	3	3,4
6. The Safety Promotion uses various and diverse media	Yes	31	35,6
	No	56	64,4
7. The Safety Promotion medias always replaced and updated	Yes	46	52,9
	No	41	47,1
8. There is a media platform that shows the Safety Promotion messages,which contains picture of thepractices, training or video	Yes	58	66,7
	No	29	33,3
<b>Goal Target</b>			
9. The Safety Promotion has delivered equally to all workers	Yes	55	63,2
	No	32	36,8
10. At least every week the workers received Safety Promotion	Yes	33	37,9
	No	54	62,1
<b>Target Involvement</b>			
11. The workers are involved in planning and making of the Safety Promotion	Yes	25	28,7
	No	62	71,3
12. The workers can give advice or feedback on the Safety Promotion	Yes	81	93,1
	No	6	6,9
<b>Leader Involvement</b>			
13. The leader of the company is involved in the planning and the making of the Safety Promotion	Yes	73	83,9
	No	14	16,1
14. Safety Promotion is given bythe SHE (Safety, Health & Environment) department	Yes	85	97,7
	No	2	2,3

Based on **Table 1**, the 4 components have a less effective category. Respondents who have assessed the messages on the Safety Promotion said that the messages weren't emotional or does not create a fear and deterrence emotion. Respondents considered the Safety Promotion doesn't use various and diverse types of media. Respondents considered the safety promotion is not applied every week. While some workers, felt that they were not involved in the design and manufacture of the safety promotion .

**Table 2: Frequency distribution total effectiveness of safety promotion**

Safety Promotion	N	%
Effective	70	80,5
Less effective	17	19,5
Total	87	100

Overall, 70 respondents (80.5%) agree that the safety promotion applied at PT. Aneka Gas Industri Region V have been effective. While as many as 17 respondents

(19.5%) say that the safety promotions that was applied is still not as effective.

**2. Perception of Use of PPE:** The perception of the use of PPE consists of 4 components, namely perceived risk, perceived benefits, perceived barriers and perceived self-efficacy. Each component consists of 5 statements that are answered based on a Likert scale.

**Table 3: Frequency distribution Perception of Use of PPE**

Perception of the use of PPE	Category	N	%
Perceived Risk	Positive	76	87,4
	Negative	11	12,6
	Total	87	100
Perceived Benefits	Positive	56	64,4
	Negative	31	35,6
	Total	87	100
Perceived Barriers	Positive	59	67,8
	Negative	28	32,2
	Total	87	100
Perceived Self-Efficacy	Positive	86	98,9
	Negative	1	1,1
	Total	87	100

Based on Table 3, all components are included in the positive category. The number of respondents with the highest number of positive perception category is the perceived self-efficacy (98.9%). While the number of respondents with the least positive perception category is perceived benefits (64.4%). Overall, 29 respondents (33.3%) had negative perceptions while 58 respondents (66.7%) had positive perceptions about the use of PPE.

**3. Relationship Between Safety Promotion and Perception of the Use of PPE:** Based on Table 4, the highest value shows that the workers who assess the safety promotion agrees that the promotion have been effective and create positive perception about the use of PPE during work (58.6%). The relationship between the effectiveness of safety promotion and the perception of the use of PPE was then analyzed using the Pearson chi-square statistical test and obtained a p-value = 0.013 ( $p < \alpha$ ). This shows that there is a relationship between the effectiveness of safety promotion and the perception of the use of PPE.

**Table 4: Frequency distribution Perception of Use of PPE**

Safety Promotion	Perception of the Use of PPE				Total		Pearson Chi-Square
	Positive		Negative		N	%	
	N	%	N	%			
Effective	51	58,6	19	21,8	70	80,5	0,013
Less effective	7	8,1	10	11,5	17	19,5	
Total	58	66,7	29	33,3	87	100	

**Discussion**

**1. Effectiveness of Safety Promotion:** Overall, majority of respondents agree that the safety promotion applied at PT. Aneka Gas Industri Region V have been effective. But there are 4 components show as a less effective category. The first component is the messages on safety promotion aren't emotional or does not form a feeling of fear and deterrence. The most frequently way to arouse emotions is to touch the feeling of fear. According to Planek (1998) in Primadana (2013), emotional messages can increase the strength of safety promotion because it can cause feelings of pressure, which makes workers be more careful when working<sup>(9)</sup>.

The second component is Safety Promotion doesn't use various and diverse types of media. According to Notoatmodjo (2005), the use of several diverse and integrated media will increase the scope, frequency, and the effectiveness of the messages delivered to the target audience. The diversity of media will be able to attract the attention of the workers so that workers are not bored and always interested in seeing and understanding the content of the messages<sup>(10)</sup>

The third component is frequency of applying the safety promotion, which so far has been done weekly. According to the Department of Safety, Health, and Environment (SHE), most of the safety programs has been done daily, including the safety talk. However,

other programs, such as renewal of safety sign and OHS training, are rarely implemented. The frequency of communication about safety messages is useful to reach a broad range of target population and also to deepen the recognition, understanding, and formation of images of these messages (Salmon, 2003)<sup>(11)</sup>

The fourth component is that workers are not actively involved in the design and manufacture of the safety promotion. According to Planek (1998) in Primadana (2015), the involvement of workers in planning and designing safety promotion is beneficial to increase the positive effect of the safety promotion<sup>(9)</sup>. Involving the workers in the process of creating the safety instructions will increase the interest of the workers. In addition, feedbacks from the workers is needed so that the company can choose messages that suit the needs of the workers accordingly.

- 2. Perception of the use of PPE:** Based on the results of the questionnaire, 76 respondents (87.4%) responded positively towards the perceived risk of the use of PPE. This shows that the workers are aware of the risk when they do not use PPE at work. Individuals who believe that they have a high risk of an illness or accident are more likely to carry out healthy or safer behaviors<sup>(12)</sup>. Perceived self-efficacy is classified on the positive perception category (98.9%). The workers in the company feel confident that they are able to implement safe and obedient behavior in using PPE. The behavior to prevent health problems can be influenced by how confident the individual is to their ability in making healthy behavioral changes. People tend to adopt healthy behaviors if they think they will succeed<sup>(13)</sup>

Perceived benefit in using PPE has a positive value, but is not too high (64.4%). This shows that a number of respondents have a negative perception about the use of PPE. So, the company must evaluate their safety promotion actions by assessing each aspects of the information, more importantly information that may increase workers' perception about the benefits of implementing PPE. Perceived barrier also has a positive value that is not too high (67.8%). Some respondents felt there were still some barriers in using PPE when working. Perceived barriers will affect a person's healthy behaviour and decision. If there are a lot of barriers exist in performing the behavior, then the individuals are less likely to adopt the behavior.

- 3. Relationship Between Safety Promotion and Perception of the Use of PPE:** The results of this study shows that there is a relationship between the effectiveness of safety promotion with the perception of the use of PPE. The results of this study are in line with Tinoco *et al.* (2019) research which explains that the perceptions of using PPE is related to daily behavior as a result of the interpretation of external stimuli (information). External factors, such as safety training, have an indirect effect on the behavior of using PPE through its influence on risk perceptions. Thus, the higher the availability of instructions on matters relating to health, work safety, and the correct use of PPE, the higher the chance of using PPE effectively<sup>(14)</sup>. Saragih's research (2016) also shows a similar result where most workers have a positive perception of PPE when a company held a safety talk every morning before starting work<sup>(7)</sup>

### Conclusion

1. The majority of the respondents agree that the safety promotion at PT. Aneka Gas Industri Region V has been effectively applied. However, the company needs to reconsidered several components related to the existing safety promotion, such as messages that are less emotional, limited variety of media use, not enough frequency of application that needs, and the lack of workers involvement in designing the safety promotion
2. Respondents have a positive perception regarding the use of PPE.
3. There is a relationship between the effectiveness of safety promotion with the perception of the use of PPE.

**Funding:** Self

**Conflict of Interest:** There are not any of conflicts amongst the authors

# Correlation of Multidetector 64 Ct Pulmonary Angiography and Well's Clinical Score in Pulmonary Embolism

Ibrahem E. Ali

*Radio diagnosis Department, Elminia University*

## Abstract

**Objective:** To correlate the findings of 64 MDCT Pulmonary angiography & Well's clinical scoring system in cases of pulmonary embolism

**Patients and Method:** The study was done between April 2010 to May 2012, 50 patients with suspected clinical pulmonary embolism underwent 64- Multislice CT pulmonary angiography. CT angiography was used in examination and evaluation for patients suspected of having PE with Correlation with clinical Well's scoring system.

**Results:** Images from "41 of 50" thoracic CT pulmonary angiography examination revealed clots within pulmonary arteries, which equals a prevalence of PE of 82%, overall (10 of 41 at pulmonary trunk, 8 of 41 at segmental pulmonary arteries and 18 of 41 at subsegmental pulmonary arteries, of 24%, 19.5% and 43.9% respectively, 5 of 41 at multiple central/segmental and segmental/subsegmental arteries of 12%)

Patients with low Well's score probability confirmed to have very low incidence of pulmonary embolism, while patients with both medium & high Well's score probability having high incidence of pulmonary embolism in CT Pulmonary angiography in our study

**Conclusion:** Correlation of Both 64-MDCT Pulmonary Angiography & Clinical Scoring Well's systems showing high relation in-between, considering that group having low clinical probability to have PE,

**Keywords:** MDCT, Angiography, Pulmonary

## Introduction

Multidetector CT has allowed the development of new imaging techniques such as CT angiography, which has become a reliable noninvasive technique for vascular imaging <sup>(1)</sup>.

MDCT technique allows increase in gantry speed and acquisition of contiguous sections with a section thickness of 1 mm or less throughout the thorax, with a reduced acquisition time. The reduced acquisition time

yields optimal contrast enhancement on all acquired sections. <sup>(2)</sup>.

A variety of congenital and acquired pulmonary vascular disorders can be diagnosed using pulmonary CT angiography (PCTA) including pulmonary embolism, pulmonary artery aneurysm, pulmonary hypertension, pre-therapeutic management of bronchial carcinoma, postoperative incidents, AVM, primary pulmonary artery sarcoma, and pulmonary arterial and venous anomalies <sup>(3)</sup>.

PCTA it is now the imaging modality of choice in pulmonary embolism and has replaced other investigations as scintigraphy and conventional angiography in many institutes <sup>(4)</sup>.

PCTA plays a role in detecting pulmonary artery hypertension where dilatation of the pulmonary artery

suggests increased pressure in the pulmonary system. In addition, evaluation of the lung windows helps in detection abnormalities of perfusion. It is also of great value in detecting pulmonary obstruction in the most common cases of secondary pulmonary hypertension <sup>(5)</sup>.

### Patients & Method

The study was done in between April 2010, and May 2012, 50 patients with suspected clinical pulmonary embolism (31 women, 19 men; age range 19-73 years, were recruited from Assuit university hospital, included patients presenting to the emergency, coronary, general ICU & surgical inpatients at the time of diagnosis presenting with signs & symptoms of suspected pulmonary embolism.

#### The 50 patients divided into two groups:

**Group I :** 40 patients with high risk

**Groups II:** 10 patients with low risk

Division & groups were done according to the clinical Well's scoring system

Also group I was reclassified according to heart rate into tachycardiac group with HR > 100 and normal heart rate group with HR < 100

Group I was divided according RV / LV ratio measured on computed tomographic (CT) angiography into 2 groups with no RVD (RV/LV<1) and with RVD (RV / LV > 1) "CT feature".

#### Inclusion Criteria:

- Sudden onset of dyspnea sudden deterioration of existing dyspnea sudden onset of pleuritic chest pain without another apparent cause.
- Any other symptoms like haemoptysis, syncope or unilateral leg pain.

#### Exclusion Criteria:

- Pregnancy
- Allergy to intra-venous contrast agents
- Renal insufficiency.

### Method

**All patients were examined and subjected to the following:**

#### I. Full history taking:

- Age, sex, Special habits
- Risk factors for venous thromboembolism as
- Surgery and related conditions:
- Surgical procedures
- Medical conditions
- Cancer
- immobilization
- Previous DVT or PE
- Increased age
- Obesity
- Pregnancy
- Certain medications
- Smoking
- Heart failure
- Kidney problems
- **Presenting symptoms including:** Dyspnea .Chest pain, Hemoptysis, Fainting, cough .leg pain or swelling.
- **Associated co-morbidity including:**
  - Ischemic heart disease
  - Hypertension
  - Diabetes mellitus
  - Stroke
  - Malignancy
  - Chronic lung disease

#### II. Referred clinician Clinical examination:

**Vital signs:** Examination of extremities either upper or lower limbs to detect signs of DVT.

**Local Examination:** Local examination (chest and heart) with emphasis on signs of pulmonary hypertension as accentuated second heart sound also presence of signs of consolidations, Pleural effusion

**Assessing Clinical Likelihood:** Different probability scores for pulmonary embolism were calculated for each patient.

### III. Imaging:

**CT Pulmonary Angiography (CTPA):** All patients underwent **64 Multislice CT** pulmonary angiography. CT angiography was used in examination and evaluation for patients suspected of having PE.

**CTPA diagnostic criteria for acute Pulmonary embolism included:**

- Complete arterial occlusion with failure to opacify the entire lumen and the artery may be enlarged in comparison with the pulmonary arteries of the same order of branching
- Central arterial filling defect surrounded by IV contrast material
- Peripheral intraluminal filling defect that makes an acute angle with an arterial wall.

### Results

The proportion of dyspnic patients was 74), patients with chest pain was 40%, and patients with positive DVT was 34% . The proportion of acute presentation of **PE** on the obtained CT findings was 80.5%, and chronic presentation was 19.5% with patients with normal CT pulmonary angiography with no evident embolism with average percentage of 19.5%

Images from “41 of 50” thoracic CT pulmonary angiography examination revealed clots within pulmonary arteries, which equals a prevalence of **PE** of 82%, overall (10 of 41 at pulmonary trunk, 8 of 41 at segmental pulmonary arteries and 18 of 41 at subsegmental pulmonary arteries, of 24%, 19.5% and 43.9% respectively, 5 of 41 at multiple central/segmental and segmental/subsegmental arteries of 12%). In *eight* patients referred for suspicion of acute pulmonary embolism **PE**, thoracic CT angiography showed abnormalities typical of chronic **PEs**, with marginal clots or arterial retraction, which was combined in *three* patients with pulmonary trunk enlargement (range 3.2 – 3.8-cm). Marginal clots were seen in labor arteries in *two* patients, and were associated with chronic obstruction, which in the other *three* patients marginal clots were present only at segmental levels. All patients with chronic clots had mosaic attenuation of the pulmonary parenchyma at lung window settings.

The proportion of dyspnic patients was 74% (37 of 50), means most of our patients presented with dyspnea representing that it is of great clinical significance, only (13 of 50) patients not presented with dysnea

The proportion of patients with chest pain was 40% (20 of 50) with (30 of 50) not presented with chest pain, representing that chest pain is not of great clinical value

Patients with positive DVT was 34% (17 of 50) & 66% (33 of 50) wasn't having DVT prior to the CT Pulmonary angiographic study

Most of patient in our study presented with acute presentation of pulmonary embolism about 33 (80.5%) of overall 41 patients with only 8 patients representing about only 19.5 % were presented with Chronic PE

Most of our patients were presented with Subsegmental pulmonary embolism (18 of 41 positive patients) representing about (43.9%) with the second common findings were in the pulmonary trunk (10 of 41 patients) about 24%, 8 patients were diagnosed to had segmental PE with 19.5% & 5 patients (12%) were diagnosed to had mixed site of the emboli

There were several risk factors for pulmonary embolism within study population . DVT was present in 34% of patients while immobility was present in 50% of patients, estrogen use was present in 8%, surgery was present in 24% of patients while malignancy was equal 6%, 4% of patients was in the postpartum period and 14% of patients had no identifiable risk factor.

Therefore Immobility is the most common risk factor for PE, followed with DVT In the present study table 13 shows comparison between the two groups group I was 41 patients in whom mean age was 44±13 ranging from 19 to 73,median 55 and IQR 33 :62.

Male patients was 35% and Female was 65%, the most frequent co morbidity was hypertension represent 27% followed by ILU & COPD 19% and 17% of cases have more than one co morbidity while no co morbidity was found in 29% of cases.

Group II was nine patients in whom mean age was 50 ± 16 ranging from 21 to 73, with median 57 and IQR 33 :63 .

Male patients was 55% while Female patients was 45%, the most frequent co morbidity was diabetes, ILD & COPD 22% for each followed by hypertension in

11% of cases and 33 % of cases have more than one co morbidity while no co-morbidity was present in 66 % of cases

The study representing dyspnea in 82% in group I and 33% in group II followed by haemoptysis 48% in group I and 22% ill group II, haemoptysis Was 48% in group I and 22% in group II and syncope was 17% in group I with no cases of syncope in group II .

Clinical probability score wells score was in group I  $6.5 \pm 2$  and in group II was  $2.5 \pm 1$  the sensitivity and specificity of well's clinical probability score in CT diagnosing pulmonary embolism showing that it has Sensitivity 90.00% and Specificity 50% (it seems to be of high sensitivity & moderate specificity).

Group II had 9 patients with low clinical probabilities according to Wells scoring system and 3 (37.5 %) patient was confirmed to be -ve according to PERC rules

CT finding in cases of pulmonary embolism there was no associated parenchymal abnormality in 22 cases (54%), 8 cases (19%) with pulmonary consolidation, 4 cases (10%) with interstitial lung disease, 6 cases (14%) with pleural effusion, peripheral wedge shaped density (Humpton's Hump), pleural thickening was 5 cases (12%) & 2 cases with 5% show mediastinal LNs

The most common finding is pulmonary consolidation, followed by pleural effusion with no parenchymal abnormalities were detected in more than 50% of patients.

**Fig 1-a:** Axial CT cuts showing a large hypodense filling defect seen at the lower aspect of the pulmonary trunk and extending to the proximal portions of both main pulmonary arteries more on the right side occluding it with a thin rim of contrast at its periphery. An irregular thick walled cavitary lesion is seen at the apical segment of the right lower lobe.

**Fig 1.b:** Oblique coronal images showing the hypodense filling defect within the main, right pulmonary artery and the proximal portion of the left one.

**Diagnosis:** Saddle pulmonary embolism involving the bifurcation of the pulmonary trunk and mainly the right pulmonary artery.

**PCTA:**

**Fig 2-a: Axial CT cuts showing a central hypodense filling defect in the right posterobasal sub segmental right lower lobe (arrow).**

**Fig 2-b: Sagittal and Coronal reconstructed images showing a right basal subsegmental filling defect (railway track sign) (arrow).**

**Diagnosis:** Right basal subsegmental acute pulmonary embolism.

**PCTA:**

**Fig 3-a:** Axial CT cuts showing dilated main pulmonary trunk. Bilateral large hypodense filling defects in both main pulmonary arteries with a thin rim of contrast surrounding the filling defects. Bilateral few subsegmental basal pulmonary embolic filling defects

**Fig 3-b :** Sagittal and Coronal CT images showing the bilateral pulmonary arteries emboli.

**Diagnosis:** Bilateral main and subsegmental pulmonary emboli associated with pulmonary hypertension evident by dilated main pulmonary trunk.

**PCTA:**

**Fig 4-a :Axial, Coronal and Sagittal CT images (mediastinal window) showing multiple bilateral variable sized aneurysmal dilatation of the segmental and subsegmental pulmonary arteries.**

**Diagnosis:** Bilateral multiple pulmonary aneurysms in a known patient with Behcet’s disease with Mural thrombus. Most of them are surrounded by mural thrombus and one of them on the right side is nearly totally occluded.

**Fig 4-b:VR images showing the multiple bilateral pulmonary artery aneurysms & Thrombus.**

### Discussion

Diagnosing pulmonary embolism can be difficult. Problems may arise not only because symptoms and signs can be nonspecific or occult, but because in assessing the accuracy of any diagnostic test for PE there is no universally accepted reference standard (7).

Both under diagnosis and over diagnosis are associated with substantial morbidity and mortality rates. Untreated pulmonary embolism can be fatal, and over treatment exposes the patient who does not have pulmonary embolism to an unjustified risk for major bleeding . The BTS guidelines for the management of suspected acute pulmonary embolism in 2003 recommended

that all patients with possible PE should have clinical probability assessed and documented(7).

On correlating the results of the current study regarding PE with other studies using-64MDCT scanners, we found that lower percentages were detected by Revel et al (2005) detected PE in only 24.5% (in a study population of 220 patients), this could attributed to wide variation of risk patient in that study involving high percentage of low risk group compared with our study

The difference of the results in our study in some entities compared to other studies can be attributed to the fact that PCTA is being nowadays a routine investigation, so the referred patients were those highly suspected of having PE. Also, the available scanner in our study is a

64-MDCT which relatively provides more accurate data compared to other studies using a lower scanners.

All patients in our study showed variable degrees of pulmonary artery dilatation, but, only some of them showed other CT signs of pulmonary hypertension.

We found that lower percentages were detected by *Hofman* et al.,<sup>(9)</sup> study showing that only 5 cases (10%) having mainpulmonary trunk PE, compared with about 10 cases (24%) in our study

According to<sup>(7)</sup>, with 70 Patient examined with 64-MDCT 60% were female & 40% were males, with also similar high percentage In our study where we found 51.7 PE in female patients & 48.3 in Males

Regarding pulmonary parenchymal signs in our study, emphysema was seen in four patients, mosaic attenuation in three, bronchiectatic changes in three, peribronchial thickening in one, and a large area of right perihilar consolidation in one patient.

Similar findings were seen in the<sup>(9)</sup> where honeycombing and bronchiectasis were seen in one patient each.

Compared with study population of 120 patients<sup>(7)</sup>, that shows high percentage of chronic presentation of PE . (43% 52 patient of 120) were found, compared with 8 patients (19.5 %) in our study; this is attributed to larger volume of patients

Compared with<sup>(7)</sup> study that show low percentage of patients presented with dyspnea (70 patient of total 120 study population, 58%), compared with (37 patient from 50 total population study, 74%); this could be seen as a result of being most of our study population are in-patients & admitted to intensive care unit

### Conclusion

Correlation of Both 64-MDCT Pulmonary Angiography & Clinical Scoring Well's systems showing high relation in-between, considering that group having low clinical propability to have PE, MDCT was at the lest positive level, with the other group with high clinical possibility to have PE, MDCT findings are at the high level of positive results

64-MDCT Pulmonary Angiography has as great correlation with the clinical probability Well's scoring system

64-MDCT is the first imaging modality of choice in cases suspecristted with pulmonary embolism

Other radiological imaging modalities involving X-ray chest & MRA maybe of great value

**Ethical Approval:** This study was approved by the Institutional Ethics Committee of School of Medicine, Minia University, Egypt, and all patients gave informed consent before participation in this study. The study conducted in accordance with the ethical guidelines of the 1975 Declaration of Helsinki and International Conference on Harmonization Guidelines for Good Clinical Practice.

**Source of Funding:** None

# Functional Lapin-Human Simulation of Knee Joint Synovial Mucosal Cytokine Responses in Staphylococcus Aureus Septic Arthritis

Ibrahim M S Shnawa<sup>1</sup>, Aljanabi IAA<sup>2</sup>, Almohana A<sup>3</sup>, Busisi HA<sup>4</sup>, Abiaes AA<sup>5</sup>

<sup>1</sup>Prof, Department of Biotechnology, College of Biotechnology, University of Qasim, IRAQ, <sup>2</sup>Lecturer, College of Pharmacy, University of Kufa, IRAQ, <sup>3</sup>Prof, Department of Biology, College of Science, University of Kufa, IRAQ, <sup>4</sup>Ass, Prof, College of Medicine, University of Kufa IRAQ, <sup>5</sup>Ass. Prof., College of Veterinary Medicine, University of Kufa IRAQ.

## Abstract

A functional simulation approach has been tempted between clinically proven lapin and human septic arthritis, in which twenty experimentally induced lapin S aureus septic arthritis and 20 natural human S.aureus septic arthritis were the human simulation materials. Lapin synovial fluids were aspirated by the veterinarian of the team and human synovial fluids were aspirated by the rheumatologist of the team. Direct synovial fluid Giemsa stained smears were showing neutrophilic infiltration responses both for lapin and human. Cell free synovial supernatants for lapin and human were found positive for S.aureus agglutinins up to the titre of 32. Sandwich eliza for TNF alpha, INF gamma and IL4 for lapin synovial fluid and same for human synovial fluid TNF alpha, INF gamma and IL4. Lapin knee joint synovial mucosal compartment was found valid model for human synovial mucosal compartment during the course of S, aureus septic arthritis. Likewise, the lapins knee joints synovial mucosal cytokine responses simulate that of man. Herd immunity concept was found operable in both lapin and human populations. Herd tripartite nature of the immune responses as low moderate and high responders both for rabbit and man. The herd immune plots were of skewed type for TNF alpha, normal distribution curves to INF gamma and IL4 both for lapin and human. This functional simulation study appear to be novel contribution in knee joint synovial mucosal cytokine responses.

**Keywords:** Agglutinins, arthritis, compartment, cytokines herd immunity, herd plots

## Introduction

The pathogenesis of lapin and human arthritis can be traced into three pathways, haematogenous, lymphogenous and osteogenous. The osteogenic infection spread from the local affected bone<sup>[1]</sup>. In comparison, the immunopathogenesis of both rabbit and man septic arthritis may be triggered by the immunodominant epitope(s) of the infectious agent which might be; immunogenic, allergenic and/or autoimmunogenic<sup>[2]</sup>. The local synovial mucosal compartment immune responses can be humoral, cellular and/or humoral and cellular<sup>[3,4]</sup>. Such responses actually are both of mucosal and cellular responses<sup>[5]</sup>. Excess antibodies and/or excess cytokine production may take part in the local

immunopathogenesis for both of lapin human septic arthritis through the mechanisms of immune tissue injuries<sup>[6]</sup>. The families of lapin cytokines are somewhat limited so far compared human cytokine families<sup>[7]</sup>. To date the known cytokines of rabbits are; IL 1 alpha, IL4, IL8, IL17A, INF gamma, IL21, TGFB<sup>[8]</sup>. While, that of man are; IL1, IL2, IL4, IL5, IL6, IL8, IL17, IL18, IL21, IL23 and so on<sup>[7]</sup>. S.aureus are known to trigger proinflammatory and immunomodulatory molecules<sup>[4]</sup>. The nature of the Saureus induced immune responses are humoral, cellular, humoral and cellular mucosal and systemic immune responses in septic arthritis<sup>[3,4]</sup>. Herd systemic immunity has been found operable in human arthropathy patients<sup>[9]</sup>. The objective of the

present communication was aimed at the investigation of knee joint synovial mucosal cytokine responses in experimental lapin septic *S. aureus* septic arthritis as compared to cytokine synovial mucosal immune responses in man. Where by, macrophage cytokine responses was represented by TNF alpha, Th2 was represented by IL4 while TH1 was represented by INF gamma. To check for; the extent of individual variation, herd immunity, herd plots and lapin-human functional simulation

## Materials and Method

1. **Patients:** In a group of 400 human arthropathy patients, the rheumatologist in this research team interviewed patients, request confirming laboratory investigations and reached to a disease entity of septic arthritis. Twenty of these patients were found in association with *Staphylococcus aureus* and considered to be the test patients<sup>[2,10]</sup>.
2. **Staphylococcus Aureus Strain 6:** Erythrogenic, coagulase positive, beta haemolytic *S. aureus* strain 6. The genetic background of its virulence was found with an array of several virulence genes as; sea+, spa+, hla+, protein a gene+ and, leukocidin gene+<sup>[11]</sup>. This test strain was elected from ALJanabi [the second author] *S. aureus* strain collection.
3. **Infectious Doses:** A series of *S. aureus* cell suspensions were made ranging from 1x10 to three up to 1x10 to nine CFU/ml. as a test infectious doses<sup>[12]</sup>.
4. **Rabbits:** A group of Newzealand white rabbits were brought to the animal house, checked for any gross pathologic lesions. Abnormal ones were excluded. The rest were acclimatized for the housing conditions for two weeks before setting experimentation during which they were kept ad libidum<sup>[13]</sup>.
5. **The program for induction of lapin septic arthritis:** 0.1 ml of each of the test infectious doses were injected by the veterinarian of the research team through intra-articular in the knee joints in a rate of three rabbits per each test dose. The inoculated rabbits were followed up for up to five days. The dose of 1 x10 to eight was the infectious dose. Thus this dose were used for the experimental induction of septic arthritis. In which, 0,1 ml of the infectious dose were injected by the veterinarian [the fourth author in the team] for each of the twenty test rabbits through the knee joint. Ten rabbits were injected by 0.1 ml sterile saline in the same as controls. Rabbits were followed for up to five days to score arthritis<sup>[12,14]</sup>.
6. **Synovial fluid:** The twenty *S. aureus* natural human septic arthritis patient were subjected to synovial fluid aspiration by the rheumatologist. Likewise, the infected rabbits were subjected for synovial fluid aspiration by the veterinarian in the team. The synovial fluid aspirate samples were centrifuged for 15 minutes at 3000 rpm, Giemsa Stained films were made. Cell free synovial fluid supernatants were collected in 0.5 ml. amounts and kept at -20 C till use. They were used for antibody and cytokine determinations<sup>[15,16]</sup>.
7. **Antibody Determinations:** Lapin and human cell free synovial fluids supernatants were checked with *S. aureus* 6 cell suspension for the presence of direct agglutinins through slide and tube agglutination tests<sup>[17]</sup>.
8. **Cytokine Determination:** Lapin and human sandwich elizakets for TNF alpha, INF gamma and IL4 were imported from Usobio Co. USA to check for synovial mucosal cytokines in accordance with manufacturer recommendations.
9. **Cytokine Balance:** The cytokine concentrations of the individual rabbit and individual human patient was compared to mean values of corresponding control to measure the number of folds increase than normal. The number of folds increase of IL4 was compared with that of TNF alpha and INF gamma, then the balance was deduced in each case<sup>[7]</sup>.
10. **Biometry:** The individual variation parameters; minimum, mean, medians, ranges and maximum as well as the class intervals usable in herd plots were measured as in<sup>[18]</sup>.

## Results

- I. **Gross Pathobiologic Features:** Both knee joints of lapin and human shown; limping. limitation of motion, tenderness, lameness, loss of weight as well as marked swelling which is an indication of inflammatory and immune responses.
- II. **Synovial Mucosal Immune Responses:**
  1. **Mucosal *S. aureus* antibodies:** The slide agglutination tests of the lapin and human cell free synovial fluid supernatants with *S. aureus*

suspensions were positive for S.aureus specific agglutinins. The specific agglutinin titres were; up to 16 for lapin and up to 32 for human.

**2. Synovial Mucosal Cellular Immune Responses:**

**3. Knee Joint Synovial cytokines:** The statistical range values of the lapin and human synovial TNF alpha, INF gamma and IL4 cytokines were spanning between 11 and 42, which indicates the individual variation limits, Table 1. The lapin cell free synovial fluid supernatants have shown evident cytokine responses. The S.aureus infection lead to around 15 folds rise for TNF alpha than normal rabbit .While human cell free synovial fluid supernatants have increased around 30 folds than in normal human .For INF gamma of rabbit synovial fluid samples were two folds more than normal rabbits. Human synovial INF gamma were around three folds than normal .Rabbit synovial IL4 values were around eight folds than normal .In comparison, human synovial IL4 values were around 20 folds than in normal human subjects, Table 2.

**4. Herd Immune Responses and herd plots:** Both of infected rabbits and arthritis human patients have express herd cytokine responses as low, moderate and high responders, Table 3. Skewd type immune herd plots were evident in TNF alpha cytokine responses both for rabbits and man. Normal or Gaussian distribution plots were noted in INF gamma and IL4 cytokine herd plots[IL4 not shown in plots] both in rabbits and man, Figures 1 and 2.

**III. Cytokine Balance:** In both of rabbit and man synovial mucosal IL4, INF gamma and TNF alpha were generally showing an in-balance state between IL4 and THF alpha, IL4 and INF gamma.

**IV. Comparative Immune Features:** The major functional immune features of induced lapin septic arthritis and natural human septic arthritis are even similar, Table 5.

**Table 1 : The individual Variation of the synovial cytokine responses in term of concentration pg/ml\*..**

## Discussion

Rabbit have been tempted as a model for simulation of several human diseases, in which cytokine responses are evident; such as reagenic stimulation induced TH2 cytokines in the airway smooth muscle cell cells<sup>[19]</sup>, prenatal fetal infection induced IL1 and TNF alpha<sup>[20]</sup>, experimental pancreatitis initiate pro-inflammatory cytokines, IL5, IL1B and TNF alpha<sup>[21]</sup> and the experimental induced shigellosis provokes IL22, IL17A and IL17F<sup>[14]</sup>.

Lapin *S.aureus* septic arthritis induces mucosal humoral and cellular immune responses, Tables 1-4. The mucosal cytokine was used to; i-match limits of individual variation, ii –mapping the possibility of taking parts in herd immunity, iii-nature of herd responder types, iv – Immune herd plots natures and v-contouring the functional lapin-human simulation.

The TNFalpha be produced by either mucosal resident or migratory macrophages. INF gamma released from mucosal or migratory T cells. IL4, however may be produced by TH2 cells<sup>[1,5]</sup>. The individual variations in the cytokine concentration values were noted both in health and disease in rabbits and man<sup>[22]</sup>. The infectious *S.aureus* intra articular in rabbits induced three to 15 folds rise synovial mucosal cytokine as compared to that of normal control rabbits. Likewise, human *S.aureus* septic arthritis patients lead to an increase in cytokine concentration ranged between three to 25 folds as compared to that of normal human controls. The cytokine in-balance state reported in the current study have been reported by other workers in various forms of arthritis in human beings and implicated in evolution of the immune tissue injuries, as well as the deformities in the bone and cartilage<sup>[7]</sup>.

Herd immunity have been found in a number of infectious<sup>[22,23,24]</sup> and non-infectious<sup>[25]</sup> human disease conditions. Systemic herd immunity of human arthropathy patients was reported in this area by<sup>[9]</sup>. In the present communication a novel report on herd immunity in knee joint synovial cytokine responses with a three main responder types<sup>[23,24]</sup>. By this lapin knee joint synovial mucosal immune compartment can be a model compartment simulating the local human diseased knee joint mucosal immune compartment<sup>[22]</sup>.

## Conclusion

*S.aureus* infection in rabbit induce knee joint

synovial mucosal responses in both lapin and human. In which the synovial compartment was constituting valid model for knee joint synovitis in man. Mucosal herd immunity parameters were operable both in lapin and human. Hence, rabbit was functionally simulating human in sense of knee joint cytokine responses.

**Conflict of Interest:** Non-conflict.

**Source of Fund:** Self

**Ethical Clearance:** The research project is formally registered in the affiliated departments. Clinical samples were taken from patients with complete their own satisfaction. Rabbits were reared and kept under standard Add Libitum conditions during the experimentation period. On handling of rabbits, authors followed the international ethical guidelines for animals.

# Influence of Predisposing Factors of Elderly on the Utilization of Health Services At the Health Centre in Sidoarjo District

Ika Santi Widyasari<sup>1</sup>, Ernawaty<sup>2</sup>

<sup>1</sup>Department of Health Administration and Policy, Faculty of Public Health, Universitas Airlangga, Surabaya, East Java, Indonesia, <sup>2</sup>Department of Health Administration and Policy, Faculty of Public Health, Universitas Airlangga, Surabaya, East Java, Indonesia

## Abstract

**Context:** Sidoarjo District is one of the districts in East Java Province, Indonesia which has an increase in the number of people aged 60 years and over each year. The achievement of health service performance indicators for residents aged 60 years and over in Sidoarjo District has not reached the standard of 60.31% of the target of 100%. Based on the results of the interviews, information was obtained that the target had not been achieved due to individual internal factors. The purpose of this study was to analyze the influence of predisposing factors of elderly individuals on the utilization of elderly health services held by the Sidoarjo district health centre. This type of research is analaitic observational and cross sectional. The population in this study were elderly people in Sidoarjo District. The sampling technique is proportional stratified random sampling so that the sample is 200 people. Data analysis using statistical tests of the influence of the dependent and independent variables.

The results showed that the predisposing factors of the elderly who influenced the utilization of Integrated Services Post for elderly were age ( $p = 0.029$ ) and gender ( $p = 0.000$ ). The predisposing factors for the elderly that influence the utilization of Community Health Centre services are Spatial Factors ( $p = 0,000$ ). The older the age increases the higher the utilization of the elderly Integrated Services Post for elderly. The utilization of Integrated Services Post for elderly services for elderly men is lower than for women. Elderly people who live in rural areas use health centres more than the elderly in urban areas. The recommendation of this study is that health centre needs to give education about the importance of medical examinations at older age can be done since the pre-elderly age. Integrated Services Post for elderly cadres can persuade elderly women to invite their husbands to take medical examinations. Elderly in addition to rural areas, namely urban and small urban areas, they need to get socialization regarding elderly health care programs in health centres to increase the interest of small urban and urban seniors to health centres.

**Keywords:** *Elderly, predisposing factors, utilization of healthcare.*

## Introduction

The elderly population in Indonesia is predicted to increase higher than the elderly population in the world

after the year 2100.<sup>(1)</sup>One of the districts in Indonesia that has an increase in the number of elderly population each year is Sidoarjo District. The increase in the number of elderly people is followed by the increase in diseases faced by the elderly population. The increasing number of elderly residents with a variety of diseases is felt because the aging process needs to be followed by an increase in visits of the elderly in health and routine examinations in health service activities held. Health service activities are held in the community health centre and outside the building in the form of an elderly Integrated Services Post for elderly. Health service activities are carried out

in the form of promotive, preventive and rehabilitative activities. The population of the elderly has not been followed by an increase in the scope of utilization of health services by the elderly in Sidoarjo District. Coverage of elderly who get health services according to standards from 2014 to 2017 in Sidoarjo District has not yet reached the predetermined target of 100%. Coverage of elderly who get health services according to standards in 2017 is 60.31%.<sup>(2)</sup>

According to Green (1980) there are several factors that influence changes in health behavior, one of which utilizes health services to check health status. The influencing factors consist of predisposing factors, enabling factors, and reinforcing factors.<sup>(3)</sup> Predisposing factors consist of Socio demographic factors such as age, gender, education level, and marital status; Economic factors such as employment, income level; and spatial factors such as the area of residence. Enabling Factors consists of facilities or facilities available such as information from mass media. Reinforcing factors consist of reference group attitudes and behaviors that can influence changes in a person's behavior.

### Material and Method

This research is observational analytic research because researchers only make observations without giving treatment or intervention to the respondents and aim to determine the effect of the variables to be studied. The design of this study uses quantitative design. Based on the duration of the study, this study included a cross sectional study. Data retrieval is done by using questionnaire instruments and interviews with elderly people in several health centre areas in Sidoarjo District.

Instrument of data collection is a questionnaire. The study sample was 200 elderly people in Sidoarjo District who were calculated using proportional stratified random sampling technique. The independent variables in this study were individual predisposing factors in the form of socio-demographic factors, economic factors, and spatial factors. The dependent variable in this study is the score on the utilization of health services for elderly.

Calculation of the level of wrinkle utilizing elderly health services is by giving a score on each item question.

The scores on each question are explained as follows:

- a. Never (not utilized at all in the last 3 months) = 1
- b. Rarely (using the Integrated Services Post for elderly 1 time in the last 3 months or utilizing a Community Health Centre 1-2 times in the last 3 months) = 2
- c. Frequently (utilizing the Integrated Services Post for elderly 2 times in the last 3 months or utilizing the Community Health Centre 3 times in the last 3 months) = 3
- d. Always (utilizing the Integrated Services Post for elderly 3 times in the last 3 months or utilizing the Community Health Centre >3 times in the last 3 months = 4)

Measurements by adding up scores from the utilization of the Integrated Services Post for elderly as well as the utilization score of the Community Health Centre. The number of scores is categorized into three groups, namely:

- a. No = 4 - 7
- b. Rarely = 8 - 11
- c. Often = 12-15
- d. Always = 16-18

### Findings:

- A. Distribution of respondents based on Predisposing Factors:** Predisposing factors are factors that come from within an individual that can affect in a person's behavior. Predisposing factors consist of socio demographic factors, economic factors, and spatial factors. The following is the distribution of respondents based on their predisposing factors.

Based on Table 1, it can be seen that the majority of respondents aged 60-64 years, female sex, have an education level graduated from elementary school, are married. While the economic factors of the majority of respondents are not working and low income. The spatial factors of the majority of respondents are living in rural areas.

**Table 1: Distribution of Respondents Based on Predisposing Factors**

No.	Predisposing Factors		n	(%)
1	<b>Socio-Demographics Factors</b>			
	Age	60- 64 years	98	49,0
		65- 69 years	65	32,5
		>70 years	37	18,5
	Sex	Men	52	26
		Women	148	74
	Educational Level	Not School	17	8,5
		Elementary School	97	48,5
		Junior High School	25	12,5
		Senior HighSchool	46	23,0
		College	15	7,5
	Marital Status	Not Married	1	0,5
		Divorce	5	2,5
		Death Divorce	69	34,5
		Married	125	62,5
	2	<b>Economic Factors</b>		
Job		Retired	30	15,0
		Entrepreneurship	32	15,0
		Private Companies	11	5,5
		Farm Workers	19	9,5
		Not employed	102	51,0
		Others	6	3,0
Income Level		Low	114	57,0
	High	86	43,0	
3	Spatial Factors	Rural area	105	52,5
		Small Urban area	76	38,0
		Urban area	19	9,5

**B. Distribution of respondents based on the Routinity Utilizing Elderly Health Services:** Elderly health services consist of two types, namely outside and inside the building. Outside health services in the form of Integrated Services Post for elderly held in each village. Services in the building are health services carried out at the Community Health Centre. Health services carried out at the Integrated Services Post for elderly consist of routine health checks, elderly gymnastics, health socialisation and providing supplementary food. Health services carried out in the Community Health Centre building consist of health checks, elderly gymnastics, counseling, and treatment. The following is the distribution of respondents based on the level of routine utilization of health services for last three months of 2019.

**Table 2: Distribution of Respondents Based on the Routine Use of Elderly Health Services for the Last Three Months of 2019**

Elderly Health Services	Routinity Level							
	Not utilize		Rarely		Often		Always	
	n	%	n	%	n	%	n	%
Integrated Service Post For Elderly	86	43,0	27	13,5	67	33,5	20	10,0
Community Health Centre	171	86,5	24	12,0	3	1,5	2	1,0

Based on Table 2, it can be seen about the health care coverage of the elderly outside the building, namely the integrated elderly service post, respondents didnot use it for the past three months by 43%. Likewise in the utilization of health services in Community Health Centre, the majority of respondents did not use health services in the Community Health Centre for the past three months, which amounted to 86.5%.

**C. The Influence of Individual Predisposing Factors on the Use of Health Services:** Influence analysis used to determine the effect of socio-demographic factors consisting of age, sex, education level, marital status, economic factors including employment and income level, and spatial factors for the utilization of health services is multiple linear regression analysis. The test results of the influence of individual predisposing factors on health services can be seen in the following table.

**Table 3: Results of the Influence of Individual Predisposing Factors on the Use of Health Services in the Integrated Service Post For Elderly in Sidoarjo District**

No	Independen Variables	Dependen Variable	Sig.	Explanation
1	Age	Utilization of Health Services at Integrated Service Post for Elderly	0,029	Significant
2	Sex		0,000	Significant
3	Educational Level		0,796	Not Significant
4	Marital Status		0,452	Not Significant
5	Job		0,147	Not Significant
6	Income Level		0,120	Not Significant
7	Spatial Factors		0.234	Not Significant

Based on Table 3, it can be seen that the predisposing factors that influence the utilization of health services in the integrated service post for elderly age ( $p = 0.029$ ) and the sex of the respondents ( $p = 0,000$ ).

**Table 4. Results of the Influence of Individual Predisposing Factors on the Use of Community Health Services in the Sidoarjo District**

No	Independen Variables	Dependen Variable	Sig.	Explanation
1	Age	Utilization of Health Services at Community Health Centre	0,670	Not Significant
2	Sex		0,727	Not Significant
3	Educational Level		0,535	Not Significant
4	Marital Status		0,418	Not Significant
5	Job		0,945	Not Significant
6	Income Level		0,901	Not Significant
7	Spatial Factors		0,000	Significant

Based on Table 4, it can be seen that the predisposing factors of the elderly who influence the utilization of health services in the Community Health Centre are the area of residence of the respondents ( $p = 0,000$ ). More people living in rural areas use health services in Community Health Centre.

### Discussion

Based on the results of the study, it is known that the socio-demographic factors that influence the utilization of health services in Integrated Services Post for elderly are age and sex. Respondents who have an older age are increasingly utilizing health services. This is in line with research in the elderly in Malaysia, namely respondents with 65 years of age have higher utilization of out-patient and in-patient rates than other age groups (Institute of Public Health, 2011).<sup>(4)</sup> Based on Exavery research (2010) found that the elderly aged 60-69 years are significantly higher in using health services than those aged 50-59 years.<sup>(5)</sup> The older the age increases, the more often the elderly use health services. This is because increasing age is followed by a decrease in health and various diseases. The aging process which is followed by a decline in the body and physical condition of the elderly affects the utilization of health services by the elderly.

Based on the results of the study it was found that gender had an effect on the utilization of the elderly

Integrated Services Post for elderly. Elderly women are more likely to take part in Integrated Services Post for elderly activities because of the its activity attract the interest of elderly women such as gymnastics. In line with the study of Yunus, et al (2014) that gender is related to the utilization of health services.<sup>(6)</sup> Women are known to have a longer life expectancy than men but are reported to have a greater risk of disease and thus make the use of health services greater than men (Macintrye, et al., 1996).<sup>(7)</sup> Women are more proactive in seeking medical help than men. (Bertakis & Azari, 2011).<sup>(8)</sup> According to Redondo-Sendino (2006) this is indicated because women use health services more than men to visit medical practitioners and home medical visits, number of medications, and some utilization.<sup>(9)</sup> According to Intarti & Khoiriah (2018) there are more elderly women who use the elderly Integrated Services Post for elderly. This is because the elderly women pay more attention to their health condition than men. In addition, elderly women are more diligent in seeking information regarding health problems in their old age.<sup>(10)</sup>

Based on the results of the study, it is known that the predisposing factors that influence the utilization of health services in the Community Health Centre are spatial factors. More people living in rural areas use health services in Community Health Centre. According to Dinatya (2012), the majority of people in rural areas with livelihoods as farmers use services in Community Health Centre because of their strategic location of being on village or village roads.<sup>(11)</sup> Based on Anhar, et al. (2016) research, it was found that there were differences in utilization of health services between rural communities in the working area of the Lepo-Lepo Community Health Centre.<sup>(12)</sup> Based on observations it was found that more people in urban areas used health services in clinics, family doctor practices, private midwife practices compared to Community Health Centre. This is caused by clinic opening hours are more flexible and are suitable for treatment at their family doctor.

### ConclusionS

Based on the results of the study, the conclusion of this study can be seen that the socio-demographic factors of the respondents in Sidoarjo District are the majority of those aged 60-64 years, female sex, have graduated from elementary school and are married. The economic factor of respondents majority are not working and having low

income. The majority of respondents' spatial factors are living in rural areas. Based on the level of reliability of respondents in utilizing health services in the Integrated Services Post for elderly and Community Health Centre, majority did not use health services during the last three months of 2019.

The predisposing factors of the elderly who influence the utilization of health services in the Integrated Services Post for elderly are age and sex. The predisposing factors for the elderly who influence the utilization of health services in the Community Health Centre are regional factors.

The research recommendation for the Sidoarjo District Health Office and Community Health Centre is to train health workers to disseminate information on the importance of medical examination that can be started from the pre-elderly age. In addition, there is a need for the role of health workers and Integrated Services Post for elderly cadres to persuade elderly women inviting their husbands to be more aware of their health and take medical examinations. Elderly in urban and small urban areas need to get socialization regarding elderly health care programs in health Centres to increase the interest of small urban and urban elderly. Health workers need to innovate preventive health service activities to increase the interest of elderly in utilizing the Community Health Centre compared to only being treated at a family doctor/clinic.

## Abstract

**Context:** Of great interest to modern researchers are processes that affect vascular tone in patients with coronary heart disease. It is known that in the atherosclerotic process in the coronary vessels there is a varying degree of severity of endothelial dysfunction with the dominance of vasoconstrictor mechanisms. The results of the examination of 63 patients with coronary heart disease and type II diabetes mellitus with concomitant arrhythmias and 20 practically healthy individuals aged 51 to 62 years are presented. All examined were divided into 6 groups. It was shown that the development of cardiac arrhythmias in patients with coronary heart disease with concomitant type II diabetes mellitus is accompanied by an increase in the level of endothelin-1, which reflects impaired endothelial function. Along with this, the activation of the renin-angiotensin-aldosterone system due to an increase in the level of angiotensin II, the activation of the sympathoadrenal system with a decrease in the level of cyclic guanosine monophosphate form the conditions for persistent cardiac arrhythmias and require timely intervention to eliminate neurohumoral disorders.

**Keywords:** Cardiovascular system, dysfunction, endothelium, coronary heart disease, heart rhythm disturbances, diabetes mellitus.

## Introduction

The vascular wall is an important link in maintaining homeostasis as a whole. In this case, the endothelium plays a crucial role in it. It is an autocrine, paracrine and endocrine organ with numerous regulatory functions. In addition to regulating vascular tone and hemostasis, the endothelium takes part in the immune response, ensures the migration of blood cells through the vascular wall, the synthesis of inflammatory factors and inhibitors, and performs a barrier function. The

balance of oppositely directed processes depends on the state of the endothelium: vascular tone (vasodilation / vasoconstriction), their anatomical structure (remodeling / inhibition of proliferation factors), hemostasis (synthesis and inhibition of fibrinolysis factors and platelet aggregation), local inflammation (production of pro-inflammatory and anti-inflammatory factors)<sup>1</sup>.

The vascular wall is multifunctional and is associated with other systems, organs that affect the state of aggregation of blood. The constant identification of new factors of the vascular wall deepens the understanding of the mechanisms of its regulation in physiological and pathological conditions, and opens up the possibility of predicting disorders in cardiac patients. For various cardiovascular pathologies, the synthesis of various biologically active substances by endotheliocytes is especially affected<sup>2</sup>.

Coronary heart disease is currently considered as one of the most common diseases in the civilized world, often combined with metabolic disorders<sup>3</sup>.

In this regard, the study of processes that affect vascular tone in patients with coronary heart disease is of great interest<sup>4</sup>. As is known, with the development of the atherosclerotic process in the coronary vessels, varying degrees of severity of endothelial dysfunction with a predominance of vasoconstrictive mechanisms are observed<sup>5</sup>. In such conditions, periodic deterioration of coronary circulation leads to aggravation of myocardial ischemia, the occurrence of cardiac arrhythmias<sup>6,7</sup>. The relationship between local endothelial tissue hormones and the development of arrhythmias is not well understood, especially in clinical settings. In this regard, it is of great interest to study the mechanisms of endothelial dysfunction in supraventricular and ventricular extrasystoles, as well as atrial fibrillation in patients with coronary heart disease with and without concomitant diabetes mellitus.

Objective: to determine the leading mechanisms of the development of endothelial dysfunction in arrhythmias in patients with coronary heart disease and type II diabetes mellitus.

**Material and Research Method**

The study was approved by the local ethics committee of the Russian State Social University on September 15, 2017 (protocol №11).

83 people were examined, including 52 women and 31 men aged 50 to 62 years.

To determine the role of neurohumoral factors in the development of endothelial dysfunction and cardiac arrhythmias, all examined were divided into 6 groups:

1st group - healthy (n = 20);

Group 2 - patients with coronary heart disease and type II diabetes mellitus who did not have cardiac arrhythmias (n = 15);

3rd group - patients with coronary heart disease and type II diabetes mellitus, having supraventricular extrasystole (n = 12);

4th group - patients with coronary heart disease and type II diabetes mellitus, having ventricular extra systole (n = 13);

5th group - patients with coronary heart disease and type II diabetes mellitus, having a paroxysmal form of atrial fibrillation (n = 12);

6th group - patients with coronary heart disease and type II diabetes mellitus, having a constant form of atrial fibrillation (n = 11).

Statistical processing of the data obtained in the studies was carried out using variation statistics based on the program Statistica 5.0 for Windows, including the determination of t-student criterion and correlation analysis. Differences starting from p<0.05 were considered statistically significant.

**Research results and Discussion**

The Content Of Endothelin-1 in patients with coronary heart disease and type II diabetes was significantly higher than in healthy individuals (p<0.05). Its concentration was maximum in patients with a paroxysmal form of atrial fibrillation 11.2±0.49 (p<0.05), and ventricular extrasystole 8.3±0.44 (p<0.05).

Endothelin-1 levels were somewhat lower in patients with supraventricular extrasystole, a constant form of atrial fibrillation, and in patients with coronary heart disease without concomitant arrhythmias.

When analyzing the content of endothelin-1 in patients with coronary heart disease with type II diabetes mellitus, depending on the type of rhythm disturbances, it was found that in patients with ventricular extrasystole, a paroxysmal form of atrial fibrillation, its level was significantly higher than in patients with supraventricular extrasystole and constant form of atrial fibrillation (p<sub>1</sub><0.05, p<sub>3</sub><0.05). There were no statistically significant differences in the level of endothelin-1 between groups of patients with supraventricular extrasystole and a constant form of atrial fibrillation (p<sub>2</sub><0.05).

**Table 1: Plasma endothelin-1 level in patients**

Groups surveyed	Level endothelin-1 (ng/l)	P
1. Healthy	3.8±0.39	
2. Coronary heart disease + type II diabetes without heart rhythm disturbances	6.4±0.46	p<0.05
3. Coronary heart disease + type II diabetes mellitus + supraventricular extrasystole	6.4±0.37	p<0.05 p <sub>1</sub> <0.05

Groups surveyed	Level endothelin-1 (ng/l)	P
4. Coronary heart disease + type II diabetes mellitus + ventricular extrasystole	8.3±0.44	p<0.05 p <sub>1</sub> <0.05 p <sub>2</sub> <0.05
5. Coronary heart disease + type II diabetes mellitus + paroxysmal atrial fibrillation	11.2±0.49	p<0.05 p <sub>1</sub> <0.05 p <sub>2</sub> <0.05 p <sub>3</sub> <0.05
6. Coronary heart disease + type II diabetes mellitus + persistent atrial fibrillation	6.4±0.38	p<0.05 p <sub>1</sub> >0.05 p <sub>2</sub> >0.05 p <sub>3</sub> <0.05 p <sub>4</sub> <0.05

**Note:** The significance of differences is estimated with the indicators of previous groups.

The level of endothelin-1 in patients with a paroxysmal form of atrial fibrillation significantly exceeded its value in patients with ventricular extrasystole.

The values are respectively 11.2±0.49 ng/l and 8.3±0.44 ng/l (p<sub>3</sub><0.05). As is known, endothelin-1 is the main form of endothelin, which is formed only in vascular endothelial cells and plays the most important role in the regulation of vascular tone, cardiac output and permeability of the microvascular bed. Endothelin-1 significantly increases myocardial contractility, causes vasoconstriction of the coronary vessels, which leads to increasing ischemia and arrhythmia<sup>8,9</sup>. The formation and release of endothelin-1 is influenced by a number of factors<sup>10,11</sup>. The mechanisms of stimulation of the production and release of endothelin-1 are angiotensin-II, catecholamines, insulin, vasopressin and others<sup>12,13</sup>.

In this regard, the state of the renin-angiotensin-aldosterone system and the catecholamine content in the same groups of patients with coronary heart disease and

type II diabetes mellitus with and without concomitant arrhythmias were studied (tables 2 and 3).

To assess the state of the renin-angiotensin-aldosterone system, it was justified to determine the plasma renin activity, the level of angiotensin-II, aldosterone, as well as sodium and potassium electrolytes<sup>14,15</sup>.

Plasma renin activity was significantly higher than the control group only in patients with ventricular extrasystole and paroxysmal atrial fibrillation (p<0.05). Significant differences in the content of aldosterone in groups of patients were not identified.

The content of angiotensin-II was the highest - 22.8±0.75 ng/ml and 27.8±0.81 ng/ml in patients with frequent ventricular extrasystole and paroxysmal atrial fibrillation. This indicator was significantly higher than in other groups of patients and in persons of the control group (p<0.05, p<sub>1</sub><0.05, p<sub>2</sub><0.05). Among themselves, the indices of endothelin-1 in other groups did not statistically significantly differ (p<sub>3</sub>>0.05).

Note: the significance of differences is estimated with the indicators of previous groups.

The level of electrolytes in blood plasma of sodium and potassium did not statistically significantly differ between the groups of patients, although a tendency to a decrease in potassium levels, which did not reach statistical significance, was observed in groups of patients with ventricular extrasystole and a paroxysmal form of atrial fibrillation (table 2).

Along with endothelin-1, catecholamines also play an important role in the development of rhythm

disturbances<sup>16,17</sup>. As is known, through the stimulation of β-adrenoreceptors, catecholamines activate the adenylcyclase mechanism, which increases the content of cyclic guanosine monophosphate, which leads to increased calcium intake into the cell and its mobilization from the sarcoplasmic reticulum<sup>18,19</sup>. As a result of overflow of cardiomyocytes with calcium, the integrity of the membranes is violated, cell necrosis occurs, and prerequisites for the development of rhythm disturbances arise<sup>20,21</sup>.

**Table 3: The content of catecholamines in the plasma of the examined**

Groups surveyed	Adrenaline, nmol/l	Norepinephrine, nmol/l
1 healthy	3.22±0.26	30.12±0.75
2 coronary heart disease + type II diabetes without heart rhythm disturbances	3.48±0.32	33.75±0.96
3 coronary heart disease + type II diabetes mellitus + supraventricular extrasystole	3.52±0.30	31.52±0.38
4 coronary heart disease + type II diabetes mellitus + ventricular extrasystole	5.69±0.36*	37.51±0.41
5 coronary heart disease + type II diabetes mellitus + paroxysmal atrial fibrillation	7.23±0.42*	46.40±0.38*
6 coronary heart disease + type II diabetes mellitus + persistent atrial fibrillation	4.16±0.34*	37.12±0.73

Note: \* the significance of differences in indicators compared with the group of healthy (p<0.05).

Table 3 presents the results of a study of the level of adrenaline and norepinephrine in groups of patients with coronary heart disease and type II diabetes mellitus with and without arrhythmias.

The results indicate that in patients with cardiac arrhythmias, especially with a paroxysmal form of atrial fibrillation, and, to a lesser extent, ventricular extrasystole, an increase in the activity of the sympathoadrenal system is determined, which manifested itself in a statistically significant increase in adrenaline and norepinephrine levels (in patients paroxysmal atrial fibrillation) and increased levels of adrenaline (in patients with frequent

ventricular extrasystoles) compared with the control group (table 3).

It is known that cyclic guanosine monophosphate has an antiarrhythmic effect under experimental conditions against the background of the introduction of sympathomimetics<sup>22,23</sup>. In this regard, it was important to evaluate the content of cyclic guanosine monophosphate in all groups of patients taken into the study<sup>24</sup>. The level of cyclic guanosine monophosphate was lower in groups of patients with cardiac arrhythmias, however, this decrease was statistically significant in patients with a paroxysmal form of atrial fibrillation and to a lesser extent in patients with ventricular extrasystole (table 4).

**Table 4: The level of cyclic guanosine monophosphate in the plasma of the examined**

Groups surveyed	The concentration of cyclic guanosine monophosphate, nmol/l
1 healthy	7.28±0.26
2 coronary heart disease + type II diabetes without heart rhythm disturbances	7.45±0.22
3 coronary heart disease + type II diabetes mellitus + supraventricular extrasystole	6.24±0.38
4 coronary heart disease + type II diabetes mellitus + ventricular extrasystole	5.79±0.29*
5 coronary heart disease + type II diabetes mellitus + paroxysmal atrial fibrillation	5.38±0.31*
6 coronary heart disease + type II diabetes mellitus + persistent atrial fibrillation	6.23±0.39

Note: \* the significance of differences in indicators compared with the group of healthy (p < 0.05).

In other patients, when compared with the control group, a decrease in this indicator did not reach the level of statistical significance.

### Conclusion

The development of heart rhythm disturbances in patients with coronary heart disease with concomitant type II diabetes mellitus is accompanied by an increase in the level of endothelin-1, which indicates the development of endothelial dysfunction. The activation of the renin-angiotensin-aldosterone system under these conditions, the activation of the sympathoadrenal system with a decrease in the level of cyclic guanosine monophosphate create the conditions for chronic heart rhythm disturbances. In view of the presence of a relationship between rhythm disturbances and factors that can aggravate myocardial ischemia, it is advisable to use medications for the treatment of such patients that affect endothelial dysfunction, sympathoadrenal, renin-angiotensin-aldosterone systems, cyclic nucleotides

and angiotensin-converting inhibitors, beta-blockers, statins).

## Abstract

**Context:** Modern studies have shown that one of the risk factors for recurrent thrombosis, coronary heart disease and cerebrovascular pathology is the level of homocysteine in the blood. An analysis was made of the severity of homocysteinemia in patients with coronary heart disease with episodes of painless myocardial ischemia, and it was corrected with B vitamins. 84 patients with coronary heart disease with functional angina pectoris I-III were examined. It was found that the combination of hyperhomocysteinemia and frequent episodes of painless myocardial ischemia is recorded mainly in patients with a high functional class of angina pectoris. Reception of B vitamins can significantly reduce the concentration of homocysteine in blood plasma and the frequency of episodes of painless myocardial ischemia.

**Keywords:** *Hyperhomocysteinemia, coronary heart disease, angina pectoris, painless ischemia.*

## Introduction

Currently, the pathology of the cardiovascular system occupies a leading position in the morbidity and mortality of the population worldwide<sup>1</sup>. Coronary heart disease has the status of the leading cause of death in most developed countries and accounts for about 30% of total mortality, with no tendency to decrease this indicator<sup>2</sup>. Moreover, back in 2001, cardiovascular diseases claimed the lives of about 16 million people, that is, a third of global world mortality, then by 2025 it is predicted that this figure will be 25 million and in almost half of the cases will be caused by coronary heart disease<sup>3,4</sup>.

In this regard, the search for new risk factors continues, the identification of which would allow to influence the mortality rate from cardiological causes. Today there is no doubt that inflammation factors and procoagulants circulating in the blood play an important role in the pathogenesis of vascular lesions and atherosclerosis<sup>5,6</sup>. It has been established that hyperhomocysteinemia is an important risk factor for recurrent thrombosis, coronary heart disease and cerebrovascular pathology<sup>7,8</sup>.

Homocysteine is a sulfur-containing amino acid that is not involved in the synthesis of protein. It is a demethylated derivative of the essential amino acid methionine, which in humans and animals is the only metabolic precursor of homocysteine. Foods in a normal diet contain an insignificant amount of homocysteine. The low content of this potentially cytotoxic amino acid in the cells is ensured by its remethylation to methionine, by its transulfonation to cysteine, or by the formation of its oxidized forms<sup>9</sup>.

Normally, the level of homocysteine in blood plasma is 5-15  $\mu\text{mol/l}$ . In children and adolescents, this indicator is approximately 5  $\mu\text{mol/l}$ . During life, the average level of homocysteine increases by 3-5

---

e-mail: ilmedv1@yandex.ru

micromol/l and it is slightly higher in men compared with women. Hyperhomocysteinemia is diagnosed if the level of homocysteine in the blood exceeds 15  $\mu\text{mol/l}$ . Its plasma concentration of 15-30  $\mu\text{mol/l}$  indicates moderate hyperhomocysteinemia, from 30 to 100  $\mu\text{mol/l}$  - intermediate, and more than 100  $\mu\text{mol/l}$  - heavy<sup>7,8</sup>.

Hyperhomocysteinemia negatively affects endothelial and smooth muscle cells of blood vessels, platelets, blood lipids, nitric oxide and coagulation factors<sup>9</sup>. This is manifested even with moderate hyperhomocysteinemia. In addition, it stimulates atherosclerosis, disrupts the vasomotor function and anticoagulant properties of endothelium<sup>10,11</sup>.

For patients with coronary heart disease, regardless of the clinical form, elevated plasma homocysteine levels and episodes of painless myocardial ischemia are very characteristic<sup>12,13</sup>. According to modern concepts, the phenomenon of painless myocardial ischemia is found in 2–5% of the healthy population, in 30% of patients with post-infarction cardiosclerosis, and 40–100% of patients with stable and unstable angina<sup>14</sup>. The proportion of episodes of painless myocardial ischemia reaches 75–89% of the total number of cases of myocardial ischemia in these patients<sup>15,16</sup>. The detection of painless myocardial ischemia in combination with other high-risk criteria in a patient with coronary heart disease and confirmed angina pectoris is an indication for surgical treatment, since it significantly increases the likelihood of fatal cardiac complications in the near future<sup>17,18</sup>.

Along with hyperhomocysteinemia, the presence of painless myocardial ischemia is now regarded as one of the risk factors for the development of complications of coronary heart disease, including myocardial infarction and prognostically unfavorable heart rhythm disturbances<sup>3,19</sup>. It is believed that the combination of hyperhomocysteinemia and episodes of painless myocardial ischemia worsens the course of coronary heart disease. A relationship was suggested between the level of homocysteine in blood plasma in patients with coronary heart disease and the incidence of episodes of painless myocardial ischemia due to the presence of moments in their pathogenesis and the point of application that damages the effects of hyperhomocysteinemia<sup>20,21</sup>.

It is believed that metabolic elimination of hyperhomocysteinemia is possible with the help of vitamins<sup>22,23</sup>. When they are prescribed, there is a

decrease in the initially elevated level of homocysteine in all cases<sup>24</sup>. Particularly effective injections of B vitamins<sup>25,26</sup>.

The purpose of the study was to analyze the severity of homocysteinemia in patients with coronary heart disease with episodes of painless myocardial ischemia and its correction with a combination of vitamins B<sub>1</sub>, B<sub>6</sub> and B<sub>12</sub>.

## Materials and Method

The research was approved by the local ethical committee of the Russian State Social University on September 9, 2018 (protocol №9).

84 patients (62 people – the main group and 22 – the control group) who had a diagnosis of coronary heart disease with functional angina pectoris I-III, were examined at a clinic in Kursk State Medical University. The average age of the patients was 53.8±1.45 years, of which 58 were men and 26 women. The study did not include patients with acute myocardial infarction, valve defects, and chronic heart failure stage III (according to the classification of Strazhesko-Vasilenko), cardiomyopathy and endocrine pathology, with any kidney pathology and oncology.

To study the frequency and characteristics of painless myocardial ischemia, electrocardiography was used according to the standard method, two-dimensional echocardiography, bicycle ergometry, electrocardiography with dosed physical activity after canceling antianginal therapy, except nitroglycerin, which was used in case of an angina attack.

All patients with coronary heart disease were determined the concentration of homocysteine in plasma on the first and on the fourteenth day of observation. Blood sampling was carried out on an empty stomach after 12-hour fasting from a cubital vein in an amount of 10 ml. For quantitative determination of total homocysteine in blood plasma by enzyme-linked immunosorbent assay, a test system from Axell Biochemicals (Oslo, Norway) was used.

In addition to standard antianginal therapy, for the correction of hyperhomocysteinemia, patients additionally received B vitamins: B<sub>1</sub> at a dose of 150 mg/day, B<sub>6</sub> - 150 mg/day and B<sub>12</sub> - 3 mg/day.

The effectiveness of treatment was evaluated by re-determining the concentration of homocysteine in

blood plasma on the 14 day, as well as the frequency and intensity of angina attacks and exercise tolerance.

Statistical processing of the data obtained in the studies was carried out using variation statistics based on the program Statistica 5.0 for Windows, including the determination of t-student criterion and correlation analysis. Differences starting from  $p < 0.05$  were considered statistically significant.

### Results and its Discussion

For the convenience of comparative characteristics of patients with coronary heart disease of the main group, they were divided into 3 groups, depending on the functional class of angina pectoris. The 1st group (n=20) included patients with the I functional class, the 2 group (n=21) - the patients with the II functional class and the 3rd group (n=21) were the patients with the III functional class. Patients of group 1 showed a milder course of coronary heart disease, fewer complications than in groups 2-3. The presence of postinfarction cardiosclerosis in the first group was noted in 11.5% of cases, and episodes of painless myocardial ischemia in 11.7% of cases; in patients of the 2nd group, postinfarction cardiosclerosis was in 32.6% of cases, episodes of painless myocardial ischemia in 38.4%, in patients of group 3 postinfarction cardiosclerosis was recorded in 69.6% of cases, and in 72.3% - episodes of painless myocardial ischemia. When analyzing homocysteinemia in patients with coronary heart disease, it was taken into account in combination with concomitant pathology, taking into account previous myocardial infarction. Thus, the highest concentration of homocysteine was observed in patients with coronary heart disease with post-infarction cardiosclerosis and averaged  $18.5 \pm 1.8 \mu\text{mol/l}$  compared with patients with coronary heart disease without complications -  $15.2 \pm 0.9 \mu\text{mol/l}$  ( $p < 0.05$ ). Patients with coronary heart disease, who also had hypertension —  $17.6 \pm 1.7 \mu\text{mol/l}$  — were distinguished by a rather high level of homocysteine compared with patients without arterial hypertension. With a combination of coronary heart disease with post-infarction cardiosclerosis and hypertension, the level of homocysteine remained elevated -  $16.8 \pm 1.4 \mu\text{mol/l}$ .

Among patients included in group 2 and 3, the highest percentage of concomitant pathologies, such as hypertension, was noted - 31.9% and 55.6%, respectively.

Painless myocardial ischemia was diagnosed in 28 patients (33.3%) of the total number examined with

coronary heart disease in the form of stable angina pectoris of functional class III, with a history of post-infarction cardiosclerosis in 30 (35.7%) cases (table 1).

**Table 1: The dynamics of the level of homocysteine in the plasma of patients with coronary heart disease while taking vitamins of group B**

Patient groups	The level of homocysteine, $\mu\text{mol/l}$ , $M \pm m$		p
	for 1 day	for 14 days	
1 group (n=20)	$11.9 \pm 1.3$	$9.1 \pm 0.8$	$< 0.05$
2 group (n=21)	$15.6 \pm 0.5$	$13.1 \pm 0.7$	$< 0.05$
3 group (n=21)	$19.5 \pm 0.6$	$15.0 \pm 1.2$	$< 0.05$
Control group (n=22)	$16.6 \pm 0.8$	$17.2 \pm 0.8$	

The duration and frequency of episodes of painless myocardial ischemia directly depended on the severity of the course of coronary pathology and occurs in patients with coronary heart disease with a high functional class of stable angina pectoris, that is, in the 2-3 group, as well as in people who have suffered myocardial infarction. After myocardial infarction, 44% of patients with coronary heart disease who had had angina attacks before, ceased to feel pain typical of angina pectoris, therefore, the study of the frequency of detection of painless myocardial ischemia in these patients is of no small importance. When conducting physical exercise tests in patients with coronary heart disease in the late post-infarction period, despite the absence of angina attacks in most patients, almost 45.2% of them revealed episodes of painless myocardial ischemia.

An analysis of homocysteinemia in patients with coronary heart disease revealed a tendency to significantly increase homocysteine levels as the functional class of exertional angina increases. So in patients of 1 group the average level of homocysteinemia was  $11.9 \pm 1.3 \mu\text{mol/l}$ , in 2 group the concentration of homocysteine reached  $15.6 \pm 0.5 \mu\text{mol/l}$ , in 3 group  $18.5 \pm 0.6 \mu\text{mol/l}$  ( $p < 0.05$ ). That is, in patients with tension angina of functional class III, the concentration of homocysteine was higher than in functional class I by 63.8%. When re-determining the concentration of homocysteine after taking B vitamins, a significant decrease in homocysteine was noted ( $p < 0.05$ ). So, its average level in group 1 after 14 days decreased to  $9.1 \pm 0.8 \mu\text{mol/l}$ . In 2 group after 14 days it decreased to  $13.1 \pm 0.7 \mu\text{mol/l}$  and in group 3 to  $15.0 \pm 1.2 \mu\text{mol/l}$  ( $p < 0.05$ ). In the control group homocysteine levels did not experience dynamics (table 1).

The results obtained indicate that with the additional intake of vitamins B1, B6 and B12 in combination with antianginal therapy, the level of homocysteine in plasma in patients with coronary heart disease significantly decreases. Moreover, in patients with initial hyperhomocysteinemia, the decrease is more pronounced.

Against the background of a decrease in the level of homocysteine in patients, the quality of life improved by reducing the number of angina attacks and thereby reducing the use of nitroglycerin per week, compared with the control group. So in the 2 group, the number of nitroglycerin tablets consumed by patients after 14 days decreased by 25.8%, in the 3rd group this amounted to 36.1%. In the control group, the dynamics of nitroglycerin consumption were not detected ( $p < 0.05$ ). Also, against the background of the treatment, all patients noted an improvement in overall health, a decrease in the frequency and intensity of angina attacks, as well as increased tolerance to physical activity. In this regard, the need for early diagnosis of painless myocardial ischemia and correction in such patients with hyperhomocysteinemia should be recognized. This will help to slow the progression of angina pectoris and reduce the number and duration of episodes of painless myocardial ischemia<sup>27</sup>.

### Conclusion

The level of plasma homocysteine is directly proportional to the functional class of angina pectoris. The more pronounced homocysteinemia, the more severe the clinical manifestations of stable exertional angina. An additional intake of B vitamins statistically significantly reduces the level of total homocysteine in blood plasma in most patients. This is accompanied by a decrease in the number and duration of episodes of painless myocardial ischemia. There is reason to hope that the optimization of homocysteine will inhibit the progression of coronary heart disease and lower the functional class of angina pectoris.

## Astract

**Context:** Currently, chronic obstructive bronchitis remains a very common disease in adolescence. The study involved 42 adolescents 13-14 years old suffering from at least 5 years of chronic obstructive bronchitis without signs of respiratory failure. At the time of the examination of adolescents, this disease was in a state of unstable remission. For adolescents with chronic obstructive bronchitis, a decrease in the vital capacity of the lungs and diameter of the bronchi of any caliber is characteristic. This quickly leads to a significant decrease in the functionality of the external respiration apparatus. With this disease, resistance of the respiratory center to hypoxia and a weakening of the adaptive capabilities of the respiratory system arise early. Regular performance of asanas in adolescents with chronic obstructive bronchitis leads to the restoration of the functional properties of their respiratory system and circulatory system, and optimizes their hypoxia resistance.

**Keywords:** Rehabilitation, respiratory system, lungs, chronic bronchitis, adolescents.

## Introduction

The life of each organism is associated with its continuous interaction with the environment, which often affects it negatively<sup>1,2</sup>. The total environmental effect on the body is formed in it by a whole series of

regular reactions<sup>3,4</sup>, contributing to its adaptation to the existing conditions of life<sup>5,6</sup>. Due to the severity of harmful environmental influences and sometimes due to the imperfection of adaptation processes in some cases, various dysfunctions and sometimes obvious pathology can develop in the body<sup>7,8</sup>.

Very often, pathological processes in the human body are noted in the cardiovascular system, blood system and respiratory system<sup>9</sup>. They are life support systems and, as a result, significantly support the overall viability of the mammalian organism<sup>10,11</sup>. Currently, the society has seen an increase in lung diseases, especially in childhood and adolescence<sup>12,13</sup>. A very common disease among them is obstructive bronchitis<sup>14</sup>.

This disease is often accompanied by changes in the sensitivity of the walls of the bronchi and the development of their hyperreactivity. It manifests itself as a cough with sputum and frequent shortness of breath during physical exertion. The disease is aggravated by hypothermia or the ingress of industrial impurities into the air<sup>15</sup>.

The widespread prevalence of chronic obstructive bronchitis and its sometimes severe course currently creates an urgent need to improve approaches to the rehabilitation of this patient population using the entire available arsenal of healing effects<sup>16,17</sup>. The purpose of the study was to assess the state of the function of external respiration in adolescents with chronic obstructive bronchitis performing the asanas complex.

### Materials and Research Method

The study was approved by the local ethics committee of the Russian State Social University on September 15, 2017 (protocol №11). The study was performed on the basis of the Russian State Social University, Moscow, Russia. The study was conducted on 42 adolescents aged 13-14 years suffering from at least 5 years of chronic obstructive bronchitis without respiratory failure. At the time of the first examination, the disease was in all teenagers in a state of unstable remission. The control group consisted of 20 clinically healthy adolescents of a similar age.

All adolescents with bronchitis underwent rehabilitation for 3 months, including yoga system exercises aimed at diluting and removing sputum from the respiratory tract, eliminating bronchospasm, increasing the elasticity and lability of the chest and strengthening its muscles.

1. Asana "Onion". Starting position - lie on your stomach, raise your legs bent at the knees, hold your ankles with your hands. Take a deep breath and pull both legs up, arching your back. Remain in this position, hold your breath, then slowly lower your legs as you exhale. During the exercise, try to ensure that only the stomach touches the floor. First, knees apart, then raise your legs high, after finishing the deflection, knees, hips, ankles to connect. Repeat asana 10-12 times.

2. Asana "Blacksmithing Furs". Starting position - sitting in the "lotus" position. After a complete exhalation, quickly inhale and exhale through the nose - 10 times, then exhale, hold your breath for 7-10 seconds, inhale with a subsequent breath hold for 10-15 seconds. Repeat the same, but throwing his head back to the limit, and then lower the chin to the chest. Gradually bring the number of breaths in one cycle to 25-30. Repeat asana 5 times.

The study used the spiograph SMP-21/01- "R-D" produced by the scientific and production enterprise "Monitor" (Russia). With its help, a spiogram was recorded, which evaluated the minute volume of respiration, vital capacity of the lungs, maximum lung ventilation, reserve volume of inspiration, reserve volume of expiration, forced vital capacity of the lungs, volume of forced expiration in 1 second, peak volume velocity, maximum volume velocity at the level of 25%, 50% and 75% of the value of the forced vital capacity of the lungs.

In the work, all examined had a functional test of Stange, determining the maximum possible time of breath holding on inspiration<sup>18</sup>.

A functional test of Genchi was carried out for all those taken under observation, determining the maximum possible time for breath holding on exhalation<sup>18</sup>.

To assess the overall functional state of the cardiorespiratory system in the examined, the Skibinsky index was calculated. This indicator characterizes the overall functional state of the external respiration system and its resistance to hypoxia.

The magnitude of the excursion of the chest was measured with a centimeter tape which was placed at the back at the level of the angles of the shoulder blades, and at the front over the mammary glands (in girls), calculating the difference between the maximum inhalation and exhalation<sup>18</sup>.

To identify the statistical difference between the indicators in the group of patients and in the control group, t-student criterion was used.

## Research Results and Discussion

In sick adolescents, a significant violation of the indicators was noted (Table 1).

**Table 1: Indicators of external respiration function in adolescents with chronic obstructive bronchitis**

Estimated performance	Group of sick teenagers, n=42, M±m		Control group, n=20, M±m
	At the beginning of observation	At the end of the observation	
Vital lung capacity, l	1.9±0.11	2.4±0.22 p <sub>1</sub> <0.05	2.4±0.12 p<0.05
Forced vital capacity, l	1.7±0.09	2.2±0.16 p <sub>1</sub> <0.01	2.3±0.17 p<0.01
Forced expiratory volume in 1 second, l	1.6±0.12	2.1±0.12 p <sub>1</sub> <0.01	2.2±0.15 p<0.01
Minute breathing volume, l/min	12.3±0.43	10.6±0.30 p <sub>1</sub> <0.05	10.1±0.45 p<0.05
Maximum ventilation, l/min	47.7±0.36	56.4±0.42 p <sub>1</sub> <0.05	57.9±0.82 p<0.05
Peak space velocity, l/s	2.7±0.25	4.0±0.21 p <sub>1</sub> <0.01	4.2±0.32 p<0.01
Maximum space velocity <sub>25</sub> , l/s	3.2±0.24	4.2±0.18 p <sub>1</sub> <0.05	4.3±0.27 p<0.05
Maximum space velocity <sub>50</sub> , l/s	2.4±0.22	2.8±0.14 p <sub>1</sub> <0.05	3.0±0.20 p<0.05
Maximum space velocity <sub>75</sub> , l/s	1.6±0.10	1.7±0.12	1.8±0.16 p<0.05
Stange Result, s	41.8±0.41	59.2±0.27 p <sub>1</sub> <0.01	61.2±0.48 p<0.01
Gencha test result, s	24.9±0.52	31.2±0.32 p <sub>1</sub> <0.05	32.6±0.42 p<0.05
Chest excursion, sm	2.8±0.36	5.5±0.29 p <sub>1</sub> <0.01	5.8±0.39 p<0.01
Skibinsky index, conventional units	28.5±0.72	59.1±0.40 p <sub>1</sub> <0.01	61.3±0.71 p<0.01

Legend: p - reliability of differences in indicators between a group of patients and a control group, p<sub>1</sub> - reliability of dynamics of indicators against the background of recovery.

It was found that the values of lung vital capacity in sick adolescents were inferior to the level of the control group by 26.3%. The value of the forced vital capacity of the lungs was 35.3% lower than the control level. Moreover, in terms of forced expiratory volume for 1 second, the control group exceeded the same indicator in sick adolescents by 37.5%.

By comparing the values of the minute volume of breathing, it was possible to establish its increase in adolescents with chronic obstructive bronchitis compared with the control by 21.8%. In addition, in the group of patients, the maximum ventilation rate was reduced by 21.4%.

In the initial state in patients with adolescents, the peak volumetric rate was reduced by 55.5%. This was accompanied by a decrease of 34.4% in the average value of the maximum volumetric rate indicator at the level of 25% of the value of the forced vital capacity of the lungs. Their maximum volumetric rate, which is at the level of 50% and 75% of the value of the forced vital capacity, was reduced by 25.0% and 12.5%, respectively. In addition, when taking adolescents with chronic obstructive bronchitis in the study, the indicators of hypoxic tests and the level of chest excursion were significantly lower than those in the control group. Moreover, the average Skibinsky index in sick

adolescents in the outcome was significantly lower than in the control group (2.1 times).

As a result of conducting rehabilitation measures in adolescents with chronic obstructive bronchitis for 3 months, an increase in lung capacity was reached to the level of the control group (by 26.3%). At the same time, the magnitude of the forced vital capacity of the lungs also reached the control level, increasing by 29.4%. By the end of the observation, in terms of forced expiratory volume in 1 second, the control group equaled that of sick adolescents due to its growth of 31.2%.

During physical rehabilitation, sick adolescents achieved normalization of the minute respiratory volume due to its decrease by 16.0% and maximum lung ventilation as a result of its increase by 18.2%. In addition, they experienced an increase in peak volume velocity by 48.1%. This was accompanied by an increase of 31.2% in the average value of the maximum volumetric rate indicator at the level of 25% of the value of the forced vital capacity of the lungs. In these adolescents, by the end of the observation, the maximum volumetric velocity indicator, which was at the level of 50% and 75% of the value of the forced vital capacity, increased by 16.7% and 6.2%, respectively. In addition, in patients with bronchial asthma, against the background of the rehabilitation, the indicators of hypoxic tests and the level of chest excursion significantly increased and approached those in the control group. At the same time, the average Skibinsky index in sick adolescents significantly increased and by the end of the observation corresponded to the level of the control group.

## Discussion

In modern society, chronic obstructive bronchitis is a very common pathology in adolescents. Often, he manifests already in childhood and is rapidly progressing<sup>19</sup>.

The revealed initial decrease in patients with adolescents with a maximum volumetric rate of 25% of the level of forced vital capacity of the lungs indicated a progressive deterioration in their patency at the level of large bronchi<sup>20</sup>. The average value of the maximum volumetric velocity index found in patients at the level of 50% and 75% of the forced vital capacity of the lungs proved a decrease in the patency of the bronchi of medium and small caliber. The initial negative changes in the indicators of hypoxic tests and a decrease in the volume of chest excursion<sup>21</sup>. The initially low Skibinsky

index indicates the presence in the group of adolescents with chronic obstructive bronchitis of functional weakness of the respiratory and circulatory organs, and, consequently, the low resistance of their body to hypoxia<sup>22</sup>.

Rehabilitation had a pronounced positive effect on sick adolescents. It provided patients with a clear control of the respiratory act, restoration of full breathing, the correct ratio of the length of the inspiration and expiration, the necessary depth and frequency of respiration.

It was established that the complex of asanas ensured in patients an increase to the level of normal vital capacity of the lungs. The bronchial obstruction eliminated in them ensured an increase in their expiratory volume to a control level in 1 second. In sick adolescents there was an increase in the maximum ventilation rate. This should be considered as a normalization of the functional capabilities of the external respiration apparatus, as well as an increase in the reserves of respiratory function<sup>23</sup>.

The rehabilitation provided in adolescents increased functional capabilities of the respiratory muscles and optimized patency of large-caliber bronchi. Changes in the maximum volumetric rate index found at the level of 25% of the level of the forced vital capacity of the lungs found during rehabilitation indicated the development of a significant increase in patency of large bronchi in rehabilitated teens<sup>24</sup>. Achieved during recovery of adolescents with bronchitis, the growth of average values of the maximum volumetric rate indicator at the level of 50% and 75% of the forced vital capacity of the lungs proved the optimization of bronchial patency of medium and small caliber. Positive changes in them against the background of improvement in indicators of hypoxic tests and the volume of chest excursion proved the possibility of normalizing, with this pathology, the sensitivity of the respiratory center to hypoxia and the adaptive capabilities of the entire external respiration system. Normalization of the Skibinsky index can be regarded as an increase in patients with functional activation of the respiratory and circulatory organs and normalization of their body's resistance to hypoxia<sup>25</sup>.

## Conclusion

The development of chronic obstructive bronchitis changes the sensitivity of the walls of the bronchi to external influences and leads to their hyperreactivity. This leads to an increase in functional weakness of the respiratory system and circulatory system. Tested

in adolescents with chronic obstructive bronchitis, the asanas system gradually eliminated disturbances in the external respiration system, establishing normal relations between the cerebral cortex and internal organs. She optimized breathing, helped to eliminate the tendency to bronchial obstruction in patients, normalize the respiratory act and increase the general resistance of the body.

# Predicting Behavioral Intentions to Control Type 2 Diabetes Mellitus from Social-Cognitive Variables at Haji Surabaya General Hospital, Indonesia

Irma Dian Permata<sup>1</sup>, Shrimarti Rukmini Devy<sup>2</sup>, Oedojo Soedirham<sup>2</sup>

<sup>1</sup>Health Promotion and Behavioral Sciences, Master Program of Public Health Sciences, Faculty of Public Health, Universitas Airlangga, Indonesia, <sup>2</sup>Departement of Health Promotion and Behavioral Science, Faculty of Public Health, Universitas Airlangga, Indonesia

## Abstract

**Context:** From 2015 through 2018, the number of visits of patients diagnosed with type 2 diabetes mellitus (DM), without complication, with an age range of 40-59 years, at the Internal Medicine section, Outpatient Installation of Haji Surabaya General Hospital (HSGH), has increased. It was an indicator that shows the non-optimal handling and control of DM in communities, and it needs to be followed by health efforts to restrain this non-communicable disease. Therefore, this study aims to analyze the factors that influence the control behavior of type 2 DM based on the concept of the Health Action Process Approach (HAPA). Respondents in this study were 120 patients that suffered type 2 DM, with no complication, who met the study inclusion criteria, who visit the Internal Medicine section, Outpatient Installation of HSGH. Primary data from the respondents included knowledge, risk perception, outcome expectancies, the action of self-efficacy, behavioral intention, planning, maintenance of self-efficacy, recovery of self-efficacy, and action, which collected through survey instruments in the form of adopted questionnaires with cross-sectional research design, and it analyzed statistically using the Path Analysis, through AMOS software, with a significance level ( $\alpha = 0.05$ ). During the motivational phase, social cognitive variables, namely the outcome expectancies and the action of self-efficacy, could predict an individual's behavioral intention to control type 2 DM ( $p < 0.05$ ). In contrast, risk perception variable did not affect behavioral intention to control the disease.

**Keywords:** Behavioral intention, outcome expectancies, risk perception, self-efficacy, diabetes

## Introduction

The era of globalization led to lifestyle and epidemiological transitions that marked by a shift in the pattern of diseases; from infectious to non-communicable diseases. A non-communicable disease that affects the morbidity, mortality, and health crisis in the world and ranked as the third highest in the world is type 2 diabetes

mellitus (DM). In 2017, the number of people with type 2 DM had reached 425 million in the world and was estimated to increase by 48% in 2045<sup>1</sup>. According to the results of the 2018 Basic Health Research<sup>2</sup>, in 2013, the prevalence of type 2 DM was 6.9% and increased to 10.9% in 2018. The Ministry of Health of the Republic of Indonesia<sup>3</sup> revealed that the prevalence of type 2 DM patients in East Java was 275,462 in 2007 and increased to 605,974 in 2013. Surabaya, as the capital of East Java province, is one of the cities with a high prevalence for cases of type 2 DM; the number of cases of type 2 DM was 15,961 in 2009 and increased to 21,729 in 2010, then rose again to 26,613 in 2013<sup>4</sup>.

The Hospital Information System notes that DM ranks 5th out of the top 10 non-communicable diseases

causing outpatient in hospitals in Indonesia<sup>5</sup>. Besides, type 2 DM was ranked second out of five diseases with the majority of patients treated by outpatient installations in type B hospitals<sup>6</sup>. From 2015 to 2017, type 2 DM ranks first on the top 10 list of diseases in Outpatient Installation, HSGH, and experienced an upward trend<sup>7</sup>. From 2015 through 2018, type 2 DM was ranked first for the diagnosis of the top 5 most diseases in the Outpatient Installation of HSGH<sup>8</sup>. The increasing trend of the number of visits and diagnoses of type 2 DM indicates that efforts to control non-communicable diseases are needed by making changes in health behavior. However, it is certainly not easy to be implemented; therefore, a concept needed to motivate the patients to apply the control behavior.

The concept of Health Action Process Approach (HAPA) used to explain in detail the motivational phase or pre-intentional phase and focuses on the process of increasing motivation to build intention in behaving<sup>9</sup>. HAPA consists of social-cognitive aspects such as risk perception, outcome expectancies, and the action of self-efficacy that can influence the intention to behave to control type 2 DM. Therefore, the motivation of this study was to analyze social-cognitive variables in predicting behavioral intentions to control type 2 DM in the motivational phase.

### Materials and Method

This observational study uses a cross-sectional design which conducted from March to April 2019. Data collected through visiting the 120 respondents, based on a random sampling, who suffered type 2 DM, without complication, who treated as an outpatient at the Internal Medicine section, Outpatient Installation of the HSGH. All respondents met the research inclusion criteria, aged 40-59 years, able to communicate well and able to read and write, willing to be interviewed, and have failure in controlling the type 2 DM.

Data was collected through an adapted questionnaire which consists of five parts, namely demographic information, risk perception, outcome expectancies, the action of self-efficacy, and behavioral intention, which measured on a 4-point Likert scale<sup>10</sup>. The dependent variable is the intention to behave to control type 2 DM, while the independent variables are risk perception, outcome expectancies, and the action of self-efficacy. The validity and reliability of the questionnaire are

examined by collecting data from 20 respondents who had similar characteristics at another Health Center. Validity test uses Pearson Product-Moment correlation, while the reliability test uses alpha Cronbach coefficient with a significance level ( $\alpha = 5\%$ ). Data analyzed by Path Analysis that test the effect of risk perception, outcome expectancy, and action self-efficacy on behavioral intention to control type 2 DM.

### Results

Table 1 shows the characteristics of respondents. Based on the criteria of the dependent and independent variables, the majority of respondents felt “at risk” of suffering from complications of type 2 DM if they did not practice control behavior. Half of the respondents have high outcomes expectancies related to the control behavior of type 2 DM. Most of the respondents had confidence in their ability to carry out control behaviors of type 2 DM before starting action. The majority of respondents have the intention to control type 2 DM to maintain the quality of life that manifested by checking blood sugar levels regularly, eating healthy foods, and exercise regularly.

**Table 1: Characteristics of Respondents**

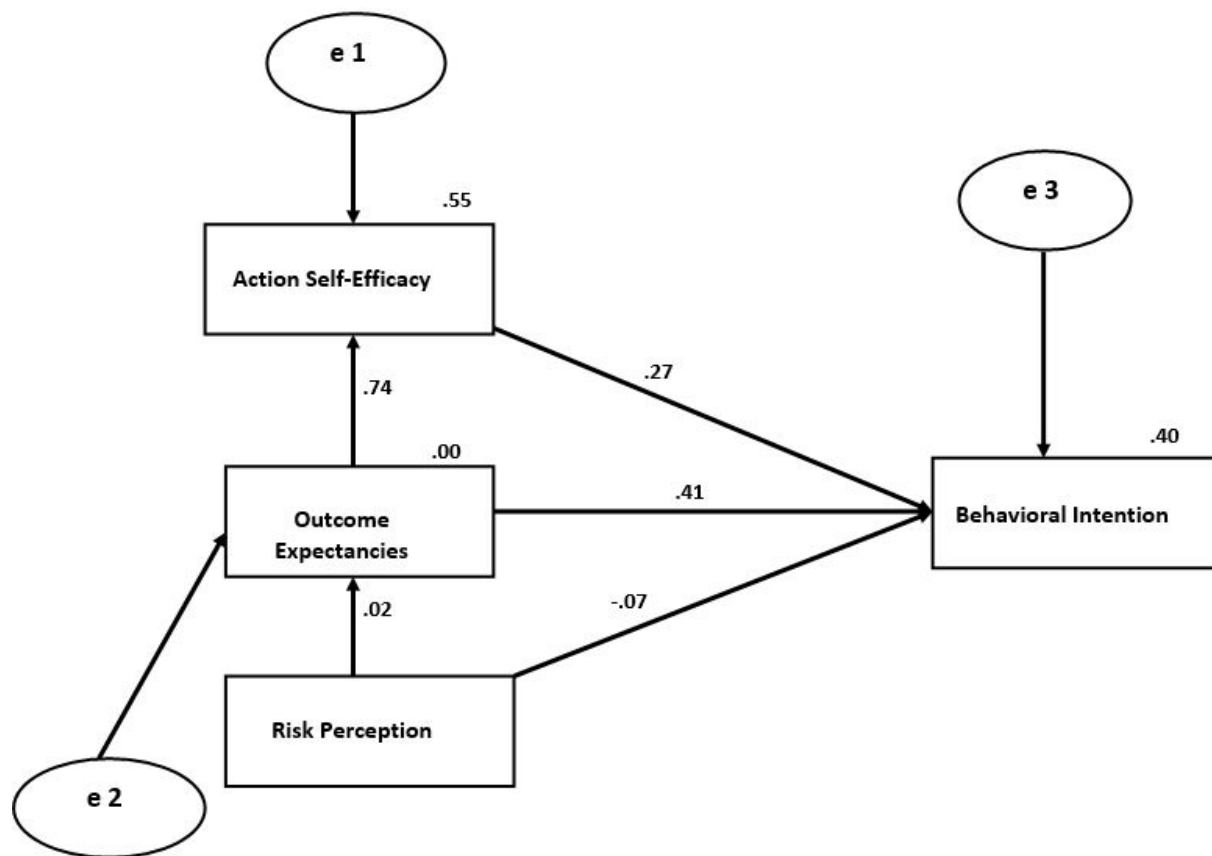

No.	Characteristics	Frequency	Percentage (%)
<b>1.</b>	<b>Age Group (Year)</b>		
	40-49	26	21.7
	50-59	94	78.3
<b>2.</b>	<b>Gender</b>		
	Male	28	23.3
	Female	92	76.7
<b>3.</b>	<b>Diabetes Family History</b>		
	Yes	63	52.5
	No	57	47.5
<b>4.</b>	<b>Risk Perception</b>		
	No risk	16	13.3
	At risk	104	86.7
<b>5.</b>	<b>Outcome Expectancies</b>		
	Not hope	60	50.0
	Hope	60	50.0
<b>6.</b>	<b>Action Self Efficacy</b>		
	Not confident	7	5.8
	Confident	113	94.2
<b>7.</b>	<b>Behavioral Intention</b>		
	No intention	9	7.5
	With intention	111	92.5

**Table 2: Result of Influence Analysis Risk Perception, Outcome Expectancies, and Action Self-Efficacy to The Behavioral Intention to Control Type 2 Diabetes Mellitus**

No.	Variable	B	P value	Description
1.	Risk Perception	-.066	0.35	Not significant
2.	Outcome Expectancies	0.408	<0.001	Significant
3.	The Action of Self-Efficacy	0.266	0.012	Significant

Table 2 shows that respondents' expectations for controlling this non-communicable disease and

avoiding future complications are contributing factors in determining the behavioral intention of respondents to control type 2 DM to prevent complications, which indicated by the lower value of p than 0.05 for the variable of the outcome expectancies. Respondents' self-confidence in practicing control behaviors of type 2 DM before starting action are an essential factor in developing respondents' behavioral intentions. In contrast, risk perception is not a factor that influences the intention to control type 2 DM. Figure 1 shows that the outcome of self-efficacy influences behavioral intention directly and indirectly through the action of self-efficacy.

**Figure 1: The final model of Path Analysis according to the theory of the Health Action Process Approach (HAPA)**

Based on the model criteria, the threshold of criteria's value, and model result, the model considered as good and fit to explain the direct and indirect effects of the independent variables on the dependent variable (Table 3). The HAPA model explained that behavioral

intentions could be predicted by risk perception<sup>11</sup>, since the risk perception is the main factor that triggers the formation of outcome expectancies and action self-efficacy at a later stage<sup>12</sup>.

**Table 3: The quality of the final model of the Path Analysis according to the theory of the Health Action Process Approach (HAPA).**

Model Criteria	Threshold Value	Model Result	Notes
Chisquare	Chisquare value expected to be low	2.98	Good/Fit
Probability	Probability more than 5%	0.084	Good/Fit
CMIN/DF	≤ 5	2.98	Good/Fit
GFI	≥ 0.90	0.987	Good/Fit
TLI	≥ 0.90	0.922	Good/Fit
NFI	≥ 0.90	0.98	Good/Fit

This study found that the high risk of complications of type 2 DM perceived by respondents did not affect their behavioral intentions. Fear and risk perception may stimulate respondents to make decisions to adapt to control behavior. However, it could be more efficient if combined with the intervention of the attitude transformation such as subjective attitudes and norms<sup>13</sup>. Parschau et al.<sup>14</sup> stating that there is no significant influence between risk perception and the intention to do physical activity on those who are suffering from obesity. Another study conducted by Rohani et al.<sup>15</sup> also in line with these findings that there was no relationship between risk perception and behavioral intention. Other studies show that perceptions of disease severity also play an essential role in the process of forming intentions to adopt healthy behaviors<sup>16</sup>.

The results of Path Analysis show that the respondents more intend to control type 2 DM if they have high outcomes expectancies. Schwarzer and Renner<sup>17</sup> also states that the outcome expectancies along with the action of self-efficacy significantly influence the formation of an intention to implement a healthy food diet. Other studies also show that the intention to exercise can be well predicted by the action of self-efficacy, outcome expectancies, and risk perception simultaneously<sup>18</sup>. There is a high level of confidence that obese people have that they will get a positive impact if they actively engage in physical activity both individually and in groups<sup>19</sup>.

The HAPA model explains that risk perception, outcome expectancies, and action self-efficacy are the best predictors of behavioral intention<sup>20</sup>. In the process of adopting the control behavior, people also need to understand the contingency between the type 2 DM

control behavior and the results or benefits that will be obtained in the future. Therefore, people need sufficient knowledge about the benefits that could be achieved from a series of actions that must be accomplished and how to regulate behavior<sup>21</sup>.

The results of the Path Analysis test show that the respondents' belief in their ability to control type 2 DM, before starting the action, is one of the crucial factors that determine whether the intention to control type 2 DM. This finding is in line with Renner et al.<sup>10</sup> which shows that the intention to apply a low-fat and high-vitamin diet predicted by action self-efficacy. Another study conducted by Renner and Schwarzer<sup>21</sup> showed that the behavior of a low-fat diet is influenced jointly by three social cognitive variables; risk perception, outcome expectancies, and self-efficacy actions.

The HAPA theory explains that the outcome of expectancies will stimulate someone to develop self-efficacy actions<sup>12</sup>. The study indicates that most of the respondents have confidence in their ability to control type 2 DM even though they must reconsider, find difficulties when applying it, motivate themselves, and make plans to control type 2 DM. Conversely, when someone feels unsure, then s/he will imagine failure, doubt, and tend not to have the intention to control type 2 DM.

The findings of this study have implications for health interventions. In the phase of intention formation (pre-intentional or motivational), research findings indicate that strategies are needed to improve the outcome of expectancies and action self-efficacy<sup>22</sup>. In this case, respondents can be given counseling to increase their self-confidence in anticipating various obstacles during the process of adopting the type 2 DM control behavior. Glanz et al.<sup>23</sup> explained that an effort to improve self-efficacy is to provide training skills in performing recommended behaviors. Thus, these results can be a basis for making a recommendation of a health promotion program, namely behavioral training in controlling type 2 DM by health workers, especially for DM health educators and hospital health promoters in the Hospital Health Promotion activities. The active role of trained DM health educator and collaboration with hospital health promoters is needed and synergized with nutritionists to provide healthy diet counseling for patients with type 2 DM so that they will have the ability to control and avoid complications.

## Conclusion

The majority of respondents are aged between 50-59 years, women, feel at risk of suffering from complications of type 2 diabetes mellitus, have hopes to avoid complications due to their illness, feel confident in their ability to make control behaviors, and have the intention to control this non-communicable disease. Behavioral intention to control type 2 DM can be predicted well by the outcome expectancies and the action of self-efficacy, but it could not be predicted by risk perception. Outcome expectancies and the action of self-efficacy play an essential role in the process of forming behavioral intention to control type 2 DM in the motivational phase. In contrast, risk perception does not contribute to determining whether the respondent will intend to control type 2 DM or not.

# Relationship Between Mother's Knowledge of Rubella with Measles Rubella (MR) Immunization Status in Children Age 9-59 Months at MR Campaign, Java Island - Indonesia 2017

Irma Gusmi Ratih<sup>1</sup>, TriYunisMiko Wahyono<sup>2</sup>

<sup>1</sup>Master of Epidemiology, Faculty of Public Health, University of Indonesia, <sup>2</sup>Departemen of Epidemiology, Faculty of Public Health, University of Indonesia

## Abstract

**Background:** MR (Measles Rubella) campaign is one of Indonesia's efforts to achieve the world target without measles, rubella, and Congenital Rubella Syndrome (CRS) in 2020. However, the results show that MR campaign immunization coverage is not optimal. This study aims to determine whether the knowledge of mothers about rubella is related to MR immunization status in MR campaign at Java Island.

**Method:** This cross-sectional study used secondary data from the survey of Independent Evaluation of MR Immunization in 6 provinces at Java Island in 2017. There were 5,971 samples of mothers who had children aged 9-59 months were obtained based on cluster sampling technique. Bivariate and multivariate analysis were used to see the relationship between mother's knowledge of rubella and MR immunization status.

**Result:** Mother's knowledge about rubella interacted with belief (POR 1,899 95% CI 1,267-2,848) and interacted with education (POR 1,675 95% CI 1,086-2,583) to form a statistically significant relationship with MR immunization status.

**Conclusion:** Mother's knowledge of rubella is very important in increasing MR immunization coverage. Therefore, the government is expected to cooperate with active stakeholders to provide information on MR immunization.

**Keywords:** *Mother's knowledge, MR campaign.*

## Introduction

Immunization is one of the best efforts in global health and has an important role in achieving 14 out of 17 SDGs<sup>(1)</sup>. In the Global Vaccine Action Plan (GVAP), endorsed by the 194 Member States of the World Health Assembly in May 2012<sup>(2)</sup>, measles and rubella are targeted to be eliminated in 5 WHO regions by 2020.

In line with GVAP, the 2012-2020 Global Measles & Rubella Strategic Plan maps out the strategies needed to reach the world target without measles, rubella, and Congenital Rubella Syndrome (CRS). One of the efforts made by Indonesia to achieve this target is to carry out the MR campaign in children aged 9 months to less than 15 years in 2 phases; phase 1 in August-September 2017 in 6 provinces on Java Island and phase 2 in August-September 2018 in 28 other provinces outside Java Island. The MR campaign is the first step to introduce MR vaccines, replacing the measles vaccine, into the immunization program<sup>(3)(4)</sup>.

The MR campaign is informed massively through all media (newspapers, flyer, booklet, banner, television ads, and social media) which aims to increase public

knowledge, especially mothers, about the importance of MR immunization. But the results of the MR campaign immunization coverage is not optimal, which is below the target of 95% coverage<sup>(5)</sup>. This unoptimal coverage can be influenced by several factors, the lack of the knowledge of the mother<sup>(6)(7)</sup> especially the knowledge of rubella, negative beliefs about immunization (the implementation of the MR campaign is enlivened by polemic on haram MR vaccine)<sup>(8)</sup>, and lack of support from health workers. This study aims to determine whether the knowledge of mothers about rubella is related to the MR immunization status in the MR Campaign at Java Island.

**Material and Method**

This study uses secondary data from a survey of Independent Evaluation of MR Immunization (MR Campaign) in 6 provinces at Java Island in 2017. There were 5.971 mother who had children aged 9 - 59 months who were willing to fill out the questionnaire in the survey, which was obtained based on cluster techniques sampling<sup>(9)</sup>. The dependent variable is the status of MR immunization based on a yes / no answer to the question of whether the child received MR immunization in the MR campaign. The independent variable is the mother’s knowledge of rubella based on the answer to the question of whether the mother knows that rubella disease can be prevented by immunization. The covariate variable is the education of mothers who were categorized as low if the last education is junior high school, and high if the last education is high school and above; attitude measured by questions related to comfort when immunizing; belief measured by questions related to vaccine issues and believe that children are entitled and obliged to receive immunizations; information access measured by asking where did the mother get information about

the MR campaign; and the support of health workers as measured by the opinions of mothers about the support of health workers to carry out MR immunization in the MR campaign. The answers to these questions are scored and measured mean values to see the cut-off-point to determine for good or less good criteria.

This study used a cross sectional study design with risk measures using prevalence odds ratio (POR). Data were analyzed by logistic regression test with 95% confidence interval through several stages; (1) Bivariate analysis, to see POR crude, (2) Interaction test to see whether there was an interaction between mother’s knowledge about rubella and MR immunization status, (3) Confounding test was carried out by comparing POR crude with adjusted POR, if the difference between the two PORs is more than 10% then the variable is considered as a confounder and included into multivariate analysis, and (4) Multivariate analysis.

**Results**

The proportion of children whosenot immunized in the MR campaign at Java Island is 11.8%. The proportion of MR immunized children is 88.2% or still below the target of immunization coverage, which is 95%. Table 1 shows that mothers who have lack of knowledge about rubella have a higher proportion (81.1%) compared to those with good knowledge. The children who were not immunized had a higher proportion in mothers’ negative beliefs about immunization (68%) and the lack of support from health workers (82.1%). Bivariate analysis shows that variables which have significant relationship with MR immunization status are mother’s knowledge of rubella, attitude, informationaccess, and support of health workers.

**Table 1: MR Immunization Status Based on Independent and Covariate Variables**

Variables	MR Immunization Status				POR (95% CI)	p-value
	No		Yes			
	n=703	%	n=5.268	%		
<b>Independent Variable</b>						
<b>Mother’s Knowledge of Rubella</b>						
Less Good	570	81,1	3410	64,7	2,335 (1,918-2,844)	0,000
Good	133	18,9	1858	35,3		
<b>Covariate Variables</b>						
<b>Mother’s Education</b>						
Low	311	44,2	2220	42,1	1,089 (0,930-1,276)	0,290
High	392	55,8	3048	57,9		

Variables	MR Immunization Status				POR (95% CI)	p-value
	No		Yes			
	n=703	%	n=5.268	%		
<b>Attitude Towards Immunization</b>						
Less Good	243	34,6	830	15,8	2,825 (2,378-3,355)	0,000
Good	460	65,4	4438	84,2		
<b>Belief</b>						
Negative	478	68	3499	66,4	1,074 (0,908-1,271)	0,406
Positive	225	32	1769	33,6		
<b>Information Access</b>						
No	139	19,8	60	1,1	21,392 (15,612-29,312)	0,000
Yes	564	80,2	5208	98,9		
<b>Support of Health Workers</b>						
No	577	82,1	3477	66	2,359 (1,929-2,884)	0,000
Yes	126	17,9	1791	34		

After analyzing the interaction test and confounding test, the final model of multivariate analysis was obtained (Table 2). The final model shows that mother's

knowledge of rubella interacts with mother's education and belief in order to form a significant relationship with MR immunization status and there is no confounder.

**Table 2: Final Model on The Relationship Between Mother's Knowledge of Rubella With MR Immunization Status**

Variables	B	p-value	POR	95% CI	
				Lower	Upper
Mother's Knowledge of Rubella	0,270	0,111	1,310	0,940	1,827
Mother's Education	-0,409	0,043	0,664	0,448	0,986
Belief	-0,456	0,012	0,634	0,444	0,903
Mother's Knowledge of Rubella by Mother's Education	0,516	0,020	1,675	1,086	2,583
Mother's Knowledge of Rubella by Belief	0,642	0,002	1,899	1,267	2,848

### Discussion

This study shows that the relationship between mother's knowledge about rubella interacts with education and belief. Regarding belief, Indonesia is the country with the largest Muslim population, so the issue related to haram vaccine was greatly influences the low coverage during the MR campaign. Although The Council of Indonesian Ulama(MUI) has issued a fatwa which states that MR vaccine is permissible (mubah) because there is an emergency and compulsion condition and has not found a halal vaccine<sup>(10)</sup>, but this still keeps people, especially mothers, from moving and does not immunize their children<sup>(11)</sup>.

One of the factors that influence a mother's knowledge, in this case knowledge of rubella, is the

level of education.<sup>(12)</sup> However, even though mother's education is low, knowledge can be obtained by seeking information through various media regarding rubella disease and MR immunization itself. In this era of high connectivity, it is hoped that a mother will be able to gather information about MR immunization from trusted sources, for example from official government websites or social media of a community leader who has the knowledge about immunization.

The limitations in this study is because this study uses a cross sectional study design, so it cannot see the temporal relationship and also cannot be ascertained the causality relationship between them. Another limitation in this study is not examining the potential confounders that may have potential relation to immunization status

such as mother's occupation, family economic status (because the MR campaign is free of charge), family and community support, and the quality of immunization services. In this study, selection bias can be minimized by using a total sampling of mothers who have children aged 9-59 months. Information bias regarding outcome variables on the survey is very minimal because immunization status although it was being asked directly to respondents, it is also compared with immunization status lists in Primary Health Center (Puskesmas) (9), while for knowledge of rubella, attitudes, and beliefs may have the potential to cause non-differential information bias. The results of this study have a narrow 95% confidence interval, so the role of chance is quite small. And this study is also consistent with other studies which state that mother's knowledge is related to immunization, in this case knowledge of rubella, related to immunization status of children<sup>(13)(14)(15)</sup>.

### **Conclusion and Recommendation**

A positive relationship between mother's knowledge about immunization, in this case the knowledge of rubella, with the the status of immunization of children in the MR Campaign at Java Island shows that knowledge is needed to provide an understanding of the importance of immunization. Belief that interacts with knowledge (POR 1,899 95% CI 1,267-2,848) proves that the mother's behavior to bring their children immunized is strongly influenced by beliefs (in this case because the MR vaccine has not been declared halal and most of the population is Muslim). Education that interacts with knowledge (POR 1.675 95% CI 1,086-2,583) proves that education and knowledge have a very close relationship, although knowledge can still be obtained from reliable sources of information, but an understanding of immunization in a mother with higher education will have an impact on the high coverage of immunization. Therefore the government is expected to cooperate with relevant stakeholders to actively provide socialization through various media and dialogue with religious / community leaders about the importance of MR immunization in order to achieve high MR immunization coverage, so that the chain of transmission of measles and rubella diseases can be stopped.

**Ethical Considerations**| This study uses data from the survey of Independent Evaluation of MR Immunization (MR Campaign) in 6 provinces at Java Island in 2017 which have received permission from the principal researcher of the survey and the Ethics

Committee of the University. The confidentiality of the data collected in the survey and used in this study is very well maintained.

**Source of Funding:** This research is at its own expense

**Conflict of Interest:** Both author declared that no conflict of interest

**Acknowledgements:** Both author thank to the Indonesia Ministry of Health, Health Office of 6 Province at Java Island (Banten, Special Capital Region of Jakarta, West Java, Central Java, Yogyakarta Special Region, and East Java), and all the researchers who provided the data survey.

## Abstract

**Objectives:** To determine the prevalence and pattern of drug abuse, and also explore the health and socio-economic impact of drug abuse among the students of the School of Health Technology (SHT), Jega Local Government Area (LGA), Kebbi State, Nigeria.

**Method:** This study was a survey of 254 students of SHT, Jega LGA. Study tool was a questionnaire. Collected data was analyzed using the SPSS Version 20 software.

**Results:** The mean age ( $\pm$ SD) of the respondents was 22.9 ( $\pm$ 3.7) years and 54.3% were males. About one-fifth (17.8%) of the respondents had used drugs other than those required for medical reasons, 14.2% had history of abuse of prescription drugs, 17.7% abused drugs that were not prescribed for medical reasons, and 19.3% abused more than one drug at a time. Furthermore, >four-tenth of those respondents who were abusers of drugs had developed medical problems as a result of its use. More than 1/3 of those respondents who gave a positive history of drug abuse had in one way or the other suffered from the socio-economic and health consequences of drug abuse, some of these include strained relationships with close persons and employers, loss of job, involvement in crime, and arrest.

**Conclusion:** The above findings recommend the need for an urgent social intervention targeted at curbing the menace of drug abuse in the surveyed institution.

**Keywords:** Drug abuse, substance use, students, mental health, addiction, socio-economic, impact, burden, Nigeria.

## Introduction

Drug can be defined as a medicine or other substance which has a physiological effect when

ingested or otherwise introduced into the body<sup>1</sup>. This term is used, generally, to refer to a substance taken for therapeutic purposes and/or for abuse<sup>2</sup>. The abusive use of drugs is known as “drug abuse”. Drug abuse can be elaborately defined as the use of illegal drugs or the use of prescription or over-the-counter drugs for purposes other than those for which they are meant to be used, or in large amounts<sup>3</sup>. Over the years, there has been a growing data base indicating that drugs are being abused among young people (4,5). In 2010, the United Nations Office on Drugs and Crime (UNODC) reported that about 27 million people in the world are problem drug users<sup>6</sup>. Globally, and even locally, drug abuse is

a serious public health and social problem which has associated effects on people's health, cultural welfare, socio-economic welfare, and security<sup>7-15</sup>.

Abused drugs can generally be categorized into three groups: hallucinogens (such as marijuana, ecstasy); depressants (such as heroin, barbiturates); and stimulants (such as cocaine, crack, amphetamines)<sup>5,16</sup>. The use of these drugs does not only affect the individual user, but also their families, friends, neighbors, co-workers, and communities as well<sup>5</sup>.

In Nigeria, it has been consistently reported that drug abuse is a popular social practice among tertiary school students<sup>17,18</sup>. Many factors have been found to influence tertiary school students to indulge in drug abuse. These factors include family factors (e.g. lack of parental care, poor family background), school factors (e.g. educational stress, poor teacher-student relationships, nature of extra-curricular activities), economic factors (e.g. unemployment) psychological factors (e.g. frustration and emotional stress), and others<sup>12,19-22</sup>.

Unfortunately, drug abuse is becoming a monstrous problem in the Nigerian society<sup>9</sup>. Despite the various measures taken by the government and other agencies at curbing the abuse of drugs in Nigeria, yet many people are still indulging its use; hence reducing them to puppets and zombies due to the addictive effect following its use<sup>9,12,19-22</sup>.

Different literatures had reported the prevalence of drug abuse in Nigerian tertiary schools. The prevalence of drug abuse was: 69.2% among tertiary school students in Abeokuta, 27.5% among University of Uyo students, 46.6% among university students in Benin City, and 55.4% (stimulant drink use) among university students in Sokoto<sup>17,24-26</sup>. However, after extensive online literature search, no study was found exploring the prevalence rate of drug abuse among tertiary school students in Kebbi State.

From our experience as scientific researchers, clinicians, and teachers, practicing in Kebbi State, Nigeria, we have come in contact with drug abusers living in Kebbi State, either on the street, motor parks, clinics, schools or somewhere else. Based on this, coupled with absence of published studies on drug abuse in Kebbi State, we aim to conduct this study to determine the prevalence of drug abuse and also explore the health and socio-economic consequences of drug abuse among students of the SHT, Jega LGA, Kebbi

State, Nigeria. The findings made from the study will definitely help the stakeholders in the Nigerian socio-economic, educational, and health sectors in their strategic planning.

## Method

The study was a cross-sectional study conducted among students of the SHT, Jega LGA, Kebbi State, Nigeria. The school is a mono-technic with over 2,500 students in enrolment. A convenience sample of 300 students was used for the study. Simple random sampling technique was used in the recruitment of participants for the study. The study instrument was a paper questionnaire on drug abuse developed by the Addiction Research Foundation Inc, Canada<sup>23</sup>. The questionnaire obtained information on the participants': socio-demographic characteristics; history of drug use; history of drug dependence; and experience on the negative socio-economic and health consequences of drug abuse.

The students of the surveyed school were implored to gather themselves in one of the large halls in the school premises for a survey. They were informed about the purpose of the survey, and that their participation in this survey will be duly appreciated. They were also informed that their participation is completely voluntary and confidential. Out of all the students that volunteered to participate in the study, only 300 were selected and their selection was done using simple random sampling technique. Verbal informed consent was obtained from all the participants, before they were interviewed using the study questionnaire. All questionnaires were self-administered. Out of the 300 participants given questionnaires to fill, only 254 had their questionnaires properly filled and returned.

Collected data was computed into the SPSS version 20 software, for analysis. The frequency distribution of all variables was determined; test of associations between variables were done using Chi square test with a  $p$ -value  $< 0.05$  considered to be statistically significant.

## Results

The response rate for this study was 85% (254/300). The majority (54.3%) of the respondents were males, 51.6% were in 100 level, 80.7% were not married, 87.0% were Hausas, and 94.5% were Muslims. Also, their mean age ( $\pm$ SD) was 22.9 ( $\pm$ 3.7) years.

A total of 45 (29 males, 16 females) respondents had used drugs other than those required for medical reasons. Thirty six (22 males, 14 females) respondents had abused prescription drugs; 49 (27 males, 22 females) respondents had abused more than one drug at a time.

After grouping those respondents with positive history of drug abuse into 3 categories: category A– those respondents that used drugs other than the drugs required for medical reasons; category B– those respondents that abused prescription drugs; and category C – those respondents that abused more than one drug at a time, we observed that: 39.1%, 27.8%, and 42.9% of those respondents in categories A, B, and C, respectively, reported that they could not get through the week without using drugs; 41.3%, 63.9%, and 49.0% of those respondents in categories A, B, and C, respectively, reported that they developed medical problems as a result of their abuse of drugs; 39.1%, 61.1%, and 53.1% of those respondents in category A, B, and C, respectively, reported that they have been involved in a treatment program specifically related to drug use; 32.6%, 61.1%, and 51.0% of those respondents in categories A, B, and C, respectively, reported that drug abuse created problems between them and their spouse/parents; 34.7%, 44.4%, and 42.9% of those respondents in categories A, B, and C, respectively, reported that drug abuse made them lose friends; 39.1%, 47.2%, and 40.8% of those respondents in categories A, B, and C, respectively, reported that they have engaged in illegal activities in order to obtain drugs; 39.1%, 55.6%, and 44.9% of those respondents in categories A, B, and C, respectively, reported that drug abuse made them lost a job; and 43.5%, 50.0%, and 49.0% of those respondents in category A, B, and C, respectively, reported that they have being into trouble at work as a result of drug abuse.

## Discussion

The findings made in this study shows that drug abuse has a very high negative health and socio-economic impact among those who engage in such behavior. Although relatively lower than that reported in some Nigerian studies<sup>24-26</sup>, the prevalence of drug abuse among the students surveyed in this present study poses a big threat of serious concern, as roughly 1 out of every 5 of the surveyed students had engaged in drug abuse in one way or the other.

Furthermore, the population surveyed in this study is health professions trainees. Despite their supposed

awareness of the detrimental effects of drug abuse on human body, yet some of them still got engaged in such unhealthy behavior. However, this is not very surprising, as a similar finding had also been reported even among health professionals in Nigeria<sup>11</sup>. These findings just conclude that drug abuse is not only being practiced among the lay population, but also among health professionals and trainees as well<sup>13-15,27</sup>.

It is also noteworthy that drug abuse had a heavy negative impact on the health of those respondents with history of drug abuse as more than two-tenth of those respondents that were abusers of drug could not live a week without abusing drugs and roughly. Also, a third of these respondents reported that they do not always have the will power to avoid abuse of drugs; this concludes that they are dependent of these drugs. This is a serious problem that requires urgent attention. Sadly, many (>four-tenth) of those respondents who reported themselves of be abusers of drugs had at one time developed some medical problems as a result of its use. Similar finding had also been reported even among health professionals in Nigeria<sup>11</sup>.

The medical consequence of drug abuse is huge. Drug abuse can result into kidney problems, intestinal problems, mental illness, and even death<sup>28-32</sup>. It is so unfortunate that many abusers of drugs are dependent on such drugs and they will at one point develop medical problems as a result of its chronic use<sup>28-30,32,33</sup>.

In this study, it was also found that drug abuse have a heavy negative social impact on those respondents with history of such. It is so alarming that more than a third of those respondents that gave a positive history of drug abuse: felt guilty for their engagement in drug abuse practices; had experienced problems with their spouses, friends, and parents; had engaged in a fight and/or illegal activity as a result of drugs; and had got arrested as a result of drug abuse. These findings obviously show that many of these drug abusers are living in poor social quality of life. Losing loved ones (spouse, parents, and friends) as a result of drug abuse could even worsen the social health and wellbeing of this category of respondents (i.e. drug abusers), therefore increasing their risks of developing mental illnesses like depression, aggression, etc.

Furthermore, there was a record of heavy negative economic impact among those respondents with history of drug abuse. Roughly half of those who respondents who engaged in drug abuse had at one time entered into

trouble at work as a result of drug abuse. Also, many of them had lost a job as a result of drug abuse. By implication, many of these category of respondents may end up engaging in organized crimes if they have no economic capacity to acquire these drugs.

However, this study has its limitations. First, this study was a single-institution study conducted in just one local government area, out of the 21 LGAs in Kebbi State<sup>34</sup>; hence it is difficult to make generalizations on the drug abuse profile of tertiary school students in this State, based on the data obtained from this study. Second, the study sample size was determined based on the convenience of the authors, as the study was self-funded. Therefore, the study data may not be fully representative of the school.

### Conclusion

The prevalence and pattern of drug abuse among the students of the SHT, Jega LGA, is fairly significant. Unfortunately, those among them that were drug abusers had suffered huge consequences associated with drug abuse. There is a need for urgent social intervention programs to curb the problem of drug abuse in this surveyed tertiary academic institution.

**Ethical Clearance:** Approval to conduct the study was obtained from the Office of the Director, Kebbi State Study Centre, National Open University of Nigeria, Kebbi State, Nigeria.

# Saturated Fat Acid Food Consumption Correlation with Hypertension in Elderly Woman

Khirdiyah Mauly Azzannabillah<sup>1</sup>, Wirjatmadi<sup>2</sup>

<sup>1</sup>Department of Nutrition, Faculty of Public Health, Universitas Airlangga, Surabaya, East Java, Indonesia,

<sup>2</sup>Department of Health Administration and Policy, Faculty of Public Health, Universitas Airlangga, Surabaya, East Java, Indonesia.

## Abstract

**Context:** Hypertension is a disease often encountered in the elderly. This occurs due to physiological and lifestyle changes including eating habits. Food consumption habits of high cholesterol sources can result in the accumulate of fat in blood vessels and forming plaque. It result in an increase in blood pressure that leads to hypertension. The purpose of this research is to analyze the correlation of food consumption habits saturated fat sources with hypertension in elderly woman.

This study uses case control design with sample of elderly female in Health Centre Gunung Anyar Surabaya. Subject consisting of 28 cases and 28 controls. Data food consumption of saturated fat obtain through recall method Semi Quantitative Food Frequency Questionnaire (SQ-FFQ). Blood pressure is measured using sphygmomanometer. The statistical test performed is the chi square test.

The result showed that there was a significant relationship between food consumption saturated fat acid sources with hypertension among elderly woman ( $p = 0,01$ ).

The conclusion of this study is that there is a significant relationship between the food consumption of saturated fat acid with hypertension in elderly women.

**Keyword:** *Hypertension, saturated fat acid, elderly woman*

## Introduction

The elderly are a group of population aged 60 years or more. The increase number of elderly people is followed by the increase in diseases faced by the elderly population especially the degenerative disease. <sup>(1)</sup>This process occurs at age decreased the ability of networks to improve and maintain the normal functions of the body one is on cardiovascular. Changes in the

structure of the arteries thicken and become increasingly rigid causes the onset of arteriosclerosis. This condition forces the blood flowing through the blood vessels to narrow, so that an increase in blood pressure and leads to hypertension. Hypertension experienced by particularly vulnerable age group. An increase in blood pressure is more prone to occur in the elderly women. <sup>(2)</sup> This occurs due to hormonal changes and a decline in estrogen produced by elderly women who have undergone the process of menopause, so vasoconstriction blood vessels and result in an increase in blood pressure. <sup>(2)</sup>

e-mail: khirdiyahmauly@gmail.com

Hypertension is one of the diseases with a high incidence in the developing world middle income down. The disease is influenced by a variety of risk factors, grouped into two, namely the risk factors can be modified and cannot be changed. Risk factors can be modified, among others, eating habits and lifestyle, while

risk factors cannot be changed include age, gender, and history of family hypertension.<sup>(3)</sup> High blood pressure is to be one of the risk factors to the emergence of other health problems such as heart disease, stroke, kidney and may cause death of.<sup>(4)</sup>

Hypertension in the elderly regard very closely with changes in physiological condition and lifestyle changes such as eating habits. Dietary intake and foods high in saturated fatty acid can cause the occurrence of elevated levels of LDL cholesterol in the blood is saturated fat and cholesterol may trigger someone experiencing high blood pressure and heart problems. High cholesterol in the blood can stimulate the formation of plaque in the arteries and cause constriction of the arteries and decrease the rate of elasticity of blood vessels.<sup>(5)</sup>

Prevalence of hypertension in Indonesia experiencing an increase from 25,8% in 2013 to 34,1% in 2018. East Java was ranked the sixth highest Indonesia hypertension cases.<sup>(6)</sup> Gunung Anyar subdistrict which is in Surabaya. The subdistrict has a Clinic with five elderly Posyandu units. The disease has become the number one ranking among the top ten trends of other health problems that occur on the elderly as Diabetes Mellitus (DM), tuberculosis, coronary artery disease, and others. The number of hypertension in Gunung Anyar Surabaya enough experience increased dramatically more than doubled in the year 2016-2017.<sup>(7)</sup>

Based on the result of observation of the eating habits of the community showed that the rate of consumption of food sources of fat high enough, frequent consumption of food ingredients such as coconut milk, duck meat, organ meats, chicken skin and other as well as the confusion of ways of processing food such as fried oil that its use is already more than twice. Based on the above discussion, the author would like to examine the relationship between consumption pattern food sources of saturated fat with incident hypertension in elderly women in Gunung Anyar Surabaya.

## Material and Method

This research is observational analytic research because researchers only make observations without giving treatment or intervention to the respondents and aim to determine the effect of the variables to be studied. The design of this study uses quantitative design case control study.

The research was carried out in March and April 2019. The population used in this study was all members of the clinic group in Health Centre Gunung Anyar Surabaya with total population of 210 elderly people. Entirely divided into five clinic group. The total population, sample taken using a purposive sampling method taking into account the criteria already defined by the researchers. Sample calculation using the formula with a large proportion of Kuntoro exposure control group 0,82. Based on the results of the calculation, obtained the number of samples as many as with division 28 cases and 28 control group.

The sample was chosen following a predetermined inclusion criteria according to their respective group that is listed as a member of the clinic group elderly Health Centers Gunung Anyar that attend activities in age range 60-70 years, measured hypertension systolic  $\geq 130$  mmHg and diastolic  $\geq 80$  mmHg or when the research process is underway for the case group, and not hypertension with measurement result systolic  $< 130$  mmHg and or diastolic  $< 80$  mmHg when research underway for the control group. Blood pressure measurement are conducted by doctor of clinic group. As for the criteria of exclusion among others are currently taking any medication-related hypertension while research progresses, and not willing to research respondents. After selected using these criteria, the respondent provided an explanation of the information research that will be done and signed a research agreement if the sheet was prepared following a series of research. The collected data on food consumption level source of saturated fatty acid via questionnaire sheet Semi Quantitative Questionnaire (SQFFQ) that contain food sources of saturated fat. Next, measurement of blood pressure using Sphygmomanometer. Assessment of SQFFQ through multiplication between the frequency of consumption, and serving of food consumed of 1 month. It also carried out related data collection characteristics of the respondents include age, family history of hypertension, level of education and employment of the respondent through the questionnaire sheet characteristics of respondent. The data already collected and the processed by computer software programs and use statistical analysis univariate and bivariate. Data characteristics of respondents subject presented in the form of frequency distribution, then to consumption patterns of food sources of saturated fatty acid are analyzed with the application NutriSurvey and compared with the percentage of

recommended consumption is then grouped into two categories namely enough if  $\leq 10\%$  in a day, and more if  $> 10\%$  in a day.<sup>(8)</sup> dyslipidemia, elevated blood pressure and insulin resistance. Metabolic syndrome affected by changes in lifestyle and unhealthy dietary patterns with high cholesterol, saturated fatty acid and trans fatty acid. Objective. The study conducted to know relationship between fat consumption with metabolic syndrome among adult people in Denpasar city. Method: The case control study designed was applied. The cases were adult people who had metabolic syndrome, and the control was healthy people from the case-neighboring household. Total subject were 130, taken by consecutive sampling: 65 cases and 65 controls. The subject identity, fat intake, waist circumference, blood pressure and fasting blood sugar were collected. The food frequency questionnaire (FFQ) analysis using correlation chi-square test with application of SPSS v20 done to analyse the relationship between the consumption patterns of food sources of saturated fatty acid with incident hypertension. Analysis of the Odd ratio (OR) was conducted to access the relationship or the magnitude of the risk factors of consumption patterns of food sources of saturated fatty acid with incident hypertension.

**Findings:**

**A. Characteristics of Respondents:** The characteristics of respondents who examined in this research include age, family history of hypertension, the final level of education and employment of the respondent. The number of the subject involved in research is as much as 56 respondents with division 28 respondents cases group and 28 respondents controls group.

Respondent characteristics included age, education level, family history of hypertension and work. data on the distribution of respondents characteristics are presented in Table 1.

Based on Table 1, it can be seen that the majority of control group respondents aged 60-65 years, then case group respondent aged 66-70<sup>th</sup>. Majority of case group have nota family hypertensive historyan, and majority of control group have not to. Education level graduated from elementary school for cases group, then senior high school for control group. While the economic factors of the majority of respondents case and controlare housewife.

**Table 1. Distribution of Characteristics of Respondent**

No	Characteristics of Respondent	Cases	Control	
		n		
1.	Age	60- 65 years	12	21
		66- 70 years	16	7
2.	Family history of hypertension	Yes	11	10
		No	17	18
3.	Educational Level	Not School	0	0
		Elementary School	9	2
		Junior High School	8	3
		Senior High School	7	15
		College	4	8
4.	Job	Employe	0	0
		Entrepreneur	5	2
		Farm Workers	0	0
		Housewife	15	15
		Others	8	11

**B. Consumption patterns of food sources saturated fat:** Consumption patterns of food sources of saturated fat acid in this study measured by interview Semi Quantitative Food Frequency Questionnaire (SQ-FFQ) include the number, type and frequency. Each individual consumes food sources of fat with the type, amount and frequency. The consumption of saturated fat are categorized either when the maximum consumption of total energy consumed in a day. Dietary saturated fats include saturated fat percentage compared to the total energy consumed in a day and categorized into enough if  $\leq 10\%$  and more if  $> 10\%$ .<sup>(9)</sup>

Sources of saturated fats are most often consumed by respondents is coconut oil, butter and margarine. In addition, the source of the saturated fat that comes from animal is like chicken with its skin, beef and duck meat, petrol, goat meat, offal, and others. The majority of respondents to the foodstuffs processing by way of a fried in cooking oil that its use exceeded the recommendations  $> 2x$ .

**D. Distribution of fre quency food source saturated fatty acid in Health center Gunung Anyar Surabaya:** Each individual consumes food sources of fat. So did the frequency of consuming foods. Frequency is measured in units of time : day, week, month, and never.

**Table 2: Distribution frequency of food sources of saturated fat in a group of cases.**

Food source SFA	Day (often)	Week (sometimes)	Month (rarely)	Never
	N	N	n	N
Cooking oil (>2x)	28	0	0	0
Margarine	2	8	4	14
Coconut milk	0	3	22	3
Egg Chicken	5	23	0	0
Chicken meat	0	25	2	1
Chicken skin	0	20	8	0
Beef	0	12	16	0
Duck meat	0	5	16	7

Based on Table 2, it can be noted that most of the respondents case consumed cooking oil on a daily basis with the use of more than twice the number of 28 respondent. Average use oil for frying until the color turn black. As for the food the most often consumed on a weekly basis are egg, chicken, chicken skin. Next, food ingredients consumed monthly us coconut milk as much as 22 respondents.

**Table 3: Distribution frequency of food sources of saturated fat in a group of controls.**

Food source SFA	Day (often)	Week (sometimes)	Month (rarely)	Never
	n	N	n	N
Cooking oil (>2x)	28	0	0	0
Margarine	0	5	9	14
Coconut milk	0	2	15	11
Egg chicken	3	25	0	0
Chicken meat	0	20	8	0
Chicken skin	0	15	10	3
Beef	0	5	15	3
Duck meat	0	3	18	7

Based on table 3, it can be noted that most of the respondents case consumed cooking oil on a daily basis with the use of more than twice the number of 28 respondent. On this, control group respondents have started to reduce the use of oil. They prefer to use the oil as necessary, so that no oil left jelantah. So that the oil used is not to change the color to black. As for the food the most often consumed on a weekly basis is egg chicken, chicken, chicken skin cooked way fried. Next, food ingredients consumed monthly us coconut milk as much as 15 respondents.

**C. Correlation food source saturated fat with hypertension elderly woman at Health Centre Gunung Anyar Surabaya:** The result was be represented in Table 4.

**Table 4. Correlation food consumption saturated fat with hypertension**

Categorie	Case	Control	OR	95% CI	P value
	n	n			
Cukup	4	12	8	2.18-29.24	0,01
Lebih	24	16			
Total	28	28			

**Discussion**

Based on the results of research that has been done, it can be seen that the age of respondents who suffer from hypertension is mostly in the age range of 65-70 years. While respondents who did not have hypertension were in the age range of 60-65 years. This shows that the more age increases, the greater the risk of hypertension. In line with the results of Riskesdas (2013) which stated that the prevalence of hypertension will increase along with increasing age, this is in line with research conducted by Sringoringo (2013) and Pramana (2016) who found an association of age with the incidence of hypertension.<sup>(10)</sup>

Based on the result, level of education affects the level of knowledge person. In the results of the study it was found that hypertensive respondents mostly had a history of elementary education. As for the respondents who are not hypertensive, most of them have a history of high school education. This is in line with the research conducted by Fitriyani (2012) in several health centers in Cilegon City, which also stated the same thing that the education of respondents with hypertension was mostly graduated from elementary school.

Based on the results of the study it can be seen that there was no significant difference between the types of work of respondents with the incidence of hypertension. This is in line with research conducted by Iskandar et al. (2012) which shows that there is no significant relationship between work and the degree of hypertension. Although work does not have a direct effect on the incidence of hypertension, but the type of work a person is very influential on income, the selection of food ingredients, and the ability to get the type of food someone consumes. (Purnama and Prihartono, 2013).<sup>(11)</sup>

There is not much history of hypertension found in

respondents who suffer from hypertension. This is in line with the research of Yeni et al. (2010) which states that there is no relationship between hypertension and a history of hypertension. This can be due to the risk factors for hypertension not only from hereditary factors, but also other risk factors such as smoking habits, improper diets, erroneous eating patterns such as high sodium and fat, obesity and metabolic syndrome which can cause hypertension (Kementerian Kesehatan RI, 2017).<sup>(12)</sup>

Chi-Square analysis results at shows that there is a significant relationship between the consumption of saturated fats with the genesis of hypertension on respondent cases and controls with the results of the p value = 0,01 (<0,05). Respondents who consume saturated fat that exceeds the recommendations of more than 10% total energy a day can increase the risk of incident hypertension eight times more likely than respondents who consume saturated fat enough  $\leq$  10% total energy a day. This is in line with the research ever undertaken by Salsabila in 2014 of the relationship between central obesity, fat energy intake with hypertension and sodium with the genesis of hypertension suggest that there is a meaningful relationship between fat intake with incidence of hypertension with a value of statistical test p value = 0,03.

### ConclusionS

Consumption of saturated fat sources has a significant relationship with the incidence of hypertension in elderly women at the Gunung Anyar Health Center Surabaya. Respondents who had more than 10% saturated fat consumption had a risk of hypertension occurring 8.0 times than respondents who had a saturated fat consumption level of  $\leq$  10%.

**Conflict of Interest:** All authors have no conflicts of interest to declare.

**Source of Funding:** This is an article “Saturated Fat Acid Food Consumption Correlation With Hypertension In Elderly Woman” that was supported by self funding.

**Ethical Clearance:** The study was approved by the institutional Ethical Board of Universitas Airlangga Faculty of Dental Medicine Health Research Ethical Clearance Commission.

# Relationship Energy and Protein Intake with the Incidence of Stunting among Toddler Aged (25-60 Months) in Mangkung Village, District of Central Lombok

Lalu Moh. Anshori<sup>1</sup>, Bambang Sutrisna<sup>2</sup>, Sandra Fikawati<sup>3</sup>

<sup>1</sup>Masters of Epidemiology Study Program, Faculty of Public Health, University of Indonesia, Depok, <sup>2</sup>Department Epidemiology, Faculty of Public Health, University of Indonesia, Depok, <sup>3</sup>Department of Public Health Nutrition, Faculty of Public Health, University of Indonesia, Depok

## Abstract

**Background:** Stunting is a linear growth disorder that is indicated by Body Height according to the Age less than -2 Standard Deviation (short) and less than -3 Standard Deviation (very short). Lack of energy in a child over a long period of time can result in a hampered bone growth process that causes problems with height. Protein deficiency causes retardation of bone growth and maturity, because protein has a function that cannot be replaced by other nutrients, namely building and maintaining body cells and tissues. The purpose of this study was to determine the relationship between energy intake and protein intake with the incidence of stunting among toddler aged (25-60 months) in Mangkung village. Multivariate analysis using logistic regression analysis. Data was analyzed using STATA software version 13.0 for Windows.

**Results:** The energy intake variable has a p-value of 0,000 (p-value <0.05) with a POR value of 9.9 (95% CI: 6.39-15.23). The protein intake variable has a p-value of 0,000 (p-value <0.05) with a POR value of 9.1 (95% CI: 5.96-13.89). History of childbirth birth weight, history of exclusive breastfeeding, providing complementary food for breast milk, basic immunization status, history of infectious diseases, level of mother's knowledge, and family income have a test of homogeneity (p value <0.05) which means the variable has a modification effect/interaction with the relationship between energy intake and the incidence of stunting. Whereas, the variables that have modification/interaction effects (test of homogeneity <0.05) on the relationship of protein intake with the incidence of stunting are variable age of toddler, history of childbirth birth weight, history of exclusive breastfeeding, providing complementary food for breast milk, basic immunization status, history infectious diseases, level of mother's education, level of knowledge, and family income. The results of the final stage of multivariate analysis showed that the variable energy intake had a POR value of 7.7 (95% CI: 4.83 - 9.47).

**Conclusion:** Energy intake and protein intake have a significant relationship with the incidence of stunting among toddler aged (25-60 months) in Mangkung Village. Energy intake is the most dominant variable influencing the incidence of stunting among toddler in Mangkung Village after controlled for variables of childbirth birth weight, basic immunization status, history of infectious diseases, and family income.

**Keywords:** *Energy intake, protein intake, stunting, toddlers 25-60 months*

## Introduction

Malnutrition is a condition that occurs when food ingredients that enter the body do not contain enough nutrients in accordance with what is needed by the body. One assessment of poor nutritional status based on Minister of Health Decree No. 1995/MENKES/SK/

---

### Corresponding Author:

Masters of Epidemiology Study Program, Faculty of Public Health, University of Indonesia, Depok.

e-mail : lalumohanshori2@gmail.com

XII/2010 concerning Anthropometric Standards for Assessment of Child Nutrition Status is an indicator of Body Length by Age or Body Height according to Age. The term malnutrition by using BL/A or BH/A indicators is known as stunting (short and very short).<sup>(1)</sup>

The adverse effects that can be caused by stunting problems in the short term are disruption of brain development, intelligence, impaired physical growth, and metabolic disorders in the body. Whereas in the long term it is decreasing cognitive abilities and learning achievement, decreasing immunity so that it is easily sick, and high risk for the emergence of diabetes, obesity, heart and blood vessel disease, cancer, stroke, and disability in old age, and the quality of work that results on low economic productivity.<sup>(1)</sup>

Lack of consumption of energy and protein will cause the body to lack nutrients, so to overcome these deficiencies, the body will use energy and protein deposits. If this condition lasts for a long time, then the energy and protein deposits will run out so that tissue damage occurs which causes a child to experience stunting.<sup>(2)</sup>

Lack of energy in a child is an indication of lack of other nutrients. If this condition is left for a long time, it will result in the inhibition of the process of bone growth which causes problems with stunting in toddlers. Protein deficiency causes retardation of bone growth and maturity, because protein has a function that cannot be replaced by other nutrients, namely building and maintaining body cells and tissues.<sup>(3)</sup>

Data from Basic Health Research in 2018 shows the prevalence of stunting in children under five in 2013 was 37.2% and a decline in 2018 was 30.8%.<sup>(4)</sup> Even though there was a decrease in the prevalence of stunting nationally, in some provinces Indonesia was wrong the province of West Nusa Tenggara shows that the prevalence of stunting is still in the high category in 2017 at 37.30%.<sup>(5)</sup> The results of the Weighing Week Report in the Mangkung Community Health Center area in November 2018 showed a tendency to increase the prevalence of stunting from 2016 by 15.13%, in 2017 as much as 28.34%, and in 2018 as much as 30.18%.

Various efforts have been made to overcome stunting problems starting from providing adequate food intake, and improving health status. However, stunting is still a public health problem that needs to be prevented and addressed.

## Research Method

**Study Design:** This study is an analytical study using a cross-sectional study design to determine the relationship between energy intake and protein intake with the incidence of stunting among toddler aged (25-60 months) in Mangkung Village.

**Population and Samples:** The source population in this study was all toddlers aged (25-60 months) who lived in Mangkung Village and conducted weighing in each Integrated Health Post in Mangkung Village. The study population was all toddlers aged (25-60 months) who lived in Mangkung Village and weighed in each Mangkung village Integrated Health Post and fulfilled the inclusion and exclusion criteria. Inclusion criteria include toddlers aged (25-60 months) at the time of measurement, staying in the research area. Exclusion criteria include toddlers who are ill when doing research, have physical disabilities (such as deafness, mute) and mental disorders, do not have a Child health record. The number of toddlers in Mangkung village was 622 toddlers and the number of respondents in this study was 372 respondents taken by random sampling from each Integrated Health Post.

**Variable:** The independent variables in this study were energy intake and protein intake, while the dependent variable was the incidence of stunting among toddler aged (25-60 months). The covariate variables in this study were toddler age, gender, history of childbirth birth weight, history of exclusive breastfeeding, administration of breastfeeding, basic immunization status, history of infectious diseases, level of mother's education, level of mother's knowledge and family income.

**Data Collection:** This study uses primary data by conducting anthropometric measurements based on Height According to Age in infants to obtain nutritional status data and conducting interviews with respondents to obtain information on toddler feeding. Anthropometric measurements were carried out by enumerators from the field of public health nutrition as many as 3 people. Data on consumption of energy and protein intake of respondents was obtained through interviews using 1 x 24 hour food recall sheets. Other data regarding the covariate variables were obtained through interviews with the respondent's mother using a questionnaire adopted from the public health nutrition department of the Indonesian university's public health faculty.

**Data Analysis:** Bivariate analysis was conducted to determine the relationship between variable energy intake and protein intake with the incidence of stunting. The statistical test used is the chi square test. Multivariate analysis using logistic regression by including all variable candidates who have p-value <0.25 so that

the relationship between energy intake and protein intake can be seen with the incidence of stunting among toddler aged (25-60 months) after covariate variables are controlled. Data analysis using STATA version 13 software for Windows.

## Result

**Table 1: Results of Bivariate Analysis**

Variable	Nutritional Status Of Toddlers				Total		p-value	POR (95 % CI)
	Stunting		Normal					
	N	%	n	%	n	%		
<b>Energy Intake</b>								
Less	134	87,6	21	9,6	155	41,7	0,000	9,9 (6,39-15,23)
Enough	19	12,4	198	90,4	217	58,3		
<b>Protein Intake</b>								
Less	133	86,9	24	11,0	157	42,2	0,000	9,1 (5,96-13,89)
Enough	20	13,1	195	89,0	215	57,8		

The results of statistical tests on the relationship of energy intake with the incidence of stunting showed a p-value of 0,000 (p-value <0.05) which means that there was a significant relationship between energy intake and the incidence of stunting among toddler aged (25-60 months) in the village Mangkung. The Prevalence Odds Ratio (POR) is 9.9 with a range (95% CI 6.397-15.239) which means that toddlers with less energy intake will have 9.9 times the odds for stunting compared to toddlers who have enough energy intake. The results

of statistical tests on the relationship of protein intake with the incidence of stunting showed a p value of 0,000 (p-value <0.05) which means that there was a significant relationship between protein intake and the incidence of stunting among toddler in Mangkung Village. POR value is 9.1 with range (95% CI 5.968-13,897) which means that toddlers with less protein intake will have a tendency of 9.1 times to experience stunting compared with toddlers who have sufficient protein intake.

**Table 2: Analysis of Stratification on the Relationship between Energy Intake and Stunting in Mangkung Village**

Variable	POR Adjusted		Test of Homogeneity	Information
	POR	95% CI		
Toddler Age (Month)	9,4	6,10 – 14,31	0,387	not the effect of modification/interaction
25-36	7,2	4,01 – 12,98

High	19,5	6,98 – 54,67		

The results of stratification analysis on the relationship of energy intake with stunting events show a variable history of childbirth birth weight, history of exclusive breastfeeding, providing complementary food for breast milk, basic immunization status, history of infectious diseases, level of knowledge, and family income have a test of homogeneity (p-value<0.05) which means that the variable is the effect of modification/ interaction. The variable level of mother’s education is a confounder variable on the relationship of energy intake with the incidence of stunting, because the Crude

POR value of 9.9 and Adjusted POR of 6.1 have a considerable difference of 62% (> 10%). The results of the stratification analysis on the relationship of protein intake with stunting events showed variable toddler age, history of childbirth birth weight, history of exclusive breastfeeding, providing complementary food for breast milk, basic immunization status, history of infectious diseases, level of mother’s education, level of knowledge, and family income values test of homogeneity (p value <0.05) which means it has the effect of modification/ interaction.

**Table 4: Final Model Multivariate Analysis**

Variable	p-value	POR	95% CI
Energy Intake	0,036	7,7	4,83 – 9,47
Protein Intake	0,000	6,9	3,74 – 8,43
History of Childbirth Birth Weight	0,000	3,4	1,08 – 6,31
Basic Immunization Status	0,000	1,8	0,18 – 3,72
History of Infectious Diseases	0,004	2,3	0,35 – 5,51
Family Income	0,000	6,2	4,27 – 9,05

The results of multivariate analysis in the final model showed that the variable energy intake has a p-value of 0.036 (p-value <0.25) which means there is a significant relationship between energy intake and the incidence of stunting among toddlers aged (25-60 months) in the village Mangkung after being controlled by variables of underweight birth weight, basic immunization status, infectious disease history, and family income.

**Discussion**

The results of this study show that variable energy intake and protein intake variables have a significantly significant relationship with the incidence of stunting in children aged (25-60 months) in Mangkung Village. Research conducted in Sumatra regarding birth weight as the dominant factor in stunting in infants (12-59 months) showed the same results, namely there was a

significant relationship between energy consumption and the incidence of stunting with a p-value of 0.01 (<0.05) and an OR value of 1.2. <sup>(6)</sup> Low energy intake is influenced by the mother's ignorance of nutrients in food, so mothers do not have a special effort in increasing energy intake for their children, for example making food creations that can make children interested in eating it. The low energy intake in stunting toddlers can be caused by several factors including the frequency and amount of feeding, low energy density, reduced appetite and infectious diseases. <sup>(7)</sup>

Protein deficiency causes retardation of bone growth and maturity, because protein is an essential nutrient in growth. If this condition is left for a long time, it will result in the inhibition of the process of bone growth which causes problems with stunting in toddlers. <sup>(4)</sup> Below median protein intake was significantly associated with stunting (OR 1.59; 95% CI: 1.02-2.48). <sup>(8)</sup> Increased energy intake and protein intake is needed for stunting babies and children who need to grow in order to catch up. Increasing the need for protein to pursue growth is proportionally greater than the increase in energy, and depends also on age and speed of growth. <sup>(9)</sup>

### Conclusion

Energy intake and protein intake have a significant relationship with the incidence of stunting among toddlers aged (25-60 months) in Mangkung Village. Energy intake is the most dominant variable influencing the incidence of stunting in toddlers in Mangkung Village after controlled for variables history of childbirth birth weight, basic immunization status, history of infectious diseases, and family income.

**Limitation of Study:** This study uses a cross sectional study design, namely research that measures variables only once at a time so that they can lead to the emergence of temporal ambiguity. However, in this study there are several variables that have occurred before stunting, such as variable energy intake, protein intake, history of infectious diseases, history of childbirth birth weight, so that the impact of design weakness is not very influential. Information bias that is differential misclassification can also occur in this study because enumerators already know the exposure status when abstracting information from the research questionnaire. In the respondent's mother, blinding was done as much as possible so that she did not know the exposure status and disease status to be studied.

**Conflict of Interest:** The authors declare that they have no conflict of interest.

**Acknowledgement:** We thank the Mangkung health center for providing secondary data related to the data on the number and the identity of toddlers in each Integrated Health Post.

**Ethical Clearance:** This research has received an ethics pass letter from the Research Ethics Commission for Public Health Services at the University of Indonesia Faculty of Public Health with letter number 47/UN2.F10/PPM.00.02/2019.

# The Same Risk Factors of Hypertension in Women in Rural and Urban Areas (Following Analysis of Data Indonesia Family Life Survey 5 in 2014)

Lestari Febrilia Dwi<sup>1</sup>, Helda<sup>2</sup>

<sup>1</sup>Master of Epidemiology, Faculty of Public Health, Universitas Indonesia, <sup>2</sup>Department of Epidemiology, Faculty of Public Health, Universitas Indonesia

## Abstract

**Background & Objective:** Hypertension is one of the non-communicable diseases that causes other non-communicable diseases such as cardiovascular diseases and other complications which are the most common causes of death in the world. Hypertension in women must get serious attention because it increases over time and can cause further complications. The prevalence of hypertension in urban areas is greater than in rural areas. The aim of this study was to find out the risk factors for hypertension in women in rural and urban areas in Indonesia.

**Method:** Across sectional study. Women with age  $\geq 18$  years old were included in this study. The sample of this study consist of 6.503 women. The strength of the relationship between the independent and dependent variables in this study can be determined by PR association.

**Result:** In rural area, the risk factors of hypertension in women are age PR=3,60, obesity PR=2,10, education PR=2,06, and diabetes mellitus PR=2,64. In urban area, the risk factors of hypertension in women are age PR=3,69, obesity PR=2,08, education PR=2,15, smoking=1,91 and occupation PR=1,50.

**Conclusion:** The same variable associated to hypertension in women in rural and urban area are age, obesity and education.

**Keyword:** Risk factors, hypertension, women, rural, urban.

## Introduction

Hypertension is one of the non-communicable diseases that causes other non-communicable diseases such as cardiovascular diseases and other complications which are the most common causes of death in the world<sup>1</sup>. Hypertension is a condition where systolic blood pressure  $\geq 140$  mmHg and / or diastolic  $\geq 90$  mmHg at least 2 measurements with an interval of 5 minutes

in a state of adequate rest<sup>2</sup>. Based on the results of the RISKESDAS in 2013, the prevalence of hypertension in urban areas (26.1%) was greater than in rural areas (25.5%)<sup>3</sup>.

Hypertension in women must get serious attention because it increases over time and can cause further complications<sup>4</sup>. Most women die in developed and developing countries caused by cardiovascular disease especially hypertension. In America, about 85.7 million adults consisting of 44.9 million women and 40.8 million men experience hypertension<sup>5</sup>. The Indonesian Ministry of Health in the RISKESDAS (*Riset Kesehatan Dasar*) in 2013 report stated that women were more prone to suffer from hypertension than men, where the prevalence of hypertension in women was 28.8% while in men it was 22.8%<sup>3</sup>.

## Method

Across sectional study. Women with age  $\geq 18$  years old were included in this study. The sample of this study consist of 6.503 women. The strength of the relationship between the independent and dependent variables in this study can be determined by PR association. Indonesia Family Life Survey's data was used in this study.

## Result

There were 6.503 women included in this study. Of them, 3.765 were in rural area and 2.828 were in urban area. Table 1 shows characteristic of hypertension in women; age, obesity, education, physical activity,

smoking, fruit and vegetable intake, stress, alcohol intake, diabetes mellitus, and occupation.

In urban area, the risk factors of hypertension in women are age PR= 3,69, *p*-value<0,05 (p=0,000) (95%CI 3,034-4,500), obesity PR=2,08 *p*-value<0,05 (p=0,000) (95%CI 1,747- 2,476), education PR=2,15, *p*-value<0,05 (p=0,001)

(95%CI 1,378-3,380), smoking PR=1,91, *p*-value<0,05 (p=0,002) (95%CI 1,265-2,871) and occupation PR=1,50, *p*-value<0,05 (p=0,000) (95% CI 1,238-1,819).

**Table 5. Risk Factor of Hypertension In Woman In Rural And Rural Area**

Rural Area		Urban Area	
Variable	PR	Variable	PR
Age	3,60	Age	3,69
Obesity	2,10	Obesity	2,08
Education	2,06	Education	2,15

In rural and urban area, the risk factors of hypertension in women are age, obesity and education.

**Discussion**

We identified 6.503 women as respondent in Indonesian Family Life Survey 5 in 2014. Of those, 3.675 women were in rural area and 2.828 women were

in urban area. The prevalence of hypertension in rural area is 17,63% and in urban area is 18,14%.

In our study found the risk factors of hypertension in rural and urban areas are age, obesity and education. In rural area we found age PR= 3,60, which means the women aged > 36 years more at risk of hypertension of 3,60 times compared with women aged ≤ 36 years old. In urban area we found age PR= 3,69, which means women aged > 36 years more at risk of hypertension of 3,69 times compared with women aged ≤ 36 years old. In developing countries, cardiovascular disease is no longer a disease of the elderly but has also become a disease of women, young adults and even children<sup>6</sup>. The prevalence of hypertension in women is directly proportional to increasing age. According to the National Health and Examination Survey, 67% of 60-year-old adult women suffer from hypertension and the risk of death from cardiovascular disease increases<sup>7</sup>.

In rural area we found obesity PR= 2,10, which means the women with obesity more at risk of hypertension of 2,10 times compared with women who are not obese. In urban area we found obesity PR= 2,08, which means women with obesity more at risk of hypertension of 2,08 times compared with women who are not obese. Overweight is a condition where a person has a body weight above the threshold of BMI that affects the composition of the body so that it can cause damage to other organs such as the heart, liver, kidney, lungs, large intestine, skin, blood vessels and brain<sup>8</sup>. The relative risk of suffering from hypertension in people who are obese is 5 times greater than someone with a normal body weight<sup>9</sup>.

In rural area we found low education PR= 2,06, which means the woman with low education more at risk of hypertension of 2,06 times compared with women with higher education. In urban area we found low education PR= 2,15, which means the women with low education more at risk of hypertension of 2,15 times compared with women with higher education. Education is a marker of socio-economic status that is valid and easily measured and has been used in studies of relationships with adverse health effects. Low education has been reported as a predictor of hypertension<sup>10</sup>.

### Conclusion

The same variable associated to hypertension in women in rural and urban areas are age, obesity and education based on following analysis data Indonesia

Family Life Survey 5 in 2014.

# The Phenomenon of Patient Health Education by Nurses in Hospital

Lucky Amanda Fajriyanti<sup>1</sup>, Ira Nurmala<sup>1</sup>, Rachmat Hargono<sup>1</sup>

<sup>1</sup>Health Promotion and Behavior Sciences; Faculty of Public Health, Universitas Airlangga, Indonesia

## Abstract

**Context:** The National health problem in Indonesia from year to year tends to increase. The data from *riset kesehatan dasar* during 2007-2018 has shown that the trend of most diseases is increased. The increase of health problem in Indonesia mostly is caused by the lack of health education provided by hospital health worker to patient. Dealing with these challenges, a qualitative research was conducted whose aim to describe and explore the practice of patient health education done by nurses. The research method is qualitative descriptive with phenomenology study. The technique used to select the informant is purposive sampling, while the data collection done via depth interviews with 15 nurses. The research is implemented in one of the hospitals in East Java, Indonesia. The Source triangulation is done with patients and the data were analyzed using content analysis. The results of the study were that the health education was carried out in a treatment room with a small number of patients. Nurses knew that patient health education was the primary task of nurses, yet they consider it was not a priority. Health education was only provided if the patient raised questions to the nurse. Most nurses did not carry out the stage of patient health education correctly. Therefore, the hospital should make policies and regulations, develop planning, monitoring and evaluation on a regular basis so that patient health education can run optimally.

**Keyword:** Health Education, Nurse, Hospital.

## Introduction

The national health problem in Indonesia from year to year tends to increase. The data from *riset kesehatan dasar* during 2007-2018 has shown that the trend of most diseases is increasing. The increase occurred in obesity by 6%, mental disorders by 2.6%, stroke 2.4%, hypertension 9.5%, diabetes mellitus by 1% cancer and TB increased by 0.7% [1,2,3]. The Increasing health problems in Indonesia are caused by a lack of patient health education provided by hospital health care workers. Health education must be provided by all health professional workers in the hospital. Among healthcare professionals in hospitals, nurses are the front-line health workers who spend most of their time with patients and family members of patients so that they have many opportunities to provide patient health education<sup>[4]</sup> According to Kozier and Erbs (2010) health education is a major aspect in nursing practice and an important part of nurse's role and function. Health education is an interactive process between health care provider and

patient, family to improve knowledge, attitude, and skill via practice and experience [5]. Patient's education is the most interesting topic in the world [4]. The problem currently faced is that health workers mostly use a disease-centered approach rather than a patient-centered approach [6] thus even though patient health education is considered important [7] but it was neglected [8].

The patient's health education technique is a method used to implement health education in order to achieve the expected goal. Health education technique according to [8] include collecting data from the patient's family related to the education they have, analyzing the patient's education needs, planning the site and time and method of education, implementing health education, evaluating the improvement.

The benefit of health education is to increase the patient's capacity in hand hygiene to prevent nosocomial infection in hospital<sup>[9]</sup>, to overcome mental disorder, to improve symptom of illness, to increase adherence to

the treatment, to plan and support selected treatment to improve quality of life and social function<sup>[10]</sup> to reduce patient anxiety<sup>[11]</sup>, and to contribute to the prevention of relapsing patient<sup>[12]</sup>.

### Material and Method

This research is a descriptive study with a qualitative approach. Qualitative approach is chosen since it produces description of a rich phenomena and helps to investigate complex problem<sup>[13]</sup>. The qualitative approach in this study aims to explore the phenomenon of patient health education in one of the hospitals in East Java.

The selection of informants was done by purposive sampling stating that the researcher was a key instrument<sup>[14]</sup>. Purposive sampling means determining the informant who is considered to know the best related to what the researchers expect. In order to determine the number of informants, the researchers consider it to be sufficient if it reaches the level of “redundancy” (data is saturated and there are no more informants who provide new information). The research informants were 15 nurses with inclusion criteria, such as nurses who have worked for > 2 years. Triangulation of sources is patient. The initials used for nurse informants are “N” and the initial source of triangulation is “P”.

Triangulation of sources was done to keep the Source triangulation is applied to maintain the quality of data provided by informants in order to keep it valid. The analysis of research data is based on content analysis. Qualitative data collection is done via in-depth interviews. Data was collected in April-May 2019. Before the interview was conducted, informants were asked for their willingness to sign an informed consent form. Interviews were conducted using semi-structured interview guidelines with open questions. During the interview process, notebooks and recorders were employed. Researchers transcribed the information from the audio

**Findings:** Patient health education is one of the main tasks of nurse but it is still not optimally implemented. The informant said that the patient’s health education was the duty of the nurse, but it was considered unimportant so that the nurse preferred another action. This can be seen from the following statement.

“Health education is the duty of nurses but we consider health education is not emerging stuff so we

consider it unimportant. We prioritize another other nursing actions” (N4)

The similar information was also conveyed by informant N6 who stated that nurses did not always provide health education to patients. If the patient arrives at night, they will not give health education. The informant’s statement is written below

“Nurses do not provide patient health education when patients come at night. A lazy nurses also do not carry out health education, they only record on the medical record form only “(N6)

Other information revealed that patient health education was given only if the patient or family of the patient asked for it, otherwise nurses assumed that the patient was considered to understand. The quotation information supporting that statement is stated below.

“The patient’s family is not actively asking for it, if they are actively asking for it, we will definitely explain, if they don’t ask, we think that they have already understood!”(N7)

The uneffectiveness of the patient health education is also showed via informant N3 interview stating that patient health education done by the nurses so far has covered only general information such as handwashing, doctor’s schedule.

*“The health education given by the nurse only covers general information such as handwashing, doctor’s schedule. Thus, the health education is not optimum” (N3)*

Other Information found that nurses always provided health education as needed to each patient treated. The informant said that patients were given health education starting from basic human needs until further care at home. Informant N1 delivered the following statement

“The health education is provided to all patients as needed. The health education includes the function of medical devices and how long they are installed, the risk of fall, pain management, respiratory problem if a breathing disorder found, the cause of the disease and how to minimize it so that it is not infected. Discharge planning is also given to supervise of taking medication so that patients do not drop medication(N1)”

The next interview was conducted with other informants providing care for internal patient. The

informant claimed health education was given to all patients treated in the treatment room. Their statement can be seen below

*“all nurses provided health education and they were recorded on the health education form in the medical record” (N8)*

Next, the researchers triangulated with P7 patient. The patient was not cooperative because he was around 65 years old, so an interview was conducted with the patient’s family stating that he really wanted to know when the nurse entered and injected the type of drug but it was not delivered. Health education for hand washing and pain management is also not explained. So there is an inconsistency between the answers given by nurses and triangulation from source P7.

Then, an interview was conducted in the first class patient treatment room hoping that health education would be provided as needed. The interview produced satisfying answers from nurses and patients at once. The nurses gave a statement that the health education was always given. That statement was justified by the patient’s answer.

The description of health education by nurses varies, some claimed to do health education when they are on shift, and it was validated. There were also those considering that health education was not important, so it was better to take another nursing actions, there were also those stating to do it to patients, but after being validated, there was no significant effect to the patients. The conclusion of the description of patient health education is that health education is not given to all patients according to their needs.

The health education given by nurses had some stages that must be done. Most of the informants’ answers were that they immediately carried out health education to patients without following the procedures.

The informant admitted that he directly carried out the health education without analyzing first and did not evaluate the patient then. The informant admitted that if he had done health education to the patient, meaning that the task had been completed, later if they were confused they would come to the office to ask.

*“we immediately carried out health education without conducting assessment and evaluation. We prioritized to nursing care not to health education(N9)”*

Another informant stated that patient health education was only carried out in general, the more important thing was to record on the available patient health education sheet, meaning that the patient’s health education assignment has been carried out.

“We completed the health education sheet first, then we gave the education when we remembered (N3)”

Nevertheless, there was other information conveying that they did all stages correctly in health education such as data collection, needs analysis, planning, implementation, documentation, and evaluation.

## Conclusion

The implementation of patient health education by nurses varies. In the treatment room with a small number of patients, the health education is given. Meanwhile, in the treatment room whose many patients, not all health education is implemented and given to patients. There were also informants who said that the patient’s education had been given but the patient felt that he had not been given. The gap occurs as informants do not evaluate patients after conducting health education so that information is not obtained well. Another reason is that the low level of patient’s education and psychology condition. This is in line with what was conveyed by [6] health workers mostly used a disease-centered approach rather than a patient-centered approach. There are even some nurses whose perception is that nursing action is more important than health education. Research [15] showed that patient education was often given a lower priority than other nursing tasks. [16] reported that although the majority of nurses in their study believed that patient education was an important part, they ranked lower than other tasks such as physical care, medical treatment, and writing report. [17] in his study also stated that low priority and low responsibility hindered patient health education activities.

Other information obtained was that the nurse conducted health education to the patient when the patient asked for it, this indicates that the patient does not understand. They assume that patients already have and receive enough information if questions are not raised. So, nurses tend to provide information only when patients ask question. Similar research showed that nurses rarely provided information to patients. Professionals only care about their own choice of routines and problems [18]. In addition, during the education process, patients don’t have a confidence to ask questions, and nurses also

rarely provide feedback or show concern for patients' non-verbal expressions.

In addition, most of informants did not complete all the process of health education starting from the assessment of patient needs, planning, implementation, documentation and evaluation. This is consistent with the research of the Health Service Medical Corporation, Inc. which states that only one-fifth of the 1500 nurses prepare to provide health education. The result of the study <sup>[19]</sup> also showed that in the management of cancer patient, nurse did not have a strategic plan for health education, even though they all had well-structured activities and health education media.

Nurses are in a key position to carry out health education, as they are health care providers making continuous contact with patients and families and they are usually the most accessible source of information for them. If the data collection stage is carried out effectively it will be a strong foundation to determine needs in implementing health education. Evaluation is also needed so that nurses know whether health education is acceptable to patients or not. Therefore education in patients and families becomes a more important function in the scope of nursing practice <sup>[20]</sup>. The nurse motivates patients to recover by providing support. One of them is emotional support. Emotional support consists of empathy, attention given by others in the form of trust and concern <sup>[21]</sup>. If individuals get intensive support, then individual will feel cared for and also valued <sup>[22]</sup> so that they can change the lives of patients via improving quality of life and recognizing the causes of disease suffered by patient and helping to reduce stress and returning hospitalization<sup>[23]</sup>.

This finding has some implications toward policy and regulation regarding patient health education and then incorporated into hospital accreditation standard for nursing practice. In addition, the organization must formulate regular planning, monitoring and evaluation and assistance so that health education with the concept of empowerment can run optimally. The hospital provides a media for patient health education so that it could be a tool to facilitate nurses in conducting health education

# Does Recovery Prevent Myocardial Damage Due to Overtraining?

Made Kurnia Widiastuti Giri<sup>1</sup>, Muchsin Doewes<sup>2</sup>

<sup>1</sup>Faculty of Medicine, Universitas Pendidikan Ganesha Bali, Indonesia, <sup>2</sup>Faculty of Public Health, Universitas Sebelas Maret Surakarta, Indonesia

## Abstract

**Context:** The current study aims to analyze the effect of recovery in the duration of three and seven days to prevent myocardial damage due to overtraining. The research method was used through experiment only with posttest group control design on 32 rats divided into 4 groups namely 1) proportional sport, 2) overtraining, 3) overtraining with the recovery of 3 days and 4) overtraining with the recovery of 7 days. As the result, the current study proves that there is no effect from three and seven days recovery in myocardial damage in overtraining, although recovery decreases MDA myocardium concentrations, increases SOD myocardium concentrations, it does not prevent left ventricular hypertrophy, necrosis, and chromatin condensation.

**Keywords:** *Biomolecular, Pathobiology, Myocardial, Overtraining*

## Introduction

Overloading exercises are often given on the athlete's preparation for a competition. Overloading exercises that are not accompanied by adequate recovery periods would cause athletes to fall under overtraining conditions. The athlete's body condition is very vulnerable if faced with an overload dose of exercise.

On the other hand, during the period of overtraining, training also released Reactive Oxygen Species (ROS) that exceeds the protective capacity of the endogenous antioxidant system and causes deregulations in the inflammatory system, oxidative phosphorylation and neuroendocrine<sup>[1]</sup>. Increased exercise intensity has been proven through several studies to increase oxidative stress and free radical production in cells <sup>[1][2]</sup>.

Overtraining is a condition of oxidative stress that affects various organs of the body <sup>[2]</sup>. The study of the effects of overtraining on the cardiac organ is debatable, but in some studies in cardiac myositis, allegedly overtraining has led to pathological changes in the heart. Animal test studies try to start to examine with the sudden death of cardiac death in athletes, which is caused by hypertrophy of cardiomyopathy.

Hypertrophy of cardiomyopathy is a congenital

aberration which, through autopsy results in some cases of sudden cardiac death, is summed up as the cause of death in athletes <sup>[3]</sup>. A phenomenon of sudden cardiac death on the athletes is another side of a sport that has not been well documented. Athletes for the community are individuals with the image of someone with higher health status than non-athletes. The presence of sudden cardiac death cases that occurred in athletes seized public attention because it is a paradoxical case with the public's assumption about the health status of the athlete <sup>[3]</sup>. Through autopsies performed in some cases of sudden cardiac death in athletes, cardiomyopathy hypertrophy is reported to be the cause of death in cases of sudden cardiac death of young athletes <sup>[4][13]</sup>.

In other cases that are not autopsied then the cause of death in young athletes cannot be described with certainty. However, it is found that there is a tendency of incorrect training such as overtraining training, through several studies of experimental animals has proven changes in heart rate and stroke volume of the heart. In this study, myocardium damage to histologic overtraining will be demonstrated on the basis of pathomechanism that begins with the formation of excessive ROS <sup>[5]</sup>. Damage to myocardium occurring in overtraining is suspected to result in an increased risk of cardiovascular incidence.

Management of overtraining is done by detraining by decreased training load and recovery. Based on previous research, it is evident that ROS is an underlying etiology in the process of body system adaptation in sport, but its major failure adaptation is pathomechanism in cardiac organ, as well as the effectiveness of the recovery period, cannot be explained through some previous studies [5]. Recovery will induce the body's hormonal ability to decrease the amount of ROS and meet the production capacity of endogenous antioxidants, one of which is Superoxide Dismutase (SOD). SOD is an endogenous antioxidant formed by mitochondria. Detraining or recovery is management that can be given in overtraining conditions [6][11].

Furthermore, recovery will restore the cell's exhaustive condition so that it can return to its homeostatic conditions [7]. The basic principle in recovery is the recovery process whose duration depends on the type and duration of physical stress within the given training period. The duration of recovery required by body cells is explained through several studies of recovery mechanisms that occur in skeletal muscle. It is intended to restore phosphor creating reserves, glycogen and increase blood flow for oxygen consumption (reperfusion) [8][12].

The time required for the recovery process is depending on the intensity, type, and frequency of the exercise. In a study conducted on the mouse- animals - to assess phosphocreatine reserves in proportional aerobic exercise, proving that there was a significant difference between 24 hours and 72 hours recovery. In the study, it was mentioned that phosphocreatine reserves were higher in recovery with a duration of 72 hours [9]. This study analyzes the effect of recovery in protecting heart organ in overtraining conditions that have never been reviewed in previous relevant studies. The duration of recovery used in this study refers to previous relevant studies (72 hours or 3 days) and modification of extension of 7 (seven) days.

The tendency of not well documented overtraining, the complexity of overtraining pathomechanism that cannot be clearly explained, the limited research that examines the damage of myocardium in overtraining, and the limited research that examines the proper effect of recovery in the exercise program, making this study aims to analyze the effect of recovery on myocardial damage that occurs in overtraining exercise. Later results from this study can give birth to a first step in

the preparation of new protocols in the management of training programs that are cardioprotective for athletes and individuals that are not athletes.

## Method

The research method used is the true experimental method by using "randomized post-test only control group design". Data were collected only at the end of the study after treatment by comparing outcomes in overtraining treated groups, overtraining with 3 (three) days' recovery and 7 (seven) days recovery with the untreated group (proportional exercise as the control group). Randomly allocated 4 (four) treatment groups were 1 (one) control group (proportional sport), 1 (one) group without recovery treatment overtraining, 1 (one) group overtraining treatment with recovery for 3 days and 1 (one) others group were given the overtraining treatment a recovery period of 7 days.

The samples of the study used white rat type Wistar Ratus Norwegicus, male sex, aged 3-4 months, and weigh between 180-220 grams. This research has obtained ethical approval from the Research Ethics Commission of Faculty of Medicine, of Sebelas Maret University No: 717 / VIII / HREC / 2016. The treatment given to mice was reinforced in a swimming pool of 50x20x60 cm [10]. In the control group: proportional training where one hour after eating and drinking, in the afternoon the mice swam for 15 minutes, once a day, was swum on day 1,2,4,5,7 every week, and on the day-3 and 6 are periods of rest. The treatments were carried out for 8 weeks. At the end of the treatment, the mice were immediately autopsied for the blood and the heart organs.

The overtraining treatment group was swum 2 (two) times daily (except on the 7th day) until fatigue occurred and could not swim again and the treatment was administered for 8 weeks. At the end of the treatment, the mice were immediately autopsied for the blood and the heart organs. The overtraining treatment group with 3 (three) recovery experienced the same treatment with the overtraining group and was given a rest period of 3 (three) days at the end of the treatment period. The overtraining treatment group with recovery 7 (seven) days, experienced the same treatment with the overtraining group and given a rest period of 7 (seven) days at the end of the treatment period then immediately autopsy for the heart organ to be taken.

Histologic preparations were conducted by making

incisions in the heart muscle by using microtome. Then the preparations were stained with a Hematoxylin-Eosin (HE) staining technique to facilitate observation using a light microscope with 40 times magnification to assess hypertrophy, necrosis and increased chromatin activity occurring in the myocardium. To detect protein concentration in this examination which is MDA and SOD of mitochondria, hence used ELISA technique with the precipitate antibody at the well plate. The data obtained were analyzed by one way ANOVA parametric test method followed by a Post Hoc Least Significant Difference (LSD) test.

### Results and Discussion

Based on the results of the study, it was found that the mean MDA concentration of myocardium in the overtraining exercise group with recovery of seven days was lower than the control group (proportional sport) and the other two treatment groups, where the control group mean MDA was 86.45 ng/ml, the overtraining group was 112.90 ng/ml, the overtraining exercise group with a three-day recovery was 109.53 ng/ml and the seven-day overtraining exercise group was 69.27 ng/ml. Mean concentrations of MDA myocardium were presented in Graph 1.

Graph 1: Mean MDA Myocardium Concentration

The measurement result of SOD Myocardium concentration in this study showed that the mean SOD myocardium concentration in the control group (sport proportional) was higher than the other three treatment groups, where the mean SOD myocardium control group was 1516.05 ng/ml, the overtraining exercise group was

829.94 ng/ml, overtraining exercise with 3 (three) days recovery was 115,09 ng/ml and group of overtraining exercise with 7 (seven) days recovery was 939,44 ng/ml. Mean SOD myocardium concentrations are presented in Graph 2.

**Graph 2: Mean SOD Myocardium Concentration**

The histopathologic picture of the hypertrophy sample in each group is presented in Figure 1.

**Figure 1: Histological picture of left ventricular hypertrophy of the treatment group**

Description of observation and measurement result with microscope showed the overtraining exercise group with 3 (three) days recovery showed the largest index of cardiomyocyte hypertrophy was 77,625% compared with mean of hypertrophy index of control group was 26,5%, overtraining exercise group was 75,5 % and the overtraining group with 7 (seven) days recovery was 75.125%. The mean index of the cardiomyocyte hypertrophy is presented in Graph 3.

**Graph 3. Mean of Left Ventricular Hypertrophy Index**

Based on the observation of anatomical pathology experts showed that in the control group the index of myocardium necrosis was lower than the other three treatment groups. Signs of necrosis in the form of hypereosinophilic and crisis, picnosis, colitis, inflammatory cells, and remnants cell. The histopathological features of the necrosis are presented in Fig. 2.

**Figure 2: Myocardium necrosis**

Visible signs of necrosis are: hypereosinophilic and curolisis (1), picnosis 2), curolisis (3), inflammatory cells (4), remnants cell (5). The area of necrosis is characterized by a hypereosinophilic area (more pale color) with condensed, picnotic or cariorecsys nuclei. Description observation results at the nuclei by anatomical pathologist showed that in the group

of overtraining exercise with 7 (seven) days recovery obtained the largest chromatin condensation index that is 83.8% compared with chromatin condensation index rate of control group is 3.31%, overtraining exercise group was 76.6% and the overtraining exercise group with 3 (three) days recovery was 78.7%.

**Figure 3. Chromatin Condensation. A chromatin image agglomerates in the nucleus cell.**

Comparative analysis was done on the post-test mean for each group. For the concentration of MDA myocardium, the results of Analysis Of Variance (ANOVA) showed  $F = 6,248$  with  $p = 0,002$ , this made  $p$  smaller than  $\alpha = 0,05$ , so it can be concluded that there was an effect of overtraining exercise with three and seven days recovery on myocardium damage (MDA Myocardium levels). The result of Analysis of Variance (ANOVA) at mean of SOD Myocardium concentration with  $F = 19,519$  and  $p = 0.0001$  so it can be concluded that there is an impact of overtraining exercise with 7 (seven) day recovery to myocardium damage (SOD Myocardium levels). The result of Analysis of Variance (ANOVA) on the mean of Left Ventricular Hypertrophy Index was  $F = 140,732$  with  $p = .0.0001$ , so it was concluded that there was an effect of overtraining exercise with three and seven days recovery on Myocardium damage (Left Ventricular Hypertrophy Index).

The result of Analysis of Variance (ANOVA) on the mean of Necrosis Index of Myocardium between groups,

with  $F = 201,911$  with  $p = 0.0001$  so it is concluded that there is the influence of overtraining exercise with of three and seven days recovery to the Myocardium Necrosis Index. The result of Analysis of Variance (ANOVA) on mean chromatin condensation index on cardiomyocyte between group shows  $F = 524,466$  with  $p = 0.0001$  so concluded there is influence overtraining exercise with the recovery of three and seven days to damage of myocardium (chromatin condensation index of cardiomyocyte).

Through One Way ANOVA (Analysis Of Variance) test, it found differences between groups. Then it was followed by LSD (Least Significant Difference) test which presented some of the following as a result:

1. The condition of myocardium damage in proportional exercise is better than in the overtraining exercise though it has been given recovery because it resulted in lower MDA myocardium concentrations.
2. The condition of myocardium damage in

proportional exercise is better than in the overtraining exercise despite given recovery since it shows the concentration of endogenous antioxidants (SOD) in the myocardium is higher.

3. The condition of myocardium damage in proportional exercise is better than the overtraining exercise load though it has been given recovery because it resulted in a lower left ventricular myocardium hypertrophy index.
4. The condition of myocardium damage in proportional exercise is better than the overtraining exercise although it has been given recovery because it results in a lower Myocardium Necrosis Index.
5. Myocardium damage in proportional exercise is better than the overtraining exercise despite recovery because it resulted in a lower cardiomyocyte chromatin condensation index.

### Conclusion

The results of the current study prove that there is no effect of three and seven-day recovery on myocardial damage in overtraining. Although recovery decreases MDA myocardium concentrations, increases SOD myocardium concentrations, it does not prevent left ventricular hypertrophy, necrosis, and chromatin condensation.

## Abstract

**Background:** Tuberculosis is an infectious disease which is the second largest cause of death in the world after HIV / AIDS. Tuberculosis caused by Mycobacterium tuberculosis that usually attacks the lungs but can manifest in the oral mucosa. Clinical manifestations of oral tuberculosis related to age, sex, duration of treatment, systemic disease and Multi Drug Resistant therapy. There is no research on descriptive studies of oral manifestations of tuberculosis patients in South Kalimantan specifically in Banjarmasin.

**Purpose:** To analyze descriptively the clinical manifestations of oral tuberculosis in South Kalimantan, Indonesia.

**Method:** This was a descriptive analysis with a cross sectional study design, based on history and clinical oral examination. It was used 30 respondents by purposive sampling method. Data was analyzed by Chi square ( $p < 0.05$ ).

**Results:** During treatment it showed the correlation between xerostomia and systemic disease ( $p = 0.007$ ) and correlation between xerostomia and duration of treatment ( $p = 0.024$ ). The correlation between candidiasis and systemic disease ( $p = 0.024$ ). The correlation between angular cheilitis and age, sex, duration of treatment, systemic disease and Multi Drug Resistant therapy ( $p > 0.05$ ).

**Conclusion:** The clinical manifestations of oral tuberculosis are xerostomia, candidiasis and angular cheilitis. The duration of treatment and the systemic diseases are associated with xerostomia and candidiasis in the oral cavity of TB patients.

**Keywords:** Clinical manifestations, descriptive analyze, Multi Drug Resistant, oral tuberculosis, systemic disease

## Introduction

Tuberculosis is a contagious disease that is still a global concern. Tuberculosis (TB) is the second

largest cause of death in the world after HIV/AIDS<sup>1</sup>. The prevalence of the disease is increasing especially in developing countries because it is supported by several factors such as poverty, humid environment, population density, and increasing cases of resistance to antituberculosis drugs<sup>2</sup>.

Indonesia is a country with the second largest number of new cases in the world after India. In 2016 it was estimated that there were 10.4 million new cases of tuberculosis with 6.2 million cases in men, 3.2 million cases in women and 1 million cases in children. In

e-mail: maharaniroxy@gmail.com

2016, an estimated 1.7 million deaths from tuberculosis included 0.4 million tuberculosis deaths in people with HIV. The number of deaths from tuberculosis decreased 37% between 2000 and 2016, but tuberculosis remains the 10th highest cause of death in the world in 2015<sup>3</sup>.

South Kalimantan is a province that has a high prevalence of tuberculosis, where the prevalence is the same as the average prevalence in Indonesia. The prevalence of pulmonary TB in South Kalimantan based on a doctor's diagnosis in 2013 was 0.3% and in 2018 it increased to 0.4%.<sup>4</sup>

Tuberculosis is an infectious disease caused by the *Mycobacterium tuberculosis* (MTB) which generally attacks the lungs, but in 10-15% of cases can affect other organs including the oral cavity. Tuberculosis can manifest in the oral cavity in primary or secondary. It can spread through blood flow and lymphatic tract. The circumstances of individuals with productive age, smoking habits, are in a humid environment and lack of circulation, as well as a lack of knowledge will increase the risk of a person suffering from tuberculosis<sup>5,6,7</sup>.

Dentists must know orofacial TB lesions and consider them as differential diagnoses of oral lesions in order to ensure early diagnosis of TB and its treatment. This is very important because there is often a misdiagnosis. There is no descriptive studies of clinical manifestations of oral Tuberculosis patients in South Kalimantan specifically in Banjarmasin. Based on the above, it is necessary to conduct a study of descriptive studies of clinical manifestations of oral Tuberculosis that used data on patients treated at Ulin Banjarmasin Hospital. The purpose of this study was to analyze descriptively the clinical manifestations of oral Tuberculosis in South Kalimantan, Indonesia.

### **Material and Method**

This research is an analysis descriptive. It been approved by ethical clearance from the Ethics Research Committee of Dentistry Faculty of University Lambung Mangkurat, Banjarmasin, South Kalimantan, Indonesia (No.100/KEPKG-FKGULM/EC/XII/2018). It was taken place at Poli TB RSUD Ulin Banjarmasin in January-March 2019. The sampling techniques on this study were taken by purposive sampling method. All data was analyzed by chi square non-parametric test ( $p < 0,05$ ).

### **Result**

Based on the results of research that had been done in RSUD Ulin Banjarmasin obtained sociodemographic characteristics of respondents which include age, sex, duration of treatment, systemic disease and MDR (Multi Drug Resistant) status in pulmonary TB disease patients can be seen in table 1. Based on table 1 can be known characteristics of TB patients aged  $\leq 45$  years are 16 people (53.3%) which are more than the age group  $> 45$  years which is 14 people (46.7%). Based on gender the number of men is more than women, the number of men is 17 people (56.7%) and women are 13 people (43.3%). TB patients in this study had a longer duration of treatment in the span of 6 months, namely 16 people (53.3%) compared to the span of more than 6 months, namely 14 people (46.7%). Tuberculosis patients accompanied by systemic diseases were 17 people (56.7%) and patients without systemic disease were 13 people (43.3%) whereas there were 14 people based on MDR (Multi Drug Resistant) status (46.7%) and without MDR, there were 16 people (53.3%).

The results of the data were analyzed using the Chi Square Test, to determine the relationship of clinical manifestations of the oral cavity with age, sex, duration of treatment, systemic disease and Multi Drug Resistant (MDR) status in Tuberculosis patients at RSUD Ulin Banjarmasin. This analysis used by the Fisher's exact test with a significance limit ( $p < 0.05$ ).

Table 2 show that there is a significant correlation between xerostomia that manifests in the oral cavity of Tuberculosis patients in RSUD Ulin Banjarmasin January-March 2019 with duration of treatment and systemic disease ( $p < 0.05$ ). Table 3. show that there are a significant correlation between candidiasis that manifests in the oral mucosa of Tuberculosis patients in RSUD Ulin Banjarmasin January-March 2019 with systemic diseases ( $p < 0.05$ ). Based on the table, it is known that there are no significant correlation between candidiasis and age, gender, duration of treatment and MDR (Multi Drug Resistant) status in Tuberculosis patients. Based on Table 4. show that there is no significant correlation between angular cheilitis with age, sex, duration of treatment, systemic disease and MDR status ( $p > 0.05$ ).

**Discussion**

**Relationship between Age and Clinical Manifestations of the Oral Cavity in Tuberculosis Patients:** In this research there was no significant relation between age with xerostomia, candidiasis and angular cheillitis in the oraltuberculosis. The age group of TB patients in Indonesia of 75% are a productive age population of between 15-50 years.<sup>8</sup>This is in accordance with this study showed more TB patients are ≤45 years. Increasing productive activities and smoking habits at a young age in developing countries is one of the factors increasing the incidence of TB. Xerostomia can also be increased in elderly oral TB patients. In elderly xerostomia patients are often associated with degeneration due to the aging process. This causes a decline in salivary gland function where the loss of

the parenchymal gland is replaced by fat tissue and connective tissue and the lining of intermediate duct cells that experience atrophy.<sup>9</sup>

#### **Relationship between Gender and Clinical Manifestations of the Oral Cavity in Tuberculosis Patients:**

The results of this study also showed no significant correlation between sex with xerostomia, candidiasis and angular cheilitis in oral Tuberculosis patients. The male group is the group with the most tuberculosis in this study. This is also the same in the studies of Novita and Ismah (2017), the male sex group is the most suffering from TB (70%) compared to women (30%). Men have the risk condition than women.<sup>10</sup> Smoking and drinking alcohol habits in men can reduce the body's defense system. Chronic effects of nicotine can cause changes in the composition of saliva. Smokers will also experience a decrease in the velocity of saliva due to atrophic acini cells in the salivary glands. When entering the elderly group, a woman will experience the aging process. This natural process is called menopause, if a woman has entered the process, estrogen production will stop. This will affect the condition of the oral cavity so that it is vulnerable to dry mouth.<sup>11</sup>

#### **Relationship between Duration of Treatment with Xerostomia in Tuberculosis Patients:**

In this study shows the significant correlation between the duration of treatment with xerostomia in Tuberculosis patients in RSUD Ulin Banjarmasin in January-March 2019. This can be related to the level of stress experienced by patients. emotional can affect the autonomic nervous system, thus blocking the sympathetic nervous system from producing saliva. This is also related to the side effects of OAT where one of the antituberculosis drugs, Isoniazid, has side effects such as xerostomia or dry mouth.<sup>12,13</sup>

Therapy for tuberculosis is one of the long-term therapies. Prolonged treatment with a large amount of medication often makes TB sufferers complain like, dizziness, decreased appetite, anxiety, disturbed sleep patterns and dry mouth. This situation is a symptom of stress. The study explains the longer TB treatment will be more severe the stress level of TB patients.<sup>13</sup> The study shows there are the significant effect of stress and anxiety on saliva volume.<sup>12</sup> Some literature suggests that saliva volume is affected by stress and psychological conditions. Anxiety and depression can cause a decrease in salivary and xerostomia production. If someone has a chronic disease including pulmonary TB, it will tend

to experience depression because of decreased levels of monoamine in the brain. This decline in neurotransmitters in the brain can make pulmonary TB patients very susceptible to depression because neurotransmitters do not function according to their functions.<sup>14,15</sup>

#### **Relationship Between Systemic Disease and Clinical Manifestations of the Oral Cavity in Tuberculosis Patients:**

In this study there is a significant correlation between xerostomia and systemic disease. Systemic diseases that accompany respondents are Diabetes Mellitus and HIV/AIDS. DM patients increase the risk of 1.5 times the TB disease compared with respondents who do not have DM disease.<sup>16</sup> The longer a person has DM, the more complications in the oral cavity such as hyposalivation and xerostomia will appear. This is due to the relationship of blood glucose level levels of DM patients associated with the incidence of decreased salivary flow. Microvascular and neuropathic changes will affect the ability of the salivary gland to respond to neural or hormonal stimulation in TB patients<sup>17</sup>.

In this study showed the significant correlation between candidiasis and systemic disease in Tuberculosis patients. Oral candidiasis is commonly found in TB patients with HIV/AIDS co-infection. Immunocompromised conditions generally accompany HIV/AIDS patients, making them vulnerable to oral infections. These conditions produce immune deficiency and disruption of cytokine production which causes disruption of phagocytic function of PMN and macrophages. The changes in oral epithelial cells cause changes in mucosal CD4 T cells and reduction of Th1 cytokines in the saliva of chronic HIV patients. Antibiotics also can change the balance of commensal microorganisms in oral cavity and inhibit the growth of antagonistic commensal bacteria against Candida, thereby increasing the population of Candida<sup>18</sup>.

#### **Relationship Between Patient Therapy MDR (Multi Drug Resistant) Status and Clinical Manifestations of the Oral Cavity in Tuberculosis Patients:**

In this study there are no significant correlation between the treatment of Multi Drug Resistant (MDR) patients with xerostomia, candidiasis and angular cheilitis. Some drugs that are thought to cause side effects of nausea and vomiting are etionamide, para-aminosalicylic acid, and pyrazinamide. The study showed that patient with TB treatment has a significant association with renal disorders. This situation is probably caused by long-term use aminoglycoside drugs. Hearing

disorder was found to be 59.6%. Ototoxicity as well as nephrotoxicity have also been reported as side effects of aminoglycosides associated with large doses. Drug accumulation, duration of therapy, bacteremia, kidney or hepatic impairment, and also the use of MDR TB drugs with diuretics that have otocytosis effects are risk factors for ototoxicity<sup>19</sup>. This study shows that angular cheilitis did not have the correlation with all related factor. The previous study showed that angular cheilitis was the third largest prevalence of oral mucosa disease of Gusti Hasan Aman Dental Hospital in Banjarmasin.<sup>16</sup> Based on Pemantauan Status Gizi (PSG) in 2016, South Kalimantan had 21,8% of malnutrition cases. The malnutrition condition caused by folic acid, iron and vitamin B12 deficiency which tend to increase the incidence of anemia. Pathophysiology of anemia which cause angular cheilitis due to decrease the mitochondria enzymes activity in cell resulted in the disturbance of oxygen and nutrition transport.<sup>20</sup>

### Conclusion

It can be concluded that clinical manifestations of oral tuberculosis are xerostomia, candidiasis and angular cheilitis. The duration of treatment and the systemic diseases are associated with xerostomia and candidiasis in the oral cavity of TB patients.

### Declarations:

**Acknowledgement:** The authors would like to express their sincere gratitude to the Dentistry Faculty of University Lambung Mangkurat, Indonesia for supporting this research.

## Abstract

**Context:** The increasing demand for having an attractive smile becomes one of the life essentials. Oral hygiene maintenance plays a key role in maintaining oral health (healthy teeth and gum) and as a result, having an attractive smile. Thus, using routine dental cleansing through brushing, flossing and mouth rinses is mandatory.

This study aims to evaluate the role played by social media on consumers' behaviour to use dental products manufactured essentially from herbal products rather than the well-known chemical formula. The analyzed data were collected by using a face-to-face approach (unstructured interviews). At first, dentists and pharmacists were asked about their opinion regarding using herbal products and their response to social media campaigns. Then, a random sample of the audience was interviewed.

Results showed that most of the Iraqi peoples are familiar with herbal products (68.6 %) of them indicated social media has an impact on individuals.

The awareness of the importance of using toothpaste and mouth rinses made from herbal products can be increased through introducing their effectiveness, reduced side effect and their importance as green substrates...etc. This can be done by organized campaigns by a pharmaceutical company or nonprofit organization.

**Keywords:** Herbal, dental products, social media, behaviour, influencers.

## Introduction

Potent therapeutic agents may be developed from medicinal plants through its active substances<sup>(1)</sup>. Ancient

civilizations have used plants to cure a variety of human ailments<sup>(2)</sup>. Nowadays, over 50% of the modern drugs industry focuses on natural products which play an important role in drug development<sup>(3,4)</sup>.

Many of these plants have dental care properties like *Azadirachta indica* (Neem), *Melaleuca alternifolia* (Tea Tree Oil), *Gritta Kumari* (Aloe Vera)...etc<sup>(5,6)</sup>

Historically, herbal products have been used as an oral hygiene maintenance routine. The chewing stick (Miswak or Siwak) is a tradition inherited from prophetic medicine<sup>(7)</sup>.

Furthermore, in Asia, Africa, the Middle East, and the Americas, for thousands of years, chewing sticks prepared from twigs, stems or roots of a variety of plant species have been practiced despite the widespread use of toothbrushes and toothpaste<sup>(8)</sup>.

As the side effect of allopathic medicines has increased, studying medicinal plants is also increased in different parts of the globe. Health professionals are often challenged to explore relevant information to advise their patients about using these over-the-counter products safely. The use of herbal extracts in various forms is entirely consistent with the primary health-care principles because these ingredients work more in harmony with the body instead of fighting against it as seen in other conventional versions of the same herbal products<sup>(9)</sup>.

Consumer behavior defined as a sequence of physical, mental and emotional activities done by humans during selecting, purchasing, using, deciding and disposing of goods and services to satisfy their needs<sup>(10)</sup>. Marketing campaigns can be considered as leading factors affecting consumer behavior which helps companies and nonprofit organizations to predict consumer personal preferences and purchasing power<sup>(11)</sup>.

Social media nowadays play an essential role in improving consumers' satisfaction starting with the initial stages of information search, alternative evaluation, purchase decisions and ending with changing consumers' opinions and interest<sup>(12)</sup>. Thus, understanding the impact of social media in clarifying the benefit of herbal dental products over the chemical formula will help in increasing awareness of the people about the importance of using these products. This knowledge may end with reducing side effects that came

from chemical products and substantially saving more money.

## Methodology

**Study Design:** This study based on individuals' opinions obtained from face to face interviews with a random sample of dentists, pharmacists, and consumers to draw an image of their opinion about herbal dental products and to identify the role played by the advertising campaigns on social media to affect their purchasing behavior.

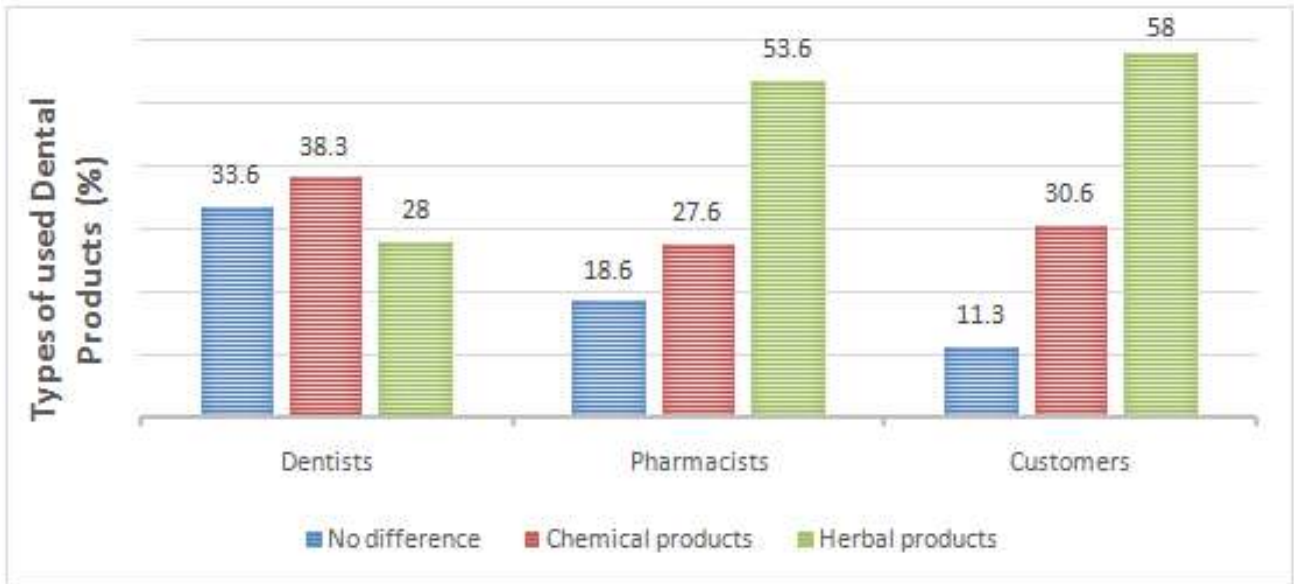

20 questions with 'yes' or 'no' closed-ended responses were designed and asked three hundred peoples; these questions were build based on literature review.

**Study Samples:** Face to face interview was conducted from February 2019 to May 2019 in Baghdad/ Iraq at two stages; the first stage included 100 dentists and 100 pharmacists. While the second stage was with 100 consumers asking them about their opinion about herbal dental products.

## Results

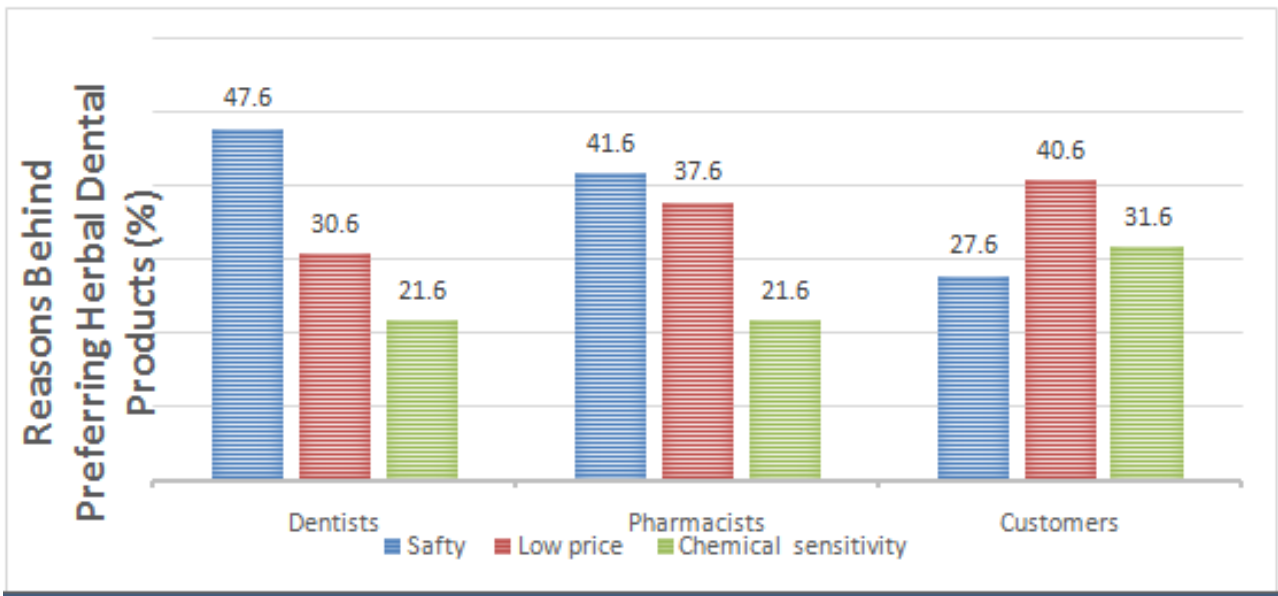

Descriptive statistics were used to analyze the results of this study using Version 21, SPSS software.

The chemical dental products show the highest rate of use among dentists (38.3%), while the herbal products used more by the other customers (58%) (Fig.1).

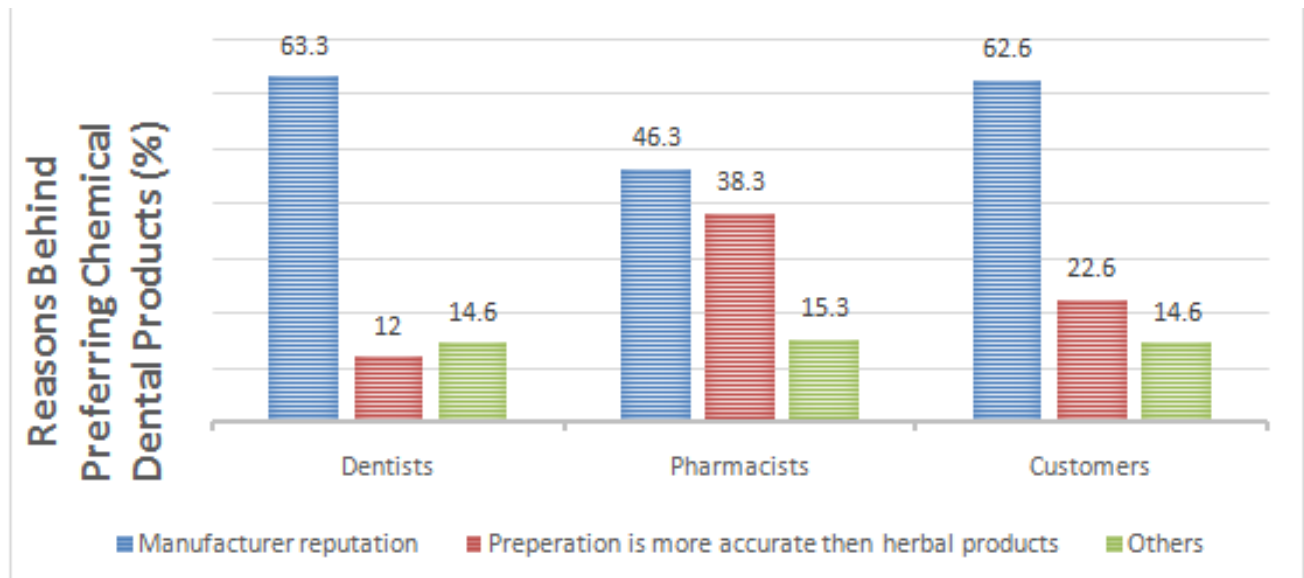

**Figure 1: Types of used dental products**

In (Fig. 2 and 3), reasons behind preferring herbal products over the chemical product and vice versa. Safety (47.6%) was the major reason behind using herbal dental care by the dentists. Whereas manufacturer reputation (brand) (63.3%) reported being the reason behind using chemical dental care products.

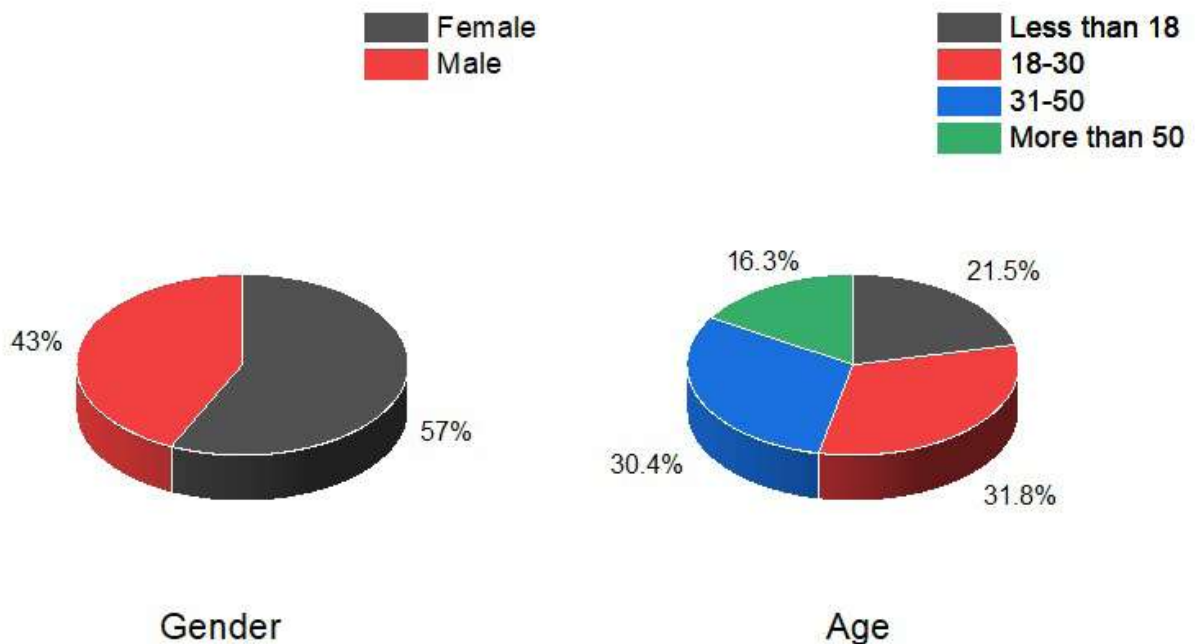

**Figure 2: Reasons behind preferring herbal dental products**

**Figure 3: Reasons behind preferring chemical dental products**

The majority of the sample were females (57%). The age of the majority of the sample was between 18-30years old (28.6%) (Fig. 4).

**Figure 4: Gender and age of the study sample**

Results reported that social messages via social media have played an essential role in changing the consumers' thoughts to use the herbal products by (68.6%) mostly via Facebook (31.6%) Where Twitter

reported to be the least social media visited by people in Baghdad-Iraq (8.6%). These social sites were viewed daily by the majority of the study sample (58.6%) (Fig. 5 and 6).

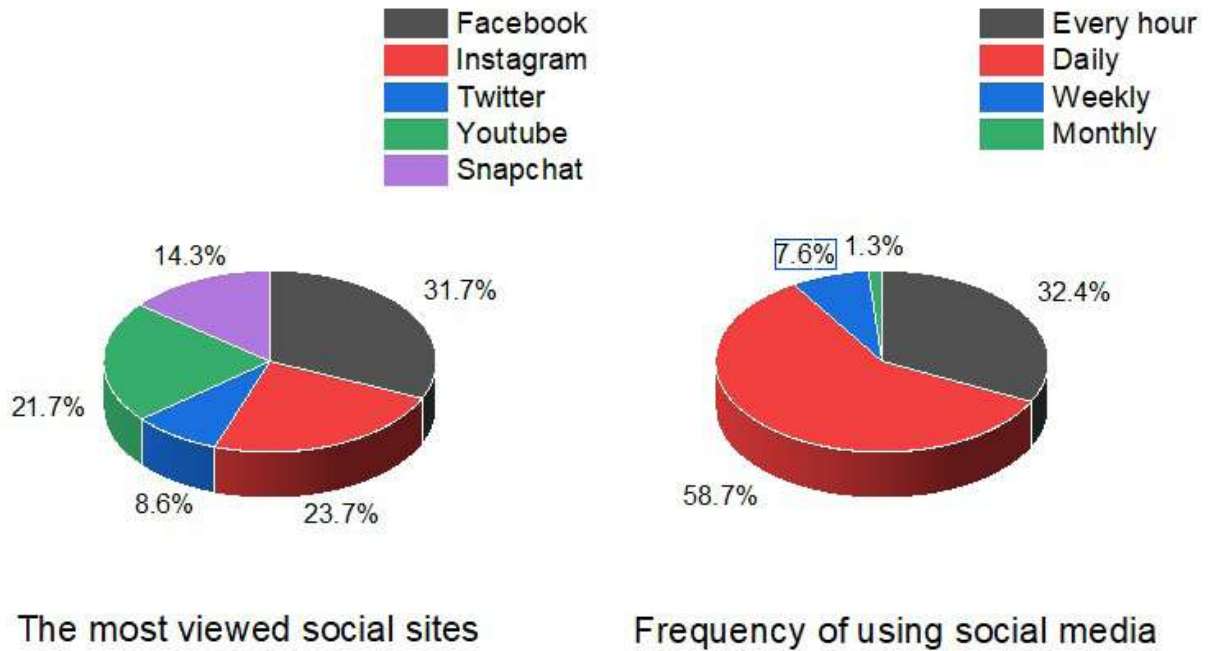

Figure 5: Most vied social media and the frequency of usage

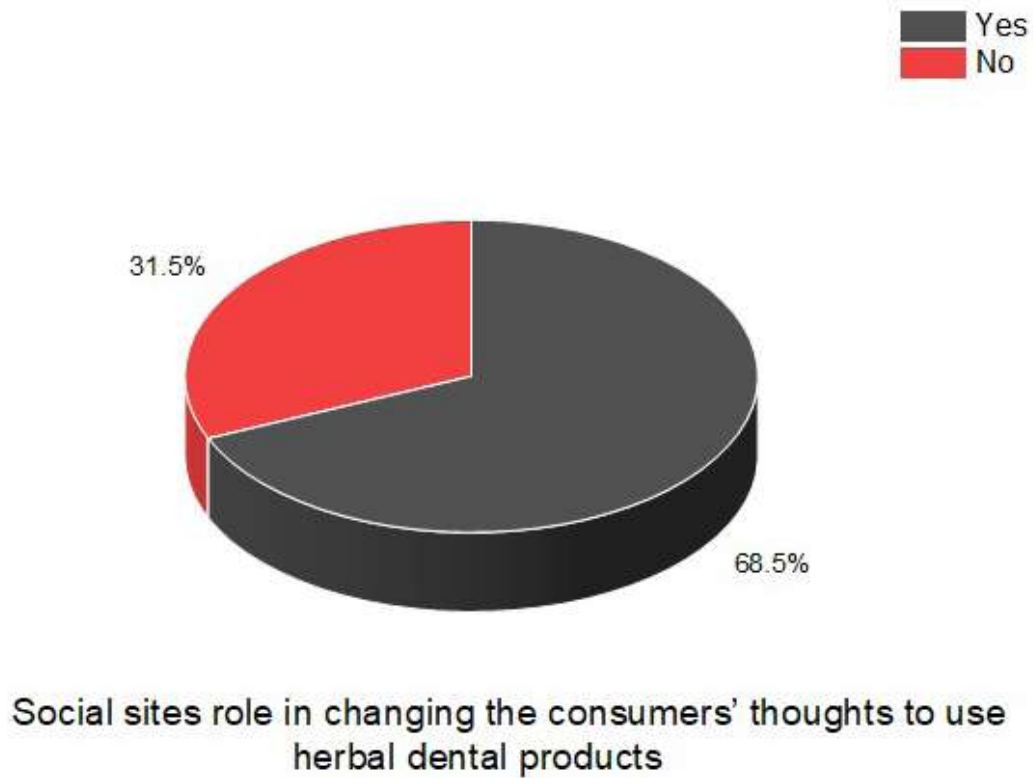

Figure 6: Social sites role in changing the consumers' thoughts to use herbal dental products

## Discussion

As stated in the literature, medicinal herbs are a potential source of therapeutics aids in health systems all over the world in the diseased condition or as potential material for maintaining proper health. Therefore, the herbal product's popularity has increased<sup>(5)</sup>.

This research focused on understanding the general orientation of people in Baghdad-Iraq toward herbal dental products and the reasons behind these beliefs. The collected data from dentists, pharmacists, and other consumers reported that herbal dental products are used frequently mainly because of its safety, low price and finally as a substitute to the chemical products as there is an idea that chemical compounds may be cause sensitivity. Furthermore, the data reveals a percentage of people that use both chemical and herbal products. While some peoples use the chemical formula as a result of the manufacturer's reputation. (Fig. 1,2 and 3)

Generally, women are more interested in their appearance than men, that is why most of the study sample were females between 18-30 years old(Fig. 4).

The second aspect of this study deals with the impact of social media on consumers' behavior toward herbal dental products; therefore, the frequency of using social media and which media is most visited is important. Data regarding these questions revealed the majority of the study sample used social media on a daily basis. Facebook and Instagram reported being the most visited social sites (Fig. 5 and 6).

Recent studies mentioned social media as a vital tool for people between 18 to 40, as they enter young adulthood, focus on the future and aware of how others see them. They feel more pressure to be "the best", are more worried about what others think about them, and are more concerned about what making their family and friends proud, as known up to 91% of social media account are in this age group with the most social media connections. These groups are the most affected by social media's on their lives<sup>(13)</sup>.

## Conclusions

1. Herbal dental products used widely by peoples regardless of their levels of education.
2. Social media can direct the audience toward a specific product when used correctly towards the targeted audience via the proper social site.

## Abstract

**Context:** Adolescent who are pregnant will experience depression due to physical and mental unpreparedness that affects cortisol which will reduce the secretion of Brain Derived Neurotrophic Factor, so that it will increase the index of apoptosis of brain neuron cells. This study aims to determine differences in the influence of adolescent and adult pregnancy on the index of apoptosis of brain neuron cells. The study used true laboratory experimental design with post test only control group design using animals tried to mice *Mus musculus*. The experimental group was divided into two groups: the control group or the adult pregnancy, and the treatment group or the teenage pregnancy group. The brain dissection of the newborn *Musculus* mice was taken and calculated the number of neuron cell apoptosis index using Immunohistochemical Tunnel. There were significant differences in the brain neuron cells apoptosis index with a value of  $p = 0.01$  (mean  $4.13 + 2.52$  in the treatment group,  $2.81 + 1.43$  in the control group). There were significant differences in apoptosis index of brain neuron cells in the newborn *Mus musculus* mice in teenage pregnancy and the control group.

**Keywords:** *Difference, adolescent pregnancy, adult pregnancy, apoptosis index, neuron cell.*

## Introduction

Pregnancy is a period starting from conception to the birth of the fetus and is a natural and physiological process, the pregnancy process is a unified chain of conception, oxidation, mother's adaptation to liquidation, maintenance of pregnancy, and hormonal changes as preparation for the baby's birth<sup>1</sup>. World Health Organization (WHO) defines pregnancy in a girl between the ages of 10-19 years referred to as teenage pregnancy<sup>2</sup>. Teenager is a period where the transition from childhood to adulthood. In adolescents who are pregnant there are complications of pregnancy that cause twice as many deaths compared with pregnancy in adult women. In addition to the causes of teen pregnancy increasing maternal mortality, pregnancy in adolescents can also cause tremendous psychological stress in these adolescents, especially in unwanted pregnancies.<sup>3</sup> which is detrimental to the health of mother and child, is a common public health problem worldwide. It is one of

the key issues concerning reproductive health of women not only in developing countries but also in developed countries. There is growing awareness that early child bearing has multiple consequences in terms of maternal health, child health and over all well-being of the society. The purpose of the article is to review current trends and issues on adolescent pregnancy to update the practitioners. The readers are provided with more recent data on adolescent sexuality, child bearing as well as suggestions for addressing the challenges of teenage pregnancy. & lt;p & gt; & lt;p & gt; Chatt Shi Hosp Med Coll J; Vol.15 (1 World Health Organization, recorded as many as 16 million adolescents aged between 15-19 years giving birth each year, equivalent to 11% of the total number of births in the world. As many as 59% of the total teenagers who give birth come from poor and developing countries. Pregnancy rates among adolescents in the United States are 67,8 pregnancies per 1000 women aged 15-19 years.<sup>4</sup> Setting, Participants,

Interventions, and Main Outcome Measures: We used records of 38,646 women who gave birth at our hospital, between January 2008 and December 2009. Five hundred eighty-two randomly selected pregnant adolescents and 2,920 healthy parity and body mass index matched pregnant women 20-34 years of age were included the study. Perinatal outcomes were compared between the groups. Results: The mean gestational ages of the adolescent and control groups at the first prenatal visit were 11.2 (range, 8-31)<sup>5</sup>

Factors affecting pregnancy such as stress can affect the growth and development of the hypothalamic Pituitary Adrenal. Maternal prenatal stress is the initial environmental factor that affects cortisol reactivity in humans <sup>6,7</sup>. Unwanted pregnancies and physical and mental unpreparedness in pregnant teenage women will have an impact on mothers who will experience depression and ultimately affect fetal growth and development during pregnancy, where one of them is maternal depression which can affect the increase in neuronal cell death in the fetal brain.<sup>5</sup> In the stressful condition of pregnancy, spurring an increase in the hormone cortisol through the placenta and an increase in glucocorticoids will inhibit the expression of Brain Derived Neutrotrophic Factor resulting in an increase in the number of neuron cells undergoing apoptosis in the hypothalamic paraventricular nucleus <sup>8</sup>. The process of apoptosis can play a role in the development of the nervous system and the final structure of brain function. Apoptosis occurs during the growth period, as a homeostatic mechanism to maintain cell populations in tissues, in reaction to cell damage.<sup>5</sup>

The purpose of this study was to analyze differences in the apoptotic index in adolescent and adult pregnancy in brain neuron cells.

## Method

This research was experimental true laboratory research with a post test only control group design study design. The subjects of this study used experimental animals, Musculus juvenile mice aged ± 1.5 months and adult mice 3 months old obtained from the Integrated Research and Testing Laboratory (LPPT) Gajah Madah University of Yogyakarta. Mothers of adolescents and adults are given the hormone Pregnant Mare Serum Gonadotropin (PMSG) and Human Chorionic Gonadotropin (Hcg), after which mice are carried out by mating female and male mice. Pregnancy age is examined based on copulatory plug. The subjects were sacrificed and followed by sectio caesarea to give birth to Mus musculus mice and decapitation of the head and brain to dissection. The neuron cell apoptosis index is the number of neuron cells that experience apoptosis or cell death in 10 visual fields stained in the cell nucleus in the cortex area. The apoptosis index interval measurement scale was seen with a microscope 400 times magnification and calculated per 100 cells divided by the total cell number, multiplied by 1000. Using the Tunnel assay method using immunohistochemical staining examination will be stained dark brown to blackish. Apoptotic kit with the brand Santa Cruse. Data analysis using the Shapiro Wilk normality test was conducted to examine data distribution, followed by T-Test and Mann-Whitney as alternatives. Probabilities are considered statistically significant when p <0.05 is obtained with a 95% confidence interval. The data obtained is displayed in graphical form. Data analysis was processed using the SPSS version 25 (SPSS, Inc., Chicago, IL).

## Results

### Subjects Characteristics:

**Table 1: Characteristics of Mus musculus mother based on body weight**

Body weight (gram)	Control		Treatment	
	N	%	n	%
15-20	-	-	16	100
21-25	3	18,75	-	-
26-30	10	62,5	-	-
31-35	3	-	-	-
Total	16	100	16	100

The characteristics of the parent Mus musculus based on the highest body weight ranged from 15-20 grams in the treatment group (Table 5.2), ie 100% and 26-30 grams in the control group and 62.5%.

**Table 2: Characteristics of Mus musculus newborn based number of children**

Number of children	Control		Treatment	
	N	%	n	%
0-2	-	-	4	25
3-4	6	37,5	4	25
5-6	10	62,5	6	37,5
Total	16	100	16	100

The characteristics of the parent Mus musculus are based on the number of children. The majority ranged from 5-6 children in the control group (Table 5.2), which was 62.5%. All Mus musculus children born to the mother Mus musculus were weighed, then three weights were chosen, the most severe, medium, and light to be sacrificed and cut to the brain. Three brains of Mus musculus children were made into one preparation and immunohistochemical staining was performed and apoptosis index was calculated.

Comparison of apoptotic index in adolescent pregnancy and control group

**Table 3: Mann Whitney Test Results on Apoptosis Index of brain neuron cells**

Group	Apoptosis index	Mean ± S/D	Nilai p
Treatment	132,3	4,13±2,52	0,001
Control	76	2,37±1,43	

The results of the average apoptosis index in the control group were  $2.37 \pm 1.43$  and the treatment group was  $4.13 \pm 2.52$ . Mann whitney test Apoptosis Index of brain neuronal apoptosis index with a value of  $p = 0.001$  ( $p < 0.05$ ) which means that there is a significant difference between the control group and the treatment.

**Figure 1. Microscopic test of Apoptotic Expressions. The description of expressing apoptosis in the brain is characterized by chromogen brown color (arrow) in almost all brain cells. Figure A. (Control) shows the presence of weak Apoptotic expression in the brain neuron cells of Mus musculus children and in Figure B. The expression of Apoptosis in brain cells is stronger than the control. 400x.**

**Discussion**

Adolescents who are pregnant due to physical and mental unpreparedness will experience depression in these adolescents.<sup>3</sup> which is detrimental to the health of mother and child, is a common public health problem

worldwide. It is one of the key issues concerning reproductive health of women not only in developing countries but also in developed countries. There is growing awareness that early child bearing has multiple consequences in terms of maternal health, child health

and over all well-being of the society. The purpose of the article is to review current trends and issues on adolescent pregnancy to update the practitioners. The readers are provided with more recent data on adolescent sexuality, child bearing as well as suggestions for addressing the challenges of teenage pregnancy. & It;p & gt; & It;p & gt; Chatt Shi Hosp Med Coll J; Vol.15 (1 The state of depression in pregnant women will cause an increase in hormones that are regulated by the hypothalamus.<sup>5</sup> As with humans, in juvenile mice that are being edited also

experience stress with signs such as fear that become more aggressive, and an increase in the hormone cortisol and ultimately can cause death in these mice. In this study the juvenile mice that were edited had more deaths and were not pregnant than the control group.

In accordance with the theory which says that the age of productive mice and ready to be impregnated is the age of 8 weeks. This is likely influenced by the readiness of the reproductive organs.<sup>5</sup>

**A. Rodent (e.g., rat, mouse)**

**B. Human**

**Figure 2: the growth and development of the hypothalamic Pituitary Adrenal<sup>9</sup>**

Factors affecting pregnancy such as stress can affect the growth and development of the hypothalamic Pituitary Adrenal<sup>10</sup>. Maternal prenatal stress is the initial environmental factor that affects cortisol reactivity.<sup>5</sup> Stress is referred to as a state in which the state of homeostasis in an organism is considered threatening by external or internal effects. The effector of the main end of the stress system is cortisol, which is produced by the axis of the Hypothalamic-Pituitary-Adrenal Axis (HPA Axis).<sup>11</sup>

Under stressful pregnancy conditions, spurring an increase in the hormone cortisol through the placenta and an increase in glucocorticoids will inhibit the expression of Brain Derived Neurotrophic Factor resulting in an increase in the number of neuron cells undergoing apoptosis in the hypothalamic paraventricular nucleus<sup>12</sup>.

Path of Stress Mechanism to Neurotransmitter Signaling in Neuron Cell apoptosis

Figure 3: Mechanism of stress in pregnancy <sup>11</sup>.

During pregnancy, the hypothalamic CRH, and the placenta also produce and release CRH into the bloodstream, causing hyperactivity of the HPA axis, and a considerable increase in the ratio of free / bound cortisol. Production of placental CRH and the presence of excess cortisol begin during the second trimester and increase linearly to term, with surges in the last 6-8 weeks of pregnancy <sup>13</sup>. The regulation of the prenatal HPA axis shown in Figure 2.5 has shown that when pregnant women progress, the cortisol response to acute stress reduction shows a blunt HPA axis due to high placental CRH levels. In humans, where the fetus is developing, the placenta enzyme 11β-HSD-2, which converts cortisol to cortisone is inactive, forms a maternal glucocorticoid barrier. However, 10-20% of maternal cortisol passes through the fetus, which under stress conditions is caused by increased maternal HPA activity, which gives effect to fetal cortisol and increases long-term effects on the developing brain of the fetus. <sup>11</sup>

Maternal stress and depression during pregnancy are reprogrammed <sup>14</sup>. The HPA axis, reducing placental

enzymes 11B-HSD2 and decreasing dopamine and serotonin levels but increasing glucocorticoid / cortisol affect behavior, nerve development and signaling pathways in offspring of mice (prenatal stress models). PS exposure interferes with hippocampal neurogenesis in offspring <sup>11</sup>.

The process of apoptosis can play a role in the development of the nervous system and the final structure of brain function <sup>15</sup>. Apoptosis occurs during the growth period, as a homeostatic mechanism to maintain cell populations in tissues, in response to cell damage <sup>16</sup>. Pregnancy stress is associated with an increase in glucocorticoids which will inhibit the expression of Brain Derived Neurotrophic Factor (BDNF) resulting in an increase in the number of neuron cells undergoing apoptosis in the hypothalamic paraventricular nucleus *Rattus norvegicus*. <sup>11</sup> The number of cells undergoing apoptosis depends on the synapse. The more synapses, the less apoptosis that occurs. Thus the more rich the neuron cells will dendritic site, the more synapses can be formed so that the number of cells that experience fewer

apoptosis, thus it can be concluded that brain capacity will be further enhanced<sup>11</sup>.

### Conclusion

From this research there are significant differences in apoptosis index of brain neuron cells in the newborn Mus musculus mice in teenage pregnancy and the control group. Future research is needed to prove the influence of adolescent pregnancy can have a long-term impact due to an increase in apoptosis index on structural growth, biomolecular and functional brain growth.

# The Affect of Zinc and Calcium Adequacy Levelon Stunting Toddler Aged 24-59 Months (In Bulak Banteng Health Center, Surabaya)

Marintan Laura Siagian<sup>1</sup>, Lailatul<sup>2</sup>

<sup>1</sup>Department of Nutrition, Faculty of Public Health, Universitas Airlangga, Surabaya, East Java, Indonesia,

<sup>2</sup>Department of Nutrition, Faculty of Public Health, Universitas Airlangga, Surabaya, East Java, Indonesia,

## Abstract

**Context:** Stunting is a undernutrition chronic status in the period of growth and development since the beginning of life. The incidence of stunting is influenced by several factors several factors. One of the factors is the adequacy of toddler nutrition during the growth period. The purpose of this study was to analyze the level of adequacy of the Zinc intake and Calcium intake for the incidence of stunting.

This research used observational method with a case-control design. The case group was a group of stunting toddlers aged 24-59 months, whereas the control group was normal toddlers (H/A) toddler age 24-59 months. Research was carried out in the working area of Bulak banteng Health Center Surabaya. The number of sample on this research was 28 for both stunting and non-stunting cases. Data was collected first by measuring height to know height of toddler, collect questioners from respondents and toddler, SQ-FFQ (Semi-Quantitative Food Frequency Questionnaire) to understand the level of adequacy. This data was analyzed of to find out the number of stunting cases.

The result showed that there were influences between the level of adequacy zinc ( $p=0,000$ ) (OR=-2,625), Calcium ( $p=0,000$ ) (or=-3,420) to stunting.

The conclusions in this study is nutrient adequacy will reduce the risk of stunting. Furthermore, mothers must improve the adequate nutrient for toddler and puskesmas (Center of Public Health must to increase the quality of public education about infants' nutrition needs

**Keywords:** *Toddler, stunting, adequate nutrition*

## Introduction

Stunting reflects a lack of nutrition status that is chronically challenging during the period of growth and development since the beginning of life. This situation is presented with a high body z-score according to age (TB / U) of less than -2 standard <sup>(1)</sup>

The prevalence of stunting toddlers in Indonesia in 2010 was 35.6%, in 2013 it was 37.2%, and 2018 was 30.8%. The stunting prevalence in East Java is 26.7% of the total number of children in the province of East Java <sup>(2)</sup>. One of the stunting areas in Surabaya is the BulakBanteng village. The BulakBanteng village was chosen as the research site because of the high number of stunting. Nutrition Monitoring Status (PSG) of the Surabaya City Health Office, the prevalence of stunting in Surabaya in 2017 was 23.50%.

Childhood is a period in which children very sensitive to the environment, so special attention is needed, especially nutritional adequacy. Nutrients that are needed during the toddler's growth period are zinc and

calcium. Low zinc levels affect cellular responses that regulate growth hormones such as insulin-like growth factor-1 (IGF-1). Zinc requirements physiologically during periods of rapid growth due to DNA replication, DNA transcription, and endocrine function. Iron is a microelement that is essential for the body. Toddlers are in a group that has the highest risk of developing iron deficiency due to rapid growth processes <sup>(3)</sup>Calcium deficiency will affect linear growth if the calcium content in bone is less than 50% of the normal content. In infants, calcium deficiency in the bones can cause rickets, whereas in children, lack of deposits can cause growth retardation. <sup>(4)</sup>so it is necessary to do research on the level of adequacy of zinc and calcium nutrients in infants aged 24-59 in the work area BulakBanteng Health Center.

**Material and Method**

The type of this research is observational research and analytic research because it makes observations without giving treatment or intervention. The design of this study uses quantitative design. Based on the duration of the study, this study included a case control study.

Data collected is toddler height using microtoise measuring grouped into Stunting if <-2 Standard Deviation and not stunting if -2 Standard Deviation to 2 Standard Deviations. Zinc and calcium adequacy levels through the Semi Quantitative Food Frequency Questionnaire (SQ-FFQ) questionnaire through multiplication between the frequency of consumption and the portion of food consumed in the last 1 month.

To determine the level of adequacy of nutrients used EAR (Estimated Average Requirement) as a reference. Given the adequacy grouped into, Zinc Adequacy at 24-48 months of age was classified as less if <EAR (2.83 mg) and sufficient if > EAR (2.83 mg). At the age of 48-59 months grouped less if <EAR (3.33 mg), and enough if > EAR (3.33 mg). Calcium adequacy at 24-48 months of age was classified as less if <EAR (541.6 mg) and sufficient if > EAR (541.6 mg). At the age of 48-59 months it was classified as less if <EAR (833.3 mg) and less if <EAR (833.3 mg). In addition, data collection was also related to family characteristics including family income and the level of maternal education.

The independent variable in this study was the level

of zinc, calcium adequacy and the dependent variable was stunting. Data analysis using binary logistic regression test with SPSS v20 application was conducted to analyze the effect of zinc and calcium consumption levels on the incidence of stunting. Odds Ratio (OR) analysis was conducted to assess the magnitude of risk factors for zinc and calcium adequacy levels on the incidence of stunting.

**Findings:**

**A. Distribution of family Family characteristics:**

The family characteristics studied in this study included family income and mother’s education level. The number of research subjects involved in the study were as many as 56 respondents by dividing 28 respondents from the stunting group and 28 respondents from the non-stunting group.

**Table 1: Distribution of Family Characteristics**

No.	Karakteristik keluarga	Stunting		Non-stunting		
		N	%	n	%	
1.	Family Income	Rendah	24	85,7	16	57,1
		Tinggi	4	14,3	12	42,9
2.	Mother’s education level	Tamat SD	19	67,9	14	50
		Tamat SMP	7	25	5	17,9
		Tamat SMA	0	0	6	21,4
		Perguruan Tinggi	2	7,1	3	10,7

Based on Table 1, the family income group in the stunting and non-stunting children was the lowest in the low category, each at 85.7% and 57.1%. While for high income category in stunting toddlers at 14.3% and in non-stunting families at 42.9%. The level of education of mothers in stunting and non-stunting children is at the primary level at 67.9% and 50% respectively.

**B. Distribution of Characteristics of Toddlers:**

Characteristics of toddlers studied in this study include birth weight and birth length. The number of research subjects involved in the study were as many as 56 respondents by dividing 28 respondents from the stunting group and 28 respondents from the non-stunting group

**Table 2: Distribution of Characteristics of toddlers**

No.	Karakteristik Balita		Stunting		Non-stunting	
			n	%	n	%
1.	Birth Weight	Low Birth Weight (<2500 gram)	21	75	13	46,4
		Normal (≥2500 gram)	7	25	15	53,6
2.	Birth Length	Low (<48 cm)	8	28,6	4	14,3
		Normal (≥ 48 cm)	20	71,4	24	85,7

Based on Table 2, the lowest birth weight occurs in stunting toddlers, which is equal to 75% while the most normal birth weight in non-stunting infants is 53.6%. The group of toddlers' body lengths showed that there were more categories in stunting toddlers, namely 28.6%, while non-stunting toddlers with less categories, namely 14.3%.

**C. The Influence Effect of Zinc Adequacy Level:** The level of toddlers' adequacy studied in this study is the intake of toddlers from food sources containing zinc. The number of research subjects involved in the study were as many as 56 respondents by dividing 28 respondents from the stunting group and 28 respondents from the non-stunting group.

**Table 3: Distribution of Zinc Adequacy Rate for Stunting and Non-stunting Children in BulakBanteng Surabaya Health Center in 2019**

Zinc adequacy level	Stunting		Non-stunting		p-value	OR
	n	%	n	%		
Less	21	75	5	17,9	0,000	-2,625
Enough	7	25	23	82,1		

Based on the results of the study it was found that the zinc adequacy rate affected the incidence of stunting

(p = 0,000) because the result of p-value < 0,005 it means significant. The risk analysis obtained an OR value of -2,625 means that toddlers with a sufficient level of zinc sufficiency will reduce the risk of stunting by 2,625 times compared to those with a lack of zinc adequacy.

**D. The Influence Effect of Zinc Adequacy Level:** The level of toddlers' adequacy studied in this study is

the intake of toddlers from food sources containing calcium. The number of research subjects involved in the study were as many as 56 respondents by dividing 28 respondents from the stunting group and 28 respondents from the non-stunting group

**Table 4: Distribution of Calcium. Adequacy Rate for Stunting and Non-stunting Children in BulakBanteng Surabaya Health Center in 2019**

Tingkat kecukupan kalsium	Stunting		Non-stunting		p-value	OR
	n	%	n	%		
Less	23	82,1	15	53,6	0,026	1,383
Enough	5	17,9	13	46,4		

Based on the results of the research, it was found that the level of calcium adequacy had an effect on the incidence of stunting (p = 0.026) because the result of p-value < 0,005 it means significant. The risk analysis obtained an OR value of 1.383 means that toddlers with a low level of calcium sufficiency would risk 1,383 times compared to stunting compared with the level of calcium adequacy sufficient.

**Discussion**

Based on the results of research on family characteristics, namely family income and mother's education. Most of the income in the family of low-stunting children under the Surabaya city minimum wage is Rp. 2,746,428. Low income is related to the source of income in the family which only comes from the father while the mother of the toddler is only a housewife. In addition, mothers of children under five mostly graduated from elementary school so that the ability of mothers was lacking in finding ways to increase family income. Family income is one of the factors that can affect economic status. Low economic status can have an impact on the inability to produce sufficient and quality food because of the low purchasing power (5)the prevalence of stunting and severe stunting in Brebes reached 26.9 % and 16.8 %. These prevalences of stunting were higher than the stunting prevalence in Central Java Province (11.0%)The education level of mothers in stunting and non-stunting children is the most elementary school education for children under five. Parental education can influence the ability to access information and knowledge related to parenting.

Based on the characteristics of toddlers, namely birth weight and birth length, the percentage of toddlers

who have a history of low birth weight (LBW) is more in stunting toddlers. Low birth weight babies (LBW) indicate a lack of nutrients during pregnancy, poor diet, poor eating quality, and frequency of frequent illnesses. Birth weight depends on maternal nutritional status during pregnancy and before conception<sup>(6)</sup>. Based on the results of the study, it was found that the proportion of infants with a history of birth length was more or less in the stunting toddler group. Babies born with short birth lengths indicate malnutrition since the womb. Mothers who experience malnutrition will give birth to babies who are malnourished as well. Nutritional deficiencies from the womb affect the organs and fetal growth. Babies who experience a lack of nutrients during pregnancy can still be repaired with good intake so that they can grow according to their development. However, if the intervention is done late the toddler will not be able to catch up with the growth delay called failure to thrive. Likewise with normal toddlers there is a possibility of growth disruption if the intake is insufficient. Nutrition that is in accordance with needs will help the growth and development of children<sup>(7)</sup> especially occurred in developing and poor countries. Stunting can increase the risk of morbidity and mortality, and suboptimal brain development so that delayed motor development and mental retardation. Stunting is a form of growth failure due to the accumulation of nutrient insufficiency from the beginning of pregnancy until 24 months old. This situation is exacerbated by inadequate catch-up growth. In Indonesia, based on Basic Health Research, there was an increase of 36.8% stunted children in 2010 to 37.2% in 2013. Over the past 20 years, handling the problem of stunting is very slow. Globally, the percentage of children who were stunted declined by only 0.6 percent per year since 1990. WHO proposed a global target reduction in the incidence of stunting in children under five years old by 40% in 2025, but it was predicted only 15-36 countries that meet those targets. The purpose of this article was to examine the incidence of stunting reduction and interventions of the policy. Focus on movement to improve nutrition to target the first 1,000 days of life, in the global order it was called Scaling Up Nutrition (SUN)

The results of the variables studied were the effect of the level of nutrient adequacy, indicating that there was an effect of zinc adequacy on the incidence of stunting. In accordance with the research study<sup>(8)</sup> democratic rights and freedom of expression have been key issues in discourses surrounding EU, Turkey

relations. Discussions on these questions often centre on state censorship and legislative constraints. The role of the media themselves, however, and the deeply-ingrained elements and historically-contingent norms and practices within public culture that shape the public sphere, have received a significantly lower level of attention. Despite recent legislative changes towards greater freedom of expression, major hurdles that limit democratic rights and freedoms persist in practice, as highlighted by the judicial trial (and the subsequent murder in January 2007) in this study, it was found that children under five who lacked zinc consumption had an odds ratio of 11.67 times for stunting compared to children under five with sufficient zinc consumption. It was also proven by the research of (9) that children who had zinc deficiency were 2.67 times at risk of stunting. Zinc interacts with important hormones involved in bone growth such as somatomedin, osteoclastin, testosterone, thyroid and insulin, besides higher zinc concentrations in bone compared to other tissues show that zinc in bone is a very important substance during the growth stage and in times child development (3)

The results showed that there was an effect on the level of calcium adequacy with stunting events similar to the study conducted by (10) is a linear growth retardation, which results from inadequate intake of food over a long period of time that may be worsened by chronic illness. Over a long period of time, inadequate nutrition or its effects could result in stunting. This paper examines the correlates of stunting among children in Ghana using data from the 2008 Ghana Demographic and Health Survey (GDHS). It was found that there was an influence between the level of calcium adequacy and the incidence of stunting. In toddlers whose calcium adequacy level has less risk of stunting 3.93 times greater than toddlers with sufficient levels of calcium sufficiency. Calcium concentrations in plasma, especially free calcium ions, are acted to transmit nerve impulses and muscle contractions, as well as catalysts for various biological reactions, such as B12 absorption, fat breakdown enzymes, pancreatic lipase, pancreatic insulin secretion, acetylcholine formation and<sup>(4)</sup> Calcium homeostasis is regulated primarily through an integrated hormonal system that controls calcium transport in the intestines, kidneys and bones. During growth, demands for bone mineralization are very high, very low calcium intake can cause hypocalcemia, despite the secretion of the maximal parathyroid gland, which can result in low bone mineralization matrix and new osteoblast dysfunction.

(11)there are 165 million children under the age of suffering from stunting. Research done showed that nationally stunting prevalence in 2013 is 37,2%. West Borneo is one of the twenty provinces with the stunting prevalence above the national average. During growth period, children need calcium especially for ossification. The lack of calcium is mainly caused by inadequate intake and or non-optimal calcium absorption. Some of previous research has showed that the level of calcium serum of children with stunting has significantly lowered than the normal children. Objective: The aim of this study was to analyse the calcium serum level of the children with stunting aged of 24-59 months in Pontianak City. Method: This study is a cross sectional design. It conducted in East Pontianak and North Pontianak subdistricts. Number of samples was 90 childrens. Statistical analysis was performed using Chi-Square, t-test, and logistic regression. Results: There was no significance in serum calcium level between stunting and non stunting children (p=0,193)

### Conclusions

Based on the results of research conducted, the family characteristics of stunting and non-stunting children are based on family income and the same level of education, namely low income and education level of elementary school mothers. Then the characteristics of stunting and non-stunting toddlers were low birth weight and the least height was in stunting toddlers. There is an influence of zinc and calcium adequacy levels on the incidence of stunting.

Suggestions given to respondents are toddlers' mothers to increase the amount of toddler food consumption so that adequate nutrition is fulfilled. In addition, Puskesmas (Center of Public Health) are advised to improve the quality of counseling by adding the theme of counseling on toddlers' nutritional needs such as the use of various types of food.

**Conflict of Interest:** All authors have no conflicts of interest to declare.

**Source of Funding:** This is an article "influence of zinc and calcium adequacy level on stunting toddler aged 24-59 months (in bulakbanteng health center, surabaya)" that was supported by self funding.

**Ethical Clearance:** The study was approved by the institutional Ethical Board of Universitas Airlangga Faculty of Public health Research Ethical Clearance Commission.

## Abstract

**Background:** Hypertensive Heart Disease (HHD) is usually followed by cardiac remodeling. Different grades of Body Mass Index (BMI) also influence the cardiac structure. Hence, we evaluate the cardiac structure of HHD patients with various BMI grades.

**Materials and Method:** This cross-sectional study involves 50 consecutive patients with HHD (hypertensive heart disease) from the Cardiology and Vascular Medicine Departement, Soetomo General Hospital Indonesia. Echocardiographic examination was done using GE vivid 7. Statistics were evaluated with SPSS 25.0.

**Results:** The research showed that the grades of BMI (body mass index) was positively correlated with LA major ( $r=0.335$ ), RA Major ( $r=0.371$ ), LVD Mass ( $r=0.341$ ), LVS Mass ( $r=0.303$ ), LVPWD ( $r=0.369$ ), LVPWS ( $r=0.391$ ), and inversely correlated with LVSI Dopp ( $r=-0.376$ ). Obese (BMI>30) patients have significantly lower ejection fraction compared to normoweight (BMI<25) patients ( $64.3\pm 3.67\%$  vs  $62.12\pm 0.98\%$ ,  $p=0.046$ ).

**Conclusions:** The grades of BMI in the HHD patient is associated with an increased volume of the left atrium and ventricle. This suggested that obese patient with HHD should be assessed carefully for atrial and ventricle enlargement.

**Keywords:** Cardiac Structure, Echocardiography, Hypertension, Obese, Remodelling

## Introduction

Hypertensive heart disease (HHD) can be manifested as asymptomatic cardiac hypertrophy to clinical heart

failure. Alteration of blood vessel and cardiac structure in the HHD was caused by the chronic elevation of the blood pressure.<sup>1</sup> This remodelling subsequently contribute to the pathophysiology of circulatory disorders in the HHD patient.<sup>2</sup> The progression of cardiac structure remodelling in the HHD patient is influenced by various factor such as type of overload, neurohormonal activation, co-existence with other diseases and genetic factors.<sup>3</sup>

Obesity rates are rising worldwide. Obesity is defined as abnormal or excessive fat accumulation that may impair health, including increased risk of cardiovascular disease and hypertension that may induce

some changes in cardiac structure and function. World Health Organizations (WHO) and National Institute of Health defines Normal weight as BMI 18.5-24.9, Overweight as BMI 25-29.9, Obesity as BMI  $\geq 30$  kg/m<sup>2</sup>, severe obesity as BMI  $\geq 40$  kg/m<sup>2</sup>, and super obesity as BMI  $\geq (50$  kg/m<sup>2</sup>).<sup>4</sup> Obesity may also induce several modifications in cardiac structure and function in the absence of other atherosclerotic risk factors, to the extent that some authors have suggested the specific form of “obesity cardiomyopathy,” which resulted in left ventricular (LV) structural and functional abnormalities.<sup>5</sup> 15 402 individuals aged 45-64, living in two towns in the west of Scotland underwent comprehensive cardiovascular screening. We analysed all deaths and hospitalizations for cardiovascular reasons occurring over the subsequent 20 years according to baseline body mass index (BMI). Obesity is well known to imply some cardiac consequences with the inducement of several modifications in cardiac structure and function, which are associated with hemodynamic volume overload. Atrial and ventricular remodeling is common in obese patients, and this pathophysiological change plays a pivotal role in atrial and ventricular dysfunction.<sup>6</sup> Hence, it is hypothesized that different grades of BMI may contribute to the cardiac remodeling progression in the HHD patient. This research investigates whether different grades of BMI status is correlated with echocardiographic findings in HHD patient.

## Materials and Method

**Research Design:** This retrospective study consisted of subject  $\geq 18$  years old with hypertensive heart disease evaluated at the Echocardiography Laboratory of the Department of Cardiology and Vascular Medicine Dr. Soetomo General Hospital, Surabaya, Indonesia between January 2018 and January 2019. Eligible patients required to have LV Ejection Fraction (EF)  $\geq 50\%$ . Normal weight, overweight, and obesity were defined according to body mass index (BMI) established criteria.<sup>4</sup> Diabetes mellitus and hypertension were defined according to current recommendations.<sup>7-8</sup>

Patients were excluded if they had a history of acute coronary syndromes, angina, or revascularization procedures or evidence of segmental wall motion abnormalities at echocardiography, or a history of heart failure. Other exclusion criteria were significant aortic or mitral valve disease, severe mitral annular calcification, hypertrophic cardiomyopathy, secondary forms of

cardiomyopathy, stroke, peripheral artery disease, and chronic kidney disease.

**Doppler Echo cardiography:** Trans thoracic two-dimensional and Doppler echo cardiographic examination was carried out by Vivid S6, Logic E9, and Vivid S60 Ultrasound instrument (General Electric) with 2nd-harmonic imaging and a 3.5-MHz transducer. Patients were examined in the left lateral decubitus position, and data were acquired in the parasternal (long- and short-axis views) and apical views (two chambers (A2C) and four chambers (A4C) and apical long-axis views). In every echo cardiographic evaluation, all parameters were derived according to current indications and considered in relation to their established reference ranges. Left ventricular volumes and EF were calculated from apical A2C and A4C views using the TEICH and Modified Simpson’s Biplane rule. LV mass was calculated and indexed according to body surface area and height. Left atrial (LA) and Right atrial (RA) size were also measured by major and minor dimension. Relative wall thickness (RWT) was derived as the ratio between 2 multiplied posterior wall diastolic thickness and end-diastolic diameter. Pulsed wave Doppler mitral velocity curves were obtained from the A4C view by positioning sample volume between the tips of the mitral valve leaflets in diastole. From mitral velocity tracings, peak early (E) and late (A) transmitral flow velocities, their ratio E/A, and E-wave deceleration time (EDT) were measured accordingly. From A4C view, tissue Doppler longitudinal velocities were recorded with the sample volume placed at the junction between LV wall (medial and lateral) and the mitral annulus. The ratio of mitral E peak velocity and averaged ratio of mitral to myocardial early velocities (E/e’) was calculated. The peak tricuspid regurgitation (TR) velocity was measured from the maximal velocity of tricuspid Doppler regurgitant jet. To derive stroke volume and cardiac output using Doppler method, continuity equation at LV outflow tract and velocity time integral were used.<sup>7,9,10</sup>

**Statistical Analyses:** Statistical analyses were performed using IBM SPSS Statistics 25.0. Data are considered significantly different if  $p < 0.05$ . Continuous variables, presented as mean  $\pm$  SD, were evaluated for normal distribution and compared using the ANOVA test, as appropriate. The correlation was evaluated with Spearman Rho analysis followed by multiple stepwise linear regression test to determine Beta Coefficient and R-square.

**Findings:**

**Demography of HHD Patients:** The echocardiographic finding was obtained from 50 HHD patients with demography as follow:

**Table 1: Characteristic of the HHD patients**

No	Description	n (%) or mean±SD
1.	Age (years)	60.34±9.83
2.	Gender

	Weigh Classification	
	a. Normoweight	24 (48%)
	b. Overweight	18 (36%)
	c. Obese	8 (16%)
6.	Systolic Blood Pressure	137.5 ± 24.35
7.	Diastolic Blood Pressure	80.0 ± 7.56

Echo cardiographic Findings from HHD Patients

**Table 2: Significant Difference in Echocardiographic Findings of HHD patients**

No	Description	BMI < 25	25 ≤ BMI<30	BMI >30
1.	LA Major	4.55±0.71 <sup>b</sup>	5.10±0.69 <sup>a</sup>	4.93±0.29
2.	RA Major	3.92±0.69 <sup>b,c</sup>	4.35±0.59 <sup>a</sup>	4.52±0.25 <sup>a</sup>
3.	Ejection Fraction	64.3±3.67	66.51±4.01 <sup>c</sup>	62.12±0.98 <sup>a,b</sup>
4.	LVD Mass	140.21±36.58 <sup>c</sup>	161.59±39.61	194.93±58.05 <sup>a</sup>
5.	LVS Mass	126.02±29.39 <sup>c</sup>	140.77±41.91	173.68±46.29 <sup>a</sup>
6.	LVSI Dopp	50.36±6.76 <sup>b</sup>	44.15±10.32 <sup>a</sup>	44.30±7.54
7.	LVPWD	1.00±0.14 <sup>c</sup>	1.11±0.21	1.29±0.35 <sup>a</sup>
8.	LVPWS	1.39±0.15 <sup>c</sup>	1.49±0.22 <sup>c</sup>	1.71±0.36 <sup>a,b</sup>

Comparison of the echocardiographic finding of normoweight (BMI<25), overweight (25 ≤ BMI<30), and obese (BMI >30) patient with HHD. Different annotation showed a significant difference (p<0.05) if compared with normoweight (a), overweight (b), obese (c).

As shown in Table 2 above, Significant difference was observed between normoweight and overweight patient in LA Major, RA Major, and LVSI Dopp (p<0.05). Comparison between normoweight and the obese patient showed a significant difference in RA Major, LVD mass, LVS mass, LVPWD,

and LWPWS (p<0.05). Comparison between overweight and obesity only showed significant difference in Ejection Fraction and LVPWS (p<0.05).

**Table 3: Correlation Between BMI with Echocardiographic Findings of HHD patients**

No	Description	Correlation	Beta Coefficient	R- Square
1.	LA Major	0.335*	0.310*	0.055
2.	RA Major	0.371*	0.359*	0.111
3.	Ejection Fraction	-		-
4.	LVD Mass	0.341*	0.393**	0.137
5.	LVS Mass	0.303*	0.362*	0.113
6.	LVSI Dopp	-0.376*	-0.313*	0.079
7.	LVPWD	0.369**	0.403**	0.145
8.	LVPWS	0.391**	0.401**	0.143

Annotation \* showed significance at p<0.05 and \*\* showed significance at p<0.01

As shown in table 3 above, Positive correlation was shown between different grades of BMI with LA Major, RA Major, LVD Mass, LVS Mass, LVPWD, and LVPWS. Inverse correlations can be observed only on LVSI.

## Discussion

Obesity induces several modifications in cardiac structure and function, which are associated with hemodynamic volume overload. Atrial and ventricular remodeling is common in obese patients, and this pathophysiological change plays a pivotal role in atrial and ventricular dysfunction.<sup>6</sup> In this research, we found that comparison between obese patients has significantly higher RA Major, LVD mass, LVS mass, LVPWD, and LVPWS. Previous longitudinal research has demonstrated that increasing BMI for 5 units from normoweight patient in the 4 years, can significantly increase the LA and LV compared to patient without increased BMI. Other cross-sectional studies also demonstrated that obesity and greater BMI are correlated with the larger LA dimensions.<sup>11</sup> Previous research also showed that patient with lower BMI (BMI <18.5) will also followed by significantly lower LVMI and smaller LV mass.<sup>12</sup> This suggested that atrial and ventricular dimension are increased in the HHD patient as BMI grades increased.

Correlation test also showed that different grades of BMI are positively correlated with LA Major, RA Major, LVD Mass, LVS Mass, LVPWD and LVPWS, suggesting that higher BMI grades will affect the volume of the left atrium, right atrium and left ventricle. Additionally it will also affect the systolic and diastolic function of left ventricle. Previous research also showed similar finding, which found a linear correlation between increased LV mass (g/m<sup>2</sup>) with BMI.<sup>13</sup> We analysed the literature in order to provide a comprehensive information on the left-ventricular structural changes, as assessed by echocardiography, associated to obesity. DESIGN: A literature search using the keywords 'left ventricle', 'left-ventricular hypertrophy', 'cardiac hypertrophy', 'obesity', 'hypertension' and 'echocardiography' was performed in order to identify relevant papers. Full articles published in English language in the past 12 years reporting studies in adult obese individuals were considered. Results: A total of 22 studies including 5486 obese individuals were considered. Overall, in the pooled obese population, prevalence of LVH, defined by 12 criteria, was 56.0% (range 20.0-85.0%). It was also

shown that increased BMI is related to both LV systolic and diastolic dysfunction.<sup>6</sup> However, another study showed that obesity might not follow by increasing the LV Mass if the obesity is followed by confounding disease, which can alter the hypertrophic progression such as myocardial infarction.<sup>14</sup> This suggested that in the patient with HHD, increasing BMI is associated with atrial and ventricular enlargement and HHD may not alter the hypertrophic progression of the heart muscle.

There are several limitations to our findings. Firstly, obesity was only measured through BMI rather than the direct measurement of central obesity, such as abdominal circumference or waist and hip circumference. While many studies have shown that central obesity measurement is more robust predictors of cardiovascular outcomes, this suggested that more detailed metrics of central adiposity will be important to be considered in future studies.

Secondly, our sample size was limited and not equally distributed between underweight, normoweight, overweight, and obese which might affect lack of significance in cardiac dimension measured through echocardiography. More samples with better distribution among the BMI grades would be beneficial for future research. Thirdly, as the data only derived from single cardiology center in urban area, the data may not be representative or generalizable to other populations

## Conclusion

BMI grades is associated with the functional and structural changes such as LA Major, RA Major, LVD Mass, LVS Mass, LVPWD and LVPWS in the heart of HHD patients.

**Conflict of Interest:** The authors declare no conflict of interest

**Source of Funding:** This research received no external funding

**Ethical Clearance:** The research was conducted in accordance with the Helsinki declaration of 1975 as revised in 2000. All participating patient has signed written informed consent. The study protocol has been approved by the local ethics committee. Data which shows patient personal information was omitted.

# Correction of the Manifestations of Attention Deficit Hyperactivity Disorder in Primary School Children

Anatoly Ivanovich Alifirov<sup>1</sup>

<sup>1</sup>*Department of Physical Education and Sport, professor, Russian State Social University, st. V. Pika 4, Moscow, Russia,*

## Abstract

**Context:** Currently, attention deficit hyperactivity disorder remains very common among children. The ongoing attempts to correct this condition, including using an integrated approach through the use of several individually selected method at once, have not yet yielded satisfactory results. In the course of the study, the correctional possibilities of the author's methodology of teaching chess for children aged 7-9 years with attention deficit hyperactivity disorder were evaluated. The technique turned out to be effective due to the integrated use of multimedia accompaniment and special techniques for switching the attention of children during classes. It is established that the author's technique helps to reduce the severity of symptoms in children with attention deficit hyperactivity disorder. Semi-annual classes provided in all cases the elimination of existing violations and the achievement in children of a balance of excitation and inhibition in the cerebral cortex during the development of a game of chess according to the author's method.

**Keywords:** *Attention deficit hyperactivity disorder, learning to play chess, children, primary school age, chess, inclusive education.*

## Introduction

Living organisms inhabiting the planet, despite the serious successes of modern science, remain heavily burdened by various pathologies<sup>1</sup>. This is equally true for wildlife, productive animals<sup>2</sup> and humans<sup>3</sup>. Despite the increased attention of science and practice of medicine to humans, significant pathological burden still remains at all ages and in all countries<sup>4</sup>. It significantly reduces the quality of life and can shorten its upcoming duration<sup>5</sup>. One of the most common pathological conditions in the children's population remains attention deficit hyperactivity disorder. The frequency of this syndrome

in children reaches 18%. Its main symptoms are impaired attention and impulsiveness due to a lack of control over behavior. In the absence of adequate treatment, attention deficit hyperactivity disorder subsequently leads to a violation of social and emotional development and often to associative behavior<sup>6</sup>.

Modern science is actively seeking approaches to the correction of attention deficit hyperactivity disorder. To achieve a good effect in such children, it is customary to use an integrated approach to correction through the use of several individually selected method at once<sup>7</sup>.

In mild cases of attention deficit hyperactivity disorder, children seek to develop creative abilities in order to correct them. To this end, children with this syndrome often use chess training programs adapted to their capabilities<sup>8</sup>. This program allows you to adjust the condition of such children by providing them with information in small, logically completed blocks (10-15 minutes each). Pauses between them are filled with physical activity, often in the form of outdoor games using chess attributes<sup>9</sup>. However, the development

of such programs for children with attention deficit hyperactivity disorder is not complete and there is a need to increase their effectiveness, which requires further research.

The purpose of the study is to assess the dynamics of the state of children with attention deficit disorder and hyperactivity using the author's methodology of teaching the game of chess.

### Material and Research Method

The conduction of the research was approved by the local Ethics Committee of the Russian State Social University in May, 15<sup>th</sup>, 2018 (Record №7).

The study was conducted in 2017-2018 on the basis of a chess school named after A.E. Karpov Gymnasium №16 of the city of Mytishchi, Moscow Region, Russia. The study involved 16 boys of 7-9 years old with a diagnosis of attention deficit hyperactivity disorder.

All examined for the purpose of correcting attention deficit hyperactivity disorder underwent six months of training in the basics of the game of chess according to the author's methodology. Its application was aimed at the development of basic mental characteristics: attention, memory, thinking; imagination, creativity, perseverance, determination and independence in decision making.

Classes were held twice a week for an hour in groups of 6 people. These groups were formed by age, taking into account the psychological characteristics of each child. Within an hour of being in a group, each child was immersed in a developing learning environment with the help of individually adapted for the whole group of developing techniques of playing chess. This ensured

the achievement of the maximum, long-lasting positive trace in the emotional sphere of children.

At the beginning of each lesson, with the help of an author's audio recording of chess in the form of a song in combination with a video collage (vivid entertaining chess pictures and photographs), children's attention was switched to chess lessons. As a result, the children reflexively developed an attitude toward the training process. During the lesson, techniques were used that smoothly switched the attention of children from one type of activity to another.

The dynamics of the condition of children was evaluated using a number of method. Emotional stability with the determination of the integral indicator of a vegetative response was recorded by the method of Suvorova V.V.<sup>10</sup>. Identification of the degree of anxiety was carried out on a scale of situational and personal anxiety Spilberger-Khanin<sup>11</sup>. Express diagnostics of the properties of the nervous system by psychomotor indices was determined by the method of the tapping test of E. P. Ilyin<sup>12</sup>. Assessment of volitional self-control was carried out according to the method of A.G. Zverkova, E.V. Eidman<sup>13</sup>. The degree of social normalization and organization was revealed according to the method of Kettel's multifactorial personality questionnaire (16-PF)<sup>14</sup>. The mathematical processing of the results with the calculation of the student criterion is applied.

### Research Results and Discussion

The results of the study of the considered characteristics of those examined with attention deficit hyperactivity disorder during their learning to play chess are presented in table 1.

**Table 1: Dynamics of personality parameters of children with attention deficit hyperactivity disorder during learning to play chess**

№	Registered indicators	Initial data	Level	At the end of observation	Level
1	Emotional stability, points	3.02±0.64	Low	3.62±0.46*	Average
2	The degree of anxiety, points	3.55±0.50	Average	3.12±0.42*	Low
3	The presence of internal tension, points	3.28±0.39	Average	2.88±0.35*	Low
4	The level of social self-control, points	1.91±0.43	Low	3.52±0.38**	Average
5	The degree of social organization, points	2.66±0.27	Low	3.94±0.31**	Average

**Legend:** reliability of dynamics during observation \* – p<0.05, \*\* – p<0.01.

When taken under observation in children with attention deficit hyperactivity disorder, low emotional stability, an average degree of anxiety, and an average severity of internal tension were noted. This was accompanied in their initial state by a low level of social self-control and a low degree of social organization.

As a result of learning to play chess, children with attention deficit hyperactivity disorder have shown significant progress in mastering chess and the school curriculum. Regular classes in the game of chess ensured six months later in children with attention deficit hyperactivity disorder positive changes in all the parameters taken into account. All examined persons managed to increase emotional stability by 19.9%, taking it to an average level. Moreover, they experienced a decrease in the degree of anxiety from medium to low (by 13.8%). This was accompanied by a decrease of 13.9% in the degree of internal tension, which ensured its exit to a low level. Regular playing the game of chess according to the author's method also ensured that the children observed had an increase to the average level of their social self-control (increase by 84.3%) and the degree of their social organization (increase by 48.1%).

Children with manifestations of attention deficit hyperactivity disorder are always at a low level of self-control, there is low productivity of cognitive processes and their high overall emotionality. They almost never have the presence of life strategies focused on solving existing problems, and almost always there is a tendency to avoid problems and social indifference<sup>15</sup>.

In many countries of the world, psychostimulants are most widely used in the treatment of attention deficit hyperactivity disorder. The effect of these psychostimulating agents is based on an increase in the content of dopamine and norepinephrine. Despite the large number of studies on the use of these psychostimulants in the treatment of attention deficit hyperactivity disorder, this issue is still accompanied by discussions about the likelihood of side effects<sup>16</sup>.

In Russia, nootropic drugs have traditionally been used to treat attention deficit hyperactivity disorder. In the presence of attention deficit hyperactivity disorder accompanying the disorder, tics, tranquilizers are allowed<sup>17</sup>.

The generally accepted position is that the treatment of attention deficit hyperactivity disorder should be comprehensive, that is, include both drug therapy and

psychotherapeutic method. The leading link in the psychocorrection of children with attention deficit hyperactivity disorder is often considered changes in the behavior of adults - parents and teachers, with the replacement of non-adaptive approaches to their children with adaptive ones<sup>15,17</sup>.

Behavioral psychotherapy method are often used to change children's behavior. Its basis is a reward for the required behavior and punishment for the wrong<sup>14</sup>.

The author has developed a methodology for treating children with attention deficit hyperactivity disorder by teaching chess.

The mechanism of teaching a game of chess is the directed activation of nonspecific activating systems of the brain and the intensification of the processes of morphofunctional development of immature elements of the cortex due to the normalization of neurodynamics. Apparently, this leads to a decrease in the degree of functional immaturity of the brain<sup>18</sup>. Such treatment allows, in the practical absence of undesirable side effects, to directionally change the functional state of the brain. The achieved results can also be regarded as a consequence of the stimulating and at the same time balancing effect of the game of chess on the author's technique on the brain. Apparently, the upcoming effect is also associated with stimulation of energy exchange in the cerebral cortex and in the subcortical nuclei<sup>19</sup>, as well as with balancing the number of inhibitory and activating mediators formed and synaptically ejected in all zones of the cortex<sup>20</sup>.

Apparently, the basis of the obtained results is such an important factor as the universal ability to morphofunctional plasticity inherent in the cerebral cortex. Many facts indicate a high plasticity of sensory functions, their ability to change their functional characteristics under the influence of training and exercises. By themselves, these facts indicate the presence of a deep interdependence between the two main mechanisms of higher nervous activity: analyzers and temporary connections. The facts of the exercise of sensory functions indicate that the development of conditioned reflexes from the analyzer increases its efficiency, makes the brain more adapted to various conditions of the physical and social environment<sup>16, 18</sup>.

Hemispheric connections between different areas of the brain, which begin to work actively during the learning of a game of chess, are even more plastic than

the intrahemispheric ones. Unlike the former, they are more inherent in individual characteristics, which are very closely related not only to cognitive abilities, but also to the nature of the activity performed. As a training effect on the brain, chess is considered the most physiological, “soft” and effective<sup>21</sup>.

The increase in the adaptive capabilities of the cortex of the children observed in the study was manifested in an increase in their academic performance at school and in their receipt of sports categories in chess.

As an illustration of the effectiveness of the author’s methodology used in the study, examples of the dynamics of the considered indicators in children with attention deficit hyperactivity disorder are given.

1. Denis P. began studying chess in the author’s technique at the age of 7. At the time of the start of classes, the child was diagnosed with attention deficit hyperactivity disorder. Initially, the child had low emotional stability (2.8 points), average anxiety (3.4 points), average internal stress (3.1 points) with low levels of social self-control (1.8 points) and social organization (2.5 point). After six months of training according to the author’s method, the child’s emotional stability (3.5 points), the degree of social self-control (3.3 points) and the severity of social organization (3.8 points) increased to an average level while lowering to a low level of anxiety (3, 0 points) and internal tension (2.9 points). In the qualification tournament, after six months of classes, the child fulfilled the norm of the 3rd youth category in chess.
2. Egor Y. 8 years old, diagnosed with attention deficit hyperactivity disorder. Initially, he had low emotional stability (2.7 points), average anxiety (3.5 points), average internal stress (3.2 points) with low levels of social self-control (1.7 points) and social organization (2.3 points). After six months of training according to the author’s method, the child showed an increase to an average level of emotional stability (3.6 points), the degree of social self-control (3.4 points) and the severity of social organization (3.9 points) while lowering to a low level of anxiety (2.9 points) and internal tension (2.8 points). In the qualification tournament, the child fulfilled the norm of the 2nd youth category in chess after six months of classes.
3. Dmitry P. 9 years old, diagnosed with attention

deficit hyperactivity disorder. Initially, he had low emotional stability (2.6 points), average anxiety (3.6 points), average internal stress (3.0 points) with low levels of social self-control (1.9 points) and social organization (2.4 points). After six months of training according to the author’s method, the child’s emotional stability (3.7 points), the degree of social self-control (3.5 points) and the severity of social organization (4.0 points) increased to an average level while lowering to a low level of anxiety (3.0 points) and internal tension (2.7 points). In qualifying tournaments, the child fulfilled the norm of the 1st junior category in chess after six months of classes.

## Conclusion

In the course of the study, the correctional possibilities of the author’s methodology of teaching chess for children aged 7–9 years with attention deficit hyperactivity disorder were evaluated. The methodology turned out to be effective due to the integrated use of multimedia accompaniment and special techniques for switching the attention of the child during classes. It has been established that the author’s technique helps to reduce the severity of symptoms of attention deficit hyperactivity disorder in children. Semi-annual classes provided in all cases the elimination of the manifestations of the syndrome that the children had and the achievement of a balance of excitation and inhibition in the cerebral cortex during the development of the game of chess according to the author’s technique.

**Conflict of Interest:** No conflict of interest is declared.

**Sources of Financing:** The study was conducted at the expense of the authors.

**Ethics Committee Resolution:** The study was approved by the local ethics committee of the Russian State Social University on May, 15<sup>th</sup>, 2018 (Record №7).

## Abstract

**Context:** In the modern world, chronic bronchitis is one of the most common diseases in childhood and adolescence that can stably degrade their quality of life. In this regard, an additional examination of patients in this category was carried out. The purpose of the work is to assess violations of the functional state of the external respiration system in adolescents suffering from chronic obstructive bronchitis. The study involved 42 adolescents 13-14 years old, suffering from at least 5 years of chronic obstructive bronchitis of moderate severity with no signs of respiratory failure. At the time of the examination, the disease was among the examined adolescents in a state of unstable remission. For adolescents with chronic obstructive bronchitis, a decrease in the vital capacity of the lungs and diameter of the bronchi of any caliber is characteristic. This inevitably leads them to a marked decrease in the functional capabilities of the external respiration apparatus. It became clear that early enough with this disease, the respiratory center becomes resistant to hypoxia and weakens the adaptive capabilities of the entire external respiration system. All identified violations lead in adolescents with chronic obstructive bronchitis to an increase in the functional weakness of their respiratory system and circulatory system, and, therefore, form a low resistance to hypoxia even at a young age.

**Keywords:** Respiratory system, bronchi, lungs, obstruction, chronic bronchitis, adolescents.

## Introduction

Ontogenesis of any organism implies its continuous interaction with the environment, which does not always positively affect<sup>1,2</sup>. All external influences on the

organism sometimes cause a whole series of genetically determined reactions in it<sup>3,4</sup>, aimed at adapting to the current conditions of existence<sup>5,6</sup>. Due to the severity of harmful environmental influences and the frequent imperfection of adaptation mechanisms and responses, various dysfunctions and sometimes pathological processes can occur in the body<sup>7,8</sup>.

---

### Corresponding Author:

e-mail: ilmedv1@yandex.ru

Often affected by the pathology in the human body are the cardiovascular system, the blood system and the respiratory system<sup>9</sup>. Being life support systems, they significantly support the overall viability of the mammalian organism<sup>10, 11</sup>. Moreover, in recent years there has been a clear increase in the number of various lung diseases, especially at a young and young age<sup>12,13</sup>.

Chronic obstructive bronchitis is currently one of the most common diseases in childhood and adolescence, capable of consistently worsening the quality of life of patients and their families, and in severe cases of pathology leading to disability. It is well established that chronic obstructive bronchitis is a chronic disease of predominantly inflammatory etiology. This disease always leads to changes in the sensitivity of the walls of the bronchi and the development of airway hyperresponsiveness<sup>14,15</sup>.

Despite the fairly widespread prevalence of chronic obstructive bronchitis in adolescents, the features of disorders in their external respiration system need to be clarified. For this reason, it was necessary to conduct additional examinations of patients in this category.

The purpose of the study was to assess impaired functional state of the external respiration system in adolescents suffering from chronic obstructive bronchitis.

### **Materials and Research Method**

The study was approved by the local ethics committee of the Russian State Social University on September 15, 2017 (protocol №11). The study was conducted on the basis of the Moscow City Children's Clinic №38 and the Russian State Social University in Moscow, Russia. The study involved 42 adolescents 13-14 years old, suffering from at least 5 years of chronic obstructive bronchitis of moderate severity with no signs of respiratory failure. At the time of the examination, the disease was in all teenagers in a state of unstable remission. The control group consisted of 20 adolescents of a similar age, clinically completely healthy.

The work was performed on the SMP-21/01- "R-D" spiograph produced by the Monitor scientific-production enterprise (Russia). A number of indicators were estimated from the spiogram: minute respiratory volume, lung vital capacity, maximum lung ventilation, inspiratory reserve volume, expiratory reserve volume, forced expiratory lung capacity, forced expiratory volume in 1 second, peak volumetric rate, maximum volumetric rate of 25%, 50% and 75% of the forced vital capacity of the lungs.

All adolescents underwent a functional test of Stange by determining the maximum possible time for holding the breath after a deep breath<sup>16</sup>.

All included in the study underwent a functional test of Genchi, determining the maximum possible time for breath holding on exhalation. After 3-5 minutes of rest in a sitting position, the examinees were offered to exhale and inhale completely, then exhale again and hold their breath<sup>16</sup>.

For a comprehensive assessment of the functional state of the cardiorespiratory system in the examined, the Skibinsky index was calculated. This indicator characterizes the overall functional state of the external respiration system and its resistance to hypoxia. The calculation of the Skibinsky index was carried out in the following way: vital lung capacity/100 × Stange test, s/heart rate. The results obtained during the calculation were evaluated on the following scale: less than 5 - very poor; 5-10 - unsatisfactory; 10-30 - satisfactory; 30-60 - good; 60 or more is very good.

The value of the chest excursion was measured using a centimeter tape, which was applied posteriorly at the level of the angles of the shoulder blades, and in front, above the mammary glands (in girls), then the difference between the maximum inspiration and expiration was calculated<sup>16</sup>.

The results were processed using mathematical statistics method using statistical packages of Microsoft Excel. The statistical processing performed included the calculation of the arithmetic mean value (M) and the error of the arithmetic mean value (m). To identify the statistical difference between the indicators in the group of patients and in the control group, t-student criterion was used.

### **Research Results and Discussion**

In adolescents suffering from chronic obstructive bronchitis, a significant violation of the indices of the function of external respiration was noted (Table 1).

**Table 1: Indicators of external respiration function in adolescents with obstructive bronchitis**

Estimated performance	Group of sick teenagers, n=42, M±m	Control group, n=20, M±m
Vital lung capacity, l	1.9±0.11	2.4±0.12 p<0.05
Forced vital capacity, l	1.7±0.09	2.3±0.17 p<0.01
Forced expiratory volume in 1 second, l	1.6±0.12	2.2±0.15 p<0.01
Minute breathing volume, l/min	12.3±0.43	10.1±0.45 p<0.05
Maximum ventilation, l / min	47.7±0.36	57.9±0.82 p<0.05
Peak space velocity, l/s	2.7±0.25	4.2±0.32 p<0.01
Maximum space velocity <sub>25</sub> , l/s	3.2±0.24	4.3±0.27 p<0.05
Maximum space velocity <sub>50</sub> , l/s	2.4±0.22	3.0±0.20 p<0.05
Maximum space velocity <sub>75</sub> , l/s	1.6±0.10	1.8±0.16 p<0.05
Stange Result, s	41.8±0.41	61.2±0.48 p<0.01
Gencha test result, s	24.9±0.52	32.6±0.42 p<0.05
Chest excursion, sm	2.8±0.36	5.8±0.39 p<0.01
Skibinsky index, conventional units	28.5±0.72	61.3±0.71 p<0.01

**Legend:** p-significance of differences in indicators between patients and the control group.

Values of lung capacity in adolescents with chronic obstructive bronchitis were lower than the control group by 26.3%. The value of the forced vital capacity of the lungs was 35.3% lower than the control level. Moreover, in terms of forced expiratory volume for 1 second, the control group exceeded the same indicator in sick adolescents by 37.5%.

By comparing the indicators of minute volume of breathing, it was possible to establish its increase in adolescents with chronic obstructive bronchitis compared with the control group by 21.8%. In addition, in the group of patients, the maximum ventilation rate was reduced by 21.4%.

In the group of adolescents with chronic obstructive bronchitis, the peak volumetric rate was reduced by 55.5%. This was accompanied by a decrease of 34.4% in the average value of the maximum volumetric rate indicator at the level of 25% of the value of the forced vital capacity of the lungs. Their maximum volumetric rate, which is at the level of 50% and 75% of the value of the forced vital capacity, was reduced by 25.0% and 12.5%, respectively. In addition, in adolescents with chronic obstructive bronchitis, the indicators of hypoxic tests and the level of chest excursion were significantly lower than those in the control group. Moreover, the average Skibinsky index in sick adolescents was significantly lower than in the control group (2.1 times).

## Discussion

Now, chronic obstructive bronchitis in adolescents is a very common pathology. Often, it manifests itself already in childhood and progresses rapidly, sometimes leading to disability in young and adulthood<sup>17, 18</sup>.

It is known that the development of the pathological process in the respiratory system at any age has a very negative effect on the parameters of external respiration. Even in adolescence with chronic obstructive bronchitis, significant violations of the external respiration function are noted. It was shown in the work that this contingent of patients is characterized by a significant decrease in lung vital capacity<sup>19,20</sup>. In addition, their average indicator of forced vital capacity of the lungs is also significantly inferior to the level of control. Their growing bronchial obstruction inevitably leads to a decrease in the volume of forced expiration in 1 second. This was confirmed in the study. The authors revealed a decrease in maximum ventilation in adolescents with chronic obstructive bronchitis<sup>21,22</sup>. These changes should be considered as evidence of the low functionality of the external respiration apparatus in adolescents suffering from chronic obstructive bronchitis, as well as their weakening ability to mobilize respiratory function reserves<sup>23,24,25</sup>.

A comparison of the indices of minute respiratory volume in both observation groups showed its increase in adolescents with chronic obstructive bronchitis<sup>26,27</sup>.

Moreover, the found decrease in peak volume velocity in the group with chronic obstructive bronchitis proved that they had low functional capabilities of the respiratory muscles and reduced patency of the large-caliber bronchi. The reduced values of the maximum volumetric rate index found at 25% of the level of forced vital capacity of the lungs revealed in the work confirmed the development of progressive worsening of patency at the level of large bronchi in adolescents with chronic obstructive bronchitis<sup>28,29</sup>. The found decrease in chronic obstructive bronchitis of the average values of the maximum volumetric rate indicator at the level of 50% and 75% of the forced vital capacity of the lungs also proved in sick teenagers a decrease in the patency of their bronchi of medium and small caliber. Negative changes in their indices of hypoxic tests and a decrease in the volume of chest excursion proved the possibility of developing, in this pathology, a pronounced resistance of the respiratory center to hypoxia and weakening the adaptive capabilities of the entire external respiration system<sup>30,31</sup>. The decrease in the Skibinsky index found in the observation group should be regarded as a manifestation against the background of chronic obstructive bronchitis of functional weakness of the respiratory and circulatory organs, and, consequently, low resistance of their body to any hypoxic conditions<sup>32</sup>.

### Conclusion

In the modern world, chronic obstructive bronchitis remains one of the most common diseases of the respiratory system. The presence of this pathology changes in the sensitivity of the walls of the bronchi to external influences and the development of their hyperreactivity creates the basis for dysfunction of external respiration. These disorders occur already in adolescence and are sometimes manifested by significant violations of the function of external respiration. Such patients are characterized by a decrease in vital capacity of the lungs and diameter of the bronchi of any caliber. This leads already in adolescents suffering from chronic obstructive bronchitis to a marked decrease in the functional capabilities of the external respiration apparatus, as well as to a weakening ability to mobilize the reserves of the respiratory apparatus. Quite early in this disease, resistance of the respiratory center to hypoxia and a weakening of the adaptive capabilities of the entire external respiration system arise.

**Conflict of Interest:** No conflict of interest is declared.

## Abstract

**Context:** An in-depth understanding of the “neurotic syndrome” phenomenon. The specificity of the neurotic syndrome of employees of organizations with professional deformities has been determined. The main symptoms of the average level of neuroticism of employees with professional deformities are: asthenia, anxiety, obsession, tension, sleep disorders, psychasthenic disorders, tendency to neurotic depression, somatic disorders, fears, anxiety, difficulties in social contacts. The links between the general level of neuroticism and psychosomatic symptoms (asthenia, sleep disorders, somatic disorders, psychasthenic disorders), social symptoms (difficulties in social contacts), emotional symptoms (anxiety and tension, anxiety, obsession, neurotic depression, fears and phobias) have been revealed.

**Keywords:** *Neurosis, neurotic states, neurotic syndrome, neuroticism, professional deformities.*

## Introduction

The functioning of the organism is clearly determined by its genetic program<sup>1,2</sup> and environmental factors<sup>3,4</sup>, which can either increase its resistance<sup>5</sup> or cause various dysfunctions<sup>6,7</sup>. Prolonged exposure to adverse environmental factors almost always leads to the development of persistent disorders in various systems

of the body<sup>8,9</sup>. A very unfavorable result of negative environmental impacts is dysregulation in the central mechanisms supporting homeostasis<sup>10,11</sup>.

Professional deformations are changes in the personality structure of workers that occur during prolonged work experience and a tense production situation that adversely affect the professional activities and personal lives of specialists<sup>12,13,14</sup>.

**The main prerequisites for neurotic and professional deformations are:**

1. at the intellectual level (impulsive thinking, impaired judgment, indecision, increased distractibility, constant negative thoughts, loss of initiative, deterioration of concentration)<sup>15</sup>,

---

2. at the motivational level (inconsistency of direction, the struggle of motives, the presence of intrapersonal conflict)<sup>16</sup>,
3. at the behavioral level (antisocial behavior, more intense smoking and alcohol consumption, finishing work at home, voice tremor, conservatism, speech disorder, neglect, low productivity, poor adaptability, poor distribution of time, loss of appetite or overeating, stubbornness)<sup>17</sup>,
4. at the physiological (psychosomatic) level (headaches, complaints of pain in the joints, itching, infections, skin rashes, indigestion, rapid and arrhythmic heartbeats, feeling of a lump in the throat, feeling of lack of air during inhalation)
5. on an emotional level (anxiety, depression, exhaustion, gloomy mood, job dissatisfaction, suspicion, irritability, reduced self-esteem, fussiness, decrease in life satisfaction, cynical and inappropriate humor, a feeling of estrangement)<sup>18</sup>.

The purpose of the study is to examine the specifics of the neurotic syndrome of employees of organizations with professional deformities.

### Materials and Method

The study involved 368 employees of organizations that have identified a level above the average and a high level of professional deformation (emotional and/or physical exhaustion, depersonalization, reduction of personal achievements).

#### Procedures for Diagnosing Professional Deformities:

1. "Maslach burnout inventory (MBI)", authors – C. Maslach & S. Jackson<sup>19</sup>; The author of an adapted version of the questionnaire - N.E. Vodopyanova<sup>20,21</sup>;
2. modification of the Burnout Inventory (Maslach burnout inventory (MBI)), authors — C. Maslach & S. Jackson<sup>22</sup>; the authors of the questionnaire modification - teachers of the Department of Psychology of Professional Activity of St. Petersburg State University<sup>23</sup>; the author of the interpretation of the results - OB Polyakova<sup>21,22</sup>;
3. the questionnaire "Definition of mental burnout", author - B.A. Farber<sup>24</sup>; Author of the adapted version - A.A. Rukavishnikov<sup>25</sup>.

#### Procedures for the Diagnosis of Neurotic Syndrome:

1. Do you have a neurosis? (authors: K. Heck and X. Hess; the goal is to carry out a preliminary rapid diagnosis of the presence or absence of neurosis in humans)<sup>26</sup>; (interpretation of results: 0-8 - low level (there is no neurosis), 9-16 - level below average (possible presence of neurosis), 17-24 - average level of neurosis, 25-32 - level of neurosis above average, 33-40 - high neurosis level);
2. Clinical questionnaire for identifying and assessing neurotic states<sup>27</sup>.
3. Symptomatic questionnaire (author - E. Aleksandrovich; the goal is to conduct a quantitative determination of the severity of the neurotic syndrome)<sup>28,29</sup>; (interpretation of results: scale "Fear, phobias": 0-18 points - low level, 19-38 points - level below average, 39-58 points - average level, 59-78 points - level above average, 79-98 points - high level; scale "Depressive disorders": 0-9 points - low level, 10-19 points - level below average, 20-29 points - average level, 30-39 points - level above average, 40-49 points - high level; scale "Anxiety, tension": 0-14 points - low level, 15-28 points - level below average, 29-42 points - average level, 43-56 points - level higher than average, 57-70 points - high level; scale "Sleep disturbance": 0-7 points - low level, 8-14 points - level below average, 15-21 points - average level, 22-28 points - level above average, 29-35 points - high level; scale "Hysterical disorders": 0-9 points - low level, 10-19 points - level below average, 20-29 points - average level, 30-39 points - level above average, 40-49 points - high level; scale "Neurasthenic disorders": 0-10 points - low level, 11-22 points - level below average, 23-33 points - average level, 34-45 points - level above average, 46-56 points - high level; "Sexual Disorders" scale: 0-9 points - low level, 10-19 points - level below average, 20-29 points - average level, 30-39 points - level above average, 40-49 points - high level; "Realization" scale: 0-10 points - low level, 11-22 points - level below average, 23-33 points - average level, 34-45 points - level above average, 46-56 points - high level; "Obsession" scale: 0-10 points - low level, 11-22 points - level below average, 23-33 points - average level, 34-45 points - level above average,

46-56 points - high level; scale "Difficulties in social contacts": 0-7 points - low level, 8-14 points - level below average, 15-21 points - average level, 22-28 points - level above average, 29-35 points - high level; scale "Hypochondriacal disorders": 0-8 points - low level, 9-16 points - level below average, 17-25 points - average level, 26-33 points - level above average, 34-42 points - high level; "Psychasthenic disorders" scale: 0-9 points - low level, 10-19 points - level below average, 20-29 points - medium level, 30-39 points - level above average, 40-49 points - high level.

To identify the statistical difference between the indicators in the group of patients and in the control group, t-student criterion was used.

### Results and Discussion

The results of the identification of symptoms of neurosis showed that the majority of employees of organizations with professional deformities (79%) determined the level above the average (the existing signs of neurotization complicate production and personal contacts and negatively affect the results of professional activity)<sup>30</sup>.

The results of the assessment of neurotic states showed that the majority of employees of organizations with professional deformities (60%) showed a level above average (there are signs of such neurotic states as: the presence of asthenia and the hysterical type of response, increased anxiety, manifestations of autonomic and obsessive-phobic disorders, a tendency to neurotic depression):

1. on a scale of anxiety, a high level dominates (48%), anxiety is constantly present in the lives and activities of employees with professional deformations;
2. on the scale of neurotic depression, a level above average was found (79%), there are symptoms of asthenia, depressed mood, sleep disorders, anxiety);
3. on the scale of asthenia, a high level (46%) is determined, at which fatigue and asthenic conditions are observed and experienced;
4. on the scale of hysterical type of response, the majority of employees with professional deformations (51%) found a level above the average (moderate hysterical manifestations become the category of hysterical type of response);

5. on the scale of obsessive-phobic disorders, the average level dominates (69%), which is characterized by manifestation of fears and obsessions, as well as vegetative and somatic disorders;
6. on the scale of vegetative disturbances, the level was found above the average (37%), there are dizziness, cough, digestive disorders).

**The results of determining the symptoms of neurotic syndrome showed that the average level (63%) with a brief experience of anxiety, tension and fears, periodic sleep disorders, unpleasant thoughts, ideas, memories, doubts, difficulties in social contacts:**

1. on the scale of fears and phobias, the average level (56%) is determined, at which fears and phobias periodically arise;
2. on the scale of depressive disorders, the majority of employees with professional deformities (55%) found a level below average, which is characterized by insomnia, loss of interest and pleasure from activity, prerequisites of depression, low mood);
3. on the scale of anxiety and tension, the average level dominates (64%) with frequent manifestations of anxiety and tension;
4. on a scale of sleep disturbance, the level was above average (68%), negative dreams, intermittent sleep, and difficulty falling asleep were observed;
5. on the scale of hysterical disorders, the level is determined below the average (51%), they show little effect, but the manipulative behavior, emotional feelings, emotional instability are alarming;
6. on the scale of neurasthenic disorders, the majority of employees with professional deformities found a level below the average (60%), moderate severity of impotence, hypersensitivity, irritability, mental exhaustion are observed;
7. on the scale of sexual dysfunction, the level below average dominates (48%), there are practically no complaints of sexual dysfunction;
8. on the scale of derealization, the average level was revealed (64%), which negatively affects the personal life more than the professional one;
9. on the scale of obsession, the average level is determined (54%), there are obsessive thoughts and actions;

10. on the scale of difficulties in social contacts, an average level was found (53%), there are conflicts, difficulties in communicating with other people, lack of communication, difficulties in achieving agreement, a feeling of loneliness<sup>31,32</sup>;
11. on the scale of hypochondriacal disorders, the level below average dominates (83%), there is almost no concern for one's health;
12. on the scale of psychasthenic disorders, an average level was revealed (75%), sometimes difficulties in decision-making, reduced mental energy, doubts are manifested;
13. on the scale of somatic disorders, the average level (80%) was determined, complaints about violations of the cardiovascular, respiratory system and gastrointestinal tract were voiced<sup>33</sup>.

The results of the study across the entire diagnostic unit showed that 67% of employees of organizations with professional deformities revealed an average level of the neurotic syndrome, which is characterized by neuroticism, anxiety, tension, fears, sleep disorders, obsessions, difficulties in social contacts, anxiety, asthenia, a tendency to neurotic depression, psychasthenic and somatic disorders.

### Conclusion

According to a study of the specificity of the neurotic syndrome, employees of organizations with professional deformations carried out a mathematical processing of the results using the Spearman's rank correlation coefficient ("SPSS Statistics" ("Statistical Package for the Social Sciences"), available on the IBM International Business Machines website) ("<https://www.ibm.com/ru-ru/?ar=1>"), access code: <https://www.ibm.com/ru-ru/products/spss-statistics>):

1. there is a significant relationship between the general level of neuroticism and asthenia (0.745 \*\*), anxiety and tension (0.984 \*\*), sleep disturbance (0.815 \*\*), somatic disorders (0.717 \*\*), anxiety (0.739 \*\*), difficulties in social contacts (0.836 \*\*);
2. here is a moderate connection between the general level of neuroticism and obsession (0.533 \*\*), neurotic depression (0.530 \*\*), psychasthenic disorders (0.605 \*\*), fears and phobias (0.548 \*\*).

Note: \*\* -  $p < 0.05$  ( $r = 0.27$ ).

For the purpose of psychological prevention and

psychological correction, it is necessary to use active forms of work (exercises and games: "Draw your own fear", "Compliments", "Technique to get out of apathy", "But", "Anxious sculpture"), continue diagnosis using the method "Diagnosis of anxiety and depression", "Diagnosis of the level of neuroticism", "Questionnaire for determining the level of neurotization and psychopathization".

**Conflict of Interest:** No conflict of interest is declared.

**Sources of Financing:** The study was conducted at the expense of the authors.

**Ethics Committee Resolution:** The study was approved by the local ethics committee of the Russian State Social University on September 15, 2018 (protocol №11).

## Abstract

**Context:** The rheological parameters of red blood cells largely determine the processes of microcirculation and metabolism in all tissues. Assessing their characteristics in people with low physical activity, who began to regularly experience moderate physical activity, can help to more fully reveal the mechanisms for optimizing the micro-rheological properties of red blood cells. The observation group consisted of 45 men of the second adulthood, who began regular classes in the athletics section 3 times a week, who previously had low physical activity. The control group consisted of 42 men of the same age who regularly visited the athletics section 3 times a week for at least 10 years. Biochemical, hematological and statistical research method were applied. For 6 months of physical training, people who previously had low physical activity noted the elimination of the imbalance of arachidonic acid metabolites, lowering cholesterol and acyl hydroperoxides with an increase in their total phospholipids. After 6 months, these individuals showed an increase in red blood cells-discocytes by 8.2% with a decrease in the number of reversibly and irreversibly altered forms of red blood cells by 18.5% and 2.1 times, respectively. It is clear that for people of the second adulthood, who began regular physical activity after a long period of low physical activity, a gradual improvement in the cytoarchitectonic properties of red blood cells is characteristic, which improved their microcirculation processes and activated metabolism.

**Keywords:** *Second adulthood, prolonged low physical activity, red blood cells, surface properties of the membrane, athletics loads.*

## Introduction

Low physical activity is very common in modern people<sup>1,2</sup>. It causes the implementation of many variants

of a hereditary predisposition to pathology<sup>3,4</sup>, which was traced in various categories of the population of industrialized countries<sup>5,6</sup>. The consequences of low physical activity in humans manifest themselves at a young age, increasing the frequency of episodes of temporary disability due to weakening of the functional reserves of the whole organism and the gradual development of pre-pathological and pathological conditions<sup>7,8</sup>. With age, low physical activity leads to a worsening of many diseases and their chronic course<sup>9,10</sup>.

It is noted that low physical activity adversely

affects many blood counts<sup>11</sup>. This is due to the fact that this condition causes the development of a number of functionally unfavorable changes in the body<sup>12,13</sup>. Low physical activity at a young age is accompanied by micro-rheological dysfunctions of some blood cells, which contributes to the onset of hypoxia in the tissues<sup>14</sup>. The chronic lack of oxygen arising under these conditions disrupts the course of anabolic processes throughout the body<sup>15</sup>. This situation creates the basis for the development of pathology in the internal organs<sup>16</sup> and contributes to the emergence of persistent vasospasm<sup>17</sup>. It was observed that against the background of low physical activity, conditions can often be created for increasing blood pressure, leading to the gradual development of arterial hypertension<sup>18</sup>. In addition, under these conditions, the rheological properties of the largest population of blood cells, erythrocytes, may worsen, which manifests itself already in young and first adulthood, aggravating the existing pathology and contributing to the formation of resistance to ongoing drug therapy<sup>19,20</sup>. The goal of the work is to assess the dynamics of the micro-rheological properties of red blood cells in people of the second adulthood with low physical activity and who started regular running exercises.

### Material and Method

The study was approved by the local ethics committee of the South-West State University of Kursk (Russia) on May 14, 2014 (protocol №7). All subjects examined gave written informed consent to participate in the study.

The observation group consisted of 45 men of the first adulthood (average age  $44.9 \pm 2.2$  years) who had not previously experienced regular physical exertion during their lives. All of them started regular running exercises 3 times a week for at least 1 hour. The control group consisted of 42 healthy men of the second adulthood (average age  $42.8 \pm 2.6$  years) who regularly trained for at least 10 years in the athletics section 3 times a week with a duration of at least 1 hour.

In the blood plasma of the examined patients, the content of the thromboxane A<sub>2</sub> metabolite - thromboxane B<sub>2</sub> and the prostacyclin metabolite - 6-keto-prostaglandin F<sub>1 $\alpha$</sub>  was determined by enzyme-linked immunosorbent assay using kits from Enzo Life science (USA).

After washing and resuspension in erythrocytes, cholesterol levels were quantified by enzymatic

colorimetric method using a set of Vital Diagnosticum (Russia) and total phospholipids by the amount of phosphorus contained in them<sup>21</sup>. The severity of the processes of intraerythrocytic lipid peroxidation was determined in washed and resuspended erythrocytes by the concentration of malondialdehyde in the reduction of thiobarbituric acid and by the number of acyl hydroperoxides<sup>22</sup>.

The amount of normal and altered forms of red blood cells in the blood was determined using light phase contrast microscopy.

In the observation group, the examination was carried out at the first examination, after 3 and 6 months. physical training. All persons in the control group were examined and examined once.

Statistical processing of the results was carried out by Student t-test.

### Results

In the blood of individuals with low physical activity, at the beginning of the observation, an imbalance of arachidonic acid metabolites was noted: the level of thromboxane B<sub>2</sub> in their plasma was increased compared to the control by 28.5% ( $p < 0.01$ ). At the same time, the level of its functional antagonist derivative, 6-keto-prostaglandin F<sub>1 $\alpha$</sub> , in individuals with low physical activity before exercise was reduced by 14.4% compared to the control group ( $p < 0.01$ ) (table).

In the erythrocyte membranes of individuals with low physical activity, before the start of regular running exercises, the cholesterol level exceeded the control by 13.8%, and the total phospholipids was lower than the control values by 14.1% ( $p < 0.01$ ). Moreover, in the erythrocytes of physically untrained individuals at the beginning of the observation, the number of acylhydroperoxides and malondialdehyde exceeded the similar indices in the control by 29.6% ( $p < 0.01$ ) and 38.9% ( $p < 0.01$ ), respectively.

At the beginning of the observation, those who had low physical activity showed a decrease of 12.2% in the blood of the content of erythrocyte-disc cells in comparison with the control group ( $p < 0.01$ ) (table). The number of reversibly and irreversibly altered forms of red blood cells in their blood was increased in comparison with the control by more than 48.4% and 2.5 times, respectively ( $p < 0.01$ ).

In the blood of people who previously had low physical activity and started regular running exercises, a decrease in the severity of arachidonic acid metabolites was noted: the level of thromboxane B2 in their plasma during the observation period decreased by 3,6 months by 5.6%, by 6.7 months by 10.7% ( $p < 0.05$ ). At the same time, the concentration of its functional antagonist derivative, 6-keto-prostaglandin F1 $\alpha$  in the observation group increased compared with the start of observation for 3 months by 4.1%, for 6 months by 12.2% ( $p < 0.05$ ).

In the erythrocyte membranes of individuals of the observation group, against the background of their physical exertion, a decrease in cholesterol level by 3.9% after 3 months and by 10.3% after 6 months of observation was noted. This was accompanied by an increase in their total phospholipids by 3.1% and 10.9% ( $p < 0.05$ ), during these periods, respectively. At the same time, the decrease in acyl hydroperoxides (by 8.6% by 3 months and by 19.9% ( $p < 0.01$ ) by 6 months) and malondialdehyde after 3 months of physical training by 11.8% was found in red blood cells of people who started physical training ( $p < 0.05$ ), after 6 months by 24.3% ( $p < 0.01$ ).

In individuals who began to experience regular physical activity, there was an increase in the blood percentage of erythrocyte-discocytes in comparison with the start of observation (after 3 months by 3.6%, after 6 months by 9.5%,  $p < 0.05$ ) (table). The number of reversibly and irreversibly altered forms of red blood cells in the blood of individuals of the observation group gradually decreased by 18.5% ( $p < 0.01$ ) and 2.1 times ( $p < 0.01$ ), respectively.

## Discussion

Long-term maintenance of a physiological optimum in the human body and its effective healing is possible only with rational, regular physical activity<sup>23</sup>. It has long been noted that low physical activity can cause pre-pathological conditions and enhance the existing pathology, sometimes drastically weakening the body<sup>24</sup>.

The excess products of lipid peroxidation in red blood cells causes rearrangements of the membranes of these cells, which impairs their function<sup>25</sup>. This is exacerbated by the development of low lipid imbalance in the erythrocyte membranes, which further contributes to the deterioration of the functioning of these blood cells<sup>26</sup>. The emerging changes in the amount and ratio of phospholipids and cholesterol in their membranes are

apparently functionally disadvantageous. They violate the selective permeability and viscosity of the membrane in red blood cells and adversely affect membrane-bound proteins as a result of the modification of their secondary structure.

A significant increase in the number of reversibly altered red blood cells and an increase in their irreversibly altered forms inevitably lead to an increase in the number of red blood cells in the blood of these people and difficulty in blood flow.

In the vascular wall of individuals with low physical activity, the synthesis of biologically active substances that can affect red blood cells decreases. Thus, the intensification of the formation of thromboxane and the weakening of the production of its functional antagonist prostacyclin, noted in the observation group, creates an imbalance of arachidonic acid metabolites. The erythrocyte micro-rheological dysfunctions formed under these conditions can themselves negatively affect the microcirculation processes and weaken trophism in the vessel walls and the production of disaggregants in them.

To improve this situation, the body in the present study was assigned regular, feasible athletics physical activity to people with low physical activity. Against their background, the examined had a reduction in the number of lipid peroxidation products in red blood cells, which helped to optimize the state of the membranes of these cells. The effect was enhanced during the increase in physical activity by the positive dynamics of the lipid composition of erythrocyte membranes, which positively affects the functioning of these blood cells<sup>27</sup>. Positive changes in the amount and ratio of phospholipids and cholesterol in their membranes were functionally advantageous and brought the selective permeability and viscosity of their membranes closer to the optimum in red blood cells, and also improved the state of the secondary structure of membrane-bound proteins of a significant part of red blood cells.

As the study showed, the beginning of regular physical exertion in people who previously had a low physical activity for a long time is characterized by a decrease in their blood levels of reversibly and irreversibly altered forms of red blood cells due to a tendency to an increase in the number of their discoid forms. At the same time, a decrease in the number of reversibly altered red blood cells and a decrease in their

irreversibly altered forms led to a decrease in the number of red blood cells in the blood of these people and a decrease in the degree of involvement of ever new red blood cells in them.

### Conclusion

Low physical activity is often accompanied by an increase in the number of superficially altered blood cells. This is especially often observed in red blood cells, which complicates their passage through the microvasculature and weakens the metabolic process. It was found that in people of the second adulthood who started regular running exercises after a long period of low physical activity, lipid peroxidation is inhibited in red blood cells. This is accompanied by a decrease in their blood number of altered forms of red blood cells, which contributes to the activation of trophism in the tissues. Given the incomplete recovery of micro-rheological disorders after 6 months physical training in people who previously had low physical activity, it seems rational to recommend that they continue to experience physical activity with monitoring the state of the cytoarchitectonics of their red blood cells.

## Abstract

**Context:** A very socially significant pathology in the modern world is arterial hypertension. The fight against it is built on the positions of prevention and rehabilitation, including using tourism. It is based on a change of scenery with the exception of monotonous living conditions and distraction from negative moments. Hiking and travel take people to a new landscape and climate environment, provide them with emotionally-colored contact with nature. The improvement of people with arterial hypertension by means of health tourism is largely based on the positive effect of natural health resources on their bodies in combination with recreational and health moments - air and sun baths, health path, herbal medicine, florotherapy. Normalization of blood pressure in people predisposed to arterial hypertension also often occurs in the conditions of camping trips. This is also facilitated by their diet with increased consumption of foods saturated with potassium and the restriction of salt.

**Keywords:** Health, tourism, prevention, arterial hypertension, blood pressure.

## Introduction

The state of prehypertension is more often recorded in men than in women, but not all researchers agree with this<sup>1,2</sup>. At the same time, most of them define arterial hypertension as the most common, very dangerous due to its complications and a very serious disease of the adult population<sup>3</sup>. Often, arterial hypertension can be a consequence of a disease and then it is called secondary hypertension<sup>4</sup>.

High blood pressure is a significant excess load on the heart, the result of which is the earlier wear of this organ<sup>5</sup>. Additional load on the heart leads from the beginning to muscle hypertrophy of the left heart, then it develops muscular dystrophy, resulting in heart failure<sup>6,7</sup>. Myocardial infarction and stroke also occurring in arterial hypertension further aggravate the clinical picture and exacerbate the immediate and long-term prognosis<sup>8,9</sup>.

One of the very effective options for the improvement of arterial hypertension is considered to be health tourism - a special type of tourism, designed to restore human strength spent as a result of labor<sup>10</sup>.

It is of great interest to consider the preventive possibility of health tourism in terms of reducing the likelihood of arterial hypertension in the presence of high normal blood pressure<sup>11</sup>.

**Purpose:** to consider the possibilities of health tourism in terms of the prevention of arterial hypertension.

**The main factors in the development of arterial hypertension:** It is recognized that the etiology and pathogenesis of arterial hypertension are closely related to emotionally stressful situations. There is an assumption that arterial hypertension occurs in individuals with a special form of mental activity<sup>12</sup>.

The existence of a connection between psychoemotional states and the nature of pathological processes suggests that mechanisms that are repeated in response to negative emotional reactions can accelerate the course of the disease to which a person is predisposed<sup>13</sup>. A very common psychoemotional state in a person with arterial hypertension is anxiety and frustration<sup>14</sup>.

Anxiety is defined by researchers as an unmet need of a person. Often anxiety is defined as an experience of emotional discomfort associated with the expectation of ill-being, with a premonition of imminent danger<sup>15</sup>.

The most acute problem of anxiety is faced by child and adolescent psychology since the consolidation of anxiety as a personality trait leads to many diseases, including arterial hypertension. A similar negative effect on the body and contributing to the development of arterial hypertension is exerted by another negative psychoemotional state - frustration. This mental state of failure, arising in the presence of real or imaginary insurmountable obstacles to a goal, is a form of stress in the face of loss of adaptation<sup>16,17</sup>.

Common to frustration is, firstly, the presence of negative experiences associated with a significant situation, secondly, the presence of insurmountable obstacles (real or imaginary), and thirdly, negative experiences arise in response to events that have already occurred<sup>18</sup>. The most common reaction to frustration is the occurrence of aggressiveness, most often aimed at obstacles<sup>19</sup>. The state of frustration can leave an imprint on a person's entire life and health, since it is a holistic reaction of the body during adaptation to the environment<sup>20</sup>.

The prolonged course of arterial hypertension also influences a person's behavior in a situation of frustration, developing a whole range of protective mechanisms. Typically, patients with arterial hypertension present numerous complaints<sup>21</sup>. At the same time, the state of

health sharply worsens during emotional fluctuations<sup>22</sup>.

Arterial hypertension is a psychosomatic disorder, the course of which is largely determined by the characteristics of the emotional sphere of a sick person (excessively high demands on himself and others; desire for power, pedantry, punctuality)<sup>23</sup>. A typical psychological state of hypertensive patients is increased anxiety, anxiety, constant fear for their state of health and related disability<sup>24</sup>.

The pathogenesis of arterial hypertension is a combination of functional changes in various control loops and, usually, as a result, a complex of structural changes in affected organs and systems. Pathologies of the cardiovascular system are no exception. In the pathogenesis of arterial hypertension, regulatory disturbances and specific structural changes in the vascular wall of the arterial bed as a whole or in its separate basins are usually referred to<sup>25</sup>.

With arterial hypertension, an increase in stroke volume and total peripheral resistance occurs. Vasoconstriction and, consequently, an increase in peripheral resistance are caused by the activation of two neurohumoral systems - the renin-angiotensin-aldosterone system and the sympathetic nervous system, while their activation is mutually stimulating. An increase in sympathetic influences, in addition, leads to an increase in heart rate and myocardial contractility, which, in turn, leads to an increase in stroke volume<sup>26</sup>.

Of particular importance in the pathogenesis of arterial hypertension is the activation of tissue renin-angiotensin-aldosterone system, which causes the formation of left ventricular myocardial hypertrophy, glomerular hypertension, vascular smooth muscle hypertrophy. Activation of angiotensin receptors leads to activation of the sympathetic nervous system, causing an increase in the production of norepinephrine. The interaction of these two neurohumoral systems is carried out both by activating the central sympathetic ganglia in the brain, and by increasing the release of norepinephrine from the pre-sympathetic nerve endings. In turn, norepinephrine activates the  $\alpha$  receptors of blood vessels<sup>27</sup>.

**The possibilities of health tourism in lowering the risk of developing and inhibiting the progression of arterial hypertension:** Health tourism is a special type of tourism with the main goal - the restoration of the physical and mental forces of man. The main effect,

for which recreational tourism is used, is to increase the efficiency of tourism. Subjectively, the effect of increasing working capacity is expressed in the form of relieving fatigue, the appearance of a sense of vitality and a surge of strength, and objectively, in improving the functional and psycho-emotional states of a person. We can assume that tourism is an option for outdoor activities<sup>26</sup>.

A variant of health tourism is sports tourism. It is very useful due to the presence of unforced loads in it. Often there is a shift in health tourism towards rehab in the presence of beneficial climatic conditions and the use of tourism in the form of dosed walking and other activities that contribute to the treatment of cardiovascular diseases<sup>27</sup>. In some sources, recreational forms of the place of physical exercises are indicated, in others physical recreation finds expression in such terms and concepts as “mass physical culture”, “mass-improving”, “improving”, “production gymnastics”, “mass sport”, “Mass-improving”, “active rest”<sup>28</sup>.

An important preventive mechanism of tourism in relation to arterial hypertension is a change of scenery with the exception of everyday, monotonous tedious living conditions and distraction from the tiring negative effects of everyday life. Hiking takes a person with arterial hypertension to a new landscape-climatic environment, giving him close and emotional contact with nature<sup>29,30</sup>.

The healing process of people with arterial hypertension using the means of health tourism is largely based on the positive effect of natural health resources on their bodies in combination with recreational and healthful moments - air and sun baths, health path, herbal medicine, florotherapy<sup>31</sup>.

Air baths can be considered as one of the effective method of hardening, when freely moving air acts on a partially or completely naked body. The healing power of fresh air lies in its richness in oxygen, light ions, volatile and other substances useful to the body. This increases appetite, improves sleep, improves mood and normalizes blood pressure, accelerates blood flow, and reduces vascular tone<sup>32</sup>.

Sunbathing is also very beneficial for the skin and internal environment of the body. Under their influence, the hemoglobin level increases in the blood, and immunity to infectious diseases is activated. They also improve the activity of the nervous system and endocrine

glands, which stimulates the metabolism.

Elimination of the adverse effects of “muscle hunger” by means of physical culture increases the physical activity of the body. Hiking and water tourism are one of the effective means of developing general physical performance<sup>33</sup>.

There is no doubt that the so-called non-drug method of treatment are of particular importance in the healing of patients with prehypertension. First of all, these are measures aimed at correcting their lifestyle. Effective recommendations of dosed physical activity, focused on reducing excess body weight, smoking cessation, normalizing the diet and stably positive psychoemotional status. Normalization of blood pressure in prehypertension is promoted by a diet based on an increase in the consumption of foods saturated with potassium and the restriction of table salt<sup>34</sup>.

The optimal duration of the wellness trip, which makes it possible to lower blood pressure levels in patients, is not clear. There is only information in the literature on health tourism that it helps to stabilize the condition of patients. Therefore, when selecting a load for hypertensive patients during a camping trip, one should take into account not only the age of the patients, but also the duration of the disease, the severity of complications and the degree of arterial hypertension, approaching individually in many ways<sup>35</sup>.

Effective therapy of already formed arterial hypertension should be comprehensive and include, in addition to health tourism, several components: the use of drugs, hardening, daily dosed physical activity, strict adherence to a healthy regime of the day, and training the patient in self-control skills.

## Conclusion

In modern society, one of the most common pathologies is arterial hypertension. The fight against it should be based on prevention and rehabilitation, including the use of tourism. Its important action in relation to arterial hypertension is a change of scenery with the exception of everyday, tiring living conditions and distraction from negative everyday life. Hiking hikes transfer hypertension to a new landscape and climatic environment, ensure its close contact with nature. Normalization of blood pressure in people predisposed to arterial hypertension also always occurs in the conditions of tourist trips. It also contributes to a

diet with increased consumption of foods saturated with potassium and the restriction of salt.

**Conflict of Interest:** No conflict of interest is declared.

**Sources of Financing:** The study was conducted at the expense of the authors.

**Ethics Committee Resolution:** The study was approved by the local ethics committee of the Russian State Social University on September 15, 2017 (protocol №11).

# Short Term Outcomes of Laparoscopic Complete Mesocolic Excision with Central Vascular Ligation for Right Colonic Cancer

Mohamed Abdel Aziz<sup>1</sup>, Abu Baker M. Mohi El-Deen<sup>1</sup>, Ayman M. Hasanien<sup>1</sup>,  
Ahmed M. Attia<sup>1</sup>, Ahmed S. Hafez<sup>2</sup>

<sup>1</sup>Surgery Department, Minia University, Egypt, <sup>2</sup>Center of Oncology - Al-Salam- Cairo

## Abstract

**Background:** Laparoscopic complete mesocolic excision with central vascular ligation, when performed in the right mesocolic plane, produces high quality surgical specimens.

Aim of the work: Assessment of feasibility, safety, and quality of surgical specimen after laparoscopic complete mesocolic excision with central vascular ligation in right colon.

**Patients and Method:** Fifty patients with right colonic cancer were assigned to receive laparoscopic complete mesocolic excision with central vascular ligation during the period from April, 2017 till June, 2019 and their data were prospectively collected.

**Results:** The average length of the ileocolic segment was  $26.67 \pm 2.10$  cm, the average distance from near bowel wall to high vascular tie was  $85.26 \pm 5.32$  mm, the average distance from tumor to high vascular tie was  $107.82 \pm 3.39$  mm, and Average number of LN harvest was number  $22.72 \pm 10.17$ .

**Conclusion:** Laparoscopic complete mesocolic excision with central vascular ligation procedure is associated with minimal operative blood loss, rapid recovery after operation, and short hospital stay and adequate number of harvested lymph nodes.

**Keywords:** *Outcome, laparoscopic, complete mesocolic.*

## Introduction

Colorectal cancer (CRC) is the third most commonly diagnosed cancer and the fourth leading cause of cancer death worldwide <sup>1</sup>.

In 2009, Hohenberger et al <sup>2</sup> translated the concept of TME to colonic cancer, noting that traditionally more favorable oncologic results of colon neoplasia was eventually overtaken by rectal cancer and a more radical

surgical approach performed along embryonic planes of development with higher quality specimens, produce better oncologic outcome; thus, complete mesocolic excision (CME) with central vascular ligation (CVL) was theorized, standardized and eventually validated by several studies 3&4.

## Patients & Method

**Patients:** Fifty patients with right colonic cancer underwent laparoscopic complete mesocolic excision with central vascular ligation in Minia university hospital and El Salam oncology center during the period from April, 2017 till June, 2019 and their data were prospectively collected.

Written consents were taken from patients explaining the details of surgery, the advantages of

minimally invasive surgery, and clarifying the possible complications of surgery and the possibility of conversion to open surgery.

All patients had preoperative examinations including chest radiographs, abdominal computed tomography, colonoscopy and biopsy, routine laboratory testing, and tumor markers. Patients were excluded from the analysis if they had metastasis, received emergency surgery due to acute intestinal obstruction or perforation, pregnant, or had severe cardiopulmonary disease.

**Surgical technique:** Surgical approach was conducted under general anesthesia. The patient is placed in supine position, the patient's left arm is tucked along his side and the right arm extended on an arm abroad. Creation of pneumoperitoneum using veress needle and insufflation of CO<sub>2</sub> is done until intrabdominal pressure reaches between 12- 14 mmHg. The first port is inserted using the optiview technique (12 mm umbilical port for the telescope) and then 3 other ports were inserted under direct vision (one 10 mm and two 5 mm) in the suprapubic region, left lower abdomen, and right upper abdomen respectively. Patients were placed in steep Trendelenburg with the right side elevated. Once the working space is created (by placing the greater omentum and transverse colon over the liver), a medial to lateral approach was used in all cases. The first step is always a thorough exploration of the abdominal cavity. The right colon was pulled upwards and toward the right lower quadrant, stretching and exposing the ileocolic pedicle (figure 1). The peritoneum was incised and the ileo-colic vessels were identified clipped and divided close to their origin. Mesenteric lymphadenectomy was conducted from the origin of ileo-colic vessels in a caudal direction along the superior mesenteric vein (SMV) to the origin of the Henle's gastro-colic trunk, and then toward the terminal ileum. Completion of devascularization, the right colic vessels were isolated and sectioned if present. Then pulling up the transverse colon, its mesentery was dissected from the root and the right branches of the middle colic vessels were identified and dissected by Endoclips. The right colon was then reflected medially from the hepatic flexure downward, dividing the peritoneal reflection in the right gutter. The specimens were exteriorized through a small Pfannenstiel incision after wound retraction using Alexis port. By using harmonic device enterotomies were done in both the small intestine and the colon. Intracorporeal side to side ileo-transverse anastomosis was done using

EndoGIA stapler (figure 2) and closure of enterotomy using 3/0 PDS sutures.

**Figure 1: identification of ileocolic pedicle.**

**Figure 2 : ileotransverse anastomosis using EndoGIA stapler.**

**Data Collection:** Patient data included gender, age, and tumor site and pathological type. Other data collected included operative time, intraoperative blood loss, conversion to laparotomy, length of postoperative hospital stay, and intraoperative and postoperative complications. Quality of surgical specimens assessed as follows: Plane of dissection (mesocolic, intramesocolic and muscularis propria), proximal & distal margins, length of ileocolic segment, distance from near bowel wall to high vascular tie (mm), area of mesentery (mm<sup>2</sup>), and number of LN harvest.

**Statistic Analysis:** The data collected were coded, tabulated, and statistically analyzed using SPSS program (Statistical Package for Social Sciences) software version 25. Descriptive statistics were done for parametric quantitative data by mean  $\pm$  standard deviation, and for non-parametric quantitative data by median, while they were done for categorical data by number and percentage.

### Results

The study was conducted on 50 patients with right colonic cancer to whom laparoscopic resections were done. The age of this group of patients ranged from 37-65 years ( the mean age was 54.86±9.27 years).56 percent of our patients complained of medical disorders and were distributed as follow 22% diabetic, 22% hypertensive,6% cardiac,and 6% hepatic. The tumor site was 38% in the ascending colon, 34% in the caecum and 28% in the hepatic flexure.

The intraoperative data discussed in table 1 revealed that the conversion rate to open technique was 6%,operative time ranged from 123 minutes to 210 minutes ( the mean operative time was 156.44±21.30), intraoperative blood loss ranged from 50 ml to 200 ml (the mean blood loss was 95.80±45.68 ml).Finally no intraopeative complications such as vascular or visceral injury occurred in any of our patients.

Postoperative data discussed in table 2 shows that the mean postoperative oral intake was 3.52±0.64 days

. As regard to postoperative complications (which occurred in 11 patients),they are, 6 cases suffered from paralytic ileus and 5 cases suffered from urinary tract infection.

The parameters that determine the quality of surgical specimen were discussed in table 3. The plane of dissection that being the mesocolic plane in 94% and the intramesocolic in 6% . The proximal and distal margins of the resected ileocolic segment which were free in all excised specimens. The length of the ileocolic segment ranged from 23.5 cm to 31 cm (the average length was 26.67±2.10 cm).The distance from near bowel wall to high vascular tie ranged from 77 mm to 96 mm (the average distance was 85.26±5.32 mm). The distance from tumor to high vascular tie ranged from 101 mm to 114 mm (the average distance was 107.82±3.39 mm). Area of mesentery ranged from 15500 mm<sup>2</sup> to 19800 mm<sup>2</sup> (the average was 18810±1146.64). Number of LN harvest ranged from 12 to 60 (with an average number 22.72±10.17).

**Table 1: The intraoperative parameters and hospital stay duration of studied sample:**

Intraoperative parameters		
Conversion to open:	n (%)	3(6%)
Operative time(minutes)	Mean ±SD	156.44±21.30
	Median (range)	155(123-210)
Intraoperative blood loss(ml)	Mean ±SD	95.80±45.68
	Median (range)	85(50-200)
Hospital stay(days)	Mean ±SD	5.92±0.87
	Median (range)	6(5-8)
Intraoperative complications: n (%)	Vascular injury	0(0%)
	Visceral injury	0(0%)
Histologic type	Well differentiated	24(48%)
Adenocarcinoma: n (%)	Moderately differentiated	10(20%)
	Poorly differentiated	16(32%)

**Table 2: postoperative data of studied samples**

Postoperative follow up		Descriptive statistics
Postoperative oral intake	Mean ±SD Median (range)	3.52±0.64 3(3-5)
Postoperative complications: n (%)	Paralytic ileus	6(12%)
	Intramural bleeding	0(0%)
	Anastomotic leakage	0(0%)
	Port site infection	0(0%)
	Abdominal abscess	0(0%)
	Port site hernia	0(0%)

Postoperative follow up		Descriptive statistics
	Pneumonia	0(0%)
	UTI	5(10%)
	DVT	0(0%)
Recurrence:	N (%)	0(0%)
Perioperative mortality:	N (%)	0(0%)

**Table 3: Quality of surgical specimen:**

Variable		Descriptive statistics
Grade of plane of mesocolic dissection: n (%)	*mesocolic *intramesocolic *muscularis propria	47 (94%) 3(6%) 0(0%)
Proximal & distal margins: n (%)	Free	50 (100%)
Length of ileocolic segment (cm)	Mean ±SD	26.67±2.10
	Median (range)	26(23.5-31)
Distance from near bowel wall to	Mean ±SD	85.26±5.32
high vascular tie(mm)	Median (range)	84(77-96)
Distance from tumor to high	Mean ±SD	107.82±3.39
vascular tie(mm)	Median (range)	108(101-114)
Area of mesentery (mm <sup>2</sup> )	Mean ±SD	18810±1146.64
	Median (range)	19200 (15500-19800)
Number of LN Harvest	Mean ±SD	22.72±10.17
	Median (range)	21(12-60)
Number of positive LN	Mean ±SD	0.72±1.62
	Median (range)	0(0-5)

**Discussion**

Complete excision of the primitive dorsal mesentery along the anatomo-embryological and surgical planes by means of CME is now the standard of care for colonic cancers. Technical strategies for CME include two aspects: sharp separation of visceral and parietal fascia, and ligation at the root of central supply vessels and more radical lymph node dissection for improving oncological outcomes <sup>5</sup>. However, the right hemicolectomy is performed routinely worldwide, the feasibility and safety of complete mesocolic excision has recently been showed in open and laparoscopic surgeries <sup>6</sup>.

In our study, the mean age of patients (16 males and 34 females) was 54.86±9.27 years. According to a study done by L. m. siani et al 2015, the mean age of patients (75 males and 40 females with a male to female ratio of 1.8) was 65±1.3years <sup>7</sup>. while in a study done by Hossam et al 2019, the mean age of patients (14 males(46.7%) and 16(53.3%) females) was 58.33±5.88 years<sup>8</sup>. Jung et al 2018, in his study reported the mean age of patients (445 (44.1%) males and 565 (55.9%) females) was

60±11 years<sup>9</sup>.

In our study, the mean operating time was 156.44±21.30 minutes and intraoperative blood loss was 95.80±45.68 ml. According to a study by Hossam et al 2019, the mean operating time was 180.0±20.0 minutes, and intraoperative blood loss was 200.6±50.5 ml <sup>8</sup>, while in a study by jung et al 2018, the mean operating time was 165± 50 minutes <sup>9</sup>. IL Yong et al 2016 also reported operating time of 178 minutes, intraoperative blood loss was 149 ml <sup>10</sup>. Finally L. m. siani et al 2015 in his study reported, mean operative length of 179±39min <sup>7</sup>. Contrasting our results with other studies, our mean operating time was slightly lower compared to others.

The mean duration of hospital stay in our thesis was 5.92±0.87 days. IL Yong et al 2016 reported hospital stay of 11 days <sup>10</sup>. Hossam et al 2019 in his study reported hospital stay 4.40±0.910 days <sup>8</sup>. According to study done by Jung et al 2018, the mean duration of hospital stay was 9.3± 3.2 days <sup>9</sup>, while L. m. siani et al 2015 reported hospital stay duration of 10.5±1.9 days<sup>7</sup>. The

mean hospital stay in our thesis was even shorter than that of other studies except a study done by Hossam et al 2019. This can be attributed to the enhanced recovery program that was followed during the study. King et al., 2006 demonstrated with the standardized postoperative program in a randomized controlled trial that the patients who underwent laparoscopic resection was associated with 32% reduction of hospital stay<sup>11</sup>. Senagore et al., 2003 showed that with a standardized technique and a standardized postoperative care plan, a reduction of mean hospital stay of 2.9 days and a low morbidity of 6.6% could be achieved<sup>12</sup>. Thus the use of laparoscopic surgery and a standardized fast track postoperative protocol is likely the optimal treatment for patients with colorectal cancer.

There were no deaths in our study, also Jung et al 2018 reported no deaths in his study<sup>9</sup>. While L. m. siani et al 2015 reported postoperative mortality of 1.7% (2 patients)<sup>7</sup>. Eleven morbidities (22%) occurred in our thesis. Sixtth Patients (12%) complained of paralytic ileus and conservative management in the form of iv fluids, NGT insertion and NBM was done and they passed successfully. Five patients(10%) developed UTI who were managed by urinary antiseptics.

Overall complication rates after laparoscopic colon resection were evaluated in many trials. Hossam et al 2019 reported an incidence of complications following laparoscopic colon resections of 26.7%(8cases)<sup>8</sup>. Jung et al 2018 demonstrated a morbidity of 18.3% (125 cases) after laparoscopic resection for colon cancer<sup>9</sup>. L. m. siani et al 2015 reported a 22.6%(26 cases) incidence of postoperative complications following laparoscopic resection for patients with right colon cancer<sup>7</sup>.

Three conversions occurred in our thesis (6%),all of them because of extensive adhesions.

In our study,plane of dissection was mesocolic in 47 cases (94%) and intramesocolic in three cases (6%). The average number of harvested lymph nodes was  $22.72 \pm 10$ . Histological examination revealed that proximal and distal margins were free of microscopic disease. The length of the ileocolic segment was  $26.67 \pm 2.10$  cm. the distance from near bowel wall to high vascular tie was  $85.26 \pm 5.32$  mm. the distance from tumour to high vascular tie was  $107.82 \pm 3.39$  mm. Area of mesentery was  $18810 \pm 1146.64$  mm<sup>2</sup>.

Jung et al 2018 in his study reported that, the average number of harvested lymph nodes was  $25.7 \pm$

10.9. Histological examination revealed that proximal and distal margins were free. The length of the proximal and distal margins were  $15.1 \pm 9.7, 15.2 \pm 7.4$  cm respectively<sup>9</sup>.

According to a study done by L. m. siani et al 2015, Colonic resection was classified as mesocolic plane in 65.2% (75 cases), intramesocolic plane in 21.7% (25 cases) and muscularis propria plane in 13% (15 cases). For mesocolic plane of surgery, mean ileocolic segment length was  $23.5 \pm 3.7$  cm and resection margins were all free of microscopic disease; distance from the nearest bowel wall to high tie was  $83 \pm 7$  mm, distance from tumor and high tie was  $103 \pm 5$  mm, and area of mesentery was  $15.350 \pm 1.570$  mm<sup>2</sup>; mean lymph nodes harvested were  $29 \pm 5$ . For non-mesocolic (i.e. intramesocolic and muscularis propria) planes of resection, mean ileocolic segment length was  $21.3 \pm 2.5$  cm and resection margins were all free of microscopic disease; distance from the nearest bowel wall to high tie was  $67 \pm 5$  mm, distance from tumor and high tie was  $87 \pm 9$  mm, and area of mesentery was  $14.135 \pm 1.150$  mm<sup>2</sup>; mean lymph nodes harvested were  $19 \pm 7$ .<sup>7</sup>

## Conclusion

Laparoscopic complete mesocolic excision with central vascular ligation procedure is associated with minimal operative blood loss, rapid recovery after operation, and short hospital stay, high quality of surgical specimen and adequate number of harvested lymph nodes

This study was approved by the Institutional Ethics Committee of School of Medicine, Minia University, Egypt, and all patients gave informed consent before participation in this study. The study conducted in accordance with the ethical guidelines of the 1975 Declaration of Helsinki and International Conference on Harmonization Guidelines for Good Clinical Practice.

**Source of Funding:** none

**Conflict of Interest:** The authors declare that there are no conflict of interests.

# Comparative Study Between Inversion and Non Inversion of the Staple Line in LSG

Mostafa A. Soliman<sup>1</sup>, Hany A. Balamoum<sup>1</sup>, Marwan S. Zahran<sup>2</sup>,  
Mohammed A. Daoud<sup>1</sup>, Mohammed S. Hassanein<sup>3</sup>, Mohamed Shaaban<sup>4</sup>

<sup>1</sup>General Surgery, Faculty of Medicine, Cairo University, Cairo, Egypt, <sup>2</sup>General Surgery, Ahmed Maher Teaching Hospital, Cairo, Egypt, <sup>3</sup>General Surgery, 6<sup>th</sup> October Insurance Hospital, Cairo, Egypt, <sup>4</sup>General Surgery, As Salam international hospital, Cairo, Egypt

## Abstract

**Background:** Morbid obesity has become a big health problem due to its multiple co-morbidities. Bariatric surgery proved to be an effective way for management of morbid obesity and its co-morbidities. In recent years, sleeve gastrectomy (SG) evolved single-stage for treatment of morbid obesity.

**Aim of the Work:** To compare inversion and non inversion of staple line in LSG as regard: the percentage of leakage, percentage of bleeding, percentage of thromboembolism and percentage of infection complication. This comparative randomized study was conducted 40 morbidly obese patients operated upon for LSG 20 without inversion of staple line & 20 with inversion of staple line and are followed up afterwards to evaluate and postoperative leakage rate in the early six months in Surgery Department, Kasr El-Aini Hospital and Ahmed Maher Teaching Hospital in the period between August 2015 and August 2016.

**Results:** There is no statistically significant difference between group A (LSG without inversion of staple line) and group B (LSG with inversion of staple line) in age(range 23 to 60 years VS 19 to 60 years), mean BMI (49.49 VS 45.06), co morbidities, time of surgery (124 min VS 108 min) and complications which include:(bleeding,infection, leakage and thromboembolism).

**Conclusion:** laparoscopic SG is effective treatment for morbid obesity with accepted range of complications. Reinforcement of staple line has no significant impact on percentage of suture line bleeding or leakage or on the operative time or hospital stay. This technique can be restricted to special individual cases depending on the operative findings. However, more intense practice and wide range of cases are required for more precise assessment.

**Keywords:** *Bariatric surgery, Laparoscopy, Morbid obesity, Leakage, Sleeve gastrectomy, Weight loss.*

## Introduction

Obesity is known as an excess of body fat relative to lean body mass <sup>1</sup>.

LSG is developed first stage of duodenal with the intention to decrease risks of complex technique. Short

term follow up demonstrated give a better outcome in term of weight loss. Weight loss is comparable with the gastric bypass, with a% EWL of 65–70% achieved at 2 year follow-up <sup>2</sup>.

Gagner et al. reported leak rate with the use of buttressed sutures. Whilst the overall incidence was 2.1% which increased to 3.3% when buttressing the staple lines with bovine pericardium and lower when absorbable polymer membrane was used with an incidence of 1.09%<sup>3</sup>.

**Aim of the Work:** To compare inversion and non inversion of staple line in LSG as regard:

1. The percentage of leakage
2. Percentage of bleeding
3. Percentage of thromboembolism
4. Percentage of infection complication

**Patients and Method:**

**Population of Study & Disease Condition:**

This comparative randomized study was conducted in Surgery Department, Kasr El-Aini Hospital and Ahmed Maher Teaching Hospital in the period between August 2015 and August 2016.

Patients who have BMIs of 40kg/m<sup>2</sup> or more, or between 35kg/m<sup>2</sup> and 40kg/m<sup>2</sup> with significant comorbidity.

**The Target Population Was Divided Into 2 Groups:** 40 patients divided into 2 groups

**Group A:** It included 20 morbidly obese patients who underwent LSG without inversion of the staple line.

**Group B:** It includes 20 morbidly obese patients who underwent LSG with inversion of the staple line

**Inclusion Criteria:** The subjects considered appropriate candidates for this study if they were:

1. Willing to give consent and comply with the evaluation and treatment schedule, are 18–65 years old (inclusive).
2. Patients who have BMIs of 40kg/m<sup>2</sup> or more, or between 35kg/m<sup>2</sup> and 40kg/m<sup>2</sup> with other significant disease that could be improved if they lost weight.
3. All appropriate non-surgical measures have been tried but have failed to achieve or maintain adequate clinically beneficial weight loss for at least six months.
4. Patients received management in a specialist obesity service.
5. Patients are generally fit for anesthesia and surgery.
6. Patients commit to the need for long-term follow up.

**Exclusion Criteria:**

**The Exclusion Criteria Included:**

1. Pregnancy or lactation .
2. A documented history of drug and/or supplements within 30 days.
3. Alcohol abuse within 2 years of the screening visit.
4. Previous malabsorptive or restrictive procedures performed for the treatment of obesity.
5. Any condition that would preclude compliance with the study.

**Methodology**

**All patients were subjected basically to the following:**

1. Written informed consent.
2. Full history taking.
3. Full clinical examination including pattern of obesity and weight, BMI measurement.
4. Preoperative investigations in the form of:
  - i. Complete blood count.
  - ii. Lipid profile, blood cholesterol and triglyceride assay.
  - iii. Liver and kidney functions tests.
  - iv. Blood glucose level.
  - v. Hormonal assay in selected patients (Cushing's disease or myxedema).
  - vi. Pulmonary function tests.
  - vii. Chest x-ray.
  - viii. Electrocardiogram.
  - ix. Abdominal ultrasound.
  - x. Upper gastrointestinal endoscopy.

**Preoperative preparation:**

1. The operation dates were recorded, with a note on the operative approach and duration of surgery.
2. Antibiotic prophylaxis in the form of intravenous injection of third generation cephalosporin 2 hours before operation.
3. Thromboprophylaxis in the form of low molecular weight heparin 2 hours before operations.

Arrangement for availability critical care bed if needed postoperatively

Operative technique:

1. After prophylactic antibiotics and general anaesthesia were administered, the patient was placed in the supine split-leg position.
2. Sequential compression boots were placed for DVT prophylaxis.
3. Five or six trocars were used for LSG.
4. The first step consisted of exploration of the entire intrabdominal cavity then we opened the gastrocolic ligament. Meticulous dissection was performed at the angle of His with full mobilization of the gastric fundus. The mobilization of the stomach continues dissecting the greater gastric curve toward the antrum up to 3-5 cm from the pylorus.
5. At this time a 36-Fr orogastric tube is inserted then stapler to greater curve started. methylene blue leaking test at the end of procedure
6. In selected group B inversion of staple line using polyglycolic acid 2/0 with rounded needle.

**Follow-Up Assessment:** Patients were followed up at regular intervals on the first week postoperatively and then at 1, 3, 6, 12 months, at each visit we recorded the following:

- 1) We measured BMI of the patient, and excess weight loss.
- 2) We took a full history and clinical examination of the patient after the procedure we assessed complications of surgery and resolution of comorbidities we asked about:
  1. Regurgitation of food and Gastro-esophageal reflux
  2. Gastritis, nausea and vomiting.
  3. Upper or lower gastrointestinal bleeding.
  4. Gastric obstruction.
  5. Dysphagia.
  6. Diarrhea or constipation.
  7. Abdominal pain.

8. Wound infection and fever.
9. Abnormal healing, hair loss and alopecia.
10. Psychological disturbance.
11. Failure to lose weight.
12. Obstructive sleep apnea.

**Statistical Analysis of the Results:** Data were statistically described in terms of mean  $\pm$  standard deviation ( $\pm$  SD), median and range, or frequencies (number of cases) and percentages when appropriate. Comparison of numerical variables between the study groups was done using Mann Whitney *U* test for independent samples. For comparing categorical data, Chi square ( $\chi^2$ ) test was performed. Yates correction equation was used instead when the expected frequency is less than 5. *p* values less than 0.05 was considered statistically significant. All statistical calculations were done using computer programs SPSS (Statistical Package for the Social Science; SPSS Inc., Chicago, IL, USA) version 15 for Microsoft Windows.

## Results

The present study included 40 morbidly obese fulfilled criteria of this study. Patients were divided into two groups A & B.

**Group A:** It included 20 morbidly obese patients who had LSG without inversion of the staple line.

**Group B:** It included 20 morbidly obese patients who had LSG with inversion of the staple line.

### Demographic data of the study group:

**Demographic data depend on age and BMI:** Mean age for patients group A 34.20years  $\pm$  8.16.with a range from 23 to 60 years. Age in B 32.95years  $\pm$  10.0 ranged 19 to 55 years with insignificant.

BMI of patients group A 49.494kg/m<sup>2</sup>  $\pm$  6.13with a range from 42.6 to 67.8 Kg/m<sup>2</sup>. Mean BMI for patientsgroup B 45.067g/m<sup>2</sup>  $\pm$  4.33with a range from 40.5 to 57.7 Kg/m<sup>2</sup> with insignificant.

**Sex distribution in both groups** There was no statistically significant difference as regard sex distribution between both groups.

**Table 1: Preoperative comorbidities in both groups**

Preoperative comorbidities	Group A	Group B
Diabetes mellitus	9	7
Hypertension	7	4
Obstructive sleep apnea	8	5
Arthritis	8	7

There was no statistically significant difference as regard preoperative comorbidities between both groups.

**Table 2: Operative time in both groups**

		Operative. Time
Group A	Mean	108.45
	N	20
	Std. Deviation	33.021
	Minimum	63
	Maximum	173
Group B	Mean	124.50
	N	20
	Std. Deviation	27.860
	Minimum	82
	Maximum	165
Total	Mean	116.48
	N	40
	Std. Deviation	31.231
	Minimum	63
	Maximum	173

P value 0.105

There was no statistically significant difference as regard operative time between both groups with a P-value of 0.105.

**Table 3: Postoperative complications in both groups**

Type of complications	Group A	Group B
Port site bleeding	1	1
Wound infection	1	2
DVT	0	1
Leak	1	0
Post op bleeding	1	0

Postoperative complications in patients group A had port site bleeding which was managed conservatively, one patient had wound infection which was managed by local wound care & antibiotics according to culture & sensitivity, one patients had postoperative internal bleeding which was managed conservatively with

packed RBC,s & fluid transfusion without surgical intervention, one patient had postoperative leakage which was managed with U/S guided pig tail drain and with mega stent insertion endoscopically. As regard postoperative complications of patients group B,one patient had left ileofemoral DVT approved with duplex and treated conservatively by anticoagulation, one patient had port site bleeding which stopped conservatively,twopatientshad wound infection which was managed by local wound care & antibiotics according to culture & sensitivity.

There was no mortality in both groups.

**Table 4: Post op. internal bleeding in both groups**

		Group A	Group B	
	Count	1	0	1
	% within Post op bleeding	100.0%	0.0%	100.0%
	% within Inversion	10.0%	0.0%	2.5%
Total	Count	20	20	40

P value 0.147

Although intraperitoneal bleeding occurred only in group A there was no statistically significant difference as regard postoperative bleeding between both groups with a P-value of 0.035

**Table 5: Post op leak in both groups**

Post op leak		Group A	Group B	
	Count	1	0	1
	% within Post op leak	100.0%	0.0%	100.0%
	% within Inversion	5.0%	0.0%	2.5%
Total	Count	20	20	40

P value 0.311

Although postoperative leakage occurred only in group A There was no statistically significant difference as regard postoperative leakage between both groups with a P-value of 0.311.

**Hospital stay in both groups:** There was no statistically significant difference as regard hospital stay between both groups with a P-value of 0.882

**Table 6: Excess weight loss in both groups.**

		<b>EBW loss%-3m</b>	<b>EBW loss%-6m</b>	<b>EBW loss%-1y</b>
Group A	Mean	33.149%	50.894%	67.306%
	N	20	20	20
	Minimum	18.4%	28.7%	41.4%
	Maximum	46.6%	67.3%	95.4%
Group B	Mean	33.567%	52.561%	69.443%
	N	20	20	20
	Minimum	16.0%	26.8%	40.2%
	Maximum	66.8%	81.2%	96.4%
Total	Mean	33.358%	51.727%	68.374%
	N	40	40	40
	Minimum	16.0%	26.8%	40.2%
	Maximum	66.8%	81.2%	96.4%

In this study we found that no significant differences regard to effect of both techniques on EWL% during first year.

### Discussion

Bariatric surgery is an effective way to treat morbid obesity and decrease the weight, or remission of comorbid, and ultimately a reduction of mortality<sup>4</sup>.

SG is a partial gastrectomy where the majority of curvature of stomach was removed. Antrum is divided 4 cm from the pylorus and a tubular stomach is fashioned around a bougie (32 to 40)<sup>5</sup>.

This thesis is a comparative prospective randomized controlled study between inversion and non-inversion of staple line in LSGas regard the percentage of leakage, percentage of bleeding, percentage of thromboembolism, and percentage of infection complication.

As regard demographic data in the study group, sex distribution in the study group showed that 28 morbidly obese patients were females and 12 morbidly obese patients were males. This indicated a higher frequency of morbidly obese patients in females as compared to males putting in mind that patients were selected randomizedly. This is in concordance with the W.H.O. where found not similar to developed centuries; obesity is prevalent among women and in urban areas in eastern land<sup>6</sup>.

According to age and BMI for patients there are no statistical significant difference between both groups.

As regards obesity related comorbidities in morbidly obese patients in the current study, were almost matched in both groups.

In the current study although inversion of staple line take a longer operative time (124 min vs 108 min) yet this was statistically insignificant results.

Inversion of staple line has no significant impact in hospital stay (4.7 days vs 4.8 days).

It can be concluded from the current study that no statistically significant difference between both groups as regard leakage, bleeding, thromboembolism and wound infection, both procedures were safe and almost having the same early postoperative complications. Leak rate in our study was 2.5%.

Prospective randomized evaluating three different ways of reinforcement (over sewing, absorbable buttress, thrombin matrix) reported similar results<sup>7</sup>.

Choi in a meta reported that, reinforced LSG lower bleeding than non-reinforced. Sub-group given lower incidence of bleeding than non-reinforced<sup>8</sup>.

In addition, inversion of staple line led to stricture of GS and leak through the tears caused by the sutures. Rogula et al.<sup>9</sup> reported that, inverting suture (Lambert's suture) improved strength and burst pressure of staple line found a positive effects on leak occurrence not similar to sutures are potentially dangerous, but evaluation was in vitro and in a small number of patients.

Two patients groups had underwent LSG, first LSG performed with a running absorbable suture placement at the staple line and second had suture was not placed, results shown more problems after reinforcement of the staple line. Dealing with possible leaks and hemorrhage of the staple line problematic after placement of the running suture<sup>10</sup>.

Study showed that both LSG with & without inversion of staple line have achieved a good reduction in the excess weight. In LSG without inversion of staple line%EWL was at 6 months and 1 years, 50.89% and 67.306%, respectively. While in LSG with inversion of stable line it was 52.56% at 6 months and 69.44% at 1 year.

Also in this study we found that no significant difference to effect of both procedures on EWL% in first year.

In a study by **Dapri et al.**<sup>11</sup>, found%EWL after SG (35% to 71.6%) in 6 months, 45% to 83% in 1 year, 47% to 83% in 2 years and 66% at 3 years. Five deaths reported (morbidity was significantly low)

### Conclusion

LSG is effective treatment for morbid obesity. Reinforcement of staple line has no significant impact on percentage of suture line bleeding or leakage or on the operative time or hospital stay.

## Abstract

**Objective:** Venous Malformations can result in severe functional and aesthetic disorders, modern trends toward sclerotherapy are backed by the fear of the potential risk of injuring vital structures associated with the traditional surgical approach. This study is presenting our center experience with intralesional Ethanolamine Oleate (EAO) in the management of VMs, over a period of 12 months.

**Method:** This study is a retrospective review of a cohort of 13 patients who were presented with VMs. All the cases were treated with intralesional injection of EAO 5%. A standardized set of data for each patient was recorded including demographic and clinical data. A dose of 1 cc diluted in 4 cc distilled water, 6 sessions, at 7 days interval. Before injection aspiration was done, all the cases were injected by the same operator.

**Results:** Thirteen patients were managed with serial injections of intralesional EAO 5% with a mean age of 3.5 years (range from 8 months to 12 years). The mean follow up was 7 months (range from 3 to 12 months). The average number of sessions was  $5.2 \pm 0.79$ . Recorded clinical response was; complete response in 5/13 (38.6%), marked improvement was detected in 4/13 (30.7%). Two cases (15.3%) showed moderate improvement and 1 case (7.6%) recorded a slight response. Only one case (7.6%) showed no response to treatment. No systemic adverse effects were reported.

**Conclusion:** Intralesional EAO injection is an effective and safe modality for treating VMs in the pediatric age group.

**Keywords:** Ethanolamine Oleate; Sclerotherapy; Intralesional injection; Venous malformations.

## Introduction

Venous malformations (VMs) are the commonest form of vascular malformations with an estimated incidence of 1 to 2 in 10,000. They are formed of small to large anomalous channels lined with vascular

endothelium and may show hamartomatous changes and microthrombi.<sup>[1,2]</sup> Accurate diagnosis depends mainly on history and clinical examination, with equal gender affection. Although VMs may occur later in life, mostly they are present at birth. Their growth is proportionate to the child growth, however, sudden increase in size may be in response to trauma or pubertal hormonal changes.<sup>[3]</sup>

Although there are many protocols for VMs treatment, yet surgical excision remains in the frontline for successful management. However, surgery may harbor many difficulties such as the inability of complete excision, bleeding, injury of adjacent vital structures, and scarring. Therefore, the topical application of

sclerosing agents emerged as a part of preoperative management by aiding in lesion size reduction, or as a part of postoperative care for residual lesions, or as a solo treatment option. [4]

Many sclerotic agents are available including ethanol, bleomycin, 3% polidocanol, and 5% ethanolamine oleate (EAO), all have been proven to be effective. Also, new sclerotic agents are developed continually, such as foam preparations (sodiumtetradecyl sulphate). One of the most widely used sclerosants is absolute ethanol due to its easy availability, antiseptic quality, and low rate of recurrence. However, complications following injections such as skin ulceration, nerve atrophy, and systemic complications occur at a high rate. [5]

EAO as a sclerosing agent is accepted for cutaneous vascular lesions and esophageal varices treatment. In 2005, Johann et al. conducted the first clinical trial to assess the safety of EAO usage in managing oral vascular anomalies. [6] Compared to ethanol, EAO causes less vascular wall invasion, thus reducing the hazardous effect on the adjacent tissues especially nerves. [7]

In this study, we present our center experience with intralesional Ethanolamine Oleate injection in the management of VMs in pediatric age group, focusing on clinical outcome evaluation, efficacy of the medication and the potential complications.

## Material and Method

This study is a retrospective review of a cohort of 13 patients who were presented with VMs to the vascular anomalies clinic at the department of Paediatric Surgery of a tertiary referral university-based children's hospital from June 2017 to June 2018. All the cases were treated with intralesional injection of EAO 5%. The mean age was 3.5 years (range: 8-months to 12-years old) and the male to female distribution was 7:6.

A standardized set of data for each patient was recorded in a sheet including age, sex, site, and size of the lesion, clinical history, dosage and timing of injections, clinical response, side effects and follow up visits.

Colored photographs were taken for each patient at the first visit, throughout the treatment course and after finishing treatment. The diagnosis was established as a VMs after clinical evaluation by a pediatric surgery consultant and confirmed by radiological studies in the form of doppler ultrasonography (US) and magnetic resonance imaging (MRI).

The treatment protocol was: Under complete aseptic conditions and ultrasound guidance for deep lesions, intralesional injection of EAO 5% at a dose of 1 cc diluted in 4 cc distilled water, 6 sessions, at 7 days interval. [8] Before injection aspiration was done, all the cases were injected by the same operator.

Clinical response was evaluated according to the following criteria: complete response (complete disappearance of vascular tissue), marked improvement (>70% disappearance of tissue), moderate improvement (40–70% of vascular tissue), slight improvement (<40% disappearance of vascular tissue), and no response. [9]

Follow up was done on weekly basis intervals alongside with injection sessions until no more intervention was needed, then every 3 months till 1 year from starting of the therapy. Two independent blinded examiners evaluated the images, to assess the degree of improvement based on the baseline images prior to starting injections.

**Statistical Analysis:** Statistical data analysis was done using Microsoft® Excel® 2013 (15.0.4420.1017) 32-bit software. Descriptive data analysis as well as analytical analysis were done using Anova: Single Factor test, t-Test: Two-Sample Assuming Unequal Variances, and F-test two-sample for variances.

**Findings:** Thirteen patients were managed with serial injections of intralesional EAO 5% with a mean age of 3.5 years (range from 8 months to 12 years). Seven males and 6 females were included in the study. Regarding the site of the lesions, six out of 13 (46.2%) occurred in the head and neck region, three cases (23.1%) in the lower extremities, four cases (30.7%) in the trunk. The mean follow up was 7 months (range from 3 to 12 months). The average number of sessions was  $5.2 \pm 0.79$ . **Table (1)** summarizes patients' demographics and clinical response.

Regarding the clinical response; five (38.6%) out of the 13 patients showed a complete response (**Fig. 1**). Marked improvement was detected in 4/13 (30.7%) (**Fig. 2**). Two cases (15.3%) showed moderate improvement and 1 case (7.6%) recorded a slight response. Only one case (7.6%) showed no response to treatment.

In the vicinity of adverse effects; two cases (15.3%) showed signs of infection in the form of epithelial sloughing and ulceration with purulent discharge, bleeding from the puncture site occurred in 1 case (7.6%).

**Table (1): Summarizes patients’ demographics and clinical response.**

Case no.	Age(yrs)	Sex	Site	Size(cm)	No. of sessions	Outcome	Surgery	Follow up (m)

**Figure 2: 2.5 years old girl with VMs in the back after 4 cycles of EAO injection.**

### Discussion

VMs are formed of dysplastic vascular channels lined with normal endothelium unlike vascular tumors that show cellular proliferation, they affect both genders equally, and they are almost always present at birth, grow proportionally with age and they never regress spontaneously. [10]

Throughout the literature, no consensus upon a single modality for dealing with VMs. With small and localized lesions surgery may offer an ideal solution; however, with head and neck lesions or markedly large lesions, debulking is much more feasible keeping in mind the high risk of injuring adjacent vital structures, scarring and functional losses. [2]

Historically, various sclerosing agents were provided for treatment of VMs, such as hypertonic solutions, surfactants, and detergents. However, none of them was superior. Familiarity with the treating physician, availability of the sclerosant, low cost, site, and morphology of the VMs were among the factors that influenced the selection of the sclerosing agent. [4]

Owing to its availability and low cost, Ethanol is the most widely used sclerosing agent; however, it harbors the risk of adjacent tissue damage due to the high neural and mucosal tissue sensitivity to ethanol, and

alcohol intoxication. Sodium tetradecyl sulfate (STS), an anionic surfactant, has the advantages of efficacy at low concentrations and compared to ethanol it is less cytotoxic. However, with extravasation, it may cause thrombosis and skin necrosis. Ethanolamine has the advantage of being less cytotoxic, but it has a deleterious side effect on the kidney. [11]

EAO is a fatty acids emulsion, it exerts its sclerosing effect via induction of thrombosis as a result of vascular endothelial damage. [12] Johann et al., in 2005 conducted his study on 30 cases, and he reported total resolution in all his cases. Kaji et al. also reported similar results in 2009. [13]

The reported overall response ranges between 88% and 100%. [14] In this study, nine (69.2%) of the cases showed more than 70% response to the injections, and about 92% showed a response which is comparable with the literature. Only one case (7.6%) did not show any response that was managed by surgical excision; that lesion was in the back.

In therapeutic doses EAO is highly diluted and once it reaches the circulation it is neutralized by serum albumin and serum globulin, which spares the patient from the hazardous systemic complications like hemolysis and renal failure. Hypersensitivity and anaphylaxis form

the drug may also occur. [15] In our study, complications recorded was local infection in (2/13, 15.3%) that was managed with withholding injections for 1 week and antibiotic application, and puncture site bleeding in (1/13, 7.6%) that was controlled by local compression for 2 minutes.

### Conclusion

Intralesional Ethanolamine Oleate injection is an effective and safe modality for treating VMs; complications are mild, and no evidence of associated systemic manifestations in our series. A larger number of patients and longer follow up will help in establishing a solid opinion about EAO usage in VMs.

**Conflict of Interest:** The authors declare that they have no conflict of interests.

**Source of Funding:** There are no funding sources to declare.

**Ethical Clearance:** Ethical approval was obtained via the departmental research ethics and scientific committee. Informed consent was obtained from all the candidates' parents prior to starting the treatment.

**Consent for Publication:** This study was conducted in a tertiary university hospital (teaching) centre which operates under directives allowing retrospective utilization of non-identifiable clinical data with no written consent. Verbal consent for publication was obtained by telephone from the parents of all cases included.

# Health Literacy Survey on Medical Students

Moza Guyanto<sup>1</sup>, Rizma Adlia Syakurah<sup>2</sup>

<sup>1</sup>Faculty of Medicine, Universitas Sriwijaya, Palembang, Indonesia, <sup>2</sup>Public Health Department, Faculty of Medicine, Universitas Sriwijaya, Palembang, Indonesia

## Abstract

**Background:** The term health literacy was first used in 1970 and has become important in public health and health services. Health literacy is defined as a level where people can access, understand, assess and communicate information to engage with the demands of different health contexts in order to promote and maintain good health in life. Poor health literacy has a relationship with a low understanding of written information and poor communication with health workers. Health literacy is important in effective communication between patients and health workers. However, there is very little research on health literacy in health workers.

**Objective:** This study aims to determine the level of health literacy in the education participants of the Sriwijaya University medical faculty general practitioner.

**Method:** Qualitative descriptive studies have been conducted. The population and sample in this study were all students of the Sriwijaya University medical faculty who were taken by convenient sampling. Frequency of distribution and relationship analysis was calculated using SPSS version 22.

**Results:** From this study 503 questionnaire data were obtained, Most questions of the health literacy questionnaire have a relationship with age and years and no relationship with work of the father, mother's work, and income.

**Conclusion:** Health literacy of general medical students of Sriwijaya University medical faculty has more relationship with age and years than the work of father, mother's work, and income.

**Keyword:** *Health literacy, public health, medical students, qualitative descriptive, sriwijaya university*

## Introduction

The term health literacy was first used in 1970 and has become important in public health and health services.<sup>1,2</sup> Health literacy is defined as a level where people can access, understand, assess and communicate information to engage with the demands of different health contexts in order to promote and maintain good health in life.<sup>3,4</sup>

According to the Institute of Medicine (IOM), health literacy arises from the interaction of individuals with social and information needs regarding health in their environment which can include the context of health services, public health, health promotion and management of chronic diseases. Our level of literacy directly influences our ability not only to act on health

information but also to better control our health as individuals, families and communities.<sup>3</sup>

Several studies have proven that the level of health literacy of each person can have a major influence on individual societies, and low health literacy is a risk factor independent of hospital care.<sup>5,6</sup> Literacy of poor health has a relationship with a low understanding of written information and poor communication with health workers.<sup>7-9</sup> Research in 2003 showed that more than a third of Americans have low health literacy.<sup>10</sup> In 2006, it was found that nearly 60% of adults in Australia had low levels of health literacy.<sup>11</sup> In 2012, only 8.80% of China's population had basic health literacy.<sup>12</sup>

Measurement of one's health literacy is carried out on attitudes of knowledge, motivation, behavioral

intentions, personal skills and self-efficacy related to health so that it leads to new knowledge, more positive behaviors, greater self-efficacy, positive health behaviors and better health.<sup>13</sup>

Health literacy is important in effective communication between patients and health workers.<sup>14</sup> However, research on health literacy in health workers is very little.<sup>15-17</sup> International research finds that there is a low level of health literacy among health workers.<sup>18</sup> Some studies show that students in the health sector and health workers in the United States have very limited health literacy.<sup>18</sup> A cross-sectional study of health-related knowledge in students shows that medical students' health literacy levels are inadequate.<sup>19</sup> Most medical students will become health workers who will interact a lot with patient. Therefore, their level of health literacy needs more attention. The importance of health literacy is indeed well understood, but most health literacy research is focused on patients, the general public, and students outside the health field. Therefore researchers want to conduct research on the level of knowledge of FK Unsri students in Palembang. The researcher also hopes that this data can be used as data and reference for future health literacy research.

## Method

This research is a qualitative descriptive study with a qualitative cross-sectional design to obtain information about the level of health literacy of students of the Medical Faculty of Sriwijaya University by using the questionnaire method. The population and sample in this study were all students of the Sriwijaya University medical faculty who were taken by convenient sampling. The study was conducted in April to May 2016. The variables studied in this study were gender, age, health literacy, BMI, Force, father's work, maternal occupation, income, health status, and personal behavior. After the data is collected, the data is presented in the form of narratives and tables. Data is then analyzed analytically in narrative form.

## Results

This research is a qualitative descriptive study by collecting data using questionnaires. Data collection was

conducted from April to May 2016. 503 samples were obtained.

From the socio-demographic frequency distribution (gender, age, BMI, years, father's occupation, mother's occupation, and income) 503 samples obtained the most results were women (69.6%), age <20 (50.9%), BMI normal (76.1%), 2011 Years (25.4%), father's job as a civil servant (37.4%), mother's job as a housewife (47.5%), monthly income of Rp. 2,200,000 - 6,599,999 (39.6%).

From the frequency distribution of health literacy surveys (Q1 to Q12) the most answers were easy Q1 (58.6%), Q2 was easy (54.1%), Q3 was difficult (49.3%), Q4 was difficult (49.9%), Q5 is easy (46.3%), Q6 is easy (46.7%), Q7 is easy (52.5%), Q8 is easy (53.7%), Q9 is easy (62.0%), Q10 is easy (53, 3%), Q11 is easy (49.9%), and Q12 is easy (44.7%). The majority of the results of the frequency distribution of health literacy surveys answered easily (10 questions) with an average percentage of 52.18% (> 50%) probably because samples were taken from general medical students who understood health.

From the frequency distribution of health status, the most obtained results were good health status (57.9%), diabetes (0.2%), hypertension (1.6%), heart disease (0.4%), hepatitis (0.2%), cancer (0.6%), cerebrovascular disease (0.2%), chronic lung disease (1.2%), kidney disease (0.6%), mental illness (1.2%), and arthritis (0.6%).

From the frequency distribution of personal behavior the most results were unlimited activity (52.9%), never smoked (92.0%), exercised for 30 minutes several times a month (61.2%), contacted emergency services for the past year < 2 (93.2%), went to the doctor for the past year <2 (72.4%), and was hospitalized for the past year <2 (93.4%).

Analysis of the Relationship Between Socio-Demographic Determinants and Health Literacy Socio-Demographic determinant data used in this study were gender, age, class, father's occupation, maternal occupation, and income. Health literacy used is Q1 to Q12.

**Table 1: Socio-Demographic Relationship Analysis with Health Literacy**

Health Literacy	Socio-Demographic	Sig.

**Discussion**

All questions on the health literacy questionnaire have no relationship with gender. Yan Zhang in his research on health literacy in medical students found that the average health literacy score for women was lower than that of men except in the ability to find health information and the ability to understand health information.<sup>20</sup> But according to Athanassios Vozikis's research on health literacy in students by random sampling showed that men had lower health literacy than women.<sup>21</sup>

Most questions of the health literacy questionnaire have a relationship with age and years. In the research conducted by Yan Zhang, there was also a relationship between health literacy and the age group where the highest years had the highest level of health literacy while the lowest years had the lowest level of health literacy.<sup>20</sup>

Most of the questions on the health literacy questionnaire have no relationship with the work of the father, mother's work, and income. This is not in accordance with the research conducted by Wafaa Hassan, Brenda Matzke, and Athassios Vozikis which

shows that there is a relationship between health literacy with parents' socioeconomic status, where the higher the socioeconomic status of parents the higher the level of health literacy.<sup>21-23</sup> In research conducted by Wafaa Hassa, mother's work has a more significant relationship than father's work.<sup>22</sup>

Most questionnaire questions have a relationship with age and force but most do not have a relationship with the work of the father, the work of the mother, and possible income because the sample taken is general medical students who have knowledge about health that is distinguished by age and years. If the sample taken is ordinary people, the possibility of father's work, mother's work, and income has a relationship with the level of health literacy.

### Conclusion

Health literacy of general medical students of Sriwijaya University medical faculty has more relationship with age and years than the work of father, mother's work, and income.

# Descriptive Study of the Implementation of Primary Health Care Services for Senior Citizens in Surabaya

Muafa Mahdi Ramadhan<sup>1</sup>, Ernawaty<sup>1</sup>

<sup>1</sup>Department Health Administration and Policy, Faculty of Public Health,  
Universitas Airlangga, Surabaya, East Java, Indonesia

## Abstract

**Context:** High life expectancy in Indonesia also increases as the population of senior citizens increases. The reduction in physical and mental abilities has the potential for older people. The eldercare health services are needed to maintain health and productivity. Puskesmas is public providers of primary health care in Indonesia. The research was descriptive and observational research. The study population was all puskesmas in Surabaya city, totaling 63puskesmas. Determination of the sample using disproportionate stratified random sampling method. The number of samples is 25 puskesmas spread in Surabaya City. The variables studied were eldercare health services efforts inside and outside the puskesmas. Secondary data was obtained from the health profile of Surabaya City and primary data was obtained through questionnaires. The implementation of eldercare health services in puskesmas starting from the registration of the elderly and as many as 15 puskesmas haven't separate the registration of elderly patients with general patients but gets a special label for registering elderly patients. Outside the puskesmas the form of services is homecare services that carried out by the majority of puskesmas many as 16 puskesmas.

**Keywords:** *Eldercare, primary healthcare, service providing*

## Introduction

The implementation of health assistance for senior citizen is aimed to maintain health and production condition, socially and economically.<sup>8</sup>Life expectancy in Indonesia also increases as the population of senior citizens increases. The older someone the greater their potential to experience health issues, mentally and physically. Most common health issues in the elderly are non-communicable diseases, such as hypertension, osteoarthritis, dental-mouth problems, Chronic Obstructive Pulmonary Disease (COPD) and Diabetes Mellitus (DM).

According to Health Law No. 36 of 2009, the government is obliged to guarantee the availability of health care facilities and facilitate the development of elderly groups. Puskesmas, as the public providers of primary health care in Indonesia, are the frontline in providing health services for the community. Surabaya City Health Profile 2015-2017 reported that the number of senior citizens in Surabaya continuously increased in the last 3 years, 2015 to 2017. The coverage of eldercare services in 2015 was 78.31% and increased to 78.81% in 2016. However, it dropped significantly in 2017 to 69.54%. The above achievement was still far from the predetermined target based on the Minimum Service Standard (SPM) for eldercare services which was 100%. In the implementation process, there were supporting and inhibiting factors for eldercare services. In 2017, Puskesmas had relatively low achievement in eldercare services. The attainment was only 69.54% out of 100% as targeted by the regulation of Minister of Health No. 43 of 2016. This might be caused due to various factors, from institutional to individual. To identify the problem, a system approach is used. Of the City

Department of Health Office, contributing factors for the low achievement of eldercare services are regulation, communication and information or messages. From the environment, the contributing factors are accessibility, social support and socio-culture, while age, gender, knowledge, education level and profession are the contributing factors from the individual. It was also due to human resource issue, facilities and infrastructure, standard operational procedure, budget and the attitude of health workers in Puskesmas toward eldercare services. Therefore, it is necessary to develop health services that prioritize efforts to improve, prevent, and maintain health, in addition to healing and recovery efforts.

### Material and Method

This is a descriptive and observational research. Data was collected by observing and measuring the variables without giving any intervention or treatment to the primary health care. In addition, data collection was also collected by describing the implementation of eldercare services in primary health care, known as Puskesmas, around Surabaya. The population were all Puskesmas in Surabaya, totaling 63 Puskesmas, with a total sample of 25 Puskesmas. Sample was selected using disproportionate stratified random sampling method.

Samples were taken disproportionately from the total member of each stratum/group. The first stratum was Puskesmas with excellent (paripurna) achievement category. There were 2 Puskesmas in this category, so the sample was only 1 Puskesmas. From the second stratum, the prime (utama) achievement category, which covered 32 Puskesmas, the samples were 13 Puskesmas. From the third stratum, the medium (madya) category, which

covered 27 Puskesmas, the samples were 10 Puskesmas and for the fourth level, the basic (dasar) achievement category, the sample was only 1 Puskesmas there were only 2 Puskesmas in the category.

Data was taken from the Puskesmas, covering data from November 2018 and ended on June 2019. The data itself was collected by the researcher on May 2019. The variable for this study is the efforts of providing eldercare services, both inside Puskesmas and outside Puskesmas. The secondary data was obtained from Health Profile of Surabaya City, while the primary was obtained from the questionnaires.

**Findings:** This study was aimed to describe the implementation of primary eldercare services in 25 Puskesmas in Surabaya. The results showed that eldercare services for which were carried out inside the Puskesmas and also outside the Puskesmas were as follows:

**Eldercare Services in side Puskesmas:** Eldercare services inside Puskesmas consisted of health services for the pre-elderly, elderly health services, elderly medical rehabilitation, elderly physical activities and physical training. It was in line with the regulation of Ministry of Health Number 67 of 2015 concerning Eldercare Services at the Puskesmas.

**Pre-Elderly Health Services:** The pre-elderly health services were gymnastic activities or physical training, health counselling, early detection for potential diseases, health checks, treatment, and rehabilitative efforts. The table below shows the number of Puskesmas that carry out pre-elderly health services:

**Table 1: Number of pre-elderly services in 25 Puskesmas in Surabaya based on the regulation of Ministry of Health No. 67 of 2015**

Pre – Elderly Services	Frequency of Puskesmas	Percentage (%)
Elderly gymnastic and brain vitalization	24	96
Health promotion	25	100
Health screening	25	100
Health check	25	100
Diseases medicine	25	100
Rehabilitation	17	68
<b>Total</b>	<b>25</b>	<b>100,0</b>

Table 1 showed that all puskesmas have provided almost all pre-elderly health services commanded by the regulation. Pre-elderly group is age group of people aged 45-59 years. At this age, degenerative process of body cells starts and the risk of the degenerative diseases start to emerge. The results showed that the application of pre-elderly health services was not only carried out in puskesmas, but also in health service post for the elderly (Posyandu Lansia).

**Eldercare Services:** Eldercare services in Surabaya have been carried out comprehensively. Full examination has been carried out regarding vital conditions, physical, social, psychosocial, mental, and independence level of the elderly. Below is the data of puskesmas that implement 8 components of examinations using a Comprehensive Geriatric Assessment (CGA):

**Table 2: The coverage of complete examinations for the elderly in 25 puskesmas in Surabaya, based on the regulation of Ministry of Health No. 67 of 2015**

Components of examination	Implementation				Total	
	Yes	%	No	%	Frequency of Puskesmas	%
Vital sign examination	25	100	0	0	25	100
Physical examination	25	100	0	0	25	100
Measuring nutritional status					25	100
Early detection with MNA	12	48	13	52	25	100
Nutrition record	7	28	18	72	25	100
Measuring body mass index	25	100	0	0	25	100
Physiology examination with ADL's Barthel and Test Up and Go Instrument.	17	68	8	32	25	100
Psychosocial Examination	22	88	3	12	25	100
Social Examination	22	88	3	12	25	100
Cognitive measuring with AMT instrument	19	76	6	24	25	100
<b>Mental health status</b>						
Two minutes method	8	32	17	68	25	100
GDS method	25	100	0	0	25	100
MMSE method	14	56	11	44	25	100

Table 2 shows that all puskesmas conducted vital aspects examinations, physical examinations, and mental health checks based on the Geriatric Depression Scale (GDS). However, the results showed that only 7 puskesmas (27.8%) conducted examinations on the elderly using CGA, while the other 18 did not. This was due to the health workers ignorance of CGA and the limited number of health workers, the available time.

Eldercare services are different from general care services. The difference is due to the decreasing physical abilities of the elderly, easily disturbed mental and psychological conditions, and decreasing independence. In addition, the shift of elderly diseases from infectious to degenerative diseases also influences the type of services provided.<sup>7</sup> Eldercare services must be carried

out thoroughly and comprehensively because the diseases that emerge in the elderly are not only caused by one factor, but many factors. Therefore, it is necessary to have a comprehensive examination in order the doctors, nurses and other health workers know the cause of the disease. The examination for the elderly is recommended to use the Comprehensive Geriatric Assessment (CGA) approach. Comprehensive Geriatric Assessment (CGA) is a process used to manage vulnerability in the elderly.<sup>9</sup> With CGA, health workers can conduct a comprehensive assessment of the elderly from the biological, cognitive, psychological, and social aspects to determine problems and plan for the Eldercare management. This examination is a thorough examination that requires all health workers not only doctors but also nurses and other professional health personnel.<sup>9</sup>

CGA consists of 8 examination components that must be carried out, namely vital signs, physical, nutritional status, functional status, psychosocial status, social status, cognitive status and mental status examination. The results of this study indicate that most puskesmas have fully implemented six of the eight components of the examination. Most of the puskesmas did not carry out nutritional and mental examination. The results of the study also showed that most of the examinations were carried out at the elderly posyandu. The examination instruments were filled by the cadres of the elderly.

**Medical Rehabilitation Services:** Medical rehabilitation services held at the puskesmas are primary medical rehabilitation services. The following table shows the distribution of puskesmas that carry out primary medical rehabilitation services:

**Table 3: The Implementation of medical rehabilitation program in 25 puskesmas in the city of Surabaya**

Implementation of medical rehabilitation	Frequency of Puskesmas	Percentage (%)
Yes	1	5,5
No	24	94,5
Total	25	100,0

Table 3 shows that almost all puskesmas do not have primary medical rehabilitation services. Based on information obtained from the person in charge of the elderly program, medical rehabilitation is an advanced level of service provided at advanced health facilities and not provided at puskesmas. Medical rehabilitation was not carried out at puskesmas due to the absence of physical therapist at puskesmas.

According to Minister of Health Decree No. 378 of 2008 concerning Medical Rehabilitation Service Guidance in Hospitals, medical rehabilitation is a health service for physical disorders and functions caused by conditions of illness, diseases or injury through a combination of medical intervention, physical therapy, and/or rehabilitation in order to achieve optimal function capability.<sup>4</sup> The efforts of medical rehabilitation services at puskesmas are intended to provide basic medical rehabilitation services. Physiotherapists and general practitioners who have medical rehabilitation skills can perform as the medical rehabilitation therapist.

The provision of medical rehabilitation services at puskesmas must be reviewed due to the inconsistency of regulations that explain the provision of medical rehabilitation. The BPJS regulation explains that medical rehabilitation is a service provided in hospitals or advanced health facilities.

In the regulation concerning puskesmas, it was also explained that the physiotherapist was not one of health workers that must be available at puskesmas, but the other regulation concerning the implementation of eldercare services stated that elderly basic medical rehabilitation is provided in puskesmas. The review of medical rehabilitation services at puskesmas must be done, so that they can provide better services.

**Physical Activity and Exercise:** According to Minister of Health Regulation Number 67 of 2015, physical activity and exercise is one form of eldercare services in puskesmas. The following table is the distribution of personnel that guide physical activities and training for elderly people in puskesmas:

**Table 4: Distribution of personnel that guide physical activities and training for elderly people in 25 puskesmas in Surabaya**

Kind of Personnel	Frequency of Puskesmas	Percentage (%)
Doctor	0	0
Nurse	8	32
Physiotherapist	0	0
Elderly cadres	17	68
Total	25	100,0

Table 4 shows that the majority of guides in the course of activities and physical training for the elderly at puskesmas are elderly cadres. This is due to the limited number of health workers in puskesmas and that it is usually carried out outside the puskesmas. Therefore, the implementation of activities and physical training is left to the elderly cadres.

**Implementation of Eldercare Services outside Puskesmas:** Eldercare service outside puskesmas is one form of eldercare services consisting of services at the posyandu, community association, elder association and home care health services.

**Eldercare Services in Posyandu/Community Association/Elder Association:** Health services at the elderly posyandu must be visited by health workers from

puskesmasat each activity. The following table shows the distribution of the attendance of puskesmas health workers in posyandu activities:

**Table 5: Number of health workers attendance in elderly posyandu in 25 puskesmas in Surabaya**

The presence of healthcare staff	Frequency of Puskesmas	Percentage (%)
Yes	16	64
No	9	36
Total	25	100,0

Table 5 shows that the majority of elderly posyandu activities had been accompanied by health workers from puskesmas. Sixteen puskesmas delegated their health workers to assist the elderly posyandu activities, while the other nine puskesmas occasionally delegated their health workers to assist the posyandu. This was due to limited human resources available at puskesmas.

Health workers are an important factor in influencing changes on people behaviour, for example by carrying out health promotion so that people can be more motivated to make behavioural changes. Health promotion itself can be done by conducting training for the community, transforming knowledge and providing support to the community (Aryantiningasih, 2014). Health workers also can act as facilitators and empower communities through posyandu activities. Posyandu activities can be said to be well-developed when the community involvement is also higher, so that the target of the health program can be materialized<sup>1</sup>

In addition to the problems related to health workers, there were other problems during the implementation of the elderly posyandu activities. The elderly attendance to the elderly posyandu was low. Aryantiningasih (2014) stated that the low visits of elderly to elderly posyandu can be influenced by several factors including knowledge, distance between their house and posyandu location, family support, posyandu infrastructure, elderly attitudes and behaviour, economic income, and health workers support. Research from Melita et al. (2018) also stated that elderly visits to the elderly Posbindu are influenced by predisposing factors such as knowledge, supporting factors such as family and health workers support, as well as needs factors.<sup>5</sup>

**Home Care Health Services:** Home care health services are one form of eldercare services outside puskesmas which aim to expand the coverage of

health services to the elderly. The following table is the distribution of puskesmas that conduct home care services:

**Table 6: Number of puskesmas that carry out home care service programs from 25 puskesmas in Surabaya**

Home Care Services	Frequency of Puskesmas	Percentage (%)
Yes	16	64
No	9	36
Total	25	100,0

Table 6 shows that the majority of puskesmas had implemented home care health services. The person in charge of the elderly health program, who carried out home care services, stated that the home care service was combined with the implementation of Community Health Care activities. Puskesmas which do not provide home care services stated that it was due to the constraints of limited human resource in their puskesmas.

Home care services are not only provided by health workers but also through friends, neighbours and cadres. The role of the environment such as friends, neighbours, and cadres is very important to reduce morbidity in the elderly.<sup>3</sup> Home care programs both formally and informally can reduce the risk of depression in older adults and improve mental health in general.<sup>2</sup> The older the more important it is to maintain mental health for poor mental health can cause a variety of disabilities.

### Conclusion

Primary eldercare services have been being carried out in puskesmas in Surabaya City. The services are divided into two types, namely inside and outside puskesmas services. Eldercare services inside puskesmas consist of pre-elderly health services, elderly services, medical rehabilitation, as well as physical activity and exercises. Eldercare services outside puskesmas consist of health services at posyandu and home care services. The implementation of the majority of pre-elderly service activities has been carried out by all puskesmas, in line with Minister of Health Regulation No. 67 of 2015. There were 18 out of 25 puskesmas that do not carry out any assessment using Comprehensive Geriatric Assessment (CGA).<sup>6</sup> All of puskesmas in this study did not have a medical rehabilitation program and assistance to physical activity. Almost all of physical exercises were guided by elderly cadres. Eldercare service outside

puskesmas in the form of home care has been carried out by most of the puskesmas.

# Intrinsic and Extrinsic Factors of Cadre Performance in Non-Communicable Disease Integrated Development Post (Posbindu Ptm): Qualitative Study on Posbindu PTM Cadre in Gadingrejo Public Health Center, Pasuruan, East Java, Indonesia

Muhamad Taufik Nurhuda<sup>1</sup>, Shrimarti Rukmini Devy, Dra<sup>2</sup>, Oedojo Soedirham<sup>3</sup>

<sup>1</sup>Health Promotion and Behavioural Sciences, Master Program of Public Health Sciences, Faculty of Public Health, Airlangga University, Indonesia, <sup>2</sup>Department of Health Promotion and Behavioural Sciences, Faculty of Public Health, Airlangga University, Indonesia, <sup>3</sup>Department of Health Promotion and Behavioural Sciences

## Abstract

**Background:** Non-communicable Disease Integrated Development Post (Posbindu PTM) is the manifestation of the public participation in the early detection and monitoring of main noncommunicable disease in integrated, routine, and periodic manners. The activities of Posbindu PTM in Gadingrejo Public Health Center Working Area are based on the Activity Performance Indicator (API) of Posbindu. Regardless of the above-target Posbindu coverage amount (in API number 1), the performance of Posbindu (API number 2, 3, 4) is below the national target and average. This article is aimed at analyzing and revealing the factors of the phenomenon occurred in Gadingrejo PHC Working Area comprehensively.

**Material and Method:** This article combines qualitative method with phenomenology approach. Thirty-eight respondents participated in this study have met the inclusion criteria. The study is conducted in April–May 2019 by in-depth interview to collect the research data. The collected data is analysed using content analysis approach.

**Result:** The performance phenomenon in Gadingrejo PHC Working Area is influenced by intrinsic and extrinsic factors. The intrinsic factors include: (a) individual factor (compulsion, skill and ability, ineffective training, and concurrent position of the cadres), (b) Posbindu internal factor (ineffective schedule, lack of infrastructure, active cadres, supporting investigation), and (c) psychological factor (shame, doubt, and lack of confidence). Meanwhile, the extrinsic factors include: (a) social factors (less support from the family and the society), (b) political factors (less support from the regional government apparatus, lack of assistance from the Public Health Center), and (c) economics factor (low budget).

**Conclusion:** The optimization of synergy and intervention for the intrinsic and extrinsic factors is needed to avoid the low performance of Posbindu PTM. Ottawa Charter can be used as a strategy for the promotion of non-communicable disease treatment which include healthy public policy, optimizing personal skill, and public movement.

**Keyword:** *Posbindu, NCD, IDP, Ottawa Charter*

## Introduction

Non-communicable disease (NCD) has become one of the main mortality factors. Death due to major NCDs besides cardiovascular disease in 2015 were cancer (8.8

million), chronic respiratory diseases (3 million), and diabetes mellitus (1.6 million)<sup>1</sup>

NCD can be avoided by risk-factor intervention including smoking and tobacco use, calorie diet, physical activities, and alcohol. The recommended healthy lifestyle by WHO includes the consumption of vegetables and fruits, diet on sugar, salt, and fat, and exercise.<sup>2</sup>

In Indonesia, NCD prevention and controlling is carried out by Non-communicable Disease Integrated Development Post (Posbindu PTM). Posbindu PTM is the integrated activities to prevent and control NCD risk factors as part of the Community Based Health Services and Culture in a specific region<sup>3</sup>. Posbindu PTM is aimed at optimizing public participation in the prevention and early detection of NCD. The main targets of the activity include individuals with NCD risks and NCD patients above the age of fifteen<sup>4</sup>.

The activities of NCD prevention and controlling by Posbindu is evaluated based on the range of Activity Performance Indicator (API). The API covers the information of village/district that implement Posbindu, blood pressure measurement, obesity measurement, women with cervical and breast cancer at the age of 30–50 years old<sup>5</sup>.

The potential of Posbindu range and the number of health cadre in Pasuruan is not accompanied with high performance achievement of the Posbindu. Gadingrejo Public Health Center (PHC) in Pasuruan is constituted with high number of Posbindu around the city (14 Posbindu). However, the cumulative performance coverage is lower than the other seven Public Health Centers (18,8%)<sup>6,7</sup>.

Gibson (2003) mentioned that work performance is influenced by both intrinsic and extrinsic factors. It is known as the theory of work behavior<sup>8</sup>. By implementing the theory, this article is aimed at discovering the work phenomenon of Posbindu in a systematic way based on qualitative study.

## Material and Method

**Research Design:** This article implements descriptive research method and qualitative approach. Qualitative approach allows the production of phenomenon description to investigate complex, undiscovered issues.<sup>9</sup> It is implemented in this article to

explore the source of problems in the performance of Posbindu PTM in Gadingrejo PHC Working Area.<sup>10</sup>

**Respondents / Research Subjects:** This article divides respondents or research subjects into two categories: main respondents and triangulation respondents. Main respondent group consists of fourteen Posbindu PTM cadres. Meanwhile, triangulation respondent group consists of fourteen Posbindu members, four Posbindu supervisors, four district stakeholders, and two Posbindu programmer or Health Office representatives. Thus, the total number of respondents who met the inclusion criteria is 38 people.

**Data Collection:** The primary data is collected by in-depth interview and direct observation. Informed consent was distributed before the interview. The supporting tools used during the interview include interview guide, notebook, and voice recorder.

**Research Location and Date:** The research is conducted in fourteen Non-communicable Disease Integrated Development Post in Gadingrejo PHC Working Area in April–May 2019.

**Data Analysis and Validity:** This article implements content analysis method to process the gathered data. Data validity is measured by source triangulation and method triangulation. Source triangulation is carried out by validating the data from the main respondents using the data gathered from the triangulation respondents. Method triangulation is carried out by validating the results of in-depth interview with the results of direct observation.

**Findings:** Intrinsic Factors In Posbindu Performance Phenomenon (Individual Factor, Psychological Factor, Posbindu Internal Factor)

According to Posbindu cadres, the training delivered by the Health Office of Pasuruan and Gadingrejo PHC was insufficient to improve their confidence in conducting examination and early detection of NCD. The practice session during the training was insufficient to provide chances for the cadres, as mentioned here:

“I have joined the cadre training. From the Health Office, Public Health Center, to Lawang (training location), I attended all of them. However, I didn’t get enough practice.” (A5)

The selection of cadres in Gadingrejo PHC working area is varied. A respondent mentioned that the cadres

were appointed by The Head of the District or District apparatus. Meanwhile, another respondent mentioned the intervention from village assistant (district nurse). There were also Posbindu cadres appointed by the sub-district cadre head. Based on the interview, some of the appointed cadres were appointed by force, as expressed below:

“I was directly appointed by the Head of the Sub-District” (A3)

“I was called by the Cadre Head and she asked me to attend the cadre training in the Health Office.” (A8)

Low participation of Posbindu members caused uneasy feelings among the cadres towards the invited health workers.

“I felt uneasy towards the doctors or nurses during the Posbindu activity. The members can hardly come to the activity as it is usually carried out during working hours.”

Another respondent admitted feeling anxious due to the Posbindu advisor’s perfectionist trait. On the other hand, another respondent whose house was used as Posbindu activity place admitted that she was busy cleaning the house and preparing the food.

According to the respondents from Gadingrejo PHC, cross-sectoral program for strengthening Posbindu partnership networks is initiated in 2015. However, the results were not felt by the Posbindu cadres.

“The sub-district does not give any intervention to the Posbindu...” (A4)

“No company acted as donors for Posbindu. Our activities are mostly voluntarily. Sometimes we borrow the money from health center service for the elderly.” (A7)

All respondents commented on insufficient resources in Posbindu. It consists of the number of Posbindu active cadre, the availability of Posbindu kit, place and food, and budget. The following is the interview excerpt regarding the issue.

“Only one or two cadres who are willing to attend the Posbindu activities while it is supposed to be five people for fair job distribution and to fill the five tables.” (A2).

**Extrinsic Factors in Posbindu Performance Phenomenon (Political Factor, Social Factor, Economic Factor):** Most respondents stated that the political support from the Head of Sub-District and the Head of District (stakeholder), Posbindu assistants (nurse), the Health Office and PHC, and the local religious/public figures is below their expectations.

**Here are the interview excerpts regarding the issue:**

“The Head of the Sub-District and the Head of District have never attended the training, We have invited the Head of Sub-District via cadre head, but he never answered.” (A3)

“Village assistant from the PHC never joined Posbindu.” (A1)

“For all I know, the Health office never visited us. They only invited us for training, seminar on IVA or cancer, and distributing Posbindu facilities.” (A14)

“We have invited public figures as participants. But they seemed to ignore us. They usually come and attend the activity as the other participants but never helped us.” (A8)

Most respondents found the public to be less supportive. They only supported Posbindu by attending the activities as participants. According to T13 respondent, the public does not care about Posbindu as they have not yet realized the importance of measuring and monitoring blood pressure and body weight. Here is the excerpt:

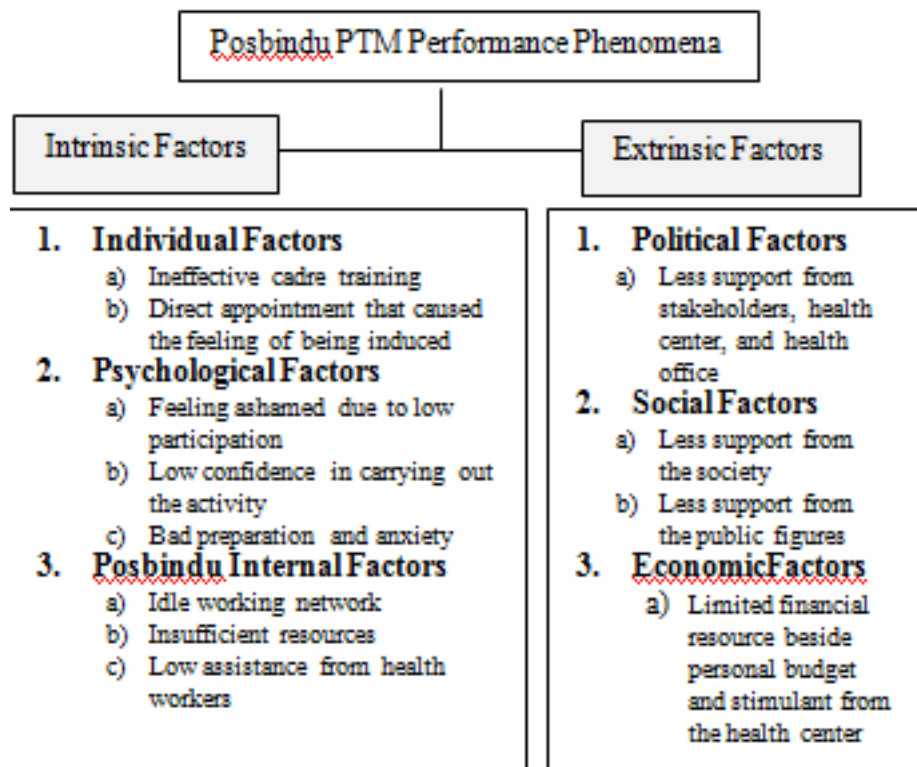

“We haven’t received much support from the society as they have not realized the importance of measuring and monitoring blood pressure and body weight.” (T13)

All respondents stated that the source of money for Posbindu was coming from the cadre with little help from the Health Center. PHC only provides incentive as a stimulant, so it is not given regularly. The money from the cadres is usually used for food. Meanwhile, they do not have any other sources.

Figure 1 summarizes our findings on the problems in Posbindu PTM performance.

**Figure 1. The summary of findings on the problems in each performance factor of Posbindu PTM.**

### Conclusion

The identified Performance Phenomenon in Posbindu PTM in Gadingrejo PHC include: (a) individual factor (compulsion, skill and ability, ineffective training, and concurrent position of the cadres), (b) Posbindu internal factor (ineffective schedule, lack of infrastructure, supporting investigation), and (c) psychological factor (shame, doubt, and lack of confidence). Meanwhile, the extrinsic factors include: (a) social factors (less support from the family and the society), (b) political factors (less support from the regional government apparatus, lack of assistance from the PHC), and (c) economics factor (low budget).

Posbindu Cadre Training by the Health Office of Pasuruan or Gadingrejo PHC is one of the health promotion strategies in improving personal skills mentioned in Ottawa Charter. Individual skill is highly expected in the attempt of developing healthy community. Knowledge on public health is undisputedly needed to develop both individual and public skills<sup>11</sup>.

The cadres were complaining about the insufficient training method that is failed to improve their soft skills. It is due to the fact that there is a positive correlation

between efficient soft-skill training method and an individual's performance<sup>12</sup>. Pedagogical approach is considered as the most efficient training method. Pedagogy is the teacher technique and method in transforming knowledge content, stimulate, monitor, and facilitate the students' development to reach the learning objectives by positioning the teacher in the central role<sup>13</sup>. Meanwhile, andragogy is an alternative method that place the teacher as a facilitator and allows multi-communication between the teacher and the learners<sup>14</sup>

Some Posbindu PTM cadres also complained the direct appointment by the apparatus that make them feel induced to work. Inducement influences an individual's intention and motivation in working. There is a positive correlation between an individual's motivation with work performance<sup>15</sup>.

Psychological problems might also disrupt their working performance in carrying out the Posbindu PTM activities. It is due to the fact that there is a negative correlation between psychological issues with work performance.<sup>16</sup> Specifically, stress and anxiety have been proven to be positively correlated with attendance, so it affects work performance.<sup>17</sup>

The dysfunctional network in Posbindu PTM caused less optimal activity. The development of working network will positively affect the organization's performance<sup>18</sup>. Further, the network is constituted with complex relations as it is influenced by several decisive factors such as job complexity, language skill, communication media, and intercultural training<sup>19</sup>.

Stimulation using incentive for cadres is expected to be able to increase participation in Posbindu activities in a specific region. Organization resource is proven to be positively and significantly affecting the organization effectivity.<sup>20</sup> Having sufficient resources will provide competitive excellence to the organization work performance.<sup>21</sup>

Political support and participation to Posbindu will provide strong motivation in the development of health quality, especially in the attempt to prevent disease and promote health.<sup>22</sup>

Insufficient assistance by health workers in the development of Posbindu PTM also affects the performance of Posbindu. The cadres admitted that they would feel confident if the health workers provided assistance to the cadre. It corresponds with the fact that participation and assistance play an important role in health education, especially in developing the program range.<sup>23</sup>

Ottawa Charter strategy can be applied by health promoter and decision makers in the bureaucracy to develop healthy public policy. It can be used to design health promotion program both for short-term and long-term duration.<sup>24</sup>

There have been several studies that explained the positive influence of social support to the development of public health in a certain region. This article found that social support gives direct impact and modifies the development of public health, especially in preventing and treating treatment, and giving intervention to the individual lifestyle.<sup>25</sup>

# Nurse Communication and Patient Safety Incident Type of Clinical Administration

Mulyamingrum<sup>1</sup>, Aldiar Lailifah Kurniavip<sup>2</sup>, Nyoman Anita Damayanti<sup>3</sup>

<sup>1,2</sup>Student of Bachelor Program, Health Policy and Administration Departement, Faculty of Public Health Universitas Airlangga, <sup>2</sup>Lecturer of Faculty of Public Health Universitas Airlangga, Indonesia

## Abstract

**Background:** The most patient safety incidents that occurred in RSU Haji Surabaya is clinical administration type of incidents. There were 12 clinical administration incidents occurred during January 2014 until June 2016 in the inpatient installation (standard zero accident).

**Objective:** The purpose of this study is to analyze the relationship between nurse communication and patient safety incident type of clinical administration.

**Method:** This study was a descriptive study with an observational approach, and this study was designed as a cross sectional study. Researchers conducted a primary data collection using a questionnaire that has been tested for validity and reliability, then studied of the incident reports document as a secondary data. The questionnaire was distributed to 48 nurses in inpatient installations.

**Result:** The results of this research showed that the effectivity of nurse communication has a relationship with clinical administration patient safety incidents occurred. If effectivity of the nurse communication among fellow nurses and related professions getting lower in the application of patient safety program, then patient safety incidents type of clinical administration getting more often occurred in the inpatient installation of RSU Haji Surabaya.

**Conclusion:** The conclusion of this study is nurse communication among fellow nurses and related professions that are involved in the implementation of patient safety programs at inpatient rooms tend to have relationships with patient safety incidents type of clinical administration occurred in Inpatient Installation of RSU Haji Surabaya.

**Keyword:** *Clinical administration, communication, nurse, patient safety.*

## Introduction

Patient safety forms the foundation of healthcare delivery just as biological, physiological, and safety needs form the foundation of Maslow's hierarchy<sup>1</sup>. Patient safety is a discipline in the health care sector that applies safety science method toward the goal of achieving a trustworthy system of safely health care delivery. The hospital, as one of the healthcare providers, has comprehensive services because it involves various professions in its activities. The hospital is also an institution that is capital intensive, labor intensive, technology intensive, and risk intensive. The complexity components in the hospital must be accompanied with

multi-system collaboration in its activities, so that it is not easy to cause errors that may endanger patient safety.

Patient safety incidents are events that lead to cause an injury for the patient<sup>2</sup>. There are many types of patient safety incident; clinical administration is the one of them. Patient safety incident type of clinical administration is an error that occurs in patient identification process, hand over, agreement, informed consent, waiting list, reference, admission, patient's return, care's transfer, job division, and response to emergencies<sup>3</sup>.

Based on the report retrieved from RSU Haji Surabaya for January 2014 until June 2016 periods, it

shows that there have been several incidents of patient safety<sup>4</sup>. Most of the patient safety incidents that occurred in RSU Haji Surabaya were clinical administration type involving 22 incidents in the first half of 2014, 7 incidents in the second half of 2015, and 9 incidents in the first half of 2016. The patient safety incident type of clinical administration in RSU Haji Surabaya mostly occurred in inpatient installations, i.e. 12 incidents. Based on the data, patient safety incident type of clinical administration that occurred at the inpatient installation in RSU Haji Surabaya were caused by nurses<sup>4</sup>. This is not in accordance with the rules which states that the number of hospital safety incidents should be 0% or zero accident<sup>5</sup>.

Communication is one of the factors from the organizational aspect that can cause patient safety incident. Communication failures are the leading causes of inadvertent patient harm<sup>6</sup>. Analysis of 2455 sentinel events reported to the Joint Commission for Hospital Accreditation in the USA revealed that the primary root cause in over 70% was communication failure<sup>7</sup>. Similar patterns can be found in many areas of healthcare.

According to the data above, the problem that can be discussed in this study is the factors that influence the high rates patient safety incidents at the inpatient Installation in RSU Haji Surabaya. This study aims to analyzing the correlation between nurse communication and patient safety incident type of clinical administration.

## Material and Method

This study was a descriptive study with an observational approach. In this case, research was conducted The study was designed as a cross sectional study. This research was carried out in the installation of Inpatient RSU Haji Surabaya. Time data retrieval on the primary and secondary research was on 3 May to 2 June 2017.

The unit of analysis in this study was 6 inpatient rooms in the inpatient installation of RSU Haji Surabaya. Sampling was done using a probability sampling technique with simple random sampling. Based on calculations using the large sample formulas minimum on one population, it can be noted that, of the total population of 94 nurses, the minimum sample amounts were 48 nurses. Researchers performed the division of the sample with the techniques of proportional based on the work units.

Researchers conducted a primary data collection using a questionnaire that has been tested for validity and reliability. In addition, researchers also conducted secondary data collection i.e. patient safety incident reports issued by RSU Haji Surabaya. Furthermore, the data acquired will be processed and presented in the cross-tabulations, and then analyzed in a descriptive to expose the relationship between the dependent variable and independent variable.

## Results and Discussion

**Nurse Communication:** Communication is the main element for nurses in performing nursing care to achieve optimal results. Effective communication will enhance professional relationships both with among nurses, other health team, as well as the patient. Nurse communication in this study was assessed through verbal interaction liveliness by nurses with fellow nurses and the other professions in the Inpatient installation of RSU Haji Surabaya. All the elements of the existing questions in the questionnaire were related to patient safety including: the experience of communication, communication techniques, communication, and understanding of the function miscommunication results. The following table shows the distribution of categories of nurse communication effectiveness level in Inpatient Installation of RSU Haji Surabaya in 2017.

**Table 1: The Distribution Category of Nurse Communication Effectiveness in Inpatient Installation RSU Haji Surabaya in 2017**

Category of Communication	Frequency (n)	Percentage (%)
Ineffective	4	66,7
Effective	2	33,3
Total	6	100,0

Table 1 shows that most nurse communication in inpatient installation rooms (66.7%) of Inpatient RSU Haji Surabaya was ineffective, whereas the rest of it (33.3%) was effective communication with fellow nurses or other professions.

Communication is a multi-dimensional, multi-factorial phenomenon and a dynamic, complex process, closely related to the environment in which an individual's experiences are shared<sup>8</sup>. Effective communication is an important aspect of patient care, which improves nurse-patient relationship and has a profound effect on the patient's perceptions of health care quality and treatment

outcomes<sup>9</sup>. Moreover, they can increase patient satisfaction, acceptance, compliance, and cooperation with the medical team, and improve physiological and functional status of the patient; it also has a great impact on the training provided for the patient<sup>10</sup>. Communication failures may occur in any context but there are pervasive barriers to effective communication that are specific to health care. These include a hierarchical culture that leads to authority gradients, differing professional communication styles and fragmented care delivery across multiple departments and settings<sup>11</sup>.

**Patient Safety Incidents Type of Clinical Administration:** Patient safety incident is any deviation from usual medical care that causes harm to a patient or presents a risk of harm. This term includes adverse events and near misses. A patient safety incident is defined as an incident where a patient is harmed or potentially harmed as a result of care<sup>12</sup>. Many rules have been made related to patient safety incidents. In Indonesia, the incident is distinguished to 15 types of patient safety incident<sup>3</sup>. Identification of patient safety incident types was retrieved from document report of patient safety incident in RSU Haji Surabaya. Based on this report, it was found that patient safety incident

type of clinical administration in inpatient installation occurred more frequently than other types, i.e. 14 incidents during January 2014 until May 2017 in RSU Haji Surabaya.

The following table shows the case distribution of patient safety incident type of clinical administration during January 2014 to May 2017 in Inpatient Installation of RSU Haji Surabaya.

**Table 2: The Case Distribution of Patient Safety Incident Type of Clinical Administration During January 2014 to May 2017 in Inpatient Installation of RSU Haji Surabaya**

Patient Safety Incidents Type of Clinical Administration	Frequency (n)	Percentage (%)
No Incident	2	33,3
Incident	4	66,7
Total	6	100,0

Table 2 shows that the patient safety incident type of clinical administration took place mostly in the inpatient room (66.7%) in the Inpatient Installation of RSU Haji Surabaya.

**Table 3: The Cross-Tabulations Between the Nurse Communication with Patient Safety Incident Type of Clinical Administration in Inpatient Installation of RSU Haji Surabaya in 2017**

Category of Nurse Communication	Patient Safety Incident Type of Clinical Administration				Total	
	No Incident		Incident		N	%
	n	%	n	%		
Ineffective	1	25,0	3	75,0	4	100,0
Effective	1	50,0	1	50,0	2	100,0
<b>Total</b>	<b>2</b>	<b>33,3</b>	<b>4</b>	<b>66,7</b>	<b>6</b>	<b>100,0</b>

**Correlation of Nurse Communication with the Case of Patient Safety Incident Type of Clinical Administration:** Research results in Table 3 show that the more ineffective nurse communication among fellow nurses and related professions in the application of patient safety program, then patient safety incidents type of clinical administration getting more often occurred in the inpatient installation of RSU Haji Surabaya. Cross-tabulate results in this research indicate that nurse communication related patient safety tend to have a relationship with a patient safety incident type of clinical administration.

The results of this research are consistent with research which stated that effective communication in the health care system is important to prevent errors and improve job satisfaction<sup>13</sup>. It is time for hospital administrators, physician and nurse leaders, and medical and nursing education institutions to enact permanent changes in team dynamics that support improved communication. The factor of communication with fellow nurses and health professions has a relationship with the occurrence of patient safety incidents in hospitals<sup>14</sup>.

Communication is essential to workplace efficiency and for the delivery of high quality and safe work. It provides knowledge, institutes relationships, establishes predictable behavior patterns and is vital for leadership and team coordination<sup>15</sup>. Specific communication tools have proven successful at improving communication among care providers<sup>16</sup>.

Educational resources are developed for care providers and patients and their families to increase awareness of patient safety issues and communication strategies<sup>17</sup>. The findings suggest that team members were able to clearly articulate the communication challenges that potentially led to patient safety issues and perceived that their team collaboration had been enhanced. Participants on this research recognized that communication was improved by ensuring that staff, patients, and families had relevant information and resources. This research suggests that healthcare teams can benefit from identification of their strengths and challenges and that educational interventions can raise awareness of patient safety issues that may reduce the number of near misses and adverse events for patients.

In safety-critical industries, pre-task briefing is regarded as extremely important as the implementation of communication principle in the workplace and this is now being introduced more rigorously in healthcare. This may identify agreed protocols that are intended to alert team members to changing conditions or other important information<sup>18</sup> comprehension of their meaning and projection of their status in the near future has been associated with human performance in high-risk environments, including aviation and the operating room. The influences on SA in inpatient medicine are unknown., METHODS: We conducted seven focus groups with nurses, respiratory therapists and resident physicians using a standardised semistructured focus group guide to promote discussion. Recordings of the focus groups were transcribed verbatim, and transcripts were qualitatively analysed by two independent reviewers to identify convergent and divergent themes., RESULTS: Three themes emerged: <sup>(1)</sup>. There are a number of briefing tools for healthcare, such as the WHO Surgical Safety checklist to be used with an operating team prior to a surgical procedure<sup>19</sup> with an estimated 234 million operations performed yearly. Surgical complications are common and often preventable. We hypothesized that a program to implement a 19-item surgical safety checklist designed to improve team communication and consistency of care would reduce

complications and deaths associated with surgery. Method: Between October 2007 and September 2008, eight hospitals in eight cities (Toronto, Canada; New Delhi, India; Amman, Jordan; Auckland, New Zealand; Manila, Philippines; Ifakara, Tanzania; London, England; and Seattle, Wa- Creating opportunities for all team members to speak up and exchange information is an important element of the briefing.

The SBAR (Situation, Background, Assessment, Recommendation) is another communication tool, SBAR (Situation, Background, Assessment, and Recommendation) is a structured communication tool that standardizes communication between health professionals<sup>20</sup>. It can be especially effective when a nurse is contacting a physician with a concern about a change in patient status. By clearly spelling out his or her concerns, observations, interpretation, and recommendations, the nurse using SBAR provides the physician with a more complete picture of the clinical situation than might be the case without the tool. In this way, the use of SBAR can prevent the scenario in which the physician underestimates the significance of a clinical finding conveyed via telephone.

Thus, it can be said that when nurse communication related to the patient safety related to the particular type of clinical administration, the nurse can do the expected effective communication to support the implementation of the patient safety program at the hospital. Similarly, it is expected that the nurse can do effective communication between fellow nurses and health professions involving in the implementation of patient safety programs. If nurses do effective communication related to patient safety in particular types of clinical administration, it will reduce the risk of patient safety incidents and ease the process of problem identification in case of patient safety incidents. Therefore, every nurse feels the need to improve communication skill and understanding the importance of communication in the implementation of patient safety programs through the following activities or specific training that can add communication skills related to patient safety.

## Conclusion

Based on the results and discussion, it can be concluded that communication between fellow nurses and health professions that are involved in the implementation of patient safety programs at inpatient rooms tend to have relationships with patient safety

incidents type of clinical administration in inpatient installation of RSUD Haji Surabaya. The problem of ineffective nurse communication is both common and complex. The strategies are needed to improve ineffective communication between nurses and physicians including culture change, use of structured communication tools, and supportive technology. It is advised that the management of the RSUD Haji Surabaya should hold socialization or seminars on effective communication techniques for all health care personnel especially nurses who directly interact with patients and other medical personnel, so that the ability of nurses in conducting communication with fellow nurses as well as between the professions related to patient safety could be done more effectively. In addition, it is advised that head room should apply the task debriefing to improve patient safety. Successful debriefing is achieved by identifying aspects of good performance, identifying areas for improvement, and suggesting what should be done differently in future. Reward system and appreciation are also important things to give to nurses who have been implementing a patient safety program that will increase the motivation of other nurses in implementing patient safety program.

# Nurse Compliance in Implementing Standard Precaution Based on Theory of Planned Behavior

Nadhif Alfia Charista Kusniar<sup>1</sup>, Nyoman Anita Damayanti<sup>2</sup>

<sup>1</sup>Student of Bachelor Program, Health Policy and Administration Departement, Faculty of Public Health Universitas Airlangga, <sup>2</sup>Lecturer of Faculty of Public Health Universitas Airlangga

## Abstract

**Background:** Standard Precaution is an activity applied by health care facility staff to reduce the risk of infection due to blood or body fluids that can potentially transmit disease. Survey conducted by RSUD Dr. R. Sosodoro Djatikoesoemo Bojonegoro in January - September 2018 found that the number of nosocomial infections in the inpatient room was 2.82% and from eleven aspects of standard precautions established to prevent it, it turned out that only two aspects were in accordance with the target.

**Objective:** The purpose of this study was to analyse factors related to nurse compliance in applying the standard precaution by nurses at the inpatient installation.

**Method:** This research was carried out by analytic observational approaches. Based on the time, this study included a cross-sectional research design. The independent variable of this study are attitude toward behavior, subjective norms, perceived behavior control and behavioral intention obtained from questionnaires filled out by nurses. While the dependent variable is the compliance of nurses in implementing standard precaution obtained from checklist of observation filled out by researcher.

**Result:** The result of this research are attitude toward behavior has a significance value of 0.001, subjective norm has a significance value of 0.001, perceived behavior control has a significance value of 0.129 and behavioral intention has a significance value of 0.000.

**Conclusion:** The conclusion of this study is factors related to nurse compliance in implementing the standard precaution are attitude toward behavior, subjective norm and behavioral intention. While factor that do not related with nurse compliance in implementing the standard precaution are perceived behavior intention.

**Keywords:** *Compliance, Nurse, Standard Precaution.*

## Introduction

Hospitals are one of the health facilities that have an important role in providing health services and improving the health of the community through the implementation of curative and rehabilitative efforts. In carrying out various types of services, hospitals are required to provide safe, good quality, non-discriminative and effective health services in accordance with hospital service standards. In addition, it is also stipulated that the hospital is obliged to provide health services that prioritize patient safety<sup>1</sup>.

In a ministerial regulation, it is said that there are

six indicators of patient safety that must be carried out by hospital. One of the indicator is a reduction in the risk of infection related to health services<sup>2</sup>. Nosocomial infection is an infection that occurs in patients during hospital care and other health care facilities. It also can be an infection due to work in hospital staff and health workers related to the process of health services in health care facilities<sup>3</sup>.

One of ten patients who are hospitalized will get a nosocomial infection even though most forms of nosocomial infection are preventable<sup>4</sup>. One of the prevention of nosocomial infections in hospitals that must be applied by health workers called standard

precaution. The standard precaution is designed to reduce the risk of patients and health workers being infected with infectious diseases both from known and unknown sources of infection<sup>3</sup>.

Developing countries have a risk of infection from poor health services as much as 2-6 times than a high income country<sup>5</sup>. Research conducted at 10 educational hospitals in Indonesia stated that in 2010 nosocomial infections occurred were quite high at 6-16%. From the various studies, it was found that nosocomial infections happened because of health workers did not implement standard precaution optimally<sup>6</sup>.

RSUD Dr. R. Sosodoro Djatikoesoemo Bojonegoro is a non-educational type B hospital that was established in 1928. The incidence of nosocomial infection is one of the important problems for RSUD Dr. R. Sosodoro Djatikoesoemo Bojonegoro. Occurrence of nosocomial infections in 2018 is 2.82%, which means exceeding the target <0.50%. Meanwhile through infection report it is also known that the application of the standard precaution is not optimal. From the eleven aspects determined, only two aspects have been carried out optimally<sup>7</sup>.

Behavior to do a compliance is influenced by behavioral intention. Several studies on nurse compliance in carrying out nursing care are analyzed through the theory of planned behavior<sup>8-9</sup>. In the theory of planned behavior, it is explored that the determinant of a behavior is behavioral intention. While the intention itself arises because of three aspects, namely attitudes toward a behavior, subjective norms and behavioral control<sup>10</sup>.

Based on the description above, it becomes the consideration for researchers to conduct an analysis of factors related to nurse compliance in applying the standard Precaution by nurses at the Inpatient Installation. This study aims to identify attitudes toward behavior, subjective norms, perceived behavior control, behavioral intention and compliance of standard precaution for nurses in Inpatient Installation.

**Material and Method**

This research was conducted with a quantitative analytic approach based on the objectives and types. The researcher did not provide intervention in the form of treatment to the research subjects so that this study was classified into observational research. Based on the time, this study included a cross-sectional research design. The independent variable in this study is divided into

four, namely attitude toward behavior, subjective norms, perceived behavior control and behavioral intention. While the dependent variable is nurse compliance in applying the standard precaution.

This research was conducted in June 2019 in the inpatient installation of RSUD Dr. R. Sosodoro Djatikoesoemo Bojonegoro. The population in this study were all nurses in the inpatient installation RSUD Dr. R. Sosodoro Djatikoesoemo Bojonegoro which is equal to 121 nurses. Sample calculation was done using simple random sampling technique and a research sample obtained are 54 nurses. Data retrieval is done by using a questionnaire filled out by respondents and observation checklist filled in by researchers. The results of questionnaire and observation will be processed using Chi Square test to analyze the relationship between the independent variables with the dependent variable.

**Result**

**Nurse Compliance in Implementing Standard Precaution:** Nurse compliance in implementing standard precaution obtained by using checklist of observations on some aspect such as hand hygiene, use of personal protective equipment, decontamination, environmental control, waste management, linen management, officer health protection and safe injection practices. From the results of these observations, they are assessed and categorized as follows:

**Table 1: Distribution of Nurse Compliance in Implementing Standard Precaution**

Variable	Category	N	%
Nurse Compli-ance	Complied	32	59,30
	Not Complied	22	40,70
	Total	54	100,00

Table 1 shows that 32 respondents (59.30%) or most of the nurses in inpatient installation RSUD Dr. R. Sosodoro Djatikoesoemo has complied the application of standard precaution.

**Theory of Planned Behavior Component:** Assessment carried out on attitude toward behavior, subjective norms, perceived behavior control and behavioral intention was carried out through questionnaires filled by nurses in the inpatient room. The results of the questionnaire are assessed and categorized as follows:

**Table 2: Distribution of Theory of Planned Behavior Component in nurses**

Variable	Category	n	%
Attitude Toward Behavior	Good	35	64,80
	Less	15	35,20
	Total	54	100,00
Subjective Norm	Good	31	61,10
	Less	21	38,90
	Total	54	100,00
Perceived Behavior Control	Good	20	37,00
	Less	34	63,00
	Total	54	100,00
Behavioral Intention	Good	23	42,60
	Less	31	57,40
	Total	54	100,00

Table 2 explains that most of respondents as many as 35 people (64.80%) have a good attitude toward

behavior in the implementation of standard precaution. In addition, most of the respondents, namely 33 people (61.10%) considered that Subjective Norm related to the application of the standard precaution was good.

On the factors of perceived behavior control it is known that the majority of respondents, 34 people (63.00) have less perceived behavior control in implementing the standard precaution. Besides that, it can also be seen that the majority of respondents, namely 31 people (57.40%) have less behavioral intention to do a standard precaution.

**Factor Related to Nurse Compliance in Implementing Standard Precaution:** Factors related to nurse compliance in implementing standard precautions were obtained through a 2x<sup>2</sup> table Chi Square test and read the Continuity Correction value in table with the following results:

**Table 3: Factor Related to Nurse Compliance in Implementing Standard Precaution**

Variable	Category	Compliance				Total		p value
		Comply		Not Comply		N	%	
		n	%	N	%			
Attitude toward behavior	Good	27	77,10	8	22,90	35	100,00	0,001
	Less	5	26,30	14	73,70	19	100,00	
Subjective Norm	Good	26	78,80	7	21,20	33	100,00	0,001
	Less	6	28,60	15	71,40	21	100,00	
Perceived Behavior Control	Good	15	75,00	5	25,00	20	100,00	0,129
	Less	17	50,00	17	50,00	34	100,00	
Behavioral Intention	Good	21	91,30	2	8,70	23	100,00	0,000
	Less	11	35,30	20	64,50	31	100,00	

Through the results of the tests conducted, it can be seen that attitude toward behavior has a significance value of 0.001. Then it can be said that attitude toward behavior related with nurse compliance in applying the standar precaution. Table 3 also explains that the subjective norm test shows a significance value of 0.001. This value indicates that there is a relationship between subjective norms and nurse compliance in applying standard precaution.

Besides the results of the tests conducted, it can be seen that the perceived behavior control has a significance value of 0.129. Then it can be said that there is no relationship between perceived behavior control and nurse compliance in implementing the standard

precaution. Table 3 also explains that the behavioral intention statistical test shows a significance value of 0,000. This value shows that behavaioral intention related with nurse compliance in implementing standard precaution.

**Discussion**

**Attitude Toward Behavior with Nurse Compliance in Implementing Standard Precaution:** Attitude toward behavior interpreted as a level of negative or positive feeling or opinion about certain behavior by individual. When an individual feel that a certain behavior have a positive impact on them self, they will do the behavior. And when an individual feel

that a certain behavior have a negative impact, he will not do the behavior<sup>10</sup>.

The results in this study showed that there is a relationship between attitude toward behavior with nurse compliance in applying standard precaution. From this study, nurse who see each other or their chief in inpatient installation implementing standard precaution assuming that they are a good role model. If they also did it, it has a good impact on their image and their safety too.

The other study that accordance with this study stated that nurses who have a good attitude toward behavior will be more motivated to implement standard precaution indicates by supporting or approving a certain kind of behavior. It is because the behavior will give a protection especially on patient and also the nurses<sup>11</sup>.

**Subjective Norm with Nurse Compliance in Implementing Standard Precaution:** Subjective norms are individual views of beliefs and expectations that come from other people around them and can influence the desire to behave or not<sup>10</sup>. The results of this study showed the same thing, there was a relationship between subjective norms and nurse compliance to applying the standard precaution.

The results of this study indicate that the more subjective norms felt by nurses so that they conduct standard precaution, will encourage nurses to produce high compliance. The subjective norm can be the head of the room which is the role model and the other nurses that carry out prevention of infection. The existence of hospital policies that make nurses conduct standard precaution is also an example of subjective norm.

The results of this study are in accordance with the other study which stated that subjective norms can influence to comply to a certain nurse caring procedure. Due to the existence of role models that apply standard precaution, the expectations of surrounding people to carry out standard precaution as well as a specific policies governing standard precaution, will make the nurse encourage to display high compliance<sup>12</sup>.

**Perceived Behavior Control with Nurse Compliance in Implementing Standard Precaution:** Perceived behavioral control or perception of behavior control consists of two aspects, namely how much an individual has control to behave and how strong the individual's beliefs are not to behave. People who have confidence that they do not have the opportunity factors

to carry out a behavior, allow the intentions formed are not strong even though the attitude they have is positive for a behavior<sup>10</sup>.

The results of statistical tests in this study shows that there is no relationship between perceived behavior control and the application of the standard precaution. From this study, obstacles related to the implementation of standard precaution did not prevent nurses from continuing to implement standard precaution. This is because if there are obstacles, but the nurse feels that they can handle it easily, then the implementation of standard precaution still continues. Meanwhile, if nurses have obtained the convenience and benefits of implementing standard precaution but they did not used it properly, the implementation will be low.

There is a study that show different results which states that perceived behavior control can influence nurses to comply with standard precaution procedures. This is because nurses feel facilitated, only have a few obstacles and have obstacles that can be anticipated when they want to implementing standard precaution. So that their control in carrying out the standard precaution procedure is high<sup>11</sup>.

**Behavioral Intention with Nurse Compliance in Implementing Standard Precaution;** Behavioral intention is a cognitive and conative representation of an individual's readiness to display a behavior. Intention is the determinant and disposition of behavior, so that individuals have the right opportunity and time to display the behavior in real terms. In general, if the individual has the intention to do a behavior, the individual tends to do the behavior. Conversely, if individuals do not have the intention to do a behavior then individuals tend not to do the behavior<sup>10</sup>.

The results of statistical tests show that there is a relationship between behavioral intention and nurses' compliance to applying the standard precaution. This is because the harder the intention of the individual to be involved in a behavior, the stronger the tendency of the individual to actually do the behavior.

This research is also same with the study which shows the relationship between intention and safety behavior. This is because intention to do a behavior is a large individual control contribution that that will convert a willingness to do a certain behavior to become a real behavior<sup>13</sup>.

## Conclusion

The conclusion of this study is that most nurses have complied to the implementation of the standard precaution. The majority of nurses have a good attitudes toward behaviors, good subjective norms, less perceived behavioral control and less behavioral intention. Suggestions that can be given to nurses at RSUD Dr. R. Sosodoro Djatikoesoemo is by encouraged each other to implement standard precaution and grow their awareness that standard precaution is a good thing to implement and the responsibility must be carried out by all health workers in the hospital. Hospital management can make a detail standard operating procedures as guidelines for nurses in implementing standard precautions. In addition, hospital management can also monitor and evaluate the obstacles that occur during the process of applying standard precautions such as availability of facilities and lack of training. So that the application of the standard precaution can run optimally and can reduce the incidence of nosocomial infections in hospitals.

# Assessing Depression among Students in Malaysia

Nor Shafrin Ahmad<sup>1</sup>, Ahmad Zamri Khairani<sup>2</sup>, Aziah Ismail<sup>1</sup>, Rahimi Che Aman<sup>1</sup>

<sup>1</sup>Associate Professor, <sup>2</sup>Senior Lecturer School of Educational Studies, Universiti Sains Malaysia, Malaysia

## Abstract

**Context:** The main goal of this study is to assess depression symptoms and resilience among students in Malaysia. This study administered The Beck Depression Inventory II (BDI-II) and Resilience Scale 14 (RS-14) to 560 students from five secondary schools. Descriptive statistics were employed to calibrate the symptoms of depression according to their severity. Meanwhile, independent sample t-tests and one-way ANOVA were employed to examine differences in gender, school locations and ethnicity on depression. Pearson correlation was used to examine the relationship between resilience and depression among students. Results showed that feeling guilty was the most severe depression symptoms followed by self-accusation and punishment. In contrast, weight loss and suicidal ideation were the two least endorsed symptoms of depression by the students. The study reported significant differences in the mean score of depression between gender and no significant difference in the depression scores in terms of locations and ethnicity. The results also reported a low negative correlation between depression and resilience ( $r = -.219$ ). Symptoms of guilt, self-accusation and punishment are common among depressed students who had lower resilience.

**Keywords:** *Depression, resilience, students, gender*

## Introduction

Mental health is defined as the promotion of positive physical, mental and social well-being.<sup>33</sup> It includes the ability to accept others and to have positive attitudes towards oneself.<sup>14</sup> Mental health is an important aspect of students' development. According to<sup>21</sup>, mental health has implications on students' self-esteem, behaviour, attendance at school, as well as educational achievement. However a prolonged state of mental health problems could also cause students to become withdrawn and develop the inclination to commit suicide. Common symptoms of mental health include anxiety, depression as well as substance abuse. This study will focus on assessing depression among students in Malaysia. A depressed person without proper intervention will create the most massive burden to the sufferers. <sup>2</sup> suggested that major depressive disorder is a common and serious

medical illness that adversely affects how an individual feel, think and act.

Research by <sup>15</sup> showed that depression is the most common illness reported in Malaysia. It is claimed by the 2008 National Suicide Registry Malaysia annual report that 31% of those who committed suicide were depressed.<sup>16</sup> Depressive disorders were ranked as the third leading cause of global burden diseases in 2004 and will move into first place by 2030.<sup>32</sup> According to <sup>12</sup>, the study on 1412 selected students, the prevalence of depression was found to be 49.2%, while the prevalence of severe depression was 7.7%. The overall prevalence of depression was significantly ( $p < 0.001$ ) higher among females (55.1%) than males (45.8%). Feeling of guilt (69.48%) was one of the most prominent clinical factors associated with depression, followed by pessimism (58.14%), sadness (56.52%), and past failures (55.81%). A previous study from <sup>22</sup> among adolescents also showed a large number of females having cognitive thoughts that prevented their recovery from depression, while the males adjusted much better.

According to <sup>4</sup>, depression if left untreated among children and adolescents may lead to failure in school, conduct disorder and delinquency, anorexia and

e-mail: sham@usm.my

bulimia, school phobia, panic attacks, substance abuse, or even suicide. Depression can also create academic, disciplinary and social problems among children and adolescents.

Resilience is one of the elements that can help students to recover and bounce back while they suffer from difficulties. The inner resilience of the students plays a fundamental role in reducing depression.<sup>5,6</sup> According to<sup>17</sup>, resilience is relevant to life satisfaction among students, and it will improve the subjective quality of life and a positive perception of the educational environment. According to<sup>28</sup>, resilience is a psychological process developed in response to intense life stressors and resilience facilitates healthy functioning. Thus, resilience connotes inner strength, competence, optimism, flexibility, and the ability to cope effectively when faced with adversity. The decrease in the level of resilience is often accompanied by an increased level of depressive symptoms.<sup>27</sup> Therefore, students need to be resilient for depression to be reduced. It is in line with the study conducted by<sup>9</sup> that a higher level of resilience is associated with a lower level of psychological distress and facilitates healthy functioning.<sup>28</sup>

### Material & Method

**Sample:** The sample consisted of 560 students from five secondary schools (male = 257, female = 303). The age mode for the sample is 16 years old. The sample ethnicity consisted of 437 Malays (78.0%), 67 Indians (12.0%) and 56 Chinese (10.0%) students. Three hundred fifty-four students (63.2%) were from schools located in the urban area, whereas 206 students (36.8%) were from rural schools.

**Instrument:** To measure intensity and severity of depression, the authors adapted the Beck Depression Inventory II (BDI-II). The 21 symptoms measured by BDI-II.<sup>26</sup> Nevertheless, in this study, the last item (loss of libido) was excluded from the instrument since based on the pilot test conducted, students were not comfortable to be asked such question. The reliability coefficient (Cronbach’s alpha) for the BDI was .824 (N = 20). The higher depression score indicating greater symptom severity.

The Resilience Scale 14 (RS-14) has been used to measure students’ resilience. It is a valid and reliable instrument to measure resilience, demonstrates the brevity, readability, and ease of scoring when selecting instruments for use with adolescents.<sup>19</sup> There liability

coefficient for RS-14 was .704. The higher scores in the scale are indicative of higher resilience level.

**Data Analysis:** Descriptive statistics, namely the mean and standard deviation, were reported to provide a summary of the information as well as the variation for each item. The depression symptoms were also calibrated in terms of severity based on the mean scores. An independent sample t-test was employed to investigate the differences in depression between gender and school locations. All the tests were conducted at p = .05 level. In addition, a correlation study was conducted between depression and resilience.

**Findings:** Feelingguilt is the most severe symptoms of depression (mean = 1.21, SD = 0.71) followed by self-accusation (mean = .92, SD = 1.01) and feeling of being punished (mean = .84, SD = 0.82). Meanwhile, the three least severe symptoms of depression are weight loss (mean = .28, SD = 0.66), suicidal ideas (mean = .37, SD = 0.66) and loss of appetite (mean = .37, SD = 0.72). Meanwhile, the Malaysian sample does not endorse insomnia even though it has been reported as the most severe symptom for Korean<sup>8</sup> as well as Iranian<sup>30</sup> sample of students.

**Table 1: Descriptive statistics of the BDI items**

Symptom	Mean ± SD
D5: guilt	1.21 ± 0.71
D8: self-accusation	.92 ± 1.01
D6: punishment	.84 ± 0.92
D10: crying	.75 ± 1.13
D15: work difficulty	.74 ± 0.73
D3: sense of failure	.73 ± 0.89
D17: fatigability	.69 ± 0.78
D11: irritability	.67 ± 1.00
D1: mood	.66 ± 0.79
D20: somatic preoccupation	.62 ± 0.78
D4: self-dissatisfaction	.60 ± 0.81
D14: body image change	.59 ± 1.00
D7: self-dislike	.59 ± 0.72
D13: indecisiveness	.55 ± 0.89
D12: social withdrawal	.54 ± 0.83
D2: pessimism	.53 ± 0.80
D16: insomnia	.48 ± 0.82
D18: loss of appetite	.37 ± 0.72
D9: suicidal ideas	.37 ± 0.66
D19: weight loss	.28 ± 0.66

In Table 2 shows that the mean score of the female ( $33.76 \pm 8.12$ ) is significantly higher than male students ( $31.49 \pm 7.85$ ),  $t(558) = 3.343$ ,  $p = .001$ . Meanwhile, there is no significant difference in the mean score of depression between students from the urban ( $32.66 \pm 7.72$ ), and those from the rural schools ( $32.83 \pm 8.79$ ),  $t(558) = 0.227$ ,  $p = .828$  as depicted in Table 3. The results from the ANOVA report no significant difference between the ethnic groups [ $F(2, 557) = 1.156$ ,  $p = .315$ ].

**Table 2. Results between gender and location of the sample**

Demographic	Mean ± SD	T	p
<b>Gender</b>			
Male	31.49 ± 7.85	-3.343	.001
Female	33.76 ± 8.12		
<b>Location</b>			
Urban	32.66 ± 7.72	-.227	.828
Rural	32.83 ± 8.79		

**Table 3. Results for the Effect of Ethnicity on Depression**

	Sum of Squares	df	Mean Square	F	Sig
Between Groups	150.697	2	75.348	1.156	.315
Within Groups	36300.735	557	65.172		
Total	36451.421	559			

Results also reported a low negative correlation between depression and resilience ( $r = -.219$ ).

### Conclusion

Results indicate that feeling guilty is the most severe symptom of depression among students, followed by self-accusation and feeling of being punished. Guilt involves feeling of regret, as well as being critical or judgmental toward themselves. Feeling guilty can lead to problems like low self-esteem that may affect students' academic achievement.<sup>1</sup> Feeling guilty will push students into a deeper and hopeless frame of thoughts. This cognitive distortion will lead to negative consequences for students' emotions and behavior. It can lead to self-blame. Excessive self-blaming will contribute to people developing negative emotions and it can be an independent risk factor in addition to having depressive symptoms. However, a study from<sup>24</sup> stated that self-blaming can function as the consequences of depression rather than causing it.

The feeling of guilt can also cause self-accusation and students tend to blame themselves for whatever failures. Another important symptom of depression among Malaysian students is the feeling of being punished. Self-accusation will lead the students to view him or herself negatively. Consistently feeling bad and negative self-esteem will lead the person to have a depressive symptom.<sup>34</sup>

Results showed that female students demonstrated higher mean score compared to males. This is consistent with many other studies documented in the literature<sup>3,7</sup>, even though it does not replicate the findings from several other local studies.<sup>10,35</sup> One possible explanation for this finding can be attributed to the constant changes in hormones, especially during puberty. In addition, premenstrual problems can also increase depression syndromes such as irritability and loss of appetite. Females also engage in more negative events and emotions.<sup>29</sup> Compared to males, females have displayed significantly higher negative cognitive distortion.<sup>36</sup> The findings are supported by Beck's theory that a person who has cognitive distortions will contribute to their negative perceptions and will view their life as hopeless.<sup>36</sup> In contrast, the male students are likely to act, by expressing anger, rather than thinking too much about the situations.

Results show that no significant difference in the mean score of depression between school locations. This is consistent as reported by.<sup>20</sup> However it contrasts from study by<sup>11</sup>.

Ethnicity is another important demographic variable even the findings are contradictory. For example,<sup>23</sup> found that the prevalence of major depressive disorder was significantly higher in whites than in African Americans and Mexican Americans. However, the finding contradicted earlier findings such as studies conducted by.<sup>25</sup> In Malaysia, the trends are similar. A study by<sup>13</sup> revealed that the Indian descendants demonstrate the highest prevalence of depression compared to other major ethnicities such as the Chinese and the Malays. This contradicts studies conducted by<sup>11,20</sup> that reported the Chinese ethnic group as having the highest depression scores. This study is essential since ethnicity is important in a country of multi-ethnicity like Malaysia.

The results also show a low negative correlation between depression and resilience. It was supported

by.<sup>18</sup> They pointed out that adolescent who has a high level of resilience will experience a low level of emotion or behavioral problem.

Depression among students is common but mostly unrecognized. Most teachers lack of knowledge to identify symptoms of depression and not aware that depression has a significant effect on academic performance. This is where schools play a critical role since schools have long-term access to the students, particularly at critical periods of their development. Delivering appropriate interventions, especially elements of resilience will help students to overcome the symptoms at an early stage and thus preventing the symptoms worsening.

# Relationship Between Age of Exposure and Media to Pornographic Exposure to Adolescents in Gorontalo City, Indonesia

Nour Arriza Dwi Melani<sup>1</sup>, Irwanto<sup>2</sup>, Ira Nurmala<sup>3</sup>

<sup>1</sup>Student Master of Public Health at Airlangga University Surabaya, Indonesia, <sup>2</sup>Department of Child Health, Faculty of Medicine, Airlangga University Surabaya, Indonesia, <sup>3</sup>Departement of Health Promotion and Behavioral Sciences, Faculty of Public Health, Airlangga University Surabaya, Indonesia

## Abstract

**Context:** Pornography is a variety of communication media that contain elements of obscenity that are perceived as violating the norms of decency in society. Adolescents in the area of DKI Jakarta and Pandeglang have been exposed to pornography by 96.7%. Globalization and the development of science and technology, especially in the field of information and communication, has become one of the parts in the creation, dissemination, abuse and development of pornographic media. This study aims to determine the relationship between age of exposure and media with exposure to pornography in adolescents in Gorontalo City, Indonesian. This study uses primary data obtained from the standard questionnaire, namely the early detection pornography exposure questionnaire (family health directorate, Ministry of Health of the Republic of Indonesia) which is filled by respondents aged 15-17 years. Analysis shows that exposure age (p value = 0,000) and media (p value = 0,000) are related to exposure to pornography. Age of exposure and media can explain 72.2% for exposure to pornography. need to involve gender, peers, relationship status, and family to see other factors related to exposure to pornography.

**Keyword:** *Pornography, adolescent, exposure, media*

## Introduction

Various statistical evidence shows the exposure and access of children, pre-teens and adolescents to pornography. Reported that 90% of children (from ages 8 to 16 years) claimed to have seen pornography on the Internet.<sup>(1)</sup> Internationally, between 75% and 90% of teenagers living in developed countries have seen pornography on the Internet before they were 18 years old.<sup>(2)</sup> According to a screening survey conducted by the Indonesian Demographic and Health Survey in 2017, it shows that adolescents aged 15-19 years, as many as 61.36% have held hands with girlfriends,

hugged with boyfriends as much as 16.07%, kissed as many as 29.61%, fingering/ feeling boyfriend as much as 8.77% and having premarital sexual relations as much as 2.34% and as many as 96.7% of adolescents in the area of DKI Jakarta and Pandeglang have been exposed to pornography and experience pornography addiction by 3.7%.<sup>(3)</sup>

Free association of adolescents in the Gorontalo city environment results in an increase in the number of child marriages and the number of people with HIV (Human Immunodeficiency Virus). According to data on underage marriage events in the Gorontalo provincial ministry's regional office in 2018, Gorontalo city ranks third most underage marriages with 89 underage children from 356 cases.<sup>(4)</sup> The high level of marriage in young age is influenced by several factors, namely the failure of the quality of education owned by the community, religious factors and encouragement from parents, and economic factors. Even more worrying, the factor of

e-mail: irwanto@fk.unair.ac.id;

early marriage is caused by pregnancy before marriage. Reported of 356 cases, 70% of cases were caused by prenatal pregnancy. Pornography is one of the causes of rape.

In Indonesia, there is a legal basis and action on pornography, namely Law Number 44 of 2008, which states that pornography is a picture, sketch, illustration, photo, writing, sound, sound, moving image, animation, cartoon, conversation, motion body, or other forms of message through various forms of communication media and / or performances in public, which contain sexual obscenity or exploitation that violates the norms of decency in society.<sup>(5)</sup>

The internet is a space with a wider range of information. Various information can be obtained easily via the internet. The topics of information presented are varied, so that one of the sources of information that is popular with the public is the internet. This is offset by increasing internet users too, so information providers are increasingly interested and incentive to disseminate their information via the internet. The positive impact obtained from internet use is very abundant, but the negative impact is also not less numerous and destructive in nature. One of the most troubling effects is pornography. This impact can slowly damage some aspects of the individual who consumes it.

The scope of the causes of exposure to pornography is still very broad. Based on the description of the background, this study aims to determine the relationship between age of exposure and media with exposure to pornography in adolescents in Gorontalo City, Indonesia.

### Method

This study used a pornography early detection questionnaire by the directorate of family health, Ministry of Health of the Republic of Indonesia. The sample used is adolescents aged 15-17 years in the city of Gorontalo. This type of research is observational analytic using cross sectional design. The research variables are exposure to pornography, age of exposure and. Data analysis was carried out using nonparametric statistical test namely chi square and multivariable logistic regression analysis using SPSS.

### Results

Gorontalo City is the capital of Gorontalo Province, Indonesia. Gorontalo City has an area of 66.25 km<sup>2</sup> (0.55% of the total area of Gorontalo Province). High school students in Gorontalo City number 6099 students. The sample used in the study amounted to 350 respondents from the total sample taken as many as 400 respondents, because 50 respondents did not meet the sample criteria in the study. This figure exceeds the minimum sample that must be used for 348 samples based on the calculation of the 1997 Lameshow formula.

Table 1 shows the respondents aged <12 years old have the highest presetase of exposure to pornography which is equal to 100%, respondents aged 12-15 years old have the highest presetase exposed to pornography that is equal to 99.5% and respondents aged 16-18 years old have the highest presetase exposed to pornography namely 93.3%. Overall the age of exposure is significantly related to pornography exposure based on the calculation of p value <0.05.

**Table 1: Age of Exposure to Exposure to Porno graphy to Adolescents in Gorontalo City**

Age of Exposure	Pornography exposure				Total		P Value
	Exposed		Not Exposed		n	%	
	n	%	n	%			
<12 years old	42	100	0	0	42	100	0.000
12-15 years old	205	99.5	1	0.5	206	100	
16-18 years old	83	93.3	6	6.7	89	100	
Never seen	0	0	13	100	13	100	

Table 2 shows the internet sites have the highest percentage of exposure to pornography which is equal to 98.6%, social media has the highest presetase exposed to pornography that is equal to 98.4%, print media has the highest presetase exposed to pornography which is

97.1% and electronic media has the highest presetase of exposure to pornography at 97%. Overall, the media used by teenagers to access pornography is significantly related to pornography exposure based on the calculation of p value <0.05.

**Table 2: Media used by Teenagers to Access Pornography on Exposure to Pornography to Adolescents in Gorontalo City**

Media	Pornography exposure				Total		P Value
	Exposed		Exposed				
	n	%	n	%	n	%	
Never seen	0	0	14	100	14	100	0.000
Print media	33	97.1	1	2.9	34	100	
Internet site	142	98.6	2	1.4	144	100	
Social media	123	98.4	2	1.6	125	100	
Electronic media	32	97	1	3	33	100	

Table 3 shows the R2 value of 0.722, which means that the ability of the independent variable to influence is the percentage of age exposed and the media to explain the amount of variation in the dependent variable, namely exposure to pornography at 72.2%, while the remaining 27.8% is explained by other variables that are not included in the variables studied.

**Table 3: Coefficient of determination pornography exposure test results**

Model	R	R Square
1	0,256	0,722

**Discussion**

The younger the age of exposure, the more often the person will often do it later on. This is because each individual experiences a period of development from year to year.

The results of statistical tests show that the age of exposure is significantly associated with exposure to pornography. The age range that is most exposed to first time when 12-15 years old is when the respondent is in the initial phase of puberty. This is consistent with research conducted by Weber (2012) that exposure to pornography was first related to child development, because children do not have maturity and sexual experience in real life, so they are very vulnerable to the internalization of portrayals of human sexuality.<sup>(6)</sup> Other studies show that the age at which pornography is exposed is related to sexuality in adulthood.<sup>(7)</sup>

The study also found that respondents were first exposed to pornographic material in the form of videos through internet sites. Most of them see pornographic material at home inadvertently with their peers.

Mass media is a tool used to convey messages from

sources to recipients using communication tools. The development of information systems and technology has led to more and more alternative mass media owned by the community. Directly or indirectly, the media is one place for the dissemination of pornographic material.

The results of the statistical test of this study indicate a significant relationship between the media used by teenagers to access pornography and exposure to pornography. Most respondents stated that they access pornographic material through social media that they access from the bedroom. This research is in line with the research conducted by Heidari (2012) who argues that sexual content circulating in the mass media will cause sexual deviations in adolescents.<sup>(8)</sup> Mass media shows that highlight aspects of pornography are believed to be very closely related to the increasing number of cases of sexual violence that occur in adolescents.

Strong stimuli from the outside in the form of sex films, soap operas, reading books and magazines with sexy images, and direct observation of sexual acts not only lead to peak sexual desire but also result in faster sexual maturity in children.<sup>(9)</sup>

Addiction to pornography can not only cause chemical changes in the brain but can cause anatomical and pathological changes that cause hypofrontal syndrome. Excessive consumption of pornography will cause consequences on the social life of adolescents. Other negative consequences may be the same as sexual addiction, thus affecting his personal life.<sup>(10, 11, 12)</sup>

Pornography is a visual representation of sexuality that is inadequate, causing an individual to have the wrong concept of a person’s sexual relationship with a sexual object that will slowly cause a change in a person’s sexual attitude and behavior. Some cases show, if someone sees pornography continuously, it will

cause mental problems / disorders especially in terms of sexuality.<sup>(13)</sup>

### Conclusion

The age of exposure and the media is significantly associated with exposure to pornography. The percentage of age exposed and the media is able to explain 72.2 percent for exposure to pornography as 27.8 percent of which are caused by other factors.

**Suggestion:** The cause of exposure to pornography needs to involve gender, peers, courtship status, and families to see other factors related to exposure to pornography..

**Acknowledgements:** On this occasion the author would like to thank the respondents who honestly filled out the questionnaire that had been given.

# Poverty or People Density Affecting Human Development? Panel Data Regression Study

Nuke Amalia<sup>1</sup>, Arief Wibowo<sup>2</sup>, Mahmudah<sup>2</sup>

<sup>1</sup>Student Master of Public Health at Airlangga University Surabaya, Indonesia,

<sup>2</sup>Departement of Biostatistics, Faculty of Public Health, Airlangga University Surabaya, Indonesia

## Abstract

**Context:** The main concept of human development introduced by United Nations Development Programs (UNDP) in 1990 was to create positive growth in long term. Human development index (HDI) is formed by three dimensions, a long and healthy life, knowledge, and a decent standard of living. The purpose of this study to determine the factors affecting HDI in Indonesia in 2012-2016. We use secondary data from free publication of Central Bureau of Statistics or as known as BPS in Indonesia. The datas were from East Java in 2012-2016 with districts/ cities as unit analysis. We analyze the data with panel data regression analysis. The results is poverty significantly affect HDI in East Java, Indonesia ( $p < 0.05$ ). The higher HDI, the smaller percentage of poverty. Policy formulation multidimensionally is needed to reduce poverty.

**Keywords:** *Human development index, poverty, people density*

## Introduction

The end of Millenium Development Goals (MDGs) implemented during the period 2000-2015 has indeed made progress for Indonesia. However, there are many indicators that still have not reached the target and required special attention. Thus, there are some homework that must be completed through this era, it is Sustainable Development Goals (SDGs).<sup>(1)</sup> The United Nations officially adopted the SDGs agenda as a global development agreement on September 25, 2015. The formulation of SDGs consist of three main pillars, Human Development, Social Economic Development, and Environmental Development. Human development can be achieved if the SDGs is also achieved.<sup>(2,3)</sup> The concept of human development introduced by UNDP in 1990 was to create positive growth in the economics, social, political, cultural, and environmental fields, as well as changes in human welfare. HDI is formed by

three dimensions, a long and healthy life, knowledge, and a decent standard of living. Healthy life measurement is described by life expectancy, is the number of years a newborn baby is expected to live. Knowledge is measured by mean years of schooling and expected years of schooling. Decent standard of living is described by adjusted per capita expenditure, which is determined by the value of expenditure per capita and purchasing power parity.<sup>(2,4)</sup>

In 2017, Indonesia has HDI 0.694 which makes this country ranked 116 out of 189 countries in the version of UNDP report. HDI in Indonesia is still below South African and Egyptian which are both developing countries.<sup>(4)</sup> Indonesia's HDI is also still far behind Southeast Asian countries. Indonesia has 34 provinces divided into several islands. One of the provinces in Indonesia that is proclaiming an increase in human development is East Java on the island of Java. In 2016, East Java had HDI of 69.74.<sup>(2)</sup> It still tends to be low compared to other provinces on one island with East Java.

The research from Qiu (2018) shows that the standard of living dimension contributes more than the other dimension of HDI.<sup>(5)</sup> One of the targets that have not been achieved in the MDGs era is high national

poverty level. Destilunna & Zain (2015) explained that increasing gross regional domestic product (GRDP) micro business, small and medium enterprises tend to be owned by region that has high population density. (6) This shows that population density is not always problems in human development, because people can help in increasing economy. This can increase the level of human development in the area.

Increasing HDI, it is need to analyze some factors that are thought to affect the dimensions of HDI that indirectly affect the HDI itself. There are many factors influencing HDI. Based on the background above, the aim of this study is to determine the factors influencing HDI, especially in East Java, Indonesia.

### Material and Method

This study was conducted in one of the provinces in Indonesia, it is East Java. This research is a non-reactive study because only carries out secondary data from free publication of Central Bureau of Statistics or as known as BPS in East Java, Indonesia. The unit analysis of this study is the districts/ cities with 38 districts/ cities. Analysis data used panel data regression analysis with effect model (FE) approach, which is analysis using

combined data between cross sectional and time series data. (7) Cross sectional data is shown by 38 unit analysis (districts/ cities) and time series data indicated by the number of periods used in this study (2012-2016). The analysis is used to determine the effect of independent variables on the dependent variables. General model from panel data regression analysis with the FE approach is:

$$Y_{it} = \alpha_{it} + \beta'X_{it} + \varepsilon_{it}$$

Where i is individual or cross sectional and t is the time of period.

Dependent variable in this study is the HDI, while the independent variables used are poverty and population density. The poverty in the percentage of poor people who are under poverty. (8) Population density is the average population per one square kilometer in a particular area. (9)

### Results

Poverty in East Java is still fluctuative. It means the percentage of poor people is still up and down in every year. Figure 1 shows the development of poverty from 2012-2016.

Figure 1. Poverty Development in East Java

Population density is increases continously in Indonesia and East Java (Figure 2). The region with the highest population density is Surabaya, considering that it is the capital of East Java.

Figure 2. Population Density in in East Java

Figure 3 shows the development of HDI in East Java from 2012-2016. In that period, most regions in East Java had HDI with moderate category ( $60 \leq IPM < 70$ ). From 38 districts/ cities in East Java, there is area with low category HDI from 2012-2016. It is Sampang.

Figure 3. Human Development Index in East Java

Table 1 shows the statistics descriptive from dependent and independent variables for all districts/ cities in East Java from 2012-2016 (panel data).

Table 1. Overviewed Dependent and Independent Variables

Variabel	Min	Max	Mean	Standard deviation
Human Development	55.78	80.46	68.47	5.45
Poverty	4.33	27.97	12.32	5.08
Pop. Density	277	8606	1824.93	2136.86

In panel data regression analysis there are three approaches to estimate model seen from the type of data, common effect model (CE), fixed effect model (FE), and random effect model (RE). Testing three approaches is needed to choose which estimation technique is the best. First, F-test to choose the best model between CE

or FE model. In the test, the value of cross section F was 0.000 ( $p < 0.05$ ). It means that the FE model is better model than the CE model. Then the Hausman test, to choose the FE model or RE model. In the Hausman test, p-value generated in the cross section random was 0.000 ( $p < 0.05$ ), it means that FE model is better model

than the RE model. Because between two testing model approaches states the FE model is the best model, the study seen is the model produced by FE model approach.

The results of panel data regression analysis with

the FE model are shown in table 2. It can be seen that the poverty is significant to the HDI which has significant value 0.000 ( $p < 0.05$ ). While in this study, the population density did not have significant effect ( $p > 0.05$ ).

**Table 2: Panel Data Regression Analysis**

Model	Coefficient	Std. Error	t-statistics	Prob.
Constant	81.663	1.503	54.339	0.000
Poverty	-1.166	0.107	-10.889	0.000
Population Density	0.001	0.000	1.949	0.053

Simultaneous significance test (F-statistics) is used to see wheter the model produced simultaneously independent variables affect the dependent variable. This study obtained p-value for simultaneous test of 0.000 ( $p < 0.05$ ), it means poverty together has an influence on HDI and has a negative coefficient value.

In table 3 shows the statistical criteria of the model. The resulting coefficient of determination is 0.984, it means that the ability of independent variables simultaneously in explaining the HDI variable is 98.4%. While 1.6% is explained by other variables that not included in this study.

**Table 3: HDI Determiation Coefficient Test Results**

Model	R-Squared	Adjusted Squared	R-	Std. error
1	0.984	0.980		0.774

So, the model formed is The value of coefficient is 81.663. If the independent variable constant, HDI at this time is 81.663.

### Discussion

The measurement of human development that has been made, not all can be used as a standard measurement, can be compared with regions or countries. Achievement of human development in Indonesia, especially in East Java is higher in the cities area than to districts area. It can bring about HDI gap problems in several regions. Human development itself is actually closely related to the objectives of SDGs. Achievement of HDI value will determine the order among regions. But the the success of human development is not absolutely depend on rank or position.<sup>(10)</sup>

The success of human development can be seen from how much the basic problems in society, such as poverty. According to the World Bank, poverty is a lack of welfare, so to measure it can use welfare indicators like income or consumption per capita (Leasiwal, 2013).<sup>(9)</sup> Poverty can reduce economic value due to limited resources. Poverty reduction policies really need to be don in a multidimensional manner.

The poverty factor shows a negative correlation with HDI in this study (-1.166). When poverty in an area decreases one percent, it can increases the rate of HDI level by 1.166. It is compatible with the research conducted by Patta (2012) in using multiple linear regression analysis which shows that the percentage of poor people affect the HDI.<sup>(10)</sup> Poverty is related to economic, social, cultural, environmental, health, education, social political, and ethical dimensions that can affect development in an area. The formulation of poverty alleviation policies really needs to be done in multidimensional manner.

### Conclusion

In conclusion, factor affecting human development in Indonesia, especially East Java Province in 2012-2016, is poverty. The smaller percentage of poverty, the higher HDI.

**Suggestion:** HDI is a measurement of development in countries involves many sectors. Thus, an analysis of factors affecting HDI is expected in several dimensions such as health, education, economics, etc.

**Acknowledgements:** On this occasion the author would like to thank the Central Bureau of Statistics, especially in East Java Province, Indonesia

# Effect of Low Density Lipoprotein (LDL) to High Density Lipoprotein (HDL) Ratio with Stroke in Adults in Bogor City

Nur Fadhilah Sari<sup>1</sup>, Bambang Sutrisna<sup>2</sup>

<sup>1</sup>Masters Program in Epidemiology, Faculty of Public Health, University of Indonesia,

<sup>2</sup>Department of Epidemiology Faculty of Public Health University of Indonesia

## Abstract

**Context:** Stroke is one of the main causes of death and neurological disability in Indonesia. Stroke is a cerebrovascular disease which increases in number every year. This study aims to determine the effect of the ratio of Low Density Lipoprotein (LDL) to High Density Lipoprotein (HDL) with the incidence of stroke in the adult population. This study used data from the PTM (non-communicable disease) cohort study in 2011. The sample in this study was adult population (25-65) years who were respondents to the PTM cohort study in Bogor in 2011 which numbered 1506 and analyzed using regression tests. logistics with statistical significance are seen based on 95% confidence intervals. Sample prevalence in adult population in the city of Bogor who suffered a stroke of 1.26%, respondents with a high ratio of LDL to HDL were 35.66%. Respondents with a age of sebesar46 years were 34.26% with the highest prevalence of sex in women amounting to 53.45% and those with low education were 54.58%, respondents who were obese were 27.42%, respondents with high total cholesterol levels were 38, 45% and respondents with high triglyceride levels of 17.07%. The results showed that there was a significant relationship between the ratio of LDL to HDL and the incidence of stroke with an adjusted prevalence odds ratio of 3.909 (95% CI 1.346-11.354). The high ratio of LDL to HDL is at risk for the incidence of stroke in the adult population.

**Keywords:** Stroke, LDL to HDL ratio, Logistic Regression.

## Introduction

Non-communicable diseases are a leading cause of death globally. WHO data shows that of the 57 million deaths in the world in 2008 as many as 26 million were caused by non-communicable diseases (PTM). In countries with low and middle economic levels, 29% of deaths occur in people aged less than 60 years and are caused by PTM. While in developed countries as much as 13% which causes death.<sup>1</sup>

Cardiovascular disease is a disease caused by a malfunction of the heart and blood vessels. Cardiovascular disease that we often know is heart disease and stroke. Stroke occurs due to a blockage of blood supply to the brain which can occur due to a ruptured or blocked blood vessel. This results in a breakdown of the supply of oxygen and nutrients to the brain which then damages brain tissue.<sup>2</sup> Cardiovascular and metabolic diseases are caused by several multifactors whose risk factors can be modified. One of the causes that can be modified

is dyslipidemia which triggers the occurrence of these diseases.<sup>3</sup>

According to the *American Heart Association* (AHA), the death rate of stroke patients in America each year is 50-100 of 100,000 sufferers.<sup>4</sup> The *American Heart Association* estimates that every year the incidence of stroke is approximately 795,000 Americans, both new strokes and recurrent strokes. About 610,000 are new strokes or first attack strokes and 185,000 recurrent stroke. While overall stroke prevalence is estimated at around 2.7%.<sup>5</sup> In the United Kingdom there are more than 100,000 stroke patients each year. There are more than 1.2 million stroke sufferers in the United Kingdom.<sup>6</sup>

Results of data from the Basic Health Research (Riskesmas) in 2007, stroke was the leading cause of death in Indonesia, with an incidence of 8.3 per 1,000 population and then increased to 12.1 per 1,000 population in 2013. This figure rose compared to the 2007 National Health Survey. Prevalence Stroke

based on diagnosis of health care was highest in North Sulawesi (10.8 %), followed by DI Yogyakarta (10.3 %), Bangka Belitung and DKI Jakarta respectively 9.7 per 1000 inhabitants. The prevalence of stroke based on diagnosed health care and symptoms is highest in South Sulawesi at (17.9%), DI Yogyakarta at (16.9 dan) and followed by Central Sulawesi at (16.6%) and East Java at 16 per mile.<sup>7</sup>

Dyslipidemia is a disorder of lipid metabolism which can be in the form of an increase or decrease in lipid fraction, namely increased cholesterol levels, increase in triglyceride levels, increase in LDL-C levels (*Low Density Lipoprotein-Cholesterol*) and decreased levels of HDL-C (*High Density Lipoprotein-Cholesterol*).<sup>8</sup> Consistently the relationship between the increased risk of stroke and dyslipidemia has been proven by various epidemiological studies. Increased risk factors for stroke associated with high levels of LDL (*Low Density Lipoprotein*), low HDL (*High Density Lipoprotein*) cholesterol and a high ratio of LDL and HDL cholesterol are then reinforced by the presence of other risk factors.

LDL has an important role in atherosclerosis which is the basis of cardiovascular and metabolic diseases among all existing lipid components. Atherosclerosis occurs because of the result of *Low Density Lipoprotein* (LDL) which has been oxidized and trapped in the subendothelial blood vessels. In Indonesia, based on the 2013 Riskesdas data, more than 40% of Indonesia's population over the age of 15 experience LDL type hyperlipoproteinemia.<sup>7</sup>

Thereport *National Health and Nutrition Examination Survey* (NHANES) from 2003 to 2006 estimated that 53% (105.3 million) of American adults had at least one Abnormal lipid level, of which 27% (53.55 million) had LDL levels -C is high, 23% (46.4 million) have low HDL-C levels and 30% (58.9 million) have high triglyceride levels. In addition, about 21% (42 million) of American adults have mixed dyslipidemia which is defined as the presence of high LDL-C levels combined with at least one other lipid disorder.<sup>9</sup>

Other studies also found the prevalence of dyslipidemia in the adult population in China as much as 41.9%, which included 17.7% hypertriglyceridemia, low HDL 11%, hypercholesterolemia 10.1% and high LDL levels 8.8%.<sup>11</sup>

In Indonesia the prevalence of dyslipidemia is still quite high. Based on the Riskesdas report in 2013 the

prevalence of total cholesterol in Indonesia was 35.9%, HDL 22.9%, LDL 15.9% and triglycerides at 11.9%.<sup>9</sup>

The ratio of LDL cholesterol to HDL is an important component as an indicator of vascular risk factors. Someone who has a high ratio of LDL and HDL cholesterol has a greater risk factor for cardiovascular disease due to an imbalance between cholesterol carried by atherogenic lipoproteins and protective lipoproteins. This occurs because of the increase in LDL levels and decreased HDL levels or both.<sup>12</sup>

## Material and Method

The study design used in this study was an analytical observational study with a study design *cross sectional*. This study uses secondary data sourced from data *baseline* the 2011 PTM cohort study carried out by the Health Research and Development Agency, Ministry of Health of the Republic of Indonesia. The sample in this study was individual household members who were selected by *simple random sampling*, namely residents aged 25-65 years who lived in the city of Bogor. Data collected by the WHO STEPS method includes interviews of home visits, physical measurements and laboratory examinations. To establish a diagnosis of symptoms and experience of stroke, interviews were conducted with trained health personnel questionnaires. Respondents who have one of the symptoms of a stroke will be followed by confirmation of stroke by a neurologist.

Respondents for this cohort study totaled 1847 respondents. Data with a complete examination is 1506 which can be analyzed further. The data included in the analysis criteria were respondents interviewed and performed a stroke confirmation check. The dependent variable is a stroke that is divided into strokes and not strokes based on the results of a stroke confirmation by a neurologist. While the independent variable is the ratio of LDL to HDL.

**Data Analysis:** This study research was analyzed using statistical software namely STATA 13. Stroke, the ratio of LDL to HDL and other covariate variables were presented in the form of frequency and percent. Bivariate analysis in this study used the *test chi square* to determine the crude prevalence odds ratio (POR). All variables with a value of  $p < 0.25$  in bivariate analysis are candidates for further analysis. Multivariate analysis in this study used a logistic regression test with a significance level seen based on the value of 95% CI.

**Findings:** Analysis were conducted on 1506 adult respondents who had complete data. The results of the analysis showed that the prevalence of stroke was 1.26% and the prevalence of respondents with a high ratio of LDL to HDL was 35.66%. The highest prevalence of respondents is at the age of <46 years which is equal to 65.74% with the highest sex in women which is equal to 53.45% and low education at 54.58%. Based on the obesity variable the most respondents were not obese at 72.58% with high total cholesterol levels of 38.45% and respondents with high triglyceride levels of 17.07% (Table 1).

Bivariate analysis was performed to determine the crude prevalence odds ratio (POR). After all the covariate variables were analyzed there were two variables that had a value of  $p > 0.25$ , namely gender and triglyceride levels. So that there are four covariate variables that meet the criteria for entering into multivariate models namely age, education, obesity and total cholesterol levels. However, in this study all covariate variables were included in the multivariate model because in substance the two variables namely gender and triglyceride levels were associated with stroke (Table 2). The results of multivariate analysis of the effect of the ratio of LDL to HDL with the incidence of stroke can be seen in table 3.

**Table 1: Characteristics of Respondents**

Variable	Frequency (n)	Percentage (%)
<b>Stroke</b>		
Stroke	19	1.26
No stroke	1487	98.74
<b>LDL to HDL ratio</b>		
High ( $\geq 2,9$ )	537	35,66

Low (<200 mg / dl)	5	26.32	922	62.00			
<b>Triglyceride levels</b>							
High (≥ 150 mg / dl)	5	26.32	252	16.95	1.75	0.488-5.198	0.280
Low (<150 mg / dl)	14	73.68	1,235	83.05			

**Table 3. Multivariate Analysis Effect of LDL to HDL Ratio on Stroke in Adult Population in Bogor City (Final Models)**

Variable	p value	POR	95% CI
LDL to HDL ratio	0.012	3.909	1.346-11.354
Age	0.008	3.804	1.426-10.146
Interaction(LDL to HDL Ratio* Gender)	0.214	0.477	0.148-1.533

In the multivariate results above, compared to respondents has a low LDL to HDL ratio of respondents with LDL ratio high p HDL has an odds value of 3.909 or an 80% risk of suffering a stroke.

**Discussion**

In this study, the prevalence of stroke in the adult population in the city of Bogor was 1.26% or 12.6 per 1000 inhabitants. This result is higher than the prevalence of stroke in Indonesia based on Riskesdas data in 2013 which was 12.1 per 1000 population and in West Java Province 12.0 per 1000 population.<sup>7</sup> While the prevalence of not strokes in this study was more than half of the respondents, amounting to 98.74%. The results of this study are also in accordance with the *National Health and Nutrition Examination Survey* (NHANES) in 2010 that 6.8 million Americans over the age of 20 had suffered strokes. Overall the prevalence is 2.8%. Whereas based on research conducted by *Behavioral Risk Factor Surveillance* (BRFSS) in 2010 estimated the prevalence of stroke was 2.6% in adults over the age of 18 years.<sup>13</sup> This

Difference in the prevalence of stroke can be caused by stroke cases that continue to increase every year. Mortality and stroke prevalence also vary in developed countries. Differences can occur due to geographical variations in each region that cause differences in the

prevalence of stroke risk factors, genetic factors and stroke management factors themselves.<sup>14</sup> In Indonesia it may also occur as such, causing a difference in the prevalence of stroke between each region with a national prevalence of stroke prevalence.

This study aims to determine the effect of the ratio of LDL to HDL with the incidence of stroke in the adult population. The results showed that respondents with a high ratio of LDL to HDL had a chance of 3,909 to experience a stroke compared to respondents who had a low ratio of LDL to HDL. The results of this study are in accordance with the research conducted by Agusti et al (2014) which found that the prevalence of stroke was higher in a person with a high LDL to HDL ratio of 60%.<sup>15</sup> The results of other studies conducted by Robert H. Glew et al in adults in Nigeria showed a significant relationship between the ratio of LDL to HDL and the incidence of stroke in both men with a p value of 0.001 and women with a p value of 0.02.<sup>16</sup>

Increased risk factors for stroke are associated with high *Low Density Lipoprotein* (LDL), low *High Density Lipoprotein* (HDL) cholesterol, and a high ratio of LDL and HDL cholesterol and are strengthened by the presence of other stroke risk factors.<sup>15</sup> Abnormal cholesterol levels where LDL levels increase and HDL levels decrease have a close relationship with

cardiovascular disease because it triggers atheroma in the arteries. Where it develops into myocardial infarction, stroke and peripheral vascular disease.<sup>17</sup>The ratio of LDL cholesterol to HDL provides more prognostic levels than assessing LDL and HDL cholesterol itself separately.

### Conclusions

The prevalence of stroke in this study was 1.26% and the prevalence of a high ratio of LDL to HDL was 35.66%. In this study it can be concluded that someone with a high ratio of LDL to HDL is at risk for stroke.

## Abstract

**Aim:** To investigate serum levels of two Immune-related functional lncRNAs, growth arrest-specific transcript 5 (GAS5) and metastasis-associated lung adenocarcinoma transcript 1 (MALAT1), in Egyptian patients with SLE and to evaluate their relationship with disease activity.

**Method:** The present study was a case-control study that was carried out on 39 patients with SLE and 46 age and sex-matched healthy controls. The expression levels of GAS5 and MALAT1 were measured using by real-time polymerase chain reaction (PCR).

**Results:** There were statistically significant differences between cases and controls in GAS5 ( $p < 0.001$ ) and MALAT1 expression ( $p < 0.01$ ). The mean GAS5 was significantly higher in the control; while the mean MALAT1 expression was significantly higher in SLE patients. The ROC curve revealed that GAS5 was a good discriminant with AUC 0.849 with sensitivity 93.5% and specificity 74.3%. Moreover, MALAT1 was a good discriminant to differentiate cases from controls with AUC 0.3 with 95% CI (0.162 - 0.438), the most suitable cut-off point was  $\geq 2.1$  with Sensitivity 93.5% and Specificity 72.5%.

**Conclusion:** GAS5 and MALAT1 may serve as potential biomarkers for the diagnosis and monitoring of the SLE, both lncRNAs exhibited a good diagnostic accuracy to discriminate between SLE patients and healthy controls.

**Keywords:** lncRNAs; Systemic Lupus; Biomarker; Diagnostic Accuracy

## Introduction

Systemic lupus erythematosus (SLE) is a progressive, chronic, disorder that affects multiple systems with recurrent episodes of exacerbations and remissions<sup>1</sup>. According to recent epidemiological figures, the estimated global incidences of SLE ranges from 0.3 – 23.2 per 100 000 person-years<sup>2</sup>sex, ethnicity and time. Method A systematic search of MEDLINE and EMBASE

search engines was carried out using Medical Subject Headings and keyword search terms for Systemic Lupus Erythematosus combined with incidence, prevalence and epidemiology in August 2013 and updated in September 2016. Author, journal, year of publication, country, region, case-finding method, study period, number of incident or prevalent cases, incidence (per 100 000 person-years). Although the exact pathogenesis of SLE is still unclear, it is widely believed that the disease arise as a result of abnormal autoimmune process; patients with SLE were found to have defective clearance of apoptotic cells with subsequent development of auto-antigens and dysregulated immune responses (affecting both innate and adaptive immunity)<sup>3,4</sup>. Various environmental and hormonal factors were linked to increased risk of SLE in genetically susceptible individuals<sup>5</sup>. SLE is

characterized by wide range of clinical manifestations that mainly affects women in their reproductive age, patients with SLE often present with fatigue, weight loss, myalgias and muscle weakness, recurrent infection, and migratory polyarthropathy<sup>6</sup>retropatellar force (RPF). Moreover, a considerable proportion of the patients present with multiple systems affection such as lupus nephritis, pericardial disorders, valvular abnormalities, and cognitive dysfunction<sup>7</sup>.

Therefore, it is critical to diagnose SLE early and identify patients with increased risk of high disease activity in order to optimize SLE outcomes. Over the past few decades, a wide spectrum of biomarkers have emerged for early detection of SLE including antibodies, complement and complement split products, cytokines, chemokine biomarkers, and epigenetics-related biomarkers such as noncoding RNAs<sup>8</sup>. The noncoding RNAs are regulatory RNAs that control many biological process such cell cycles, apoptosis, and remodeling<sup>9</sup>. Long noncoding RNAs (lncRNAs) are the largest proportion of mammalian non-coding transcriptome (larger than 200 nucleotides) that are key components of many structural, activating, and/or functional roles within the body<sup>10</sup>. Previous study has shown that lncRNAs play significant role in the pathogenesis of different diseases such as cancer and neurological disorders<sup>11,12</sup>. Recently, a growing body of evidence reported increased expression of a number of lncRNAs in SLE patients. Owing to their immune-related functions and regulatory role in apoptosis, lncRNAs are proposed to contribute significantly in the molecular pathogenesis of SLE<sup>13</sup>. Thus, they may serve as accurate biomarkers of SLE development and activities.

We performed this study to investigate serum levels of two immune-related functional lncRNAs, growth arrest-specific transcript 5 (GAS5) and metastasis-associated lung adenocarcinoma transcript 1 (MALAT1), in Egyptian patients with SLE and to evaluate their relationship with disease activity.

## Materials and Method

**Study Design and Patients:** The present study was a case-control study that was carried out from November 2017 to August 2018 in the Medical Biochemistry Department, Cairo University. The study included 39 patients who were diagnosed with systemic lupus erythematosus (SLE) and 46 age and sex-matched healthy controls. Adults patients (aged >18 years old)

with diagnosis of SLE according to the 2012 Systemic Lupus International Collaborating Clinics (SLICC) criteria were included<sup>14</sup> meet stringent methodology requirements and incorporate new knowledge in SLE immunology. Method\2014The classification criteria were derived from a set of 702 expert-rated patient scenarios. Recursive partitioning was used to derive an initial rule that was simplified and refined based on SLICC physician consensus. SLICC validated the classification criteria in a new validation sample of 690 SLE patients and controls. Results\2014Seventeen criteria were identified. The SLICC criteria for SLE classification requires: 1. We excluded patients who had any other illnesses that might affect the results of the study such as chronic liver, familial hypercholesterolemia, thyroid and parathyroid diseases, and malignancy as well as any other rheumatic disease.

**Data Collection:** All patients were subjected to full history taking and clinical examination including SLE Disease Activity Index (SLEDAI). In addition, we recorded the results of complete blood count (CBC), bleeding profile, and kidney function tests. The expression levels of GAS5 and MALAT1 were measured using by real-time polymerase chain reaction (PCR).

**Expression Levels of the Studied LncRNAs:** Whole blood samples (5ml) were taken from SLE patients and controls. Serum was separated from the whole blood for quantitative expression of long non-coding RNAs by real-time PCR. RNA was extracted from serum by miRNeasy extraction kit (Qiagen, Valenica, CA) using QIAzol lysis reagent according to the manufacturer's instructions. Sixty ng of total RNA were used in the reverse transcription (RT) step in final volume 20µl RT reactions using RT2 first strand Kit (Qiagen, Valenica, CA) according to the manufacturer's instructions. Serum expression levels of the studied lncRNAs were evaluated using GAPDH as internal control and ready made primers (MALAT-1 and GAS-5) and Maxima SYBR Green PCR kit (Thermo, USA) according to the manufacturer's protocol. The primer sequences for GAPDH were as follows: F 5'-CCCTTCATTGACCTCAACTA-3',

R 5'-TGGAAGATGGTGATGGGATT-3'.

Twenty µl reaction mixtures was used in RT-PCR by mixing 10µl master mix, 1µl readymade assay primer, cDNA, and RNAase-free water using Rotor gene Q System (Qiagen).

PCR conditions were as follow: 95°C for 10min, followed by 45 cycles at 95°C for 15s and 60°C for 60s. The cycle threshold (Ct) is the number of cycles required for the fluorescent signal to cross the threshold in real-time PCR. Gene expression relative to internal control ( $2^{-\Delta Ct}$ ) was calculated. A melt curve analysis was done to ensure specificity of the corresponding RT-PCR reactions. Fold change was calculated using  $2^{-\Delta\Delta Ct}$  for relative quantification. Using the data analysis of web portal, we calculated fold change/regulation with  $\Delta\Delta CT$  method, in which  $\Delta CT$  was calculated between gene of interest and an average of reference genes, followed by  $\Delta\Delta CT$  calculations [ $\Delta CT$  (patient) –  $\Delta CT$  (control)]. Fold change is then calculated using  $2^{-\Delta\Delta CT}$  formula.

**Study's Outcomes:** The primary outcome in the present study was the association between the expression levels of GAS5 and MALAT1 with SLE. The secondary outcome was the relation between the expression of the two lncRNAs and the activity of the disease.

**Statistical Analysis:** Data entry, processing, and statistical analysis were carried out using SPSS version 22.0. Frequency tables with percentages were used for categorical variables and descriptive statistics (mean and standard deviation) were used for numerical variables. The normality of the data was assessed using the Shapiro-Wilk Test. Tests of significance (Chi-square, student's t-test, or Mann Whitney's test) were used according

to the normality of the data. The recessive operative characteristics (ROC) curve was performed to assess the diagnostic performance of studied gene expressions in discrimination between SLE patients and control group. A p-value < 0.05 is considered statistically significant.

## Results

The present study included 39 patients with SLE and 46 normal controls were included. The mean age of the patients was 29.68 ± 6.96 years; while the majority of patients were female (89.7%). The mean duration of disease of the included patients was 5.72 ± 5.53 years. The mean ESR and CRP was 51.69 ± 36.14 mm/hr and 1.81 ± 3.86 mg/L. In addition, the mean total leucocyte count was 6.70 ± 2.96 × 1000 cell/mm<sup>3</sup>. Regarding kidney function, all mean renal function parameters were within the normal range at the baseline. Only 33.3% of the patients had vasculitis, and only one patient (2.6%) had myositis. On the other hand, 33.3% and 46.2% of the patients had arthritis and pericarditis, respectively. In addition, 15 (39.1%) of patients were ANA positive and only 5 (10.9%) patients were DNA positive. The mean of C3 of the included cases was 54.13 ± 35.13 mg/dl and C4 level was 10.12 ± 10.02 mg/dl. The mean of SLE disease activity index (SLEDAI) in included cases was 5.75 ± 5.32. Table 1 shows the baseline characteristics of the included patients.

**Table 1: Baseline characteristics of the included subjects**

Variables	Patients (N =39)	Control (N =46)	P-value
Age (Years)	29.68 ± 6.96	33.5 ± 9.5	0.1
Age at onset (Years)	24.42 ± 5.08	----	----
Disease Duration (Years)	5.72 ± 5.53	----	----
<b>Gender, No (%)</b>			
1. Female	35 (89.7%)	39 (84.7%)	0.46
2. Male	4 (11.3%)	7 (15.3%)

SLEDAI score	5.75 ± 5.32	----	----

\*Data are presented as mean (SD), median (IQR), or No. (%)

In term of the primary outcome of the present study, there were statistically significant differences between cases and controls in GAS5 ( $p < 0.001$ ) and MALAT1 expression ( $p < 0.01$ ). The mean GAS5 was significantly higher in the control; while the mean MALAT1 expression was significantly higher in SLE patients (Figure 1). The ROC curve analysis revealed

that GAS5 was a good discriminant to differentiate cases from controls with AUC 0.849 with sensitivity 93.5% and specificity 74.3%. Moreover, MALAT1 was a good discriminant to differentiate cases from controls with AUC 0.3 with 95% CI (0.162 - 0.438), the most suitable cut-off point was  $\geq 2.1$  with Sensitivity 93.5% and Specificity 72.5% (Figure 2 & 3).

Figure 1: The difference in GAS5 expression

**Figure 2: ROC curve analysis to explore the discriminant ability of GAS5 to differentiate between cases & controls**

**Figure 3: ROC curve analysis to explore the discriminant ability of MALAT1 to differentiate between cases & controls**

Notably, patients with rash and mucosal ulcer had statistically significant higher GAS5 ( $p=0.037$  and  $0.002$ , respectively). Similarly, Patients with vasculitis had statistically significant lower MALAT1 ( $p=0.023$ ). The correlation analysis showed that there were statistically significant negative correlation between MALAT1 and GAS5 ( $r=-0.314$ ;  $p=0.003$ ). In contrary, there were no statistically significant correlations between clinical variables and GAS5 or MALAT1.

**Discussion**

In the present study, both GAS5 and MALAT1 yielded good diagnostic performances for the detection of SLE. At cutoff values of  $<0.3$ , the GAS5 had a sensitivity of 93.5% and specificity of 74.3% for the detection of SLE. Similarly, an expression of MALAT1 of  $\geq 2.1$  had similar performance. On the other hand, the expression

of both lnrRNAs correlated significantly with some of the disease activities.

Over the recent few years, lnrRNAs were implicated in the development and progression of many diseases including cardiovascular diseases, cancers, and autoimmune disorders<sup>15-17</sup>. Owing to their role in the development of immune system, lnrRNAs are promising biomarkers for many autoimmune diseases including SLE. In the present study, we demonstrated that both GAS5 and MALAT1 yielded good diagnostic performances for the detection of SLE. At cutoff values of  $<0.3$ , the GAS5 had a sensitivity of 93.5% and specificity of 74.3% for the detection of SLE. Similarly, an expression of MALAT1 of  $\geq 2.1$  had similar performance. In concordance with our findings, Wu and colleagues<sup>18</sup> performed a two-stage study to explore

the plasma levels of five lncRNAs (GAS5, linc0949, linc0597, HOTAIRM1 and linc-DC) and their potential as SLE biomarkers. Compared with healthy controls, the expression level of GAS5 was significantly down-regulated. When SLE patients were divided according to the presence of LN, the results showed that the levels of GAS5 was also significantly down-regulated in both subgroups relative to healthy controls. Furthermore, the plasma level of GAS5 could distinguish SLE from healthy controls with 65.03% sensitivity and 93.75% specificity. Similarly, Suo and colleagues<sup>19</sup> assessed the expression of GAS5 and microRNA (miR)-21 in SLE, and attempted to explore their association with clinical features. The results revealed that GAS5 was significantly lower in CD4+ T cells of patients with SLE compared with those in control subjects; however, there were no significant differences in GAS5 expression regarding the presence of nephritis. Another prospective study by Li and colleagues<sup>20</sup> included 85 SLE patients and 71 healthy controls to investigate the lncRNAs expression levels. It was found that GAS5 expression level was significantly lower in SLE patients than healthy controls.

Regarding MALAT1, Yang and colleagues<sup>21</sup> analyzed the expression of MALAT1 in 39 SLE patients and 45 matched normal controls. They found that MALAT1 was abnormally increased in the patients with SLE and predominantly expressed in monocytes. In monocytes of patients with SLE, silencing MALAT1 significantly reduced the expression of IL-21. Furthermore, their study demonstrated that MALAT-1 exerts its detrimental effects by regulating silent information regulator 1 (SIRT1) signaling.

The present study also investigated the association between clinical characteristics of SLE patients and the expression of both GAS5 and MALAT1. Patients with rash and mucosal ulcer had significantly higher GAS5. In addition, patients with vasculitis had significantly lower MALAT1. Similarly, Suo and colleagues<sup>19</sup> reported that the levels of GAS5 were higher in patients with ulceration than in those without.

There was no significant association of the SLEDAI with the GAS5 or MALAT1. However, Wu and colleagues<sup>18</sup> reported that GAS5 level was significantly lower in more active SLE patients than in less active cases. In addition, GAS5 level was negatively associated with SLEDAI-2K score in patients with SLE. Moreover, plasma level of GAS5 was also negatively correlated with the ESR.

We acknowledge that the present study has number of limitations. The sample size of the included patients was relatively small which may affect the generalizability of our findings. Moreover, the study was single-center experience. In addition, we could not control for potential confounding factors such as different clinical characteristics and different treatment strategies among patients.

## Conclusion

In conclusion, GAS5 and MALAT1 may serve as potential biomarkers for the diagnosis and monitoring of the SLE, both lncRNAs exhibited a good diagnostic accuracy to discriminate between SLE patients and healthy controls. Moreover, GAS5 and MALAT1 were significantly higher in patients with rash and mucosal ulcer; while there was no statistically significant correlation between disease activity and lncRNAs expression. However, due to the descriptive nature of the present study, further studies on the exact role of lncRNAs in SLE pathogenesis are still needed.

## Abstract

**Context:** Purpose: to find out age-related changes in the micro-rheological characteristics of red blood cells in rats after hypothermia. The study included 88 healthy outbred male rats at the age of 6 months. Prior to inclusion in the study, all rats were healthy and did not participate in the studies. Animals experienced an episode of hypothermia - within 1 hour at a temperature of -10°C. The control group consisted of 32 healthy outbred male rats of a similar age. The study was conducted using biochemical, hematological and statistical research method. In rats subjected to hypothermia, an increase in the activity level of free radical oxidation processes in plasma lipids and red blood cells was found. Over time, a decrease in the level of erythrocyte-discocytes was observed in the blood of the observed rats, which was most pronounced in rats one month after hypothermia. This was accompanied by an increase in their level of changed reversibly and irreversibly erythrocyte forms and an increase in spontaneous aggregation of red blood cells. In rats, after an episode of hypothermia, a gradual weakening of the plasma antioxidant defense develops. In these rats, aggregation readiness and the degree of change in the surface properties of red blood cells progressively increased. Apparently, this creates a risk in animals of a progressive increase in morbid burden and weakening of the whole organism in relation to resistance to negative environmental influences.

**Keywords:** Rats, hypothermia, red blood cells, cytoarchitectonics, aggregation.

## Introduction

Experiments in biological science help to solve many problems of the reaction of the mammalian organism to environmental factors<sup>1,2</sup>. It is clear that the deployment of various processes in the body is associated with the

implementation of the genetic<sup>3,4</sup> program under the influence of external factors<sup>5,6</sup>. This allows the body to adapt adequately, while maintaining functional potential, to maintain viability in different conditions<sup>7,8</sup>. The dynamics of the rheological parameters of the blood and especially the formed blood elements, capable of changing under many functional conditions and effects on the body, is of great importance for maintaining life support<sup>9,10</sup>.

A significant element of the microcirculation process is cells - red blood cells, which, changing their cytoarchitectonics and aggregation activity, significantly affect hemodynamics and metabolism in tissues and determine the course of all adaptive processes in the body<sup>11,12</sup>. It is known that their rheological parameters are capable of changing against the background of

e-mail: ilmedv1@yandex.ru

physiological and pathological processes<sup>13</sup>. It is clear that excessive influence on the body can affect microcirculation in organs, sometimes exacerbating the course of pathology<sup>14</sup>.

In the process of searching for therapeutic approaches in assessing various environmental effects on humans<sup>15</sup>, it is difficult to do without studying biological processes in experimental models on laboratory animals, especially rats. Due to the importance of erythrocyte rheological parameters in the development of many dysfunctions<sup>16</sup>, including under the influence of the environment of blood disorders, it is necessary to develop options for overcoming them<sup>17</sup>. Therefore, it is important to study the aspects of aggregation and cytoarchitectonics of red blood cells in those who have fallen into adverse environmental conditions<sup>18</sup>. This information can serve as a basis for a further search in experimental approaches to optimize the rheological characteristics of red blood cells in hazardous industries and to overcome the effects on the body of harmful environmental factors in the development of habitats, including the Arctic<sup>19,20</sup>.

Given these circumstances, the goal of the work was to find out the effect of a hypothermia episode on the micro-rheological characteristics of red blood cells in rats.

## Materials and Research Method

This study was carried out in full compliance with the ethical standards outlined by the European Convention for the Protection of Vertebrate Animals, which are used for experimental and other scientific purposes (adopted in Strasbourg on 18.03.1986 and confirmed in Strasbourg on 06.15.2006).

The study included 88 healthy outbred male rats at the age of 6 months. They experienced an episode of hypothermia for 1 hour at a temperature of -10°C. Prior to inclusion in the study, all rats were healthy and did not participate in the studies. The control group consisted of 32 healthy outbred male rats at six months of age.

Animals were weighed on electronic scales of the

BM1502M-II brand (Vesta, Russia). They evaluated their endurance in a swimming test using a load of 10% of the body weight of each rat, which was fixed to the base of the tail<sup>21</sup>.

Blood from all rats was taken from the tail vein. In all rats, the level of lipid peroxidation in plasma was determined by assessing the content of thiobarbituric acid-active products using the Agat-Med kit (Russia), the amount of acyl hydroperoxides with registration of the plasma antioxidant activity value<sup>22</sup>. The erythrocyte level of lipid peroxidation was estimated by the amount of malondialdehyde and acyl hydroperoxides in them, taking into account the antioxidant capabilities of catalase and superoxide dismutase<sup>23</sup>.

Using an Olympus CX-41 light phase-contrast microscope (Olympus, Japan), which gives a magnification of 1200 times, red blood cells were divided into discoid, reversible and irreversible.

The state of erythrocyte aggregation was assessed by light microscopy using a Goryaev's camera to determine the number of red blood cell aggregates, and the values of red blood cells aggregated and not entered into aggregation after washing and resuspension. The digital values obtained were processed using Student's test using the StatSoft STATISTICA for Windows 6.0 program.

## Research Results

The initial and control values were comparable in experimental rats after hypothermia, an increase in the external manifestations of a deterioration in their general condition – dulling and thinning of the coat, a decrease in their physical activity and appetite – was revealed. Also, rats had a weakening interest in the surrounding reality. As the period after hypothermia increased, a decrease in body weight was found in rats, which amounted to 212.6±6.22 g by the end of the observation. At the same time, a gradual decrease in their endurance level was noted during the forced swimming test when weighed by cargo - a month after hypothermia by 76.5% compared with the control (table).

**Table: The rats examined**

Recorded Indicators	Rats after hypothermia, M±m			Control, n=32, M±m
	Exodus, n=88	2 weeks, n=88	4 weeks, n=88	
Body weight, g	230.6±6.17	221.0±5.36	212.6±6.22*	232.4±4.96
Swimming time, s	159.2±2.35*	134.0±3.17*	90.2±2.95**	161.2±3.62
Plasma acyl hydroperoxides, D <sub>233</sub> /1 ml	1.47±0.012	1.69±0.019*	1.88±0.037**	1.45±0.009
Thiobarbituric acid products, mcmol/l	3.40±0.014	3.90±0.025*	4.16±0.032**	3.42±0.014
Antioxidant activity,%	35.2±0.32	30.5±0.26	28.0±0.22*	35.1±0.07
Acyl hydroperoxides erythrocyte, D <sub>233</sub> /10 <sup>12</sup> red blood cells	2.86±0.019	3.46±0.015*	3.99±0.022**	2.82±0.015

Catalase erythrocyte, ME/10 <sup>12</sup> red blood cells	8900.0±11.6	8100.0±10.9*	7400.0±21.3**	8960.0±16.2
Superoxide dismutase erythrocyte, ME/10 <sup>12</sup> red blood cells	1580.0±11.82	1490.0±9.75*	1340.0±10.62**	1650.0±13.15
Discocytes,%	83.9±0.12	76.0±0.14*	70.2±0.10**	84.1±0.14
Reversibly altered red blood cells,%	9.6±0.17	12.1±0.06*	14.6±0.12**	9.5±0.11
Irreversibly altered red blood cells,%	6.5±0.08	11.9±0.15**	15.2±0.14**	6.4±0.12
The sum of red blood cells, included in the units	31.0±0.13	37.6±0.12*	40.8±0.09**	30.2±0.06
Number of units	6.0±0.07	6.9±0.10*	8.1±0.12**	6.1±0.05
The number of free red blood cells	289.9±0.20	250.1±0.29*	222.6±0.18**	292.8±0.22

In rats subjected to supercooling, an increase in the activity level of free radical oxidation processes in plasma lipids was found (the level of acylhydroperoxides and thiobarbituric acid-active products increased by 27.9% and 22.3%, respectively) with a decrease in antioxidant activity by 25.7%.

Comparable changes in lipid peroxidation in the rats studied were noted in erythrocytes - the number of acyl hydroperoxides and malondialdehyde in them increased. Their number in rats 4 weeks after hypothermia prevailed compared with the outcome by 39.5% and 36.6%, respectively. The activity of erythrocyte enzymes of catalase and superoxide dismutase in rats after hypothermia generally decreased by 20.3% and 17.9%, respectively (table).

After hypothermia in the blood of experimental rats, a decrease in the level of erythrocyte-discocytes to 70.2±0.10% after a month of observation was observed, which led to a gradual increase in their level of changed reversibly and irreversibly erythrocyte forms by 52.1% and 2.3 times .

In rats tested, with an increase in the period after hypothermia, an increase in the ability to aggregate red blood cells was noted with an increase in their total inclusion in the composition of aggregates and the number of aggregates with a decrease in the level of non-aggregated red blood cells (222.6 ± 0.18), compared

with the control level and outcome (table).

## Discussion

Many parameters of an organism that realize its viability strongly depend on the influence of unfavorable factors on it from the external environment<sup>24</sup>. Of great importance in this is the reaction in the body to the effects of the environment of hemostatic and rheological characteristics of the blood<sup>25</sup>. They determine the amount of nutrients and oxygen entering the cells of the whole body<sup>26</sup>. Of great importance for the success of microcirculation are the parameters of the shaped elements, which are exposed to the side of the vessel walls and the influence of lipid peroxidation processes<sup>27</sup>.

It was established that in rats after hypothermia, the antioxidant activity of plasma weakens, leading to an increase in the level of acyl hydroperoxides and thiobarbituric acid-active products in it. Excessive lipid peroxidation in plasma damages the walls of blood vessels and receptors on erythrocyte membranes, negatively affecting their state. At the same time, antioxidant defense weakens in red blood cells, which enhances lipid peroxidation processes in them<sup>28</sup>.

Excess lipid peroxidation in plasma and erythrocyte membranes violates the structural and functional characteristics of membranes and protein cytoskeleton of red blood cells. Against the background of enhanced

lipid peroxidation in erythrocytes, weakening of the synthesis of adenosine triphosphate occurs, lowering the activity of ion pumps, which under these conditions can no longer cope with the release of an increasing influx of  $\text{Ca}^{2+}$  and  $\text{Na}^{+}$  and maintaining the optimum  $\text{K}^{+}$  level.

Under these conditions, a gradual increase in the number of red blood cells that do not have a biconcave shape develops. The arising changes in red blood cells provides an increase in the blood content of reversibly and irreversibly altered their varieties<sup>29</sup>.

The increase in erythrocyte aggregation found in rats after hypothermia is strongly provided by the occurring changes in the level of charge on their membranes due to the degradation of a certain amount of glycoproteins on them under the influence of excess lipid peroxidation. Strengthening the synthesis of reactive oxygen species creates conditions in aging rats for oxidative membrane alteration and damage to plasma proteins, which have the ability to bind red blood cells as bridges during their aggregation.

The increase in the number of free aggregates after hypothermia in rat blood caused damage to the vascular endothelium, which contributed to the contact of the subendothelium and blood and activation of hemostasis, which significantly worsened the blood microreology in the capillaries<sup>10</sup>. An increase in the number of aggregates in the blood of rats can block part of their vasa vasorum, which can lead to degeneration of the vessel walls and weakening in the vessels of the synthesis of substances that provide control and control over the aggregation of red blood cells<sup>13,14</sup>.

### Conclusion

In rats after hypothermia, a gradual weakening of the antioxidant protection of plasma was found. This is accompanied by an increase in its levels of lipid peroxidation products. This contributed to the alteration of the outer membranes of red blood cells, negatively affecting their functions. After hypothermia, the aggregation readiness and the degree of violation of the erythrocyte properties also increased in rats. This is of great importance for lowering the resistance of the organism of animals subjected to hypothermia, which makes them very sensitive to the influence of other negative environmental factors.

## Abstract

**Background:** Alcohol is one of the psychoactive products that causes health and social problems. Scientific research helps to correct consumption disorder.

**The Objective:** is to establish the epidemiological profile by updating knowledge about alcohol consumption levels and patterns.

**Materials and Method:** prospective and random survey was conducted on 137 participants, of whom 79.6% (n=109) man and 20.4%(n=28) woman. The evaluation tests are the AUDIT (10 questions) and DPQ-4+.

**Results:** The results show a dominance of the male sex. The distribution of respondents according to the AUDIT classification shows that 75.9%(n=104) have a score lower than 8 (to 7 for women) which makes it possible to qualify these people at risk. So they must be monitored while 11, 7% (n=16) had a score between 8 and 12 (7 and 11 for woman) are probably people addicted to alcohol.

Multiple regressions shows that academic level, depressive and obsessive - compulsive personalities are factors that significantly explain the high degree of dependence on alcohol consumption.

**Conclusion:** The result of this study is to establish a national prevention program against the morbid use of alcohol especially among young adults.

**Keywords:** Alcohol - AUDIT - DPQ-4+ - epidemiology - risk factor – Morocco.

## Introduction:

Alcohol is a psychoactive substance that affects mental activity, sensations, perceptions and behavior. It

causes specific diseases that affect patients' quality of life. Excessive consumption of Alcohol is a public and societal problem<sup>1</sup>.

In addition to health, alcohol can have serious economic and social consequences such as absenteeism at work and social isolation<sup>2</sup>. Another substance of alcohol has a significant impact in terms of mortality, morbidity and social damage<sup>3-4</sup>. Its toxicity also leads to the development of cardiovascular diseases such as high blood pressure or stroke<sup>5-6</sup>. Excessive alcohol consumption may be a risk factor for developing to Pajorvi, and al.<sup>7</sup>. In contrast, low to moderate alcohol

consumption protects against ischemic vascular disease and diabetes<sup>8-9</sup>.

Factors that promote alcohol consumption include age, smoking, household income, depression and anxiety, and gender<sup>10-11</sup>. According to report of 2016 who has estimated the number of deaths worldwide at 3 million people due to alcohol abuse, the highest level of alcohol consumption observed in Europe population.

49 countries of the world listed by the World Health Organization who, Morocco ranks 43rd, with 0.45 liters of alcohol in the year.

Our job is to establish the epidemiological profile of alcohol consumption through the alcohol-related disorder identification test (AUDIT) and to investigate the determinants of this behavior.

## Materials and Method

**Population and Method:** This study was conducted in three Moroccan cities, Rabat, Kenitra and Meknes. The study lasted two months in 2019 and involved 137 participants, of whom 79.6% (n = 109) were men and 20.4% (n = 28) were women. The participants became aware of the nature, purpose and ethical interest of the survey. The choice of participants was simple and random.

### Sampling Instrument:

- **The Alcohol Use Disorder Identification Test (AUDIT):** It explores the behaviors of the last twelve months<sup>12</sup>. This questionnaire contains 10 questions, the first 8 of which describe the relationship between the person and alcohol consumption.
- **Personality Diagnostic Questionnaire (DPQ-4 +):** The second measuring instrument is the French version of the personality diagnostic questionnaire (DPQ-4 +). It intended to evaluate the ten personality disorders of DSM-IV and PDQ-4+ in addition to both passive-aggressive and depressive personality disorders (Hyler, 1994).<sup>13</sup>

**Statistical Analysis:** The collected data are subject to descriptive and analytical analysis (chi-

square test, unidirectional ANOVA, correlation). The internal consistency of the AUDIT test is evaluated by the Cronbach  $\alpha$  test<sup>14</sup>, which is a good measure of the correlation of each item with the overall total of the test. The results of the qualitative variable expressed in frequency and those of a quantitative variable in mean  $\pm$  SD.

## Results

**Socio-demographic characteristics of respondents:** Through the results of the descriptive analysis of the demographic characteristics of the survey participants, it was found that 79.56% (n = 109) of the participants are men against 20.44% women (unbalanced sex ratio). In fact, the average age of the respondents is  $32.10 \pm 5.39$  years (between 24 and 50 years of age, average age for men = 32.33 years and average age for women = 31.21 years). Moreover, 67.9% of these respondents are between 24 and 34 years old and 27.7% are between 34 and 44 years old, while 56.2% are married versus 43.8% are single.

The distribution by level of education shows that 51.8% have a bachelor's degree and 48.2% are university graduates, while 48.9% reported working in a public compared to 40.1% declared working in private sector.

### Analysis of the Alcohol Use Disorder Identification Test:

**Internal Consistency:** The reliability test of the AUDIT questionnaire shows a high internal consistency ( $\alpha = 0.898$ ). The analysis of variance shows a very significant difference (Fisher = 94.219,  $p < 0.000$ ).

Table 1 presents the results of the descriptive analysis of the consistency of Cronbach's alpha. It shows that Cronbach's alpha for 8 out of 10 questions decreased when one of these items was removed. However, item 6, "How often during the last year have you needed a first drink in the morning to get yourself going after a heavy drinking session?" and item 9, "Have you or someone else been injured as a result of your drinking?" showed the opposite. These two items therefore have near-zero averages, which for item 6 corresponds to "never" or "once a month" and for item 9 corresponds to "no".

**Table 1: Internal consistency analysis, Cronbach  $\alpha$  coefficient**

Question	Mean	SD	N	Correlation of the item with the overall score	Cronbach's Alpha when deleting the item
Audit1	,53	,738	137	0,84	0,87
Audit2	1,46	,831	137	0,78	0,88
Audit3	,60	,827	137	0,88	0,87
Audit4	,26	,515	137	0,68	0,89
Audit5	,33	,631	137	0,76	0,88
Audit6	,04	,205	137	0,47	0,902
Audit7	,34	,635	137	0,71	0,88
Audit8	,20	,483	137	0,59	0,89
Audit9	,08	,455	137	0,29	0,905
Audit10	,48	1,001	137	0,62	0,87

standardised  $\alpha = 0.898$ , SD : standard deviation, N : effective

**Alcohol Dependence:** According to the appropriate calibration: greater than or equal to 5 points indicates risky consumption; greater than or equal to 8 points (7 for women) indicates harmful use; greater than 12 points (11 for women) indicates probable alcohol dependence. The average score obtained is  $4.31 \pm 4.82$ , with a minimum score of 1 and a maximum of 21. The student test shows a significant difference between the average scores of the two sexes (Female average = 2.11 and Male average = 4.88,  $t = 7.73$ ,  $p < 0.006$ ).

The analysis of variance "age effect" shows a very significant difference (Fisher = 2.37,  $p < 0.044$ ). Comparison of the averages per tukey allowed to classify the categories as follows: respondents aged 44-54 had the highest average score of 11.33 (between 6 and 21), followed by age categories 24-34 and 34-44, with average scores of 4.31 (between 1 and 18) and 3.87 (between 1 and 16). In the last position, respondents under 24 years of age have an average score of 3 (between 1 and 7).

The distribution of respondents according to the AUDIT classification shows that 75.9% ( $n = 104$ ) have a score strictly below 8 (7 for women), which qualifies these people as being at risk, so it is necessary to monitor them. While 11.7% ( $n = 16$ ) had a score between 8 and 12 (7 and 11 for women), they therefore express harmful use. Finally, 12.4% ( $n = 17$ ) of cases scored above 12 (11 for women) are therefore probably alcohol-dependent.

**Distribution by gender:** According to the The results of the class association AUDIT / Gender. The chi-square test shows that these two variables are significantly

associated ( $\chi^2 = 6.23$ ,  $p < 0.009$ ). Moreover, the rate of men whose alcohol consumption is assumed to be at risk is 71.67% compared to 92.86% for women. On the other hand, among men the rate of alcohol dependence is 13.76%, while among women it is 7.14%. A prevalence in our sample of 12.41% was deduced, with a prevalence of 10.95% for men and 1.46% for women.

**Distribution by age class:** The distribution of respondents by age class and by AUDIT class shows that the most incriminated classes are those with ages between 24 to 34, with an alcohol dependence rate of 11.82% (11/93) and between 34 and 44, with a rate of 13,15% (5/38). For those who have had harmful use, 11 of 16 people are aged between 24 and 34, compared with only 3 aged between 34 and 44. However, among the class of respondents where alcohol consumption is at risk, we find that 97.11% are young adults (24 to 44 years).

**Correlation between AUDIT and DPQ-4 + questionnaire:** To study the relationship between the AUDIT test and the DPQ-4 + questionnaire, a multilevel regression was used, where the dependent variable was the AUDIT score and the explanatory variables (the dimensions of the DPQ-4 +, age). The results of this analysis allowed us to draw the following conclusions: The results showed a negative correlation between the AUDIT score and grade level ( $p < 0.02$ ). Indeed, Alcohol addiction is much more advanced among respondents with a low level of education. Thus, a positive correlation associates the AUDIT score with the "depressive" and

“obsessive-compulsive” dimensions with p values of 0.010 and 0.05, respectively (Table 2).

**Table 2: Analysis of Multiple Regression, Dependent Variable “Audit Score”**

Variable	Unstandardized coefficients	t	Significant
	A		
(Constant)	2,06	2,054	,0294*

Dependent	0,122	0,285	0,776
Suspect	0,496	0,486	0,628

**Discussion**

The pertinence of the present study resides in the diversity of the variables included, particularly those of a socio-demographic nature. The analysis of the data collected will obviously provide a clear and detailed view of this study sample. Indeed, the sociodemographic characteristics concern age, gender, level of education and occupation. The reliability analysis shows that AUDIT has a high internal consistency (Cronbach’s alpha= 0.898) and all items were positively correlated with the total scale. Question 2, followed by questions 1 and 3, had moderately high values. These items tend to determine the quantity and frequency of alcohol consumption. This result is coherent with those found by the AUDIT validation study conducted by the Contel Guillamon team<sup>15</sup>.

The results of this behavior as a function of age show that the most incriminated category is between 24 and 44 years of age and then decreases in both directions. This result corresponds to that described by a cross-sectional probabilistic survey conducted by telephone on a sample residing in France<sup>16</sup>. Alcohol consumption is becoming

more masculine as the frequency of drinking increases, with men being three times more likely than women to drink alcohol daily. This has also been confirmed in other studies done in Europe<sup>17-18</sup>. In Morocco, and with reference to religious and cultural considerations, the use of alcohol remains largely reserved for men, although recently there has been a slight increase in this habit, particularly among young girls.

The prevalence found in our investigation remains slightly lower than that found in European or American countries as described in Accietto Cataldo’s doctoral thesis<sup>19</sup>. The World Health Organisation, in its report entitled “Mental health: new understanding, new hope”<sup>20</sup>, explains that alcohol use disorders and depression are among the leading causes of death worldwide.<sup>21-22</sup>

**Conclusion**

The AUDIT test has shown a high sensitivity and specificity towards our respondents for the detection of alcohol problems. Alcohol dependence remains a public health problem that can have major health and socio-economic consequences. Certainly, a prevalence of more than 12% for society is still quite high, if we cannot multiply efforts to combat this disorder of conduct which according to our results affects the category of young adults.

The results of this study will also provide scientific added value to the prevention programmes of health officials to combat alcohol consumption disorders. This work could also serve as a starting point for deep reflection centred on the inclusion of a diagnostic approach based on the psychological profile in the detection of all addictive behaviours.

## Abstract

**Background:** Burnout is a syndrome that can affect all social categories including those who practice in call centers. This job requires many efforts depending on the activity undertaken. Our job is to develop a Burnout profile and look for its correlation that might exist with personality disorders.

**Materials and Method:** The study conducted in the call centers of Rabat over a period of two months. It concerned 127 tele-counselors, including 97 women (76.4%) and 30 men (23.6%). two assessment tests were chosen burnout and PDQ-4+.

**Results:** The average age of the respondents was  $27.20 \pm 6.9$  years (minimum age = 20 years and maximum age = 48 years). The results show that the prevalence of pathological individuals with high emotional exhaustion, high depersonalization and low performance is 8.66% (n = 11). A strong bond associates people in exhaustion and having a schizoid personality, negativist, depressive, antisocial and histrionic.

**Conclusion:** Faced with this urgent situation, the responsible authorities must redouble their efforts to identify this scourge and to look for major risk factors.

**Keywords:** *Burnout - PDQ-4+ - prevalence - survey - risk factor- Morocco*

## Introduction

Stress is an adaptive response to the requirements and constraints. It is essential for the proper functioning of the body<sup>1-2</sup>. Nevertheless, burnout is one of the most serious complications of occupational stress<sup>2</sup>. It characterized by a varied symptomatology around three major components: emotional exhaustion, depersonalization and self-fulfillment. In fact, the relationship between the individual and the environment is important<sup>3</sup>. Furthermore, professional stress can

be the cause of psychosomatic and cardiovascular disease. Work stress can be caused by organizational, occupational and / or personal factors<sup>4-5</sup>

Burnout is a stress-related condition with the potential for serious implications in the work. Left unrecognized, burnout could erode the framework<sup>6</sup>,

From a psychological point of view, burnout can be explained by a perceived imbalance between professional environmental demands and the individual's adaptive resources. According to the international literature review, some of these explanatory factors are generic, including professional and emotional demands: lack of autonomy; ethical conflicts; lack of social relationships; adverse social behaviors and insecurity at work<sup>7</sup>.

In psychology, work is the object of various sources of motivation and satisfaction, in relation to the conditions in which the task is accomplished<sup>8,9</sup>. For

Jimenez (2003)<sup>10</sup>social, economic and cultural aspects are relevant for burnout both in its genesis and in its impact.

Indeed, data on the prevalence of burnout remain more available in Europe and North America than in the countries of Africa and the Arab region, where studies in this area are still rare<sup>11</sup>.

In Morocco, few studies give importance to this problem, also this syndrome remains poorly evaluated and very limited. For this purpose, our work consists of assessing the prevalence of a group of tele-counselors at Morocco and to identify the contextual and personal psychosocial factors (or predictors) of the health of tele-counselors,

### Material and Method

**Population and Study Area:** The target population for this study is tele-counselors with 127 persons. In fact, the study carried out among people aged between 20 and 48 years, working in level of four call centers located in Rabat during the months of November and December 2016.

**Procedures and Scales:** A descriptive questionnaire with characteristics of the sample (socio-demographic characteristics, lifestyle habits, etc.) accompanied with Maslach Burnout Inventory and **DPQ-4 + test** distributed to tele-counselors of different subjects. A meeting held with the tele-counselors to explain the purpose and interest of our study, as well as the ethical aspects including the volunteering and anonymity of this survey.

**Maslach Burnout Inventory (MBI):** The Maslach Burnout Inventory (MBI) is used to assess burnout tele-counselors<sup>12</sup>, it is composed of 22 items divided into three dimensions: Emotional Exhaustion (EE) evaluated using nine items, the dehumanization of the relationship (DR) or "Depersonalization" (DP) (five items) and Personal Accomplishment (PA) (eight items). Each item is rated from 0 to 6. A high level of burnout manifested through high scores for the EE and DP sub-scales, combined with a low score on the PA sub-scale, with a reversal for a low burn-out level<sup>13,14</sup>.

**Personality Diagnostic Questionnaire (DPQ-4 +):** The second measuring instrument is the French version of the personality diagnostic questionnaire (DPQ-4 +). It intended to evaluate the ten personality disorders of DSM-IV and PDQ-4 + in addition to both passive-aggressive and depressive personality disorders (Hyler, 1994).

### Results

**Socio-Demographic Characteristics of tele-counselors:** Our study based on 127 tele-counselors, including 97 women (76.4%) and 30 men (23.6%). The average age of the respondents was 27.20 ± 6.9 years (minimum age = 20 years and maximum age = 48 years). The student's test did not show an average age difference between the two sexes (t = 0.14, p < 0.89, M female = 27.5 years and SD female = 6.27 years; M male = 27.07 years and SD = 5.59 years). Singles are strongly represented (73.2%) compared to 26.8% of married couples. About the level of education attained, 45.7% (n = 58) have a bachelor's degree and 54.3% (n = 69) have a university level (table 1).

**Table 1: Sociodemographic characteristics of respondents**

Variable	Modality	Gender		Khi2
		Female	Male	
Age in years ± SD		27.5± 6.27	27.07±5.59	Student=0,14 (p<0,82)
Marital status	Singles	69	24	Khi2= 0,94 (p<0,34)
	Married	28	6	
School level	Bachelor's Degree	44	14	Khi2= 2,54 (p<0,64)
	University Level	53	16	

SD: standard deviation

**MBI Scale (Maslach Burn out Inventory):** The study of fidelity and reliability by the calculation of Cronbach's alpha shows that the latter is much more important, it reaches 0.79. It should be noted that the Cronbach index has decreased in case of suppression, of one of the elements and this for all questions. The table (2) presents the results of the survey distribution according to the degree of exhaustion.

**Table 2: Representability of surveys based on the level of exhaustion.**

Dimension	Gender	Low	Moderate	High	Total	P Value	Prevalence
SEP	F	33	29	35	97	0,95 (p<0,623)	36,08%
	M	13	7	10	30		33,33%
DP	F	31	18	48	97	3.35 (p<0.049)*	49,48%
	M	14	7	9	30		30%
SAP	F	37	13	47	97	1,71 (p<0,43)	38,14%
	M	10	7	13	30		33,33%

\*: Significant difference with 5% margin of erro, SEP: Emotional Exhaustion; SD: depersonalization, SAP: Accomplishment

**Study of the total score of the dimension “emotional exhaustion”:** The mean score for this dimension is  $24.96 \pm 9.22$  points, the intra-group dispersion is 36.94%, which shows that the responses were very heterogeneous. The classification of scores according to the degree of emotional exhaustion (Table 1) shows that 35.43% (n = 45) of these respondents are in a state of high emotional exhaustion, 28.34% (n = 36) are a moderate degree and 36.22 (n = 46) questioned showed a weak or non-existent state of emotional exhaustion.

**Study of the total score of the “depersonalization” dimension:** The mean score is  $16.94 \pm 10.64$  points, with a dispersion coefficient of 62.81%, this value is much higher, which reflects a great heterogeneity in the respondents’ responses. The results of the categories of depersonalization summarized in Table (2) show that 44.88% (n = 57) of these respondents are in a state of high depersonalization, 19.68% (n = 25) with a moderate degree of depersonalization and 35.43% (n = 45) were in a poor state.

**Study of the total score of the self-fulfillment dimension:** The average score is  $33.57 \pm 10.82$  points with a coefficient of variation of 32.23%. The results of the classification according to the degree of exhaustion show that 47.24% (n = 60) of these respondents are in a high state of self-fulfillment, 15.75% are at an average degree and 37.01% at the end (n = 47) are in a poor state of self-fulfillment.

The analysis of the multiple correlation between the three dimensions shows that emotional exhaustion and depersonalization evolve significantly in the same direction, with a correlation coefficient of +0, 38 (p <0.030). However, achievement is negatively correlated with depersonalization and emotional exhaustion with r

= -0.07 (p <0.76) and r = -0.25 (p <0.043) respectively. This confirms the concern for instability or balance in people exposed to burnout and depersonalization. The analysis of the three dimensions shows that the prevalence of pathological people (high emotional exhaustion, high depersonalization and low self-fulfillment), is 8.66% (n = 11). While, 6.30% (n = 8) of respondents are in a normal state (would ensure a balance in their profession) while the rest of the respondents are in an intermediate situation and therefore require permanent monitoring to not become a pathological state.
