# Fluorosis: An Endemic Health Disease

Sakshi Chaturvedi<sup>1</sup>, Chakrapani Chaturvedi<sup>2</sup>, Ashutosh Dadhich<sup>3</sup>

<sup>1</sup>Assistant Prof. Banansthali Vidyapith Niwai Dist. Tonk (Raj), <sup>2</sup>Associate Prof. Cum Principal, B.V.M. Nursing College Gwalior; <sup>3</sup>Lecturer, Banansthali Vidyapith Niwai Dist. Tonk (Raj)

## Abstract

A study is conducted to assess the cases of fluoride affected person in selected gram pachayat, Tonk, Rajasthan. This study is conducted as initiative to conduct action research after wards. In This study symptoms of fluoride has been categorized in three type of fluorosis skeletal (SKF), non skeletal fluorosis (NSKF) and dental fluorosis (DF). In this study villagers between the age group 10-70 years were observed for the presence of fluorosis symptoms by researchers. Conclusion of the study is level of fluoride in the water or food and crops grown in that majorily has caused non skeletal fluorosis, 50% people are affected severely, 2% population study sample has developed severe skeletal fluorosis, 56% sample is affected with dental fluorosis at moderate level among which children are more affected after conducted assessment of fluorosis symptoms in fluoride endemic district, researcher has given health education to study sample and discussed many nutritional and environmental manipulations which can decrease the level of fluoride in human body as well as in ground water level

**Keywords:** Dental Fluorosis, Skeletal Fluorosis, Non Skeletal Fluorosis, Fluoride.

## Introduction

Fluorosis is a disease of oral, skeletal and non skeletal dysfunction which arises due to increase **fluoride level >1.5mg/liter** in ground water and increase fluorine gas in atmospheric air<sup>3</sup>. In North India **Rajasthan** and Gujarat and in South India Andhra Pradesh are **highly endemic** areas. Punjab, Haryana, M.P, Maharashtra are moderately endemic areas. Tamilnadu, West Bengal, Uttar Pradesh, Bihar and Assam are mildly affected endemic area of fluorosis. Fluorosis is essentially Hydrofluorosis except in parts of Gujarat and UP where industrial fluorosis also seen Which is due to fluoric acid compounds. The food and crop which is grown locally among fluoride endemic area is also found to have very high fluoride level (Richa

Miglani,2018). **WHO** has classified FLUOROSIS among 3 categories DENTAL FLUOROSIS, SKELETAL FLUOROSIS, NON SKELETAL FLUOROSIS, In **Non Skeletal Fluorosis** GIT system shows Acute abdominal pain, Diarrhea, Constipation, blood in Stool, Bloating feeling (Gas), Tenderness in Stomach, Feeling of nausea. Nervous system when affected with high fluoride concentration shows **Nervousness & Depression**, tingling sensation in fingers and toes, Excessive thirst and tendency to urinate, Frequently Polydipsia and polyuria control by brain appears to be adversely affected. Some studies reported infertility in humans and menstrual disturbance in women is also observed due to effect of high fluoride level on thyroid gland.

Research Reviews suggests that high fluoride more than 10mg/liter in drinking water and daily activity for prolong period of time can also affect skeletal system which is termed as **Skeletal Fluorosis**<sup>13</sup> causing multiple bone and joint pain, tingling, burning and pricking sensation in limbs, chronic fatigue, muscle weakness. Changes can be observed in spinal column and pelvis. In later stages osteoporosis and bone spur can be developed and crippling Skeletal Fluorosis is also observed due to

fusion of vertebra and bones. Dental fluorosis occurs due to exposure to fluoride during mineralization; fluoride replaces the hydroxyapatite crystals in teeth and gets deposited as fluorapatite crystals, which becomes clinically visible as dental mottling. Mottling of the teeth is usually seen in younger children who are developing their front teeth. Excessive fluoride also replaces the hydroxyl groups present in the hydroxyapatite crystal of the bone, forming fluorapatite. This has large crystal size due to which the bone becomes brittle and susceptible to fracture risk. Moreover, young bones retain more fluoride than older bones. Clinical manifestations of fluorosis may be aggravated by malnutrition, specifically calcium and vitamin D nutrition status which is evident from the high incidence of crippling deformities in poor residents from endemic fluorosis zones.<sup>[5]</sup> in dental fluorosis tooth enamel starts

**Material and Method**

The Research Design study for the present study is descriptive in nature which emphasize on prevalence of symptoms of fluorosis among the person who are consuming fluoride water for more than 10 years regularly multi stage sampling is done . Village is divided in to Dhani non randomly and then 3 Dhanis are selected randomly among that all person in the age

group 10-70 years are interviewed from self structured questionnaire checklist for identification of fluorosis in an endemic area privacy of all participant is maintained as part of ethical consideration while interviewing . 100 persons were observed for presence of symptom related to fluorosis on the basis of pre validated self structured questionnaire check list given below. A health talk program was organized in which caused of fluorosis, identification of fluorosis,environmental manipulation such as tulsı plant <sup>[2]</sup>,diet modification such as antioxidant rich food and treated water benefits are discussed .

**Findings:** Descriptive Statistics reveals that among all type of **Fluorosis Non Skeletal Fluorosis** has affected severely to 50% villagers,24%villagers are moderately affected,18% villagers are mildly affected with NSKF and 8% have no problem related to NSKF. The Picture of skeletal fluorosis is seen severely in 2% cases which are already diagnosed for fluorosis,17%villagers showed moderate level,73% showed mild level of SKF which is for pain some joints some time and sound coming after movement of those joint and 8%do not have any problem in skeletal system. **Dental Fluorosis** was seen moderately among 56% sample especially in age group 31-50,25% were mild cases,19% were having no dental problems.

**Table 1: Findings of socio-demographic variables**

S.No.	Name of Socio Demographic Variable	Classification	Frequency and Percentage N=100	
1.	Age	a. 10-31	42	42%
		b. 31-50	34	34%
		c. 50-70	24	24%
2.	Gender	a. Male	64	64%
		b. Female	36	36%
3.	Education	a. Illiterate	19	19%
		b. Primary	16	16%
		c. Middle	18	18%
		d. matric	15	15%
		e. Sr. sec.	6	6%
		f. Graduate	9	9%
		g. Certificate/diploma	12	12%
		h. Post graduate	5	5%
4.	Duration of consuming fluoride water	a. 10 years	14	14%
		b. 15 years	22	22%
		c. 20 years	30	30%
		d. 25 years	19	19%
		e. more than 25 years	15	15%
5.	Source of water	a. Well	66	66%
		b. Water plant	12	12%
		c. Pond	22	22%

S.No.	Name of Socio Demographic Variable	Classification	Frequency and Percentage N=100	
6.	Occupation	a. Farming	25	25%
		b. Business	23	23%
		c. Labor	19	19%
		d. Private job	14	14%
		e. Govt. job	4	4%
		f. Dependent	15	15%
7.	History of smoking	YES	44	44%
		NO	56	56%
8.	Conservation of rain water at home	YES	2	2%
		NO	98	98%

### Discussion

Data Suggests That NSKF is more prevalent among villagers. adults in age group 31-50 have developed dental fluorosis as well as non skeletal fluorosis .skeletal fluorosis is seen in elderly in complicate stage .only a few persons after leg deformity diagnosed with history of fluorosis significance related to consumption of fluoride drinking water more than 20 years and source of water well and pond suggests that these are the major contributory risk factor for fluorosis.

### Conclusion

Researcher conclude that people who are drinking fluoride water more than 10 years will develop fluorosis symptoms which will turn in to life threatening issues paraplegia, sclerosis, osteoporosis. .use of filtered water and environmental manipulation<sup>[2]</sup> can decrease the fluoride level in ground water.

**Conflict of Interest:** Researcher was not having resources to solve their problem but they realise that fluorosis is a big burden on rural community of tonk district,Rajasthan .

**Source of Funding:** By self

**Ethical Clearance:** Informed consent has been taken up by all participants and sarpanch has given permission to conduct the study .

## Abstract

**Introduction:** Fluoride is a known caries preventive agent. According to previous literature, a school based preventive program using fluoride gel could be effective in reducing the level of dental caries in children. There are very few studies that have been done in India in this regard. So, a retrospective study was planned to evaluate the preventive program of application of Acidulated phosphate fluoride (APF) gel on permanent teeth of school going children of 10-11 years till 15-16 years for 5 years.

**Material and Method:** The caries experience of the children was recorded using decayed, missing, filled teeth (DMFT) index using World Health Organization (WHO) criteria by investigator 1. Fluoride application of Acidulated Phosphate Fluoride 1.23% APF gel (Fluorovil, Vishal Dentocare Pvt. Ltd, Ahmedabad, India) for 4 minutes was carried out biannually by single trained investigator 2. This was done from 2010-11 till 2016-17. This data for 5 years was recorded and analysed retrospectively using centre records. After data collection, statistical analysis were done using (Statistical Package for Social Sciences) SPSS version 20.0. Results and Discussion: The DMFT post fluoride application was significantly lower than DMFT value pre fluoride application. No side effects were reported by this school based program.

**Conclusion:** This study results prove that APF gel application is an appropriate measure that can be recommended for other school-based programs. It is a safe and feasible caries preventive measure.

**Keywords:** Fluoride, Dental Caries, Prevention, School Dental Health.

## Introduction

Dental caries is a bacterial disease which progresses when acids that are produced by bacterial action on dietary

fermentable carbohydrates diffuse into the tooth and dissolve the hydroxyapatite crystal of the enamel.<sup>1</sup> Some of the factors which cause dental caries are acidogenic bacteria (mutans streptococci and lactobacilli), salivary dysfunction, and dietary carbohydrates. On the other hand protective factors like salivary calcium, phosphate and proteins, salivary flow, and fluoride in saliva balance, prevent or reverse dental caries.<sup>1</sup>

Fluoride works primarily via topical mechanisms which include inhibition of demineralization of hydroxyapatite crystal of enamel<sup>2</sup> increased re-

---

mineralization at the crystal surfaces (the resulting re-mineralized layer is very resistant to acid attack: fluorapatite crystal)<sup>2</sup>. Low but slightly elevated levels of fluoride in saliva and plaque provided from topical fluoride help to prevent and reverse caries by the above mechanisms.<sup>3</sup> According to a recent literature review, the level of fluoride incorporated into dental mineral by systemic ingestion is insufficient to play a significant role in caries prevention.<sup>3</sup>

Method of topical fluoride application are in the form of toothpastes, mouthrinses, gels. Another review stated that there was moderate quality evidence of a large caries-inhibiting effect of fluoride gel in the permanent dentition.<sup>4</sup> The caries-preventive effect of fluoride gel on the primary dentition, was also large, but based on low quality evidence.<sup>4</sup>

Dental caries affects the quality of life of children, with decreasing number of hours at school and poor performance. A school based preventive program using fluoride gel would be effective in reducing the level of dental caries in children. There are very few studies that have been done in India in this regard. So a retrospective study was planned to evaluate the preventive program of application of APF gel on permanent teeth of school going children of 10-11 years till 15-16 years. The study was carried out at Mahatma Gandhi Mission Higher Secondary School (Marathi medium) and Mahatma Gandhi Mission Primary and Secondary School (English medium) Nerul, Navi Mumbai.

### **Material and Method**

The objectives of this study are to assess caries using DMFT index at baseline (2012) and to assess any incidence and recurrence after five years after topical fluoride application. (2017)

**Study Participants:** A retrospective study was conducted at Mahatma Gandhi Mission Higher Secondary School (Marathi medium) and Mahatma Gandhi Mission Primary and Secondary School (English medium) Nerul, Navi Mumbai. Prior written parental informed consent was obtained in 2012 for all students. Before starting this study, ethical clearance was obtained from the Institutional ethics review committee.

Data was collected from past dental records from 2012 of school children who are presently in the class of 9<sup>th</sup> and 10<sup>th</sup>. All there cords of 200 students studying in English and Marathi medium of Mahatma Gandhi

School, Nerul who were of 10-11 years of age in 2012 were evaluated. Census method of sampling was done.

#### **Inclusion Criteria:**

- Participants of the school who regularly got fluoride treatment done at dental centre regularly.
- Participants who were of the age group 10-11 years in 2012.

#### **Exclusion Criteria:**

- Participants not willing to co-operate with the oral examination over five years.
- Children undergoing orthodontic treatment

**Caries diagnostic criteria and examination:** The caries experience of the children was recorded using decayed, missing, filled teeth (DMFT) index using World Health Organization (WHO) criteria.<sup>5</sup> After drying the tooth with compressed air, the investigator performed a visual examination and when in doubt used a WHO probe gently to check presence of decay, filled tooth. All permanent teeth whose occlusal surfaces were visible were considered for examination. Allexaminationswas done by investigator 1 in 2012 just after adoption of the centre of the department, following which fluoride application was started.

Fluoride application of Acidulated Phosphate Fluoride 1.23% APF gel (Fluorovil, Vishal Dentocare Pvt. Ltd, Ahmedabad, India) for 4 minutes was carried out biannually by single trained investigator 2. All applications were done by investigator 2 who was blinded to the study and its objectives. The fluoride application was done in the fully equipped dental centre (with dental chair) at Nerul School. After cotton roll isolation, the investigator 2 dried teeth with compressed air from 3-way syringe. APF gel was applied in well fitted flexible disposable trays. It was kept in the oral cavity for 4 minutes. Suction was also used. The child was instructed to bend their head forward during the application of APF via trays. The investigator 2 monitored the entire fluoride application procedure carefully, wiping any excess saliva. The excess gel was wiped off with gauze post removal of the tray. Also children were instructed not to eat, drink or rinse for at least 30 minutes post procedure. Also for every visit biannually oral hygiene instructions were explained to the child, for proper maintenance of oral hygiene post fluoride treatment.

**Follow Up:** The fluoride treatment was done. After 5 years of repeated fluoride application by investigator 2 and DMFT recording by investigator 1, the records were used for this retrospective study. Therefore, DMFT records of 2012 were to be evaluated, when the school program had started and in 2017 post 5 years of follow up.

**Statistical Analysis:** After data collection, statistical analysis were done using (Statistical Package for Social Sciences) SPSS version 20.0. Descriptive statistics were done. Normality was checked using Shapiro–Wilk test. The data was not normal therefore non parametric test was used. Wilcoxon Signed Ranks test was used to assess pre and post fluoride application changes in DMFT. A p value less than 0.05 was considered as statistically significant.

**Results**

After excluding dropout and incomplete records a total of 175 children records were examined in this study. Table 1 showed amongst total study group 59.4% males and 40.6% females.

Table 2 showed the results of Wilcoxon Signed Ranks test which was used to assess pre and post fluoride application changes in DMFT. The DMFT post fluoride application was significantly lower than DMFT value pre fluoride application.

**Table 1: Descriptives: Gender**

Variable	Frequency	Percent
Male	104	59.4
Female	71	40.6

**Table 2: Comparison of DMFT pre and post fluoride application:**

Variable	Pre fluoride application Mean (S.D.)	Post fluoride application Mean (S.D)	P value
DMFT	1.86 (1.64)	0.17 (0.47)	<0.01*

Wilcoxon Signed Ranks test; p<0.05 is statistically significant

**Discussion**

This study was done to evaluate the effectiveness of APF as a caries preventive agent at community level. In this study, the satellite centre which was adopted in 2012 and all children of 10-11 years were subjected to fluoride application (APF gel) with oral hygiene instructions bi annually. They were evaluated for caries recurrence or incidence of new lesions till 2017, with a 5 year follow up period. This age group was chosen, as only permanent dentition was to be evaluated in this study and according to previous literature teeth are at the maximum risk of developing dental caries up to 4 years post eruption into the oral cavity.<sup>6,7</sup>

Therefore the effect of topical fluoride application as a caries preventive agent can be evaluated on taking 10-16 years age group in school going children. A school based preventive program using fluoride gel would be effective in reducing the level of dental caries in children. There are very few studies that have been done in India in this regard. So, this retrospective study was done to evaluate the preventive program of application

of APF gel on permanent teeth of school going children of 10-11 years till 15-16 years.

Fluoride as caries preventive agent has been used in various studies in the past.<sup>1-4</sup> A recommendation of fluoride application in six to eighteen years in children showed moderate-risk patients should receive fluoride varnish or gel applications at six-month intervals to show maximum benefit of caries inhibitory effect of fluoride on tooth.<sup>8</sup> This is in accordance with results obtained in our study where topical fluoride (APF gel) professionally applied showed reduction in caries level after regular application for 5 years.<sup>4,8</sup> The results obtained in this study are in contrast to another fluoride school program done in India.<sup>9</sup> This could be due a longer follow up period, with fluoride application of 5 years in our study.

In this study, APF gel used was around 2.5 ml which is much lower than a single dose for acute poisoning (1 mg/kg body weight).<sup>9</sup> The various precautionary measures adopted were proper fitting trays, use of suction, a well-qualified investigator to carry out fluoride application and the position of child during

fluoride application (bent forward). No side effects were reported by this school based program. Thus APF gel is as effective as using Fluoride varnish or fluoride mouth rinse in school based programs.<sup>10,11</sup>

The various drawbacks in this study include 12% school dropouts. As some students left school during 5 years follow up and their records were incomplete. Also, sampling could not be done properly.

### Conclusion

With all these aspects in mind, this study results prove that APF gel application is an appropriate measure that can be recommended for school-based programs. It is a safe and feasible caries preventive measure. Such programs can be carried out in other schools, adopting this model to reduce the level of dental caries in school going children.

**Acknowledgement:** We acknowledge the effort of the staff of Mahatma Gandhi Mission Higher Secondary School (Marathi medium) and Mahatma Gandhi Mission Primary and Secondary School (English medium) Nerul, Navi Mumbai towards our study.

There are no known Conflicts of Interest of this study. No funding was taken for this study.

## Abstract

**Background:** The exponential rise in falls related to ageing is due to degeneration of sensorial system, decrease in muscle force and changes in the pattern of muscle activation. The proposed study will be conducted to examine the activation of various muscles of trunk and lower extremity during different balance control tasks.

**Objective:** Assessment of balance control and pattern of muscle activation among the various age groups

**Method:** 500 healthy individuals will be selected on the basis of selection criteria and categorized as per their age from 30-40 years, 41-50 years, 51-60 years, 61-70 years and 71-80 years in various groups. CoP excursion and EMG analysis of trunk and lower limb musculature during different balance control tasks. SPSS 25.0.0.0 will be used for Statistical Analysis.

**Conclusion:** The study will be beneficial for understanding the balance deficits and muscle activation pattern across ages.

**Keywords:** Aging, Balance, Center of pressure, EMG, Muscle activation.

## Introduction

“Population ageing is a triumph of humanity but also a challenge to society”<sup>(1)</sup> There is rapid increase in the proportion of the individuals of age  $\geq 60$  years than any other age Group across the Globe. The increased life expectancy and rapid growth of the elderly population has led to strong need for understanding of the physiological changes that occur across the lifespan. Among the several events affecting the health of the elderly, a fall is a major event resulting in a number of functional, psychological and social impairments.<sup>(2)</sup>

WHO Global report on falls prevention in older age, stated that this age group was estimated to be 688 million in 2006, projected to grow to almost two billion by 2050, by that time the total number of elderly will exceed the number of children  $\leq 14$  years. Moreover, the oldest segment of population, aged 80 and over, particularly

prone to falls and its consequences is the fastest growing within older population expected to represent 20% of the older population by 2050.<sup>(3)</sup>

The number of studies has been conducted to postulate the effects of ageing and posture-control system. Increased displacement and velocity of centre of pressure (CoP) are key characteristics of disturbed postural control system, resulting in impaired balance and consequent falls in elderly than in young and middle aged adults which is most evident in the dynamic activities of daily living.<sup>(4)</sup>

The exponential rise in Falls related to ageing is due to degeneration of sensorial systems (vestibular, visual and proprioceptive), decrease in muscle force and changes in the pattern of muscle activation are among the most cited factors. Many studies revealed that increased balance impairment in elderly is associated with the

altered pattern of muscle activation in comparison to the Young adults during various tasks reflecting the need for balance control. <sup>(5)(6)</sup>

Considering the fact that ageing alters the efficiency of muscles and their pattern of activation, the proposed study will be conducted to examine the activation of various muscles of trunk as well as lower extremity during different measures of balance control.

#### **Aims and Objectives:**

1. To evaluate centre of pressure (CoP) changes and postural sway during steady state balance activities across different age groups.
2. To investigate centre of pressure (CoP) changes and postural sway during dynamic balance activities (Proactive and reactive state) across different age groups.
3. To determine the activation of core muscle and muscles of the lower limb during steady state balance activities across different age groups.
4. To analyse the activation of core muscle and muscles of the lower limb during Dynamic balance activities (Proactive and reactive state) across different age groups

**Study Design:** The Present study is an observational cross-sectional study which will be conducted in Research Laboratory at Department of Physiotherapy, Punjabi University, Patiala for a duration of 3 years.

**Participant Recruitment:** 500 Individuals will be consecutively selected by the simple random sampling and based on the selection criteria which includes the subject of age ranging from 30-80 years in Patiala, Punjab and which will be further divided into 5 groups: 30-40 years, 41-50 years, 51-60 years, 61-70 years and 71-80 years. The participants who conform to any following conditions will be excluded: (1) Fracture or lesion in lower limbs in the previous 6 months; (2) History of recent spinal or lower limb surgery; (3) Neuropathies or neurological problems; (4) Absent knee extensor reflex or positive Babinski response; (5) Corrected visual acuity worse than 20/100 or presence of a field defect; (6) Sensory deficit in the lower limb; (7) Use of medications that might interfere with normal postural control; (8) Musculoskeletal problem interfering with the capacity to maintain an upright stance; (9) Acute illness.

**Sample Size:** The calculated sample size was 41.45, 37.23, 40.04, 28.90, 38.56 for the age group of 30-40 years, 41-50 years, 51-60 years, 61-70 years, 71-80 years respectively, on the basis of sample size estimation formula<sup>(7)</sup> ( $E = \frac{2\sigma}{\sqrt{n}}$  where E = Error( $\pm 1$ );  $\sigma$  = Standard deviation,  $n = 4\sigma^2/E^2$ ). However, to bring uniformity in number of subjects in each age group and to avoid gender bias a sample size of 100 subjects (50 males, 50 females) will be recruited for the study. Additionally, the larger sample size will minimize bias in estimating balance control across the ages.

**Ethical Considerations:** Ethical approval (letter no. 066 dated 16/08/2018) has been taken from the institutional ethical committee of Punjabi University, Patiala. The nature, purpose, aims and objective, significance and need to carry out this research was precisely explained to committee.

#### **Outcome Measures:**

1. Balance Control
2. Muscle Activation pattern

#### **Instrumentation and Procedure:**

**Measurement of Balance Control:** Balance control will be measured in terms of Excursion of CoP and postural sway in various positions, which will be recorded by **DIERS PEDO-SCAN (Force Platform)**, an assembly of arrays which are capable of precise, high-frequency measurements of foot pressure, CoP Movement, CoP Sway, Roll Over Characteristics, Foot Rotation, Foot Area(m<sup>2</sup>), contact Time, Weight Distribution, Foot Type. Considering the aims of the study, investigators will be interested in recording the anterior, posterior and lateral movement of CoP and postural sway during the different balance control tasks.

**Measurement of Muscle Activation:** The Muscle Activation pattern will be evaluated by using **wireless 6 channel surface EMG** by **DIERS** for core musculature and muscles of the lower extremity (listed in Table below). The **DIERS surface EMG** helps to record and analyse the muscular activity simultaneously while performing the static and dynamic balance control activities for a duration of 30 seconds using Butter worth low pass filter ranges from 20Hz-400Hz. The software calculated RMS at 200ms time frame will be considered for the evaluation process.

**Table 1: List of muscles to be examined in the study**

Region	Muscle	Function
Ankle	Gastrocnemius/Soleus	Ankle Plantar Flexor
	Tibialis Anterior	Ankle Dorsiflexor
Knee	Quadriceps (Vastus Medialis)	Knee Extensor
	Hamstring (Semimembranosus)	Knee Flexor
Hip	Gluteus Maximus	Hip Extensor
	Gluteus Medius	Hip Abductor
Core Muscles	Rectus Abdominis (Both Sides)	Trunk Flexor
	Erector Spinae (Both Sides)	Trunk Extensor
	External Oblique (Both Sides)	Trunk Flexor

The Electrode used will be Blue AMBU sensor N which is having a highly conductive wet gel, offset connector and superior adhesion to make sure optimal signal during short- to medium-term applications. Electrode placement will be according to SENIAM<sup>(8)</sup> project in 2000 or SENIAM recommendations for sensor locations are available here [http://seniam.org/sensor\\_location.htm](http://seniam.org/sensor_location.htm).

**Balance Control Tasks:** Cogitating the functional perspective, the team of principal investigator and co-investigators has selected static and dynamic balance control tasks. These tasks includes (1) Steady state, (2) Proactive or Anticipatory Posture and (3) Reactive posture<sup>(9)</sup>. Measurement of Balance control and muscle activation pattern will be performed in following three different forms independently.

**Steady State Posture:**

1. **Rhomberg<sup>(10)</sup>:** Eyes Open: Participants will be instructed to stand Upright and barefoot, staring at the mark on the wall and keeping the feet positioned which are shoulder width apart for 30 seconds.
  - 1.1. **Eyes Closed:** Standing in an upright position with the closed eyes subjects will be instructed to keep their feet together and maintain the position for 30 seconds.
  - 1.2. **Semi-Tandem Stance:** The subjects will stand in an upright position with right foot in front of

the left for 30 seconds while gazing the mark mounted on the wall.

- 1.3. **Single leg Stance:** The subject will stand on right leg for the duration of 30 seconds in an upright position while gazing on the black mark on the wall.

2. **Proactive or Anticipatory Posture Control: Functional Reach:** Participants will be instructed to stand with shoulder 90° flexed against the wall in an upright position with their feet together, without taking any support and try to reach forward. Horizontally a 150 cm yardstick will be mounted on the wall at level of acromion process. Succeeding to this the test, participant will be instructed to resume the starting position again after duration of 30 seconds.
3. **Reactive Postural Control: Sit to Stand:** The subjects will be instructed to sit upright with back unsupported and arms resting on the armrest. Chair will be adjusted to maintain Hip, Knee, Ankle 90°. Participant is instructed to stand from sitting position, simultaneously maintaining the upright posture while keeping arms by the side of their body and fixing the gaze at the mark on the wall. Following which participant will be instructed to resume the sitting position without looking back, uncrossing his/her hands till the command given by the investigator. The duration of 30 seconds: (5 sec seated, 20 secs upright, 5 secs seated).

**Table 2: Summary of Experimentation**

Experiment	Clinical Task	Outcome	
		Force Platform	Muscle Activity
For Steady State	1. Romberg Eyes Open Eyes Closed 2. Single Leg Standing 3. Semi Tandem Standing	1. Postural Sway 2.Center of Pressure (Antero-Posterior/Lateral)	1. Surface EMG (RMS values) over the muscles mentioned in Table 2.
For Proactive/ Anticipatory State	Functional Reach (Anterior and Lateral Direction)		
For Reactive	Sit to Stand		

**Statistical Analysis:** All statistical analyses will be performed using Statistical Product and Service Solutions (SPSS 25.0.0.0 latest version, updated on 26/4/2018) and Microsoft excel 2019. The descriptive analysis will be done for demographic variables, CoP, Postural Sway and EMG Activity. Comparison of muscle activation patterns between the different age groups will be carried out with ANOVA for excursion of CoP. Univariate and forward step regression finds the relationship of age with changes in postural sway and muscle activation patterns. Moreover, determining the gender differences in estimation of balance control will be analysed by the Multivariate forward stepwise regression.

**Significance of Study:** The study will indicate centre of pressure (CoP) changes and postural sway during steady state balance, across the ages, which will be further helpful to know whether aging affects the balance control during static positions such as sitting, standing, romberg, single leg stance, tandem stance etc. It will also suggest centre of pressure (CoP) changes and postural sway during dynamic balance activities (Proactive and reactive state) in relation with aging. This will provide better understanding regarding impact of aging on postural adjustments during functional tasks such as rising from a seated position. The findings of the study will provide database about the muscle activation patterns of core muscle and muscles of the lower limb during steady state and dynamic balance activities across different age groups. This will be helpful for identifying the differences between young and older individuals with respect to pattern of muscle activation from functional perspectives. The outcome of the study will also provide the gender based information in context to balance control across the ages (30 to 80 years)

## Conclusion

The study will be useful in understanding the balance deficits among elderly population and therefore in devising the preventive strategies so as to address a common problem of falls, which is a serious problem, demanding the attention from health care providers.

**Acknowledgement:** The Present study (EMR/2016/006917) is completely funded by Department of Science and Technology (DST) and Science and Engineering Research Board (SERB) for the duration of 3 years. DST-SERB is a governmental body that supports the emerging researcher and researches by providing financial grants to strengthen the evidence-based practice in INDIA.

# Dental Stem Cells Beyond Dentistry

Sona Baburathinam<sup>1</sup>, Vidyarani Shyamsundar<sup>2</sup>, Aravindha Babu N.<sup>3</sup>, Masthan K.M.K.<sup>4</sup>

<sup>1</sup>Postgraduate, Department of Oral Pathology and Microbiology, <sup>2</sup>Professor, Department of Oral Pathology and Microbiology, <sup>3</sup>Professor, Department of Oral Pathology and Microbiology, Center for Oral Cancer Prevention Awareness and Research, <sup>4</sup>Professor & Head of the Department, Department of Oral Pathology and Microbiology, Center for Oral Cancer Prevention Awareness and Research, Bharath Institute of Higher Education and Research, Sree Balaji Dental College and Hospitals, Tamilnadu, Chennai

## Abstract

Stem cells are unspecialised cells that can give rise to one or more different types of specialized cells. Stem cells differ from other kinds of cells in the body. Regardless of their source, all stem cells have three general properties: they are capable of renewing and of dividing themselves for long periods; they are unspecialized; and they can give rise to specialized cell types. Tooth derived stem cells or dental stem cells also represent a promising source of cells for regenerative medicine. This review highlights and upgrade the knowledge of current and future perspective of the regenerative application of dental derived stem cells in areas beyond tooth and tooth related regeneration.

**Keywords:** Dental Follicle Precursor Cells (DFPCs), Human adult dental pulp stem cells (ADPSCs), Periodontal Ligament Stem Cells (PDLSCs), Stem cells from human exfoliated deciduous teeth (SHEDs), Stem Cells of Apical Papilla (SCAPs).

## Introduction

Dental stem cells or tooth derived stem cells are categorized according to the location from which they are isolated and represent a promising source of cells for regenerative therapy. Originally, as one kind of mesenchymal stem cells, they are considered as an alternative of bone marrow stem cells. They share many commonalties but maintain differences. Stem cells of the orofacial region have been categorized as the Mesenchymal stem cells (MSCs)/Adult stem cells (ASCs)/Tissue stem cells (TSCs). Mesenchymal stem

cells (MSCs) are a prospective source of adult stem cells (with neuroectodermal origin and mesodermal origin) for regenerative medicine as they are extraordinarily plastic and when expanded into colonies which retain their multilineage potentiality. MSCs are able to differentiate into cells of mesodermal origin like chondrocytes, adipocytes, osteocytes, etc as well as give rise to representative lineages of the three embryonic layers<sup>1</sup>. Studies have identified several source of multipotent mesenchymal progenitor cells, known as dental stem cells. Considering their original function in development of tooth structures, many applications of these cells in dentistry have aimed at regeneration of tooth structure; however, the application in other than tooth structures regeneration has been attempted extensively. The availability from removed teeth or discarded teeth can be an innate benefit as a source of autologous cells. Their origin from the neural crest results in exploitation of numerous other applications. This property highlights current and future perspectives of the regenerative applications of tooth derived stem cells in areas beyond tooth regeneration.

**Source of Dental Derived Stem Cells:** Five different human dental stem/progenitor cells have been isolated and characterized:

1. Human adult dental pulp stem cells (ADPSCs) (Gronthos et al., 2000)<sup>1,2</sup>
2. Stem cells from human exfoliated deciduous teeth (SHEDs) (Miura et al., 2003)<sup>1,2</sup>
3. Periodontal Ligament Stem Cells (PDLSCs) (Seo et al., 2004)<sup>1,2</sup>
4. Stem Cells of Apical Papilla (SCAPs) (Sonoyama et al., 2008)<sup>1,2</sup>
5. Dental Follicle Precursor Cells (DFPCs) (Morsczeck et al., 2005)<sup>1,2</sup>

### Use of Dental Stem Cells

**Dentistry:** The dental derived stem cells are widely used in interdisciplinary dentistry for craniofacial regeneration<sup>3</sup>, dentin regeneration, periodontal regeneration, cementum regeneration, pulp regeneration<sup>4</sup>, cleft lip and palate, salivary gland regeneration, TMJ reconstruction, whole tooth regeneration<sup>5</sup>, also used in research dental cancer therapy<sup>6</sup>, Forensic dental profiling, Correlation and collection of Ante-mortem and Post mortem data<sup>7</sup>.

**Osseous Regeneration:** Dental derived stem cells have an (DPSC) exhibit an osteogenic differentiation profile. Upon differentiation into preosteoblasts, DPSCs deposit an extracellular matrix that eventually forms mineralized woven bone<sup>8</sup>. Due to the superior efficiency in producing bone on comparing with Bone marrow stem cells BMSCs, DPSCs are considered one of the best candidate for bone regeneration<sup>9</sup>.

In a clinical study, bio complexes prepared from DPSCs and collagen sponges were used in repair of human mandible and exhibited impressive results. In conjunction with other biomaterial platforms, DPSCs has shown to have osteogenic differentiation capacity. The topography of scaffolds was also reported to play a crucial role in clinical regeneration. Recently the role of tooth derived stem cells from dental pulp in bone regeneration around dental implants was investigated, and around titanium implants comparative study performed with BMSCs and periosteal cells showed that DPSCs exhibit the highest potential of osteogenic differentiation which as a source for tissue-engineered bone<sup>10</sup>. All type of tooth derived stem cells: Human

adult dental pulp stem cells (ADPSCs); Stem cells from human exfoliated deciduous teeth (SHEDs); Periodontal Ligament Stem Cells (PDLSCs); Stem Cells of Apical Papilla (SCAPs); Dental Follicle Precursor Cells shows greater potential of osteogenic differentiation compared to BMSCs<sup>11</sup>.

**Hepatocyte Differentiation:** Hepatocytes are the chief functional cells of the liver. Roughly 80% of the mass of the liver is contributed by hepatocytes. Hepatocytes are the main cellular component of the liver, comprising 70-80% of the total liver mass. The tooth derived stem cells from the pulp showed the potentiality to differentiate into hepatocyte like cells<sup>12</sup>. More recently, DPSCs have provided strong evidence to support a role in the treatment of irreversible liver diseases, providing hope for a future cure.

**Neural Regeneration:** DPSCs stand out as strong candidates as a source of neural stem cells, when compared with BMSCs, which have a low differentiation efficiency. Considering the origin of dental pulp, it is evident that DPSCs exhibit intrinsic neuro-glial characteristics and capable of differentiating into both neural cells and vascular endothelial cells. Consistent with this observation, recently DPSCs was demonstrated to have glial origins<sup>13</sup>. Studies have attempted neural regeneration with dental pulp-derived cells (DPCs) earlier than those with DPSCs. Nosrat et al<sup>14</sup> demonstrated that DPC grafting promotes survival of damaged motor neurons in spinal cord injury. In a subsequent report, several neurotrophic factors like glial cell line-derived neurotrophic factor (GDNF), brain-derived neurotrophic factor (BDNF), and nerve growth factor (NGF) were shown to be secreted from DPCs, which in turn facilitated survival of sensory and dopaminergic neurons. This neurotrophic effect was confirmed using in vitro models of Alzheimer's and Parkinson's disease<sup>15</sup>. DPCs have also used in regeneration of peripheral nerves injuries. Importantly, although these studies were performed using DPCs, DPSCs are expected to exhibit similar properties<sup>13</sup>. The secretion of neurotrophic factors from transplanted DPSCs has been suggested to provoke a kind of chain reaction that induces neighboring cells to differentiate and secrete other neurotrophic factors important to the repair the injury site<sup>14</sup>. In addition, DPSCs directly inhibit the activity of several axon growth inhibitors and also prevent apoptosis of neurons, astrocytes, and oligodendrocyte. As another example of CNS regeneration, many studies have proposed stem cell therapy using tooth derived stem cells as a cure for

stroke in a rodent model<sup>14, 15</sup>. On the other hand, SHEDs also potentially differentiate into dopaminergic neuron-like cells<sup>11</sup>.

**Corneal Reproduction:** A sheet of tissue-designed DPSC was transplanted on the corneal bed securing the human amniotic film. Healthy uniform corneal epithelium was formed after three months of healing. Additionally Stem cells from third molars were isolated and showed the potential of differentiating into keratocytes, which are cornea stroma cells. Epithelial cells from the oral mucosa have likewise been researched with regards to visual surface remaking<sup>16</sup>. Taking after optic nerve injury, intravitreally transplanted DPSCs have been additionally answered to advance recovery of retinal ganglion axon<sup>4</sup>.

**Treatment of Diabetes:** Diabetes is one of the most common long-lasting endocrinal sicknesses which is related to the pancreas (islet cell). Both type 1 and type 2 (disease where blood sugar swings wildly) may be successfully managed by transplantation of islet cells. The ability of DPSCs into islet-like cell groups (ICAs) has been explored, suggesting that in vitro cultured ICAs can release insulin and C-peptide in a glucose dependent manner<sup>17</sup>. Carnevale et al also reported that human amniotic fluid stem cells and hDPSCs into insulin-producing cells, suggesting their possible ability to differentiate as a nonpancreatic, low-harmful source of cells for islet regeneration<sup>18</sup>. The body-structure-related relevance of this technology was proved with the generation of islet-like cell groups together coming from both DPSCs and SHEDs<sup>5,11</sup>. The potentials of DPSC and SHEDs into all functional endocrine and exocrine subsets of pancreatic cells were confirmed in a separate study, and person with blood sugar disease/related to blood sugar disease were shown to be helped (to reduce) upon transplantation of DPSCs<sup>17</sup>. Finally, the transdifferentiation human PDLSCs cultured in Matri gel into (related to the pancreas) islet cells has been demonstrated<sup>19</sup>.

**Myocardial Infarction:** Myocardial infarction (MI) remains one of the cardinal causes of mortality worldwide. Several studies have investigated the possibility of using DPSCs for the treatment of MI. For example, Gandia et al used human dental pulp stem cells (hDPSCs) in a rat myocardial infarction model in 2008, reported an increase in the number of vessels and decrease in the size of infarct, concluding that hDPSCs secrete multiple proangiogenic apoptotic factors including

VEGF<sup>20</sup>. In 2009, the overall capability of stem cells to differentiate into cells with a cardiac phenotype was evaluated including BMSCs, adipose tissue stem cells, and DPSCs<sup>21</sup>.

**Ischemic Diseases (Angiogenesis):** Angiogenesis is characterized as the physiological procedure through which fresh recruits vessels shape from previous vessels. Vessel advancement in body is an extremely intricate and dynamic procedures, for example, debasement of the cellular layer and the extracellular network (ECM), tube development, endothelial cell expansion and relocation, and development into useful veins<sup>22</sup>. As of late, a high vasculogenic subfraction of DPSCs was disconnected from the dental mash which demonstrated various endothelial begetter cells<sup>23</sup>. In like manner SHED have likewise been shown to have the capacity to create endothelial progenitor cells<sup>[11]</sup>. Concerning paracrine enlistment of angiogenesis, DPSCs were beforehand exhibited to express various platelet determined development calculate (PDGF), fibroblast development figure (FGF) vascular endothelial development consider (VEGF), furthermore could prompt the tube arrangement of umbilical vein endothelial cells invitro<sup>24</sup>. Along these lines, DPSCs may speak to an appealing foundational microorganism hotspot for tissue designing and could be a treatment for angiogenesis, for example, stroke, endless injuries, and myocardial dead tissue.

**Future Perspective:** Skeletal muscle differentiation of DPSCs has been reported for the treatment of muscular dystrophy<sup>25</sup>. In addition, several studies have attempted to differentiate DPSCs into salivary gland cells<sup>26</sup>. Overall, studies indicate that DPSCs are more preferable than BM-MSCs for mineralized tissue regeneration<sup>27</sup>. However, differentiation of DPSCs into skeletal muscle has been reported for the treatment of muscular dystrophy<sup>25</sup> along with differentiation of DPSCs into salivary gland endothelial cells. As for the recovery of salivary glandular function with irradiation, a study reported that DPSCs differentiated into dental pulp endothelial cells(DPECs) that promotes healing of radiation damage in the irradiated salivary glands can only be speculated as potential mechanisms at present time<sup>26</sup>.

## Conclusion

Tooth derived stem cells have innate advantages and represent as a viable source of adult stem cells. They are considered as an alternative of BMSCs but

the different characteristics from difference in origin make them unique in the utilization as a cell source for regenerative therapy. Dental stem cell have a high proliferative potential to proliferate into: Odontogenic, Osteogenic, Chondrogenic, Adipogenic, Neurogenic, myogenic tissues, etc and have shown their possibility as a cell source for non tooth structures, such as bone, nerve, muscle, liver, and pancreas, etc. Dental stem cells exhibits multifactorial potential such as multi-differentiation ability, high proliferation rate, high viability, easy accessibility and easy to be induced to distinct cell lineages. However, although numerous breakthroughs in stem cell research have been made so far, their applicability and success in clinical trials remains to be ascertained. Solid research of stem cells must be performed before scientists leap into the clinical trials. Technologies using Ips and MSC cells could be the new era of personalized medicine. The heterogeneity among patient factors and the biology of different stem cell types reinforces the need for an individual-targeted approach to stem cell therapy and other cell-based treatments.

# Relationship between Maxillary Molar Root Tips and Maxillary Sinus Floor Using CBCT

Suhas Manoharan<sup>1</sup>, Jayanth Kumar V.<sup>2</sup>

<sup>1</sup>Undergraduate Student, <sup>2</sup>Reader, Oral Medicine and Radiology, Saveetha Dental College and Hospital, Saveetha Institute of Medical and Technical Sciences

## Abstract

**Introduction:** Maxillary Sinus is a triangular-shaped paranasal sinus located close to the nose and maxillary posterior teeth. It is the largest of the four paranasal sinuses and is responsible for the resonance of voice and also in the dissipation of any unwanted forces preventing injury to maxillofacial bones. Overtime pneumatization of the maxillary sinus takes where age is a significant factor. Tooth loss may also lead to loss of bone, which in turn causes reduced bone density and insufficient bone quantity and quality for the placement of implants.

**Materials and Method:** CBCT scans were gathered and analyzed to establish a relationship between the maxillary posterior root tips and the sinus floor. We had collected 30 CBCTs from the Department of Oral Medicine & Radiology, Saveetha dental college, Chennai. The distances of the root tip of the maxillary first and second molar to the sinus floor were measured. Statistical analysis was done on the collected data.

**Results:** Mean and standard deviations of the distance of each root tip of maxillary first and second molar from the maxillary sinus floor were obtained. No significant statistical difference was found between the respective roots of maxillary first and second molars.

**Conclusion:** Knowledge regarding the relationship between posterior root tips of the maxilla and the sinus is needed to prevent any unwanted complications during dental procedures

**Keywords:** CBCT, maxillary sinus, maxillary molar.

## Introduction

The maxillary sinus is one of the first of the paranasal sinuses to develop, its pyramidal in shape and completes its growth around 20 years of age with the eruption of the maxillary third molar.<sup>1</sup> Maxillary sinus has an average

volume 15cc and protrusion of the maxillary posterior root tips maybe seen in some cases which can lead to various implications during surgical and orthodontic procedures and is essential for clinicians to be aware of the apical position of the teeth in relation to the maxillary sinus.<sup>2</sup> Pneumatization is a physiologic process that occurs in all paranasal sinuses leading to an increase in the volume of the sinus. With age pneumatization of the maxillary sinus occurs. Especially following extraction of posterior maxillary teeth, marked reduction in bone density is seen accompanied by disuse atrophy of the bone accelerating the pneumatization of the maxillary sinus.<sup>3</sup>

A periapical lesion or a periodontal lesion in relation to the maxillary molars or premolars may reach the sinus leading to sinusitis. Endodontic treatment and

e-mail: doctorjayanth@gmail.com

extractions of maxillary posteriors may also lead to penetration into the sinus in some cases leading to an oroantral communication,<sup>3,4</sup> due to high caries index of maxillary first molar it is more prone to be extracted, and the possibility of an oroantral communication is marked.<sup>5</sup> OPG and IOPA are commonly used radiographic imaging modalities to visualize the maxillary sinus but being two dimensional; it has its limitations. CBCT has been a more preferred choice of imaging due to its ability to provide clear images without any overlapping of anatomic structures and also its ability to visualize distinct elevations along the floor of the maxillary sinus extending between the roots of teeth commonly called as hillocks or septa.<sup>6</sup>

This study aimed to establish a relationship between the maxillary sinus floor and the apices of the maxillary teeth roots using dental CBCT, thereby to provide clinicians with a protocol while working on posterior maxillary teeth. Though several studies have been done on the same note, we have not observed an adequate number of studies in the Indian population.

### Materials and Method

We obtained the CBCT scans for the study from the Department of Oral Medicine and Radiology, Saveetha

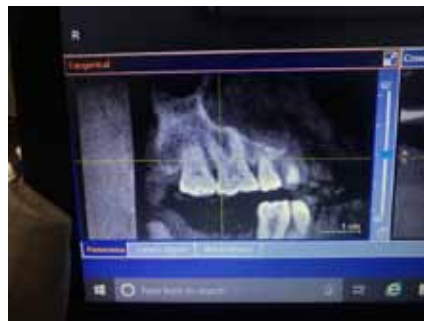

dental college. A total of 30 scans was collected. Out these 12 were men and 18 were female, and the average age was 31.8. CBCTs were all obtained during routine investigations for several procedures, among which scans with no pathology or missing teeth in the maxillary region were selected. Exclusion criteria include root canal treated maxillary posteriors, fractures, periapical lesions or patients who have undergone orthodontic treatment. Inclusion criteria consisted of patients without any periapical lesions in the maxillary posterior region, healthy maxillary bone with no break in the continuity of the bone and patients with vital maxillary posteriors. All CBCT scans obtained were analysed and lines were drawn using the GALILEOS Viewer by DENTSPLY Sirona USA, Field of view size was 8x8cm and 400 Hm resolution, to measure the distance of the apices of the maxillary 1<sup>st</sup> molars and maxillary 2<sup>nd</sup> molars. All root tips were grouped based on their relation to the maxillary sinus floor, as follows: Group 1: Root tips away from the sinus floor. Group 2; anyone root tips in contact with the sinus floor; Group 3: All root tips of the molar in contact with the sinus floor; Group 4; Root tips into the maxillary sinus.(Fig1) Unpaired T-tests were used to compare measurements between maxillary sinus floor and mesial, distal and palatal root tips of the maxillary molars. Statistical analysis was done using SPSS V.23.

Group 3

Group 4

**Fig 1: CBCT Cropped panoramic images showing the relationship of maxillary root tips to the maxillary sinus**

**Results**

Mean and standard deviations of the distance of each root tip of a maxillary first and second molar from the maxillary sinus floor were obtained and are given in the table below.

A significant 41% of the 1<sup>st</sup> molars and 43% of the 2<sup>nd</sup> molars were classified under group 1. About 24% of the 1<sup>st</sup> molars and 20% of the 2<sup>nd</sup> molars had their root tips into the sinus.

**Table 1: Mean distatances of Mesiobuccal root of maxillary molar to sinus**

Mesiobuccal Root	1 <sup>st</sup> Molar	2 <sup>nd</sup> Molar
Group 1	1.94±1.40	1.5±0.39
Group 2	0.67±0.62	0.55±0.56
Group 3	2.58±1.60	0
Group 4	1.05±0.66	0.92±0.4
Mean	0.74267	0.592

**Table 2: Mean distancies of Distobuccal root of maxillary molar to sinus**

Distobuccal Root	1 <sup>st</sup> Molar	2 <sup>nd</sup> Molar
Group 1	1.77±1.47	1.71±0.71
Group 2	1.02±0.14	1.01±0.16
Group 3	0.25±0.55	1.31±0.62
Group 4	0.8±0.44	1.18±0.66
Mean	0.801333	0.716667

**Table 3: Mean distancies of Palatal root of maxillary molar to sinus**

Palatal Root	1 <sup>st</sup> Molar	2 <sup>nd</sup> Molar
Group 1	1.51±0.75	1.64±1.08
Group 2	1.41±0.40	1.02±0.14
Group 3	1.24±0.41	1.47±0.30
Group 4	1.01±0.73	1.32±0.40

No significant statistical difference (P>0.05) was found between mean distances of each root of 1<sup>st</sup> and 2<sup>nd</sup> molar.

## Discussion

The relationship of the maxillary sinus to the posterior maxillary teeth plays a major role in treatment planning. This study was conducted to establish a relationship of roots of maxillary first molar and roots of the maxillary second molar to the floor of the maxillary sinus. Pneumatisation of the sinus and bone loss following extractions is a significant concern during prosthetic replacements.

Practitioners must be aware of the bone loss that follows extraction and the length of bone available for implant placements to prevent perforation of the sinus floor<sup>5</sup>. Oro antral spread of infections maybe associated with the relationship of the root tips of posterior teeth to the sinus floor. Cases of orbital abscess accompanied with periapical inflammation have been reported following root canal treatment of maxillary molars.<sup>7</sup> Hence, while planning for root canal treatment or endodontic surgery of maxillary molars, the proximity of the root tips to the sinus must be assessed to prevent any unwanted oroantral communication. A similar complication may also arise during periodontal or implant therapy. It has also been proven that usage of periapical radiographs for assessment of perforations of the maxillary sinus is not recommended<sup>8</sup> Advanced imaging modalities such as CBCT are currently being used to understand and analyze the anatomy of the maxillary sinus and the relationship of maxillary posterior root tips to the sinus floor. From various CBCT analysis, it can be inferred that Maxillary sinus floor thickening maybe seen in some instances due to infiltration of microorganisms and toxins from periapical lesions. These pathogens may spread the porous maxillary bone or through blood or lymph node.<sup>9-11</sup> Also, Interestingly Huang and Brundsvold reported a case of maxillary sinusitis following periodontal treatment of a maxillary first molar with deep pockets and bone loss.<sup>12</sup>

CBCTs obtained were analyzed and classified into groups based on their relationship of the root tips to the sinus floor. All root tips were grouped based on their relation to the maxillary sinus floor, as follows: Group 1: Root tips away from the sinus floor; anyone root tips in contact with the sinus floor; Group 3: All root tips of molar in connection with the sinus floor; Group 4; Root tips into the maxillary sinus. In our study, similar to what was reported by Jung<sup>9</sup>; Group 1 was found to be the majority among the classes with 41% and 43% for 1<sup>st</sup> and 2<sup>nd</sup> molars respectively in their study. The mesial

roots of the maxillary first and second molars were found to be closest to the sinus floor with an average mean distance of 0.742mm and 0.592mm from the sinus floor. On the whole, the buccal roots were found in closer proximity than the palatal roots. ANOVA test was done to compare the roots of the maxillary first and second molars and paired T-tests were done to compare each root tip to the sinus. It was also seen that 24% of the root tips of the maxillary first molar and 20% of the root tips of the maxillary second molar perforated or extended into the maxillary sinus.

## Conclusion

Good knowledge regarding the relationship of the maxillary posterior root tips and the maxillary floor is necessary for treatment planning. On statistical analysis, no significant difference was found between the root tips of the maxillary molar root tips and the sinus floor suggestive that ideally equal care and precautions have to be taken while periodontal, orthodontic, endodontic or any surgical procedures to prevent any infection of sinus or development of an oroantral communication. Given the unpredictability of the relationship of the sinus with the maxillary molar root tips, clinicians must be aware and should take necessary precautions and also calls for a need for accurate pre-operative analysis and treatment planning. Though study size was small in our study, very few studies have been conducted on an Indian population, and extensive studies on the topic may provide more information on the various relations of the maxillary molars to the maxillary sinus floor.

**Conflict of Interest:** No conflict of Interest.

**Source of Funding:** Research is entirely self funded.

**Ethical Clearance:** Study was cleared by the Institutional Review Board and informed consent obtained from all subjects

# To Study the Effect of Rotator Cuff Exercises on Tennis Elbow

Swapnil Ramteke<sup>1</sup>, Subrat Samal<sup>2</sup>

<sup>1</sup>Asso. Professor, Department of Sports Physiotherapy, <sup>2</sup>Asso. Professor, Department of Musculoskeletal Sciences, Ravi Nair Physiotherapy College, Datta Meghe Institute of Medical Sciences (Deemed University), Sawangi (Meghe), Wardha

## Abstract

**Aims and Objectives:** To study effects of Rotator Cuff Strengthening Exercises in Patients with Tennis Elbow. **Sample size:** 30 patients (15 in each group). **Study Design:** Randomised Contro Trial. **Sample and Sampling Method:** 30 patients were randomly selected and assigned in 2 groups, as Group 1(control group), Group 2 (Interventional group) in equal numbers The total subjects of 30 were included in the study the inclusion & exclusion criteria were **Inclusion Criteria:** Athletes complaining of elbow pain, Both male and female athletes, Age group 18-40 yrs, Subjects willing to participate. **Exclusion Criteria:** Subjects with pain in any other region, Subjects with shoulder, elbow, wrist, cervicothoracic surgery.

**Result:** There was no significant difference is found in the ages of both the group. Mean pain on VAS in group A it was  $4.66 \pm 1.77$  and in group B it was  $7.13 \pm 1.30$ .

**Conclusion:** The inferences from the present study suggest that Rotator Cuff strengthening protocol is significantly effective in Reducing pain,Improving functional activity.

**Keywords:** PRTEE, Lateral Epicondylitis, Rotator Cuff, Tennis, Elbow, EMG, Inflammation, Varus Torque, Theraband.

## Introduction

Lateral epicondylitis or lateral epicondylalgia, known colloquially as tennis elbow, shooter's elbow or simply lateral elbow pain, is a condition where the outer part of the elbow becomes sore and tender<sup>1</sup>. Since the pathogenesis of this condition is still unknown, there is no single agreed name<sup>1,2</sup>. While the common name "tennis elbow" suggests a strong link to racquet sports, this condition can also be caused by sports such as swimming and climbing, the work of manual workers and

waiters, as well as activities of daily living<sup>1,2,3,4</sup> Tennis elbow is a painful condition affecting the tendinous tissue of the origins of the wrist extensor muscles at the lateral epicondyle of the humerus, leading to loss of function of the affected limb<sup>3,4</sup>. Therefore it can have a major impact on the patient's social and professional life<sup>5,6</sup>. Pain around the lateral epicondyle is known by a variety of names and was described as periostitis, extensor carpi radialis brevis (ECRB)-tendinosis and epicondylalgia<sup>7,8,9,10</sup>. The most commonly used names are "tennis elbow" and "lateral epicondylitis". The use of the terms "periostitis" and "epicondylitis" was questioned over time, as histological studies failed to show inflammatory cells (macrophages, lymphocytes, and neutrophils) in the affected tissue<sup>11,12,13</sup>

Microscopical studies by Nirschl et al showed mainly fibroblastic tissue and vascular invasion that led him to describe the condition in 1999 as "angiofibroblastic tendinosis". These findings left the researchers to conclude that a more appropriate term for the condition is

“lateral elbow tendinosis”, which defines a degenerative process characterized by an abundance of fibroblasts, vascular hyperplasia, and unstructured collagen<sup>14,15</sup>. The term tendinosis or tendinopathy implies the absence of chemical inflammation. It has been postulated that tendinosis or tendinopathy is acquired by overuse of a hypovascular zone, which leads to subsequent neovascularisation<sup>16</sup>.

The need for this study is to check the efficacy of strengthening rotator cuff muscles in the treatment of lateral epicondylitis. The role of the rotator cuff in the treatment of lateral epicondylitis is not that well studied. Also to study the effect of weakness of the rotator cuff on the upper limb biomechanics leading to overuse of the Extensor Carpi Radialis Brevis<sup>37</sup>. More stress is placed on the treatment of elbow. Understanding the pattern of injury and the underlying causes in the whole kinematic chain will lead to a better treatment plan. Hence to stress the role of rotator cuff strengthening, this study is performed.

**Aims and Objective:** To determine the effects of Rotator Cuff Strengthening on Pain & Functional Activity.

**Source of Data:** Physiotherapy Center Seawoods Polyclinic, Seawoods Navi Mumbai.

**Method of Collection of Data:** Thirty Players of 18-40 years of age with the h/o pain in lateral epicondyle & diagnosed with lateral epicondylitis were taken and screened by using a questionnaire given for their inclusion in the study and assessed for pain & Functional Activity using Visual Analog Scale (VAS) and muscle strength. Patients were randomized into two groups. Group B (15 patients will receive conventional treatment and Group A (15 patients will receive rotator cuff strengthening along with good scapular control and conventional treatment).

The players were explained about the respective procedures which they would be undergoing for a period of 4 weeks and were made to sign a consent form before their participation in the study.

**Sample Size:** 30

**Sampling Design:** Simple Random Sampling

**Study Design:** Randomised Control Trail

**Study Duration:** 6 Weeks

**Outcome Measures:** Pain, functional scale, muscle strength

**Tools Used:**

- Therabands
- VAS Scale
- Mirror
- Dumbbells
- General assessment form for collecting the demographic data of the subjects
- PRTEE [Patient Related Tennis Elbow Evaluation]

### Methodology

**Procedure:** Thirty Players of 18-40 years of age with the h/o pain in lateral epicondyle & diagnosed with lateral epicondylitis were taken and screened by using a questionnaire given for their inclusion in the study and assessed for pain & Functional Activity using Visual Analog Scale (VAS) and muscle strength. Patients were randomized into two groups. Group B (15 patients will receive conventional treatment mainly electrotherapeutic modalities, elbow exercises taping) and Group A (15 patients will receive rotator cuff strengthening along with good scapular control and conventional treatment).

The players were explained about the respective procedures which they would be undergoing for a period of 6 weeks and were made to sign a consent form before their participation in the study. The protocol was followed for 10 sittings six days a week. After that, a home exercise program was given to both the study as well as the experimental group. The home program for the study group included

**Isometric wrist extensor and flexor training:**

**Active elbow range of motion exercises:** The home program for the experimental group included.

Isometric wrist extensor and flexor training, Active elbow range of motion exercises, Strengthening of the infraspinatus, supraspinatus, subscapularis along with scapular muscle rhomboids, serratus anterior levator scapulae and trapezius using therabands.

**Dependent Variable:** PRTEE Scale and VAS

**Independent Variable:** Rotator cuff strengthening the program.

**Control Variable:** Age between 18-40 yrs

**Data Analysis:****Table 1: Gender wise distribution of patients**

Gender	Group A	Group B	$\chi^2$ -value	p-value
Male	11(73.33%)	11(73.33%)	0.00	1.00 NS,p>0.05
Female	4(26.67%)	4(26.67%)		
Total	15(100%)	15(100%)		

**Table 2: Comparison of PRTEE Score in both the groups at pre and post-test****Descriptive Statistics:**

	Group	N	Mean	Std. Deviation	Std. Error Mean
Pre Test	Group A	15	69.46	10.51	2.71
	Group B	15	63.86	14.53	3.75
Post Test	Group A	15	25.86	8.15	2.10
	Group B	15	46.06	11.91	3.07

**Table 3: Student's unpaired t test**

	t	Df	p-value	Mean Difference	Std. Error Difference	95% Confidence Interval of the Difference	
						Lower	Upper
Pre Test	1.20	28	0.237NS, p>0.05	5.60	4.63	-3.88	15.08
Post Test	5.41	28	0.000S, p<0.05	-20.20	3.72	-27.83	-12.56

**Discussion**

The short term results of this prospective randomized study in athletes with lateral epicondylitis showed that treatment with rotator cuff strengthening with therabands and conservative management showed significantly reduced pain during activity and improved function<sup>1</sup>. The aim of our study was to compare the effectiveness of adding rotator cuff strengthening to the conservative approach. To try to limit bias patient they evaluated treatment. The patient recorded the amount of lateral epicondylitis pain on a PRTEE score and VAS. Patient satisfaction with treatment was also assessed [satisfied/not satisfied]

Lateral epicondylitis is a troublesome condition to treat and frequently brings athletic careers to an end<sup>2,3</sup>. Response to initial therapy is common, but so is relapsed (18% to 50%) and/or prolonged, moderate discomfort (40%)<sup>5</sup>. Keutenn and coworkers reported that 53% of athletes had to stop their sporting career due to chronic recurring lateral epicondylitis however we cannot exclude that some of these patients had other defects as well<sup>6</sup>. In tennis players, about 39.7% have reported current or previous problems with their elbow<sup>6,7</sup>. Less

than one quarter (24%) of these athletes under the age of 50 reported that the tennis elbow symptoms were "severe" and "disabling." While 42% over 50 identified severe and disabling symptoms<sup>9</sup>. More women (36%) than men (24%) considered their symptoms to be severe and disabling and in which Tennis elbow is more prevalent in individuals over 40, where there is about a 4-fold increase among men and 2-fold increase among women<sup>8,9</sup>. Observations of the patterns of activation and joint kinematics of novice tennis and advanced players, using kinematic data in conjunction with a computer model, have revealed substantial eccentric contractions of the extensor carpi, which are likely the cause of repetitive microtrauma leading to tennis elbow injuries and Adopting the technique seen in advanced players probably helps limit the eccentric contractions and reduces the likelihood of injury<sup>21,22</sup>. Tennis grip size was believed to play a crucial role in the past<sup>24,25</sup>. However, based on fine-wire electromyography studies in which muscle activity in extensor carpi radialis longus and brevis, extensor digitorum communis, flexor carpi radialis, and pronator teres were measured, tennis racquet grip size (1/4) above or below because of relatively very few studies evaluating the effectiveness

of shoulder muscle strength particularly rotator cuff in the development of lateral epicondylitis<sup>26,28</sup>. In one study conducted by Aguinaldo AL, and Chambers H studied the correlation of throwing mechanics with elbow valgus load in adult baseball pitchers<sup>52</sup>. They concluded that Valgus torque at the elbow during baseball pitching is associated with 6 biomechanical variables of sequential body motion and a condition of late trunk rotation, reduced shoulder external rotation, and increased elbow flexion appeared to be most closely related to valgus torque<sup>29,32</sup>. Sidearm pitchers appeared to be more susceptible than overhand pitchers to reduced elbow valgus torque<sup>32,33,34</sup>.

Injuries or adaptations in some areas of the kinetic chain can cause problems not only locally but as distal links must compensate for the lack of force and energy delivered through the more proximal links<sup>51</sup>. This phenomenon, called catch up is both inefficient in the kinetic chain and dangerous to the distal link because it may cause more load or stress than the link can safely handle, these changes may result in anatomical or biomechanical situations that increase injury risk, perpetuate injury patterns or decrease performance<sup>32,34,36</sup>. These deficits in the kinetic chain must be identified and corrected as part of the treatment and rehabilitation process<sup>36,37</sup>.

**Ethical Clearance:** It has been obtained by DATTA MEGHE ethical committee, DMIMS, SAWANGI MEGHE WARDHA.

**Conflict of Interest:** Nil.

# Relationship between Occupational Stress and Resilience

S. Vasantha<sup>1</sup>, R. Santhi<sup>2</sup>

<sup>1</sup>Professor, School of Management Studies, Vels Institute of Science Technology & Advanced Studies (VISTAS),

<sup>2</sup>Associate Professor and Head of Department of Commerce, Meenakshi College of Women

## Abstract

Occupational stress or stress related to workplace refers to stress experienced as a direct result of an individual's occupation, or job. Stress completely disturbs the physical, psychological and financial balances of an employee as well as employers. Due to stress employers cannot expect anticipated outcome from employees who are burnt out, drained or stressed, resulting in loss of their drive, determination, clarity and innovative thinking. Resilience is not just one's capability to recover from stress, but also ability to adjust in the face of difficult situations. There is an inverse relationship exists between stress and resilience.

**Keywords:** Occupational Stress, Employee, Employer, Organization, Resilience, Work load.

## Introduction

Occupational stress is the detrimental response that happens at physical and mental level, when there is mismatch between the prerequisites of the job and the abilities of the worker<sup>[29]</sup>. Occupational stress refers to stress on the job and it arises within a person when he faces problems in his occupation<sup>[8]</sup>. The organizational structure, employer and employees are involved in the prevalence of occupational stress and the consequent burnout responses of an individual. Occupational stress affects the organization in terms of productivity, profit, disruptions in normal operations. The employees are also affected due to bad physical and mental health<sup>[31]</sup>.

### Occupational Stress:

**The definitions provided by different authors for stress are as follows:** Occupational stress arises when there is mismatch between the requirements of the job and the capabilities of the person. It affects mental and physical health of an individual.<sup>[6]</sup>

Occupational stress is defined as the detrimental responses that develop in an individual. This phenomenon usually takes place when the job's requirements surpass the abilities, necessities or resources of the employee<sup>[18]</sup>

Workplace stress is the negative responses given out by the body and mind when it cannot handle the conflict between demands raised by the job he is performing

and the command an employee has over meeting these demands<sup>[23]</sup>.

Stress can be either beneficial or detrimental. Good stress is regarded as "eustress". Eustress motivates us to perform better. When this eustress goes beyond a limit, it causes distress and hampers the performance of the individual<sup>[34]</sup>.

**Stress Reactivity:** The categorization of stress reactivity as a three-phase process is mentioned in<sup>[27]</sup>. This process is termed as the general adaptation syndrome

**Phase 1: Alarm Reaction:** As result of stress, the body is affected and starts showing the symptom of exposure to stressor. The level of resistance is weakened if the stressor is more powerful. The result would be burns of high degree of severity, increased heart rate and temperature of the body etc.

**Phase 2: Stage of Resistance:** If Resistance supervenes and the stressor is in accord with adaptation of the condition, The physical symptoms related to the alarm stage have almost vanished and resistance level increases above the normal.

**Phase 3: Stage of Exhaustion:** After body has adjusted to the continued acquaintance to the stressor, finally adaptation energy is exhausted, the indicators of the alarm reaction come again. The symptoms of the

alarm reaction come again, but at this instant they are irreversible and the individual expires.<sup>[8]</sup>

**Causes of Work Stress:** A list of six causes of work stress has been established<sup>[7]</sup>

- (1) Job Conditions
- (2) Role Stress
- (3) Interpersonal Factors
- (4) Career Development
- (5) Organizational Structure
- (6) Home-work Interface

**a. Role Overload:** Role overload is defined as a situation when the individual is engulfed with too many tasks and assignments to be fulfilled. The individual is restrained from performing well due to the unavailability of resources<sup>[17]</sup>.

Role overload occurs when an individual is confronted with a situation to perform several roles concurrently but lacks the resources to complement the demands posed by them. The role expects the individuals to complete the tasks within a short period of time<sup>[30]</sup>.

The study has examined the impact of role overload on Job stress, Job satisfaction and Job Performance of married working women. The respondents of this study were 150 married working women. Role overload was positively related with stress and negatively related with job satisfaction and job performance<sup>[19]</sup>.

A study conducted to analyze the impact of role overload on teachers working in a university. The teachers are subject to huge amounts of stress due to the present scenario of heavy presence of technology integration in the educational sector. They are expected to extend their roles and keep performing to produce the desired results. The female teachers face a lot of pressures as they have to balance between family and work life. They are exposed to huge levels of stress. The outcomes of the study were that the significant predictor of job stress was role overload.<sup>[20]</sup>

**b. Physical Environment:** Physical environment deals with the health and safety of the individuals working for the organization. The Korean Occupational Stress Scale questionnaire states that work area

should maintain high standards of cleanliness and be free from pungent odours. Work area should have the adequate amount of lighting. The seating position should be comfortable for the employees so that they can stretch for long hours depending on the requirements of the job. The working environment should have precautionary equipment to protect the employees from any unexpected accidents<sup>[26]</sup>.

A study has been conducted to investigate the various factors of stressors among the employees of IT sector. Working in a safe and healthy physical workplace environment will ensure that the employees perform to their maximum level and improvise the productivity of the organization. The individual can suffer from health issues due to poor lighting, uncomfortable seating positions, exposure to toxic gases and erratic work schedules.<sup>[31]</sup>

The physical environment helps in maximizing the employees' performance and satisfaction, improving social relations and health of the employees. The below factors motivates an individual to deliver better performance<sup>[1]</sup>.

- a. Sound:** Sound in form of noise hampers job performance and causes stress to the employees.
- b. Temperature:** The body finds it difficult to adapt to extreme climatic conditions. The temperature of the workplace has to suit the body needs for the individual to work comfortably.
- c. Air:** Air in the workplace should be purified so that the individuals do not face breathing difficulties. It should be free from any type of strong odours.
- d. Light:** Workplace with improper and insufficient lighting might affect the efficient and quality of work of the employee. The work area should be properly illuminated.
- c. Role Responsibility:** A study conducted at Ghana Ports and Harbours Authority (GPHA), Takoradi. He has done an analysis of the stress factors among the workers of that organization. The outcomes of the investigation were that the employees felt that the organization was not concerned about their employees. The organization must take measures to resolve issues related to stress.

He states that the people working in the organization have to shoulder two types of responsibility.

- a. **Responsibility for people:** Responsibility for people triggers a lot of stress for people working as team managers, Human resource managers. Responsibility related to people usually calls for lot of meetings with different kinds of people, interacting with clients, listening to the grievances of the employees and the team members, resolving conflicts etc.
- b. Responsibility for things such as budgets, equipment etc. The person is responsible for these tangible equipments. He needs to take care of the inventory management, purchase and maintenance of the equipments<sup>[15]</sup>.

The role of multi-tasking sometimes increases the stress level of the employees and leads to bad performance. This qualitative study examines the perceived stress among graduate students by taking the various roles and responsibilities shouldered by them and the kind of social support they receive to overcome stress. The respondents answered questions related to their personal and academic life, their encounter with these stressful situations and different ways of dealing stress. The respondents felt that they had to struggle between varied responsibilities. They experienced stress due to their inability to strike a balance between both the sides. As the respondents did not receive the adequate social support in their new environment forcing them to quit.<sup>[13]</sup>

There is high level of stress prevailing among the employees working in BPO industry. It has also studied the impact of stress on employee turnover intention. The increased stress levels are impacting the performance of the employees, which, in turn affects the productivity of the organization. The employees were not able to cope up with the stress levels and this has led to increased attrition levels. The cost of replacing an existing employee increases the cost incurred to the company. The results depicted that occupational stress was caused due to role uncertainty/ambiguity, role boundary, role responsibility, and the physical environment<sup>[22]</sup>.

- d. **Social Support:** The link between occupational stress and social support (SS) was examined among the nurses working in hospitals. They found that Social Support significantly influences occupational

stress in hospitals nurses. They have suggested that the management should focus on lowering stress faced by the nurses who are married and those who have worked for many years in the same organization.<sup>[12]</sup>

A study has been conducted to examine the effect of the support provided by the people around them on occupational stress. This study was carried out among the nurses in Iran. The outcomes of the study found that there was a significant relationship between stress and social support. The support obtained from their peers and their superiors helped them to manage stress effectively.<sup>10]</sup>

Healthcare professionals undergo a lot of stress because of working environment around them. This study analyzes the influence that job demands, social support, job control and recognition have on the possibility that a worker will undergo stress. The results of the study show that a low emotional demand has more effect on reducing the likelihood of stress than low family demands. The companies should provide a accommodating work environment to the employees.<sup>[32]</sup>

- e. **Job control:** The investigation of the impact of job control on stress revealed that job control was a primary cause of stress and its outcomes either directly or by how it is influenced by other job elements like contentment, demands placed by job, concerns about future. 170 office workers participated in this study. The outcomes show that job control can influence stress, but demands placed by the jobs and concerns related to the job increases the levels of stress.<sup>[21]</sup>

The investigation study of the role of job demands and control on job stress and its relationship with demographic characteristics of Iranian prison staff concludes that the stress levels experienced by them was high due to high job demand and low job control.<sup>[9]</sup>

Depreciating levels of job control has ill effects on the mental health of a person. The researchers have conducted a longitudinal study of a national sample of working Australians. They have suggested that organizations should implement policies which can increase the levels of job control and thereby leading to better mental health of the employees.<sup>[24]</sup>

**Survey by Northwestern National Life****Survey by the Families and Work Institute****Survey by Yale University**

Source: [29]

Studies show that job stress is high among faculty members of universities due to high workload and occupational characteristics. Thus, these individuals have higher physical and mental occupational stress and less organizational commitment [11]

**Resilience:** Resilience is defined as "The capability to cope better than expected in the face of significant difficulty or threat" [33]. Resilience is one of the most important human abilities that results in effective adaptation to risk factors [3].

**Relationship between Resilience and stress:** A study was conducted in the year 2017 and investigated the correlation between occupational stress and resilience. The study highlighted that stress is common in all occupations and concluded that occupational stress can be reduced by increasing resilience level among faculty members. [2]

Resilience is described as a trait imbibed in the personality of an individual to nullify the negative effects of stress [35]. Resilience allows the individual to benefit from his adaptive skill, transform stressful situations into an opportunity for learning and growing, and consequently control stress. [4]. Resilient people use personal and social resources to reduce the negative effects of stress [5]. Occupational stress and resilience exhibits a significant and inverse relation. It is in consensus with the study conducted by Shakerina et al. [28]. The study results contradict the results obtained in the study by Mahdiah et al. [14] Previous studies state that people with high resilience levels have less chances of developing burnout. [16]

# Assessment of Practice and Attitude of Mothers in Using Over the Countermedication in a Selected Rural Area of Kanchipuram District, Tamil Nadu

Vishnu Priya S.<sup>1</sup>, Ashwin Garry Joshua I.<sup>1</sup>, Shakthivell N.S.<sup>1</sup>, Sandhiya B.<sup>1</sup>, Krupa Susan Koshy<sup>2</sup>

<sup>1</sup>B.Sc. (Nursing) IV<sup>th</sup> Year students, <sup>2</sup>M.Sc. (Nursing) Nursing Tutor, Child Health Nursing Department, Chettinad College of Nursing, Chettinad Academy of Research and Education, Kelambakkam, Kanchipuram District, Tamilnadu

## Abstract

Over the counter medication is a problem that exists world-wide. The objective of the study are assess the practices and attitude regarding over the counter medication among mothers and association of the practice scores of over the counter medication with their selected demographic variables and association of the attitude scores of over the counter medication with their selected demographic variables. A sample size is 100. A study was conducted to assess to mother using the over the counter medication and find out the association of the practice scores of over the counter medication with their selected demographic variables and association of the attitude scores of over the counter medication with their selected demographic variables. Majority of the sample are not using over the counter medication. The association between the practice and demographic variable has a significant of age, religion, educational qualification, occupation, type of family, income, no of children, usual source getting health related information. The association between the attitude and demographic variable has a significant of age, religion, educational qualification, occupation, head of the family, income, no of children, usual source getting health related information have you ever taken over the counter medication.

**Keywords:** *Over the counter medication, Practice, Attitude, Mother, OTC = Over the counter medication, health related information.*

## Introduction

Over the counter medication are drugs that are bought without a doctor's prescription. People around the world tend to treat the disease, almost 50% either wait for the problem to run its course or use a home remedy. About 25% visit a physician use a prescribed

medicine previously obtained of the same condition. The remaining 25% turn to the over the counter medications<sup>1</sup>.

Self-care and over counter medication will increase in the future for a number of factors. These factors include: socio-economic factors; lifestyle; ready and increased access to drugs and self-care products; increased and prohibitive costs of health services; change in the pattern of diseases; the increased potential to manage certain illness through self-care; the increased knowledge and awareness about health; and diseases; public health and environmental factors; and demographic and epidemiological situations . Survey and diary studies of medicine taking behavior indicated that 70% to 80% of illness is managed by self-care without the intervention of the physician<sup>1</sup>.

The consumption of medications can be considered an indirect indicator of the quality of health care services. Children and adolescents are strongly susceptible to the irrational use of drugs with and without medical control. Kids are more susceptible to cough and cold, this being infectious, if the mother or caretaker of the baby has cold, the baby will almost catch it, therefore it is very important for all the people around the baby to protect themselves from catching cold, to protect the baby getting it. Changing weather is another big cause of catching cold; protect the child from cold and sudden change in temperature. Do not give cough syrups without doctor's prescription. Although many cough and cold syrups are available on the counter, these should be administered only as prescribed by doctor. Cough syrups mostly induce sleep and hence may become addictive and some syrup affecting the liver if taken in excess<sup>3</sup>.

A study carried out by student of Manipal College of Medical sciences done in Pokhara, Western Nepal found that 59% had taken self medication including OTC drugs. The common reasons for self medication are mild illness, previous experience of illness. Similarly a study conducted in a rural village in Philippines revealed that antibiotics are routinely given in self medication for non severe childhood diarrheal illness<sup>4</sup>.

A descriptive study conducted on OTC medicines. Cross sectional study design was used. All the mothers of under five aged children visiting the Friends of Shanta Bhawan at the child OPD and had taken OTC medicines during last 6 months for child. The respondents took OTC for fever, cough and cold. 65% of respondents used OTC medicines because the pharmacy is near from their homes and 48% used it due too easy to get the medicine as compared to visit to doctors or hospital<sup>2</sup>.

### Objectives:

1. Assess the practices and attitude regarding over the counter medication among mothers.
2. Association of the practice scores of over the counter medication with their selected demographic variables.
3. Association of the attitude scores of over the counter medication with their selected demographic variables.

### Method

**Research Approach:** Non-experimental research approach was used.

**Research Design:** A Descriptive research design was used.

**Research Setting:** The study was conducted at Pooncheri, Kanchipuram (DT), Tamil Nadu.

**Population:** Married women who fulfill the sampling criteria.

**Sampling Technique:** The non- probability, purposive sampling technique was used for the study.

**Sample Size:** Sample size  $n = DEFF * NP(1-p)1/[d2/z2/2*(n-)+p(1-p)]$ .

Population size (for finite population correction factor or fpc)(N): 160

Hypothesized% frequency of outcome factor in the population(p): 50%+/-5

Confidence limits as% of 100 (absolute +/-%)(d)5%

Design effect (for cluster surveys-DEFF): 1

Confidence Level 95%

Sample Size =100

**Data Collection Instruments:** Demographic variables proforma, Practice and Attitude questionnaire were used. Practice questionnaire is 14 item questionnaire, to assess the practice of mother using over the counter medication. Attitude questionnaire is 9 item questionnaire, to assess the attitude of mother using over the counter medication..

**Scoring and Interpretation:** Their practise to self-medication was assessed using seven statements rated on a checklist grading on a five-point scale which was scored as: Never=0; rarely=1; Sometimes=2; frequently=3; everytime=4. The minimum score obtainable was 14 and the maximum 56. The mid-point (28) was used as the cut-off. A score of >28 was graded as practise is there, whereas <28 was graded as practise is less. Interpretation are Less than practice=0-14, Moderated practice=15-28, Much practice=29-42, Well practice= 43-56. Their attitude to self-medication was assessed using seven statements rated on a Likert grading on a five-point scale which was scored as: strongly disagree=0; disagree=1; neutral=2; agree=3; strongly agree=4. The minimum score obtainable was 9 and the maximum 36. The mid-point (18) was used as the cut-off. A score of <18 was graded as negative attitude, whereas ≥18 was

graded positive attitude. Interpretation are Less than inadequate=0-9, Inadequate =10-18, Moderate=19-27, Adequate=28-36.

**Data collection procedure:**

Data was collected over one week.

**Results**

**Table 1: Frequency Distribution and Percentage of practice of mothers in using over the counter medication. (N=100)**

- Majority of the practice score are moderately practice 79% and less practice 21%. There is no practice of much practice and well practice.

Interpretation	Frequency	Percentage
Less practice	21	21%
Moderately practice	79	79%
Much practice	Nil	Nil
Well practice	Nil	Nil

**Table 2: Frequency Distribution and percentage of attitude of mother in using over the counter medication. (N=100)**

- Majority of the attitude score are inadequate 59% and moderate 1%. There is no attitude of adequate.

Interpretation	Frequency	Percentage
Less than inadequate	40	40%
Inadequate	59	59%
Moderate	1	1%
Adequate	Nil	Nil

Majority sample age (49%) belongs to age group of 29-38 years as minority (0%) were in the age group of >49years. Majority of religion (75%) belongs to Hindu as minority (0%) were in other . Majority of the educational qualification(43%) is belongs to primary education and whereas minority (0%) belongs to post graduate. Majority of occupation(79%) is belongs to house wife and whereas minority (0%) belongs to Professionals and Shop and market-sales worker. Majority of the type of family (78%) belongs to nuclear family and whereas minority (0%) belongs to extended family.Majority of head of the family (99%) were father whereas minority has rest of others(0%). Majority of income (52%) belongs to 10001-20000 and minority (1%) belongs to Above 20001 . Majority of no. of the children (54%) belongs to 2 and minority (0%) belongs to more than

3. Majority of usual source getting health related informations (77%) belongs to books and minority (0%) belongs to health care worker . Majority of taken over the counter medication (99%) belongs to not at all and minority (0%) belongs to Occasionally and every time .

**Discussion**

The aim of the study was Assessmentof practice and attitude of mothers in using Over The Countermedicationin a selected rural area Kanchipuram district, Tamilnadu. The study consist of 100 samples that fulfilled the inclusion criteria were selected for the study by using convenient sampling method. The structured & standardized questionnaire was used to assess the practise and attitude of mothers in using over the counter medication. The findings of the study was discussed in this chapter with reference to the objectives of the study.

A cross sectional survey was conducted on 200 participants randomly selected from the coastal regions of south India. Each participant underwent a face to face interview with the help of a structured questionnaire the result reported self-medication use by 71% of the subjects, which ranged from a frequency of at least one time to a maximum of 5 times and above. Lack of time (41.5%), minor illness (10.5%) and quick relief (10%) were cited as the most common reason for self-medication use. The majority of the participants (93.5%) were not aware about the side effects of sm. Findings revealed females and people living in urban areas are more likely to use self-medication than males and people in rural areas<sup>5</sup>.

A descriptive study was conducted about self-medication among children and adolescents in Germany to investigate the prevalence and correlates of self-medication .17 450 children aged 0–17 years participated in the 2003-2006 German health interview and examination survey for children and adolescents. The result was 25.2% of participants reported self-medication. Self-medication accounted for 38.5% of total medicine use and included all medication classes. These clustered among drugs acting on the respiratory system (32.1%), alimentary tract and metabolism (21.6%), skin (14.2%) and nervous system (11.3%), as well as homoeopathic preparations (8.6%). Vitamin preparations were most frequently used with a weighted user prevalence of 4.7% followed by cough and cold medicines 4.4% and analgesics 3.7%<sup>6</sup>.

**Limitation:** The researcher found that there was limitation in the study.

- The mother who are all having above 18 years are not permitted to the study.

### Conclusion

On the basis of conducted research it can be concluded the Assessment of practice and attitude of mothers in using Over The Counter medication has an important determination of early prevention from complication.

**Source of Funding:** Self.

**Conflict of Interest:** Nil.

**Ethical Issues:** Department clearance was obtained from Department of Child Health Nursing, Chettinad College of Nursing. UG committee clearance was obtained from UG Research Screening Committee. Institutional Human Ethics Committee clearance was obtained from Chettinad University. Formal permission was obtained from the Principal, Chettinad College of Nursing. Formal consent was obtained from the study samples before collecting the information. Confidentiality of the study was maintained.

## Abstract

**Background:** Diabetes mellitus is characterized by hyperglycemia and disturbance of the carbohydrate, fat and protein metabolism that is associated with absolute or relative deficiencies of insulin action or secretion.

### Objectives:

1. Assess the pre existing level of knowledge of patients with Diabetes mellitus regarding lifestyle modification.
2. Administer nursing directives on knowledge regarding lifestyle modification.
3. Evaluate the effectiveness of nursing directives on knowledge regarding lifestyle modification among diabetic patient.
4. Find out the association between pre-test knowledge score with selected demographic variables of patients diagnosed with diabetes mellitus.

**Material and Method:** A pre- experimental one group pre-test, post-test design was used for the study. 70 diabetes patients were selected by using Non-Probability Convenient sampling. Nursing directives was administered to every sample after the pre-test. Post-test administration was done on the 7<sup>th</sup> day after pre-test. Data was collected through self –structured questionnaires

**Results:** Among 70 patients in pre-test(94.3%) had inadequate knowledge, (5.7%) had moderate knowledge and none of them were had adequate knowledge In Post-test (58.6%) of had the moderate knowledge and (41.4%) having adequate knowledge. And none of respondent was in the inadequate knowledge. The mean of pre test knowledge score was (7.75), sd (1.79) and the mean percentage were (39.05%). The mean of post test knowledge score was (15.63), sd (1.42) and the mean percentage were (77.16%). From the entire socio-demographic variable only 4 variable that is age, gendre, education, occupation was associated with pre-test knowledge score The mean difference of pre and post level of knowledge is 7.88 which show the effectiveness of nursing directives. The paired t calculated value of knowledge is 29.588 at 0.05 level of significance which is more than table value of “t” test.

**Conclusion:** The result of the present study shows that there is a great need for the diabetic patients to update their knowledge regarding lifestyle modification.

**Keywords:** -Knowledge, Effectiveness, Diabetic patients, diabetes mellitus.

## Introduction

Diabetes mellitus is an issue of universal health problem affecting human societies at all stages of

development. Around the world at least 30 million diabetic patient; the majority of them are lack even the rudiments of care. The Hindustan times newspaper

stated that the total number of people suffering in the country (India) as a whole is estimated at 15.2million<sup>1</sup>.

Diabetes mellitus is a chronic condition that arises when the pancreas does not produce enough insulin or when the body cannot effectively use the insulin it produce. Failure of insulin production, insulin action or both lead to raised glucose levels in the blood (hyperglycemia). This is associated with long-term damage to the body and the failure of various organ and tissue.<sup>2</sup>

One of the greatest challenges faced by the modern world is Diabetes mellitus (DM). The physical, social and economic factors involved in the management of diabetes are a continuous strain for the health sector and the government agencies. It is expected that approximately 366 million people will be affected by Diabetes mellitus by the year 2030.<sup>3</sup>

Diabetes is a disorder characterized by hyperglycemia or elevated blood glucose (blood sugar). Our body function best at a certain level of sugar in the blood stream. If the amount of sugar in our blood runs too high or too low, then we typically feel bad. **Diabetes is the name of the condition where the blood sugar level consistently runs too high.** Diabetes is the most common endocrine disorder. 16 million Americans have diabetic, yet many are not aware of it. Americans have a higher rate of developing diabetes during their lifetime. Diabetes has potential long term complication that can affect the kidney, eye, heart, blood vessels, and nerves.<sup>4</sup>

**Need for the Study:** Diabetes is key to management, except, possibly when the patient is ill with like secondary disease. The expert patient pilot Centre, the heart of Birmingham teaching primary care trust, has addressed the issue who has with diabetes mellitus. Diabetes specialist nurses alongside management and group discussion, health education, education sessions for the person about diet, exercise, drugs, education are include as norm for diabetic patient for lifestyle modification.<sup>5</sup>

Lifestyle modification has resulted in changes in the way people obtain advice about health and using the internet are now common way of accessing health information and also from the radio, television, promotional agencies. So patient with diabetes therefore target-setting and determining priorities for managing their condition are important aspects of care or their worsening progression can be slowed. The target for

glycated hemoglobin (hbA1C) for those with type 1 diabetes is 7.5% and below for those with type 2. Blood pressure is known to be a factor in diabetic progression. Total cholesterol should be below 5mmol/l, with an HDL of greater than 1.0 and LDL less than 3. These targets may be set through diet for lifestyle modification<sup>6</sup>

Diabetes patients must have knowledge about medication, its effects and side effects, diet, exercise, disease progression, prevention strategies and blood glucose monitoring techniques. A crucial element in secondary prevention is self-care. That is the diabetic patient must take a major responsibility for his/her own care with medical guidance. Providing an appropriate knowledge and skills to a diabetic patients is the prime responsibility of a nurse.<sup>7</sup>

**Statement of Problem:** “A study to assess the effectiveness of nursing directives on knowledge regarding lifestyle modification among diabetes mellitus patient admitted at Dhiraj General Hospital Waghodia, Vadodara.”

#### **Objectives:**

- Assess the pre- existing level of knowledge regarding lifestyle modification among diabetes mellitus patient.
- Administer Nursing directives on knowledge regarding lifestyle modification among diabetes mellitus patient.
- Evaluate the effectiveness of nursing directives on knowledge regarding lifestyle modification among diabetes mellitus patient.
- Find out the association between pre-test knowledge and selected demographic variables of patients diagnosed with diabetes mellitus.
- Hypothesis

**H<sub>1</sub>:** There will be a significant difference between pretest and posttest knowledge score of Patients regarding lifestyle modification after administration of nursing directives.

**H<sub>2</sub>:** There will be a significant association between pre-test knowledge score and with selected demographic variables

#### **Methodology**

**Research Design:** The research design used for the study was Pre-experimental research design

**Setting:** The main research project was conducted at Dhiraj General Hospital of Vadodara city.

**Sample:** The 70 participants included in this study. The sample for the study was selected by non-probability sampling technique according inclusion criteria as availability of sample. **Inclusion criteria:**

1. Patients with diabetes mellitus who all are admitted in wards.
2. Patients who are available during the period of data collection.

**Exclusion criteria for sampling:**

1. Patients those who are suffering from gestational DM.
2. Patients who are acutely ill.

**Tool for data collection**

**This consists of two parts:**

**Section 1:** Demographic variables such as Patients age, Gender, occupation, education qualification, source of information of diabetic mellitus.

**Section 2:** Self-structured questionnaire will be used to assess the knowledge regarding lifestyle modification among patient with diabetic mellitus at Dhiraj General Hospital Waghodia, Vadodara.

**Scoring interpretation of knowledge:**

- Adequate knowledge - >67%
- Moderately adequate knowledge - 34-66%
- Inadequate knowledge - < 33%

**Data collection procedure**

The formal permission was obtained for the approval of the study from concerning authorities. The data collection done within a given period of 1 week.

The investigator selected the subject and established the rapport by explaining purpose of the study, the co-operation required and the anonymity assured before obtaining verbal consent. Initially the demographic tool, self structured questionnaire, administered to the sample to know existing level of knowledge regarding lifestyle modification. After 7 days post test was administered to assess the effectiveness of nursing directives on knowledge regarding lifestyle modification among diabetes patient.

**Statistical Design:** Data were verified prior to computerized entry. The Statistical Package for Social Sciences (SPSS version 20.0) was used. Descriptive statistics were applied (e.g., mean, standard deviation, frequency and percentages). Test of significance (chi square and paired t test) was applied to test the study hypothesis

**Findings:**

**Section 1:** Analysis of pre-test & post test knowledge score of patient regarding lifestyle modification.

**Table 1: Distributions of pre test knowledge score of diabetes patient regarding lifestyle modification.**

Sr. No.	Knowledge Score	Frequency	Percentage
1	Inadequate	66	94.3%
2	Moderate	4	5.7%
3	Adequate	00	00%

**Table 2: Distributions of post test knowledge score of diabetes patient regarding lifestyle modification.**

Sr. No.	Knowledge score	Frequency	Percentage
1	Inadequate	00	00%
2	Moderate	29	41.4%
3	Adequate	41	58.6%

**Section 2: Effectiveness of health teaching programme**

**Table 3: Comparison of pre test and post test knowledge score of diabetes patient**

Variable	Pre test	Mean	Mean Difference	Std. Deviation	t- Value
Knowledge Regarding Lifestyle Modification	Pre-test	7.7571	7.8858	1.7972	29.588
	Post-Test	15.6329		1.4217	

**Section 3: Association between pre test knowledge score with socio-demographic variables.****Table 4: Association between pre test knowledge score and socio-demographic variables**

Sr.No.	Variable	0-10	11-20	$\chi^2$	D.F.	Level of significance
1	<b>Age in Years</b>			8.07	3	8.07>7.815 S
	41-45	11	0			
	46-50	14	1			
	51-55	15	1

	Society and friends	14	0			
	Mass media	4	0			
	Family member	39	2			
	Any other	9	2			

**Discussion**

The finding of the study based on its objectives

**Assess the pre existing level of knowledge regarding lifestyle modification among diabetes mellitus patient.**

Out of 70 diabetes patients (94.3%) had inadequate knowledge, (5.7%) had moderate knowledge and none of them were had adequate knowledge. In the pre-test level of knowledge. Thus the investigator assumes there is the need of imparting knowledge.

**Administer the nursing directives on knowledge regarding lifestyle modification among diabetes mellitus patient.**

Out of 70 diabetic patient in post-test level of knowledge were (58.6%) having adequate knowledge and (41.4%) having moderate level of knowledge. So

investigator assumes that the levels of knowledge were increased in the post test.

**Evaluate the effectiveness of nursing directives on knowledge regarding lifestyle modification among diabetes mellitus patient.**

Out of 70 diabetic patients had improved the level of knowledge regarding lifestyle modification after administering the nursing directives. The results were shown in post test. The (58.6%) having adequate knowledge and (41.4%) having score the moderate level of knowledge. So researcher assumes that the level of knowledge of effectiveness of nursing directives regarding lifestyle modification had increased.

**Find out association between pretest knowledge and selected demographic variable of patient diagnosed with diabetes mellitus.**

From the entire socio-demographic variable only four variables that is Sex, education, occupation and age were associated with pre test knowledge score and only source of information was not significant with pre test knowledge score.

**There will be significant difference between pre test and post test knowledge score of Patients regarding lifestyle modification after administering the nursing directives.**

The pre test means score of knowledge of diabetes patients is 7.75 and post test mean score of knowledge is 15.63. The mean difference of pre and post level of knowledge is 7.88 which show the effectiveness of nursing directives. The paired t calculated value of knowledge is 29.588 at 0.05 level of significance which is more than table value of "t" Hence, hypothesis H<sub>1</sub> is accepted.

**There will a significant association between pre-test knowledge and selected demographic variables.**

Socio-demographic variable are age of diabetes patients with  $\chi^2$  value 8.07, gender of diabetes patients with  $\chi^2$  value 5.52, occupation 8.71, education 13.125 so, for this variable hypothesis is accepted. The non significant demographic variable is Source of information. So, for this variable research hypothesis H<sub>2</sub> partially accepted.

### Conclusion

One of the factors increasing diabetes patients was lack of lifestyle modification among them so it is important that health care provider should provide the knowledge regarding lifestyle modification to the diabetic patient.

This study was undertaken to assess the effectiveness of nursing directives on knowledge regarding lifestyle modification among diabetic patient. The study involves one group pre- test post-test pre experimental design with non probability convenient sampling technique, 70 samples of diabetic patients were selected on the basis of inclusion and exclusion criteria. A conceptual framework used for this study was modified "Ludwing Von Bertalanffy general system model." Analysis of obtained data was planned based on the objectives and hypothesis of the study, both descriptive and inferential statistics were used for the analysis of the data. The data is interpreted in the forms of tables and graphs.

**Recommendations:** Based on the findings of the present study recommendation offered for the future study:

- The similar study can be conducted in different settings.
- The similar study can be conducted on staff nurses.
- The similar study can be conducted on mothers to assess the knowledge & attitude regarding lifestyle modification.
- The similar study can be conducted in large sample.

**Acknowledgement:** The authors express their gratitude and thanks towards all who have directly or indirectly helped them to complete this study and their support in each major step of the study.

**Conflicts of Interest Disclosure:** The authors declare that there is no conflict of interest statement

**Source of Funding:** Source of Funding was managed by researcher own funding.

**Ethical Clearance:** Ethical clearance for this dissertation was obtained from the ethical committee SVIEC of Sumandeep Vidyapeeth University.

# Assessment of Mycobacterium Tuberculosis Sensitive Antibiotics from the Isolation of LJ Media

Zafar Nowshad Wani<sup>1</sup>, Pushpa Yadav<sup>2</sup>, Garima Jaiswal<sup>3</sup>, Mridul Malakar<sup>4</sup>

<sup>1</sup>Microbiologist STDC Srinagar, IRL, Jammu & Kashmir, <sup>2</sup>Ph.D. Scholar, Dr. Ram Manohar Lohia Institute of Medical sciences, Lucknow, <sup>3</sup>District Microbiologist, IDSP, DPHL, Daman, <sup>4</sup>District Microbiologist, IDSP, DPHL, Kamrup-M, India

## Abstract

Pulmonary tuberculosis (PTB) is the major public health air borne disease of India. Socio-economic burden of this disease is also high due to its morbidity and mortality. Patients become resistant to antitubercular antibiotics due to not selecting proper antibiotics and non continuity of antibiotics. Our study tried to find out the most sensitive antibiotics for treatment as antituberculin antibiotic. AFB microscopy positive (ZN stain microscopy positive) sputum samples were collected and tested for culture and sensitivity tests. The results showed that most effective antibiotic is Rifampicin followed by Isoniazid. Both male and female may equally affect by this disease but higher age groups are in more at risk in comparisons with children.

**Keywords:** PTB, AFB, ZN stain, Culture, sensitivity.

## Introduction

Tuberculosis is most common worldwide public health burdening air borne disease. Every year 9.6 million new TB (tuberculosis) infection or cases are reported and 1.5 million deaths are reported worldwide as per the article of Raviglione M. and Sulis G<sup>1</sup>. World Health Organization (WHO) declared TB as “Global Emergency” this shows that how WHO is concern about TB,<sup>2</sup>. India also is a high risk country for TB which contributing 32% of global TB mortality,<sup>3</sup>. This indicates how India is important for study of TB and severity of TB in India. In 2015 India reported 217 lakh new TB cases and 36 lakh deaths due to TB. In 2017, India reported highest burden of TB as well as multi drug resistant TB<sup>4</sup>. Jammu & Kashmir also burdening the TB to India like other states<sup>5</sup>. The National TB control programme i.e RNTCP (Revised National Tuberculosis Control Programme) facing problems due to its hilly-

plane routes or communications ways. Government of India aims to eliminate the TB or target <1 case of TB out of 10 lakh populations from India<sup>6</sup>. This is possible only after proper research, planning and implementation. Our study tried to find out the proper antibiotic or to select most suitable antibiotic for the treatment of the patients.

*Mycobacterium tuberculosis* is the TB causing bacteria. The Cell wall of this bacterium contains mycolic acid which makes it different from other bacteria. The bacterium was discovered by Robert Koch in 1882. The most common symptoms of pulmonary TB are cough (two weeks, more or any duration), fever (more than 2 weeks), weight loss (more than 1.5 kg in a month), and night sweating etc<sup>7</sup>. As this disease is an airborne disease it can spread easily to the immuno-compromised peoples.

## Methodology

Our study included the districts Anantnag, Budgam, Baramulla, Pulwama, Kupwara, Kargil, Leh and Srinagar of Jammu & Kashmir of India. Morning sputum samples were collected from the suspected patients who were clinically diagnosed as TB by treating physicians. Smears were prepared and stained with ZN (Ziehl-

Neelsen) stain after found positive under microscopic oil immersion field cases were included for our study for culture & sensitivity tests. Fresh sputum samples were collected and inoculated in LJ (Lowenstein-Jensen) medium and incubated at 37°C temperature. The culture growths were read after 5-7 days of inoculation (image 1) and thereafter weekly up to 8 weeks. Further the growths were processed for solid antibiotics sensitivity tests or drug sensitivity tests (image 2). The antibiotics included for this study were first line antibiotics i.e. SHRE or streptomycin, isoniazid, rifampicin and ethambutol. The tests were performed at IRL (Intermediate reference laboratory) Jammu.

Total 126 (one hundred twenty six) numbers of positive AFB (Acid fast bacilli) patients were enrolled for our study bacterial growths were isolated from LJ media and confirmed by different biochemical tests. No extra-pulmonary cases were included for the study. Both sex and all age groups were included in this study. After successfully completion of solid DST the data were analyzed.

## Results

68 (sixty eight) numbers of male and 58 (fifty eight) numbers of female positive patients were found during our study. The male positivity rate is 53.96% (68/126)

and female positivity rate is 46.03% (58/126). Only 1 (one) female reported within the age range 0-10 years and no male case was found within this range. 4 (four) male and 10 (ten) female were reported within the range of 11-20 years. 12 (twelve) male and 13 (thirteen) female of 21-30 years, 12 (twelve) male 5 (five) female of 31-40 Years, 7 (seven) male 7 (seven) female of 41-50 years and 33 (thirty three) male 22 (twenty two) female of 51-above years cases reported (Figure 1).

The culture & sensitivity results showed that streptomycin was sensitive for 57 (fifty seven) male and resistant for 11 (eleven) male whereas streptomycin was sensitive for 50 (fifty) female and resistant for 8 (eight) female (Figure 2). The analysis of isoniazid showed it was sensitive for 66 (sixty six) male and 56 (fifty six) female again isoniazid was resistant for 2 (two) male and 2 (two) female (Figure 3). Rifampicin was not resistant for any patients i.e. it was sensitive for 68 (sixty eight) male and 58 (fifty eight) female (Figure 4). The antibiotic ethambutol was found sensitive for 66 (sixty six) male and 55 (Fifty five) female which was resistant for 2 (two) male and 3 (three) female (Figure 5). 15.38% (4/26) patients were found with resistance to more than one antibiotic. Out of which 11.53% (3/26) were resistance to streptomycin and isoniazid and 3.84% (1/26) was resistance to streptomycin and ethambutol.

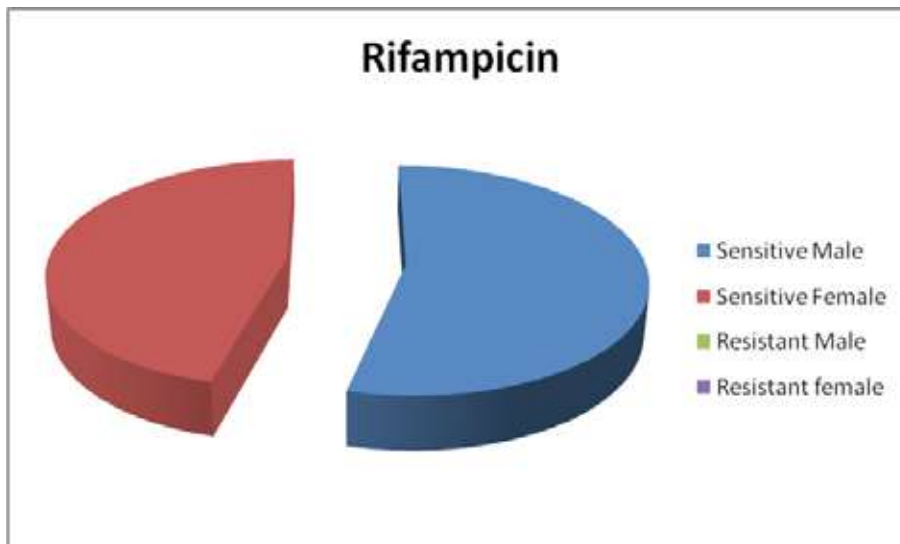

Figure 4: Sex wise rifampicin DST results

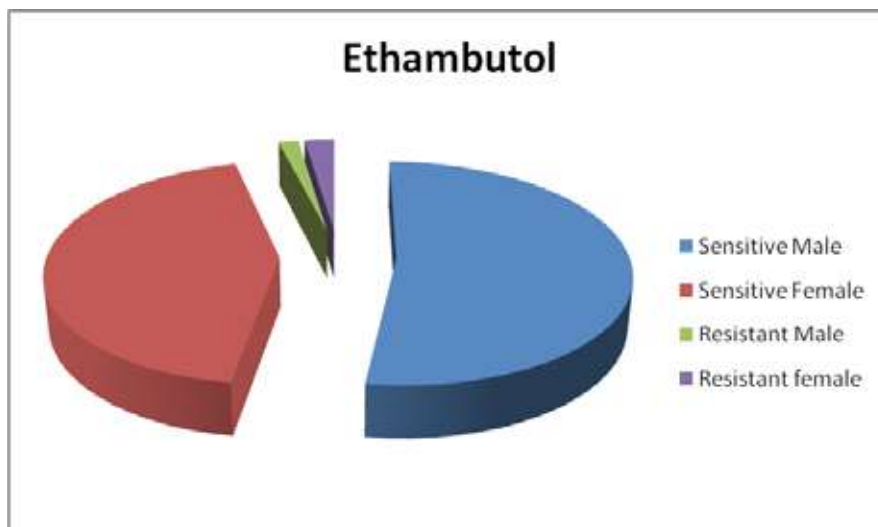

Figure 5: Sex wise ethambutol DST results

## Discussion

There are various studies which reported the prevalence of pulmonary TB and its severity in Jammu & Kashmir<sup>8,9</sup>. Our study also reported 126 (One hundred twenty six) numbers of positive cases in a quarter. Which itself indicates the severity of pulmonary TB in study areas. Male patients were higher than female patients and cough was common in all patients which were similar with Datta BS et al., (2010)<sup>10</sup>. The test results showed that higher age groups are high in risk in comparisons' with children. Chakraborty A. et al., in 2014 also found maximum cases age range groups were within 30-50 years. They were also enrolled maximum males patients in comparison with females<sup>11</sup>.

In a study by Mathuria JP et al., in 2013 found rifampicin as resistant 16.2% from Varanasi, Uttar Pradesh, 7.1% from Sawai Madhopur, Rajasthan and 25% from Buxar, Bihar which was completely opposite with our study as no resistance of rifampicin reported by our studies<sup>12</sup>. But if we compare their data with their other first line antibiotics results showed that rifampicin resistance is lower. Another studies by Dam T et al., (2005) found 27.03% rifampicin resistant and 14% multi drug resistant i.e. resistant to rifampicin and isoniazid<sup>13</sup>. The comparative study with Sinha P et al., (2017) also showed dissimilarities as they got only 28.9% isolates sensitive to all first line antibiotics but we got 79.36% (100/126) isolates sensitive to all first line antibiotics<sup>14</sup>. In our study 73.07% (19/26) patients were found resistant to streptomycin followed by ethambutol 19.23% (5/26) and isoniazid 15.38% (4/26) another study by Menon S et al., (2012) found streptomycin resistant to 70%, followed by isoniazid 53.2% and ethambutol 21.7%<sup>15</sup>. Kalo D., et al., in 2017 found first line mono drug resistant patterns as follows Isoniazid 38.9%, streptomycin 28.3%, ethambutol 29.5% and rifampicin 16.9% and in our study it was streptomycin 57.69% (15/26), ethambutol 15.38% (4/26) and isoniazid 3.84% (1/26)<sup>16</sup>.

In our study all the samples were tested before antibiotics but as streptomycin is commonly advised by physicians in other diseases too that may be one of the cause for found streptomycin resistant in 19 (nineteen) cases out of 26 (twenty six) resistant patients. This is also clear that the sensitivity/resistant pattern may varies patient wise, places wise etc. So, it will be good for culture & sensitivity tests for each and every case.

## Conclusion

Every year we are celebrating world TB day on 24<sup>th</sup> March to aware the people about TB to control, to minimize the risk, to inform the people about the facilities available in health facilities etc<sup>17</sup>. But still the cases are arising. Government of India or RNTCP, India is planning to eliminate TB by 2025<sup>18</sup>. To control the disease each and every samples must process for culture & sensitivity to find out the proper antibiotics before treatment, DST laboratory must be introduce at least one in every districts, all patients must complete the full drug course, proper nutrition, awareness etc are also equally important. We all health workers, NGOs, media, food & nutrition department, environmental department etc. all must cooperate to Health department to full fill the TB elimination target.

# Level of Stress and Coping Strategies among Institutionalised and Non-Institutionalised Elderly

Soumya Raj K.<sup>1</sup>, Anagha Raj M.<sup>2</sup>, Amulya N.<sup>2</sup>

<sup>1</sup>Lecturer, Amrita College of Nursing, Amrita Vishwavidyapeetham, AIMS, Kochi, Kerala, India,  
<sup>2</sup>IV<sup>th</sup> Year B.Sc. Nursing, Amrita College of Nursing, Amrita Vishwavidyapeetham, AIMS, Kochi, Kerala, India

## Abstract

**Objective:** The objective of the study is to assess and compare the level of stress and coping strategies experienced by the institutionalized and non-institutionalized elderly.

**Methods:** A descriptive comparative research design and convenient sampling was used in this study, with this technique the researcher selected 70 sample from community (Nayarambalampanchayath) and 70 samples from two old age homes. Demographic Proforma, Sheldon Cohen Perceived Stress Scale and the Deakin Coping Scale were used to assess and compare the level of stress and level of coping.

**Result:** Among institutionalized elderly people 18.6% are having no stress, 32.9% are having mild stress. 37.1% are having moderate stress and 11.4% are having severe stress. Among non institutionalized elderly 37.1% are having no stress, 55.7% are having mild stress, 7.1% are having moderate stress and none of them having severe stress. While considering level of coping among institutionalized elderly people 21.4% members coping strategies are not effective, 50% are having effective coping strategies and 28.6 are having most effective coping strategies. Among institutionalized elderly 18.6 are having not effective coping strategies, 62.9% are having effective coping strategies and 18.6% having most effective coping strategies. There is a significant correlation between stress and coping among institutionalized elderly.

**Conclusion:** The feeling of loneliness along with the natural age related decline in physical and psychological functioning makes elderly prone to psychological disturbance, so institutionalized elderly feels more moderate and severe stress than non institutionalized elderly.

**Keywords:** Assess, stress, coping strategies, institutionalized elderly, non institutionalized elderly.

## Introduction

Old age is the closing period in the life span. It is a period when people “move away” from previous, more desirable period of ‘usefulness’. Age sixty is usually considered the dividing line between middle and old age.<sup>1</sup>

The status of the elderly had changed in the present family system. Earlier aged members were having

supreme power and their experience and wisdom were utilized to solve important family issues. However, younger members of the family are the product of changed social system. This conflict in the value pattern makes elderly people, particularly those who are retired from service and other occupations, mentally isolated from the family. The feeling of loneliness along with the natural age related decline in physical and psychological functioning makes them prone to psychological disturbance, In some cases elderly members of relatively rich family or aged persons who have nobody to look after takes shelter in old age homes.<sup>2</sup>

While we hope that the Indian family continues to be stronger than in most countries and provides caring

environment for the elderly, it can't be the basis of our ability to support the elderly. India need to take a serious look at the need of the elderly in a more pragmatic and holistic manner.<sup>3</sup>

Today the old age homes are indispensable as they are needed Institutionalization of elderly people continues to be a national problem. On the one hand because of the low number of institutions which are not capable to take over the increased number of elderly, and on the other hand due to lack of needed funds for adequate endowment of this institution. Many of the elderly people's pensions are ridiculously small and not meeting the possibilities to satisfy the basic needs, without counting the fulfillment of some wishes or desires of the elderly. Regardless of location or cost, many older adults cannot access services due to discriminatory attitudes and practices based on age, gender, race, ethnicity, language, sexual orientation, gender identity and expression, physical, psychological, or cognitive disability, or other diversity factors-or forego using available services that are not culturally appropriate or physically accessible.<sup>4</sup>

Ageing is a progressive generalized impairment of function resulting in the loss of adaptive response to stress and growing risk of age associated disease.<sup>5</sup>

The purpose of the study was to compare the level of stress and coping strategies among institutionalized and non institutionalized elderly and also the association between selected demographic variables and stress and coping strategies.

### Methodology

A Comparative study is conducted in Ernakulum district owing to the highest population Elderly, 70 elderly people residing in 3 old age homes in Ernakulum district and a group of 70 elderly living with their families from different areas in Ernakulum namely Nayarambalam were randomly selected for the study. To study the background details of the selected subject the investigator formulated a questionnaire .A perceived stress scale was used to study the pattern of stress experienced by them. It consisted of 10 items. All questions were given with 5 options and each option was ranked according to the scores they were assigned. A Deakin coping scale was used to assess the level of coping among two groups. It consisted of 19 items with 5 options and each options were ranked according to the scores they were assigned. The investigator sought

permission from the Director of the selected old age homes for conducting the study among the inmates in the selected old age homes. After prior appointment the investigator met the inmates of old age home and interviewed them. They were helped to mark their responses appropriately. The investigator met the non-institutionalized elderly in Nayarambalampanchayath after getting permission from Panchayath Predient. The purpose of the study was explained to them and they were also given detailed instructions for filling up the questionnaire. The data obtained and consolidated and scored, analysed.

### Results

#### Description of Sample According to Demographic

**Data:** In this study most of the institutionalized and Non institutionalized elderly were in age group of 60-69 years (45.7% and 61.4% respectively), and some of them were in 70-79 years age group(57.1% and 17.1% respectively). While considering their gender 72.9% of institutionalized elderly were females and 58.6 % of non institutionalized elderly were females. 58% of institutionalized elderly and 74% of non institutionalized elderly were having only privary level education. Most of the institutionalized and non institutionalized elderly belongs to not having any job category(57.1% and 42.9% respectively) but in non institutionalized elderly45.7% were having business now also. While considering marrietal status 62.9% of institutionalized elderly and 98.6% non institutionalized elderly were married. Sourse of income was the main problem for most of the elderly,78.6% of institutionalized elderly depends others for income were in non institutionalized elderly only 10% were depending on others for their income and 61.4% having pension. Among Institutionalized elderly 72.9% of their living period is below 5 years and while considering their reason for living in institution,67.1% of them came because there is no one to look after them and 15.7% persons came by their own decision. 21.4% of Institutionalized and 17.1% of non institutionalized elderly having both diabetes and hypertension. 52.9% of institutionalized and 58.6% of non institutionalized elderly are suffering from other diseases especially heart diseases,vision problems,respiratory diseases .95.7% of institutionalized elderly having stress where as 34.3% of non institutionalized elderly having stress. Most of the institutionalized elderly depends prayer to cope with stress (60%), were as 74.3% non institutionalized elderly were coping with stress by talking with others.

**Figure I. Level of stress among institutionalized and non-institutionalized**

**Elderly:** Figure 1 shows that among institutionalized elderly people 18.6% are having no stress. 32.9% are having mild stress. 37.1% are having moderate stress and 11.4% are having severe stress and

among non institutionalized elderly 37.1% are having no stress, 55.7% are having mild stress, 7.1% are having moderate stress and none of them having severe stress.

**Figure II. Level of Coping strategies among institutionalized and non-institutionalized Elderly**

Figure 2 shows that while considering level of coping strategies among institutionalized elderly people 21.4% members coping strategies were not effective,50% are having effective coping strategies and 28.6 are having most effective coping strategies. Among institutionalized elderly 18.6 are having not effective coping strategies,62.9% are having effective coping strategies and 18.6% having most effective coping strategies

**Table 1. Correlation between stress and coping among institutionalized elderly**

Variables	R Value	P Value
Stress and Coping	.310	.009

\*\* . Correlation is significant at the 0.01 level (2-tailed).

Above table shows that there is a significant correlation between stress and coping among institutionalized elderly.

**Table 2. Correlation between stress and coping among Non institutionalized elderly**

Variables	R Value	P Value
Stress and coping	.281	.018

\*. Correlation is significant at the 0.05 level (2-tailed).

Above table shows that there is a significant correlation between stress and coping among non institutionalized elderly

**Table 4: Coping strategy of institutionalized and non institutionalized elderly**

Variables	T Value	df	P Value
Coping	.513	138	.609

There is no significant difference in level of coping between institutionalized and non institutionalized elderly.

**Table 5: Association between Gender,education and marrietal status with level of stress among institutionalized and non institutionalized elderly**

Variables	Categories	Category of Stress				Chi Square Test	df	P Value
		No Stress	Mild Stress	Moderate Stress	Severe Stress			
Gender	Female	22	39	24	7	5.286	3	.152
	Male	17	23	7	1			
Education	Primary	31	45	26	8	5.386	9	.799
	Secondary	6	14	5	0			
	Predegree	11	1	0	0			
	Degree	1	2	0	0			
Occupation	Coolie Worker	18	25	10	3	6.346 <sup>a</sup>	9	.705
	Government Job	2	5	0	0			
	Business	2	2	1	0			
	No Job	17	30	20	5			
Marriatal Status	Married	31	51	27	4	11.886	9	.220
	Un Married	6	11	3	4			
	Widow	0	0	2	0			

Above table shows that there is no significant association between selected demographic variables like gender,education, occupation and marital status

with level of stress among institutionalized and non institutionalized elderly.

**Table 6: Association between Gender, education and marital status with level of coping among institutionalized and non institutionalized elderly**

Variables	Categories	Level of Coping			Chi Square Test	df	P value
		Not Effective	Effective	Most Effective			
Gender	Female	20	52	20	.788	2	.674
	Male	8	27	13			
Education	Primary	26	62	22	8.187	6	.225
	Secondary	2	15	8			
	Predegree	0	1	1			
	Degree	0	1	2			
Occupation	Coolie Worker	13	30	13	13.761 <sup>a</sup>	6	.032
	Government Job	0	3	4			
	Business	2	0	3			
	No Job	13	46	13			
Marrietal status	Married	21	66	26	6.096	6	.413
	Un Married	5	12	7			
	Widow	2	1	0			

Table 6 shows that there is a significant association between occupation and level of coping among institutionalized and non institutionalized elderly and there is not having any significant association with other demographic variables like Gender, education and marital status

**Discussion**

Older adults are the most rapidly growing segment of the population, in India life expectancy at birth are increased by about 20 years in the past 5 decades. The 1<sup>st</sup> of October every year is celebrated as “World elder’s day” globally.<sup>6</sup>

Aging is a universal process. In the words of Seneca “old age is an incurable disease”. But more recently Sir James sterling Ross Commented” you do not heal old age, you protect it, you promote it and you extend it. These are in fact the principles of Preventive Medicine. A man’s life is normally divided into five main stages namely infancy, childhood, adulthood and old age. In each of these stages an individual has to find himself in different situations and face different problems. The old age is not without problems. In old age physical strength deteriorates, mental stability diminishes; money power becomes bleak coupled with negligence from the younger generation.<sup>7</sup>

A descriptive research was conducted in SRM College Of Nursing, Kattankulathur, Tamil Nadu

with Purposive sampling technique . A sample 100 was selected. The data were analyzed by the means of descriptive and inferential statistics. The study results for the psychological problems of elderly persons reveals that majority 60% of them were had moderate level of psychological problems and 43% of the elderly persons were had at fair level of coping strategies. The present study concluded that there was negative correlation found between Psychological problems and Coping strategies. It means if their coping increases psychological problems decreases .<sup>8</sup>

In the present study over all data shows that among institutionalized elderly people 18.6% are having no stress.32.9% are having mild stress.37.1% are having 11.4%are having severe stress and among non institutionalized elderly 37.1% are having no stress,55.7% are having mild stress,7.1% are having moderate stress and none of them having severe stress while considering level of coping strategies among institutionalized elderly people 21.4% members coping strategies were not effective,50% are having effective coping strategies and 28.6 are having most effective coping strategies. Among institutionalized elderly 18.6 are having not effective coping strategies,62.9% are having effective coping strategies and 18.6% having most effective coping strategies. There is a significant correlation between stress and coping among non institutionalized and non institutionalized elderly (r valu is .310 and p value is .009 and r value is .513 and p value

is .609 respectively) and is a significant association between occupation and level of coping among institutionalized and non institutionalized elderly .

### Conclusion

Aging is a universal phenomena but it is not experienced uniformly by the elderly. The common changes of old age are physical and psychological which bring disabilities. They face number of problems such as dependency, ill health, absence of social security, loss of social role and recognition and non availability of opportunities for creative use of leisure. Falls and consequent injuries in older people are a significant public health problem among older adults in Kerala<sup>9</sup>. With the emergence of nuclear family, urbanization, influence of western culture and changes of lifestyle there is no space for elders in the family and may go for institutionalization. Institutionalization is emerged to improve the caring of aged and lack of personales to care for them. Lack of proper facilities and funds made the institutionalization stressful. Institutionalized are living in a disciplined manner which lacks their freedom and privacy, which also contribute to stress. In the case of non institutionalized elderly the presence of family members helped decrease the effects of stressful situations by building up their strengths and comforting them in times of need. Communication with family members also helps in reducing stress.

# Quality of Sleep among Diabetes and Non-Diabetes—Pilot Study

Neenu Merin<sup>1</sup>, Regina Antony<sup>2</sup>

<sup>1</sup>Lecturer, Department of Medical Surgical Nursing, Amrita College of Nursing, Amrita Vishwa Vidyapeetham, Kochi, Kerala, <sup>2</sup>Associate Professor, Department of Medical Surgical Nursing, Amrita College of Nursing, AMRITA Vishwa Vidyapeetham, Kochi, Kerala

## Abstract

Almost everyone has trouble sleeping once in a while, but if occasional episodes of sleep escalate into an unhealthy night time routine, and it will hamper the productivity and sap the patients quality of life<sup>1</sup>.

**Objective:** Of this pilot study was to compare the quality of sleep among patients with and without diabetes.

**Methodology:** Quantitative approach with a descriptive design was used. A non-probability convenience sampling technique was used to select samples in this study. A semi-structured questionnaire prepared by the investigator was used to collect the socio-demographic and clinical data from the subjects. A standardized Pittsburgh Sleep Quality Index tool was used to compare the sleep quality among 37 diabetic and 37 non-diabetic subjects.

**Results:** The study findings shows that in both diabetic (DM) and non-diabetic (NDM) subjects majority of the subjects 75.7% and 43.2% respectively were of the age group of 56-65 years. In both the groups majority were male (DM-24 and NDM – 27). The results also showed that among the groups most of the subjects were had high school education, were employed, and were married and had a monthly income >Rs.15,000. Among diabetic subjects 22(59.4%) were hypertensive whereas among non-diabetic subjects 9(51.35%) were hypertensive. The study findings revealed that, majority of the subjects with diabetes had poor sleep quality 78.4% (29), whereas among non-diabetic subjects only 51.4% (19) subjects reported poor sleep quality and the quality of sleep among non-diabetic subjects were better than diabetic subjects at (p=0.014).

**Conclusion:** As a healthcare practitioner, the health care providers should focus their attention to the quality of sleep of their patients and should take initiative to make the people to aware about the importance of sleep in their day to day life to live healthy.

**Keywords:** *Diabetes Mellitus, Quality of Sleep, Non-diabetes.*

## Introduction

It is a long time Diabetes was discovered but no one really knows about its exact history. This silent epidemiology is still a health concern with an increasing prevalence. According to international Diabetes federation, in 2025 the number of patients with type 2 diabetes will be 40 million with an increase of 80%. More than 3 million people have diabetes in Iran, which triples every 15 years. Increasing number of diabetes cases is more serious in the Middle East and is due to the economic changes, compliance with western customs and the aging population<sup>2</sup>.

Diabetes can be a debilitating disease associated with reduced quality of life, severe complications, shorter life expectancy, and increased economic burden. Much effort has been devoted to identifying factors associated with the increased risk of developing type 2 diabetes and improved prognosis of people with type 2 diabetes to improve the lives of millions of Americans. Disturbed sleep has recently been proposed as a novel risk factor<sup>3</sup>. A range of sleep disorders are common among people with type 2 DM, including sleep apnoea, insomnia, periodic limb movements, in which sleep apnoea is the most common reported sleep disorder<sup>4</sup>.

There is evidence that approximately one third of people with diabetes suffered from sleep problems whilst it was only 8.2% in control group without DM<sup>5</sup>. In another study more than half of the people with type 2 DM were poor sleepers<sup>6</sup>. One more study also shown that using the Pittsburgh Sleep Quality Index as the validated tool for measuring quality of sleep, lower score of PSQI (52%) were reported by people with type 2 diabetes<sup>7</sup>. Evidences showed that poor sleep quality among people with type 2 DM is associated with longer duration of diabetes, poor glycemic control, normal body mass index and hypertension<sup>4</sup>. Hypertension is extremely common in patients with diabetes<sup>8</sup>. Another study investigated the association of sleep duration daytime nap duration with deaths and major cardiovascular events. And its results shows that estimated total sleep duration of 6-8 hours per day is associated with the lowest risk of death and the major cardiovascular events and both short duration (<6 hours) and long duration (>8 hours) are associated with increased cardiovascular events and death<sup>9</sup>.

Studies also reported that high prevalence of poor sleep quality among people with type 2 DM has a negative impact on glycemic control. A good sleep

quality should be considered as an important component in the prevention and management of type 2 DM<sup>4</sup>. To date, there is a lack of case-control studies investigating quality of sleep among persons with and without type 2 diabetes. We investigated whether differences in sleep quality exist between persons with type 2 diabetes and non-diabetic controls.

### Methodology

A quantitative approach and a comparative descriptive design was used. The data was collected from 74 patients attending OPDs of Amrita Institute of Medical Sciences and Research Centre Kochi by using non-probability convenient sampling technique. The setting was selected because of the easy accessibility of the group, familiarity of the setting. The researcher explained the purpose of the study and obtained an informed consent from each subject. The tool for data collection include; Tool I- Socio-demographic data and clinical data and Tool II- Pittsburgh Sleep Quality Index (PSQI) to assess the quality of sleep among patients with diabetes and without diabetes. Data analysis was performed using descriptive and inferential statistics.

## Results

### Section I: Description of socio-demographic and clinical variables of the subjects

Age:

Figure 1: Bar diagram showing distribution of subjects based on age

Figure 1 indicated that in patients with diabetes mellitus majority 28(75.7%) of the subjects w belonged to the age group of 56-65 years and in patients without

diabetes mellitus also most of the subjects 16(43.2%) were of the age of 56-65 years.

**Figure 2: Conical bar diagram showing the gender distribution of subjects with and without diabetes mellitus**

The data presented in figure 2 indicated that, in gender wise distribution in both diabetic and non diabetic subjects the majority were males. (13) 35.1% diabetic subjects and (10) 27% non diabetic subjects were female.

Among the subjects with high school education level 51.35% had DM and 45.94% were NDM, and 27.02% subjects were graduated and 97.29% of the subjects were married in both the groups. However, 72.97% of

the subjects with DM were employed whereas only 54.05% were employed among NDM subjects. Majority of the subjects had a monthly income > Rs 15,000/- in both the groups.

Considering the BMI 20 (54.1%) among diabetic subjects and 15(40.5%) non-diabetic subjects were overweight. And in the case of Neck Circumference 32 (86.5%) diabetic and 29 (78.4%) non-diabetic subjects had a high neck circumference.

**Section II: Comparison of Quality of sleep among patients with and without Diabetes**

**Figure 3: Cylindrical bar diagram showing comparison of sleep quality among subjects with and without diabetes mellitus**

In figure 3 the cylindrical bar diagram depicted that majority of the subjects with diabetes mellitus (29) 78.4% reported poor sleep quality whereas non-diabetes

mellitus subjects only (19) 51.4% showed poor sleep quality.

**Table 1: Comparison of sleep quality among diabetic and non diabetic patient**

Group	Quality of Sleep				Chi-square	df	p
	Good		Poor				
	f	%	f	%			
DM	8	21.6	29	78.4	5.929	1	0.014*
NDM	18	48.6	19	51.4			

\*significant (p<0.05)

The data presented in table1 revealed that among the diabetic patients (29) 78.4% had poor quality of sleep whereas in non-diabetic patients (19) 51.4% had poor quality of sleep. So the results shows that the quality of sleep among non-diabetic subjects were better than diabetic subjects at (p=0.014).

**Section IV: Association of sleep quality with selected clinical variables**

Among 37 diabetic subjects, 21 subjects were sleeping less than 6 hours per night and majority 20 (95.2%) had poor quality of sleep whereas 16 subjects sleeping 6-8 hours per night, only 9 (56.3%) had poor quality of sleep. There is a significant association between sleep duration and quality of sleep at p value 0.012. However in the case of non-diabetic subjects 27 subjects had a normal sleep duration of 6-8 hours per night and only 10 subjects were sleeping less than 6 hours per night. Among that 10 subjects 9 (90%) had poor quality of sleep. There is also a significant association found between sleep duration and sleep quality at p= 0.008. When looking into the sleep duration and sleep quality, the sleep quality of non-diabetic subjects is better than the diabetic subjects.

**Discussion**

The present study investigated the quality of sleep and its compared among patients with diabetes and without diabetes. The results of the present study indicated that (29)78.4% subjects with diabetes have poor quality of sleep and only (19)51.4% non-diabetic subjects have poor quality of sleep and the quality of sleep among non-diabetic subjects were better than diabetic subjects at (p=0.014). Clinical researches has shown that up to one third of patients with DM suffered

from concomitant sleep disorders, as compared with 8.2% of controls without DM. In another study, more than half of the patients with type 2 DM are likely to report being “poor sleepers”, according to a research poll conducted at University of Pittsburgh. The patients with type 2 DM were more likely to have low Pittsburgh Sleep Quality index (PSQI)<sup>10</sup>.

In this study among diabetic subjects those who are sleeping less than 6 hours per night (95.2%) had more poor quality of sleep compared to those who are sleeping 6-8 hours per night (56.3%) where as in non-diabetic subjects majority 27 subjects had a normal sleep duration of 6-8 hours per night and only 10 subjects were sleeping less than 6 hours per night. Among 27 subjects sleeping 6-8 hours per night, 63% reported good quality of sleep and only 37% had poor quality of sleep.Both poor quality of sleep and short sleep duration (#6 h) were associated with increased prevalence of diabetes, with higher rates in relatively healthy Chinese people. Compared with the group with good quality of sleep and 6e8 h sleep duration, diabetes was the most prevalent in individuals with poor sleep quality and #6 h sleep duration<sup>11</sup>. Previous studies found that self-reported short sleep duration is associated with diabetes. Some studies have reported that long sleep duration is also associated with diabetes<sup>12,13,14</sup>.

**Conclusion**

To our knowledge, not much study in this area has been conducted, so the researcher out of interest decided to conduct a descriptive pilot study to assess the difference in quality of sleep among subjects with diabetes and without diabetes. Based on the study findings sleep quality improvement plays an important

role in glycemic control among people with type 2 DM. A good sleep quality should be considered as an important component in the prevention and management of type 2 DM.

# Competency Based Core Infusion Curriculum in Indian Setup-An Imperative Need

Anand L.<sup>1</sup>, Gandhimathi M.<sup>2</sup>, Unmona Borgain<sup>3</sup>

<sup>1</sup>Reader, Associate Professor, College of Nursing, AIIMS, Bhubaneswar, India, <sup>2</sup>Professor, Rani Meyammai College of Nursing, Annamalai University, Annamalai Nagar, Tamilnadu, India, <sup>3</sup>Professor cum Principal, Asian Institute of Nursing Education (AINE), Guwahati, India

## Abstract

Intravenous cannulation and intravenous therapy are the most common procedure performed by nurses in Indian Set up. The complications and risks associated with Intravenous are greater extent depend up on the depend up on the Nurses knowledge and skill. Competent nurse who has trained in specialized area of infusion nursing may have impact on patient and institutional related outcomes. This article highlights the need of competency-based core curriculum on infusion nursing in Indian set-up.

**Keywords:** *Competency, Infusion Nursing, Competency-based curriculum, Intravenous therapy.*

## Introduction

The scientific and technological advancement in the last two decades had affected all spheres of the health care industry. The transition of principles related to Intravenous (IV) therapy has been evolving to align with technological development. The establishment of various quality standards demand the nursing care of the highest quality. The majority of peripheral intravenous (PIV) cannulation and maintenance in India are performed by Nurses. However, the educational opportunities to update their knowledge and practice in infusion nursing are limited owing to the lack of core curriculum. Their practice is highly depending up on the basic level education and experience gained in the work environment.

Hence, this article discusses the importance of competency-based core infusion curriculum in India by highlighting risks associated with Intravenous therapy

and strategies adopted to minimize these risks and complications.

**Complications of Peripheral Intravenous catheter (PIVC):** It is estimated that a PIV catheter is placed in 80% of all patients admitted to hospitals.<sup>[1]</sup> The number of complications such as phlebitis, thrombophlebitis, infiltration, extravasation and infections are associated with IV therapy.

Studies have determined that the overall development of infusion-related phlebitis rates ranging from 2.5% to 70%.<sup>[2-5]</sup> In India, the incidence of phlebitis was 56.5% and 29.8% which occurred in the same setting at different time periods.<sup>[6-7]</sup> It is well above the accepted rate of 5% or less. Despite the high rates of phlebitis, the associated bacteremia remain very low at < 0.2%.<sup>[8,9]</sup> and even then also it adds 7.4 days to the average hospital stay.<sup>[10]</sup>

Incidence of infiltration were 7.5% and 13.9% among the Vascular Access Device (VAD) inserted by infusion nurses and generalist nurses respectively<sup>[12]</sup> In India, Incidence of infiltration was found to be 31.5% which was quite higher than any published reports.<sup>[6]</sup> The incidence of infiltration and extravasation is seldom reported in India. Even in the published studies<sup>[6-7]</sup>, no reliable conclusion can be drawn as the criteria and definitions regarding extravasation and infiltration were not listed.

The wide variation in incidence rates of phlebitis may be attributed to measurement error, observational biases, limited samples, used a wide variety of tools, retrospective and lack of control. The published reports may be underestimating the true incidences of phlebitis, infiltration, and extravasation in clinical set up that pose a greater threat as the magnitude of the problem goes unnoticed.

**Risk factors of Infiltration, Extravasation and Phlebitis:** The causes of Phlebitis, infiltration and extravasation are multi factorial. There are enough evidence available in the literature regarding role of mechanical factors such as small size and poor condition of veins,<sup>[13]</sup> larger catheter size relative to vein size, site of placement, poor securement, catheter fracture,<sup>[14]</sup> and physiologic factors<sup>[13,15]</sup> such as clot formation at the tip of the catheter and edema of the cannulated limb and pharmacologic factors such as pH, osmolarity and irritant drugs.

The role of factors such as age, sex, size & type of catheter, skin preparation and dressing material in the development of phlebitis remain controversial. The published studies reported varying results.

**Knowledge and skills of Nurses - Paramount risk factor:** Knowledge and skill of the nurses can minimize PIVC related complications.<sup>[16]</sup> It is found that nurses' practice was inappropriate during insertion and handling PIVC. It is also observed that PIVC was placed over joints and the presence of soiled securement device. The PIVC and drip-set were not replaced as per recommended guidelines.<sup>[6]</sup>

A questionnaire survey revealed that knowledge of risk factors of infusion phlebitis is incomplete even among experienced nurses in Swedish.<sup>[17]</sup> It has been shown that the skills of the staff, who insert and maintain the PIVC, are of importance for the incidence of phlebitis.<sup>[18]</sup> The studies also reported that the knowledge levels of the nurses were inadequate and was not up to date. The good manual skill had resulted in low risk of phlebitis.<sup>[19]</sup>

**Review of Strategies to reduce the risks associated with PIVC placement and maintenance:**

**Documentation and surveillance:** Proper documentation, surveillance, and expert skills in early identification of these complications would assist in proper reporting of cases and subsequent treatment.

However, only 46.2 % of records contain the data regarding insertion site, hand side and lumen size of PIVC, the extent of PIVC documentation in medical records was very low and suggested that education of nurses on proper PIVC documentation should be given priority.<sup>[19]</sup>

Researchers have found that surveillance may lead to a reduction in phlebitis rates and recommended that VAD sites, particularly those that are used for drugs and/or fluids, be inspected daily and that these inspections be recorded.<sup>[20-22]</sup>

In most of the hospitals, peripheral catheters are inserted by nurses, house staff, or residents with limited experience in IV catheter care. Because the assessment of insertion sites may not be performed regularly and many complications resulting from IV therapy have subtle early clinical manifestations, these problems are often overlooked.<sup>[23]</sup>

**IV Therapy team:** Intravenous therapy team comprises experts in the field of infusion and do a dedicated function of IV cannula placement and maintenance. The beneficial effects of IV teams have been recognized. There was 30% increase in catheter related complications when IV catheters were maintained by staff nurses compared with by IV teams and had resulted in significant reduction in phlebitis rates..<sup>[4,24,25,27,28]</sup>

**Infusion Nurses:** The benefits of infusion Nurse is well documented in reducing catheter related complications lower leakage rate (6.4% Vs 15.3%), a lower infiltration rate, a lower phlebitis rate(7.5% Vs 13.9%)<sup>[11]</sup> and decreased the health care costs.<sup>[29-30]</sup> The definition of an infusion nurse remains unclear in the literature. It is assumed that the nurse who undergone specialized training or education on infusion nursing and whose competencies are validated at a regular interval.

**Education and training:** It is well recognized that education and training had a positive effect on practice and in reducing catheter related risks and complications. The educational program had significantly improve the compliance of nurses to evidence based guidelines and resulted in 57% reduction in catheter related infections which sustained for many months.<sup>[31-33]</sup>

Multiple method of dissemination and periodic surveillance were found to be an appropriate strategy for sustaining the nurses' compliance with guidelines and

improving nurses knowledge<sup>[33,34]</sup>.

Nurses' education and experience significantly predicted overall ratings of peripheral intravenous cannulation. Nurses with graduate diploma qualifications had higher performance ratings. The variation in nurses' education and experience affects their performance of peripheral intravenous cannulation.<sup>[33]</sup>

**Indian Scenario:** In India, Nurses practice related to intravenous therapy largely depend up on personal experience, knowledge gained during basic nursing program, and day to day practice. They are seldom exposed to any form of continuing education program. Intravenous cannulation skills are primarily acquired by an apprentice system and the manner by which intravenous cannulations are subsequently placed, may be governed by the habits formed early in training. Current practices are not supported by evidenced based guidelines. Saini<sup>13</sup> reported that hand washing was not practiced in any case of peripheral intravenous cannula insertion and subsequently while handling the peripheral intravenous cannula. Further, the documentation system remains inadequate which makes it difficult to estimate true incidences of phlebitis, infiltration and extravasation. To date, No specific recognized curriculum or course is available to update the knowledge and practice of the nurses regarding infusion or intravenous curriculum in India.

Although, IV teams and dedicated infusion nurses seem to be effective in reducing IV related complications, implementation of such approach in Indian set up won't be cost-effective and feasible, considering direct and indirect costs associated with training, dedicated manpower etc. The best alternative will be training the existing nurses in the field of infusion nursing.

The Indian Nursing Council(INC) (regulatory body for maintaining uniform standards in India) had yet to develop a curriculum in this thirist area. Infusion Nurses Society of India (INS) had ventured to sensitize the nursing community regarding importance of specialized education in the area of infusion nursing by organizing conferences and workshops. It started yielding promising results. The INS-India also developed online courses on Peripheral Intravenous cannulation. However, the response and acceptance of nursing community in India have yet to be evaluated.

**Need for competency-based curriculum:** The basic curriculum of nursing education in India focus on

behavioral objectives, norm-referenced evaluation, and set us 50% achievement in their overall knowledge and skill set. As a result, the hospital administration spent a considerable cost for training, induction and orientation of newly recruited nurses. Further, It also poses a greater risk to patients and society as a whole as the nurses involving in medication administration and other invasive procedures such as peripheral cannulation and care of PICC with limited knowledge and skill.

It is the general opinion of nurses in India that the gap between education and practice are widening. They often suggest for adopting competency-based models to design the curriculum. The competency-based curriculum demands 80% to 95% achievement in essential areas and it is based on criterion-based performance measures. The major focus of competency-based models is to determine practice competencies of real-life practice and identifies where need exists to correct deficiencies.<sup>[35]</sup>

The importance of competency-based model in nursing education in India is well recognized. However, the implementation has been going at very slow pace. Recently, INC also ventured out with competency-based basic nursing curriculum and placed in public domain for comments. Unfortunately, the draft curriculum also does not have any mention about dedicated infusion nursing module.

The quality control and accreditation standards demand the competency of the employee must be validated at regular interval.

Therefore, the development of a competency-based curriculum is an imperative need in India like the Infusion Nurses Society Competency Validation Program in the United States and worldwide. The program also should facilitate the nurses to undergo training at limited cost and validate their competencies at regular interval.

**Recommendations:** The regulatory bodies and associations should incorporate competency-based curriculum in general basic education as a mandatory module. There must be clear mention regarding scope of practice in the curriculum to facilitate legal protection of extended practice. Competency-based curriculum should be based on well-established frameworks. The Lenburg's Competency Outcomes and Performance Assessment (COPA) model is suggested as it is well accepted by nursing community in designing and implementing Competency-based education. Each

learner competency must be certified with high quality assessment method. The number of testing centers across India to validate and certify competency of the practitioners should be increased and conveniently located. The Indian Association Pediatrics (IAP) model of BLS certification may also be adapted to train general nurses in infusion nursing.

### Conclusion

It is concluded that competency of the practitioner is a paramount factor in enhancing patient safety. Each graduate should demonstrate competency related to infusion practice before awarding degree. Further, the competency should be validated at regular interval to ensure safety of the clients..

Hence, the regulatory bodies like Indian Nursing Council and Universities should focus on developing and implementing Core curriculum on Infusion Practices which is an imperative need.

# Patanjali Yoga Practice and its Effect on Mental Health and Moral Judgment Amongst Juvenile Delinquents

Dayal Sandhu<sup>1</sup>, Amit Kumar<sup>2</sup>, Monika Agarwal<sup>3</sup>

<sup>1</sup>Assistant Professor, Faculty of Education GLA University, Mathura (U.P.), India, <sup>2</sup>Research Scholar, Department of Pedagogical Sciences, Faculty of Education Dayalbagh Educational Institute (Deemed University) Agra (UP), India, <sup>3</sup>Research Scholar, Faculty of Education, GLA University, Mathura (U.P.), India

## Abstract

Research awareness and involvement in yoga for health-related results are growing worldwide. Patanjali Yoga relieves stress and fatigue which have turned into one of the few major challenges confronting the medical fraternity in present times. Yoga let go the body from any type of muscular or chronic strain and rejuvenates the body from exhaustion, body aches, stress, aids to ease the body and mind, enhances concentration and alertness, and frees the soul. It helps one to create integrity amongst his outward self as well as his innermost self. If the practices are followed meticulously then Patanjali Yoga develops a constructive effect both in the inward and outer selves of an organism. Patanjali's yoga practice aims to bind the individual self with the Ultimate One and one can achieve this union by regulating and discarding the ever- arising 'vrittis' or amendments of the mind. With Patanjali Yoga mind can be balanced through the exact kind of discipline and training. The purpose of this paper was to study the effect of Patanjali Yoga practice on mental health and moral judgment of experimental group of juvenile delinquents. Pre and post experimental design was used in this research work. Patanjali Yoga practices were used as independent variables whereas mental health and moral judgments of delinquents as dependent variables. A sample of 70 delinquents of age group (13-18 years) from Government Observation Home in Agra district was chosen with random selection method. There were two groups –experimental group (n=35) and control group (n=35). Patanjali Yoga practices were imparted to delinquents for 90 days with duration of one hour each day. For measuring the moral judgment of delinquents, moral judgment test by Juri Baruh (2004) and for measuring mental health, mental health battery by A.K. Singh and Alpana SenGupta (2008) were used. Mean, Standard deviation and t-test were carried out for data analysis. The findings suggest that mental health factors like emotional stability, adjustment, autonomy, security-insecurity and self-concept were found to be of average level and intelligence ranged from average to low in experimental and control group delinquents. It was also found that Patanjali Yoga plays a significant role by strengthening emotional stability, adjustment and self-concept in delinquents, however, the Patanjali yoga does not significantly affects mental health factors like autonomy, security-insecurity and intelligence in delinquents. The findings also concluded that Patanjali Yoga does not affect moral judgments of delinquents.

**Keywords:** *Patanjali Yoga, Mental Health, Moral Judgment, Juvenile Delinquents.*

## Introduction

Children are greatest national asset and resource. Children should be allowed and provided opportunity to grow up to become robust citizens, physically fit, mentally alert and morally healthy, endowed with skills and activations needed by the society. In recent years, it has become very clear that juvenile delinquency is the most important aspect of the subject matter of

criminology. The juvenile is a child who is alleged to have committed/violated some law which declares the act or omission on the part of the child as an offence. Delinquency is an act or conduct of a juvenile which is socially undesirable. Juvenile delinquency generally means the failure of children to meet certain obligations expected of them by the society. Research awareness and involvement in yoga for health-related results are

growing worldwide. Patanjali Yoga relieves stress and fatigue which have turned into one of the few major challenges confronting the medical fraternity in present times. Yoga let go the body from any type of muscular or chronic strain and rejuvenates the body from exhaustion, body aches, stress, aids to ease the body and mind, enhances concentration and alertness, and frees the soul. It helps one to create integrity amongst his outward self as well as his innermost self<sup>1</sup>. If the practices are followed meticulously then Patanjali Yoga develops a constructive effect both in the inward and outer selves of an organism. Patanjali's yoga practice aims to bind the individual self with the Ultimate One and one can achieve this union by regulating and discarding the ever-arising 'vrittis' or amendments of the mind. With Patanjali Yoga mind can be balanced through the exact kind of discipline and training. In Patanjali's Yoga Sutra, the eightfold path is called *ashtanga*, which literally means "eight limbs" (*ashta*=eight, *anga*=limb). These eight steps which are Yama (control), Niyama (rules of conduct), Asana (posture), Pranayama (control of breath), Pratyahara (withdrawal of sensory perceptions), Dharana (concentration), Dhyana (uninterrupted meditation), Samadhi (effortless meditation, absorption, equilibrium) basically act as guidelines on how to live a meaningful and purposeful life<sup>2</sup>. They serve as a prescription for moral and ethical conduct and self-discipline; they direct attention toward one's health; and they help us to acknowledge the spiritual aspects of our nature.

### Objectives Of The Study:

1. To study the effect of Patanjali Yoga Practice on mental health of experimental group of juvenile delinquents.
2. To study the effect of Patanjali Yoga Practice on moral judgment of experimental group of juvenile delinquents

### Hypothesis of the Study:

1. There is significant effect of Patanjali Yoga practice on mental health of experimental group of Juvenile delinquents.
2. There is significant effect of Patanjali Yoga practice on moral judgment of experimental group of Juvenile delinquents.

**Operational Definition:** Juvenile Delinquents- In the present study, Juvenile delinquents is in context with those who are unaccepted through society and are punished through law and justice and they are kept

at government observation homes for improvement through rehabilitation method.

**Mental Health-** In the present research, mental health is in context with to six factors incorporated in tool constructed by Sen and Gupta (2008) and these six factors are emotional stability, adjustment, autonomy, security-insecurity, self-concept and intelligence.

**Moral Judgment-** In the present research, moral judgment is in context with in which a person takes decision in perspective of moral standards and moral values in different circumstances.

**Patanjali Yoga-** In the present research, Yoga is in context with Patanjali's Ashtanga Yoga and its three stages that is Asana, Pranayama and Dhyana.

## Methodology

**Method:** In the present research, pre and post experimental design was used for studying the effect of mental health and moral judgment on juvenile delinquents. Juvenile delinquents were divided in two groups that is Experimental (N=35) and Control (N=35) group. Patanjali Yoga practices were imparted to Juvenile Delinquents for 90 days with duration of one hour each day.

**Variables of the study:** Patanjali Yoga practices and its three stages that is Asana, Pranayama and Dhyana were used as independent variables whereas mental health and moral judgment of delinquents are dependent variables

**Sample of the Study:** A sample of 70 delinquents of age group (13-18 years) from Government Observation Home in Agra district was chosen with random selection method.

**Research Tool:** For measuring the moral judgment of delinquents, moral judgment test by Juri Baruh (2004) and for measuring mental health, mental health battery by A.K. Singh and Alpana SenGupta (2008) were used.

**Statistical Techniques:** Mean- In the present research, Mean was used for knowing average achievement of mental health and moral judgment factors of juvenile delinquents.

**Standard Deviation:** In the present research, standard deviation was used for knowing how much deviation is there between obtained scores of mental

health and moral judgment factors of juvenile delinquents from average scores.

**T-test:** In the present research, t-test was used for knowing significant difference between pre and post obtained scores.

**Delimitation of the study:**

1. Present study was delimited to Government observation home in Agra district, India.
2. Present study was delimited to juvenile delinquents of 13-18 years of age group.

3. Yoga practices were delimited for 90 days with duration of one hour each day.
4. There was no usage of any other psychological treatment other than Patanjali yoga practices.

**Analysis and Interpretation of Data:** For knowing the effect of Patanjali yoga practice on juvenile delinquents the researcher calculated mean and standard deviation of obtained scores of pre and post patanjali yoga practice (after three months) as given in table 1.

**Table 1: Exhibiting mean, standard deviation and t-test value of obtained scores of mental health of juvenile delinquents in reference to Patanjali yoga practice**

Group Test	Control Group (N=35)		Experimental Group (N=35)		T-test	Significance Level
	Mean	Standard Deviation	Mean	Standard Deviation		
Pre Test	71.51	13.72	72.28	12.16	0.90	<0.05
Post Test	71.97	11.42	87.20	6.94	6.95	>0.01

From table 1 it is revealed that before giving Patanjali yoga practice mean of obtained scores are 72.18 and 71.51 whereas standard deviation is 12.16 and 13.72. When t-test was computed value came out to be 0.90 which was found insignificant at 0.05 level of significance and hence at the time of pre-test there is uniformity between control and experimental group. From table 1 it is also revealed that t-test value has been found 6.95 between experimental group of juvenile delinquents whom Patanjali yoga practice has been given and control group of juvenile delinquents whom Patanjali yoga practice has not been given which is

found significant at 0.01 level of significance<sup>3</sup>. Hence, it can be said that Patanjali yoga practice makes mental health of juvenile delinquents remarkable.

From Table 2 it is revealed that there is significant effect of Patanjali yoga practice on mental health factor ‘emotional stability’ between experimental group of juvenile delinquents which has been given Patanjali yoga practice and control group of juvenile delinquents which has not been given Patanjali yoga practice which is confirm by t-test value which is found to be 5.45 which is significant at 0.01 level of significance.

**Table 2: Exhibiting mean, standard deviation and t-test value of obtained scores of mental health factor emotional stability of juvenile delinquents in reference to Patanjali yoga practice**

Group Test	Control Group (N=35)		Experimental Group (N=35)		T-test	Significance Level
	Mean	Standard Deviation	Mean	Standard Deviation		
Pre Test	8.40	2.52	9.14	2.18	0.27	<0.05
Post Test	9.17	2.53	11.94	1.32	5.45	>0.01

From the table 2 it is also revealed that before giving Patanjali yoga practice to experimental and control group of juvenile delinquents the t-test value found to be 0.27 on the basis of the obtained scores of mental

health factor ‘emotional stability’ which is found to be insignificant at 0.05 level of significance<sup>4</sup>. Hence, it can be said at the time of pre test there is uniformity between control and experimental group of juvenile delinquents.

From Table 3 it is revealed that there is significant effect of Patanjali yoga practice on mental health factor ‘adjustment’ between experimental group of juvenile delinquents which has been given Patanjali yoga practice

and control group of juvenile delinquents which has not been given Patanjali yoga practice which is confirm by t-test value which is found to be 5.34 which is found to be significant at 0.01 level of significance.

**Table 3: Exhibiting mean, standard deviation and t-test value of obtained scores of mental health factor adjustment of juvenile delinquents in reference to Patanjali yoga practice**

Group Test	Control Group (N=35)		Experimental Group (N=35)		T-test	Significance Level
	Mean	Standard Deviation	Mean	Standard Deviation		
Pre Test	23.80	4.79	25.62	4.03	0.12	<0.05
Post Test	24.45	4.76	30.22	3.50	5.34	>0.01

From table 4 it is revealed that there is insignificant effect of Patanjali yoga practice on mental health factor ‘autonomy’ between experimental group of juvenile delinquents which has been given Patanjali yoga practice

and control group of juvenile delinquents which has not been given Patanjali yoga practice which is confirm by t-test value which is found to be 0.24 which is found to be insignificant at 0.05 level of significance<sup>5</sup>.

**Table 4: Exhibiting mean, standard deviation and t-test value of obtained scores of mental health factor autonomy of juvenile delinquents in reference to Patanjali yoga practice**

Group Test	Control Group (N=35)		Experimental Group (N=35)		T-test	Significance Level
	Mean	Standard Deviation	Mean	Standard Deviation		
Pre Test	9.77	2.71	9.54	2.16	0.72	<0.05
Post Test	9.25	2.04	9.82	2.37	0.24	<0.05

From table 5 it is revealed that there is insignificant effect of Patanjali yoga practice on mental health factor ‘intelligence’ between experimental group of juvenile delinquents which has been given Patanjali yoga practice

and control group of juvenile delinquents which has not been given Patanjali yoga practice which is confirm by t-test value which is found to be 0.001 which is found to be insignificant at 0.05 level of significance.

**Table 5: Exhibiting mean, standard deviation and t-test value of obtained scores of mental health factor Intelligence of juvenile delinquents in reference to Patanjali yoga practice**

Group Test	Control Group (N=35)		Experimental Group (N=35)		T-test	Significance Level
	Mean	Standard Deviation	Mean	Standard Deviation		
Pre Test	11.65	5.09	11.40	6.12	0.80	<0.05
Post Test	11.00	5.05	14.25	2.68	0.001	<0.05

From table 6 it is revealed that there is insignificant effect of Patanjali yoga practice on moral judgment between experimental group of juvenile delinquents which has been given Patanjali yoga practice and

control group of juvenile delinquents which has not been given Patanjali yoga practice which is confirm by t-test value which is found to be 0.018 which is found to be insignificant at 0.05 level of significance.

**Table 6: Exhibiting mean, standard deviation and t-test value of obtained scores of moral judgment of juvenile delinquents in reference to Patanjali yoga practice**

Group Test	Control Group (N=35)		Experimental Group (N=35)		T-test	Significance Level
	Mean	Standard Deviation	Mean	Standard Deviation		
Pre Test	17.97	3.97	18.17	4.34	0.84	<0.05
Post Test	16.34	4.35	18.68	4.14	0.018	<0.05

**Findings and Conclusions**

It can be said that Patanjali yoga practice makes mental health of juvenile delinquents remarkable. There is significant effect of Patanjali Yoga practice on mental health factors which are emotional stability, adjustment and self concept. It is also revealed that there is insignificant effect of Patanjali Yoga practice on mental health factors which are autonomy, security-insecurity and intelligence. It was also found that Patanjali yoga practice do not effect moral judgment of juvenile delinquents. Hence, after having conversation with authority it was clear that there was a positive change seen amongst juvenile delinquents due to Patanjali Yoga practice and they want these yoga practices to be contionusly scheduled from time to time.

**Ethical Clearance:** Not required as per study

# Quality of Life of Wives of Alcoholics

Shiji P.J.<sup>1</sup>, Neetha Kamath<sup>2</sup>

<sup>1</sup>Associate Professor and HOD, Department of Community Health Nursing, Father Muller College of Nursing, Ph.D. Scholar NITTE Deemed to be University, Mangaluru, <sup>2</sup>Associate Professor and HOD, Department of Community Health Nursing, Nitte Usha Institute of Nursing Sciences, NITTE Deemed to be University, Mangaluru

## Abstract

**Background:** Alcoholism is a common problem both in developing as well as developed countries. It leads significant harm to the physical, psychological and social health of individuals, families and communities as a whole. Wives of the alcoholics are the persons who suffer the consequences of alcoholism and its effects the most.

**Objective:** To assess the quality of life of wives of alcoholics.

**Materials and Method:** Quantitative approach with descriptive survey research design was adopted in the study. Total 150 men residing at Mangalore and Bantwal taluk of Dakshina Kannada district were administered the AUDIT tool through house to house survey, of which 132 men who scored 8 to 10 were taken as alcoholics and their wives were selected as participants through purposive sampling technique. Participant information sheet and informed consent was obtained. The data was gathered by using WHOQOL-BREF tool to assess the quality of life.

**Results:** Shows that mean quality of life score of wives of alcoholics in physical domain (11.73), psychological (9.43), social (5.04) and environmental (13.10) respectively. The chi-square test shows that there is a highly significant association between QOL scores of subjects and selected variables such as income of family ( $p \leq 0.001$ ) and number of children ( $p \leq 0.018$ ).

**Conclusion:** The study findings revealed that wives of alcoholics are having poor quality of life. Hence need to adopt effective interventions to promote the wellbeing of the wives of alcoholics and to improve their quality of life.

**Keywords:** *Quality of life, Wives of alcoholic, Alcohol, AUDIT, WHOQOL-BREF.*

## Introduction

Alcoholism is a serious global health concern which affects not only the individual but also his family and

the society as a whole. It creates major problem to the family members especially the wife and they face untold misery. Wives of the alcoholics are the persons who suffer the consequences of alcoholism and its effects the most. Wives of alcoholics first they try to adjust with the problems but finally they begin to feel depressed, confused, and even guilty<sup>1</sup>. WHO reported that about 140 million people throughout the world suffer from alcohol dependence<sup>1</sup>.

The wife of an alcoholic, who enters into marital life with a heart full of expectations, becomes exhausted, when she faces tough life situations from alcoholic husband. Social influence process plays an important

role in the etiology and maintenance of problematic alcohol use<sup>2</sup>.

Alcohol abuse is a known public health problem in the world. The harmful use of alcohol results in 3.3 million deaths each year. It was estimated that the age of 15 years and above people drinks 6.2 L of pure alcohol per year. About (38.3%) of population actually drinks alcohol; which indicates that people who do drink consume on an average about 17 L of pure alcohol annually. Nearly, 15.3 million persons had drug use disorders. It was reported that among 148 countries the injecting drug use; of which 120 people reported HIV infection<sup>3</sup>.

In Indian society, alcoholism is one of the major social problems which have negative effects on the spouse of an alcoholic<sup>4</sup>. This problem directly affects the health of family structure, feeling of hatred, self pity, avoidance of social contacts, divorce, irresponsibility of husbands, suicide, homicide, broken home, poor academic performance of children, poverty are all the outcome of this evil. The community support system, including the mental health services can be a good resource for them to bring them out of this contagious problem.

From all the above statistics it is evident that there is an increased with multi factorial problems among the wives of alcoholics, which decreases the quality of life. So it demands special attention. Hence the present study was undertaken to assess the quality of life of wives of alcoholics.

## Materials and Method

A quantitative approach with descriptive survey research design was adapted in this study to meet the objectives. The study was conducted in two villages of Mangalore and Bantwal taluks of Dakshina Kannada district. The investigator administered the Alcohol Use Disorders Identification Test (AUDIT) tool to 150 men through house to house survey, of which 132 men who scored more than 8-10 scores were considered as alcoholics and their wives were selected as subjects through purposive sampling technique for the study. Ethical Clearance: obtained from Institutional Ethics committee of Father Muller Medical College, Mangalore.

**Inclusion Criteria:** The study includes

- Wives of alcoholics who are living with their alcoholic husbands for more than two years

- Wives who are not consuming the alcohol

**Exclusion Criteria:** The study excludes

- Wives of alcoholics, who are diagnosed with any psychological problems and chronic illness
- Wives of alcoholics who are separated from her alcoholic husbands

The permission to conduct study was obtained from District Health Officer (DHO) Mangalore. Informed consent was obtained from the study subjects. The need and purpose of the study was explained to the participants in their local language and confidentiality was assured. The quality of life of wives of alcoholics was assessed by using WHOQOL-BREF scale. WHOQOL-BREF tool is a standardized, valid and reliable tool which assesses the QOL under four areas such as Physical, Psychological, Social and Environmental with a total of 26 items. The socio demographic data was collected from the subjects'. The data gathered were analyzed by using descriptive and inferential statistics.

## Results

### Section 1: Description of Sample characteristics:

This section deals with the description of the baseline characteristics of 132 subjects presented in frequency and percentage. Majority 73(55.3 %) of the subjects belongs to the age group of 36 years and above .Most of the subjects 114(86.4%) of them belongs to Hindu religion. Educational status majority 73 (55.3%) had primary education .Most 104 (78.8%) of the family belongs to BPL family, 97 (73.5%) daily wages. Family income 47(35.6%) had income of Rs.10, 001 to 15,000 per month. About 55 (41.7 %) belongs to nuclear family .Place of residence 61 (46.2 %) of subjects were residing in the rural area. About 56 (42.4%) of the subjects had moderately adequate family support. Majority 87(65.9%) had social support from social organizations .Duration of marital life of subjects had more than 10 years 87(65.9%).Number of children 57 (43.2%) had two children .Primary decision maker in the family majority had mutual consent 92(69.7%) .About 50(37.9%) of them had duration of alcoholism about 6-10 years. History of domestic violence 25(18.9%) of them were reported.

**Section II: Assessment of QOL of Wives of Alcoholics:** Data depicted in Table 1 shows that most 129 (97.7%) of subjects had poor quality of life. Whereas 3 (2.3%) had average quality of life and none of them had good quality life whose husbands are alcoholics.

The levels of quality of life of subjects are categorized as follows:

**Table 1: Frequency and percentage distribution of level of quality of life of subjects n= 132**

Level of QOL	(f)	(%)
Excellent (97 – 120)	0	0.0
Good (73 – 96)	0	0.0
Average (49 – 72)	3	2.3
Poor (24 – 48)	129	97.7

**Section III: Domain wise Mean, Standard deviation & Mean % of QOL of subjects:** The data presented in Table 2 & Figure 1 shows that the mean scores of QOL in physical domain (11.73), psychological

domain (9.43), social domain (5.04) and environmental domain (13.10). Standard deviation in physical domain is (2.029), psychological domain (1.786), social domain (1.206), and environmental domain (2.529) .Mean percentage of QOL scores in different domains like physical (33.53), psychological (31.42), social (33.60) and environmental (32.74) respectively.

**Table 2: Domain wise Mean, Standard deviation & Mean % of QOL of subjects n-132**

Domain wise quality of life	Mean	SD	Mean %
Physical	11.73	2.029	33.53
Psychological	9.43	1.786	31.42
Social	5.04	1.206	33.60
Environmental	13.10	2.529	32.74

**Figure 1: Pyramid diagram showing the distribution of mean percentage scores according to domains of QOL**

**Section IV: Association of quality of life scores of subjects with selected demographic variables:** Chi square test was computed to determine the association between the quality of life scores with selected demographic variables. The following null hypothesis was stated:

H<sub>01</sub>: There is no significant association of QOL scores of wives of alcoholic with selected demographic variables.

The data findings shows that there is a significant association between QOL scores of subjects and

selected variables such as income of family ( $p \leq 0.001$ ) and number of children ( $p \leq 0.018$ ). Since calculated chi square value is more than the tabled value .Hence the null hypothesis is rejected and research hypothesis is accepted.

There is no significant association between QOL scores of subjects and rest of the selected variables since the calculated chi square value is less than the tabled value .Hence the null hypothesis is accepted and research hypothesis is rejected.

## Discussion

The present study was envisaged to assess the quality of life of wives of alcoholics. The findings revealed that the mean scores of quality of life of wives of alcoholics as per domains, physical domain (11.73), psychological (9.43), social (5.04) and environmental (13.10) respectively. The scores indicated that the quality of life is low in all the four domains. The study findings also revealed that most 129 (97.7%) of subjects had poor quality of life and only 3 (2.3%) had average quality of life and none of them had good quality life whose husbands are alcoholics.

Similar study was conducted to measure disability and quality of life of individuals with AUD (Alcohol use disorders) using standardized instruments<sup>5</sup>. Another study was conducted in selected de-addiction centre; Puducherry to assess the quality of marital life among the wives of alcoholic dependents. The results revealed that majority of samples 62% had moderate quality of marital life, whereas 20% subjects had low quality of marital life, while 18 % had high quality of marital life<sup>6</sup>.

These findings are supported by a cross-sectional study was carried to evaluate quality of life and presence of stress in caregivers of drug-addicted people. Results revealed that, 55.9% were mothers with a mean age of 47.66 years; 23.8% had depressive symptoms. Mean stress among caregivers was 2.24. The study findings show that there is a significant correlation in quality of life, depression and care givers stress. Results also proved that quality of life is compromised and stress is high among caregivers, indicating the need for providing emotional and moral support<sup>7</sup>.

Another study was conducted to understand the level of Perceived Quality of life among the wives of alcoholics and wives of non-alcoholics. The result revealed that with regard to the overall perceived quality of life, majority (66.7%) of the wives of alcoholics report that they have low level of perceived quality of life whereas, majority (66%) of the wives of non-alcoholics report that they have high level of perceived quality of life<sup>8</sup>.

A descriptive study was conducted to investigate the problems faced and coping strategies used by the wives of alcoholics. Sample comprised of 30 wives of alcoholics selected for the study. The study findings show that most of the women had faced problems in multiple domains and the majority of them were having

emotional problems and only few of them reported the problems of physical violence. Coping strategies used by wives of alcoholics were reported in three major styles: engaged, tolerant and withdrawal<sup>9</sup>.

A cross sectional comparative study was carried out to explore two important areas related to the spouses of alcohol addicted individuals i.e. marital quality and their social functioning .A total of 60 subjects; of which 30 spouses of Alcohol dependent (AD) who fulfilled the criteria of ICD-10-DCR and rest of 30 subjects were from normal population. Results showed that spouses of alcohol addicted individual's perceived significantly lower marital quality and social functioning than the spouses of non-alcoholic individuals. There is positive relation between marital quality of life and social functioning of spouses of alcohol dependent individuals<sup>10</sup>.

In the present study the association between quality of life and selected demographic variables depicted that there is a significant association between QOL scores of subjects and selected variables such as income of family ( $p \leq 0.001$ ) and number children ( $p \leq 0.018$ ). Similarly a quantitative approach, Pre experimental one group pre test post test design study was conducted to assess the level of stress among spouse of alcoholics, to evaluate the effectiveness of Guided imagery on stress and to determine the association between stress and demographic variables among spouse of alcoholics. The overall pre-test mean score was 20.25 and for the post test is 14.25. There was a significant difference in the mean score of stress before and after Guided imagery i.e. the calculated 't' value was 19.613 and it was statistically significant at 0.05 level. Further there was no significant association between the stress score and selected demographic variables<sup>1</sup>.

Similarly, the present study results showed that the quality of life of wives of alcoholics in all domains is low. Hence need to adopt measures to improve their quality of life.

## Conclusion

Alcoholism is a family disease, it not only damages health of the addicted persons but it also causes comprehensive damage to the family and marital life. Keeping the study results in mind, it can be concluded that there are various problems faced by the wives of alcoholics. Being health care professionals need to identify such families and adopt a comprehensive

measure which includes effective teaching and interventional programs to improve the quality of life of wives of alcoholics.

# A Study on Knowledge, Attitude and Practice on Mosquito Borne Diseases in Thirumazhisai, Thiruvallur District, Tamilnadu

B. Charumathi<sup>1</sup>, D. Jayashri<sup>1</sup>, R. Rajayamini<sup>1</sup>, Gomathy Parasuraman<sup>2</sup>, Ruma Dutta<sup>3</sup>, Timsi Jain<sup>4</sup>

<sup>1</sup>Post Graduates, <sup>2</sup>Associate Professor of Community Medicine, <sup>3</sup>Associate Professor of Community Medicine, <sup>4</sup>Professor and Head of Department of Community Medicine, Saveetha Medical College Hospital, Thandalam, Kanchipuram District-602105

## Abstract

**Background:** In recent years, mosquito-borne diseases (MBD'S) have emerged as a serious public health problem in countries of the South-East Asian Region. The most important ones are malaria, dengue fever, chikungunya fever, lymphatic filariasis and Japanese encephalitis. Asia endures about 70% (47-94 million infections) of this burden, whereas India alone is responsible for 34% (24-44 million infections) of the global total. Objective: To assess the knowledge, attitude and practice about mosquito borne diseases and its prevention.

**Methodology:** A Community based cross-sectional study was conducted in suburban area -Thirumazhisai of Thiruvallur district. The Sample size of 141 was calculated. The study population was selected by simple random sampling technique. A pre-designed; pre-tested semi-structured questionnaire was used to collect data. Data entered in MS excel and analyzed using proportions.

**Results:** Among 144 household of Thirumazhisai, Thiruvallur District, majority of the residents interviewed were males (63.1%). Majority of participants belong to age group 25-34(38%). Mean age of the participants was 29±9.1 years Most of them belong to upper middle class (39.5%). 99% (142) knew that mosquitoes transmit diseases. With regards to breeding sites, 92.3%(133) of residents knew the breeding place of mosquitoes. Majority of the residents knew that mosquitoes breed in sewage and waste water (36.8%). About 132(91.6%) knew at least one preventive measure and 12(8.3%) of them knew none. 134(93%) people felt mosquito borne diseases could be prevented. Among the 134, majority (78.4%) felt that having clean surrounding and household could prevent mosquito borne disease. 66.6% of the population (96) under study are bitten by mosquitoes every day. 69.4% of them use coil and liquid for protection. Conclusion: Thus, by knowing the existing knowledge of the study population regarding mosquito-borne diseases and its prevention, evidence-based effective prevention and control strategies as well as sustainable community participation can be achieved.

**Keywords:** Mosquito-borne diseases, knowledge, practices, mosquito bite prevention method, breeding sites.

## Introduction

In recent years, vector-borne diseases have emerged as a serious public health problem in countries of the South-East Asia Region, including India. Mosquito-borne diseases constitute an important cause of morbidity and mortality, especially in India.<sup>1</sup>

The most important ones are malaria, dengue fever, chikungunya fever, lymphatic filariasis and Japanese encephalitis. In India, every year there are millions of cases of malaria.<sup>1</sup>

Malaria is an important disease with annual occurrence of 300-500 million cases and 1.1-2.7 million deaths globally.<sup>2</sup> An estimated 96 million apparent dengue infections were reported globally in 2010. Asia endures 70% (47-94 million infections) of this burden whereas India alone is responsible for 34% (24-44 million infections) of the global total.<sup>3</sup>

The mosquito-borne diseases result in avoidable ill-health and death which also has been emphasized in National Health Policy<sup>1</sup>. National Vector Borne Disease Control Programme (NVBDCP) under the aegis of National Rural Health Mission (NRHM) is one of the most comprehensive public health programs in India including prevention and control of mosquito-borne diseases.<sup>4</sup>

Owing to upcoming urbanization and the poor quality of living at rural areas, this study is aimed to assess the existing knowledge and practices of the people regarding MBD's, along with various personal protective measures and community measures undertaken in this area.

Assessment of knowledge and practices of community about prevention of mosquito borne diseases is important for designing community-based interventions.

Mosquito-borne diseases constitute an important cause of morbidity and mortality. For example, around 2 million people die due to malaria every year. These numbers can be easily swindled with proper awareness.

Mosquito borne diseases are largely preventable yet they can cause various life -threatening illness. Knowledge and practices of community about prevention of mosquito borne diseases are an important aspect to assess the need of community-based interventions.

## Methodology

A cross-sectional descriptive study was conducted in a suburban population at Thirumazhisai, Thiruvallur District, Tamilnadu from July 2016 to September 2016.

This area falls under the suburban field practice area of Department of Community Medicine, Saveetha Medical College and Hospital, Thandalam. Study population: Households of Thirumazhisai. Study unit: Head of the family. Sampling Method: Simple random sampling. Sample Size: On the basis of the prevalence of mosquito borne diseases of (90.3%)<sup>5</sup> and taking relative precision as 5.3% of prevalence, at 95% Confidence level, the minimum sample size calculated was 144. There were 1175 households in this area, of which 144 households were identified for the study using simple random sampling technique. From each of these selected households, one person whoever was available at the time of visit was interviewed. Inclusion criteria: 1. Inhabitant of study area 2. Of sound mind 3. Can communicate by at least one of the means viz. speaking or writing. Exclusion Criteria: 1. Inhabitant outside the study area. 2. of insane mind. 3. Unable to communicate 4. Not willing to participate. Data Collection: The data was collected from the household covered under our suburban area, literate and illiterate population belonging to that community. This ensured the homogeneity of sample. The sample population consists of income groups of different level and having different life styles. A pre-designed; pre-tested semi- structured questionnaire was used to collect data on demographic background and mosquito borne diseases. It was administered to the member of the household available at the time of the visit after obtaining an informed consent. Institutional ethical committee approval was obtained prior to the conduct of the study. Statistical analysis: Data entry and analysis was done using statistical package for social sciences (SPSS) version 16 software. Descriptive statistics were calculated for background variables and the prevalence of mosquito borne diseases.

## Results

**Socio-Demographic Details:** This cross sectional study was conducted among 144 household of Thirumazhisai, Thiruvallur District, Tamil Nadu. In the present study, majority of the residents interviewed were males (63.1%). Majority of participants belong to age group 25-34(38%). Mean age of the participants was 29 ±9.1 years. Most of them belong to upper middle class (39.5%) according to Modified Kuppaswamy socio-economic scale. (Table 1).

**Table 1: Background characteristics of the participants**

No.	Background Characteristics	Total no of participant (N=144)	Percentage %
1.	<b>Age of the participants</b>		
	15 -24	23	15.9%
	25 -34	56	38%
	35 –44	48	33.3%
	45 - 54	17	11.8%
2.	<b>Sex of participants</b>		
	Male	91	63.1%
	Female	53	36.1%
3.	<b>Socioeconomic status (Modified Kuppuswamy Scale)</b>		
	Upper class (I)	21	14.5%
	Upper middle class (II)	57	39.5%
	Lower middle class (III)	36	25%
	Upper lower class (IV)	16	11.1%
	Lower class (V)	14	9.7%
4.	<b>Education</b>		
	Illiterates	27	18.7%
	Primary	34	23.6%
	Middle school	15	10.4%
	High school	35	24.3%
	Graduation	26	18%
	Post Graduation	7	4.8%
5.	<b>Occupation</b>		
	Unemployed	31	21.5%
	Unskilled	47	32.6%
	semiskilled	19	13.1%
	Skilled	23	15.9%
	Professional	24	16.6%

**Knowledge:**

**Knowledge regarding mosquito borne diseases:** Among the 144 residents, 99% (142) knew that mosquitoes transmit diseases while 1% (2) did not know.

Among the people who were aware of transmission of disease (142) by mosquito, dengue (69%) was the most common disease known to the population. This was because there had been an outbreak of dengue in nearby areas in the recent past. 43(30.2%) people knew about malaria while 6 of them couldn't name any of the disease. (Table 2).

**Table 2: Knowledge regarding mosquito borne diseases**

Mosquito borne diseases	Number N = 142	Percentage
Malaria	43	30.2%
Dengue	98	69%
Filariasis	3	2.1%
Chikunkunya	16	11.2%
All of the above	9	6.3%
Don't know	6	4.2%

\*Multiple response questions

**Knowledge regarding mosquito breeding sites:** With regards to breeding sites, 92.3 % (133) of residents knew the breeding place of mosquitoes.

Majority of the residents knew that mosquitoes breed in sewage and waste water (36.8%). (Table 3).

**Table 3: Knowledge regarding mosquito breeding sites**

Mosquito breeding sites	Number N = 133	Percentage
Rivers and ponds	20	15%
Sewage and waste water	49	36.8%
Pots	3	2.2%
Artificial collection of water	33	24.8%
All of the above	38	28.5%
Don't know	1	0.75%

\*Multiple response questions

**Knowledge regarding prevention of mosquito breeding:** About 132(91.6%) knew at least one preventive measure and 12(8.3%) of them knew none. (Figure 1).

**Attitude:** When questioned about prevention of mosquito borne diseases, 134(93%) people felt that mosquito borne diseases could be prevented while 4 of them had no opinion. 6 members (4%) felt that these diseases cannot be prevented. Among the 134, majority (78.4%) felt that having a clean surrounding and household could prevent mosquito borne diseases. (Figure 2).

Figure 1: Knowledge regarding prevention of mosquito breeding

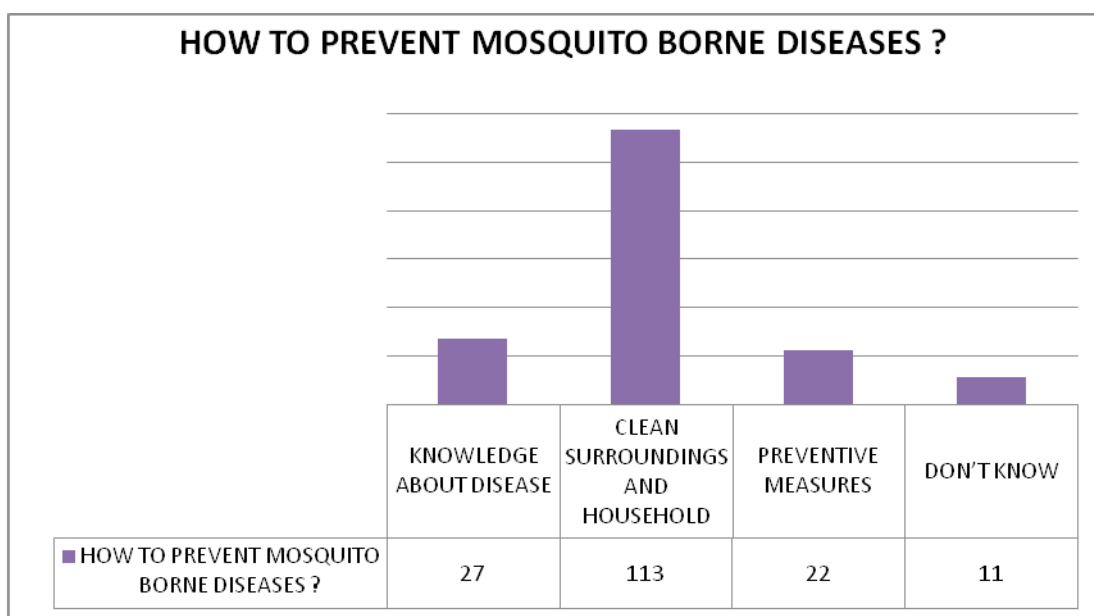

Figure 2: Attitude towards prevention of mosquito borne diseases

Majority (48.6%) understood that everyone’s active participation is required to control these diseases. 30% felt that residents role is important in controlling these diseases. 16% felt that government role is important in controlling these diseases. Only 6% felt that it’s the role of health department in controlling these mosquito borne diseases.

66.6% of the population (96) under study are bitten by mosquitoes every day followed by 15% of them bitten

by mosquitoes few days a week. It is also found half of them are bothered by mosquitoes and have altered their behaviour. These people stay indoors for the same reason.

**Practice:** Among the interviewed, 4 of them were affected in the past one year and 2 relatives/friends were also affected. Among them, 5 had dengue and one of them had malaria.

When asked about the treatment taken among the people affected, 2 have received tablets and 2 have received IV injections, one have received both tablets and IV injection. Only one did not receive any treatment.

With respect to place of treatment, 5 of them had received care from government hospitals while 1 of them in a private hospital.

When residents were questioned about protecting themselves from mosquito bites, majority (69.4%) of them use coil and liquid followed by the use of mosquito net (29.8%). (Table 4)

**Table 4: Protective measures used by the residents**

Protective Measures	Number OD People Used (%)
Mosquito net	43(29.8%)
Coil and liquid	100(69.4%)
Proper clothing	12(8.3%)
Repellent creams	12(8.3%)

\*Multiple response questions; Figures in parentheses indicate percentages.

Only 8% of residents practice any method for protecting themselves from mosquito bite. Among them, 47% practice it during rainy season and 44% practice the method always, whereas 9% of them practice only during an outbreak

Each house where the residents had been interviewed was checked for breeding sites inside and also outside the house. 84% of the population live in pucca houses, 5% katcha and 11% in semi pucca.

There were no potential breeding sites inside 70 of the households and outside 57 households. Inside the house, dustbin was the common breeding site. Rain water collection was found to be a major potential site outside the houses.

### Discussion

In the present study, majority of the residents interviewed were males (63.1%). Similar findings were obtained from a study conducted in Belagavi city<sup>6</sup> which reported 56.3% males. Other studies conducted in Puducherry<sup>7</sup>, Mangalore<sup>5</sup> and Delhi<sup>8</sup> reported majority of participants being female.

In the present study, majority of participants belong to age group 25-34(38%). Mean age of the participants was 29 ±9.1 years. A study conducted in Belagavi city<sup>6</sup> reported that 45.8 % of participants were in the age

group of 20-29. Study conducted in Mangalore<sup>5</sup> reported higher mean age of 41.2±14.1 years.

In the present study, 39.5% of participants belong to upper middle class (II). A study conducted in Belagavi city<sup>6</sup> reported that majority (41.4 %) belongs to class IV socio-economic status.

The present study revealed that 18.7% of participants were illiterates. This was similar to study conducted in Belagavi city<sup>6</sup> (19.3%). Whereas a study conducted in Mangalore<sup>5</sup> revealed only 5% illiteracy level.

The present study was focused on the awareness and practices of mosquito borne diseases and its prevention. In the present study, 99% were aware that mosquitoes transmit a disease which was found to be higher than study conducted in Puducherry<sup>7</sup> and Mangalore<sup>5</sup> which reported 76.8% and 90.7% awareness.

Majority of people in the present study were aware of Dengue (69%) which was similar to study conducted in Delhi(62.3%) by Kohli Cet al.<sup>8</sup> but was higher than study reported from Mangalore<sup>5</sup> which reported only 18.4%.

The present study reported that 36.8% of the residents knew that mosquitoes breed in sewage and waste water. Study conducted by Pallavi V Tenglikar et al in Karnataka<sup>9</sup> and study in Mangalore<sup>5</sup> reported higher awareness of 85% and 74% regarding mosquito breeding in sewage water.

In the present study, 93% people felt that mosquito borne diseases could be prevented while 4 of them had no opinion. 66.6% of the population (96) under study are bitten by mosquitoes every day. It is also found half of them are bothered by mosquitoes and have altered their behaviour. These people stay indoors for the same reason.

In the present study, majority of residents 69.4% were protecting themselves from mosquito bites, by using coil and liquid, which was found to be higher than the study conducted in Karnataka<sup>8</sup> and Belagavi city<sup>6</sup> which reported 57.4% and 57.8% of repellents usage to protect themselves from mosquito bites.

Each house where the residents have been interviewed was checked for breeding sites inside and also outside the house. In the present study, 84% of the population live in pakka houses. A study in Belagavi city<sup>6</sup> reported that 71.4% in pakka house.

Inside the house, dustbin was the common breeding site. Rain water collection was found to be a major potential site outside houses. It's also observed that rain water collection on roads is present outside 45 households. Necessary steps must be taken by the local authorities at the earliest.

### Conclusion

From this study it is important to note that 8% of the population don't know where mosquitoes breed and 6% felt it cannot be prevented. Thus knowledge and awareness must be improved. Thus, by knowing the existing knowledge of the study population regarding mosquito-borne diseases and its prevention, evidence-based effective prevention and control strategies as well as sustainable community participation can be achieved.

**Limitations of the Study:** This study was conducted in our field practice area covered by one Urban PHC, therefore the findings cannot be generalised to other urban areas.

**Conflict of Interest:** Nil

**Source of Funding:** Nil

**Ethical Clearance:** Ethical approval was obtained from the Institutional Review Board (IRB) and Institutional Ethics committee. Written informed consent was obtained from the study participants and information sheet regarding the study was given to all the participants.

# Awareness, Attitude and Obstacles in Research among Dental Professionals in Chennai: An Institutional Based Survey

Akila Ganesh<sup>1</sup>, Janani Krishnamachari<sup>2</sup>, Janani K.<sup>2</sup>, M. Rajkumar<sup>3</sup>, B. Archana<sup>4</sup>, S.K. Balaji<sup>5</sup>

<sup>1</sup>Professor and Head(I/c), Department of Public Health Dentistry, Faculty of Dental Sciences, Sri Ramachandra Institute of Higher Education and Research, Chennai, <sup>2</sup>Postgraduate Student, Saveetha Dental College and Hospital, Chennai, <sup>3</sup>Reader, Department of Public Health Dentistry, <sup>4</sup>Tutor, <sup>5</sup>Professor & Head, Department of Periodontics, Faculty of Dental Sciences, Sri Ramachandra Institute of Higher Education and Research, Chennai

## Abstract

**Background:** Advancement in treatment modalities has improved as a result of research. Individual's critical thinking and analysis has enhanced. In the advent of incorporating their clinical trials into practice, it had greatly improved in treating patients and enhancing patients care.

**Aim:** To compare the awareness, attitude and obstacles in the field of research among interns, postgraduate students and faculty members among Dental professionals.

**Materials and Method:** An institutional based cross sectional questionnaire survey was conducted among interns, postgraduates and faculty members of the dental profession. A sample size of 261 was determined. Ethical clearance was obtained from Institutional Ethics Committee.

**Statistical Analysis:** Descriptive statistics, chi-square test and student's t-test were used to analyze the data.

**Results:** On analyzing the questionnaire, 61.2% of study subjects were currently guiding and undertaking research projects. Majority of the subjects stated that doing research enhanced their critical thinking and knowledge. The most common obstacle stated for research was lack of time and lack of financial incentives. When assessing barriers to publishing an article, it was reported that lack of publication related knowledge was the most major obstacle in all groups. Majority of the post graduates and faculty members prefer to conduct recent advance based research; whereas interns prefer to do research based on innovative idea which was statistically significant.

**Conclusion:** This research study revealed positive attitude toward research among dental professionals.

**Keywords:** Research, Awareness, Obstacles, Dental professionals.

## Introduction

Research occupies a central role in recent years

and has increased greatly among developed countries<sup>1</sup>. The word 'research' was derived from the French word 'Recherché' which means 'to go about seeking'<sup>2,3</sup>

Advancement in treatment modalities has improved as a result of research. Individual's critical thinking and analysis has enhanced<sup>4</sup>. In the advent of incorporating their clinical trials into practice, it had greatly improved in treating patients and enhancing patients care<sup>5</sup>

In the past decade, developing countries relied on western world for their research findings to be applied

in for patients' care. This did not give a solution to the problems in the developing countries. In the recent years, awareness in research has been instilled in the minds of the younger generation<sup>6</sup>.

Many studies have been reported regarding the awareness of research among medical population. Very few studies have been done among dental professionals<sup>7</sup>.

In recent times, intern's involvement in research work has been increased to a great extent. Postgraduates are involved in research as a part of their curriculum. All of them need the guidance of faculty members. There are no previously published literature done in Tamil Nadu which assesses the awareness, attitude and obstacles in the field of research among dental professionals. With this in mind, a survey was conducted to assess the awareness, attitude and obstacles in the field of research among institutional based dental professionals.

**Materials and Method:** This is a questionnaire based cross sectional study carried out among dental professionals who are affiliated to institutions. Ethical clearance was obtained from Institutional Ethics Committee of the institution (Ref. No.: CSP/16/JUN/49/209). Random sampling methodology was used to select three institutions. The questionnaire was administered to the participants who were present on the day of study and who gave verbal consent.

15 close ended questions were formulated and validated by three experts of different specialties. The questionnaire consists of basic demographic details of the participants and questions related to awareness, attitude and obstacles in research.

The sample size was calculated based on a study done by Vijay Kumar et al<sup>3</sup> and was estimated to be 218 assuming 95% confidence interval and 5% marginal error. Furthermore, the sample size was increased by 20% to maintain an adequate sample size and to compensate for non response or faulty response. This was estimated to be 261.

**Statistical Analysis:** The collected data were analysed with IBM.SPSS statistics software 23.0 Version. To describe about the data, descriptive statistics like frequency analysis, percentage analysis were used. To find the significance in categorical data, Chi-Square test was used. In the above statistical tool, the probability value of 0.05 was considered as significant level.

**Results:** The overall distribution of sample shows 36% males and 64% females. The percentages of interns were 32% while post graduates were 40% and faculty were 27 %.

On analyzing the questionnaire, it was found only 52% of the subjects understood the right concept of research.

Approximately 63% of them reported that reading journals and participating in research helps in enhancing evidence based clinical practice, and this was found to be statistically significant. 56% of the subjects admit that they read journal only when need arises. But it is even more surprising that 52% post graduate also do the same. It was reported that around 25% of the interns did not have the habit of reading journal at all.

It was found that around 69% interns did not involve themselves in research activities. Out of those involved in research, 65% of them failed to publish their completed research projects. (Fig.1) Both of these results were found to be statistically significant.

Majority of the subjects prefer to do experimental based study compared to descriptive and analytical studies.

Although 92% of the dental professionals felt that they should have knowledge on statistics, yet they preferred a statistician for the analysis.

46% of the post graduates and 42% of faculty members said that the motive behind conducting research at post graduate level was to appraise knowledge and this showed statistical significance. However 23% post graduates and 35% of faculty members said that they do it mandatory as a part of curriculum. (Fig. 2)

Majority of the subjects stated that doing research enhances their critical thinking and knowledge on analyzing. Personal barriers like financial incentives and lack of time as a personal barrier on the research had an almost equal impact. (Fig.3)

When assessing professional barriers, it was found that 59% reported lack of time and 20% reported lack of mentorship. (Fig. 4). This was found to be statistically significant ( $p = 0.02$ ).

Difficulty in following up patients was the barrier among 43% of the participants. Out of this, 46% were interns and 36% were postgraduates (Fig.5).

Fig. 1: Efforts to publish completed research projects

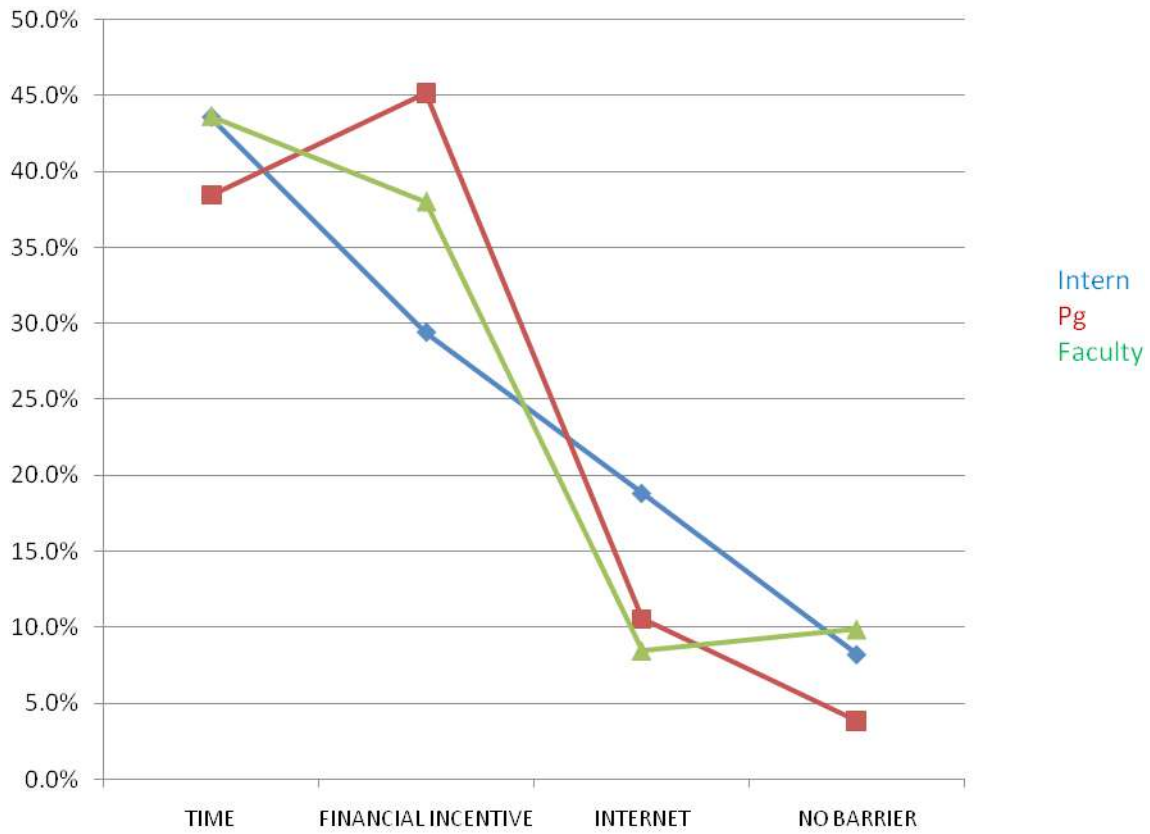

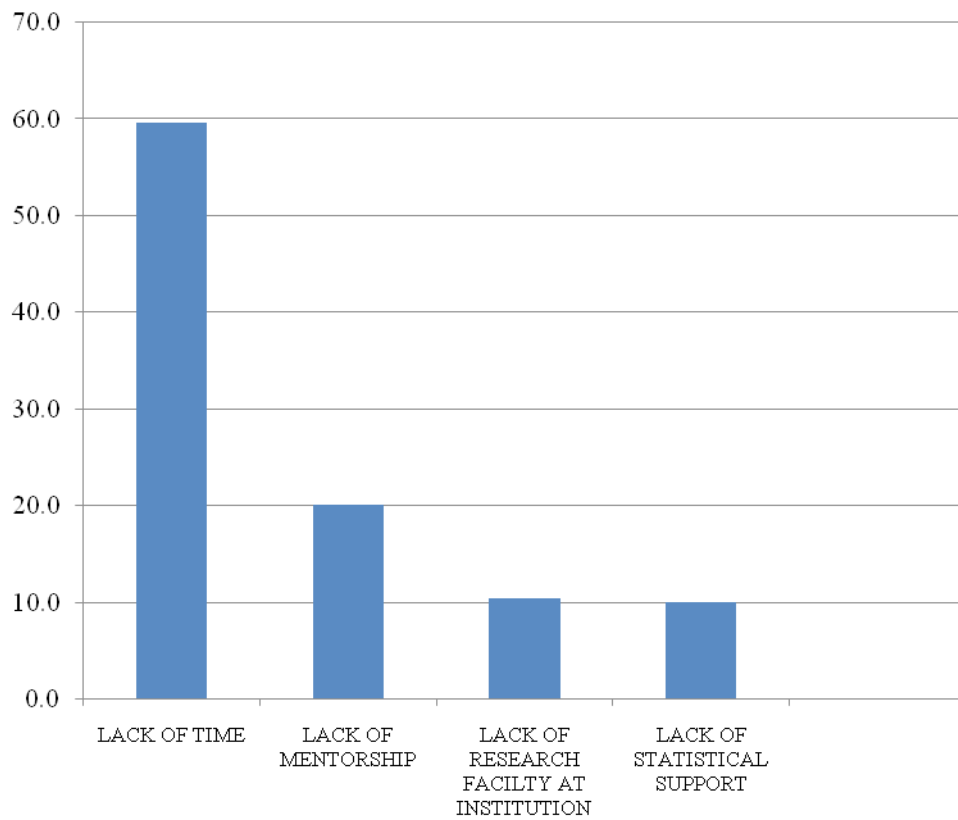

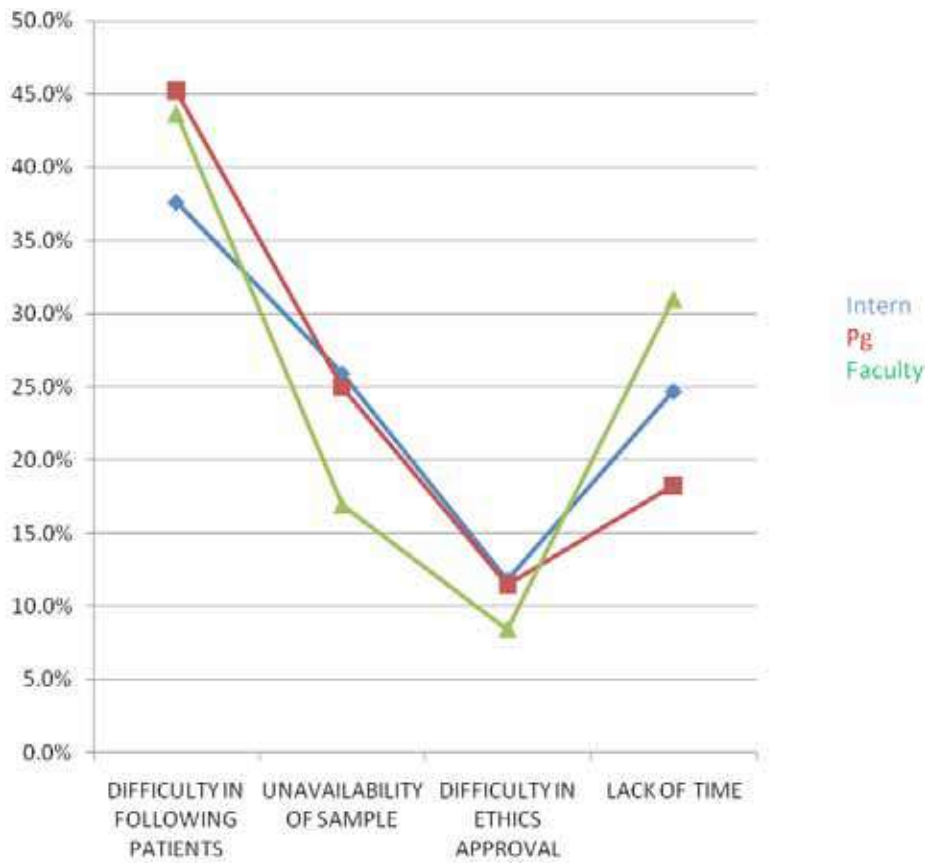

Fig. 2: Motive behind conducting research at postgraduate level

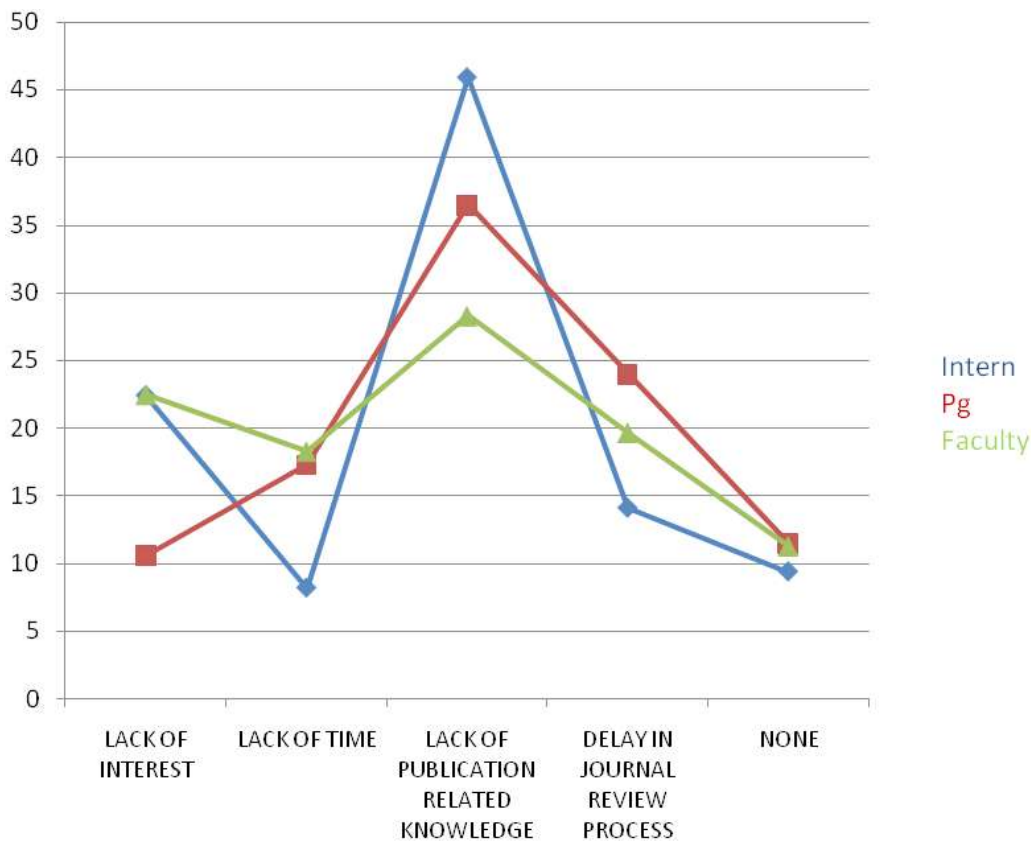

**Fig.3 : Personal barrier in your research**

**Fig 4 : Professional barrier in your research**

**Fig 5: Barrier among students participating in research**

**Fig .6: Barriers in publishing**

When assessing barriers to publishing an article, it was reported that lack of publication related knowledge was the most major obstacle in all groups. 33% of the students reported that there was lack of interest from the guide. Similarly 22% of the faculty members said that there was lack of interest from the students (Fig. 6).

Majority of the post graduates and faculty members prefer to conduct recent advance based research; whereas interns prefer to do research based on innovative idea. This was found to be statistically significant ( $p = 0.05$ ).

## Discussion

In many developed countries research programs has been included as a part of undergraduate curriculum for medical students. It is necessary for them to attain publication for taking up their final examination<sup>9</sup>. In Germany research occupies an important role in the undergraduate curriculum for medical students. 28% of medical students attained for publication<sup>10,11</sup>. Academics and research should go hand in hand<sup>9</sup>. Dentistry can be brought to the next level in India by incorporating research into the curriculum at the undergraduate level<sup>8</sup>.

In a study conducted by Jamuna Rani,<sup>2</sup> it has been stated that there is interest among the undergraduate medical students to participate in research. However, not many of them were actively involved in research. According to the present study, though undergraduates are involved in research, very few had participated and had taken efforts to publish it.

Postgraduates and faculty members frequently read journal as they are regularly involved in journal club discussions. Habit of reading journal and taking part in research at the undergraduate level help the students so that they will have an idea about how to carry out further research during higher education.

Kumar et al<sup>3</sup> reported that dentist should have knowledge on statistics. This study also supports the same. Jamuna Rani et al,<sup>2</sup> cited various reasons for lack of participation of undergraduate medical students in research. A few of them included lack of knowledge, time and guidance. Alghamdi, et al<sup>11</sup> in a similar study among senior students reported a lack of training courses and lack of professional supervisors as the major barriers.

In this study lack of time for research due to clinical work was cited as an obstacle faced by most of the students. There should be separate time allotted for the

students to carry out research projects. Lack of financial incentives was a personal barrier in the present study. Students should be provided with fund to undertake research. Giri et al<sup>13</sup> reported that lack of financial incentives and inadequate support from the guide and supervisor was a major obstacle

Lack of interest by the guide in publishing the journal was reported in this study. Before starting the study, protocol of the research study should be discussed with the faculty members. The guide in addition to periodic assessment of research work they should provide necessary information and guidance to the students.

Saniya et al<sup>1</sup> reported that lack of training in research was the major barrier among medical students.

Oliveira et al<sup>12</sup> reported that the most important barrier for not taking up research as lack of time, followed by lack of guidance by faculty.

In this study, lack of publication related knowledge can be overcome by training the students in research methodology. Awareness and knowledge regarding publication of journal should be educated to the students in the colleges.

Since there was very few studies have been reported among dental professionals, the comparison was made with medical population.

**Recommendations:** It is necessary to impart research related knowledge amongst undergraduate dental students in order to explore the lacunae in research. Encouragement and motivation should be given to the budding dentists for overall betterment of dental profession.

# “Chewing Technique” Using Gums toward Mucositis Prevalence on Chemotherapeutic Cancer Patients

Hernita Frisnawati Purba<sup>1</sup>, Laili Rahayuwati<sup>2</sup>, Titis Kurniawan<sup>3</sup>, Ikeu Nurhidayah<sup>4</sup>, Kusman Ibrahim<sup>5</sup>

<sup>1</sup>RSUD Dr. M. Haulussy Ambon, Maluku, Ambon, <sup>2</sup>Department of Community Nursing, <sup>3</sup>Department of Medical Surgical Nursing, <sup>4</sup>Department of Pediatric Nursing, <sup>5</sup>Department of Medical Surgical Nursing, Faculty of Nursing, Universitas Padjadjaran, Bandung

## Abstract

Mucositis treatment is currently developed more focusing on treatment rather than prevention. Therefore, more therapy related studies with the concept of prevention is essential to be conducted. Chewing techniques using chewing gum become an optional treatment to prevent the occurrence of chemotherapy-related mucositis. This study aimed to determine the effect of chewing techniques using chewing gum to prevent the occurrence of mucositis in patients who received chemotherapy at Hasan Sadikin Hospital Bandung. This quasi experimental study employs the pre-posttest without control design. There were 30 cancer patients from a population of 75 patients who received chemotherapy recruited through consecutive sampling. The incidence of mucositis was measured using the Oral Assessment Guide (OAG) before treatment (day 1) and after treatment (day 6). The results of the study revealed that median pre-test mucositis score was constant (8-8) but the maximum post-test score of mucositis score increased (10). There was no significant difference in pre-posttest mucositis score indicating that the mucositis incident after treatment did not differ significantly compared to before treatment. Chewing activity by using chewing gum stimulates the parasympathetic nerves resulting in dilation of blood vessels in the salivary glands that drain saliva. The mucosal protective process will increase and can prevent the decline of oral mucosal conditions. Simultaneously chewing gum technique has a tendency to prevent increased oral mucositis score among patients who received chemotherapy at Hasan Sadikin Hospital Bandung. The hospital may consider chewing gum techniques in the nursing care for patients who received chemotherapy to prevent increased mucositis score and to improve quality of life.

**Keywords:** *Chemotherapy, mucositis, chewing gum technique.*

## Introduction

International Agency Research on Cancer (IARC) Globocan in 2012 states that there are 14.1 million new cancer cases and 32.6 million cancer patients (within 5 years of diagnosis) worldwide, 48% of which (15.6 millions) occurs in developing countries. The result of the Basic Health Survey from the Ministry of Health (2015) show the prevalence number of tumor/cancer illness in Indonesia, which is 4.3 per 1000 people. Lung,

liver, stomach, colorectal, and breast cancer are the biggest causes of death each year.<sup>1-2</sup> Moreover, cancer has brought about a number of negative impacts on physique, psychology, social relationship, spirituality, and finance. A study to cancer patients show some physical handicaps suffered by patients, including pain, exhaustion, nausea, asthma, insomnia, decreasing appetite, and increasing heart rate.<sup>3</sup>

Four primary method for cancer therapy are surgery, chemotherapy, radiation, and biotherapy.<sup>4</sup> In Indonesia, most cancer patients are tardy for diagnosis and treatment; therefore, patients who consulted the healthcare service are already on the last stadium stage. It leads them to dealing with fewer choices in treatment with chemotherapy as the last resort. It is designed to destroy cancer cells, but its practice can also destroy the

---

Department of Community Nursing, Faculty of Nursing, Universitas Padjadjaran, Bandung  
e-mail: laili.rahayuwati@unpad.ac.id

healthy ones. Of many side effects of chemotherapy, one in particular is mucositis. Approximately 61% of all cancer patients undergoing chemotherapy have suffered mucositis. Oral mucositis can be extremely painful, destroying an abundant network of cells. It can also give impact to the patient’s life quality, increase infection risk, cause delay/interruption or even failure of the entire treatment, and be in dire need hospitalization as well as budget gridlock. Some actions toward mucositis treatment include oral cryotherapy, low laser level therapy (LLL), utilization of honey topical agent, Chlorhexidine, Nistatine, and Triamcinolone acetonid. From these interventions, it is believed that it can cure mucositis, despite the inaccuracy of the chemical compounds, the augmentation of budget, and the difficulty applying it onto healthcare service providers. Currently, there is no concensus regarding proper treatment in oral care to prevent mucositis due to chemotherapy.<sup>5</sup>

Until recently, no consent has been done regarding the proper treatment in oral care to prevent mucositis due to chemotherapy. Although several implementations with therapy intervention are being developed, no effective action has come to fruition regarding oral care treatment to prevent mucositis due to chemotherapy. In the research, the main idea of mucositis prevention is the process of chewing rather than the content of the gum. There for utilization of gums in this research is anticipated to optimize the process.

**Method**

This research applies the *quasi-experiment pretest and posttest without control* design. The researcher implements intervention only on a group which is the intervention group without counterparts. The impact of behavior is assessed by comparing the posttest and pre-test values.

The oral care protocol was done to 30 respondents to chew gum. Data sampling was done twice including the first day before the experiment and the following sixth day. Analysis on the respondent’s oral condition applied Oral Assessment Guide (OAG) tools.

During pre-chemo, the respondents were asked to chew 2 gums for 5 minutes before disposing them, followed by another chewing during chemo for 10 minutes. Later, they were asked to keep chewing gums 3 times a day for 10 minutes and a total of 5 days after each chemotherapy. The oral care protocol was done 10 minutes after breakfast, lunch, and dinner. Six days after chemotherapy, an analysis was done using Oral Assessment Guide tools adopted from Eilerset.al., (1998).<sup>6</sup>

**Result**

The research was conducted for 2 weeks from 19 to 27 June 2017 at Asnawati Ward in Hasan Sadikin Hospital Bandung, followed by respondent’s individual homes because they were non-admitted patients. On the 6<sup>th</sup> day, the researcher met the respondents to assess the scores for posttest mucositis.

**Table 1. Respondent’s Characteristics**

Characteristics	Respondents	F (n=30)	Percentage
Age (Mean±SD 45.40 ± 6.63)	< 40 years	7	23.3
	≥ 41 years	23	76.7
Gender	Male	3	10
	Female	27	90
Education	Elementary	14	46.7
	Junior High	9	30.0
	Senior High	7	23.3
Chemotherapy Cycle	< 3rd chemo	16	53.3
	≥ 3 <sup>rd</sup> chemo	4	46.7
Cancer Types	IDCM	27	90.0
	Ca Colon	2	6.6
	Ca. Lung	1	3.3
Types of Chemotherapy Agents	Fluorouracil, Cyclophosphamid	22	73.3
	Paclitaxel, Carboplatin	6	20.0
	Xeloda, Oxaloplastin	1	3.3
	Docetaxel Carboplatin Doxorubicin	1	3.3

Table 1 shows the age of most respondents  $\geq 41$  (76.7%) with a mean of 45.40 whose majority is female (90%) and elementary schooler (46.7%), with the most chemotherapy cycle is on  $< 3$  (53.3%), the type of cancer is IDCAM (*Intra Ductal Carcinoma Mammae*) (90%) and the most chemotherapy agent applied are Fluorouracil, Doxorubicin, and Cyclophosphamid (73.3%).

The analysis result of mucositis frequency before and after the intervention of chewing gums can be seen on table 2.

**Table 2. Frequency of Mucositis Pre-post test**

Respondent's Category	Pretest		Posttest	
	f	%	f	%
Mucositis	0	0	3	10
Not Mucositis	30	100	27	90

Table 2 shows that during pretest all respondents do not experience mucositis where each parameter with the score of 1 is normal. The normal state indicates normal voice, normal chewing ability, soft pink and damp lips, complete and pink gingiva, as well as strong and clean teeth. On the other hand, the post-test shows that 3 respondents undergo increase the mucositis scores during research.

**Table 3. Analysis Result of Wilcoxon Test for Pre-Posttest Mucositis Scores**

OAG Score	Median (Min-Max)	p-value
Pretest	8 (8-8)	0.102
Posttest	8 (8-10)	

Table 3 shows the median result (min-max) of mucositis pretest score of 8 (8-8), meaning that the value of the respondent's pre-test mucositis score is on the normal range. It indicates that all respondents have normal oral mucosa condition. Meanwhile, the median (min-max) of mucositis posttest score of 8 (8-10) increases on 3 respondents. The analysis result of Wilcoxon test of mucositis pre-posttest score with p-value 0.102 ( $>0.05$ ). There is indicates that no significant average difference of mucositis score before and after the intervention of chewing gums. In a nutshell, it does not improve mucositis score for patients undergoing chemotherapy.

Table 4 shows that the variable which influences mucositis result and is strongly interrelated is that of age with p value 0.00 and correlation value 0.735. It shows that age has positive correlation direction with strong correlation with mucositis score.

**Table 4. Respondent's Characteristics that Influence Mucositis Result**

Category	Median (minimum-maximum)	P value
Age	r = 0,735c	0,00c
Gender	2 (1-2)	0.550a
Education	2 (1-3)	0.502b
Chemotherapy Cycle	2 (1-6)	0.392b
Cancer Type	1 (1-4)	0.949b
Type of Chemotherapy Agent	1 (1-4)	0.760b

<sup>a</sup>Mann-Whitney Test, <sup>b</sup>Kruskal-Wallis Test<sup>b</sup>, <sup>c</sup>Spearman Correlation Test<sup>c</sup>

Meanwhile the variables of gender (p value 0.550), education (p value 0.502), chemotherapy cycle (p value 0.392), cancer type (p value 0.949) and the type of chemotherapy agent (p value 0.760) do not have significant interrelation.

### Discussion

The act of chewing gum has an impact on mucositis prevalence. This can be proven by no significant changes in pretest-posttest mucositis score with p-value 0.102 ( $>0.05$ ). It means that there is no decline in the respondent's oral mucosa condition.

Before chemotherapy, the oral condition of all respondents is normal. Until the 5<sup>th</sup> day of chemotherapy, all respondents chewed gums. Twenty-seven respondents show no increase on mucositis score up to the 6<sup>th</sup> day of post-chemotherapy. This is due to the fact that the chewing activity using gums is a set of mechanical movements that stimulate parasympathetic nerves. Then, it is followed by dilatation in blood vessels to saliva glands, serving as a canalizer.

Saliva is an important factor in preserving the health of teeth and mouth taking the role a protector. It helps as a lubricant covering mucosa and protects oral cavity against mechanical, thermal and chemical irritations. It claims similarly regarding one group pretest-posttest design. She advocates that gums are advantageous to stimulate saliva secretion and increase plaque pH and saliva, hence the best to clean oral cavity. Chewing gums for at least 10 minutes regularly can stimulate the increase of saliva secretion. It also shows similar view, stating that the stimulated saliva secretion may induce its promptness, resulting in a bigger saliva volume. All of this may influence the concentration of saliva

component. Added volume and more watery saliva will reduce the chance of microorganism to colonize the cavity.<sup>6</sup>

Moreover, it will cause the increase of organic and inorganic saliva substances. The components included are immunoglobulin A (IgA), mucin, lysozyme, lactoferrin, and lactoperoxidase, all repressing bacteria growth. On the other hand, the inorganic saliva included are bicarbonate and thiocyanate; while the former protects through repressing the fluctuation of pH saliva's degree of similarity, the latter operates in the lactoperoxidase system by oxidizing bacterial enzymes to cell membranes that may hamper acid production and *streptococcus* growth. This is also similar to what researcher statement that chewing gum may reduce the bacteria population in saliva significantly.<sup>7-8</sup>

Saliva is a complex and colorless oral liquid, secreted from major and minor saliva glands to maintain homeostasis inside the oral cavity<sup>8</sup>. For healthy adults, saliva is produced about 1.5 liters in 24 hours. Its secretion is controlled by innervation system, mainly by cholinergic receptors. The main trigger to increase the saliva secretion is through mechanical trigger.<sup>6</sup>

Saliva has several important functions in the oral cavity, including lubricant, cleaning action, dissolution, chewing and digestion, speaking process, buffer system and, most importantly dental caries repression. Saliva and its glands are crucial parts of the mucosa immune system. The plasma cells inside produce antibody, particularly from Immunoglobulin A (Ig A) to saliva. Besides, there are several types of antimicrobial enzymes which contain lysozyme, lactoferrin, and peroxidase.<sup>9</sup>

Saliva also is a result of a myriad glands located under the oral mucosa. Every day, the human's saliva gland produces almost 600 ml serous saliva and mucin that contains minerals, electrolytes, buffers, enzymes and their inhibitors, growth factor, cytokine, secretory immunoglobulin A (sIgA), and glycoprotein. Proteins in saliva include lactoferrin, lysozyme, peroxidase, defensins and histatin, which may hamper or block microorganism growth in the mouth; e.g., histatine has the characteristics of fungicides.<sup>4-9</sup>

With the increase of saliva production, the process of mucosa protection will accumulate; therefore, it may prevent the decrease of oral mucosa condition. That being said, there is an intervention influence of chewing gum shown by Wilcoxon analysis test displaying that

the intervention may prevent the increase of mucositis score through a mechanical process. This process will trigger the saliva glands. Saliva itself is crucial due to its strong bond with a biological process occurring inside the mouth. Generally, saliva plays a role as a protector of the oral surface, water adjustment, virus issuance, and the product of organic metabolism itself and microorganism, food digestion and tasting as well as differentiation and skin cells growth, epithelium, and nerves.

The respondents with increasing mucositis score are 40, 38, and 35 years old respectively. No significant increase on mucositis score occurs because the age category between children and the elderly is not included in this research. According to researchers, both children and the elderly retain a higher risk of suffering from mucositis compared to other ranges of age. It is due to epithelial cells and mucosa membranes more sensitive to suffer from toxicity. Moreover, the elderly is more known to experience a decline of new cells growth and is related to the function of the liver and kidney<sup>9-10</sup> also supports this view, claiming that young respondents have larger impact in lowering mucositis degree. This is because their bodies have better capability of repairing cells or damaged network than those of the elderly. According Hondst, et.al, the patients above 50 years old have higher risks due to the DNA's low-level capability of repairing itself. Although several researches claim that young age and the elderly are prone to suffer mucositis, they do not share similar views because the respondent's age in this research does not involve children and the elderly.<sup>7-11-12</sup>

According to the chemotherapy cycles, the respondents with increasing mucositis score are undergoing the 1<sup>st</sup> and 3<sup>rd</sup> chemotherapy cycles. This is not entirely supported by the research result by Hendrawati, et.al showing the number of the most oral mucositis cases which occur in patients undergoing chemotherapy the 4<sup>th</sup> cycle (86%) and 1<sup>st</sup> cycle (52%) compared to other cycles. This is due to the number of respondents which is higher in the < 3<sup>rd</sup> cycle.<sup>13</sup>

In this research, the most common type of cancer is IDCM (*Intra Ductal Carcinoma Mamae*) which is 90%. It shows that it is quite common for patients undergoing chemotherapy. The respondents with increasing mucositis score have the IDCM cancer type. As a literature, recollects mucositis mostly occurs in patients with blood cancer undergoing chemotherapy due to

leukemia, knowing that it causes myelosuppression. Patients neutropenia are prone to bacterial infections like mucositis<sup>13</sup>. The increase of mucositis score occurs on respondents with IDCM cancer similarly with most patients in this research. In fact, there are no respondents with the hematologic malignancy or lessercancer types.

The act of chewing gum not only helps increase mucositis score to patients undergoing chemotherapy, but also makes them face difficulty in fulfilling nutrition as well as prevents from much severer mucositis impacts due to chemotherapy. The implication of this research for nursery is that the act of chewing gum may be considered as one of the analysis material in the field of nursing to give intervention to patients undergoing chemotherapy.

### Conclusion

This research concludes that the analysis of *Wilcoxon* test of pre-posttest mucositis score with p-value 0.102 (>0.05) indicates no significant average difference of mucositis score before and after the intervention of chewing gum. It means the intervention of chewing technique using gum does not increase the mucositis score for patients undergoing chemotherapy. The value of pre-test mucositis score of all respondents are within the normal range. However, there are some respondents with increasing posttest mucositis score. The parameter increases in posttest mucositis score occurs in the 4 parameters which are tongue, gingiva, chewing process, and lips.

**Conflict of Interest Statement:** The authors of this research declare that there is no conflict of interest related to this study.

**Source of Funding:** All funds used to support this research comes from the researchers themselves, and Faculty of Nursing Universitas Padjadjaran.

**Ethical Clearance:** Ethical Clearance was obtained from the Committee of Ethics of Universitas Padjadjaran, Bandung with number “531/UN6.C10/PN/2017”.

<sup>4</sup>Associate Professor, Physiology, Army College of Medical Sciences, New Delhi

## Abstract

Pollutants are important determinants of respiratory morbidity. This study endeavours to explore the role of vegetation in air quality improvement. The 24 hour average of prevailed ambient levels of air pollutants, (PM<sub>2.5</sub>), (NO<sub>2</sub>) and (NO) at four sites of Delhi were recorded. The abundance, frequency and density of vegetation was assessed using belt transect method. Software i- Tree Canopy was used to assess the amount of pollution removal and carbon sequestration potential by vegetation. Results indicate that Pusa had highest abundance (6.7), frequency (86%) and density (6.2) of vegetation as compared to Dwarka, Rohini and ITO sites. ITO had minimum abundance (2.0), frequency (50%) and density (1.9) of vegetation. The correlation between the abundance, frequency and density of vegetation and ambient levels of air pollutants was negative. The i-tree software indicates that the potential of vegetation in removing the load of air pollutants was significant. The quantity NO<sub>2</sub> and PM<sub>2.5</sub> removed by vegetation of Pusa, Dwarka, Rohini and ITO sites were 331.2g and 128.5g; 117.7g and 46.4g; 67.6g and 26.6g and 37.6g and 15g respectively. The carbon sequestration potential was maximum (520Kg in year) and minimum (60.2Kg in year) at Pusa and ITO respectively. Regression equations were accordingly computed, which could predict the potential pollution removal with vegetation. Objective evidence based estimation of potential reduction of pollutants with planting trees, has important implications on public health.

**Keywords:** Air quality, Vegetation, Pollution removal, Carbon sequestration, Belt transect, Respiratory morbidity.

## Introduction

New Delhi faces disrepute owing to high pollution levels. Air pollution has emerged as a major challenge, particularly in urban areas. The problem becomes more complex due to multiplicity and complexity of

air polluting source mix (e.g., industries, automobiles, generator sets, domestic fuel burning/ waste incineration, road side dust, construction activities, lack of energy efficiency systems etc.). Being a major centre of commerce, industry and education, Delhi has experienced a phenomenal growth in recent years. The burgeoning population coupled with rapid growth in terms of vehicles, construction, and upsurge in coal consumption by power plants has resulted insidious environmental concerns in Delhi.

Air pollution continues to remain a major public health concern despite various actions taken over two decades: relocation of polluting industries, introduction of improved emission norms for vehicles, phasing out lead from gasoline, reduction of sulphur in diesel and benzene in gasoline, city public transport fleet on CNG,LPG, banning of 15-year old commercial vehicles,

restriction on transit freight traffic, prohibiting open incineration/combustion, introduction of metro rail, etc. Increasing pollution levels cause diseases such as asthma, bronchitis, cough, lung cancer etc.

There is a need to take stock of the levels of air pollutants at various locations in the city, as different pollutants might have different determinants and thus varying remedial measures. Plants are well known to remove various pollutants in the environment. Delhi has a relatively rich plant and forest cover which facilitates pollution control. But the vegetation cover varies from location to location. It is therefore important to assess the vegetation cover and to correlate it with pollutant levels. Pollution removal is a function of the quantity (abundance, frequency and density) and quality (shrubs/trees) of vegetation at a particular place.

The pollution level and vegetation cover at different sites in Delhi was measured and further, the removal of pollutants by vegetation was estimated. Regression equations worked out, predict the potential pollution removal with vegetation.

**Materials and Method**

This analytical study was undertaken at New Delhi, (area 1484 sq km). Pollution levels and vegetation was estimated during January to March 2018, at four selected sites catering to North, East, Central and South-West directions, located far away from each other:

1. Dwarka (DAV School) - South West Delhi (28.59° N, 77.06°E)
2. ITO crossing - East Delhi (28.63° N, 77.25° E)
3. DTEA Senior Secondary School, Pusa Road - Central Delhi(28.64°N, 77.17°E)
4. Rohini (Delhi Technical University) - North West Delhi(28.75° N, 77.11° E)

Data of PM<sub>2.5</sub>, NO<sub>2</sub> and NO levels, on daily basis was downloaded from Central Pollution Control Board (CPCB) nearby monitoring sites displayed on website for the entire study period. <sup>1</sup>

**Estimating Vegetation:** Belt transect methodology was used to monitor and quantify vegetation as proposed by Bhaskar, *et.al.* (2015).Belt transects were marked between two points of 500 m area. The length of the belt transect was taken as 500 m at each selected site, where 30 quadrats were laid down, each of size 0.5m x 0.5m.<sup>2</sup>

The vegetation in each quadrat was identified, counted and tabulated. The abundance, frequency, density of vegetation was quantified using standard definitions<sup>3</sup>:

**Abundance** = Total no of individuals/No of quadrats of occurrence

**Frequency (%)** = No of quadrats in which species occurred x 100/Total no of quadrats studied

**Density** = Total no of individuals/Total no of quadrats studied

**Estimating Pollution Removal:** The ‘i-tree canopy’ software was used to study pollution removal levels. It reviews Google Maps aerial photography at random points and conducts a vegetation cover assessment within a defined project area. The selected study site was entered in i-tree canopy- location linked to google map. The area of the selected sites (assessed for vegetation) was marked using polygon feature of the programme. Relevant ‘type’ of vegetation i.e., trees and grasses were entered. The software estimated the amount of various pollutants removed by vegetation in that area on annual basis. It also determined the amount of CO<sub>2</sub> sequestered in trees/plants.<sup>4</sup>

**Equipment Used for Monitoring Vegetation:** Quadrat of 0.5 x 0.5 m, Measuring tape of 30 m, Nails, Thread, Camera, Laptop

**Analysis:** Microsoft Excel was used for correlation and regression between abundance, density and frequency of plants with pollutant levels and their removal.

**Findings:**

**Pollutant Concentration:**

Average Pollutant concentration for PM<sub>2.5</sub>, NO<sub>2</sub> and NO was ascertained, Table 1.

**Table 1: Average pollutant concentration (January-March 2018)**

Site	Level of pollutant		
	PM <sub>2.5</sub> (µg/m <sup>3</sup> )	NO <sub>2</sub> (µg/m <sup>3</sup> )	NO (µg/m <sup>3</sup> )
Pusa	91.5	24.6	29.1
Dwarka	157.4	40.0	27.1
Rohini	205.5	26.9	41.2
ITO	146.2	73.5	129.6
Standard	60.0	80.0	80.0

**Abundance, Density and Frequency of Vegetation:** Quadrat analysis was carried out to determine the abundance, density and frequency of vegetation at the four selected sites (Table 2). Vegetation was highest in Pusa and lowest in ITO. A total of 11

species were recorded at the four sites. Three plant species were common at each sites namely *Euphorbia hirta*, *Cynodon sp.* and *Amaranthus sp.* (Figure 1). Tree species, typically *Polyalthia longifolia* was also occasionally prevalent.

**Figure 1: Common plants at three sites: Euphorbia hirta (top left), Cynodon sp (top right), Amaranthus sp (bottom) (Source : Google Images)**

**Table 2: Abundance, density and frequency of three common plants**

S.No.	Site	Species	Abundance	Frequency	Density
1.	Pusa	Euphorbia	2.46	86	2.13
		Cynodon	14.9	96	14.4
		Amatanthus	2.95	77	2.26
		Mean	6.77	86	6.15
		Tree sp	1	70	0.7
2.	Rohini	Euphorbia	1.85	90	1.66
		Cynodon	6.1	93	5.7
		Amaranthus	2.13	76	1.63
		Mean	3.36	86	1.65
		Tree sp	1	50	0.5
3.	Dwarka	Euphorbia	2.15	86	1.86
		Cyndon	12	90	10.76
		Amaranthus	2.56	83	2.13
		Mean	5.57	86	4.9
		Tree sp	1	56.6	5.66
4.	ITO	Euphorbia	1.92	46	0.9
		Cynodon.	2.41	40	0.97
		Amaranthus	1.78	63	1.13
		Mean	2.03	50	1.97
		Tree sp	1	16.6	1.66

**Correlation of Pollutants Versus Abundance, Density and Frequency of Plants:** An inverse correlation was seen between frequency of various plant species (*Euphorbia*, *Cynodon*, *Amaranthus*) and levels of NO and NO<sub>2</sub>. (statistically significant for *Euphorbia* and *Cynodon* with NO<sub>2</sub> and NO) and *Amaranthus* with NO (Table 3).

**Table 3: Correlation of frequency, abundance and density of three plant species with pollutants**

Pollutant	Correlation coefficient (r) with		
	Frequency Euphorbia	Frequency Cynodon	Frequency Amaranthus
PM <sub>2.5</sub>	0.13	0.003	0.037
NO <sub>2</sub>	-0.96*	-0.96*	-0.78
NO	-0.98*	-0.99*	-0.95*
Pollutant	Correlation coefficient (r) with		
	Abundance Euphorbia	Abundance Cynodon	Abundance Amaranthus
PM <sub>2.5</sub>	-0.87	-0.57	-0.61
NO <sub>2</sub>	-0.44	-0.71	-0.74
NO	-0.51	-0.83	-0.81
Pollutant	Correlation coefficient (r) with		
	Density Euphorbia	Density Cynodon	Density Amaranthus
PM <sub>2.5</sub>	-0.31	-0.55	-0.43
NO <sub>2</sub>	-0.91	-0.76	-0.78
NO	-0.96*	-0.85	-0.91

\*P<0.05

An inverse statistically significant correlation was also seen between abundance of two plant species (*Amaranthus and Cynodon*) and levels of NO. Abundance of *Amaranthus* also exhibited a statistically significant inverse correlation with NO level.

As abundance, frequency and density of plants increase, the pollutant levels decrease. ITO is one of the most polluted areas in Delhi. Pollution is caused by

high vehicular density; Pusa on the other hand has green areas, and less vehicular pollution resulting in lower levels of PM<sub>2.5</sub>, NO<sub>2</sub> and NO.

**Pollutant Removal Versus Abundance, Density and Frequency of Plants:** Annual pollution removal at these four sites was estimated using software i- Tree Canopy. Similar analysis was repeated for other sites and results are summarized in Table 4.

**Table 4: Annual removal of pollutants by plants**

Pollutants	Removal of pollutants annually			
	Pusa	Dwarka	Rohini	ITO
CO (g)	58.8	21.2	12.1	6.8
NO <sub>2</sub> (g)	331.2	117.7	67.6	37.6
O <sub>3</sub> (g)	2514	910.5	521	4661.3
PM <sub>2.5</sub> (g)	128.5	46.4	26.6	15
SO <sub>2</sub> (g)	160	58	33.1	18.4
PM 10 (g)	44.7	258	148.2	82.6
CO <sub>2</sub> Sequestered (kg)	520.0	188.2	108.0	60.2

**Table 5: Correlation of frequency, abundance and density of three plant species with removal of pollutants**

Removal of Pollutant	Correlation coefficient (r) with		
	Frequency Euphorbia	Frequency Cynodon	Frequency Amaranthus
PM <sub>2.5</sub>	0.45	0.55	0.44
NO <sub>2</sub>	0.40	0.53	0.31
CO	0.44	0.54	0.44
SO <sub>2</sub>	0.45	0.55	0.44
O <sub>3</sub>	0.91	0.85	0.86
CO <sub>2</sub> (seq)	0.44	0.54	0.44
	Abundance Euphorbia	Abundance Cynodon	Abundance Amaranthus
PM <sub>2.5</sub>	0.95*	0.75	0.91
NO <sub>2</sub>	0.96*	0.76	0.91
CO	0.94*	0.74	0.92
SO <sub>2</sub>	0.95*	0.75	0.90
O <sub>3</sub>	0	0.1	0.38
CO <sub>2</sub> (seq)	0.91*	0.73	0.91
	Density Euphorbia	Density Cynodon	Density Amaranthus
PM <sub>2.5</sub>	0.77	0.78	0.87
NO <sub>2</sub>	0.77	0.87	0.87
CO	0.78	0.86	0.78
SO <sub>2</sub>	0.76	0.86	0.86
O <sub>3</sub>	0.66	0.45	0.56
CO <sub>2</sub> (seq)	0.78	0.87	0.87

(\*P&lt;0.05)

It was observed that, in most cases plant parameters were well correlated with removal of pollutants, esp. abundance ( $r=0.73$  to  $0.96$ ) and density ( $r=0.76$  to  $0.87$ ). However, statistically significant correlations were observed for abundance of plants with pollutant removal. It was particularly true for abundance of Euphorbia ( $r=0.91$  to  $0.96$  for most pollutants i.e., PM<sub>2.5</sub>, NO<sub>2</sub>, CO and CO<sub>2</sub> sequestered, with  $p<0.05$  for all of these). (Table 5)

Since the correlations for abundance of Euphorbia with pollutant removal were observed to be very high and statistically significant, regression equations were estimated.

Abundance *Euphorbia* vs NO<sub>2</sub> removal:  $y = 459.32x - 823.75$ ,  $R^2 = 0.9071$

Abundance *Euphorbia* vs PM<sub>2.5</sub> removal:  $y = 177.67x - 318.09$ ,  $R^2 = 0.9089$

Abundance *Euphorbia* vs CO removal:  $y = 81.417x - 145.84$ ,  $R^2 = 0.9092$

Abundance *Euphorbia* vs SO<sub>2</sub> removal:  $y = 221.5x - 396.66$ ,  $R^2 = 0.9095$

Abundance *Euphorbia* vs CO<sub>2</sub> sequestered:  $y = 719.05x - 1287.3$ ,  $R^2 = 0.9088$

## Discussion

PM<sub>2.5</sub>, NO<sub>2</sub> and NO are dangerous pollutants which adversely affect human health and environment. They inflame lung epithelium; reduce immunity causing/aggravating short and long-term conditions like wheezing, coughs, asthma, colds, influenza and bronchitis. Pollutants also increase the mortality from bronchial asthma, chronic bronchitis, lung cancer and heart disease.

Reducing pollution will thus have a huge positive effect on health. Pollution removal is directly proportional to higher vegetation in an area. As PM<sub>2.5</sub> and NO<sub>2</sub> levels increase the PM<sub>2.5</sub> and NO<sub>2</sub> removal decreases and vice versa. Increased frequency abundance and density of plants reduces pollutants. Areas with higher vegetation

and lower pollution levels will have higher pollution removal, in-turn lowering mortality rate and morbidity.

Results of carbon sequestration were found to be in tune with the effect of pollution removal seen in proportion to plants. Carbon sequestration describes long-term storage of carbon dioxide or other forms of carbon to either mitigate or defer global warming and avoid dangerous climate change. Trees play major role in carbon sequestration.

Regression equations were computed for abundance of *Euphorbia* (independent variable) and pollution removal (dependent variable). Equations indicated the resultant change in pollutant removal with each unit change in abundance of plants, eg. taking  $x = 2$  in all equations i.e. doubling abundance of *Euphorbia*, we find that removal of  $\text{NO}_2$ ,  $\text{PM}_{2.5}$ ,  $\text{CO}$ ,  $\text{SO}_2$  and  $\text{CO}_2$  (sequestered) will increase by 94.9g, 37.25g, 17g, 46.34g and 150.8 kg respectively.

### Conclusion

India takes a step with National Clean Air Programme to focus on real time monitoring stations, research and pollution control.<sup>5</sup> Countries like Norway have made the transition from coal to renewable energy. Milan, Italy plans to plant three million trees by 2030 which will absorb 5 million tonnes of carbon dioxide a year and remove  $\text{PM}_{2.5}$  by 3000 tonnes over decade, helping reduce temperatures by  $2^\circ\text{C}$ .<sup>6</sup>

The Indian policy makers need to realise that the more they wait, the more they will lose on environment,

public health and economy. We need to plant more and more trees, for a cleaner change and a better community health.<sup>7</sup>

# A Trailer of Health Care Spending in Indian Scenario

S. Chandrachud<sup>1</sup>, S. Sudha<sup>2</sup>, Telu Suvarna<sup>2</sup>, S. Saravanan<sup>2</sup>, E. Siva<sup>3</sup>

<sup>1</sup>Professor, <sup>2</sup>Assistant Professor, <sup>3</sup>Researcher, Department of Economics, VISTAS, Chennai, India

## Abstract

**Background:** Health care spending is an important public health issue, liable for public health expenditure of the country which influences life expectancy of the citizen. The roots of health care spending are complex and sensitive but inevitable. The average life span of an Indian is ranging to 59.3 years which is comparatively less with other developing countries of Asia.

**Objectives:** The objective of the current study is to estimate the value of per capita health of India and to access the factors associated with the Health care spending of an average Indian.

**Method:** A cross sectional study conducted from January 2019 to June 2019 among the components of health care services in and around Chennai city. House-to-house interview was conducted using pre-designed and pre-tested questionnaire with likert scale on health care spending. The sample size is 160 families. Data are analyzed with proportions, linear regression model, dispersion and other diagrammatic representation – histograms and pie diagrams are used.

**Result:** The overall spending on health care issue is less than 2 percent of the total family income. People are not interested in spending money to maintain the health and are ignorant with health issues and also knowledge regarding medical insurance and other public health programs. The prevalence of such ignorance in non-communicative diseases is higher and medication with local pharmacist is a common phenomenon.

**Keywords:** HDI, per capita, health, WHO, health care, per capital expenditure.

## Introduction

Development is a process of migration from the given position to the better position. The Indian economic development is also moving towards the better position, in terms of Human Resource Index (HDI). India's HDI value for 2017 is 0.640 increased from 0.624 in 2016. The post liberalization era has witnessed an increase of nearly 50 percent in value of HDI, irrespective of millions of people in poverty which is a notable achievement in Indian history as the HDI value in 1990 is only 0.427.

According to United Nations Development Programme, India is ranked 130<sup>th</sup> position among 189

countries and positioned above the average of 0.638 for the region. Neighboring countries with similar demographic conditions like Bangladesh and Pakistan, have reached only 136<sup>th</sup> and 150<sup>th</sup> position respectively. However, India can achieve new heights, subject to the change in the health care spending which restrain the growth of Human Development Index. As on this date, the per capita expenditure on health is at a dismal \$63 which is lesser than Bhutan and Sri Lanka.

According to World Health Statistics Report 2018, India's per capita health expenditure is the lowest compared to other developing countries of Asia. China's per capital spending on health is \$ 426, Thailand \$217, Malaysia \$386, Philippines \$127, Sri Lanka \$118, Indonesia \$112 and Bhutan \$91, but Pakistan is spending only \$38. This indicates that investment on health care spending will improve the Human Development Index. In easy words, the country which has higher per capita expenditure on health, achieved higher Human Development Index.

## Methodology

The current study focuses on impact of Health Care Spending on Economic Development in terms of per capita health. For this purpose, a pilot study was conducted with 20 samples. Based on the pilot study, Pre-designed and Structured Questionnaire was prepared and sample survey was conducted during the period January 2018 to June 2018.

### Hypothesis:

$H_0$  : Health Care Spending influences the Human Development Index of the nation.

$H_1$  : Health Care Spending not influences the Human Development Index of the nation.

### Data Collection:

Sample Size	: 160 Families
Type of Data	: Primary data
Area of Sampling	: In and around Chennai City, Tamilnadu, India
Method of sampling	: Random Sampling
Initiation of study	: Pilot study on HCS
Statistical tools used	: Proportions, Chi-square test and pictorial representation
Source of data	: Both primary data and Secondary data

**Review of Literature:** There are many recent studies are conducted relating to Human Development Index and health care spending. Some of the studies supports the present discussion.

Simon Grimaetal<sup>1</sup>The average public spending in Mediterranean countries spends less on total healthcare expenditure than the European Union Average both in terms of GDP proportion and per capita spending on health. The overall health infrastructure is comparatively good but delivery of health service by physician is not significant.

George J Schieber, Jean-Pierre Poullier<sup>2</sup>. The united states spends more on healthcare spending in terms of GDP proportion compared to any other countries and Physician-Population Ratio is average for the OECD countries. In terms of inpatient medical care beds, physician visits, hospital days and average length of stay are lowest in OECD countries which are much higher in united states.

William D Savedoff<sup>3</sup> this study throws light on importance of per capita health spending and provides 5 different approaches to improve the public health care spending. When a country reaches five percent of its national income on health care spending, result in developmental activities of the nation improves in reaps and bounds which in turn significant values on economic indicators.

Irene Papanicolas, Liana R Woskie and Ashish K. Jha<sup>4</sup> some explanations for high spending, social spending and health care utilization in the United states did not differ substantially from other high-income nations, Prices of labour and goods, including pharmaceuticals and devices, and administrative costs appeared to be the main drivers of the differences in spending.

Jennifer Prah Ruger, Hak Ju Kim<sup>5</sup> the current article made an attempt to measure out-of-pocket health care spending their burden ratio, that is out-of-pocket spending burden ratio employing household equivalent income in Korea Republic. The lowest income people spent 12.5 percent of their total income out of pocket on medical expenditures, which was 6 times that of highest income group (2 percent). The factors influencing the healthcare spending are socioeconomic status, insurance type, healthcare facilities and socio demographic variables. Korean has highest out-of-pocket spending burden ratio.

**Pragmatic Approach:** The practical difficulty in choosing the econometric tool is to measure the per capita spending of health resulted in analyzing the health spending, started from income factor, not the individual but the family income. The Education level and proximity of health care components, like hospitals and medical clinics etc are also included while measuring the per capita spending on health. Different medical systems are available to the public which influences the medical spending of the medical customer i.e., the patients. The affordability of medical expenses is also the deciding factor of health care spending. The current study considered several approaches to express the per capita spending and finalized with the linear regression model to calculate the per capita spending on health.

**Simple Linear Regression Model:** Before running the multiple regression for health care spending with five variables, it is decided to express the influence each variable to the health care spending, for the purpose of

better understanding, simple linear regression model is applied with each variable to the health care spending

$$Y_1 = \beta_0 + \beta_1 X_1 \text{ - Family Income}$$

$$Y_2 = \beta_0 + \beta_1 X_2 \text{ - literacy level}$$

$$Y_3 = \beta_0 + \beta_1 X_3 \text{ - proximity of health care components}$$

$$Y_4 = \beta_0 + \beta_1 X_4 \text{ - alternative medical treatment}$$

$$Y_5 = \beta_0 + \beta_1 X_5 \text{ - affordability of medical expenses}$$

Out of five independent variables, family income and proximity of health care components influence more than the other three variables such as literacy level, alternative medicine and affordability of medical expenses.

**Multiple Regression Model:** In order to calculate the per capita spending on health, linear regression model is framed with the specific variables.

A multiple linear regression model with 5 predictor variables  $X_1, X_2, X_3, X_4$  and  $X_5$  and a response  $Y$ , can be written as

$$Y = \beta_0 + \beta_1 X_1 + \beta_1 X_2 + \beta_1 X_3 + \beta_0 + \beta_1 X_4 + \beta_1 X_5 + \mu$$

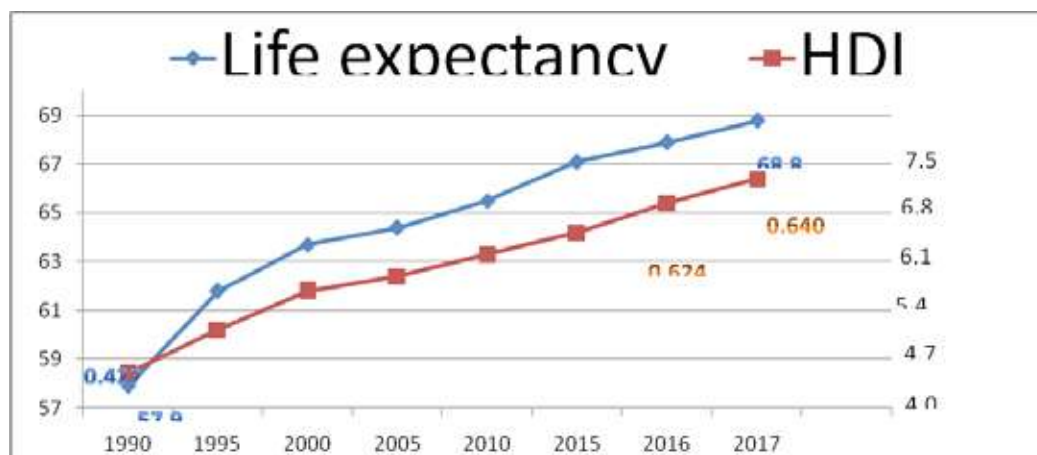

Where  $Y$  is cost of health spending,  $\beta_0$  autonomous spending on health,  $\beta_1$  the regression coefficient of Family income  $x_1$ ,  $\beta_2$  is the regression coefficient value of literacy level of the respondents  $x_2$ ,  $\beta_3$  is the regression coefficient value of proximity of health care components  $x_3$ ,  $\beta_4$  is the regression coefficient value of alternative medical treatment  $x_4$  and  $\beta_5$  is the regression

coefficient value of affordability of medical expenses  $x_5$ . The term  $\mu$  is the residual term.

Instead of simple linear, while conducting multiple regression model, negligence amount of spending attitude towards the health care spending. The family income coefficient  $\beta_1$  and proximity of health care components  $\beta_3$  have positive effect with health care spending and the other three variables such as literacy level, alternative medicine and affordability of medical expenses are having relative influence over the health care spending. On order to find the impact of Health Development Index (HDI), the life expectancy is compared with HDI under the discussion of current status of India in Global health ranking.

**India’s Position in Global Health ranking:**

During the post liberalization era of Indian economy i.e., from 1990, she has witnessed tremendous growth in both quantitative and qualitative economic indicators. During the period from 1990 to 2017, the Gross National income has increased nearly 266 percent and the Human Development index has increased nearly 50 percent, from 0.427 to 0.640 in the same period. These two economic indicators are the right elements understand that India march passing towards the successful path in lifting millions of Indians out of poverty. It is to be noted that within the year it has increased 0.16 points in HDI as it is 0.624 in 2016 and 0.640. The movement in the HDI has made positive changes in education, income and health. This steady growth of HDI improves the economic process in the economy mainly in the per capita spending on health. The following diagram (fig. 1) shows the comparative chart of life expectancy and HDI in India during 1990 -2017.

Source : timesofindia.com<sup>6</sup>

**Fig. 1: Comparison of HDI and Life expectancy**

**Health Care Spending–per capita health:** The result of this minor project pave way for the awareness of health related issues particularly in the developing countries like India. As for as the relation between health spending and the family income is concerned, there is an insignificant portion of family income spent for the health purpose. It is not even two percent of the total income. The current study surprisingly understood that literacy level on health care spending has negative correlation with the health care spending. This is mainly due to lethargically spending attitude of the middle income group of the nation. Easy going and sense of expediency influence the poor spending of health care issues. The vital factor for the poor healthcare spending is the non-availability of health care components in the local areas. In easy words, proximity of health care components shows a positive symptom for the health care spending which indicates that nearby health clinics and health care centers induces the public to spend on health related issues. In other words, transportation cost and boarding cost restricts the health consultations and treatments.

**Findings:** Based on the observation and the primary data collected, Health Care Spending influences the Human Development Index of the nation

### Discussion

Now-a-days the consultation fees of medical practitioners and cost of medicine are not affordable by majority of the public. This happens mainly due to business motive of health care centers and fees structure of private medical institutes. Medical profession becomes artificial hereditary nature as father or mother is doctor, then son or daughter of the respective couple are becoming doctor. Most of the doctors try to marry another doctor only for professional convenience. If this extends, there will be new caste called medical caste (MC) in near future.

### Conclusion

The government of India is devoted to improve the health in terms quality of the life for its entire people.

The success of India’s national development schemes like Beti Bachao Beti Padhao, Swachh Bharat, Make in India and initiatives aimed at universalizing the school education and health care, will be crucial in ensuring that the upward trend on human development accelerates and also achieve the Prime Minister’s vision of development for all the key principle of the Sustainable Development Goals – to leave no one behind.

## Abstract

**Objective:** There is a need to find the effect of balance training with pulmonary rehabilitation in subjects with COPD. The Purpose of this study is to find the effectiveness of balance training with pulmonary rehabilitation on improvement of balance, exercise tolerance, health related quality of life and risk of falls.

**Method:** A 20 moderate COPD subjects randomised into experimental group and control group. The experimental group with 10 subjects were treated with balance training along with pulmonary rehabilitation and control group with 10 subjects were treated with pulmonary rehabilitation for eight weeks. The outcome measurements such as Berg Balance Scale, Timed Up and Go Test, Activities Balance Confidence (ABC) scale, 6 minutes walk test and St George Respiratory Questionnaire was measured before and after 8 weeks of intervention in both the groups' subjects.

**Results:** There is a statistically significant difference ( $p < 0.05$ ) in means of balance measures, Six minutes walk test, and St. George respiratory questionnaire between the groups. There is no statistically significant difference in St. George respiratory questionnaire components- Symptoms, and Activity score between the groups.

**Conclusion:** The subjects with moderate COPD shown greater improvement in balance, exercise tolerance, health related quality of life and reduced risk of falls in pulmonary rehabilitation with balance training

**Keywords:** Moderate COPD, balance, Berg Balance Scale, Timed Up and Go Test, , Activity specific balance Scale, health related quality of life.

## Introduction

The GOLD defines that "Chronic Obstructive Pulmonary Disease (COPD) is a preventable and treatable disease with some significant extra pulmonary

effects that may contribute to the severity in individual patients. Its pulmonary component is characterized by airflow limitation that is not fully reversible.<sup>1-4</sup> In India according to chest clinics nearly 25-30 % of cases data are COPD.<sup>3</sup> COPD is ranking 3rd in 2020 in global burden of disease and it is one of the most important cause of death worldwide.<sup>5</sup>

COPD is recognized as a systemic disease associated with a broad array of physical and functional limitations<sup>6</sup>. The skeletal muscle performance deteriorate in COPD

by reduced muscle mass, fibre type profile, strength and endurance.<sup>7</sup> Studies have proven that patients with mild COPD shown a significant reduction in skeletal muscle endurance and strength compared with healthy and sedentary subjects.<sup>5</sup> Balance and mobility are the important elements of most of the activities of daily living. Studies have shown that due to hypoxia to peripheral muscles in COPD there is reduced muscle strength that impairs balance.<sup>7</sup>

Recent Studies have also shown that there is reduced static as well as dynamic balance in patients with COPD.<sup>8,9</sup> Studies have also shown that there is reduction in the functional balance and mobility in individuals with COPD relative to healthy controls in western population. This reduction may be due to systemic effects of COPD.<sup>7</sup>

The exercise component of pulmonary rehabilitation includes upper limb, lower limb, and respiratory muscle training but balance training is not considered in the standard guidelines of pulmonary rehabilitation.<sup>10</sup> From the literature it is evident that individuals with COPD has defects in balance control that is associated with an increased risk of falls.<sup>5</sup>

The aim of the study is to find the effectiveness of balance training with pulmonary rehabilitation on improvement of balance, exercise tolerance, health related quality of life and risk of falls in subjects with moderate COPD.

## Methodology

The approval for the study was obtained from the scientific and Research Ethical committee of RGUHS. Subjects included in the study were referred by Pulmonologist and the physician diagnosed with moderate COPD based on spirometry test FEV1/FVC < 0.70 and FEV1  $\geq$  80%, age group between 40-60 years<sup>5,6</sup>.

Subjects were excluded with pathological condition affecting muscle, joint and bone such as rheumatoid arthritis, cardiovascular conditions like ischemic heart disease. Subjects who met inclusion criteria was allotted into Experimental Group and control Group. The purpose of the study was explained to the subjects and the informed consent was obtained from the subjects.

**Intervention procedure for Experimental group:** In this group, subjects received balance training and pulmonary rehabilitation program.

**A. Conventional Pulmonary Rehabilitation:** Consists of 60 minutes rehabilitation program with adequate rest period for 3 days a week for 8 weeks and has 4 main components consistent<sup>10</sup> during both endurance and resistance training

**1. Supervised Endurance Exercise Training:** Subject received an individualized exercise training in the form of walking was given 3 times in a week and advised the subjects to do walking at home based on the Rate of perceived Exertion. A Borg score of 5–6 for dyspnoea or fatigue was set as a target. The progression in the walking endurance was made by increasing the distance based on RPE.

**2. Upper and Lower extremity Strength Training:**<sup>11,12</sup> Upper extremity strength training includes biceps, triceps and deltoids and lower extremity training includes quadriceps, hamstrings, hip flexors, hip extensors and hip abductors using free weights. The amount of resistance based on subject's ability to complete 10-15 repetitions. Progression includes increased resistance and number of sets. During both endurance and resistance training, subjects were asked to rate their dyspnea and leg fatigue using a visual analog scale (Borg 0-10) to monitor their exercise intensity and document to progress their intensity of exercises.

**B. Balance Training:** Training consists of 15-20 minute session 3 times per week for 8 weeks by using Circuit training include standing exercises, transition exercises, ambulatory exercises and functional exercises for balance.<sup>12-14</sup>

**Intervention procedure for Control group:** Subjects in this group received 60 minutes of conventional pulmonary rehabilitation program for 3 days a week for 8 weeks.

**Outcome Measurements:** The assessment of balance by using, Berg Balance Scale, Timed Up and Go Test, Single limb stance time, Activities Balance Confidence (ABC) scale, Assessment of risk of falls using Elderly falls screening test, Exercise tolerance capacity by using 6 minutes walk test and for health related quality of life using St George Respiratory Questionnaire was measured before and after 8 weeks of intervention.

## Statistical Method

Descriptive statistical analysis was carried out and presented as mean  $\pm$  SD. Significance was assessed at 5 % level of significance with p value was set at 0.05. To analyses the variables pre to post test within the groups, 'paired t test' and 'Wilcoxon signed rank test' were used. To compare the variables between the groups, Independent 't' test and Mann Whitney U test were used.

## Results

The study was conducted on total 20 subjects (Table-1) in experimental group there were 10 subjects with mean age 55.20 years and in each Group. Analysis with in Experimental and control group (Table-2) shows

that there is a statistically significant difference ( $p < 0.05$ ) in pre to post-intervention means of variables measured for balance, exercises tolerance, risk of falls and health related quality of life.

Comparative analysis of means of variables measured between the Experimental and control group shown that there is a statistically significant difference ( $p < 0.05$ ) in means of balance measurements, exercises tolerance, risk of falls and St. George respiratory questionnaire. There is no statistically significant difference in St. George respiratory questionnaire components- Symptoms, and Activity score between the groups. (Graph 1-4).

### Discussion

The present study has found that eight weeks of balance training with pulmonary rehabilitation given in experimental group and pulmonary rehabilitation without balance training given in control group shown there is a significant improvement of health related quality of life, balance, exercise tolerance and reduction in risk of falls in subjects with moderate COPD. When the improvements in Experimental group was compared with control group shown that there is a statistically significant difference in means of balance, health related quality of life, exercises tolerance and risk of falls.

The improvement in health related quality of life, balance and exercise tolerance in both the groups could be because of effect of pulmonary rehabilitation program. In our study both the group subjects received the same program of pulmonary rehabilitation. Exercises given in pulmonary rehabilitation induces changes in the biochemistry of muscle cells that increases the tolerance of higher levels of activity which is associated with improvement in exercise tolerance.<sup>15,16</sup> Stav et al (2009) in their study, Pulmonary rehabilitation found that there was increase in exercise endurance time which was assessed at six-month intervals up to three years.<sup>17</sup>

A study has been found that after individualized pulmonary rehabilitation program there was a significant

effect on improvement in dyspnea peak and the maximal heart rate in 6MWT, it was stated that this could be due to improved physical conditions response to exercise which decreased sensation of dyspnea<sup>29</sup> and by some physiological changes like better cardiac adaptation, decrease in lactic acid production and reduction in metabolic cost of exercise. The relationship between muscle weakness and postural instability is well established in older adults; it is likely that the small improvements in balance observed in this study were due to the strength training component of PR, albeit of low-intensity.

Comparative analysis of means of variables measured between the Experimental and control group shown that there is a statistically significant difference ( $p < 0.05$ ) in means of balance measurements and exercises tolerance measurements and St. George respiratory questionnaire components- impact and total score between the groups with large effect size. There is no statistically significant difference in St. George respiratory questionnaire components- Symptoms, and Activity score between the groups with small effect size. The greater percentage of improvement found in experimental than control group. This could be due to the effect of balance training along with pulmonary rehabilitation. In both the groups following pulmonary rehabilitation shown significant effect in reduction

of symptoms where as there is significant difference between the group, therefore the addition of balance with pulmonary rehabilitation may not have significant effect on improvement of symptoms.<sup>18</sup>

Studies have shown the effect of balance training with pulmonary rehabilitation on improvement of various balance related outcome measures. Decrease in the skeletal muscle performance is seen in COPD which is exhibited by reduced muscle mass, fibre type profile, strength and endurance,<sup>7</sup> a significant reduction in skeletal muscle endurance and strength is found in subjects with mild COPD compared with healthy and sedentary subjects<sup>5</sup> and the quadriceps fatigability is more in individuals suffering from COPD compared to healthy control subjects.<sup>19,20</sup>

This could be because of increased load and oxygen need of respiratory muscles in COPD and reduced venous return that competes with an impaired delivery of oxygen to the limb muscles.<sup>15,20</sup>

The study was conducted on small sample size. The eight weeks of balance training with pulmonary rehabilitation given in experimental group found there is a significant effect on improvement of health related quality of life, balance, falls and exercise tolerance in subjects with moderate COPD,

Further study can be studied to find the effect of balance training along with pulmonary rehabilitation on muscle strength and endurance that related to effect on muscle mass, aerobic capacity, pulmonary function test.

### Conclusion

The study concludes that pulmonary rehabilitation with or without balance training for subjects with moderate COPD found statistically and clinically significant effect on improving variables measured for balance, exercise tolerance, Health related quality of life and risk of falls. However adding balance training with pulmonary rehabilitation found greater percentage of improvement in balance, exercise tolerance, health related quality of life and reduced risk of falls in subjects with moderate COPD.

## Abstract

**Background:** The goal of CML therapy is to achieve complete hematological response first, then cytogenetic response and complete molecular response at the very end. Achieving a complete hematological response is the easiest and relatively inexpensive to detect. Several factors are thought to have an association with achieving hematological response. This study sought to determine the factors associated with achieving hematological response in CML patients

**Method:** We conducted an observational retrospective cohort study of CML patients at Wahidin Sudirohusodo Hospital and its network on 2018-2019 period. Diagnosis was done by positive BMP (Bone Marrow Punctie) results for CML, then a monthly blood check until a hematological response was achieved.

**Results:** There wer 39 research subjects, 19 male (48.7%) and 20 female (51.3%). No association found between age, gender and achievement of hematological response. Type of therapy was significantly correlated with the achievement of hematological response, with the highest number found in Nilotinib therapy compared to other group. (54,1%;  $p = 0.046$ ) Subjects who achieve hematological response had a lower percentage of blast cells. (6.1% vs. 7.9% ;  $p = 0.016$ )

**Conclusion:** The use of Nilotinib therapy was significantly associated with a succesful achievement of hematological response. A lower percentage of blast cells was found in CML patients who achieved hematological response.

**Keywords:** CML, factors, complete hematological response.

## Introduction

Chronic myelocytic leukemia (CML) is a chronic myeloproliferative disease caused by genetic defects obtained in pluripotent stem cells that are characterized by the presence of the philadelphia (Ph) chromosome with a main consequence as the fusion of ABL and BCR genes on chromosome 22.<sup>1,2</sup>

CML is 14% of all leukemias and 20% of leukemia in adults. The incidence per year is 1.6 cases per 100,000 adults with a slightly dominant male. Data on CML in Indonesia in 2018 obtained 2,374 patients, mostly in the area of Surabaya as many as 516 patients, at least in Banda Aceh as many as 40 patients, in Makassar obtained a total of 110 pasien.<sup>3</sup>

The goal of CML therapy is to achieve complete hematological response at first, then cytogenetic response and complete molecular response at the very end.<sup>4,5</sup> Achieving a complete hematological response is the easiest and relatively inexpensive to detect. Several factors are associated with the achievement of hematological response. Singh and colleagues

stated older age and female sex were related with a poor achievement of haematological, cytogenetic and prognostic responses.<sup>6</sup> Type of therapy also has an association with achieving hematological response. Breakthroughs in molecular targets of tyrosine kinase inhibitor (TKI) have brought changes in the history of disease and in therapeutic approaches to the treatment of CML patients. The high percentage of blast cells number is a poor prognostic factor and hematological response in CML disease. We sought to study various factors associated with achievement of hematological response in CML patients

## Method

This study was a retrospective cohort study by observational analysis of CML patients at Wahidin Sudirohusodo Hospital Makassar, on the period of 2018-2019. Inclusion criteria were CML patient, age  $\geq 18$  year. Exclusion criteria were (1) Other myeloproliferative diseases (2) Patients with acute infections. CML diagnosis was done by BMP (Bone Marrow Puncture) analysis showing CML pattern.

The types of therapy given to the subjects of this study were the hydroxy urea, imatinib and nilotinib. The percentage of blast cells obtained from BMP results at the beginning of the study. Monthly Complete Blood Count and differential count examination was done until a complete hematological response is achieved (Platelets

$\leq 450 \times 10^9 / L$ , Leukocytes  $\leq 10 \times 10^9 / L$ , and normal differential count) Statistical analysis was done using *Statistical Package for Social Science (SPSS) v.22 (IBM®)* with 95% confidence interval. Non parametric analyses was done using *fisher test* and *Mann Whittney U test* for comparison between groups.

## Results

Baseline characteristics of the 39 study subjects are displayed on Table 1. Female gender predominates over male gender (51,3% vs. 48.7% respectively). The mean age was  $40.2 \pm 13.3$  years.

**Table 1. Baseline Characteristics of The Study Subjects**

Variable		n	%
Gender	Male	19	48,7
	Female	20	51,3
Type of Therapy	Hydroxy Urea	14	35,9
	Imatinib	8	20,5
	Nilotinib	17	43,6
CML Phase	Chronic Phase	36	92,3
	Acceleration Phase	1	2,6
	Remission Phase	2	5,1
Hematological Response	Achieved	24	40,9
	Not Achieved	15	39,1

**Table 2. Baseline Hematological Characteristics of The Study Subjects**

Variable	Minimum	Maximum	Mean	Std. Deviation
Blast Cell (%)	2	15	6,8	2,3
Leucocyte	1.400	163.700	2.5587,2	36.141,2
Trombocyte	35.000	1.083.000	277.284,6	242.183,4

The types of therapy given consisted of Hydroxy Urea to 14 study subjects (35.9%), Imatinib to 8 research subjects (20.5%), and Nilotinib to 17 research subjects (43.6%). In this study, 36 research subjects (92.3%) experienced chronic phase CML, 1 research subject (2.6%) experienced acceleration phase CML, and as many as 2 research subjects experienced remission phase CML (5.1%). Achievement of hematological responses

in research subjects by 24 research subjects (40.9%), and that was not achieved by 15 research subjects (39.1%).

Table 2 shows the percentage of Blast cells ranging from 2-15% with an average of  $6.8 \pm 2.3\%$ . The number of leukocytes ranged from 1.400 - 163.700 with an average of  $25.587.2 \pm 36.141,2$ . Platelet counts ranged from 35.000-1.083.000 with an average of  $277.284,6 \pm 242.183,4$ .

**Table 3. Association between age group and hematological response achievement**

Age		Hematological Response		Total	p (C.I. 95%)
		Achieved	Not Achieved		
< 40 years old	n	12	9	21	0,542
	%	57,1%	42,9%	100,0%	
≥ 40 years old	n	12	6	18	
	%	66,7%	33,3%	100,0%	
Total	n	24	15	39	
	%	61,5%	38,5%	100,0%	

Table 3 shows the achievement of hematological response at age ≥ 40 years was higher than at age <40 years (66.7% vs. 57.1% respectively). However, no significant association was found between age and hematologic responses achievement (p = 0.542).

**Table 4. Association Between Gender and Hematological Response Achievement**

Gender		Hematological Response		Total	p (C.I. 95%)
		Achieved	Not Achieved		
Male	n	11	8	19	0,648
	%	57,9%	42,1%	100,0%	
Female	n	13	7	20	
	%	65,0%	35,0%	100,0%	
Total	n	24	15	39	
	%	61,5%	38,5%	100,0%	

Successful hematological response was seen more in female subjects than male subjects (65% vs. 57.9% respectively), as shown in Table 4. There was no statistically significant association between gender and hematological responses achievement (p = 0.648).

**Table 5. Type of Therapy And Its Conjunction with Hematological Response Achievement**

Type of Therapy		Hematological Response		Total	p (C.I. 95%)
		Achieved	Not Achieved		
Hydroxy Urea	n	5	9	14	0,046
	%	35,7%	64,3%	100,0%	
Imatinib	n	6	2	8	
	%	75,0%	25,0%	100,0%	
Nilotinib	n	13	4	17	
	%	76,5%	23,5%	100,0%	
Total	N	24	15	39	
	%	61,5%	38,5%	100,0%	

Table 5 shows hydroxy urea therapy resulted in the hematological responses achievement of 5 subjects (35.7%), less than those who did not achieve hematological responses (n = 9 ; 64.3%). Imatinib therapy resulted in the hematological response achievement of 6 subjects (75%); a higher number than those who did not achieve hematological responses. (n = 2 ; 25%) Nilotinib therapy, resulted in the hematological response achievement of

13 subjects (76.5%), a higher number than those who did not achieve a hematological response (n = 4 ; 23.5%) . A significant association between types of therapy with the achievement of hematological response (p = 0.046). Nilotinib therapy resulted in the highest number of hematological response achievement, compared to Imatinib and Hydroxy Urea therapy (54,1% vs. 25.0% vs. 20.9% respectively).

**Table 6. Comparison of Blast Cell Percentage In Different Hematological Response Achievement**

Hematological Response	n	Mean (%)	SD	p (C.I. 95%)
Achieved	24	6,1	1,8	0,016
Not Achieved	15	7,9	2,6	

The mean of blast cell was found to be significantly lower in subjects who achieved a hematological response compared to subjects who did not (6.1% vs. 7.9% respectively,  $p = 0.016$ ).

### Discussion

**Age:** Subjects who achieved hematological response at age  $\geq 40$  years (66.7%) was higher than at age  $< 40$  years (57.1%). However, there is no statistically significant association between age and the achievement of hematological response.

Increasing age was commonly associated with CML development into an advanced stage. Research conducted by Cortes and colleagues, showed that patients treated with Imatinib achieve a better hematological response and cytogenetic response in patients under 65 years compared with those above 65 years of age, but there is no significant correlation between age and induction remission of hematology.<sup>7</sup> Research conducted by Safaa and colleagues in Egypt found there was no significant difference between age, gender, and social status in achieving therapeutic targets.<sup>8</sup>

Age is related to tolerability and poor adherence so it influences the response of therapy. Old age experiences many drugs side effects of both hematological and non-hematological compared to young age. Research by Rosti and colleagues found that old age was associated with poor prognostic factors for outcome in CML Philadelphia chromosome (+) patients.<sup>9</sup> Arora's study explained that age also affect drug pharmacokinetics, besides adherence, number of transporters, drug interactions and drug - plasma protein binding.<sup>10</sup>

**Gender:** In this study, there was no significant difference in the percentage distribution of hematological responses achievement between male and female, although it was seen to be higher in female (65%) than in male (57.9%) ( $p = 0.648$ ). No significant association was found between gender and the achievement of hematological responses.

Research by Singh and colleagues explains that the achievement of a hematological response and poor

cytogenetic and prognostic responses are found in patients with older age and female gender, but do not elaborate further on the cause of this.<sup>6</sup>

Differences in achievement between male and female are explained as a result of poor adherence and tolerance found in male gender.<sup>11,12</sup> Pharmacokinetic variability also has an important role. Differences in body weight might also explain the differences in drug concentrations in male and female. Lighter weight in female mean female get an average dose of milligrams per kilogram of body weight higher than male, which means higher plasma drug concentrations.<sup>13</sup>

**Type of Therapy:** The percentage of subjects who achieved hematological response was found to be significantly higher in the administration of Nilotinib than those with Imatinib and hydroxy urea (54,1% vs. 25.0% vs. 20.9% respectively). A significant association was found between types of therapy and the hematological response achievement ( $p = 0.046$ ).

The study of Safaa and colleagues in Egypt found that 71.6% and 67.2% of patients who received Gleevec (Imatinib) achieved complete hematological response and cytogenetic responses. Patients who received hydroxy urea therapy, only 34.1% and 31.9% achieved a complete therapeutic response.<sup>8</sup>

Research conducted by Zhao et al. In 116 early chronic phase of CML patients treated with imatinib in China, obtained a complete hematological response of 94.1%.<sup>14</sup>

Research by Parveen Jain et al., Which compared treatment with tyrosine kinase inhibitors in this case imatinib with hydroxy urea, obtained 95% results achieving complete hematological response compared to 30% receiving hydroxyurea.<sup>15</sup> In a study conducted by Druker<sup>16</sup>, O'Brien<sup>17</sup>, and Kantarjian<sup>18</sup>, around 95% of patients achieved a complete hematological response. Research conducted by the Benelux CML study group, by Hehlmann and colleagues, shows that about 35% of patients achieve a complete hematological response with the use of hydroxy urea.<sup>19</sup>

Treatment of CML has experienced a rapid rate of progress over the past few years. Breakthroughs in the molecular targets of tyrosine kinase inhibitor (TKI) in recent years have brought changes in the history of the disease and in the therapeutic approach to patient treatment. The action mechanism of this TKI class of drugs are to selectively inhibit tyrosine kinase activity by occupying the ATP binding domain in ABL thereby preventing substrate phosphorylation.<sup>20</sup>

**Blast Cells Percentage:** The mean of blast cells was found to be significantly lower in subjects who achieved hematological response (6.1% vs. 7.9%,  $p = 0.016$ ). The percentage of the number of blast cells has a prognostic factor in CML disease. The large number of blast cells circulating in the peripheral blood is also associated with the clinical phases of CML (chronic phase, acceleration, blast crisis), where the further phase, the more the number of blast cells circulating in the peripheral.

The increased blast in CML is a direct consequence of continued BCR-ABL activity, possibly through oxidative stress and reactive oxygen species, resulting in DNA damage and impaired DNA repair, and subsequently causing genetic instability and clonal evolution with additional cytogenetic aberration and multiple mutations in the kinase domain BCR-ABL.<sup>21</sup>

Based on this study, age and gender did not have an association with achieving hematological response. There is a significant association between type of therapy and the percentage of blast cells with achieving complete hematological response. However, further research needs to be done on other factors that might affect the achievement of hematological response in CML patients, such as medication adherence and the possibility of resistance to drug administration.

### Conclusion

The type of therapy (nilotinib) and the low percentage of blast cells have an association with achieving complete hematological response.

**Conflict of Interest:** No Potential conflict of interest relevant to be declared

**Source of Funding:** This study was conducted with self funding, no external funding sources for this study

**Ethical Clearance:** The study protocol was approved by the Ethics Committee in Research of our

institution (Hasanuddin University), following the ethical recommendations from the Helsinki Declaration of 1975.

# 'My Live is Meaningful and Adherence to Antiretroviral Therapy' Men Who Have Sex with Men (MSM) Who Live with HIV/AIDS; Mixed Method

Yafi Sabila Rosyad<sup>1</sup>, Hema Malini<sup>2</sup>, Rika Sarfika<sup>2</sup>

<sup>1</sup>STIKes Yogyakarta, Daerah Istimewa Yogyakarta, Indonesia, <sup>2</sup>Andalas University, Padang West Sumatera, Indonesia

## Abstract

**Purpose:** To identify the distribution of meaning in life frequency and adherence to antiretroviral therapy (ART) as well as to perceive and explore the association between meaning in life and adherence to antiretroviral therapy (ART) of HIV-seropositive within MSM in Padang City, West Sumatra, Indonesia.

**Method:** This research used a mixed method with an approach of exploratory sequence design, which was in quantitative stage through a cross-sectional design approach that intended to know the relationship between variables. 102 sample size. In the qualitative stage, the researchers used the conceptual content cognitive map (3CM) method as a data retrieval technique and then continued with the interview.

**Results:** Characteristics of MSM in West Sumatra more than half were gay with early adulthood who were mostly on ART treatment less than one year. Almost all MSM were middle and upper educated, and they worked in sixteen sectors of employment in which the private sector was the largest. Most MSM had a meaningful life. More than half of MSM were discipline to go through ART treatment. There was a significant correlation between the meaning in life and the adherence of ART  $p(0,000)$  with the identification of several aspects that related to the meaning in life and ART adherence. They were spiritualism, lifestyle, psychological, life purpose, life achievement, knowledge, and motivation.

**Conclusion:** The importance of meaning in life within HIV-seropositive MSM that might influence the ART adherence. Therefore, the researchers recommend to conduct a compliance monitoring activity and provide logotherapy for MSM whose life is not meaningful.

**Keywords:** MSM, Meaning in life, ART adherence, HIV/AIDS, 3CM.

## Introduction

The use of ARV requires a high adherence rate of 90-95% in order to achieve therapy success and can prevent the emergence of drug resistance<sup>(1,2)</sup>. WHO has a target that 90% of People Living with HIV/AIDS

(PLWHA) already underwent ART by 2016, but the target realization is only 53%. PLWHA who undergo antiretroviral therapy is increasing. In 2016, there are 19.5 million or about 53% of the total number of PLWHA, and in mid-June 2017 the number has progressed to 20.9 million or about 56.9% of the total number of PLWHA<sup>(3)</sup>. Meanwhile, PLWHA in Indonesia who have undergone ART based on Ministry of Health report (2016), in 2015 there were 63,066 people where 2,056 of them experienced ART on the second line, and by 2017, PLWHA who had accessed antiretroviral therapy were 77,780 people where 2,374 people were on ART on the second line. From the data above, we can conclude that

---

### Corresponding Author:

STIKes Yogyakarta, Daerah Istimewa Yogyakarta,  
Indonesia

e-mail: rosyad2yafi@gmail.com

there are still many PLWHA who have not accessed ART, while the number of PLWHA in the second line shows improvement from year to year<sup>(4)</sup>.

According to research by Audet, Wagner, & Wallston (2015), meaningfulness of life by PLWHA associated with the psychological welfare of patients<sup>(5)</sup>. There has been no research on the relation of meaning in life toward ART, but based on research conducted by Corless et al.,(2006), about the relation of meaning in life to TB treatment adherence, it can conclude that there is a relationship between the meaning in life and the level of TB treatment adherence<sup>(6)</sup>. The meaning of life is a daily experience in life that is real<sup>(7)</sup> in both pleasant and unpleasant situations<sup>(8)</sup> and if someone can live every event to meets then his life will be happy<sup>(9)</sup>. The feeling of happiness can be achieved if someone who can achieve his life goals<sup>(10)</sup>.

Researchers in preliminary study at NGOs Taratak Jiwa Hati with interview six participant find that all PLWHA are still difficult to remember to consume medicine and sometimes late to consume it and there are still MSM who feel their lives are meaningless. This study is important to undertake because it can give a description of ART adherence and the meaning in life of HIV-seropositive MSM. This study aims to identify the characteristics of HIV-seropositive Men who have sex with men (MSM), the distribution of meaning in life frequency and adherence to antiretroviral therapy (ART) as well as to perceive and explore the association between meaning in life and adherence to antiretroviral therapy (ART) of HIV-seropositive within MSM in Padang City, West Sumatra, Indonesia.

## Material and Method

This research was mixed method through explanatory sequel design approach, where the qualitative data that was obtained in the research will help the explanation of the quantitative data result<sup>(13)</sup>. In quantitative phase, researchers used a cross-sectional design<sup>(13)</sup>. Total sampling use in this research with 102 Sample size MSM with HIV at NGOs Taratak Jiwa Hati West Sumatra Indonesia. Before conducting the research, the researchers tested the validity and reliability of the Meaning in Life Questionnaire (MLQ) in Indonesian version<sup>(14)</sup> and Morisky-8 Scale<sup>(15)</sup> also in Indonesian version, and all question items of both questionnaires were valid and reliable<sup>(16,17)</sup>. In the qualitative phase, the researchers used The Conceptual Content Cognitive

Map (3CM) method as a data retrieval technique. This method was a method developed by Kearny & Kaplan,<sup>(18)</sup> by using open-ended questions that were used to deeply understand the important concepts of informants' perceptions concerning the relationships between the meaning in life and ART adherence.

## Results and Discussion

**Research Sample:** The characteristics of respondents including sexual orientation, age, education level, duration of ART, and occupation. More than half of the MSM were gay with early adulthood, a majority of them were on ART for less than one-year treatment, almost all MSM were middle and upper educated, and they worked in sixteen sectors of employment in which the private sector was the largest<sup>(19)</sup>. Based on research that the respondents who have sexual orientation as gay was 56 people and as bisexual men were 46 people. The age range of respondents was in the adulthood age between 25-45 years old, where this age range was for both early and late adulthood<sup>(4)</sup>. The education level of respondents, most of them, was in the middle and upper education with a percentage of 81.4%. Various researches indicated that the level of education was one of the factors that will interact in health status. Where, if a person had a higher educational status, it could reduce mortality and increase the income, even reduce twice as much mortality either directly or indirectly<sup>(20,21)</sup>. In terms of time span on undergoing antiretroviral treatment, more than half or 54% of respondents were categorized as a newbie because it was still under one year time.

**Meaning in life of HIV-seropositive MSM:** The majority of respondents (64.71%) had a meaningful life and about 35.29% felt a meaningless life. Of the 102 respondents, 72.5% felt that there was no distinct purpose in life, and almost all respondents (91.2%) were looking for something that made their life meaningful. Meaning in life had a different function for each individual, but according to Mackenzie & Baumeister (2014), the function of meaning in life could be divided into three function themes<sup>(22)</sup>. The meaning in life according to Starck (2014), was said to be the phase where a person reached his life goal<sup>(10)</sup>. According to Audet et al., (2015), the low meaning in life indicated non-adherence ART and provided a stimulus of management for handling the suffered disease<sup>(5)</sup>. We were able to analyze that most respondents had been able to find the meaning of their lives although the meaning in life that was found was from an unpleasant experience. The need for counseling

to improve the meaningfulness of life of seropositive MSM (35.9%). By doing so, MSM population especially seropositive one will get more external support or motivation and can improve their meaningfulness in life.

**ART treatment adherence of HIV-seropositive MSM:** From the research results obtained that 57.8% respondents were adherence to antiretroviral therapy and the rest did not comply as much as 43 respondents or 42.2%. This level of adherence was seen from the accuracy of the dosage and the frequency of time-consuming ARV. According to Bangsberg, Kroetz, & Deeks, (2007), ART adherence should be observed to discern the compliance level of the treatment, as some studies indicate that with treatment adherence of (95%) or more indicates the effectiveness of antiretroviral

therapy<sup>(23)</sup>, but on adherence (75%) shows a rise of viruses with retention against drugs<sup>(24)</sup>. Some patients fail to maintain ART adherence<sup>(25)</sup>. Treatment and handling management of HIV are part of the management of chronic diseases, which have principles of medication adherence, prevention of drug retention, and morbidity prevention management<sup>(25)</sup>. This condition becomes a challenge for health workers. Nurses can maximize counseling services particularly for HIV counselor and psychiatric nurses that can provide special therapies to turn negative behaviors into the positive. Apart from health workers, peer advocates also need to improve their role to remind the companions to take the drugs in a timely and appropriate dose given.

**The relationship of meaning in life with ART adherence treatment within HIV-seropositive MSM:**

**Table 1: The relationship of meaning in life with ART adherence treatment within HIV-seropositive MSM n=102**

Meaning in life	ART adherence				Total		p	OR (CI95%)
	Non-adherence		Adherence					
	f	%	f	%	f	%		
Meaningless	31	86.1	5	13.9	36	100	0,000	27,90 (8.98-86.82)
Meaningful	12	18.8	54	81.8	66	100		

Table 1 showed that there was a relationship between meaning in life and ART adherence. When a person whose life was meaningless will have 27.90 times risk to be non-adherence in undergoing antiretroviral therapy than a person whose life was meaningful. The exploration results obtained 23 statements which consisted of 7 categories. The category are the purpose of life, the achievement of life, knowledge, motivation, spiritualism, lifestyle, and psychological.

Farber et al (2003), the meaning of the success of good treatment is directly proportional to the high expectation and inversely proportional to the level of depression<sup>(26)</sup>. There has been no research on the relation of the meaning in life to the level of ART adherence, but based on a research that conducted by Corless et al (2006), about the relation of meaning in life to TB treatment adherence, it can conclude that there is a relationship between the meaning in life and the level of TB treatment adherence<sup>(6)</sup>.

The exploration of the relationship between the meaning in life and ART adherence can occur due to the fulfillment of the basic components of the formation of meaning. According to Mackenzie & Baumeister (2014), there are four basic components that form the meaning in life. First is the necessity for a purpose of life which can be categorized into results attainment and fulfillment of more abstract desire<sup>(22)</sup>. The exploration result from this life purpose component was that the participant had a life purpose to get married “... *Although I am an LGBT, I have a plan to have a wife (P2)*”.

The life accomplishing of each participant was unique and different in interpreting the achievement of their life. “...*Can overcome all by thinking positively... experiencing the life...just like before HIV...(P1)*”.

The other achievement of the meaning in life was always being motivated to experience the life “...*Always keep the spirit, always optimistic and not pessimistic...*”.

(P3)” In addition, the participants also live his life by becoming a better person “...*experiencing the life...by becoming a better person... (P4)*”.

The next necessity is trust and faith. Participant’s spirituality indicated the existence of belief or faith by placing his trust in God “...*Pray regularly...ask God by tahajud prayer (Moslem’s prayer near midnight), what is the crux of this problem so that it can be solved well (P3)*”. Participants believed that by counseling their life purpose can be achieved, following the participant’s statement;

“...According to the hospital, as a person with HIV, I can have a wife and have offspring without spreading the disease by doing the program (P2)”

The last necessity is that one must have positive self-esteem. The meaning in life according to Starck (2014), by having a sensitive feeling with the experience of how to love his life<sup>(10)</sup>.

“...meet other people living with HIV..feeling no burden of thinking and ... should be motivated in undergoing this antiretroviral therapy.. there is a desire to behave better again ... optimist to maintain health ... be firm in facing this life and keep struggling do not get desperate (P3)”.

The freedom to choose what the participants did was to live a healthier life “...*enough exercise, a good diet and have a deeper understanding of what HIV is (P2)*”. Human suffering is the third concept of the meaningful theory.

“..with despairing by not taking ARV (P3) and why doing a healthy life while I’ve HIV and no one willing to befriend me, to approach me...(P2)”.

The uniqueness of a person’s meaningful life that is stimulated by various things ultimately can make someone adherence to undergoing antiretroviral therapy. However, to gain meaningfulness of life, one must be able to accept who they are and where their position now. The meaningfulness of life can be obtained not only in a pleasurable event but also be found from unpleasant events. HIV-seropositive is an unpleasant experience for everyone especially the respondents. Thus, health workers need to assist respondents in order to rediscover the purpose of their life so that they have the meaning in life as before HIV-seropositive.

## Conclusion

PLWHA adherence to consume ART was influenced by the meaning in life, where, when PLWHA had a clear purpose that he wanted to accomplish in life, then that PLWHA will adherence to consuming ART. Meanwhile, PLWHA adherence was also influenced by peers, information attainment, and self-motivation. This research provides important suggestions for health workers to be actively involved in enhancing the motivation of PLWHA, especially MSM to behave openly so that the quality of life monitoring can be done.

# The Development Model of Post Malaysia Sports School's Athlete Alternative Career Pathway

Zulakbal Abd Karim<sup>1</sup>, Yusop Ahmad<sup>1</sup>, Najib Razak<sup>1</sup>

<sup>1</sup>*Sultan Idris Education University, Tanjong Malim, Perak, Malaysia*

## Abstract

The purpose of this study is to identify the challenges, issues, threats and potential among athletes post Malaysia National and State Sports Schools, of what hinder them from making their debut at the professional sports scene post sports schools. Based on the objectives of the study, eventually a model of alternative career pathways will be developed and propose to sports division ministry of education to help make sure sports schools athlete wellbeing and welfare post sports schools can be well secure in the future. This research was guided by the principles of thematic analysis (TA) (Patton, 1990) in data collection and analysis and also related closely with the research on the needs of career pathways development. 10 participants post sports schools athlete, parents, teachers, as well as an administrator of the schools were involved and interview sessions with all participants conducted which each interview lasted ranging from 45 minutes to 90 minutes length. The findings of the study highlight three important themes in ensuring athlete post sports school's future are well taken care of by the governing body of the schools, which are pre sports schools, during sports schools, and post sports schools. In conclusion, this model may assist the most important "stakeholders" who is the athletes to be sure of them of welfare and wellbeing post sports schools and to improve knowledge on the pathways development for the governing body of sports schools training provider in order to implement them into practice.

**Keywords:** *Sports school's athletes, Training, Knowledge, Challenges, issues, threat, potential, and career pathways.*

## Introduction

In the reality, not all former elite athletes in sports schools have finally become professional athletes. High competition, injuries, limited opportunities and impairment may be the cause of this drop out. For those who have enough academic qualifications, the opportunity to continue their studies or choose employment in most areas including sports is always open to them. For former sports schools athletes who have dropped out in both academic and sports fields,

their chances are very limited and not as extensive. If this happens, then the time, sacrifices, and sweat for many years in training at sports schools come to a waste and almost does not mean anything as job they are currently doing after sports schools years, not require schools sports participation as a prerequisite.

**Problem Statement:** Not all sports school athletes become professional athletes. For former sports school athletes who have dropped out in both academic and sports fields, some of them work as general workers and other jobs that can be applied without qualification in sports. If this happens, then the time spend, sweat and sacrifices for many years in sports school does not mean anything. Hence a study is critically needs to be carried out to obtain a data base of the total number of student dropouts from sports schools in order to understand this phenomenon thus formulate the strategy of assisting the post sports schools athletes to continue their career in sports-related fields.

e-mail: [zulakbal@fsskj.upsi.edu.my](mailto:zulakbal@fsskj.upsi.edu.my)

**Research Objectives:** This research was based on education, aims to present a solution to the education issue that is a high dropout rate among athletic sports athletes. For that, the following objectives need to be met:

1. Understand current career-related needs and demand for dropout sports school athletes.
2. Develop concepts and strategies to give second “route” to sports schools’s athletes a chance to become a professional athletes or work or study opportunities.
3. Propose post-school sports alternative career development model for post sports schools athletes.

**Literature Review:** Experience dropped out of the team also has an impact on the potential to be dropped out of the current sport.<sup>1</sup> However, other likelihood of dropouts among athletes at sports schools will only be known when this proposed study is implemented; because every problem is unique to its context. In one study by Jin<sup>2</sup>, the results of the study have shown that the career module can improve career maturity among students effectively.

According to Surujlal and Nguyen<sup>3</sup>, most of the football coaches will face some challenges, heartbreaks, conflicts, tensions and these issues should not be underestimated. Launder<sup>4</sup> (2009) states that even though a coach’s job is quite complex, the knowledge they have is the main factor that influenced athlete or team’s preparations.

This is because it influences the contentment of athletes or players to practice. According to Zulakbal Abd Karim<sup>5</sup>, coaches who are more knowledgeable and intelligent in facing the challenges in the process of building their careers as a coach tend to do better in their responses toward every challenge they encounter<sup>6</sup>,state that a coach needs to have knowledge on coaching in order to help improve their coaching skills.

Almost all remain in jobs related to the training they receive<sup>7</sup>. Therefore, the level of retention of athlete students in athletics since training in sports schools should also be identified through this study. “Burn out” is among the factors of retirement from athletics<sup>8</sup>. The formation of a model in determining athlete’s career direction is not a foreign matter for foreign researchers. Developmental Model of Sport Participation<sup>9,10</sup> for example provide a framework that demonstrates various

sports engagement paths<sup>11</sup>. Hence, the formation of an alternative career path model in this proposed study is an important thing that is necessary for specific use to sports athletes in Malaysia.

## Methodology

The study was based on the principles of thematic analysis (TA)<sup>12</sup> and is closely related to research on individual career needs and it allows wider analytical and analytical techniques to understand the complexity of the former sports schools athlete career path. The method used allows technique analysis. This enabled richer and detailed frame of work in order to understand the complexity of more dynamic post sports schools athlete career development pathways needs and demands<sup>13</sup>. In this research, the researchers have utilized purposive sampling technique by conducting “semi structured open ended in-depth interview”, observation and study notes to 10 participants (post sports schools athletes). The number of samples was determined by “saturation of information”. Due to this, three main strategies were used to collect data which was “semi structured open ended in-depth interview”, observation and study notes. The usage of these three data sources is necessary in order to increase the credibility of the findings and to reduce the possibility of misinterpretation.

**Findings:** The findings are based on the diversity of perceptions and Sports Schools former athletes as a source of information that results in changes in their cognitive structure<sup>15</sup>. The data were collected based on thematic analysis (TA)<sup>12,13</sup>, method, covering interviews, observations and study notes. The number of samples is in the range of 1 - 10 people; where 10 is the maximum if the amount has not yet been found “saturation of information”.

**Pre-Sports Schools:** In the opinion of most of the participants of this study and they mentioned with special interest, that the sports schools need to have a very strong, qualified and knowledgeable group of person to conduct the Talent Identification Process, Talent Scouting process and better or improved competition at the national level (MSSM). For example participant P1 mentioned as followed,

I feel the sports schools need to re look at their recruitment process to make sure that only the most qualified and high quality athlete will be included there. This TID process must be carried out by also most qualified coach.

According to O'Connor, Larkin and Mark Williams<sup>16</sup>, talent identification and selection for youth development programmes is based on the ability of coaches and talent identifiers to predict future sporting success based on current youth performance. The issue with talent identification and development programmes is the assumption that the factors which contribute to successful senior performance can be generalized and measured within an adolescent group to predict future senior ability<sup>17</sup>.

### **Talent Identification and Development:**

Participants hope that the talent identification process must be carried out collectively with the sports governing body, expert from the university and as well as other important stakeholder in respective sports. As an example participants:

### **Talent Scouting**

One of the example participants I labelled as P10 mention as follows:

*Now the TID carried out by the group of teachers of sports schools, but I think they need to carry out TID collectively also with the sports governing body representative. To make sure what are the demand of the sports industry and what is the expectation of the industry from the athletes of the sports schools, this will therefore make sure the athletes will be hired by the professional club upon completing their study in sports schools, not only teachers.*

The challenging task of policymakers and administrators of youth sport programmes is to develop a structure that meets the multiple needs of young participants and serves the different outcomes of youth sport<sup>18</sup>. Siedentop<sup>19</sup> has suggested that the contrasting natures of the different outcomes of youth sport are not achievable within single programme and should be promoted by different programmes.

### **During Sports Schools:**

**Input:** Participants convey their thought that professional sports body needs to be involved in the technical part of the curriculum for sports schools. Input from the sport's governing body need to be taken into consideration.

*Highly qualified coach must help coaches in sports schools, they must collaborate and work together. The state football F.A. must send their A licence coach to*

*work with the schools coach, change of ideas and give their professional input. Our student, therefore can do better.*

Peel, Cropley, Hanton & Fleming<sup>20</sup> state that experiential learning by facilitating transferability of experience is built by reality based learning.

**Intervention:** Participants believed that teachers/coaches in the sports schools needs to be working together with an expert from the professional sports organisation.

The highest sport governing body must intervene to help schools layout their coaching programme. Help educate the coaches and the administrator at sports schools. Like in Japan schools work closely with Japan FA, that what I've heard.

According to Ministry of Youth and Sports<sup>21-24</sup>, The Football Association of Malaysia (FAM) welcomes the steps taken by the government through the Ministry of Youth and Sports (KBS) to draft and implement the National Football Development Plan (NFDP).

**Post Sports Schools:** The governing body of sports schools cannot just leave it to the athlete and their family to determine or secure their own future career. An official networking between sports schools and an industrial "player" needs to be done.

**Memorandum of Understanding (MOU):** Participants of this study mention that this effort can be done through an agreement or memorandum of understanding with three main bodies as follows:

### **Study and still playing agreement with higher education institution:**

One of the example, participants (P4) mentioned as follows:

*There must be university or college, IKBN for example that create new sports related programme starting with certificate, and sports schools student can go straight in there using their playing experience. If they have a special agreement between sports schools and the education provider, it will make our future more secure. Now we need to look after ourself.*

One way to start understanding the processes behind dropout is to utilise a framework such as that proposed by Uehara, Button, Falcous, and Davids<sup>25</sup>.

## Discussion

In pre sport school phase, a player selection quality assurance body need to be set up especially for student intake to sports school. Player selection method should be tightened by involving individuals that professional or from own industry. During sport school phase programme, dual curriculum should be carried out where learning programs passed through by students should fulfill industry will and the programme should have joint venture with industry so that training passed through by those able in parallel adaptation with industry will. When it come to post sport schools phase, before student finish their schooling in this sports school, the ministry should have MOU along with IPT, IKBN and other educations institute.

## Conclusion

These three core themes are divided into other sub themes to address other requirements which serve as the basic guidance for governing body of the National and state sports schools to enhance the quality of the service provided to their athletes and their future's sake. In conclusion, this model may assist the most important "stakeholders" who is the athlete to be sure of them of welfare and wellbeing post sports schools and to improve knowledge on the pathways development for the governing body of sports schools training provider in order to implement them into practice.

**Ethical Clearance:** The study has been done in accordance with human research ethics as per required by the declaration of Helsinki".

**Source of Funding:** The authors would like to extend their gratitude to the Research Management and Innovation Centre (RMIC), Sultan Idris Education University (UPSI) for the University Research Grants (code: 2018-0158-106-01) that helped fund the research.

# A Narrative Review of Literature of Health Information Seeking Behaviour

T.R. Gopalakrishnan<sup>1</sup>, Rachel Jacob<sup>2</sup>

<sup>1</sup>Assistant Professor, <sup>2</sup>Research Scholar, Department of Journalism and Communication, University of Madras, Chennai, Tamil Nadu, India

## Abstract

The empirical study of Health Information Seeking Behaviour (HISB) has used multiple models and measures that are tuned to the context of the traditional media environment in which there was a clear separation of interpersonal, mass media computer-mediated communication channels. In this context, there is a need to update the understanding of HISB that takes into account the complex multimedia environment in which information is generated, sought and consumed today. This study presents a narrative review of literature on HISB that addresses tries to provide an explication of the current understanding of HISB with specific focus on the need for re-conceptualisation of HISB and convergence of core internal divisions in the field.

**Keywords:** Health Information Seeking Behaviour (HISB), Human Information (HIB), Narrative Review, Information Seeking Behaviour (ISB), Convergence.

## Introduction

Health Information Seeking Behaviours (HISB) is a marriage of human instinct for sense making, felt need and social context. It has been nurtured within a large joint family of theories of human Information behaviour (HIB), Everyday Life Information Seeking (ELIS), Information Practices. More recently, Information Seeking behaviour (ISB), of which HISB is a sublet, is emerging as a distinctive field of research. This trend not only provides a historically rooting, but enables drawing on the rich and varied traditions, theoretical models and empirical findings from studies on human information behaviour. From an evolutionary perspective, human information seeking behaviour has shifted from being seen as a secondary need to primary need which has played a significant role in the evolutionary adaptive behaviour of humans. (Spink, 2010)<sup>24</sup>.

**Review of Literature:** HIB studies emerged from the discipline of Library and Information Science (LIS), but its close connections with communication have been self-evident and well recognized. (Wilson, 1994)<sup>30</sup> observed “information science, particularly in relation to the study of user behavior, can derive much benefit from a closer liaison with communication studies”. Early studies on HIB focused on information and information needs and uses/users and behaviour, information retrieval, user studies. Study of HIB and IS B dramatically increased with the widespread adoption of the Internet between 1998 and 2001 (Bawden, 2006)<sup>3</sup>; (Blessinger & Hrycaj, 2010)<sup>4</sup>; (Milojevic, Sugimoto, Yan, & Ding, 2011)<sup>22</sup>; (Lariviere, Sugimoto, & Cronin, 2012)<sup>18</sup>; (Tuomaala, Jarvelin, & Vakkari, 2014)<sup>28</sup>. In most studies, HIB is interchangeably used as information needs, seeking and uses.

Information seeking has been examined from four major perspectives – the everyday life information seeking, sense-making approaches, the information foraging approach and the problem–solution perspective on the information seeking approach and theory of information use (Spink & Cole, 2006)<sup>25</sup> Most studies focus on cognitive, affective and behavioral aspects of information (Afzal, 2017)<sup>1</sup>; (Lee, 2016)<sup>19</sup> identified

e-mail: jacobrachel@gmail.com

five theories (Theory of Planned Behaviour by Martin Fishbein and Icke Ajzen (1980), Uses & Gratification by Jay Blumer and Denis McQuail (1969), Information Seeking Model (Wilson's Model, 1981), Diffusion of Innovation theory by Everett Roger (1962) and Information Seeking Model by Kuhlthau (1982) were highly cited. (Lee, H. S., 2016)<sup>19</sup>. A review from 1988 - 2007 based on bibliometrics/scientometrics analysis of LIS discipline, found that IS B is emerging as a separate sub-discipline within the broader HIB literature. (Milojevic, Sugimoto, Yan, & Ding, 2011)<sup>22</sup>

With the advent of the Internet and changes in the cognitive landscape, there was a tremendous growth in IS B studies since 1998. While the application context of HIB studies is widening as many disciplines embrace ideas from HIB, it has special salience in the field of health and medicine. (Milojevic, Sugimoto, Yan, & Ding, 2011)<sup>22</sup>. Scholars from health/medical sciences, psychology and health communication have acknowledged the importance of IS B studies from its early stages (Lariviere, Sugimoto, & Cronin, 2012)<sup>18</sup>. Surprisingly, there are very few attempts to integrate IS B and communication models (Wilson, 1994)<sup>30</sup>; (Wilson, 2018)<sup>31</sup>. Many scholars have noted that different vocabularies being in use in different disciplines to refer to same or similar phenomenon (Wilson, 2018)<sup>31</sup>; (Kim, 2017)<sup>16</sup>; (Taylor, 2016)<sup>27</sup>; (Julien, H. (1995)<sup>14</sup>; (Julien & Duggan, 2000)<sup>15</sup>; (Chang, 2011)<sup>8</sup>. This has led attempts to clarify terminologies and construct an integrated model that can support cross-disciplinary research and applications of insights from HIB studies (Lambert & Loiselle, 2007)<sup>17</sup>; (Martzoukou, 2005)<sup>21</sup>. Study of information seeking activities of health consumers and patients have incorporated models of IS B without sufficient focus on conceptual refinements that are taking place in wider HIB field. As a consequence, several internal contradictions and paradoxical conclusions have marked the studies on HISB.

Johnson, J. D. (2015)<sup>13</sup>, summarizing the significant empirical findings of HISB, identifies seven "deadly tensions" in the literature. These include 1) continued importance of interpersonal communication as a primary source of health information despite widespread use of the Internet. 2) accessibility gets more traction than quality when people are looking for information. 3) Individuals level of skill and prior experience in using new media determines the extent of HISB. 4) the law of diminishing return works with information-the more

information one gets, the less likely they are to derive value from it. 5) Individuals are "cognitive misers," and hence, they depend on tried and tested sources for health information despite the availability of better alternatives. 6) Individual differences in personality, seeking style, professional training and aesthetic preferences take precedence over the credibility of information sources. 7) People tend to undervalue the gains of knowing about their health compared to its cost. Johnson concludes that these tensions are "masked by their seemingly irrational behaviour" and hence "ignored by policymakers and system designers. (Johnson, J. D., 2015)<sup>13</sup>

However, Johnson (2015)<sup>13</sup> does not explicitly consider how these tensions are played out in the information-rich media ecosystem. The mediatized environment not only create a demand side pull factor of information seekers but also the supply side push by the healthcare industry which seeks to commodify and market healthcare devices, products and services. This internal tension is best captured by two conceptions of users -- user as consumer and user as the patient. As a consequence of this pull-push dynamics, the seven tensions appear to be accentuated and reconfigured in ways that are yet to be understood and carefully studied. By examining the way by which health and medical fields are approaching the study of information seeking behaviour, we can develop a better understanding of how new information and communication technologies (ICTs) is shaping health information seeking behaviour and its consequences.

This paper attempts to reframe the tensions identified by Johnson (2015)<sup>13</sup> in terms of convergence of set of themes that has divided the wider field of HIB and IS B. The research question that we seek to address are: 1) How and why HIB/IS B models are used within health and medical sciences? 2) What are the gaps and disjunction between wider HIB/IS B and narrower HISB literature as a consequence of encountering technology?

## Method

This preliminary analysis involves a scoping review of previous literature reviews conducted on Health Information Seeking Behaviour (HISB), in comparison with similar HIB reviews from the wider field (Wilson, T. D., 1994; Larivière, V., et al., 2012)<sup>30,18</sup>. The scoping exercise undertaken here is closer to the concept of information scanning in HIB literature. The study adopted the guidelines suggested by Arksey, H., & O'Malley, L., (2005)<sup>2</sup> for the conduct of scoping studies.

The study identified a total number of 161 review articles as of 01, June 2019 from PubMed and Google Scholar. All articles provided a review of HIB, IS B and HISB literature. The oldest article was in 1996(Godin & Kok, 1996)<sup>11</sup> on the theory of planned behaviour in health context, while the most recent article was on Consumer needs for Cancer Patients (Sung Jo, Park, & Jung, 2019)<sup>26</sup>. Five reviews were located before 1998, 39 reviews between 1999 - 2009 and 117 reviews from 2010 - 2019. The review by (Welch, Petkovic, Pardo, Rader, & Tugwell, 2016)<sup>29</sup> had longest coverage between 1946 – 2014, which included research on HISB but did not give any special focus to health information.

Several reviews of HIB and HISB have been conducted, along with a more comprehensive overview of the field of HIB. (Chang, 2011)<sup>8</sup> This study is presented in the form of a narrative review. Authors define narrative review as a tool to identify the current knowledge, trends and pattern of a particular topic. (Dixon-Woods, Agarwal, Jones, Young, & Sutton, 2005)<sup>10</sup>.

The study identified a convergence of multiple approaches that have historically marked the HIB field. HISB being a subset of HIB reflects these convergences only in a limited way. Calls for an integration of multiple approaches has been a recurrent theme in HIB literature, but HISB studies are yet to adopt integrated models.’ (Larivière, V., et al. 2012)<sup>18</sup>. An attempt is being made here to provide a focused synthesis of previous reviews of HIB and HISB literature.

## Results

In the following sections, the study considers the implications of emergent media ecosystem to the literature on HIB and HISB. The study employs the reviews from the broader discipline of HIB to assess what health information seeking studies have left out. The aim is to locate disjunctions and gaps between HIB and HISB. (Lambert, S. D., & Loiselle, C. G., 2007; Larivière, V., Sugimoto, C. R., & Cronin, B., 2012)<sup>17,18</sup>

The field of HIB has been remarkably responsive to the development of new information and communication technologies (ICTs). After a period of low interest in the late 80s to mid-90s, HIB, research output increased significantly since 1998 following the widespread adoption of the Internet amongst the general public. (Larivière, V., et al., 2012; Milojević, S., et al., 2011)<sup>18,22</sup>. Several theoretical, methodological, systematic reviews

and citation analyses were conducted to provide a summary and overview of the trends and to identify dominant models that guide the research program. HISB research has made attempts to adopt many of these perspectives in the context of health (Case, Andrews, Johnson, & Allard, 2005)<sup>7</sup>; (Julien, H., & Duggan, L. J., 2000)<sup>15</sup>.

With these efforts, HISB research has also inherited several internal tensions in conceptualization and practical applications of the HIB approaches. These tensions have been accentuated growth in social and mobile media of communication, creating opportunities for convergence of several strands of HISB empirical and theoretical debates. Overall, it was found that far from being “deadly tensions,” the study sees these issues as a sign of convergence. The study presents a narrative overview of these multiple convergences and disjunctions between HIB and HISB, for which the study has the most evidence.

The study identified seven convergences: 1) Convergence of Information Seeking and Sense Making Paradigm, 2) Convergence of Active and Passive Seeking: Unified User Seeker/Adaptive Seeker, 3) Convergence of Objective and Subjective Measurement of HISB: Representing Digital Patient, 4) Convergence of Mediated and Interpersonal Communication: Being Perpetually Connected, 5) Convergence of Opinion Leaders and Regulated Professional: Emergence of Lay Experts, 6) Convergence of Availability and Accessibility: Information Visibility and 7) Convergence of Information Competencies. Taken together, these reviews indicate scholarly attempts to make sense of the implications of the widespread adoption of new media to health.

**Implications of Convergence: Outsourcing HISB?:** New forms of convergence of human cognition and machine cognition are emerging, such as chatbots and AI Information Assistants. Just as much as users seek information, information is too is seeking a context and user for its continuity. Smartphones powered by AI and facilitated by health sensors and health information architecture that serves as its resources can be conceived as attention seeking bots.

(Halko & Kientz, 2010)<sup>12</sup>; (Marcus, 2015)<sup>20</sup> point out that persuasive technologies and products nudge individuals to certain health sources and services. In this sense, information is seeking an individual as much

as individuals seeking information. Persuasive design could lead to anticipatory information and service needs assessment and delivery, based on an individuals' persuasive profile and preferred persuasion style. (Pariser, 2011)<sup>23</sup>

Along with technological developments, several socio-economic, commercial and enlightened self-interest drives the development of the information habitat that we increasingly migrate. Intelligent technologies like AI, Chabot's, IoT, Wearables and Apps are rapidly meshing our body and mind with technology (Brodie, et al., 2018)<sup>5</sup>; (Carr, 2011)<sup>6</sup>; (Clarke, Shim, Mamo, Fosket, & Fishman, 2003)<sup>9</sup>.

**Ethical Clearance:** This is a systematic review analysis of previous literature on HISB. Hence, no ethical clearance required.

**Source of Funding:** This is a self-sourced project.

**Conflict of Interest:** There is no conflict of interest in the paper.

# Empirical Investigation between Occupational Stress and its impact on Job Satisfaction among Medical Practitioners' of Jawaharlal Nehru Medical College

Yogendra Pal Bharadwaj<sup>1</sup>, Aruna Dhamija<sup>2</sup>, Somesh Dhamija<sup>3</sup>

<sup>1</sup>Assistant Professor, IBM, GLA University, Mathura and PDF Fellow, ICSSR, Ministry of HRD, New Delhi & Department of Commerce, AMU, Aligarh, <sup>2</sup>Professor, IBM (U.G),

<sup>3</sup>Professor & Head-Management (UG), IBM, GLA University, Mathura ((U.P.), India

## Abstract

**Background/Aims:** The motivation behind this paper is to recognize the relationship between determinants of occupational stress and their effect on medicinal practitioners' fulfillment and that improves their engagement towards Jawaharlal Nehru Medical College (JNMC).

**Method:** Based on convenience sampling approach, data was gathered from 210 medical practitioners' working in JNMC through self administered questionnaire based on five point Likert scale. A descriptive cum inferential statistical technique was embraced while structural equation model likewise used to investigate the significance of proposed model.

**Findings:** The outcomes indicated that structure of organization is the most foremost determinant for medical professionals' fulfillment, trailed by environmental factor, job-demand factor and family-work factor. They nearly share similar connections as far as medical practitioners' satisfaction is concerned. Be that as it may, medical practitioners' fulfillment set out the best effect on the engagement for JNMC. While, family-work factor underscored incredibly on engagement in JNMC and the least on medical specialists' satisfaction among all the four determinants of occupational related stress.

**Practical Implications:** It will enormously help both JNMC authorities and medical specialists in creating suitable systems to build the inclination of medical experts' fulfillment for an effective and desired administration commitment for a superior wellbeing arrangement.

**Originality/Value:** This research is spearheading as in the contemporary era medical practitioners' satisfaction had moderately been less investigated in the Indian setting of JNMC and it is acting like a source that gives standard stuff to increase engagement of medical practitioners' for the medical care industry.

**Keywords:** *Occupational Stress, Medical Practitioners' Satisfaction, Engagement and Jawaharlal Nehru Medical College.*

## Introduction

Occupational stress is a perceived issue in medical

services and practitioners' have higher level of mental dreariness, self-destructive propensities and poor controls in the tantamount of social class<sup>2,16</sup>. Stress is conceptualized from the interactionist model that thinks about the natural connection of the individual as liable for the whittling down<sup>1,18</sup>. Among the elements setting off the procedure of psychological instability among JNMC experts, the most significant are those related with work, such as, over-burden, working conditions, pressure for meeting objectives and absence of self-

e-mail: yogendra\_pal07@yahoo.ac.in

governance<sup>13,20</sup>. Engagement makes them connected to their work with high sentiments of motivation, prosperity and bona fide joy for what they are expected to perform expertly<sup>1,2,5</sup>. On account of JNMC advancement and sustenance of engagement among the medical practitioners' group, it is prescribed to execute this study to recognize the connection between factors of occupational stress and medical specialists' satisfaction with particular to engagement in Jawaharlal Nehru Medical College<sup>11</sup>. In this investigation, four determinants of occupational stress (environmental factor, job-demand factor, structure of organization and family-work factor) are utilized to assess the connection between perception of medical experts' towards these measurements in Jawaharlal Nehru Medical College<sup>11</sup>. After a brief plotting of occupational stress factors, medical professionals' satisfaction and engagement of JNMC, the research speculation is proposed with a conceptual model of the examination and demonstrated with certain inferential research and a path diagram<sup>1,7</sup>.

The accompanying hypotheses, in light of various examinations, give the degree and profundity of this empirical investigation:

H1: Environmental Factor has a significant influence on satisfaction of medical practitioners' in JNMC.

H2: Job-Demand Factor has a significant influence on satisfaction of medical practitioners' in JNMC.

H3: Structure of Organization has a significant influence on satisfaction of medical practitioners' in JNMC.

H4: Family-Work Factor has a significant influence on satisfaction of medical practitioners' in JNMC.

H5: Medical Practitioners' Satisfaction has a significant impact on their engagement in JNMC.

H6: Environmental Factor has a significant influence on engagement in JNMC.

H7: Job-Demand Factor has a significant influence on engagement in JNMC.

H8: Structure of Organization has a significant influence on engagement in JNMC.

H9: Family-Work Factor has a significant influence on engagement in JNMC.

## Materials and Method

**Research Design:** This study is based on a conclusive research, where, the dependent variable is engagement (ENG) and independent variables are determinants of occupational stress (OS). Medical Practitioners' Satisfaction (MPS) plays a mediating role between engagement and determinants of occupational stress. The items of 'environmental factor' were derived from the studies of Vagg & Spielberger<sup>19</sup> (1998); Szilagyi & Holland<sup>18</sup> (1980), whereas, 'job-demand factor' were derived from the studies of Beehr, Jex, Stacy & Murray<sup>2</sup> (2000); Smither<sup>17</sup> (1998). The studies exercised by Ivancevich, Matteson, Freedman and Phillips<sup>13</sup> (1990) have identified in terms of 'structure of organization' and for the evaluative purpose of 'family-work factor', studies of Netemeyer, Maxham, & Pullig<sup>16</sup>(2005) were acknowledged in the factors of occupational stress. While, the studies of Wong JG<sup>20</sup> (2008) and Caballero, Bermejo, Nieto and Caballero<sup>5</sup> (2001) have identified for 'medical practitioners' satisfaction'. Moreover, for the purpose of 'engagement', few studies conducted by Coetzee & De Villiers<sup>7</sup> (2010) and Baumruk, R.<sup>1</sup> (2004) have adopted to select the relative items.

**Sample Design and Procedure:** Convenience sampling approach was used in terms of adapted questionnaire depended on a five-point Likert scale. The initial segment involved demographic profiles (gender, professional diversification, service engagement duration, age and education level) of the medicinal practitioners', while, the subsequent segment managed the autonomous factors, intervene variable and the dependent variable. The information was gathered in two phases from July 2019 to December 2019. In the main stage, information was produced from 50 respondents with the end goal of pilot study. In the subsequent stage, information was created from larger sample of 210 respondents. The populace in this investigation is all representatives who work as a medical practitioner in JNMC. According to the annual reports published by its central record section, the different divisions have sufficient medical practitioners according to the statutory administering bodies<sup>11</sup>. Thinking about this, we had disseminated 250 questionnaires as past examinations have watched a level of similar response<sup>6,15</sup>. Out of 240, just 210 respondents returned the questionnaires and according to rule of thumb method, the sample size of 210 medicinal practitioners' is aggregate<sup>14,15</sup>. This demonstrates 87 percent of responses rate which is

higher than the normal of reaction rates revealed in such kind of studies<sup>6</sup>. The general reliability of the scale was .874 which is viewed as adequate<sup>6,8</sup>.

**Table I: Reliability Value of the Scale**

Variables	No. of Items	Cronbach's Alpha ( $\alpha$ )
Environmental Factor	7	.781
Job-Demand Factor	5	.873
Structure of Organization	4	.722
Family-Work Factor	5	.871
Medical Practitioners' Satisfaction	8	.762
Engagement	6	.860

**Source:** Survey data and prepared by the researcher In the light of assistance taken from SPSS 20.0 and AMOS 20.0, descriptive statistics, factor analysis, regression analysis, analysis of diverse and ultimately structural path were made to advance the proximity of the stated model<sup>4,10,12</sup>. The subsequent table clarifies the estimates of the variable and its criticalness for the structural path analysis through confirmatory factor analysis and basic elements of 35 items.<sup>3,5,6,14</sup>

### Data Analysis and Results

**Descriptive Analysis of Demographic Factors:** As per the practitioners' summary based on gender, 160 were males and 50 were females. While, 19.04 per cent were aged 19 to 34 years, 66.67 per cent were aged 45 years and above and 14.29 per cent were aged 35 to 44 years that means most of the practitioners' are matured enough to understand the proximity of medical engagement and dimensions of occupational stress<sup>6,8</sup>. In terms of professional diversification of medical practitioners', majority of the practitioners' belonged to physician and surgeon category (38.09 per cent), whereas, other class of practitioners' were 19.07 per cent, ophthalmologist and dentist (19.04 per cent), gynecologist and obstetrics pediatrics (14.28 per cent) and junior resident class had 9.52 per cent practitioners', as far as education profile, 57.16 per cent were doctorate and other certification holder, 23.80 per cent were post graduate and remaining 19.04 percent were medical graduate. It means majority of practitioners' know the exemplar approach to select their occupation prudently. As far as service engagement duration is concerned, 57.14 per cent practitioners' were of more than ten years, 19.06 per cent were of 5 to 10 years duration, 14.28 per cent were of 2 to 5 years and 9.52 per cent were of less than 2 years duration which means still practitioners are matured enough to understand the paradigm approach of their occupational stress with service engagement in the medical industry of JNMC<sup>17, 19</sup>.

**Analysis of Model and Findings:** As far as hypotheses testing, the outcomes demonstrated decidedly huge impact of determinants on occupational

related stress, for example, job-demand factor on medical practitioners' satisfaction ( $p=0.048$ ), though, its ( $\beta=.62$ ) shows 62 percent JDF measurement influence practitioners' towards occupational related stress, while the critical ratio ( $CR=6.769$ ) escalates it as a significant determinant of medicinal practitioners' satisfaction, so this hypothesis got accepted<sup>19,21</sup>. Different measurements like environmental factor ( $p=0.015$ ;  $\beta=.58$ ), structure of organization ( $p=0.177$ ;  $\beta=.65$ ) and family-work factor ( $p=0.437$ ;  $\beta=.57$ ) emphatically not impacted medicinal practitioners' satisfaction towards occupational stress created by JNMC, so these hypotheses got rejected<sup>13,16</sup>. While, medical practitioners' satisfaction ( $p=0.010$ ;  $\beta=.72$ ) is decidedly impacted towards their engagement to give JNMC benefits all the time, so this hypothesis

is accepted<sup>5,7</sup>. It additionally expressed that the medical workforce is increasingly worried about professionals' issues to develop and retain affinity with them<sup>2</sup>. So as to test the connection between measurements of occupational related stress and medicinal practitioners' engagement, all determinants were discovered having irrelevantly effect on engagement except family-work factor ( $p=0.024$ ;  $\beta=.53$ ) which had huge effect on engagement in JNMC services, so this hypothesis got accepted<sup>18,19</sup>. Thus, the investigation further expressed that environmental factor ( $p=0.682$ ;  $\beta=.56$ ), job-demand factor ( $p=0.338$ ;  $\beta=.59$ ), structure of organization ( $p=0.148$ ;  $\beta=.61$ ), were not much affecting, so these hypotheses got rejected<sup>1,13</sup>.

**Table III: Regression paths of research model, estimates, critical ratio and P-value**

Hypotheses	Effects	Estimate	S.E.	C.R.	P	Result
H1	MPS <--- EF	.642	.071	6.632	0.115	NotSupported

Source: Survey data and prepared by the researcher

Subsequently after extracting the entire model, structure of organization ( $\beta = .65$ ) is one of the most central determinant of medicinal practitioners' satisfaction, while environmental factor ( $\beta = .58$ ), job-demand factor ( $\beta = .62$ ) and family-work factor ( $\beta = .57$ ) making a decent attempt to have a similar connection between medicinal professionals' satisfaction and determinants of occupational related stress<sup>7,17</sup>. Be that as it may, medical experts' satisfaction distinguished the greatest impact on engagement variable ( $\beta = .72$ ) to create positive proximity of connection between these two factors<sup>2,16</sup>. The consequent components of engagement are additionally impacted by determinants viz., structure of organization ( $\beta = .61$ ), family-work factor ( $\beta = .53$ ) and job-demand factor ( $\beta = .59$ )<sup>7, 20</sup>. It shows structure of organization has been the most impacting factor for engagement and medical practitioners' satisfaction

towards occupational related stress in JNMC<sup>7, 17</sup>.

**Table IV: Estimated Model's Test Statistics**

Fit Index	Recommended Values*	Observed Values
CMIN/DX	<0.30	2.121
GFI	0.90	0.935
AGFI	0.80	0.895
NFI	0.90	0.954
CFI	0.90	0.986
RMSEA	<0.70	0.052

Notes: CMIN/D. F – Chi-square value/degrees of freedom, GFI – Goodness of Fit Index, CFI – Comparative Fit Index, NFI - Normated Fit Index, AGFI – Adjusted Goodness of Fit Index, RMSEA – Root Mean Square Error of Approximation.

Source: Survey data and prepared by the researcher

RMSEA scores beneath 0.10 are commonly considered to be of good signal fit and our value is 0.07, which is a solid match for the model<sup>3,4,6</sup>. Taking all this into consideration, it is demonstrated that all hypotheses are essentially impacting the connection between

dimensions of occupational stress and medicinal practitioners’ that improve the hierarchical picture of JNMC through their engagement in the medical industry for better and efficient services<sup>14,15,16</sup>.

**Figure I: Empirically Validated Model for Occupational Stress and Engagement among Medical Practitioners’ of JNMC**

Source: Survey data

**Discussion and Implications:** This study distinguished the connection between the determinants of occupational related stress and medicinal practitioners’ satisfaction and inspected the effect of these measurements on engagement in JNMC including a sample of 210 practitioners’ to whom structured questionnaire was directed. The outcomes featured that the structure of organization is viewed as the most principal factor among all the measurements for medical specialists’ satisfaction<sup>19,20</sup>. Moreover, medical professionals’ satisfaction applies the best effect on engagement with due understanding of behaviour of

experts’ so that the occupational stress component may not hamper their satisfaction and engagement towards JNMC<sup>13,16</sup>. As far as engagement, family-work factor end up being the most elevated applying factor among all the dimensions created a lot of successful traits in the minds of focused medical professionals’ so they may not misjudge with their work culture, whereas, medical practitioners’ satisfaction is concerned, family-work factor is by all accounts the least ruling factor among all of the dimensions in JNMC<sup>17,18,20</sup>. All of these discoveries could fill in as recommendations for JNMC authorities to assess their relationship and its results for

medicinal practitioners' so it can give pragmatic yield to the medical service industry<sup>2,7,13</sup>.

**Limitations and future research directions:** This research was restricted to exploring the relationship of measurements of occupational related stress on medical practitioners' satisfaction in JNMC. Further examination in different sorts of organizations may give diverse knowledge into the discoveries of this investigation. As indicated by the prerequisite of the separate business, these measurements could be added or changed to fit the association explicit qualities and additional examination is proposed to be done longitudinally so as to evaluate the relationship after some time, nature and area wise. The sample comprised of medicinal practitioners' working in medical care industry and it might be additionally directed among categorical of different practitioners'.

# Validation of the World Health Organisation 5-Item Well-Being Index (WHO-5) among the Adult Population Living in a Chronically Arsenic Affected Area of Rural West Bengal in India

Pallabi Pattnaik

*Research Scholar, Rural Development Centre, IIT, Kharagpur, India*

## Abstract

**Objective:** The aim of this study was to validate the World Health Organisation 5-item well-being index (WHO-5) in a sample of the adult population living in a chronically Arsenic affected area in rural West Bengal.

**Materials and Method:** The reliability was measured through Cronbach's alpha. For evaluating the validity of the construct, Barlett sphericity test and the Kaiser-Meyer-Olkin sample adequacy test was conducted. Exploratory factor analysis was done to study the dimension of factors. Correlations were explored between the WHO-5 scores and study variables.

**Results:** The mean score of the total WHO-5 score was 13.09(SD=5.276). A Cronbach's alpha of 0.794 indicated acceptable internal consistency. The Bartlett's Test of Sphericity was significant (Chi =167.86, df=10, p<0.001). The KMO measure for sampling adequacy was 0.826. So the sample was factorable. Exploratory factor analysis confirmed the one-factor structure that accounted for 56.49% variance with an eigenvalue of 2.825. A significant correlation was observed for WHO-5 with health expenditure and postponement of check-up.

**Conclusion:** The WHO-5 well-being index showed acceptable internal validity and construct validity with a one-dimensional structure.

**Keywords:** *WHO-5 well-being index; Arsenic; Reliability; Validity; Factor analysis.*

## Introduction

Quality of drinking water is very much related to health and socio-economic development<sup>(7)</sup>. Arsenic contamination in groundwater has been reported in Bangladesh, India, China, Vietnam, USA, Argentina, Chile and Mexico<sup>(2)</sup>. Long term exposure to Arsenic

contamination both carcinogenic and non-carcinogenic health effects<sup>(4)(6)(10)(11)(19)(24)</sup>.

The World Health Organisation has defined the general definition of health as "a state of complete physical, mental and social well being"<sup>(27)</sup>. The quality of life is affected by health and subjective well being of the individual<sup>(23)</sup>. To assess subjective well-being of individuals, the World Health Organization (WHO), developed the WHO-Five-Well-being Index (WHO-5), a brief, self-administered questionnaire, consisting of 5 questions evaluating mood, vitality and general interests<sup>(3)</sup>. The WHO-5 has also been successfully used different researchers to assess depression in the elderly<sup>(1)(18)</sup>. However, the amount of published literature intending to ascertain the utility of the WHO-5

as a measure of subjective well being in context to the Indian population are few. This study is carried out to test the validity of the WHO-5 as a measure of subjective well being of the adult population chronically affected by Arsenic contamination in drinking water.

## Materials and Method

**Participants:** The study has been conducted in Basirhat-1 blocks, one of the worst Arsenic affected block in North Twenty Four Praganasin West Bengal<sup>(22)</sup>. Total 14 villages were selected for the study with two villages randomly selected from each of the GP. Out of the currently functional common drinking water sources one common drinking water source was randomly selected for each of the 14 villages. All the randomly selected water sources were found to be Arsenic contaminated<sup>(20)</sup>. By multi-stage random sampling, 125 houses were selected. Door to door survey was conducted with one adult member more than equal to 18 years of age from each family. 116 respondents gave their consent and participated in the study. The study sample size of 116 meets the required sample size for conducting psychometric analysis<sup>(28)</sup>.

**Procedure:** The participants responded to a semi-structured questionnaire capturing socio-demographic characteristics, the Bengali version of the WHO-5 well-being index and the self reported health status. Correlations were studied between WHO-5 scores with socio-demographic status and health status.

The 5-item WHO-5 well-being index (1998 version) is designed with positively worded questions to measure the subjective well being over the past 2 weeks<sup>(23)</sup>. The WHO-5 is available for free in different languages<sup>(26)</sup>. The five items of the WHO-5 are:

1. I have felt cheerful and in good spirits
2. I have felt calm and relaxed
3. I have felt active and vigorous
4. I woke up feeling fresh and rested
5. My daily life has been filled with things that interest me

Each of the above items are rated on a 6 point Likert scale with responses to the questions recorded from 0 (at no time) to 5 (all of the time). The raw score ranges from 0 to 25, with 0 representing the worst possible and 25 representing the best possible quality of life. Low well-being indicates likely depression<sup>(25)</sup>. A score below 13

indicates poor well being and is an indication for testing for depression under ICD-10. It is recommended to administer the Major Depression (ICD-10) inventory if the raw score is below 13 or if the respondent has answered 0 to 1 in any of the five items. To obtain a percentage score ranging from 0 to 100, the raw score is multiplied by 4. A score below 28 is indicative of depression<sup>(16)</sup>.

**Measurements:** A pre-tested, semi-structured door to door interview schedule was carried out to collect the information. For socio-demographic characteristics, age, gender, religion, education, marital status, income and occupation were included. The English version of the WHO-5 was available at the WHO website. The WHO-5 scales were translated from its original English language into Bengali and Hindi language. The translated version was finalised after a pilot study with 13 representative samples. The health status of the respondent was recorded around BMI of the respondent, presence of any disease for more than one year, annual health expenditure of the family, whether an asset was sold for treatment in last one year, whether the respondent has missed any doctor's check-up due to financial issues.

**Data Analysis:** The study was analysed in the Statistical Package for the Social Sciences (SPSS) 20. Internal consistency of the scale was determined by evaluating Cronbach's Alpha. Item-total and inter-item correlations were calculated to assess the reliability of the scale. The validity of the construct was evaluated through exploratory factor analysis. The factorability was determined by Bartlett's test of sphericity and the Kaiser-Meyer-Olkin (KMO) measure of sample adequacy. Then Principal Component Analysis (PCA) was performed to understand the structure of factors. The eigenvalues are the amount of total variance explained by the dimension. Only eigenvalues greater than 1 were retained.

The chi-square test was used to examine the relationship of categorical variables like gender, religion, education level, marital status, occupation, having any disease and postponement of a check-up with WHO-5 scores. Correlations between the WHO-5 with variables age, income, health expenditure and BMI were explored using Pearson correlation coefficients with  $p < 0.05$  considered a significant difference.

## Findings

**Participant Characteristics:** A total of 116 elderly

individuals participated in the study, out of which 52% were women and 48% were men. The sample had a mean age of 36.85 years (SD=10.02). The sample consisted of 66% Muslims community and 34% Hindus. Majority of the study participants, 107(92.24%) were married. With regard to education, 54.3% had studied up primary, 34.5% had studied up to secondary, 1.2% up to higher secondary and rest 9.5% had studied up to graduation. 15.5% of the respondents have kucha house, 29.3% had semi-kucha house, 34.5% had semi-pucca house and 20.7% had pucca house. Agriculture and allied activities were significant livelihood for 36.2% with 21.6% dependent on business activities and 42.2% on Bidi making and other wage activities. About monthly average family income, 16.4% had income less than Rs5000/-, 63.8% had income in the range of Rs5,000/- to Rs10,000/- and rest 19.8% had income more than Rs10,000/-.

**WHO-5 well-being index:** The mean score of the

WHO-5 was 13.09 (SD=5.276) (Table-1). 52 (44.82%) out of the total respondent had total WHO-5 score below 13.31 (51.66%) female 21 (37.50%) male had overall WHO-5 score below 13.69 (59.48%) respondents, 42 (70%) female and 27 (48.21) male had score of 0 to 1 in at least one of the item (Table-2). With regards to a count of 100,16 respondents had a score below 28, out of which 11 were female and 5 were male.

**Table-1: Item Statistics of WHO-5 items and total score**

Items	Mean	Std. Deviation	N
who-1	2.76	1.406	116
who-2	2.69	1.386	116
who-3	2.71	1.451	116
who-4	2.57	1.499	116
who-5	2.36	1.274	116
Total Score	13.09	5.276	116

**Table-2: Age-group wise distribution of respondents and poor well being as per WHO-5 score**

Age (years)	N (%)	Mean Score	SD	% of total score <13	% of N with at least 1 item with score 0 to 1
<26	16(13.79)	12.75	4.31	43.75	8.62
26-35	44 (37.93)	14.55	5.20	36.36	18.10
36-45	34(29.31)	12.50	5.37	52.94	19.83
46-55	19(16.38)	10.95	5.81	57.89	11.21
>55	3 (2.59)	13.67	1.15	0.00	1.72

The Cronbach's alpha for total score was 0.794. The correlations between item scores and the total score of the WHO-5 were high ranging from 0.642 to 0.797 (Table-3). The Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy was 0.826, indicating sample adequacy. Bartlett's test of sphericity was 167.862 (df=10, p<0.001), confirming that factor analysis was justified in the sample. The results of the

exploratory factor analysis confirmed one factor. Only one dimension accounted for 56.49% of total variance with an eigenvalue (Fig-1) of 2.825. This means each of the questions is correlating with others. So there is an underlying dimension being observed by these questions<sup>(13)</sup>. This underlying dimension in WHO-5 is called "subjective well being". Table-4 captures the factor loading of each item.

**Table-3: Inter-Item Correlation Matrix**

Items	who-1	who-2	who-3	who-4	who-5	Total Score
who-1	1	0.546	0.502	0.528	0.408	0.797
who-2	0.546	1	0.447	0.467	0.369	0.753
who-3	0.502	0.447	1	0.561	0.378	0.777
who-4	0.528	0.467	0.561	1	0.319	0.779
who-5	0.408	0.369	0.378	0.319	1	0.642
Total Score	0.797	0.753	0.777	0.779	0.642	1

**Table-4 Factor loadings of WHO-5 questions**

WHO-5 Questions	Factor loading
who-1	0.806
who-2	0.757
who-3	0.777
who-4	0.776
who-5	0.63

**Figure 1: Scree plot of Eigenvalue**

**Correlation of WHO-5 with study variables:**

WHO-5 score was not significantly associated with gender, religion, education level, marital status, occupation and having any disease. WHO-5 was found to be significantly correlated with the postponement of check-up due to financial issues with  $p=0.035$  (Chi-square test). WHO-5 did not differ for age, income and BMI. WHO-5 was found to be negatively correlated with health expenditures ( $r = -0.209, p=0.024$ ).

**Discussion**

The Cronbach’s alpha was 0.794, indicating good reliability. The internal consistency is in good agreement with the findings in other studies. An alpha of 0.88 was

obtained when the local language version of the WHO-5 tool was used for women in Odisha, India<sup>(5)</sup>. In Brazil, a Brazilian Portuguese version of the WHO-5 well-being index amongst the adult population showed an internal consistency of 0.83<sup>(9)</sup>. In a study using the Korean version of WHO-5 amongst the elderly, the Cronbach’s alpha was 0.8<sup>(18)</sup>.

The study found an one-dimensional structure of the Bengali version of the WHO-5 well-being index. Only one dimension accounted for 56.49% of the variance. This confirms that a single underlying factor is assessed by the WHO-5 well-being index. The finding concurs with the findings of the other studies<sup>(9)(18)</sup>.

The mean score of the WHO-5 in this study was found to be 13.09 (SD=5.276). Study of subjective well-being amongst elderly in Indian context has reported mean raw WHO-5 score of 14.80 (SD=5.49)<sup>(21)</sup>. In another study conducted with psychiatric patients, the Iranian version of WHO- showed a mean score of 8.95 (SD=5.49)<sup>(8)</sup>. 52 (44.82%) out of the total respondent had total WHO-5 score below 13 and 69 (59.48%) respondents had score of 0 to 1 in at least one of the item. 16 respondents had score below 28%. This signifies poor well-being status of the study population

The result of a negative correlation between the WHO-5 scores and health expenditure shows that poor well being is positively associated with health expenditure. This finding also resonates with another study <sup>(15)</sup> which found that high health expenditure affects well being and is more pronounced for patients with chronic disease.

**Strengths:** Very few studies have been done to assess the quality of life in India's context by using the WHO-5 questionnaire. This study is first of its kind which studied the subjective well-being of the adult population residing in Arsenic affected Rural West Bengal by using WHO-5 well-being index.

**Limitations:** WHO-5 have been an accepted tool for screening depression and this can be further validated by using tools which validates depressive symptoms.

### Conclusion

The study aimed to evaluate the WHO-5 well-being index scale in the local language to measure subjective well-being in rural areas chronically affected by Arsenic contamination in drinking water. The findings demonstrated that the WHO-5 well-being index is a reliable and uni-dimensional tool. This can be further used to measure subjective well being of the adult population chronically affected with Arsenic contamination in drinking water. The findings also encourage the use of the WHO-5 well-being index in researches related to environmental health.

**Conflict of Interest:** The author reports no conflicts of interest. The author alone is responsible for the content and writing of this article.

**Source of Funding:** The research has been conducted with the funding support of IIT, Kharagpur.

**Ethical Clearance:** The study protocol has been

approved by IIT, Kharagpur and the consent of the participants have been taken individually before conducting the interviews.

# Socio-economic Determinants in the Utilization of Maternal Health Care in India: Exploring National Level Data

R. Vivekanandhan<sup>1</sup>, A.K. Ravishankar<sup>2</sup>, Nawaz Rasool<sup>3</sup>

<sup>1</sup>Research Scholar, <sup>2</sup>Assistant Professor, Department of Population Studies, Annamalai University Annamalai Nagar, Tamil Nadu, <sup>3</sup>Research Scholar, International Institute for Population Sciences, Mumbai, Maharashtra, India

## Abstract

**Introduction:** The maternal health generally refers to the health of women during pregnancy, childbirth and postpartum period. Utilization of maternal health care services has been recognized as a significant factor in influencing maternal and child mortality. The Maternal Mortality Ratio (MMR) estimate for the country indicates an overall decline from 212 in 2007-09 to 178 per one lack live births in 2012, resulting in saving lives of about 9,000 mothers per year<sup>2</sup>. The aim of maternal health care services to reduce infant mortality, maternal morbidity and mortality was recognized at the Cairo Conference on Population.

**Materials and Method:** This paper has utilized the data collected by the National Sample Survey Organization (NSSO) during January -June, 2014. It is a cross sectional dataset available in public domain. The dataset provides information on Social Consumption and Health scenario of the population. To carryout the research, descriptive statistics, bivariate and logistic regression analysis has been used.

**Findings:** The study shows that place of residence, marital status, educational status and wealth index plays an important role in determining the utilization of ante-natal care and post-natal care services. Utilization of services from private sector increases with the increase in the level of socio-economic characteristics. Southern and Western regions of India have 97 percent utilization of ante-natal care and more than 90 percent utilization of post-natal care services in India. Multivariate analysis also depicts close relationship with different predictors as urban place of residence, currently married women, higher educational status and richest wealth category.

**Conclusion:** Place of residence, educational status and wealth index plays an important role in determining the utilization of maternal health care. Western and Southern regions have better utilization of maternal health care services.

**Keywords:** *Ante-natal care, Post-natalcare, Maternal health, Place of delivery.*

## Introduction

Utilization of maternal health care services remained weak in India despite increase in the private and public sectors provision of the health care services. The high maternal mortality, majorly due to disadvantageous position of women, poor quality of services and different factors that affects the utilization of maternal health care services. Women of reproductive age group are still the most-vulnerable population in terms of their health, especially during and after pregnancy. The maternal

health generally refers to the health of women during pregnancy, childbirth and postpartum period. Due to various complications during pregnancy or childbirth, a large section of pregnant women dies annually. Developing countries contribute larger in these deaths. The decline rate of maternal mortality is very slow, but the annual decline required rate is 5.5 percent to meet the MDG target of reducing by three-quarters the maternal mortality ratio by 2015<sup>1</sup>.

There are a range of socioeconomic and cultural

factors that affects the maternal mortality i.e. Status of women, educational and economic status, availability and accessibility facility (distance, transport, etc.) and quality of care (staff, equipment, infrastructure in the health facility).

The aim of maternal health care services to reduce infant mortality, maternal morbidity and mortality was recognized at the Cairo Conference on Population. In order to accomplish it, Andersen's health care utilization and behavior model was adapted for system-level measures and to focus on the availability, accessibility and organization of services. Keeping it in mind the appropriate behavioral model for maternal health care utilization was adopted. This study has included predisposing factors, enabling factors, need factors and environmental variables<sup>2-3</sup>. Existing studies have found that people living in the poorest neighborhoods are least likely to receive adequate care<sup>4</sup>. These deaths were unadjusted and might be avoided with essential health interventions, like provision of antenatal care and medically assist redelivery<sup>5</sup>. Women's autonomy has also been found to be associated with lower child mortality and better maternal and child health<sup>6</sup>.

Differentials in utilization of maternal care services were higher across deprivation levels in the states where service coverage was low than states where service coverage was high<sup>7</sup>. Moreover, income differences in access to maternal care were widening across and within countries as poor women were receiving fewer services than those who are better off<sup>8</sup>. Health care financing between and within countries, with the changes of government. These variations not only have strong implications for income distribution, but also affect the manner of health care utilization<sup>9</sup>.

India is a developing country with a high level of maternal mortality. Government has launched many maternal health care (MHC) programmes to reduce MMR and some other maternal and child health complication. But it still lacks behind to fulfil Millennium Development Goal<sup>10</sup>. So, there is a need to analyze the situation of utilizing the maternal health care services and determining the factors that affects the utilization of maternal health care services in India.

## Materials and Method

This paper has used the data collected by the National Sample Survey Organization (NSSO) during January – June, 2014. This round provides data and information

on Social Consumption and health. The dataset provides enough information related to the prevalence, nature of treatment, level of care and financial expenditure for different morbidity in India.

Descriptive statistics is used to provide simple summaries about the sample and also about the observations that have been made. It is used to show the prevalence of ante-natal care, post-natal care and place of delivery with respect to the different socio-economic characteristics and also with respect to different regions. Binary and multi-variate logistic regression is used to find out the odds of maternal health care with respect to the different predictor variables.

In this study, complete ante-natal care comprises of tetanus injections, IFA tablets and reception of any other services. Incomplete ante-natal care depicts the services who has not received any one of the ante-natal care services. Place of delivery represents the place women has consulted for delivery or abortion.

**Findings:** The table 1 represents the percentage distribution of ante-natal care and post-natal care with respect to the different predictor variables. Women residing in the urban areas show more than 95 percent utilization of complete ante-natal care services. But, the utilization of post-natal care is low in rural areas. Moreover, more than 50 percent, post-natal care in urban areas are received from private services.

Primary educated women show 94 percent of utilizing ante-natal care while secondary and higher educated women show 97 percent and 96 percent respectively. Utilization of post-natal care is also low for primary educated women than secondary and higher educated women. With the increase in educational status, reception of post-natal care from private services is higher than public services. Women belonging to other category show 96 percent of ante-natal care utilization than the women belonging to scheduled tribe (96 percent) and scheduled castes (94 percent). The utilization of post-natal care services is higher for women belonging to others category (88 percent) than scheduled tribe (82 percent) and scheduled caste (83 percent) population.

Women having religious affiliation to Islam show 93 percentage of ante-natal care services and 88 percentage of post-natal care services while Hindus show 95 percent of ante-natal care and 86 percent of post-natal care and others religious category show 96 percent of ante-natal care and 80 percent of post-natal care. Women belonging

to richest wealth quintile shows higher percentage utilization of complete ante-natal services (96 percent) than the women belonging to poorest wealth quintile (94

percent). The utilization of post-natal care also increases with the increase in the wealth quintile from poorest (83 percent) to richest (89 percent).

Source: NSSO 71<sup>st</sup> Round

Figure 1: Percentage distribution of Ante-natal care with respect to the different regions in India.

The figure 1 represents the percentage distribution of ante-natal care with respect to the different regions in India. East India shows 94 percentage utilization of complete ante-natal care while Western, North-Eastern

and Southern India show 97 percent, 97 percent and 96 percent utilization of complete ante-natal care respectively.

Source: NSSO 71<sup>st</sup> Round

Figure 2: Percentage distribution of Post-natal care with respect to different regions in India.

The figure 2 represents the percentage distribution of post-natal care with respect to different regions of India. Northern States of India shows less percentage utilization of post-natal care than Eastern, North East and Central India respectively. Southern and Western India show high percentage utilization of post-natal

care in India. In southern and western regions of India, mainly the services are utilized from private services i.e. 56 percent and 62 percent respectively. North East region of India show 73 percent of services from public sector followed by Central India (65 percent).

Source: NSSO 71<sup>st</sup> Round

Figure 3: Percentage of place of delivery with respect to different regions in India.

The figure 3 represents the percentage distribution of place of delivery with respect to different regions in India. Home delivery is in higher percentage in Northern India and Eastern India than other regions of India. Western and Southern region show 62 percent and 55

percent of private place of delivery respectively. North East, Central and Eastern India show 90 percent, 79 percent and 72 percentage utilization of public place of delivery respectively.

Source: NSSO 71<sup>st</sup> Round

The figure 4 represents the percentage distribution of place of delivery with respect to the different predictor variables. Women residing in the urban areas show 56 percent of private services than the women residing in the rural areas (33 percent). Primary educated women show 2 percent home delivery care than the secondary (0.66) and higher educated women (0.66) respectively. Higher educated women show 77 percent reception of services from private sector than secondary educated (i.e. 50 percent). Women belonging to other category has higher utilization of private place of delivery (43 percent) than the women belonging to scheduled tribe (21 percent) and scheduled castes (28 percent). Women having religious affiliation to Islam has 60 percent public place of delivery than Hindus (58 percent). Women belonging

to richest wealth quintile show 68 percentage utilization of private place of delivery than the women belonging to poorest wealth quintile (21 percent). Women belonging to poorest wealth quintile show 3 percentage of home delivery in India.

### Conclusion

With the increase in the educational status, wealth status, place of residence from rural to urban there is an increase in the utilization of maternal health care. Similarly, the utilization of maternal health care services from private sector also increases with the increase in the levels of these socio-economic characteristics. Western and Southern regions of India show better utilization of maternal health care services than other regions in India.

# Catastrophic Health Care Expenditure on Maternal Health Care in India: Evidence from National Level Data

R. Vivekanandhan<sup>1</sup>, A.K. Ravishankar<sup>2</sup>, Nawaz Rasool<sup>3</sup>

<sup>1</sup>Research Scholar, <sup>2</sup>Assistant Professor, Department of Population Studies, Annamalai University Annamalai Nagar, Tamil Nadu, <sup>3</sup>Research Scholar, International Institute for Population Sciences, Mumbai, Maharashtra, India

## Abstract

**Introduction:** Catastrophic health expenditure is defined as payments for health services exceeding 40% of household disposable income after subsistence needs are met. Utilization of maternal health care services has been recognized as a significant factor in influencing maternal and child mortality. India continues to account for a quarter of all maternal and child deaths at the world level. The cost of health care is comparatively higher in private sector than the public health facilities. Households using private inpatient services are more likely to face catastrophic expenditure.

**Materials and Method:** This paper has utilized the data collected by the National Sample Survey Organization (NSSO) during January-June, 2014. It is a cross sectional dataset available in public domain. The dataset provides information on Social Consumption and Health scenario of the population. To carry out the research, descriptive statistics, bivariate and logistic regression analysis has been used.

## FINDINGS

The study shows that urban sector, primary educated and women belonging to poorest wealth quintile bear high catastrophic health expenditure than their other counterparts. Western and Southern region have low percentage of women going for catastrophic expenditure on maternal health care. The likelihood of catastrophic health expenditure on maternal health care decreases with the increase in wealth quintile from poorest to richest.

**Conclusion:** Place of residence, educational status and wealth index plays an important role in determining the catastrophic health expenditure on maternal health care. Further research needs to be done in exploring the factors that leads to inequity of the expenditure used in the utilization of maternal health care.

**Keywords:** *Ante-natal care, Catastrophic expenditure, Child Health, Maternal health care, Post-natal care.*

## Introduction

The progress in improving maternal health, as envisaged in the UN Millennium Development Goals (MDGs), critically depends on the availability, afford ability and effective use of reproductive health services<sup>1-4</sup>. India is one of the rapidly developing country where health is still a challenge at the national level, although maternal and child health indicators have shown a little or no progress.

India continues to account for a quarter of all maternal and child deaths at the global level<sup>5</sup>. The

maternal mortality ratio in India showed a decline from 301 deaths per 100,000 live births in the period 2001–03 to 254 and 212 during 2004–06 and 2007–09 respectively, but the ratio still lags behind the MDG target of 109 by the year 2015<sup>6</sup>.

People living with poverty, accessibility and unawareness are the major reasons for poor uptake of maternal health care services in India. For example, in Bihar, one of India's poorest states where over 80% of births are home births, approximately 50% of women reported financial concerns as the reason for not opting

for institutional delivery care<sup>7</sup> despite the fact that maternal health care services are provided free-of-charge in public health facilities in India. Majority of states in India has the higher utilization of public maternal healthcare services than the private health care services. The delivery care services utilization has almost equal share with the public and private sectors.

In India, the total health expenditure constituted 4.3% of GDP (2009), with private and public sectors accounting for 78 and 20% respectively<sup>8</sup>. Out-of-Pocket Expenses (OOPE) and catastrophic health expenditure contribute to over 70% and 30% of the total health expenditure respectively. These additional expenses deteriorate and makes the women vulnerable pushing their households further into poverty. Peters et al. estimated that a quarter of the Indian population fall into poverty as a direct result of the medical expenses incurred through hospitalization<sup>9</sup>. Data from the National Sample Survey Organization (NSSO) show an increase in household poverty in both rural and urban India after accounting for OOPE<sup>10</sup>. This has further deteriorated the catastrophic health expenditure on maternal health care.

So far, very less pieces of research are available on catastrophic health expenditure for maternal health care services in India. In many southern and western states of India, the utilization of maternal healthcare is high. Furthermore, catastrophic health expenditure on maternal health care services is neglected by policy makers and planners.

A recent study by Bonuet al. analyzed national data

to examine maternal health care expenditure in Indian households<sup>11</sup>. However, this study does not take into account the indirect costs associated with maternal health care expenditures. The main aim is to consider the socio-economic characteristics that determine the catastrophic health expenditure on maternal health care in India.

### Materials and Method

This paper has used the data collected by the National Sample Survey Organization (NSSO) during January–June, 2014. This round provides data on Social Consumption and health. The dataset provides enough information related to the prevalence, nature of treatment, level of care and financial expenditure for different morbidity in India.

Descriptive statistics is used to provide simple summaries about the sample and also about the observations that have been made. It is used to show the prevalence of maternal health care with respect to different predictor variables and also with respect to different states. Logistic regression is used to find out the odds of catastrophic health expenditure at 40 percent with respect to the different predictor variables.

In this study complete maternal health care comprises of women who has taken ante-natal care and post-natal care. Incomplete maternal health care comprises of women who has taken either ante-natal care or post-natal care. In majority of the literature available, catastrophic health expenditure is measured at 40 percent cut off levels.

### Findings:

Source: NSSO 71<sup>st</sup> Round.

Figure 1: Catastrophic health expenditure at 40 percent with respect to the different predictor variables.

Figure 1 represents the catastrophic health expenditure at 40 percent with respect to the different predictor variables. Women residing in rural and urban areas undergoing catastrophic health expenditure is 17 percent and 14 percent respectively. Rural sector has higher percentage of catastrophic health expenditure than urban sector.

Women who have primary educational status have higher percentage levels of catastrophic health expenditure than secondary and higher educated women. Higher and secondary education status depicts 10 percent and 14 percent of women undergoing catastrophic health expenditure while primary educational status shows 19 percent level respectively. Women belonging to scheduled tribe bear higher catastrophic health expenditure than scheduled castes and others category.

Twenty one percent women of scheduled tribe, 20 percent women of scheduled caste and 15 percent belonging to other category undergo catastrophic health expenditure. Affiliation to Hindu religion depicts 17 percent of women for catastrophic health expenditure at 40 percent level. The catastrophic health expenditure beard by Hindus is higher than women affiliated with Islam (16 percent) and other religious groups i.e. 14 percent. Poorest wealth quintile shows 20 percent women undergoing catastrophic health expenditure. The catastrophic health expenditure decreases with the increase in the wealth quintile from poorest to richest category. Fourteen percent women belonging to richest wealth quintile undergo catastrophic health expenditure on the utilization of maternal health care.

Source: NSSO 71<sup>st</sup> Round.

Table 1 represents the determinants of catastrophic health expenditure at 40 percent on the utilization of maternal health care with respect to the different predictor variables. Secondary and higher educated women are 20 percent and 40 percent less likely to bear catastrophic expenditure on maternal health care than primary educational status respectively. Women affiliated to Islam is 13 percent less likely to have catastrophic expenditure on maternal health care than Hindu affiliated women. Similarly, the likelihood of women belonging to other religious category is 15 percent than Hindus. Women belonging to richer and richest wealth quintile is 13 percent and 15 percent less likely to have catastrophic health expenditure than poorest wealth quintile respectively. As the educational status and wealth quintile increases, the likelihood of women undergoing catastrophic health expenditure decreases.

### Conclusion

With the increase in the educational status, wealth status, place of residence from rural to urban there is an increase in the utilization of maternal health care. Western and Southern region in India are less prone for catastrophic health expenditure on the utilization of maternal health care. Similarly, the catastrophic health expenditure on maternal health care also increases with the increase in the place of residence from rural to urban, educational status from primary to higher and wealth index from poorest to richest.

# Effectiveness of Planned Teaching Programme on Knowledge Regarding Child abuse among Mothers

Rajashri B. Karale<sup>1</sup>, Pradnya Malgi<sup>2</sup>, Vaishali R. Mohite<sup>3</sup>, Samir K. Choudhari<sup>4</sup>

<sup>1</sup>Ph.D. Schooler, Associate Professor, <sup>2</sup>First Year Nursing Student, <sup>3</sup>Dean, <sup>4</sup>Clinical Instructor,  
Krishna Institute of Nursing Sciences, Karad

## Abstract

**Background:** The issue of child abuse is a major global social problem within and outside the homes and among all socio-economic groups of both the developed and the developing nations of whole world.

**Objective:** study investigated the effectiveness of Planned Teaching Programme on Knowledge regarding child abuse among mothers

**Method:** One group pretest post test design was used to conduct the study among mothers totally 100 mothers with 3-6 years of children were selected by Purposive sampling technique. Study conducted at Malkapur Anganwadi, Karad. Data was collected by using structured questionnaire. Pre-test was conducted to assess the existing knowledge of mother regarding child abuse. Then Planned Teaching Programme was conducted on child abuse. Post-test conducted after seven days of planned teaching programme.

Results: The pre-test mean was 11.75 where post-test mean was 15.81 and calculated t value was 12.907 found significant at the level of  $p < 0.0001$ .

Conclusion: Planned teaching programme was found to be very effective for improving knowledge of preschooler mothers regarding child abuse.

**Keywords:** Child abuse, planned teaching programme, mothers.

## Introduction

The issue of child abuse is a major global social problem within and outside the homes and among all socio-economic groups of both the developed and the developing nations of whole world. The World Health Organization (WHO) defines child abuse as all forms of physical, emotional and sexual abuse, neglect and exploitation leading to actual and potential damage to a child's health and development.<sup>[1]</sup> Child abuse is a state of

emotional, physical, economic and sexual maltreatment meted out to a person below the age of eighteen and is a globally prevalent phenomenon. Government of India study on child abuse the findings of the Study on Child Abuse clearly point out that a large number of children in India are not even safe in their homes.<sup>[2]</sup> Child abuse occurs all religions and at all levels of education at every socioeconomic level, across ethnic and cultural lines.<sup>[3]</sup>

Prevention of child abuse is an inevitable part of the society. The impact of child maltreatment can be profound. Child abuse has harmful outcome in children and adolescents that can extend into adulthood. Abused children often suffer physical problems and stress that may disturb early brain development. Children who are abused are at higher risk for health problems such as depression, alcoholism, drug abuse, smoking, suicide and certain chronic diseases.<sup>[4]</sup> Child abuse represents

a deviation in a basic social function, namely caring for socializing a child until he reaches independence.<sup>[5]</sup> Family is the most important and influential factor on education. Children's are talented from the birth to get what they observe and listen from others. Therefore, the family could be the first educational environment for child. Child abuse occurs for various reasons, including risk factors in parents and caregivers, risk factors in children, relationship factors, community and social factors.<sup>[6]</sup>

Child abuse can have damaging effects not only on the children who suffer it, but on communities that must address the aftermath of abuse.<sup>[7]</sup> According to data from National Statistics on Child Abuse reports that nearly five children die every day in America from abuse and neglect. In 2011, an estimated 1,570 children died from abuse and neglect in the United State. <sup>[8]</sup> However, in India, as in many other countries, there has been no understanding of the extent, magnitude and trends of the problem.<sup>[9]</sup> It has found that in developing countries like India, the problem of child abuse exist in severe forms and is interrelated with poverty, malnutrition, communicable diseases. <sup>[5]</sup> Hence we felt there is need to select this study and to assess the knowledge of mothers regarding child abuse and improve mother's knowledge regarding child abuse.

### **Method:**

One group pretest posttest design was used to conduct the study among mothers totally 100 mothers with 3-6 years of children were selected by Purposive sampling technique. The samples included in this study were who fulfilled the inclusion criteria with who were willing to participate in the study, mothers who had child between age group of 3-6 years were included in the study. Ethical permission was obtained before the data collection. After obtaining permission from the setting, the patients were asked their willingness to participate in the study and informed consent was obtained. Study conducted at Malkapur Anganwadi, Karad. Data was collected by using structured questionnaire. Pre-test was conducted to assess the existing knowledge of mother regarding child abuse. Then Planned Teaching Programme was conducted on child abuse. Post-test conducted after seven days of planned teaching programme

Statistical analysis used: To compare the two means Paired t test was used and to find out association between demographic variables and pretest knowledge score Chi Square test was used.

## **Results**

**Description of sample characteristics:** Most of 34 (34%) mothers were in the age group of 26-28 years, the remaining 24 (24%) were in the age group of 20-22 years and age group of 23-25 years. Majority 42 (42%) mothers having two children and 40 (40%) mothers having one child. As regards to education 36(36%) mother had taken secondary education, 34 (34%) had taken under graduate education and 22 (22%) had illiterate. Most of mother 42 (42%) mother were housewife, 27 (27%) were business women. Regarding monthly income 35 (35%) had monthly income Rs. 5, 000-10,000, followed by 29 (29%) had income Rs. 11,000-15,000. Majority of mothers belonging from joint family i.e. 53 (53%) and total 47 (47%) mothers are from nuclear family. In relation to religion 50 (50%) of the mothers belongs to Hindu family, total 20 (20%) were Muslim and 18 (18%) were Christian. Majority of 43 (43%) mothers had 3-4 year and 4-5 year children's and only 14 (14%) mother had children's 5-6 year children's. Majority children's were male i.e. 59 (59%) and 41 (41%) were female children. Most of the 33 (33%) of women getting information from television and newspaper about child abuse, 22 (22%) mothers received from mobile, only 2 (2%) got information from other resources.

**Knowledge of mothers regarding child abuse:** Data presented in Table no. 1 majority of mothers 56(56%) had average knowledge, whereas 37 (37%) had good knowledge and 7(7%) poor knowledge regarding child abuse before administration of planned teaching programme. Most of the mothers 82 (82%) had good knowledge, whereas 17 (17%) had average knowledge and only 1 (1%) poor knowledge regarding child abuse after administering planned teaching programme.

**Effectiveness of planned teaching programme regarding mother's knowledge about child abuse:** Table no. 2 shows that the mean and standard deviation of knowledge score obtained before and after the administering the planned teaching programme. This is considered to be extremely significant improvement in knowledge regarding child abuse. The pre-test mean was 11.75 and post-test mean was 15.81 and calculated t value was 12.907 found significant at the level of  $p < 0.0001$ .

The association between pre-test knowledge score on mothers regarding child abuse with their demographic variables.

Table no. 3 reveals that there is significant association between mother’s knowledge with variable of Religion, Monthly income of family and Education of mother at the level of  $p < 0.05$  other variables like Age, Number of children, Occupation of mother, Type of family, Age of child, Sex of child and Source of getting information about child abuse was not found significant association between mother’s knowledge at the level of  $p < 0.05$ .

**Table No. 1: Pre-test and post-test Knowledge of mothers regarding child abuse:**

Phase	Knowledge score	Pre-test Knowledge		Post-test knowledge	
		Frequency	Percentage	Frequency	Percentage
Poor	0-6	7	7%	1	1%
Average	7-13	56	56%	17	17%
Good	14-20	37	37%	82	82%

**Table No. 2: Pretest and Posttest Mean and SD regarding mother’s knowledge about child abuse:**

Pre Test		Post Test		t value	P Value
Mean	SD	Mean	SD		
11.75	4.205	15.81	2.718	12.907	<0.0001

### Discussion:

The present study was held to assess the Effectiveness of planned teaching programme on knowledge regarding child abuse among the mothers. The result shows that the pre-test knowledge that is 56(56%) had average knowledge, whereas 37 (37%) had good knowledge and 7(7%) poor knowledge regarding child abuse. The result shows the pre-test mean was 11.75 and post-test mean was 15.81 and calculated t value was 12.907 found significant at the level of  $p < 0.0001$ . Which means planned teaching programme was found effective to improve the knowledge of the mothers regarding child abuse. It also found that there is significant association between mother's knowledge with variable of Religion, Monthly income of family and Education of mother at the level of  $p < 0.05$ .

For confirming result of the present study it can pointed out the study of Taniya Thapa et al. The findings of the study revealed that majority of mothers 224 (77.8%) had average level of awareness regarding girl child abuse and only 21 (7.3%) had good level of awareness with mean score  $\pm$ SD of 45.94  $\pm$  9.94 (total score-76).<sup>[3]</sup>

Study conducted to Assess the Level of Knowledge Regarding Child Abuse among the Mothers in Selected Areas at Latur, findings of the study concluded that 15% (03) samples are having inadequate knowledge, 85% (17) sample are having moderately adequate knowledge and 0% samples having adequate knowledge. <sup>[2]</sup>

A study conducted by Jyotsna Jacob et al. Study results shows that majority of the mothers (60%) had average level of knowledge; about 30% of the mothers had good level of knowledge whereas only 3% had poor knowledge level. The overall mean knowledge score of

mothers on prevention of child abuse is  $16.72 \pm 2.947$ .<sup>[4]</sup>

A study conducted with title of Effectiveness of Planned Teaching Program on knowledge of "Child Abuse and its Prevention" among mothers of school aged children, study results shows that the significance of difference between pre-test and post-test knowledge scores of mothers which was tested and founded to be ( $t_{49} = 17.802$ ,  $p < 0.05$  significant). The findings of the study show that the planned teaching programme was effective in all the areas for improving the knowledge of "child abuse and its prevention" of the mothers of school of school age children.<sup>[10]</sup> The result of the present study and other studies shows that the mother had lack of knowledge regarding child abuse; there is a need of some intervention to provide awareness so that mother's knowledge gets improved regarding child abuse.

### Conclusion

Based on the analysis of the findings, the study concluded that Planned Teaching Programme was found effective to improve the Knowledge regarding child abuse among mothers.

**Acknowledgement:** Our sincere thanks goes to all the study participants who have provided us their valuable time and willingness to participate in the study.

**Conflicts of Interest:** There are no conflicts of interest.

**Financial Support and Sponsorship:** Nil

## Abstract

**Background:** Although Dental Caries and Cardiovascular Diseases CVDs share certain common risk factors, its effect on the development of caries needs to be established.

**Objectives:** To find any association, if present between cardiovascular risk factors and dental caries.

**Material and Method:** This case-control study employed a stratified random sampling with every 10<sup>th</sup> patient visiting the OPD was asked for voluntary participation in the study. Following a written consent, participants underwent height, weight and blood pressure measurement, diagnosis of dental caries using the DMFT index and collection of blood sample (FBG and lipid profile). Increase in values in any of the above criterias (except DMF) or having a history of smoking were included as the cases. Data were transferred to SPSS version 21.0 and the students paired samples t-test and multiple logistic regression were applied. Values were considered significant when p was  $\leq 0.05$ .

**Results:** Caries incidence (mean DMF) was higher in cases (3.54 $\pm$ 2.8) as compared to controls (2.74 $\pm$ 2.1) with significant differences between mean DMF (.03), BMI (0.003) and TG (0.01) observed among cases. A statistical significance (p=.01) was observed especially when DMF was  $\geq 5$ . Multivariate logistic regression revealed a significant association in relation to DMF(0.90-1.02), FBG(0.47-0.81) and TG(0.40-0.91). The odds of the cases having elevated diastolic blood pressure and TC was 1.09 (CI:0.95-1.26) and 2.42 (CI:1.68-3.49) times higher as compared to controls.

**Conclusion:** The need of dentists as well as medical practitioners to provide anticipatory guidance to their patients having presence of cardiovascular risk factor (s) and/or increased DMF scores is emphasized to help reduce the burden of both these diseases.

**Keywords:** Cardiovascular Diseases, Dental Caries, Risk Factors.

## Introduction

Cardiovascular diseases (CVD) have the highest mortality rates worldwide.<sup>1</sup> By the year 2020, approximately three-fourth of all deaths within developing nations can be attributed to non-communicable diseases

(NCD) amongst which, CVD shall remain a vital reason for those deaths.<sup>2-4</sup> Risk factors that make the cardiovascular system susceptible to diseases are now being embraced by young adolescents and those leading a high-risk lifestyle may have an increased susceptibility towards CVDs later in life.<sup>3,4</sup> Risk factors for CVD have also been related to dental caries and poor oral hygiene.<sup>5-7</sup>

As per WHO, an estimated 17.9 million people died from CVDs in 2016 representing 31% of all global deaths with over three quarters of these deaths taking place in low- and middle-income countries. In the India, CVDs accounted for around one-fourth of all deaths and grew at an annual pace of 9.2% between 2005-2015. The incidence of CVDs has increased significantly (24.8%) among people aged 25-69 years implying a loss of people in their productive ages.<sup>8</sup>

Dental caries can severely compromise oral health status of an individual. Dental caries and CVDs share certain common risk factors (e.g. smoking, tobacco chewing, obesity, diet and physical inactivity). In India, the prevalence of dental caries varies from 50-60%<sup>9</sup>, to 82.4% in urban<sup>10</sup> and 80% in rural areas.<sup>11</sup>

Clinicians have tried to establish a link between cardiovascular risk factors and dental caries. Kelishadi R et al. (2010) revealed a significant association between dental caries and CVD risk factors.<sup>12</sup> Similarly, in 1995 Lohman TG et al. documented that adolescents with two or more medical factors reaching unfavorable levels had significantly higher incidence of caries (when DFS $\geq$ 9), Making it seem that the presence of cardiovascular risk factors might increase dental caries in an individual.<sup>14</sup>

**Objectives:** To find any association, if present between cardiovascular risk factors and dental caries and how these risk factors could be modified for an overall benefit of the patients.

## Material and Method

The present study adopted a case-control study design among patients visiting the OPD of the Department of Public Health Dentistry, I. T. S Dental College, Hospital and Research Centre, Greater Noida. Prior to the commencement of the study, a due clearance was obtained from the Institution's Ethical Committee vide letter number IEC/PHD/02/12.

Before recruitment, a signed informed consent was

obtained from the patients which was available in both English and Hindi (local language) after duly explaining the study protocol, voluntary participation, risks and procedures involved by the investigators.

The patients were selected through stratified random sampling with selection of every 10<sup>th</sup> patient visiting the OPD. Over twelve months and keeping the case: control ratio as 1:1, the study recruited 100 patients. Patients aged 20 years and above and consenting to participate were included in the study while those suffering from any systemic disease were excluded.

Three examiners were duly standardized according to current norms (inter examiner kappa,  $\kappa$  value = 0.6-0.8) and recorded a detailed case history of the patient. The following protocol was then followed: 1). Measurement of height and weight, 2). Measurement of Blood pressure (BP) using mercury sphygmomanometer. The readings at the first and the fifth Korotkoff phase were taken as systolic and diastolic BP (S BP and DBP), respectively.<sup>14</sup> The average of the three BP measurements was recorded and included in the analysis. 3). Diagnosis of Dental Caries: Using direct illumination from the dental chair, dental caries was checked using a sickle explorer, flat-surface mouth mirror after drying teeth with sterile gauze (ADA type 3 examination) and was evaluated using the DMFT index (Klein, Knutson & Palmer, 1997 modification) and 4). Collection of blood sample: On the next day after oral screening, the patients were instructed to fast overnight for 12 hours and report to the attached hospital. The compliance with fasting was determined by an interview in the morning. Blood samples were taken from the antecubital vein between 8:00 and 9:30 AM and were centrifuged for 10 min at 3000 rpm within 30 min of venipuncture. Fasting blood glucose (FBG), total cholesterol (TC), high density lipoprotein cholesterol (HDL-C), low density lipoprotein cholesterol (LDL-C) and triglycerides (TG) were measured by enzymatic method using autoanalyzer (Merck microlab 300). HDL-C was determined after dextran sulphate-magnesium chloride precipitation of non-HDL-C.<sup>15</sup> The autoanalyzer was calibrated prior to the commencement of the study. Participants were given refreshments and were advised to have a proper meal before commencing their daily duties.

CVD risk factors were defined by identification of study subjects who were at a high risk of developing CVD which were BMI $\geq$ 85th percentile for age and sex, TC >200 mg/dL, LDL-C >100 mg/dL, TG >160mg/dl

(males), >135mg/dL (females), HDLC < 35 mg/dL was considered to be low as well as systolic and diastolic blood pressure >90th percentile for age, sex and height. According to the recommendations of the Indian Diabetic Association, FBG  $\geq$  110 mg/dL was considered to be elevated. Patients with any of these risk factors, or having a history of smoking (in combination to the above factors or alone), were considered as the cases (Figure 1). Data were transferred to SPSS version 21.0<sup>16</sup> via a blinded operator. After application of descriptive statistics, students paired samples t-test and multiple logistic regression were applied for statistical analysis. Values were considered significant when p was  $\leq$  0.05.

## Results

The assessed variables are shown in table 1. Among cases, there were an equal number of males and females (25 each), while the control group consisted of 27 males and 23 females. The mean age of cases and controls were 41.6 $\pm$ 17.02 and 42.8 $\pm$ 17.3 respectively. Caries incidence was seen to be higher in cases (3.54 $\pm$ 2.8) as compared to controls (2.74 $\pm$ 2.1). Significant differences between the mean values of DMF (.03), BMI (0.003)

and TG (0.01) between the case and control groups were observed.

The mean DMF scores of cases and control are depicted in table 2. Analysis revealed a statistical difference in the t-values of both the groups, respectively (p=.03). The DMF values were further divided into four categories: DMF=0, DMF $\leq$ 3, DMF $\leq$ 5, DMF>5 and a statistical significance (p=.01) was seen DMF was >5, leading to an indication that people with presence of cardiovascular risk factors might be prone to have increased DMF scores.

Table 3 depicts the analysis of the multivariate logistic regression between the cardiovascular risk factors and dental caries among the study population. A significant association between the cases and controls in relation to DMF (0.90-1.02), FBG (0.47-0.81) and TG (0.40-0.91) while as compared to other variables. (p>0.05). It was revealed that the odds of the cases having elevated Diastolic Blood Pressure (1.09, CI: 0.95-1.26) and TC levels (2.42, CI: 1.68-3.49) was higher as compared to the controls.

**Discussion**

The significant association found between dental caries and cardiovascular risk factors in the present study can often make a clinician the first line to suspect the presence of potential cardiovascular risk factors and ultimately help reduce the global burden of such a disease and promote healthy lifestyles among patients.

The significant differences in DMF (p=.03) and in particular, among cases having DMF>5 (p=.01) was one of the main highlights of the study and is supported by Kelishadi et al.<sup>12</sup> Although there is a strong evidence of a relationship between periodontal disease and cardiovascular disease, very few studies have explored the association between dental caries and the presence of cardiovascular risk factors.<sup>17</sup> Despite all efforts (use of mass media, regular screenings, promoting tooth brushing, using fluoride in either systemic and topical form) directed towards improving the oral hygiene among people, dental caries still remains as one of the most common prevalent dental diseases across the globe.<sup>18</sup> In contrast, although case control studies by Simonka M et al.<sup>19</sup> and Ziebolz et al.<sup>20</sup> did not find any significant differences between acute coronary syndrome and dental caries, we can safely assume that

difference in DMF in cases can be related to the presence of cardiovascular risk factors as both groups belonged to the same region and used the same aids for oral hygiene maintenance.

Among the five lipid profile variables assessed, only FBG and TG were seen to have a significant association with DMF among cases and is partially supported by Kelishadi R et al.<sup>12</sup>, Loyola-Rodriguez JP et al.<sup>21</sup> and Johansson I et al.<sup>22</sup> Concepts regarding dental caries in the 20th century indicated the presence of lipids in the dentin of carious teeth with decays being described as “fatty degradation” of the tooth.<sup>23</sup> Studies have documented that saliva of people without carious lesions contains lesser amounts of less free fatty acids, triglycerides, cholesterol esters and phospholipids and slightly lesser concentrations of cholesterol and mono and di-glycerides.<sup>24,25</sup> Adolescents have been documented to show increased concentration of triglycerides and total cholesterol in saliva during the course of dental decay.<sup>26</sup> The above associations were however, contradicted by the results documented by Timonen P et al.<sup>27</sup> and Larsson B et al.<sup>13</sup>

The odds of the cases having elevated Diastolic Blood Pressure was found to be 1.09 (CI:0.95-1.26). A

thorough literature search did not present the evidence of any direct association, however few patients belonging to the sample of hypertensive patients (Kumar P et al.) documented an increased incidence of dental caries attributed to the hypo salivation in patients under anti-hypertensive therapy; and also reported association between hypertension and gingival/periodontal pathology in their sample population.<sup>28</sup>

A limitation of the study in could be the erroneous reporting of fasting duration by the study participants. Barring three cases (who could not be contacted), the remaining were advised to undergo further medical screening and/or adopt healthy lifestyle practices and this is the strength of the study as it promotes an early intervention leading to a reduction in burden of disease among cases. In future studies of the same kind but with a bigger magnitude, we hope that the cases of the present study could be included as controls.

### Conclusion

The results of the present study provides an avenue for future research to further furnish evidence on the effect of cardiovascular risk factors on dental caries. We advise both dentists and medical practitioners to be aware of such an association and provide anticipatory guidance to potential patients. The need for interdisciplinary co-ordination with dieticians, nutritionists and other departments can lead to adoption of healthy lifestyles among patients and is strongly advised.

# A Review of Glass Ionomer as ‘ART’ Sealant

Savil R Uchil<sup>1</sup>, Baranya Shrikrishna Suprabha<sup>2</sup>, Arathi Rao<sup>3</sup>

<sup>1</sup>Post Graduate Student, <sup>2</sup>Professor and Head, Department of Pediatric and Preventive Dentistry, <sup>3</sup>Professor, Department of Pediatric and Preventive Dentistry, Manipal College of Dental Sciences, Mangalore, Manipal Academy of Higher Education, Manipal, India

## Abstract

Pit and fissure sealants are a highly effective method for prevention of dental caries by forming a physical barrier, preventing accumulation of micro-organisms and food debris in the fissures. Currently, resin-based sealants and glass-ionomer sealants are the two main forms of sealants used clinically. Resin-based sealants are highly moisture sensitive and hence, glass-ionomer sealants which are less sensitive to moisture are used. With the advent of the Atraumatic Restorative Treatment (ART), high-viscosity glass-ionomers were introduced as ART sealant, which are retained longer than low and medium viscosity glass-ionomers, but shorter than resin-based sealant materials. Use of ART sealants is an effective caries preventive approach in partially erupted young permanent molars of children and in community based dental programs where electrically powered dental equipment is not available.

**Keywords:** *Atraumatic restorative treatment, Resin-based sealants, Glass-ionomer sealants.*

## Introduction

Pit and fissure sealants are highly effective method that helps in preventing caries development and arresting caries progression, by forming a physical barrier which helps in preventing accumulation of micro-organisms and food debris in the fissures<sup>(1)</sup>. In the current scenario, resin-based sealants and glass-ionomer sealants are the two main forms of sealants used clinically. However, the efficiency of resin-based pit and fissure sealant in preventing occlusal caries is dependant primarily on the retention of sealant mainly the moisture control, which may not be available in some situations like community

based dental programs, uncooperative children, partially erupted permanent molars and contamination of the operating field.<sup>(2,3)</sup> In these conditions, the rate of failure are higher for resin-based sealants and hence glass-ionomer based sealants can be used which are less moisture sensitive.<sup>(2)</sup>

Glass-ionomer materials are easy to apply than resin sealants and chemically bond to the tooth structure and release fluoride, which contributes to caries prevention.<sup>(4)</sup> Glass-ionomer sealants have the disadvantage of poor retention and reduced strength, hence strengthened high viscous glass-ionomer sealant can be used, using Atraumatic Restorative Treatment (ART) technique.<sup>(4,5)</sup> ART is a preventive and restorative technique implemented 25 years ago, in management of dental caries in underprivileged populations. ART approach involves the restoration of tooth cavities and sealing of caries-prone pits and fissures.<sup>(6)</sup> For ART, the material of choice is strengthened highly viscous glass-ionomer cement, which has rapid setting property, significantly decreased sensitivity to moisture during the initial setting stage and decreased solubility in oral fluids, which makes it suitable to be used as sealants.<sup>(7)</sup> Application of ART sealant uses a form of glass-ionomer cement material to seal pits and fissures

using a “finger-press” technique similar to that used in the ART restoration procedure. When comparing to low viscosity glass-ionomer sealant it has been observed that retention rate of ART sealants was higher.<sup>(8)</sup> For a long term, low-viscosity glass-ionomers with the powder liquid ratio less than 1.5:1 was used although it had poor retention and did not provide caries preventive effect. Till mid 1990s medium-viscosity glass-ionomers sealants but over the years it was replaced by the high-viscosity glass-ionomers.<sup>(9)</sup>

**When are ART sealants indicated?:** Children with high caries risk, with presence of decay in primary dentition, tortuous pits and fissures on non-carious teeth and persistent enamel lesions are indicated for use of ART.<sup>(10)</sup> Application of sealants to deep pits and fissures, regardless of child’s risk status must be deemed over-treatment.

In comparison to the resin-based sealants, glass-ionomers are hydrophilic in nature and hence they are indicated in partially erupted molars, where the operculum covers the distal half of the tooth and releases crevicular fluid. In case of moist to dampened conditions, application of resin-based pit and fissure sealant is contra indicated as they are Bis-GMA based materials, which are mainly hydrophobic in nature and necessitates a dry field. Electrically powered dental equipment and good clinical conditions are required for placement of high quality resin-based sealant. In community based programs where availability of modern equipment is limited, ART sealants should be the choice of sealants.<sup>(2)</sup>

**Placement of ART sealants:** The technique is characterised by the “press-finger” method, which ensures that the sealant penetrates deep into the pits and fissures.<sup>(8)</sup> A thorough oral prophylaxis and polishing, is followed by rinsing with water to remove any traces of polishing material. Isolation of the tooth is done with cotton rolls and kept free from saliva. 10% polyacrylic acid conditioner is applied on the fissures for 20 sec, rinsed with water for 20 sec and dried by blotting with cotton pellets and gently blowing with an air syringe. Care should be taken not to desiccate the enamel surface. Glass-ionomer cement is mixed in accordance to the manufacturer’s instruction and applied using the round end of the ART applicator/carver in all pits and fissures or agitate the encapsulated glass-ionomer in an appropriate mixing machine and the material is expelled into deep retentive grooves. A thin layer of petroleum jelly is applied on to the gloved finger and

pressed against the sealant, such that the sealant is pressed deeply into the grooves and after 10-15 sec, the finger is removed sideways and excess cement which is visible is removed using carver/excavator (press finger technique).<sup>(11)</sup> Bite is checked using articulating paper and adjusted until comfortable. When the mixture is partially set, petroleum jelly is removed from the top surface and a new layer is applied. To surmount the problem of moisture sensitivity and to retain the water balance during maturation, petroleum jelly is applied over the sealant material immediately following the initial set. Patient is asked not to eat for at least one hour.<sup>(4,12)</sup>

**Clinical performance of low viscosity ART sealants:** In a systematic review by Beirut et al<sup>(5)</sup> on the effectiveness of prevention of caries by resin sealants in comparison to low-viscosity glass-ionomer sealants, out of 12 eligible publications analyzed, two studies depicted statistically significant difference in caries prevention. After 3.8 years, in one study, low viscosity glass-ionomer sealant performed better, while after 3 years the auto-curing resin composite sealant performed better in another study. Four studies reported results of more than 3 to 7 years, of which two studies reported statistically significant difference in the two forms of sealants in preventing development of dentine lesions. However, due to lack of enough studies the systematic review was unable to prove that either of these materials was superior to the other. A critical review by Simonsen<sup>(13)</sup> suggested that the efficiency of caries-prevention was equivocal between composite resin and glass-ionomer sealants. However, retention rate of composite resin sealants is higher in comparison to low viscosity glass-ionomer sealants. Torppa-Saarinen and Seppa<sup>(14)</sup> also reported low retention rate of low-viscosity glass-ionomer. They examined the pits and fissures of recently erupted permanent second molars and premolars under scanning electron microscope (SEM) which had partial or complete loss of low-viscosity glass-ionomer sealant after 4 months. In majority of the cases examined, the deepest part of the grooves showed presence of low viscosity glass-ionomer. The small quantities of sealants are left at the bottom of the fissures tend to release fluoride and serves as a plug and the tags of glass-ionomer cement persist when applied even under moist conditions.<sup>(9,15)</sup> The remnants render the pit and fissures to be of less than normal depth, thus permitting better plaque control and prevention of demineralization.<sup>(12)</sup> In vitro studies<sup>(15,16)</sup> have revealed

initial release of large amount of fluoride from the glass-ionomer cement (burst effect). The fluoride release continues over the next few weeks, possibly due to slow dissolution of the glass particles into acidified water of the hydrogel matrix. Thus, inspite of the loss observed during examination, protection of the fissures against dental caries continues both due to physical presence of the tags, release of fluoride which help in enamel remineralization and increase in surrounding enamel resistance to demineralization.<sup>(17)</sup>

**Clinical performance of high viscosity ART sealants:** With the introduction of high-viscosity glass-ionomers, the rate of retention of glass-ionomer (ART) sealants increased significantly compared with that of previously used low and medium viscosity glass-ionomers.<sup>(6,8)</sup> Better retention of ART sealants is due to better mechanical strength and due to application procedure using press finger technique, resulting in better penetration of the material into the fissures.<sup>(18)</sup> A meta-analysis exhibited a weighted mean score of 71% after 3 years for completely and partially retained ART high viscosity glassionomer sealants, while during the 3 year observation period the caries-preventive value was 97%<sup>(8)</sup>. Systematic review by Mickenautsch and Yengopal<sup>(19)</sup> suggested that teeth sealed with high viscosity glass-ionomer cement are 71% less likely to be affected by dentine carious lesions than if sealed with composite resin.

Multiple studies have shown that the effectiveness of caries-prevention of high viscosity glass-ionomer sealants applied using ART was higher than that of resin sealants.<sup>(3,5)</sup> In a study carried out in newly erupted permanent molars, where it is difficult to isolate the tooth from saliva contamination during sealant application, at 5 year follow up, 29% of glass-ionomer sealants applied with ART procedure were retained, whereas only 21% of resin sealants were retained. 22% of teeth developed caries in the resin group in comparison to 11% in the glass-ionomer group<sup>(3)</sup>. Similar findings were seen by Taifour et al.<sup>(20)</sup> They concluded that ART sealants is an effective measure for caries prevention in newly erupted molars among children with high risk of caries. Compared to the complete and partial-retention survival percentage of resin-based sealants, the comparable retention survival of high viscosity glass-ionomer sealants used according to ART technique is lower.<sup>(6,12)</sup> On the other hand, Hilgert et al<sup>(18)</sup> did not find difference between the retention rate of resin sealants and glass-ionomer ART sealants at 3 year follow up. In this study<sup>(18)</sup>, as well as

a study carried out in Chinese population<sup>(6)</sup>, occurrence of new carious lesion lagged sealant survival. Caries prevention remained high, 85% at 6 year follow up. However, to prevent cavitation it was recommended that missing sealants should be further resealed.

Use of additional measures such as application of topical fluorides or application of curing light does not improve the caries preventing ability of ART sealants. This was shown in a study by Liu et al<sup>(4)</sup>, where application of sodium fluoride or silver diamine fluoride did provide any additional benefit. In another study, Chen et al<sup>(21)</sup>, did not find any additional benefit in caries preventing ability of ART sealant by addition of light curing of the glass-ionomer sealant.

For describing the success rate of a sealant, retention of sealant alone should not be considered as the endpoint, as the biological outcomes take preference over mechanical outcomes.<sup>(12)</sup> Complete retention of fissure sealants is therefore not a valid surrogate endpoint for evaluating their caries-preventive effect. The caries preventive effect is more significant than sealant survival.<sup>(19)</sup> The reason for better caries prevention ART sealants was further investigated by Frencken and Wolke.<sup>(15)</sup> They evaluated high viscosity glass-ionomer sealants placed according to ART technique under SEM. Traces of high viscosity glass-ionomer sealant material were left behind in the deeper parts of pits and fissures that clinically appeared to be free of sealant material. These remnants of sealants retain probably because unlike resin-based materials, which tend to have adhesive fracture, glass-ionomer fractures cohesively.

**Comparison of ART sealants with other pit and fissure caries prevention method:** A study by Cabral et al<sup>(22)</sup> compared the effectiveness of preventing caries and the retention rates of resin modified glass-ionomer based fluoride varnish used as pit and fissure sealants and high viscosity glass-ionomer sealant applied according to ART approach. High-viscosity GIC performed better than the resin modified GIC based fluoride varnish over 2 years in terms of retention, however, results were not statistically significant for caries prevention. Monse et al<sup>(23)</sup> measured and compared the impact of a single application of 38% SDF with ART sealants and no treatment for the prevention of caries on the occlusal surfaces, with a school-based tooth brushing program with fluoride over 18 months. They concluded that single application of 38% SDF is not an efficient technique in preventing carious lesion.

Thus, in comparison to other materials like glass-ionomer based fluoride varnish and silver diamine fluoride, ART sealants have better retention as well as caries preventing ability.

Adding to the benefit of glass-ionomer as ART sealants, most of the resin-based sealants release Bisphenol A (BPA) derivatives which have been known to cause various biological disorders.<sup>(12)</sup>In accordance with this evidence a policy statement on BPA was issued by the World Dental Association (FDI). This policy discouraged the need of manufacturing of BPA containing dental materials, raised awareness and emphasized the need of preventing caries.<sup>(24)</sup> Therefore use of ART sealants with their high level of effectiveness, has a future scope in caries management.

Further studies are required to prove the effectiveness of high viscosity glass-ionomer sealants in caries prevention as the current studies are limited by risk of bias, lack of sufficient sample size and inadequate randomization. Hence, the choice of high viscosity glass-ionomer sealant for caries prevention of fully erupted permanent molars should be done cautiously based on clinical indications.

### Conclusion

Retention and caries prevention of high viscosity glass-ionomer sealant appears to be longer in comparison to low and medium viscosity, although it is shorter than resin-based sealants. The use of ART sealants in permanent teeth to prevent and treat tooth decay is shown to be highly appropriate, effective and acceptable. It is an effective caries preventive approach in partially erupted young permanent molars of children and in community based dental programs where electrically powered dental equipment is not available.

# Treatment Seeking Pattern of Relapse Cases of Substance Use Disorder in Bangladesh

Iqbal Masud<sup>1</sup>, Mohammad Hayatun Nabi<sup>2</sup>, Tasnuva Humaira<sup>3</sup>,  
Amir Hussain<sup>4</sup>, Farah Naz<sup>5</sup>, Sanjana Zaman<sup>6</sup>, Mohammad Delwer Hossain Hawlader<sup>7</sup>

<sup>1</sup>Director, Health Sector, Dhaka Ahsania Mission, Bangladesh, <sup>2</sup>Senior Lecturer, Department of Public Health, North South University, Dhaka, Bangladesh, <sup>3</sup>Technical Officer, Addiction Management and Integrated Care, Dhaka Ahsania Mission, Bangladesh, <sup>4</sup>Senior Counselor and Project Coordinator, Improvement of the Real Situation of Overcrowding in Prisons in Bangladesh (IRSOP) Project, Dhaka Ahsania Mission, <sup>5</sup>Associate Professor, Department of Physiology, Green Life Medical College, Dhaka, Bangladesh, <sup>6</sup>Assistant Professor, <sup>7</sup>Associate Professor, Department of Public Health, North South University, Dhaka, Bangladesh

## Abstract

**Background & objective:** Despite the high prevalence and numerous adverse health consequences, many individual with substance uses don't seek proper treatment. Therefore, this study was aimed to explore the treatment seeking pattern of relapse cases of substance use disorder in Bangladesh.

**Method:** Cross-sectional study was conducted among 911 relapse cases from all over Bangladesh during January to December 2018. Data were analyzed by SPSS v 23. Descriptive statistics were performed and results were expressed by number and percentage.

**Results:** Majority (48.0%) of the substance users were young adult (19-30 years). Most of them were businessman (35.0%) or unemployed (29.7%) and lived with family (96.3%). In multiple response, 70.0% of them received money to purchase drug from parents and 56.1% their own. 70.0% of relapse cases came to treatment center unwillingly and mostly with family (63.2%) and majority (98.9%) received residential treatment. Individual (68.4%) and group counseling (61.3%), psycho-social session (50.5%), life-skill session (48.0%), medical treatment (45.9%), family counseling (36.6%) and couple counseling (11.1%) was treatment approaches. Detoxification and rehabilitation alone or combination was most common rehabilitation.

**Conclusion:** Combination of treatment is common in Bangladesh for relapse cases of substance use disorder. Long term follow up is needed to see the ultimate outcome.

**Keywords:** Relapse, substance use, drugs, treatment, Bangladesh.

## Introduction

It is estimated that globally, around 164 million

people had substance use disorder in 2016. The proportion is usually being higher among male in compare to female which is 68%<sup>1</sup>. The prevalence of substance use disorders varies from region to region and is highest across Eastern Europe and the United States, which is 5-6% of the total population. This means around 1 in every 20 people suffers from substance use disorder in that part of the world. Across Western and Central Europe, the Americas and Oceania, this prevalence typically ranges from 2-5%. Across Africa, the Middle East and Asia this is typically lower at 1-2%<sup>2</sup>. Globally around 318,000 deaths occurred due

to direct result of substance use disorder (both drug and alcohol) in 2016. It has been strongly argued that, this statistics significantly underestimate the true mortality impact because it only account for direct deaths from alcohol and drug use but not the suicidal death related to substance use<sup>3</sup>. It's estimated that an individual with alcohol, opioid, or psychostimulant dependence has 10, 7 and 8 times increased risk of suicide compare to the individual without dependence<sup>4</sup>.

Despite the high prevalence and numerous adverse health consequences, many individual with substance uses do not seek proper treatment<sup>5, 6</sup>. Although they seek treatment but often a decade or even more after the onset of symptoms (Ronald et al., 2001). One of the reason is lack of developmentally appropriate and effective methodology for treatment of substance use<sup>7</sup>. Some other factors are; negative social support, fear of treatment, privacy concerns, time conflict and admission difficulty. These factors are moderateto highly correlated, suggesting that they interact with one another<sup>8</sup>. Scientific research since mid-1970s shown that, treatment can help drug users to stop using it, avoid relapse and successful recover their lives. Researches also suggested that single treatment is not effective and medications are important elements of treatment and effective when it combines with counseling and other behavioral therapies. Moreover, for effective treatment, there is a need to understand the profile, family dynamics and associated problems of substance users<sup>9</sup>. Until now, there is no study in Bangladesh to explore the treatment seeking patterns of relapse case of substance use disorder. That's why aim of our study was to explore the treatment seeking pattern of relapse cases of the substance users in Bangladesh. This is the first ever study in Bangladesh of its kind.

## Materials and Method

We have conducted this descriptive type of cross-sectional study to assess the treatment seeking pattern of relapse cases of substance use disorder among Bangladeshi population during January to December 2018. Sample size was estimated by using 30.42% prevalence rate, 3.0% design error, 96% confidence interval and adjusting 10.0% non-response. By considering all those parameters, our sample size was 994. A total of 50 drug treatment centres were randomly selected from Narcotics department's enlisted 171 treatment centres from all over the country including the centre of Dhaka North City Corporation. We have

planned to recruit the relapsed drug use cases from those 50 centres, where maximum 20 patients from each centre have been taken. But in case we did not find sufficient number of patients from a centre, they were recruited from nearby centre out of those 50 centres. Ultimately we had to visit 138 centres, as many of the selected centres did not have the desire number of patients. Considering all those things, we could able to recruit 939 relapsed cases, out of them, 28 cases were excluded due to incomplete data. Finally, we could analyse data of 911 cases. The patients who has been at least one relapse after getting his/her treatment for drug addiction was defined as relapse case and was eligible to be recruited in our study. Who were suffering from any severe psychiatric disorder and were not able to communicate properly were excluded from the survey.

Permission from the centre's owners were obtained before data collection. A written permission letter was sent to all selected centres from the chief investigator of this study. Before starting data collection, a day long training has been provided to all data collectors including individual practice to ensure quality data from the respondents. Trustworthy rapport has been built with respondents before data collection. Information was collected through an in-depth interview using a structured questionnaire. All interviews were conducted by maintaining privacy and confidentiality of the respondents. Informed written consent was obtained from each respondent before data collection. Ethical approval was obtained from the institutional review board of North South University before start of data collection.

## Results

In terms of source of money for drug among the users, we found that most of the users used more than one source for money. Majority (70%) of them used parent's money, 56.1% used own money, 20.7% used the money from selling household goods, 15.6% used friend's money, 15.5% used to do robbery and 14.2% used relative's money for drug (table 1).

The study explored the treatment seeking pattern of the participants and found that majority (70.0%) came to the treatment centre unwillingly and the remaining (30.0%) came willingly. Majority (63.2%) of the participants came to treatment centre with their family members, 16.1% came by themselves, 14.9 by forcefully and 3.8% with their relatives. A very few

number of substance users came with social workers, law enforcement agency, drug recovered person and NGO (table 2). Regarding the participant's treatment of drug addiction, majority (98.9%) received residential treatment. Among the residential treatment receiver (901), times of treatment received varied where 33.5% received treatment twice, 18.6% received only once, 17.1% received 3 times, 8.9% received 4 times, 8.8% received 5 times and the remaining received more than 5 times. Among the non-residential treatment receivers' majority (60.0%) received the treatment only one time (table 3).

Table 4 represented the type of treatment received by the participants and the findings showed that respondents received more than one type of treatment. Most of the substance users (65.8%) received rehabilitation (31-90 days), followed by 31.9% received detoxification and rehabilitation (90-180 days), 25.2% received rehabilitation (16-30 days), 14.5% received detoxification and rehabilitation (180 days+) and 12.5% received only detoxification (1-15 days). Table 5 revealed that, most of the participants received more than one type of treatment. Out of many approaches, 68.4% of the participants received individual counselling, 61.3% received group counselling, 50.5% received psycho-social session, 48.0% received life skill session, 45.9% received medicine treatment, 44.2% received general health treatment, 36.6% received family counselling, 30.8% involved with nothing, 29.6% assessed by counsellor, 29.1% planned on drug free life during discharge, 20.6% received treatment planning and 11.1% received couple counselling.

**Table 1: Source of money for drug use (n = 911)**

Source of money for drug	Number	Percentage
Parent's money	638	70.0
Own money	511	56.1
Selling household goods	189	20.7
Friend's money	142	15.6
Robbery	141	15.5
Relative's money	129	14.2
Selling assets	82	9.0
Hijacking	54	5.9
Selling drugs	43	4.7
Keep the property mortgaged	38	4.2
Others	15	1.6

## Discussion

In our study, 98.9% relapse cases of substance use disorder were male. It is very common scenario worldwide that most of the substance users are male and the results is supported by a recent published article from Kathmandu<sup>10</sup>. Study also found that majority of the participant's age were in between 19 to 45 years. Several recent studies from different parts of the world have found similar results<sup>11</sup>. Businessman (35.0%) and unemployed (29.7%) were most common occupation among the relapse cases of substance use disorder. Probable cause might be the businessman have more flexibility in terms of family time and economy. On the other hand, unemployed people have more time to hang around and make friends with similar status. That's why these two groups are more vulnerable in compare to the others. Our finding in accordance with a recent published article from Spain<sup>12</sup>. Majority of our study participants (96.3%) were living with family. It is might be due to

young age group of the participants and extended family structure of Bangladesh. However, socio-cultural trend and family structure has been changing and many people are started living either in nuclear family or alone and soon or later it will be increased<sup>13</sup>. Majority (70.0%) of the substance users in our study used parent's money to buy drugs, most probably because of many were unemployed and living with family.

70.0% of relapse cases came to treatment centre unwillingly and whoever came, mostly (63.2%) with family members. It is very common that substance users don't seek treatment willingly and don't go to treatment centre alone. 98.9% of the relapse cases of substance use in our study took residential treatment. Various authors have studied the effectiveness of residential treatment for substance users, predominantly in non-randomized and uncontrolled pre and post-tests, leading to little evidence about its efficacy or effectiveness. Also for illicit drug users, residential treatment has been found to be more effective<sup>14</sup>. Rehabilitation of 31 to 90 days was most common treatment approach in Bangladeshi substance users, followed by Detoxification and Rehabilitation (90-180 days) and Rehabilitation (16 to 30 days). Previous study has supported that substance users should undergo rehabilitation, counseling, behavioural therapy and physiotherapy<sup>15</sup> which is supportive to our study. Our study found most common treatment approaches were individual and group counseling, psycho-social session, life skill session, family counseling and couple counseling. Previous study done in the field of treatment approach for substance use disorder found that similar approaches were effective<sup>16</sup>. Strength of this study are nationwide survey and large number of relapse cases of substance use. Limitation is, we could not see any risk factors for relapse.

## Conclusion

Young adult population are mostly engaged with drug use in Bangladesh, that's why relapse cases are more common among this group of population. Majority of the drug users used either their parents money or own money to buy drug. Most relapse cases of drug use got residential treatment and came to treatment centre unwillingly. Multiple treatment approach was the most commonly used to get maximum benefit of the treatment such as, individual and group counselling, psycho-social session, life-skill training, medical treatment, family and couple counselling etc. Among the medication; detoxification and rehabilitation alone or combination

was most common approach. A long term study is recommended to follow up their ultimate outcome.

**Acknowledgements:** We are grateful to the Department of Narcotic Control, Bangladesh for their tremendous support and cooperation. We also thankful to the centre owners and management of all 138 centres for their assistance during data collection. We would like to express our sincere thanks and gratitude to the study participants and their family members for their patience and support during the data collection process.

**Conflict of Interest:** Authors declare that they have no financial or scientific conflict among them.

Source of support: The study did not receive fund from any donor organization. Dhaka Ahsania Mission (DAM) managed the study from its own organizational fund.

## Abstract

People who have high emotional intelligence create understanding or know how to manage their own emotions and they know how to read emotions of others. Emotional intelligence was positively connected to physical, psychosomatic and mental health. The studies on the predictors of emotional intelligence, particularly in India are limited. For this purpose focus of the present study was to investigate the predicting effect of personality traits (neuroticism & extraversion) on emotional intelligence among the student of Raipur, India. A sample of the study comprised 300 P.G. students (male=50; female=50). Mangal Emotional Intelligence Inventory and Eysenck's Maudsley Personality inventory (M. P. I.) were used to measuring emotional intelligence (EI) and personality traits. SPSS 16<sup>th</sup> version, structure equation model (SEM) with ADANCO, jamovi. (Version 1.0) were used for analysis. Measurement model was excellent fit in the samples [CFI = .968, TLI=0.904, SRMR=.033 and RMSEA = 0.11 (RMSEA 90% CI: Lower-0.0495, Upper-0.189)]. The findings revealed that personality traits, neuroticism emerged as significant predictors of emotional intelligent, intra personal awareness, inter personal awareness and inter personal management. Age emerged as significant predictors of emotional intelligent and its dimension. The findings also revealed that gender and extraversion have no impact on emotional intelligent and its dimension. A stable personality, age and their psychological wellbeing are important in enhancing the emotional intelligence of young students as there is a possibility in improving their emotional intelligence.

**Keywords:** Emotional Intelligence, Neuroticism, Extraversion, Structure equation model.

## Introduction

The ability of individuals to recognize their own emotions and those of others determine between different feelings and label them is emotional intelligence, appropriately emotional information useful to guide

thinking and behavior and manage emotions to adapt to environments or achieve one's goal<sup>(1-2)</sup>. There are several models of emotional intelligence namely: ability, trait and mixed emotional intelligence models. The ability model is perceives and integrate emotion, as well as to understand and regulate emotion to promote personal growth<sup>(3)</sup> it is proposed by Mayer and Salovey<sup>(4)</sup>. Trait model as described by Petrides and Furnam<sup>(5)</sup> it encompasses behavioral dispositions and self-perceived abilities and is measured through self report<sup>(6)</sup>. Mixed model as described by Golemann, (1995)<sup>(3)</sup> it can be viewed as the set of interrelated competencies skills, abilities, personal qualities and personality trait.

Emotional Intelligence is the biggest predictor

of workplace performance compare to IQ. Emotional competence is another term of emotional intelligence: refers to one's ability to express or release one's emotions. It also decides one's ability to successfully and effectively lead. Emotional Intelligence (EI) competency is evaluation method of interpersonal communication skills, behaviors and patient care <sup>(7)</sup>. Competences of emotional intelligence and empathy are necessary components for physician in 21th century <sup>(8)</sup>. Emotional intelligence can be contributes to, increased empathy, communication skills, stress management, organization commitment, leadership, teamwork and higher academic performance <sup>(9-11)</sup>. For the reason that emotional competence can be helpful to enhanced empathy, higher stress tolerance, greater flexibility to change, better health and recovery from illness. People with high emotional intelligence have better mental health Spiritual well-being <sup>(12)</sup> job performance and leadership skills.

Both emotional intelligence and empathy associated to the personality of students and their ability as successful physicians. Evidence for a strong association between emotional intelligence and various personality traits has been established <sup>(13)</sup>. Personality traits have an impact on the development of the emotional quotient and emotional quotient has an influence on the application and development of the personality of the individual <sup>(4)</sup>. The significant relationship between emotional intelligence and all Big Five personality factors was observed <sup>(14-15)</sup>. Extraversion, Openness to experience, Agreeableness and Conscientiousness have been found to be positively correlated with emotional intelligence, whereas, Neuroticism negatively correlated with emotional intelligence, it is a vulnerability factor for stress, <sup>(16-18)</sup>. McCrae and Costa, (1987), McCrae and John, (1992) described neuroticism are regarded as depression and low self-esteem tendency for experiencing anxiety, tension, self-consciousness, hostility, impulsiveness, timidity, illogical thinking. Extraversion is (sociability, positive affect and energetic behavior). Emotional intelligence and empathy have been found to be affected by gender and culture <sup>(13,19)</sup>. Females have to be more empathetic <sup>(20-21)</sup>. The students, especially in Asia, are reported lower empathy scores compare to Western students <sup>(18, 20)</sup>.

After the education of a P.G. degree, Most of the students while performing as leadership role in different institutes and faced some problems that influenced their performance and mental wellbeing. One foremost

important factor leading to this problem was the low emotional intelligence and unstable personality. There are very few studies to report the association of personality traits with emotional intelligence in India. Therefore this study was conducted to find out the predicting effect of personality trait, age, gender on emotional intelligence among the Indian P.G. students.

## Material and Method

**Sample:** A sample of the present study consisted of 300 P.G. students (male = 50%; female = 50%) studying in University of Raipur, India from ninth UTD departments: Geography, Economics, History, English, Hindi, Anthropology, Master of social worker, Rural development and Sociology. The age range of the participants was 20–25 years. Participants fulfilling the inclusion/exclusion criteria and who gave written informed consent were included for the study. The sampling technique applied for drawing out the sample was an incidental random sampling method.

### Inclusion Criteria:

1. Adult Men or women aged between 20-25 years.
2. Graduate Educated.
3. Able to understand and participate independently in survey.

### Exclusion Criteria:

1. Past or current history of any psychiatric illness.
2. Patients whose current condition limits their participation in a prolonged interview (ex. Debilitating physical condition, agitation, intoxication or drug withdrawal, etc)

**Design:** In the present piece of research, the correlational research design was employed. Here, the criterion variable is emotional intelligence and its dimension; age, gender and personality (neuroticism & extraversion) acted as predictive variables in this study.

**Instruments:** The Mangal emotional intelligence inventory was used it is developed by S.K. Mangal and Mrs. Shubra in 1971. Items of the test relate to the four dimension of emotional intelligence (a) intera personal awareness, (b) intera personal management (c) inter personal awareness (d) inter personal management.

The Eysenck's Maudsley Personality inventory was used it is adapted in Hindi language by Jalota and Kapoor (1964). The test contains 48 items and 2 personality

dimensions in Bi-polar Dimensions- Neuroticism-stability and Introversion-extraversion.

A demographic sheet was used it measured variables like subjects, age, gender and education.

**Procedures:** The students were contacted in UTD department of University invited to participate in a survey. Participants were assured that their involvement was voluntary and anonymous and that they maintained the right to withdraw their participation at any time. Written consent in printed Performa was obtained from the individual participants of the sample included in the study. This study was approved by the departmental research committee. The investigator explained the purpose of the research to the participants. Then after the instructions are given on the questionnaire were explained to them. The participant first completed a Mangal emotional intelligence inventory and then the Personality inventory with demographic. At the completion of the inventory, participants were thanked for their contribution and provided with pertinent contact information should they want to request the results of the study upon completion.

**Statistical Analysis:** Data obtained was analyzed with the help of SPSS (16th) version, ADANCO version 2.0.1. and jamovi. (Version 1.0.). ADANCO

(advanced analysis of composites) software was used for the estimation of variance through structure equation modeling.

### Results

First, a measurement model was tested for all samples using confirmatory factor analysis (CFA) with jamovi. (Version 1.0.)<sup>(21, 22)</sup>. In this model, an emotional intelligence (EI) predicts the four measures comprised in the dimension: intra personal awareness, intra personal management, inter personal awareness and inter personal management. Several types of research have suggested that all the indexes are supposed to be above 0.90 to be a good fit<sup>(23-26)</sup> as cited by Kumar & Shrivastava (2019)<sup>(27)</sup>. The inconsistency in chi-square is the level of acceptance once > 0.05. RMSEA should be accepted in the range of 0.05 to 1.00 the lower value is said to be a good level. Model fit was excellent in the samples [CFI = .968, TLI=0.904, SRMR=.033 and RMSEA = 0.11 (RMSEA 90% CI: Lower-0.0495, Upper-0.189)]. Figure 1 shows the regression weights. All values depicted in Fig. 1 for the all students - intra personal awareness, inter personal awareness and inter personal management show the largest values (>.67). Intra personal management shows the lowest weight for the sample (0.664).

Figure 1: Measurement model (Confirmatory factor analysis) for all samples.

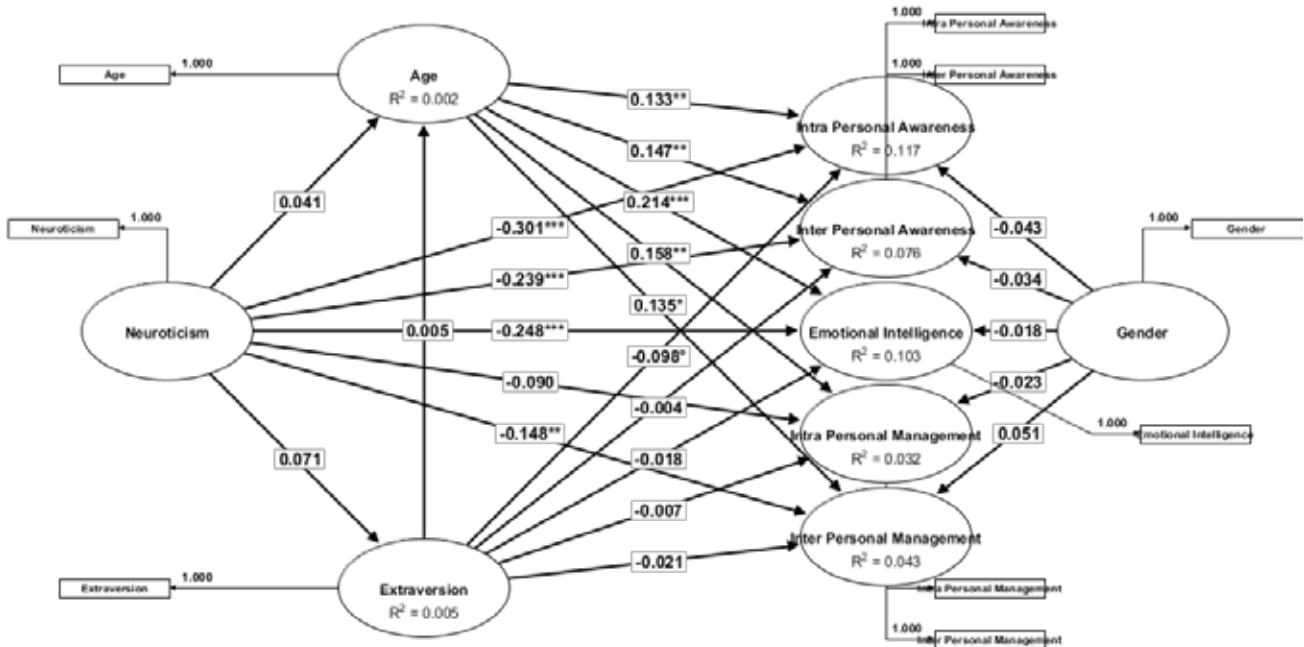

The direct and indirect effect of personality trait (Neuroticism & Extraversion) age, gender on emotional intelligence and its dimension

Direct effect hypotheses testing analyses were performed with structural equation model using ADANCO version 2.0.1. Software. Maximum likelihood estimation was performed with standardized estimates.

The goodness of Model fit analysis was performed for the direct and indirect effect. The fitness of model was excellent with the data (table-1) and was evaluated with guideline [{the Unweighted least squares discrepancy ( $d_{ULS}$ )  $P < .01$ , the geodesic discrepancy ( $d_G$ )  $P < .01$  and the standardized root mean squared residual (SRMR)  $P < .01$ }].

**Table 1 Goodness of model fit value**

	Value	HI95	HI99
SRMR	0.0000	0.0000	0.0000
d <sub>ULS</sub>	0.0000	0.0000	0.0000
d <sub>G</sub>	0.00	0.0000	0.0000

**Figure 2: Direct and Indirect effect of Neuroticism, Extraversion, age and gender on emotional intelligence and its dimension**

Figure 2 which indicate the estimation variance of the predictors (neuroticism, extraversion, age and gender) accounting (R<sup>2</sup>=0.103), 10.3% of variance for emotional intelligence; (R<sup>2</sup>=0.117), 11.7% of variance for intra personal awareness; (R<sup>2</sup>=0.076), 7.6% of variance for inter personal awareness; (R<sup>2</sup>=0.032), 3.2% of variance for intra personal management; and (R<sup>2</sup>=0.043), 4.3% of variance for inter personal management (figure-2). The neuroticism was negatively related to emotional intelligence (-0.2480, p<0.001), intra personal awareness (-0.3006, p<0.001), inter personal awareness (-0.2394, p<0.001) and inter personal management (-0.1482p<0.01). The age of the participants was positively related with the emotional intelligence (0.2136, p<0.001), intra personal awareness (0.1326, p<0.001), inter personal awareness (0.1470, p<0.001) intra personal management (0.1577, p<0.001) and inter personal management (0.1350, p<0.01). Whereas, extraversion and gender were not showing a significant role in emotional intelligence, intra personal awareness, inter personal awareness, intra personal management and inter personal management. Results

of the study reveals that age as a mediator variable does not have any significant role in the association between emotional intelligence and personality trait (neuroticism & extraversion). Extraversion as a mediator variable does not have any significant role in the association between neuroticism and age. The insignificance of mediation was examined by bootstrap. This study shows that the personality trait neuroticism and age were significant predictors for the progression of emotional intelligence; meaning thereby that increase in the level of neuroticism, there is an increase in risk for low emotional intelligence in students.

### Discussion

The main objective of the present study was to find out the predictors of Environmental factors for the development of Emotional Intelligence. Here, 300 Indian post graduate students were considered from five independent and large representative samples of Chhattisgarh from Urban areas. Their EI level was measured by the mangal emotional intelligence scale 2.

This study shows that the personality trait neuroticism of the participants was negatively related to emotional intelligence and its dimension. That means high neurotic personality students reported a lower level of emotional intelligence. Similar findings are reported by Park et al, (2015)<sup>(16)</sup>, Saklofske, et al. (2007)<sup>(17)</sup> and Petrides et al. (2010)<sup>(18)</sup> high neurotic personality a vulnerability factor for stress, negatively correlated with emotional intelligence. Findings also indicated that there is no significant impact of gender on emotional intelligence and its dimension. The findings are supported by Nawal et al., (2017)<sup>(28)</sup> and the similar results by a study “Women’s Leadership Edge: Global Research on Emotional Intelligence, Gender and Job Level” conducted in 2012<sup>(31)</sup>.

The present study also found a positive relationship of age with emotional intelligence and its dimension. It is indicated that older adults may obtain higher emotional intelligence due to lifelong learning and accumulating knowledge<sup>(29)</sup>. The reason for such findings of the study could be that neurotic personalities have suffered from anxiety, fearfulness and insecurity in relationships. Age-related changes during life circumstances such as physical health, income and social support education competition that can influence on a wide variety of social relationships. Some experts even suggest that emotional intelligence may actually be more important than IQ in determining overall success in life. Future researches are needed for improving emotional intelligence with the changing life circumstances to maximize their wellbeing. Emotional intelligence can be learned and is trainable<sup>(20)</sup>.

### Conclusions

Neurotic personality and age emerge as a significant predictor for emotional intelligence and its dimension. A stable personality, age and their psychological wellbeing are important in enhancing the emotional intelligence of young students as there is a possibility in improving their emotional intelligence. Results of the present study can be applied in educational institutions to draw out of improvement of emotional intelligence.

# Synthesis of Rosemary Oleoresin Mediated Silver Nanoparticles and its Characterisation Using UV-Vis Spectrophotometry and TEM

T. Ushanthika<sup>1</sup>, Roy Anitha<sup>2</sup>, S. Rajeshkumar<sup>2</sup>, T. Lakshmi<sup>2</sup>

<sup>1</sup>Graduate Student, <sup>2</sup>Associate Professor, Dept of Pharmacology, Saveetha Dental College, Saveetha Institute of Medical and Technical, Sciences, Chennai, Tamil Nadu, India

## Abstract

Preparation of nanosized silver based materials, is amongst the most emerging areas in the field of nanotechnology. Green synthesis of silver nanoparticles using different plant extracts and its resources are received many appreciation due to its environment al friendly capping and reducing properties. In this study, silver nanoparticles were synthesised using rosemary oleoresin. The synthesised nanoparticles were confirmed using UV-spectrophotometer and the size and shape were characterised by Transmission electron microscope. TEM analysis showed the size of silver nanoparticles from 10 – 25 nm. In conclusion, the reduction of the silver nitrate ion through rosemary oleoresin important to the formation of silver nanoparticles with so much of economic viability and valuable.

**Keywords:** Rosemary oleoresin, silver nanoparticles, Transmission electron microscope, UV-Vis spectrophotometer.

## Introduction

Nanoparticles are in the size from 1 to 100 nm<sup>1</sup> and has certain characters such as stability, distribution, size and structure reveal a completely new and better properties compared to other materials. Nanoparticles with decrease in size present a pertinent for catalytic reactivity and other applications such as antimicrobial activity of silver nanoparticles<sup>2</sup>. Silver has been recognised to have inhibitory effect towards bacterial strain and microorganisms<sup>3</sup>. Silver and silver nanoparticles are widely implemented in medical industry. Silver containing topical ointments are used to prevent infection in exposed wounds<sup>4</sup>.

Another widely implemented use of silver is in medical devices prepared with silver impregnated polymers<sup>5</sup>. Many synthetic process have been used for the production of silver based nanoparticles which include physical, chemical<sup>6</sup> and biological techniques<sup>7</sup>. The synthesis of chemical based nanoparticles are discouraged as they involve toxic substance like sodium borohydride<sup>8</sup> and toxic solvent<sup>9</sup>. Synthesis by biological method using microorganism<sup>10</sup> enzyme<sup>11</sup>, plant extract<sup>12</sup> are of recent interest. There is an increased focus on green chemistry as it is eco friendly and reduces toxicity . Hence, compounds like glucose<sup>13</sup>, microorganism and plant extract<sup>14</sup> are widely used. This has attracted research interest as it is a safer alternative. The herbal plants are having beneficial importance and widely used to control the shape and size of the silver nanoparticle<sup>15</sup>. Silver nanoparticles hold the guarantee to kill microorganism. Silver nanoparticle have a wide scope of target locales both extracellularly also intracellularly<sup>16</sup>. In fact, organisms have a harder time creating protection from silver than they do to antibiotics<sup>17</sup>. In this study, rosemary oleoresin was used for the synthesis of silver nanoparticles. Rosemary extracts have been

utilised in the treatment of diseases because of its hepatoprotective potential<sup>18</sup> restorative potential for Alzheimer's ailment<sup>19</sup> and its antiangiogenic impact<sup>20</sup>. They have been used in food conservation, since they block oxidation and microbial contamination. Rosemary extract could therefore be used for reducing chemical antioxidants in food. As additives, rosemary offer a few technological focal points and advantages.

### Materials and Method

**Synthesis of nanoparticles:** Silver nanoparticles were synthesized using 1 mM of silver nitrate with 10 mL

of the Rosemary oleoresin extract was added with 90 mL of metal solution and mixed well and kept in a magnetic stirrer for the synthesis of silver nanoparticles. The colour change was observed visually and photographs were recorded<sup>21</sup>. [Figure 1 a & Figure 1b]

**Confirmation of nanoparticles:** The synthesised nanoparticle solution was preliminarily confirmed by UV-Vis spectroscopy; 3 mL of the solution was taken in a cuvette and scanned in double beam UV-Vis spectrophotometer from 300 nm to 700 nm wavelength. The results were recorded for the graphical analysis. [Figure 2]

### Results and Discussion

Figure 1 a: Rosemary Oleoresin extract and 1b: Rosemary oleoresin mediated AgNPs

Figure 2: UV-Vis Spectroscopy of Rosemary oleoresin mediated silver NPs

**Preparation of nanoparticle powder:** The nanoparticles solution was centrifuged using to Lark refrigerated centrifuge. The solution was centrifuged at 8500 rpm for 10 minutes and the pellet were collected and washed with distilled water twice. The final purified pellets were collected and dried at 60 °C for 24 hours. Finally, the nanoparticles powder were collected and stored in air tight eppendroff tube.

**TEM analysis of silver nanoparticle:** The silver nanoparticle was analysed for its morphological character using TEM. The morphology such as size and shape of the silver nanoparticles were clearly analysed using this technique.[Figure 3].

**Figure 3: TEM analysis Rosemary oleoresin**

In the present work, silver nanoparticle have been synthesised, the reduction of silver ions were done with rosemary oleoresin and colour changes clearly shown in figure 1. It was notable that silver nanoparticles display yellowish-darker shading in aqueous arrangement because of excitation of surface plasmon vibrations in silver nanoparticles (22). Decrease of the silver ions to silver nanoparticles due to the exposure to extract could be seen by colour change and was further confirmed by UV-Vis spectroscopy (Figure 2). The size and shape of the prepared nanoparticles were evaluated by transmission electron microscopy (Figure 3). The majority of the particles in the TEM pictures were not in physical contact but rather are isolated by a genuinely uniform inter particle distance. This TEM analysis showed particles size ranging from 10-25 nm. The prepared rosemary oleoresin mediated silver nanoparticles may be further studied for its antioxidant, antiinflammatory and antidiabetic activities.

## Conclusion

The present study used rosemary oleoresin for the synthesis of silver nanoparticles. The synthesized nanoparticles were less than 100 nm confirms the usage of silver nanoparticles for the biomedical applications in future. This study indicates the role of rosemary oleoresin in the stabilization and capping properties of the AgNPs. The applications of rosemary oleoresin in already proved and in this study highly applicable silver nanoparticles were synthesized using this novel materials may use in many applications in future.

# Serum Cotinine Level as a Biomarker for Tobacco-Related Oral Cavity Malignancy

Vekariya Mayank<sup>1</sup>, C.Z. Pardeshi<sup>2</sup>

<sup>1</sup>Resident, <sup>2</sup>Assistant Professor, Department of General Surgery,  
Krishna Institute of Medical Sciences, Karad, Maharashtra

## Abstract

**Background & Objective:** Relationship between cotinine and oral cancer is still an unexplored area. Limited availability of studies embarks to investigate its importance in cancer. This study aims to quantify serum cotinine level as a biomarker for tobacco exposure related oral cavity malignancy.

**Methodology:** Patients (n=150) of either sex, aged between 31-80 years, were distributed into group A (Oral cancer), group B (Chronic tobacco chewers) and group C (Control) with 50 in each group. Details of gender, age and tobacco habit were recorded. For Group A, clinical data for anatomical site of tumour, type of lesion and pathology oral hygiene were collected. Serum cotinine levels were estimated by ELISA. Chi-square test, unpaired t-test, two-sample proportion test were performed using SPSS software.

**Results:** Significant difference was observed in the duration, frequency of tobacco consumption and serum cotinine levels among group A and B (P<0.01). Group B showed higher levels of serum cotinine (32.458 ±0.31ng/ml). The mean serum cotinine levels in group A, B and C were 6.218±0.34ng/ml, 5.753±0.62ng/ml and 0.245 ±0.81ng/ml.

**Conclusion:** Chronic tobacco chewers had high serum cotinine levels and could be at high-risk group for oral cavity cancer indicating the effectiveness of serum cotinine as a tobacco exposure related biomarker in oral cancer.

**Keywords:** Oral hygiene, Oral cancer, Tobacco chewers.

## Introduction

Oral malignancy, the sixth most recurrent cancer in the world, has high mortality rate, 7% in case of males and 4% in females.<sup>[1]</sup> In India, it accounts for around 40% of cancer mortality<sup>[2]</sup> with 48,000 deaths and 70,000 new cases.<sup>[3]</sup> Tobacco chewing is major risk

factor and is due to nicotine<sup>[4]</sup>. Cotinine, metabolite of nicotine, is detected in body fluids by economical techniques.<sup>[5,6]</sup> Studies have investigated serum levels of cotinine to differentiate between tobacco users and non-users as it is a long-term marker of nicotine<sup>[7-9]</sup> with greater specificity and sensitivity.<sup>[10,11]</sup>

In majority of previous studies, biomarkers of tobacco exposure have been analysed for smokers.<sup>[12,13]</sup> Studies have targeted biomarkers among smokeless tobacco users<sup>[14]</sup> and have evaluated the serum cotinine levels among tobacco chewers for clinical use.<sup>[8,15]</sup>

The purpose of this study was to quantify serum cotinine levels as a biomarker for tobacco-related oral malignancy in controls, chronic tobacco chewers and oral cavity cancer patients.

## Materials and Method

With the institutional ethics committee approval, this case-controlled study was conducted at tertiary care hospital in Karad (Maharashtra) for two years. For effect size (Cohen's  $d=0.6$ , medium), significance level 95%, power 80%, the sample size is ~46 in each group for independent sample t test. The study involved 150 patients, aged between 31–80 years, who were distributed into three groups—Group A included 50 patients diagnosed with oral cancer and had not undergone chemotherapy/radiotherapy prior to inclusion; Group B (chronic tobacco chewers) included 50 patients taking half pouch (1 pouch=70-80 gm) of tobacco per day for >5 years; and Group C (control) included remaining 50 patients with no tobacco consumption, in any form. Patients suffering from cancer other than oral cancer, patients with smoking habit, chronic tobacco chewers with abstinence of >15 days (after 15 days of abstinence, cotinine level cannot be detected in serum),<sup>[16]</sup> and patient already treated for oral cancer were excluded

from the study. Informed consent was obtained from all the subjects included in the study.

Demographic data and details of tobacco consumption—type, duration, frequency was collected. For Group A, clinical data including anatomical site of origin of tumour, type of lesion, adjacent structure involved with tumour, pathology of tumour patient and oral hygiene, was also collected. Blood samples were collected and analysed by Enzyme-linked immunosorbent assay.<sup>[17-19]</sup>

Data was analysed in R software. Quantitative variables were analysed by using t-test and Qualitative variables were analysed using chi-square test, sample proportion test at 95% confidence interval.

## Results

The three groups are comparable in terms of demographic parameters and the results were presented in table 1.

**Table 1: Age and gender distribution**

		Age (Years) N (%)					Total	P value <sup>c</sup>
		31-40	41-50	51-60	61-70	71-80

	Female	02 (4)	04 (8)	03 (6)	01 (2)	00 (0)	10 (20)	
<b>Total</b>		<b>30</b>	<b>52</b>	<b>31</b>	<b>29</b>	<b>8</b>	<b>150</b>	

C = Chi-square test; N=Number

Age distribution of patients among the groups had no significant difference ( $P>0.05$ ). Majority of patients were between 41-50 years. However, a significant difference was observed with respect to gender distribution ( $P<0.05$ ) as males were found to be more affected than

females. Majority of oral cavity malignancy patients were male (82%) and 18% were female, while in chronic tobacco chewer group also male preponderance was clearly visible (Table 1).

**Table 2: Tumour Distribution of Clinical data of Group A**

	Number (Percentage)	P value
<b>Anatomical Site</b>		
Buccal mucosa	26(52)	3.50e <sup>-07c</sup>
Bucco-gingival sulcus	9 (18)	
Tongue	7 (14)	
Hard Palate	1 (2)	
Lip	7 (14)	
Retromolar region	0(0)	
<b>Lesion Type</b>		
Ulcerative	16(32)	0.00*
Ulcerproliferative	34 (68)	
Proliferative	0 (0)	
<b>Adjacent Structures Involved</b>		
Lymph nodes	22 (36.66)	2.46e <sup>-10c</sup>
Mandible	5 (8.33)	
Skin (cheek)	5 (8.33)	
Mandible + Lymph node	4 (6.66)	
Mandible + Skin (Cheek)	1 (1.66)	
Skin (cheek) + Lymph node	4 (6.66)	
Mandible + Skin (Cheek) + Lymph node	1 (1.66)	
None	18 (30)	

c-Chi-square; \*-2-sample proportion test

In group A, anatomical site of origin, type of lesion and adjacent structures involved with tumour was significant (P<0.05); majority of patients had tumour in the buccal mucosa site with ulcer proliferative lesions and involvement of adjacent lymph nodes (Table 2).

**Table 3: Type of tobacco consumption among Group A and B**

	Number of Patients, N (%)		Total	P value <sup>c</sup>
	GroupA	Group B		
<b>Types of tobacco consumed</b>				
Tobacco Chewing	22(44)	26(52)	48	0.86
Mishri application	9(18)	8(16)	17	
Tobacco Pan + Gutakha	13(26)	10(20)	23	
Tobacco + Smoking	6(3)	6(3)	12	
<b>Duration of tobacco consumption (in years)</b>				
5-10	5(10)	20(40)	25	0.00
11-15	9(18)	8(16)	17	
16-20	11(22)	14(28)	25	
>20	25(50)	8(16)	33	
<b>Frequency of tobacco chewing consumed (packets per day)</b>				
6 to 10 (90 to150 g)	23(46)	20(40)	43	0.279
10 to 15 (150 to 225 g)	16(32)	12(24)	28	
>15/day (>225g)	11(22)	18(36)	29	

C=Chi-square test; N-Number; %-Percentage; g. -grams

No significant difference was observed among the two groups ( $P>0.05$ ) with respect to type of tobacco chewing. Although, as compared to mishri, pan and gutakha consumption, majority of patients were only into tobacco chewing (Table 3).

**Table 4: Duration of tobacco consumption, on serum cotinine level**

	Serum Cotinine Levels (ng/ml)		P value <sup>t</sup>
	Group A (M±SD)	Group B (M±SD)	
<b>Duration of tobacco consumption (in years)</b>			
5 to 10	7.397 ±0.372	6.539 ±0.37	0.00
11 to 15	33.050 ±0.221	37.452 ±0.29	2.87e <sup>-08</sup>
16 to 20	32.361 ±0.273	30.731 ±0.61	3.32e <sup>-08</sup>
>20	28.268 ±0.244	32.458 ±0.31	9.94e <sup>-12</sup>
<b>Frequency of tobacco chewing/amount of tobacco consumed (packets/day)</b>			
6 to 10 (90-150 g)	6.744±0.24	9.563±0.12	8.54e <sup>-33</sup>
10 to 15 (150-225 g)	10.119±0.22	12.562±0.34	3.32e <sup>-14</sup>
>15 (>225 g)	27.923±0.34	25.325±0.48	1.06e <sup>-15</sup>

M±SD- Mean± Standard deviation; t-t test.

In both the groups, most subjects had tobacco 6-10 times/day indicating no significant difference ( $P>0.05$ ) and duration of tobacco consumption indicated a significant difference among the groups ( $P<0.05$ ), with many subjects consuming tobacco for more than 20 years. (Table 4).

The levels of serum cotinine and duration of tobacco consumption among the groups was observed to be significant ( $P<0.001$ ). Similar observations were made upon analysis of serum cotinine levels with frequency of tobacco chewing/consumption ( $P<0.001$ ; Table 4). These results show that longer the duration and frequency of tobacco consumption, more the chances of having higher levels of serum cotinine, which could be an indicator of being in high risk group for oral cancer.

During the histopathological examination in Group A, majority of the patients observed to have well-differentiated squamous cell carcinoma (48%); the distribution of patients with respect to histopathology was significant ( $P=6.52e^{-05}$ ). A significant difference was observed among the patients in terms of oral hygiene in Group A ( $P=7.21e^{-06}$ ) stipulating that majority of patients demonstrated poor oral hygiene.

**Table 5: Serum cotinine levels in squamous cell carcinoma patients in Group A**

Serum Cotinine Level (ng/ml)	N (%)	P value <sup>c</sup>
<b>In well differentiated squamous cell carcinoma</b>		
1 to 10	11 (45.83)	0.03
11 to 20	2 (8.33)	
>20	11 (45.83)	
Total	24 (100)	
<b>In moderately differentiated squamous cell carcinoma</b>		
20 – 40	3 (18.75)	0.44
41 – 60	6(37.5)	
>60	7 (43.75)	
Total	16(100)	

c- Chi-square test

A significant difference in the serum cotinine level was observed among the well differentiated squamous cell carcinoma patients in Group A ( $P<0.05$ ) with majority of patients having serum cotinine level between 1-10 ng/ml and >20 ng/ml (Table 5). This indicates that well differentiated squamous cell carcinoma patients show varying degree of serum cotinine levels depending on the extent of spread of carcinoma among the cells.

**Table 6: Mean serum cotinine among groups**

Study Groups	Serum Cotinine (ng/ml)		P value <sup>t</sup>
	Study Groups	Group C (N=50)	
Group A (N=50)	6.218±0.34	0.245 ±0.81	0.00
Group B (N=50)	5.753±0.62	0.245 ±0.81	3.26e <sup>-14</sup>

t- sample t-test; M±SD- Mean± Standard deviation

Mean serum cotinine values showed a significant difference between Group A and Group C (P<0.05) and significant difference between Group B and Group C (P<0.01) stipulating that the presence of high levels of serum cotinine indicates tobacco exposure (Table 6).

**Discussion**

This study aimed at determining the serum cotinine levels as a biomarker for tobacco related oral cavity malignancy. In this study, the average age of tobacco chewers was between 41-50 years, this is complying with the literature where the average age of tobacco chewers is around 36.5–45 years,<sup>[20]</sup> indicating early-age addiction of tobacco chewing.<sup>[15]</sup>

Male preponderance was clearly visible in majority of oral cavity malignancy patients and in chronic tobacco chewers group. However, this fact cannot be ignored that females do use tobacco exclusively in smokeless form. Similar findings were observed by Dhanya.<sup>[8]</sup> High usage of tobacco among males could be attributed to culture-based reasons.

In India, consumption of betel quid is strongly associated with risk for oral cancer.<sup>[21]</sup> In contrast to this, in our study the average type of tobacco consumption was tobacco chewing<sup>[21]</sup>. In Gupta et al. study<sup>[9]</sup> maximal risk of oral cancer was for the cases who chewed tobacco more than ten times/day.<sup>[9]</sup> However, in our findings the chewing of tobacco for 6 to 10 times/day increased the chances of oral cancer. Further, in tobacco chewers, duration of chewing is strongly associated with risk of oral cancer as majority of them were chewing tobacco for > 20 years. These findings are consistent with previous epidemiological study.<sup>[22]</sup>

In the current study, majority of patients suffered with well-differentiated squamous cell carcinoma. In a previous study also the higher rates of oral cancer were associated with buccal mucosa causing widespread exposure and squamous cell carcinoma.<sup>[23]</sup> This is

due to increased and localized absorption of tobacco products and also depends on duration of chewing, pH value, amount of nicotine.<sup>[15]</sup> On comparing the effect of duration of tobacco chewing, the levels of serum cotinine were significantly higher (32.458 ±0.31ng/ml) for chronic tobacco chewers with duration of tobacco chewing > 20 years as compared to oral cancer patients (28.268 ±0.244ng/ml). Similar results were observed by Rostron et al.<sup>[24]</sup>

The serum cotinine levels increased with increasing frequency of tobacco use in oral cancer patients and chronic tobacco chewers and agreed with Castelino et al. <sup>[25]</sup> Poor oral hygiene is related with a significant risk of oral cancer in our study and was in accordance with previous literature.<sup>[26]</sup> The study should be conducted on bigger sample size and other techniques estimation serum levels should be analysed.

**Conclusion**

This study identified that serum cotinine level in chronic tobacco chewers was high and near to serum cotinine level in oral cancer patients, they can be included in high risk group for oral malignancy. Consequently, these levels offer advantage as biomarker for oral cancer screening.

**Ethical Clearance:** Taken from institutional ethics committee

## Abstract

**Background:** The breast cancer is most common cancer found among women in developed countries. Early detection plays a very important role in breast cancer. The Breast self-examination is simple, non-invasive and inexpensive method for early detection of breast cancer.

**Objectives:** (1) To assess the level of knowledge of self breast examination among non-medical female employees. (2) To assess the capacity to do regarding self breast examination among non-medical female employees. (3) To find the association between pre-test knowledge score and selected socio demographic variables.

**Method:** The research approach adopted for this study was an evaluative approach, where the research design was used one group pretest posttest research design. The study was conducted in tertiary care hospital, Karad. The sample consists of 49 non medical female employees. A purposive sampling technique was used to select the sample. The data were collected by structured questionnaire. The data were analyzed using descriptive and inferential statistics.

**Results:** The mean pre-test knowledge score was 4.551 and post-test mean score was 17.265. The t-test value was 61.053 and was found significant at  $p < 0.0001$  level.

**Conclusion:** The result of study shows that non-medical female employees have improved their knowledge and practice regarding self breast examination.

**Keywords:** *Breast Self Examination, Non-Medical Female Employees, Capacity to do.*

## Introduction

The breast cancer is most common cancer found among women in developed countries. In the world over 1.15 million cases of breast cancer are diagnosed every year and 502,000 women die from the disease each year.<sup>[1]</sup> In India the breast cancer is second most

common cancer in women and it is stated that 90% of the times breast cancer is first noticed by the person herself.<sup>[2]</sup> Early detection plays a very important role in breast cancer. The screening method like Breast self-examination mammography and clinical breast examination which is used to detect early breast cancer. The Breast self-examination is simple, non-invasive and inexpensive method for early detection of Breast cancer. <sup>[3]</sup> Early detection of breast cancer has an important part in decreasing mortality and morbidity and breast self-examination is an important screening way for early detection.<sup>[4]</sup>

Breast self-examination can be carried out by women

themselves and its not required to visit hospital. Breast self-examination method involves women looking at and feeling each breast for possible lumps, distortions or swelling as an approach in detecting early stage breast cancer. Knowledge and skills of Breast self-examination can saves life of women's. For increasing the knowledge and skills regarding Breast self-examination more health teaching programmes and demonstration need to be conducted.<sup>[5]</sup> The study conducted by Pravin N Yerpude et al. concluded that the level of knowledge and practice of breast self examination among female is unacceptably low. Efforts should be made to increase level of knowledge and practice of breast self examination through health education programmes.<sup>[6]</sup> The nurses plays a vital role in to educate people about breast cancer their risk factors and types of screening practices and to influence behaviors that will reduce the risk of future breast cancer morbidity and mortality. In context, the present study was intended to assess the capacity to do Self Breast examination among non-medical female employees of tertiary care hospital.

### Material and Method

The pre-experimental design was used to conduct the study among non-medical female employees in Tertiary Care Hospital from Western Maharashtra. The 49 employees selected by purposive sampling technique. The samples included in this study were who fulfilled the inclusion criteria with the age above 30 year and who were willing to participate in the study and available during data collection period. Ethical permission was obtained before data collection. After obtaining permission from setting, the employees were asked their willingness to participate in this study and informed consent was obtained. After collecting the demographic data, the pre-test level of knowledge and practice among non-medical female employees was assessed with using structured questionnaire and observational checklist. At the end of the seventh day, the post-test level of knowledge and practice was assessed by using the same tool.

**Description of the tool:** The structured questionnaire comprised three sections covering the following areas.

**Section I:** It consist of socio demographic data include age, religion, marital status, education, pair occupation, type of family, Residence, number of

children, history of breast cancer.

**Section II:** The questionnaire on knowledge regarding breast self examination.

**Section III:** The questionnaire on capacity to do self breast examination.

**Statistical Test:** Paired t test was used to compare the means and chi square test was used to find out association between pre-test knowledge score regarding Breast self Examination and selected socio demographic variables

### Results

**Description of sample characteristics:** Table No. 1 reveals that among all of the participants 44.89% were within the age group of 30-39 year and 44.89% within the age group of 40-49 year and most of them 65.30% were Hindu religion. Nearly 75.51% they were married. The data concerning 51.02% were from joint family and it was found 48.97% had primary education. The majority of samples 95.91% were not having any pair occupation. In relation to residence 61.22% were in rural area. Majority of women's 67.34% were having two children's and Majority 100% was not having history of breast cancer.

**Knowledge among non-medical employees regarding Breast self examination:** Table 2 indicates that most of the samples (98%) were having poor knowledge and (2%) were having average knowledge in pre-test. In the post-test knowledge 100% of non-medical employees were having good knowledge.

**Practice among non-medical employees regarding Breast self examination:** The data presented in table No. 3 shows that 100% of samples practice of Breast self examination before and after the demonstration 100% of samples done the practice of Breast self examination.

The data presented in Table 4 show that the mean difference between the pre- and post-test knowledge score was 12.714 and computed paired t-test value was  $t=61.053$  was found significant at  $p<0.001$  level. Hence, there was a significant improvement of knowledge among the non-medical female employees.

**Association between pre-test knowledge score and selected socio demographic variables:** There was no significant association between the knowledge score

and selected socio demographic variables at the level  $p < 0.05$ .

**Table 1: Frequency and percentage distribution of socio-demographic variables of samples**

Sr.No.	Variables	Frequency	Percentage	
1.	Age	30yr-39yr	22	44.89%

		Sister	0	0%
		Aunty	0	0%
		None	49	100%

**Table 2: Frequency and percentage distribution of pre-test and post-test knowledge scores among non medical female employees**

Grade	Score	Pre-test		Post-test	
		Frequency	Percentage	Frequency	Percentage
Poor	0-6	48	98%	0	0
Average	7-13	1	2%	0	0
Good	14-20	0	0	49	100%

**Table 3: Frequency and percentage distribution of pre-test and post-test practice score among non medical female employees**

Pre-test Not done practice before	Post-test Done practice after demonstration
--------------------------------------	--

Frequency	Percentage	Frequency	Percentage
49	100%	49	100%

**Table 4: Comparison of pretest and posttest level of knowledge among the non-medical female employees.**

Sample	Pre-test		Post-test		Paired 't' value
	Mean	SD	Mean	SD	
Non- medical female employee's	4.551	0.792	17.265	12.714	61.053 Significant

teachers was average before the administration of the PTP. The post-test knowledge scores showed significant increase in the level of knowledge of teachers. Hence the PTP is an effective teaching method for providing information and improving the knowledge of teachers.<sup>[8]</sup>

**Discussion**

The results of the present study show that there was a significant difference in knowledge score among non-medical female employees. The knowledge and practice was improved among non-medical female employees after demonstration. The findings of different studies also show that the knowledge and practice regarding breast self examination was poor but after planned teaching programme improvement was seen in knowledge and practice regarding breast self examination. Confirming the results of the present study, it can be pointed to the study of John Molly et al. study showed that the knowledge and practice of breast self- examination among women were very less. The planned teaching programme on breast cancer and Breast self examination carried out in the study was found to be effective in improving the knowledge and skill of mahilamandal women as evidenced by the significant difference between pre-test and post-test knowledge score. So the health personnel should intensify health education on knowledge of breast cancer and should be initiated to improve women’s practice of Breast self examination.<sup>[7]</sup>

A study conducted by Salomy Chacko with title of “Effectiveness of Planned Teaching Programme on Knowledge of Early Detection of Breast Cancer among School Teachers. The result reveals that the mean post-test knowledge score (O2 =24.05) was higher than the mean pre-test knowledge score (O1=12.48). The computed ‘t’ value (24.14) was higher than the table value (t (59) = 1.67) at 0.05 level of significance, suggesting that the PTP was effective in increasing the knowledge of female teachers on early detection of breast cancer. Interpretation: The result showed that the PTP was effective in increasing the level of knowledge of teachers on early detection of breast cancer. The findings of the study showed that the knowledge of

**Conclusion**

The result of study shows that non-medical female employees have improved their knowledge and practice regarding Breast Self examination. Awareness programs are needed to be conduct so that all women can know and practice Breast Self Examination, which is going to help to the women to identify any abnormal changes in the breasts so that they will be able to seek medical advice immediately.

<sup>2</sup>Lecturer, Department of Dental Therapist and Hygienist, Poltekkes Kemenkes Tasikmalaya, Tasikmalaya, Indonesia

## Abstract

**Background:** This study presents “Tomon” or Tooth Monster Hunter for assisting the parents or medical staffs to help children for learning proper brushing skills. The importance of maintaining oral health needs to do since the best time to instil the values of positive behaviour maintaining dental health is the age of children. The problem within the oral counselling method is that cannot change the dental health behaviour of children.

**Method:** The research is an experimental study with a pre-test and post-test control group design. Our research uses a technological approach to create educational wearable sensor for children. This experimental method is testing cause and effect. The cause in this research is the Tomon game and the effect is dental health status. We also analyse the brushing behaviour change of the children.

**Results:** The results show that Debris Index of the experimental group change from the moderate category which is 66.7% and poor category which is 33.3% to all good category. In the control group, there is a change from the poor category which is 66.7% and the moderate category in 33.3% to all good category. The statistical analysis show that there is a significant change influence of Tooth Monster Hunter in the brushing behaviour of children.

**Conclusion:** The research suggest Tomon improve the health promotion towards the children’s dental and oral health.

**Keywords:** *Children, debris index, dental and oral health, tooth monster hunter.*

## Introduction

The development of the industrial revolution 4.0 brings changes to human life, which now relies on technology such as in the health field. Dental and oral health is crucial for the body. Damaged and untreated teeth and gums can cause dental and oral diseases such as pain, dental caries and interfere with other bodily health. In 2018, in Indonesia the proportion of dental and oral problems reached 57.6% with only 10.2% of medical staff. In addition, it is known that the proportion of daily tooth brushing behaviour in the population aged more than 3 is 94.7% but the proportion of proper tooth brushing behaviour is only 2.8%<sup>(1)(2)</sup>. The importance of maintaining dental and oral health needs to be taken into account early, in which the most appropriate time to instil

the values of positive behaviour to maintain dental and oral health is in the age of children. This is because pre-school or kindergarten age is a good age for practicing children’s motor skills. The risk of dental disease in children can cause disruption or difficulty in mastication, reduced nutritional intake so that weight loss decreases and the result is the child growth and development is not optimal. The failure on keeping the dental and oral health can affect other body health<sup>(3)</sup>. On average, 5-years-old children brush their teeth only about 25% of the entire tooth area. This is because children are not perfect in the act of brushing their teeth<sup>(4)</sup>. Thus, the solution is to instil in themselves about the behaviour of maintaining dental and oral health.

So far, the various research efforts have been carried

out in maintaining oral health. Dental and oral health was done by psychologists to change behaviour as a basis for intervention and the level of patient knowledge can be done through verbal oral health from a health practitioner. The leaflet method and written material were also carried out as a step to promote health. The success in providing health promotion depends on health practitioners. However, it cannot guarantee the output.<sup>(5)</sup>

The first effort can be done to prevent plaque formation is brushing thoroughly and regularly. Because maintaining dental and oral health at an early age affects the development of dental health in adulthood. Tooth brushing behaviour is related to plaque scores. Knowledge of good tooth brushing has an opportunity not to experience dental caries<sup>(6)</sup>. This maintenance effort becomes a challenge for parents and teachers to provide motivation to children in the behaviour of maintaining dental and oral health. Because verbal persuasion is not enough to motivate children. So there must be a way to give an interesting demonstration to children about brushing their teeth<sup>(7)</sup>. In addition, Smart Toothbrush has been made as an assistant in detecting human behaviour in maintaining healthy teeth in a vision-based system. This system cannot classify good and proper brushing

of teeth<sup>(8)</sup>. The dental plaque estimation system using camera images has also been carried out as healthcare management. This method is used as a teaching tool for brushing teeth. The tool used is compatible with all types of cameras. However, it is still difficult to maintain individual dental health<sup>(9)</sup>. Children need a tool to play in order to develop their abilities<sup>(10)</sup>.

Based on the above problems, then in this study with a background of industry 4.0, it will use a technological approach as an educational aid for dental health games for children.

### Methodology

This research is an experimental study. This experimental method will answer the question “If a virtual game is given to a group under study, then can it improve dental health status?”. Figure 1 shows the research model in which the range of experimental research is more than one group with pre-test and post-test. There are two groups that are given different treatment with the aim to test the health status of their teeth both for the Tomon game intervention or not.

Figure 1: Research Model

Based on the data had been obtained, the it was analysed by doing the calculation tabulation process. Next an analysis of comparative studies on the results of dental health status was produced. We used paired sample T test analysis. The T test was used to test the effect of independent variable on the dependent variable. This test is done by comparing T arithmetic with T table . If the p-value is less than 0.05, then  $H_0$  is rejected, which means there is an influence of Tooth Monster Hunter on dental health status. If the p-value is more than 0.05, then  $H_0$  is accepted which means there is no Tooth Monster Hunter effect on the dental health status. In addition,

the dental behaviour and health was analysed based on observations.

### Results

**A. Univariate Analysis:** Dental and oral hygiene can be measured using an index. The Index is a clinical condition which is obtained when an examination is held. Analysing the degree of dental and oral health of children is by looking at the OHIS (Oral Hygiene Index Simplified) score before and after the treatment is given. The standardization used in calculating OHIS score is according to the Ministry

of Health of Republic of Indonesia Year 1995 is through examination of debris on certain teeth and on certain surfaces of the teeth. The examination was divided into 6 sextans in the buccal, lingual and palatal sections. The Debris Index assessment standards classified into Good, Moderate and Poor category. Good category stands on score 0 to 3.333. Moderate category stands on score 3.444 – 6.666 while Poor Category stands on 6.777 – 10.

Table 1 shows the Debris Index of experimental group. It is known that the Debris Index of the experimental group before the intervention of Tooth Monster Hunter game media is mostly in the sufficient criteria in 66.7%, while after the intervention using Tooth Monster Hunter game media, the criteria for overall children’s Debris Index score is in good criteria.

**Table 1: Frequency Distribution of Debris Index Score of Experimental Group**

Category	Before		After	
	Frequency	%	f	%
Good	0	0	9	100
Moderate	6	66.7	0	0
Poor	3	33.3	0	0
<b>Total</b>	<b>9</b>	<b>100</b>	<b>9</b>	<b>100</b>

Table 2 shows the Debris Index of control group. Almost all of the frequency is categorized poor as much as 66.7%. After the manual brushing, which means without intervention, the category change into good, in 100%.

**Table 2 Frequency Distribution of Debris Index Score of Control Group**

Category	Before		After	
	Frequency	%	f	%
Good	0	0	9	100
Moderate	3	33.3	0	0
Poor	6	66.7	0	0
<b>Total</b>	<b>9</b>	<b>100</b>	<b>9</b>	<b>100</b>

Table 3 shows the brushing skill of experimental group. Before the treatment using Tooth Monster Hunter game media, most of the criteria are sufficient in 66.7%, while after the treatment, the criteria are mostly in good criteria in 77.8%.

**Table 3 Frequency Distribution of Brushing Skill of Experimental Group**

Category	Before		After	
	Frequency	%	f	%
Good	0	0	7	77.8
Moderate	6	66.7	2	22.2
Poor	3	33.3	0	0
<b>Total</b>	<b>9</b>	<b>100</b>	<b>9</b>	<b>100</b>

Table 4 shows the brushing skill of control group without using Tooth Monster Hunter. Before brushing, most of the criteria are poor in 66.7%, while after manually brushing, the criteria are still in poor category in 44.5%.

**Table 4: Frequency Distribution of Brushing Skill of Control Group**

Category	Before		After	
	Frequency	%	f	%
Good	0	0	3	33.3
Moderate	3	33.3	2	22.2
Poor	6	66.7	4	44.5
<b>Total</b>	<b>9</b>	<b>100</b>	<b>9</b>	<b>100</b>

**B. Bivariate Analysis:** Table 5 shows the bivariate analysis on brushing skill. The first output on experimental group shows that the mean treatment before intervention is 6.65 with a standard deviation of 1.52 while after the treatment is 0.257 with a standard deviation of 0.275. Then the Mean value is greater before the treatment with difference of 6.393. The Tvalue is 12.41 with a degree of freedom of 16 and a P-value of 0.000 where this result is less than the critical limit of 0.05 so that the hypothesis answer is reject  $H_0$ . meaning that there is a significant difference between before and after the treatment.

While on the control group, the output shows that the mean treatment before is 7.41 with a standard deviation of 1.33 while the after treatment is 1.028 with a standard deviation of 0.727. Then the Mean value is greater in the treatment before the difference of 6.382. It can be seen that the result at t arithmetic is 12.61 with a degree of freedom of 16. It is seen that the p-value produced is 0,000 where the value is less than 0.05 so it is concluded that there is a significant difference between the Debris Index values before and after brushing teeth. The results of the significant differences in the before and after conditions in both the experimental and control groups give an idea that brushing has an effect on dental and oral hygiene.

**Table 5: Brushing Skill Analysis on Experimental and Control Group**

Variable	Pre-test		Post-test		Mean Treatment Gap	P -value
	Mean treatment	Std. D	Mean treatment	Std. D		
Brushing skill on Experimental Group	6.65	1.52	0.257	0.275	6.393	0.000
Brushing skill on Control Group	7.41	1.33	1.028	0.727	6.382	0.000

Changes in the value of the degree of dental health affect the skill of brushing. The change in behaviour was assessed from a questionnaire filled out by the research team. The indicators used are the stages of brushing teeth from the right, left, top, bottom and front. The results of the ability to brush teeth are given in the form of tooth brushing practice. Skills are measured by adding up scores on the observation sheet with a score technique of yes = 1 and no = 0. Figure 2 shows that Tooth Monster Hunter game has 7 game steps, so that a block of yellow dental reports will reduce the number of teeth that are scrubbed correctly. This tooth brushing skill assessment com are brushing skills between the experimental groups that were given the TOMON treatment game with the control group.

**Figure 2: Dental Report in Tooth Monster Hunter**

To see the results whether there is a significant comparison between Debris Index of the post-test of the experimental group and the control group, we conducted p-value test that produces the value shown in Table 6.

**Table 6: Debris Index Analysis on Experimental and Control Group**

Variable	Pre-test	
	Mean treatment	Std. D
Debris Index on Experimental Group	0.257	0.275
Debris Index on Control Group	1.028	0.727

Based on the calculation results, it shows that the post Debris Index score on the experimental group 0.257 with a standard deviation of 0.275. While on post Debris Index score on the control group shows 1.028 with a standard deviation of 0.727. The difference between the experimental and control group is -0,771 and the resulting T value is -2.98, not to mention the p-value is 0.009. This value is less than the critical standard of 0.05. That is, there is significant difference between the experimental and control group, meaning that Tooth Monster Hunter game have an effect on children’s dental health status compared with a control group that was not given Tooth Monster Hunter game treatment.

**Discussion**

Our research results show that there is a change of Debris Index of the experimental group from the moderate category in 66.7% and poor in 33.3% to overall good. In the control group there is a change from the poor category of 66.7% and moderate which is 33.3% to all good. However, the percentage of reduction is significantly found in the experimental group, reaching 100%.

To prove whether there is a significant influence on the experimental group on pre and post-test, p-value analysis was used. The results of paired T test statistic obtained p-value less than 0.05, that is, there is a significant difference to the Debris Index once Tooth Monster Hunter is given. The results of this study indicate that the educational media of the game TOMON has an effect on decreasing the children’s Debris Index score compared to manual brushing. This is supported by the theory put forward by Putra et al, 2016 that the game has a function that is useful in children, that is, children can understand computer technology so they can follow directions and rules, practice solving problems and logic, train motor nerves and spatial abilities.

The results of the study of tooth brushing skill on the experimental group show that there is a change from most in the moderate category of 66.7% to a good

category in 77.7%. On the control group, there is a change from the sufficient category of 66.7% to a good number of 33.3%. The percentage increase in the group given Tooth Monster Hunter game is higher than the group that was not given counselling using Tooth Monster Hunter. To prove whether there is a significant influence on the experimental group before and after the Tooth Monster Hunter treatment was given; p-value analysis was used. The results of paired T test statistic obtained p-value less than 0.05, which means reject H<sub>0</sub>, so it is concluded that there is a significant influence on teeth brushing skill using the Tooth Monster Hunter game. This shows that the group given counselling using the Tooth Monster Hunter game media has better skills than in the control group, because the Tooth Monster Hunter game can increase children’s active participation through game play so that the skills increase. Educational games are games that are not only entertaining but contain knowledge conveyed to its users<sup>(11)</sup>. Where someone who has knowledge, will use his skills to use material that he has learned in actual situations or conditions, for example a child will brush his teeth every day when he has understood dental health material<sup>(12)</sup>.

**Conclusion**

In conclusion, there is a significant influence on the dental health status of children with treatment using the game media TOMONS (Tooth Monster) into the Good category as indicated by the p-value test that produces a value of 0.009. Besides, there is a significant influence on the ability to brush children’s teeth with treatment using the game media TOMONS (Tooth Monster) into the Good and Enough category with the p-value test producing a value of 0.014.

# Infant Massage Promotes Growth in Full-term Infants

Rahma Dian Hanifarizani<sup>1</sup>, Yulia Silvani<sup>1</sup>, Mergy Gayatri<sup>1,2</sup>, Prasetya Ismail Permadi<sup>3,4</sup>

<sup>1</sup>Lecturer at Department of Midwifery, Faculty of Medicine, Universitas Brawijaya, Malang, Indonesia,

<sup>2</sup>Researcher at Center for Health Financing Policy and Health Insurance Management, Faculty of Medicine, Public Health and Nursing, Universitas Gadjah Mada, Yogyakarta, Indonesia, <sup>3</sup>Lecturer at Department of Child Health, Faculty of Medicine, Universitas Brawijaya, Malang, Indonesia, <sup>4</sup>Pediatrician at Saiful Anwar Hospital, Malang, Indonesia

## Abstract

The achievement of optimal growth is the result of the interaction of various factors, such as genetic factor, environment, behavior and stimulation. There are several other factors that influence the increase in the infant's weight including drugs, congenital abnormalities or chronic diseases of the infant, the sex of the infant, family socioeconomic conditions, nutrition and provision of baby massage stimulation. The study aims to assess the effectiveness of baby massage in promoting baby growth, i.e. weight, length, chest circumference and head circumference.

The study uses a quasi-experiment with pretest-posttest control group design. Subjects were recruited from visitors in integrated service post (in Indonesian: Posyandu), independent midwifery practices and community health sub-centers. We collected data of baby growths in Malang regency where the residents are a homogeneous group. 30 infants were included in the study. They, subsequently, were randomly divided into experimental and control group. The experimental group babies aged 3-6 months participated in the baby massage for four weeks. The control group (N=15) was paired with the experimental group (N=15) by matching the baby's age and sex. The growth indicators were measured two times and statistically analysed using independent t-test and eta-squared test.

Growth assessment used measurement results from variable body length, weight, chest circumference, head circumference. After four weeks of massage, we found that weight, length, chest circumference and head circumference increased among babies aged 3 to 6 months who received stimulation of baby massage. Overall, the results of this study reassure that baby massage affects the growth of the infant.

**Keywords:** *Baby massage, infant growth, length, weight, chest circumference, head circumference.*

## Introduction

Massage is ordered physical stimulation, such as holding, causing movement and/or pressuring to the body that is used to treat medical conditions<sup>1,2</sup>. Massage

has been used for intervention purposes in China in 2760 Bc<sup>3</sup>. In the 21<sup>st</sup> century, it became more popular in North America. Since 1980s, many researchers, clinicians and academicians started to pay attention to massage for pre-term and term babies<sup>4, 5</sup>. Many literatures reported that growth and development of term and preterm babies as a result of baby massage<sup>6-9</sup>. Moderate pressure stroking as well as the flexion and extension of the upper and lower extremities in baby massage could increase bone mineral density and improve bone growth<sup>10</sup>.

Indonesian cultures have recognized traditional massage for an infant for more than a decade and most of them have been done by Traditional Birth

Attendants (TBAs). To the present, Indonesia becomes more interested in modern infant massage. Some health professionals have been implementing it for recent years. Nevertheless, to the present, there is no national guideline on baby massage. In addition, less is known about the effect of infant massage to baby growth with full-term babies in Indonesia. Thus, the aim of this study was to explore the effect of baby massage to growth among babies with normal birth weight.

The present study focuses on baby aged 3 to 6 months old as it is the period of time for baby growth. It is important to seek a treatment in optimizing baby growth in order to prevent growth delay. We assessed the effect of baby massage in autonomous midwifery practices and integrated service post (in Indonesian: Posyandu) in Malang Regency using quasi-experimental design. Malang is a homogenous population regency in Indonesia where baby massage is popular and usually given by TBAs. Lessons about in this study are relevant to others who look for a treatment for optimizing baby growth.

## Method

**Design:** The research used quasi experiment, with the pre-test post-test with control group design. The population in this study was 3-6 months old healthy babies in 1 integrated service post (in Indonesian: Posyandu) and 5 autonomous midwifery practices in Malang regency, totaling 30 babies. The sample of the study was 30 babies who were divided into 2 groups of observations, i.e. the control group and the experimental group. The first group was a control group or infants without massage treatments consisting of  $n = 15$  infants and another group as a massage experimental group consisting of 15 infants. The total of respondents in the study was limited because the baby in the regency generally had been received a massage by health care professional or Traditional Birth Attendants (TBAs) before they turned to 3 months old.

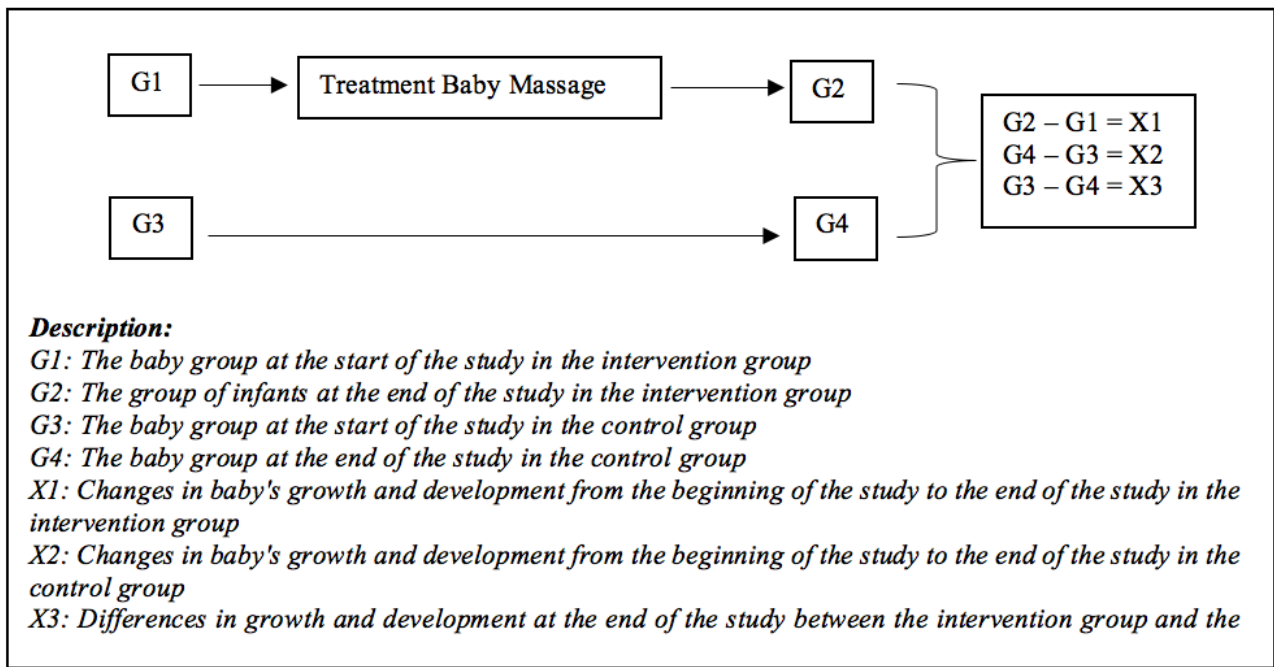

**Sample:** The respondents were selected using consecutive sampling method. The samples were matched on their characteristics, such as age, sex, number of siblings and characteristics of parents. The samples,

moreover, were divided into two groups randomly. The odd sequence numbers were the group receiving massage therapy (the experimental group) while the even numbered numbers were the group that did not receive massage therapy (the control group). Hence, 15 babies would be treated and 15 babies would be used as controls. The inclusion criteria in this study were full-term healthy infants with exclusive breastfeeding while the exclusion criterion was the baby who had congenital abnormalities and received baby massage.

## Data collection

We asked midwives in integrated service post and autonomous midwifery practices to select respondents who met the inclusion criteria. At the first meeting, we measured infants' weight, length, head circumference and chest circumference which the results were recorded in notes. We used baby weight scale for weight measurement, infantometer for length measurement and midline for head circumference and chest circumference measurement. We, subsequently, taught the mothers by demonstrating the baby massage. The massage was performed by the team who were lecturer midwives and student midwives from Universitas Brawijaya who had been trained of baby massage. The steps of baby massage followed the standardized standard operational procedure of baby massage by the Indonesia Holistic Care Association (IHCA)<sup>11</sup>.

After the demonstration, we let the mothers performing the baby massage directly to their baby. In the process, the mothers were observed by the team. After the meeting, we provided the mothers a leaflet containing the steps of baby massage and asked them to do a baby massage twice a week for a month. We reminded them to do the massage by a phone call. In the process of massage, the team observed the mother while performing the massage to ensure the steps and techniques. In the duration of research, the mothers were encouraged to not massage the baby by other people, including health care professionals and TBAs in order to prevent bias. In general, every baby received approximately 15 to 30 minute massage in one time massage. After receiving massage for one month, the four criteria of growth were remeasured by the team.

**Figure 1. Design of the study**

**Data Analysis:** Data were analyzed using SPSS for Windows version 25 and presented descriptively to indicate means and standard deviations. Independent sample t-test was used to analyse the difference (deviation) in the variables studied in the control group and the experimental group. Finally, to measure the effect of baby massage to variables studied, we used Eta-squared test<sup>12</sup>. All parents of the respondents agreed to participate in the research by signing informed consent form. Informed consent was obtained from all parents and each experimental group parent was provided with a leaflet on baby massage steps.

**Results**

**Parent Characteristics:** The observed characteristics of the baby's parents consisted of the mother's age, mother's occupation, mother's education

level, mother's parity number, father's age, father's occupation, father's education level and parents' income level. The characteristics of the parents chosen were similar after the characteristics of the baby were matched.

The table 1 reveals that the distribution of mother's age data between the control group and the experimental group are similar. With regard to parents' age data, the mothers' and fathers' age of the experimental group is older than the age of the control group. The data on the types of mothers' work are spread almost equally and evenly between the two groups while father's occupation types show exactly the same between the two groups. In terms of parents' education, fathers' and mothers' education data are spread almost equally and evenly. This is also the same with parity data and income level that are spread almost equally and evenly.

**Table 1. Parents characteristics**

V a r i a b e l	Parents group	
	Control	Experiment
Mother's age (years old)	26.4±5.9	29.4±5.3
Father's age (years old)	29.6±4.8	34.1±5.2
Mother's occupation:		
<i>Unemployment (housewife)</i>	10	10
<i>Private</i>	5	2
<i>Entrepreneur</i>	0	3
Father's occupation:		
<i>Private</i>	13	13
<i>Entrepreneur</i>	2	2
Mother's highest educational level:		
<i>Primary</i>	2	1
<i>Junior high school</i>	5	5
<i>Senior high school</i>	7	8
<i>University</i>	1	1
Father's highest educational level:		
<i>Primary</i>	1	2
<i>Secondary</i>	3	3
<i>High school</i>	9	8
<i>University</i>	2	2
Parity (number of delivery):		
<i>1</i>	8	5
<i>2</i>	6	8
<i>3</i>	1	2
Income per month (Indonesian Rupiah) :		
<i>&lt;2.000.000</i>	5	9
<i>2.000.000 - 2.500.000</i>	9	2
<i>2.500.000 - 3.500.000</i>	0	2
<i>&gt; 3.500.000</i>	1	2

**Baby Characteristics:** The characteristics of the observed infants consisted of the age of the baby, sex and number of siblings. The selection of research subjects was based on the similarity or compatibility of the three characteristics.

**Table 2. Infant characteristics**

Variabel	Infant group	
	Control	Experiment
Infant's age (months old)	3.53±0.8	3.53±0.8
Number of siblings:		
0	8	6
1	6	7
2	1	2
Sex :		
Male	8	8
Female	7	7

Table 2. shows that baby age data in the control group and experimental group with mean ± stan.dev is 3.53 ± 0.8 months showing the age of infants spread between 2.73 months and 4.33 months. Data on the number of siblings in the control group and experimental group is spread almost equally and evenly while the sex data in the control group and the experimental group are

the same, consisting of 8 babies (53.33%) and 7 babies (46.67%).

**Effect of infant massage on growth of 3-6 month infants:** The study used an independent t-test to determine whether there was a difference in infant growth before and after the infant massage in the experimental group and the control group.

**Table 3. Before and after the infant massage**

Variable	Group	Before treatment (x <sub>1</sub> )	After treatment (x <sub>2</sub> )	p-value (x <sub>2</sub> -x <sub>1</sub> )	η <sup>2</sup> (Eta-squared)
Body length	Control	60.87±3.96	63.27±4.71	0.35	0.03
	Experiment	59.60±3.51	62.70±3.93		
Weight	Control	6246.7±946.3	6763.3±944.1	0.04	0.14
	Experiment	6100±920.4	6986.7±1080.3		
Chest circumference	Control	40.47±2.68	41.77±2.60	0.46	0.02
	Experiment	40.80±2.49	42.43±3.01		
Head circumference	Control	40.10±2.02	41.23±1.94	0.86	0.00
	Experiment	40.12±1.23	41.32±1.68		

Table 3 shows that he growth of infants in the intervention group and the control group, the t-value was 0.35 for body length, 0.04 for body weight, 0.46 for chest circumference and 0.86 for head circumference. P-value calculated was used to assess the value of the effectiveness of a treatment using Eta-squared test. The value of Eta-quared test in this study is 0.03 for the body length category, 0.14 for the weight category, 0.02 for chest circumference and 0.00 for head circumference. Thus, baby massage has a small effect for the growth of body length, chest circumference and head

circumference. In addition, baby massage has a great effect for infants growth.

**Discussion**

This study found that there was a great effect for weight gain among babies aged 3 to 6 months who received regular baby massage. Several studies also confirm that baby massage supports weight gain and growth in term babies<sup>6,13,14</sup>. The findings of experimental study confirm that 6 week baby who received four week

massage increased in weight gain<sup>6</sup>. Another experimental also found that baby massage supports weight gain among five- to ten-week term neonates born from HIV mothers who who were massaged a week for ten weeks<sup>14</sup>. A study found that weight gain after receiving baby massage might be because of variety of massage parts and the longer massage duration<sup>15</sup>. Baroreceptors are innervated by tactile stimulation that release food absorption hormones and increase insulin level<sup>16-17</sup>. As a result, it stimulates vagal activity that supports preterm infant weight gain<sup>16-17</sup>. Better food absorption due to increased activity of *nervusvagus* causes the baby to feel hungry fast, so that the baby will suckle the breast milk more often<sup>18</sup>.

We found that infant massage only had a slight effect on the growth of the baby's length. The growth of infant length in the two groups is in accordance with the growth curve of the National Center for Health Statistics (NCHS), where the curve shows body length increased approximately 1 inch (2.5 cm) every month for the first 6 months. A study reported a more significant growth in length in the group treated with infant massage with a longer duration of treatment and more frequent of measurements in the study<sup>13</sup>. Growth in length occurs due to changes in cartilage to hard bone<sup>18</sup>. At the beginning of infant growth, more *osteoblasts* are formed than *osteoclasts*, both of which are influenced by growth hormones. The growth hormones can be stimulated through infant massage therapy, with baby massage treatments causing secretion of serotonin. In infant physiology, it is mentioned that serotonin secreted by the nervous system in the *hypothalamus* will increase the speed of growth hormone secretion<sup>18</sup>. Reducing tactile sensation will increase *beta-endorphine neurochemical* release which will reduce the formation of growth hormone due to decreased amount and sensitivity of ODC (*Ornitin Decarboxilase*) tissue activity<sup>18</sup>. ODC only responds actively to stimulation, so touch stimulation or baby massage will help the responsiveness of ODC<sup>18</sup>.

The mean of chest circumference in the experimental group was greater than the mean of the control group, yet it had a small effectiveness value. These finding is similar with a study discovering that when baby turned to 3 months old, only a few variables could affect the growth of chest circumference<sup>19</sup>. Prenatal life and early baby's life are most of the factors that can affect chest circumference<sup>19</sup>. The results of measurements on head circumference showed no significant growth between the experimental group and the control group. This

means that baby massage did not increase infants' head circumference. Predisposing factors of a baby's head circumference have been widely studied, maternal age, height, weight gain during pregnancy, socioeconomic background, lifestyle and environmental exposure were identified as significant factors.

Our study explored the effectiveness of baby massage in homogenous populations and discovered that baby massage supports growth of babies aged 3 to 6 months. Yet, we acknowledge that our study has limitation. Our findings maybe influenced by the babies who dropped out from exclusive breastfeeding. It could shows that although there were babies in the experimental group stopped receiving exclusive breastfeeding, their growth increased significantly compared to those who were not massaged.

## Conclusion

Stimulation of infant massage at 3-6 months old had an effect on increasing in infant growth, such as weight, length, chest and head circumference. Suggestions are given for further researchers to increase the number of samples; extend the duration of the study; examine more closely the factors related to the growth and development of infants such as: hormonal, genetic, parenting, nutritional patterns (both mother and baby), rest patterns (sleep quality) and patterns of infant activity; and do more infant massage stimulation. With the frequency of massage more often by parents, it is expected that the increase in growth and development in infants is more significant, besides bonding attachments between parents and babies will be formed properly.

# The Outcome of Myringoplasty with and without Cortical Mastoidectomy Comparative Study between Elastic Nail Versus Plates and Screws in the Treatment of Diaphyseal Both Bone Forearm Fracture in Children

Farhad Jalil Khayat<sup>1</sup>, Laysaa Adil Rashid<sup>2</sup>, Hayder A. Fawzi<sup>3</sup>

<sup>1</sup>Processor, College of Medicine, Hawler Medical University, Erbil, Iraq, <sup>2</sup>Lecturer, Iraqi Board for Medical Specializations, Erbil, Iraq, <sup>3</sup>Senior Lecturer, Department of Pharmacy, Al-Rasheed University College, Baghdad, Iraq

## Abstract

**Objective:** Evaluate the outcome of myringoplasty with and without cortical mastoidectomy regarding the graft take and hearing improvement in none-cholesteatomatous chronic suppurative otitis media.

**Materials and Method:** This prospective study was done on 50 patients who suffered from long-standing perforation of the tympanic membrane. Among these patients who underwent surgery 34 patients were subjected to myringoplasty with cortical mastoidectomy (Group I) and in the remaining 16 patients had myringoplasty alone (Group II).

**Results:** The hearing gain (dB) in myringoplasty combined with cortical mastoidectomy in (group I) after 6 months was (16.03) dB and in (group II) who underwent the only myringoplasty was (15.31) DB. Overall Graft uptake was 88.0 %. Although myringoplasty with cortical mastoidectomy was better than a group of myringoplasty alone in hearing improvement and graft take the differences between the two groups were statistically not significant. Age, sex and the side of perforation had no bearing on graft take in this study.

**Conclusion:** Myringoplasty is an effective method for closure of the tympanic membrane perforations and for hearing improvement.

**Keywords:** Myringoplasty, Cortical mastoidectomy, Graft uptake, Hearing improvement, tympanic membrane.

## Introduction

Tympanic membrane (TM) perforation represents a defect in the function and integrity of the eardrum that needs repairing in most cases as it may lead to significant

morbidity like hearing loss, recurrent otorrhea, middle ear infection<sup>1</sup>. Although most acute TM perforations heal spontaneously, large or chronic TM perforations, especially from chronic suppurative otitis media, always fail to heal and require grafting<sup>2</sup>.

Myringoplasty is the surgical procedure used to reconstruct the perforated tympanic membrane without dealing with any pathology in the middle ear cleft, such as chronic infection, cholesteatoma, or problems with the ossicular chain<sup>2</sup>.

Different graft materials and techniques have been described like temporalis fascia, perichondrium, periosteum, vein, duramater and cartilage<sup>3</sup>.

The most commonly used grafting material is temporalis fascia because of its accessibility at the surgical site. Although, in situations such as advanced middle ear pathology, large perforations, atelectatic ears or retraction pockets, temporalis fascia may cause lower success rates regardless of the surgical technique used<sup>4</sup>.

On the other hand, the cartilage is found to be resistant to; the retractions, middle ear pressure and infections during the healing period due to its rigidity and stiffness, as well as it is assumed to be minimally contributive to the inflammatory tissue reaction due to lack of capillary feed and is well incorporated with tympanic membrane layers<sup>5</sup>.

In cartilage myringoplasty, the graft material can be harvested from tragus, concha, crus of the helix, or costal cartilage. Cartilage for myringoplasty is prepared by several method like perichondrium/cartilage island graft, cartilage shield, palisade, inlay butterfly graft and others.<sup>6</sup>

Myringoplasty can be performed through many techniques but the most used are; overlay technique (lateral grafting); graft put lateral to the remaining tympanic membrane, underlay technique (medial grafting); graft put medial to tympanic sulcus and lateral to the malleus handle and<sup>7</sup>.

The aim of the current study to assess the final outcome of myringoplasty with and without cortical mastoidectomy regarding the graft take and hearing improvement in none-cholesteatomatous chronic suppurative otitis media.

## Method

**Study setting and time:** This study was carried out during the period from July 2017 till July 2018 at otolaryngology department, at Rizgary Teaching Hospital/Erbil.

**Study Design:** Prospective randomized comparative study.

**Patients:** This study included 50 patients in which 34 patients underwent tragal cartilage myringoplasty with cortical mastoidectomy (Group I) and 16 patients underwent tragal cartilage myringoplasty alone (Group II).

### Inclusion Criteria:

1. More than 14 years

2. Dry perforation for 3 months at least
3. Chronic perforation of the tympanic membrane, the perforation was medium to large size central perforation
4. Tubotympanic type of CSOM
5. Ct-scan of temporal bone revealed a well-pneumatized mastoid and middle ear included in the study.

### Exclusion Criteria:

1. less than 14 years
2. Persistent discharging ear or CT-scan show the feature of possible cholesteatoma
3. Marginal or attic perforation
4. Associated otitis externa
5. Previous mastoid operation
6. Diabetes mellitus
7. Patients that were lost in the post-operative follow-up
8. Ossicular chain problem
9. Patient with sensorineural hearing loss
10. Suspected Eustachian tube dysfunction with severe septal deviation and persistent Allergic Rhinitis.

**Pre-operative Planning:** The examination begins with an inspection of the auricle for any scar, sign of inflammation, perichondritis or discharge. Microscopic ear examination to evaluate tympanic membrane perforations size, site and state of remainder of the tympanic membrane if there is any tympanosclerosis.

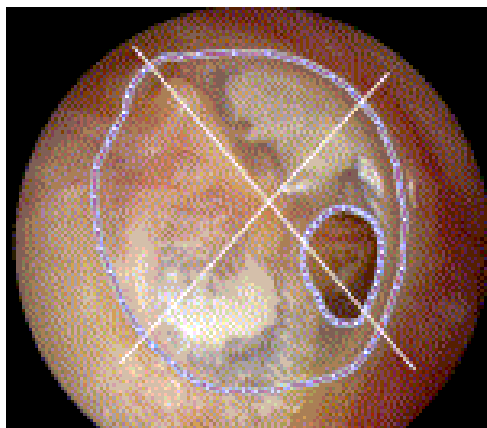

Size of perforations according to the surface area of the perforated tympanic membrane. The sizes of the perforations were graded according to the surface area of the perforated tympanic membrane, in which ( $\leq 25\%$ ) considered small size, (26%-50%) considered as medium size perforations, while (51%-100%) regarded as large size one.

Endoscopic images were taken for each TM perforation by a digital camera and using a 4 mm diameter, 0-degree angulation endoscope (Karl Storz, Germany) connected to a Sony TV screen. By using Adobe acrobat 8 professional software which computes the surface area of the perforation separately then the surface area of the whole TM. The percentage of the perforation was calculated by the equation:

**TM area** = 9644.03 mm<sup>2</sup> and **perforation area (Pa)** = 782.34 mm<sup>2</sup>

The percentage of the perforation area = 100 x Pa/ TM area = 8.1%

This perforation is classified in the grade I (small perforation = perforation less than 25% of the TM surface).

**Figure 1: Percentage of TM perforation**

**Hearing Assessment:**

The preoperative hearing level was assessed using:

- Tuning fork 512 Hz (Rinne and weber’s test)

- Pure tone audiometry to evaluate the air-bone gap and bone conduction depending on the following frequencies (500, 1000, 2000, 4000 Hz) all of the results were recorded to evaluate the air-bone gap of each side. and a minimum hearing improvement of 10 dB was regarded as an audiological success.

**Tragal cartilage harvesting:** After an injection to the tragus, a small incision is made on the medial aspect of the tragus, both sides of the tragal cartilage dissected using curved scissors leaving perichondria on both sides of cartilage than a large part of cartilage together with perichondrium are resected.

**Postoperative Outcome:** Successful operation (regarding graft) was considered if the graft was still in situ with the absence of residual perforation. Operation failure was labeled if the graft was rejected or residual perforation was present after 6 months. Hearing improvement was achieved if there was a hearing gain for at least more than 10 dB by comparing it to the mean of the air-bone gap of the preoperative results.

**Statistical Analysis:** All analysis carried out using the chi-square test, or independent t-test and SPSS version 20.0 was used to perform the analysis

**Results**

Group II	16.79 ± 5.75	5.0 ± 0.01	<0.001

## Discussion

Regarding the side of perforation in this study, the left-sided ear was found to be affected in 31 cases (62.0%) and the right side was affected in 19 cases (38.0%) and this side predominance could not be explained. This was in agreement with Nagle et al, perforation was more on the right side<sup>8</sup>.

There was a high prevalence of large perforation (72.0%) in subjects. This was in agreement with Vybhavi et al study in which most of the patients had a large central perforation in both groups 50% in the group of myringoplasty and 56.66% in the group of myringoplasty with cortical mastoidectomy<sup>9</sup>. This was contrary to another study done by Biswas *et al* medium-sized perforation was commonest one<sup>10</sup>.

The site of perforation was highly prevalent in anterior (80%) with no significant differences between the two groups. Site is one of the factors contributing to graft failure, (anterior superior perforations) has more incidence of graft failure. This may be due to technical difficulty with anterior perforation.

Total success rate in our study was 88% which was higher in group I (88.2%) than group II (87.5%) the differences was statistically not significant, this was comparable to Doifode et al study<sup>11</sup> and Vybahvi et al<sup>9</sup> in which they observed success rate of 92% and 86.6% for myringoplasty with cortical mastoidectomy compared to 79% and 93.3% for myringoplasty alone, however, the result was statistically not significant.

While graft success rate was higher than Bhat et al<sup>12</sup> and Albu et al<sup>13</sup> in which they observed a success rate of 82.85% and 82.8% for myringoplasty with cortical mastoidectomy compared to 75% and 76% for myringoplasty alone. However, the result was non-significant between the two groups.

Regarding hearing improvement in our study, the mean of overall hearing gain in dB of the whole sample was 16.2. The present study revealed that in group I pre- and postoperative pure tone average was 31.62 and 15.59 respectively and this was statistically significant. While in group II pre- and postoperative pure tone average was 32.81 and 17.50 respectively and this was statistically significant. But when these values are compared between the two groups, it was non-significant.

In Toroset al study the mean hearing gain was higher in the group of myringoplasty alone  $10.52 \pm 10.49$  as compared to the group of myringoplasty with cortical mastoidectomy  $9.66 \pm 9.0$  and the difference was not statistically significant<sup>14</sup>.

In Vybavi et al study the mean pre- and postoperative pure tone average was  $42 \pm 10.43$  dB and  $34.9 \pm 9.94$  dB in the group of patients who underwent myringoplasty with cortical mastoidectomy with a mean hearing gain of  $7.1 \pm 8.85$  dB. The mean pre- and postoperative pure tone average was  $42.4 \pm 10.53$  dB and  $32.8/13.02$  dB (inpatient underwent myringoplasty alone) with a mean hearing gain of  $9.5 \pm 11.33$  dB, no statistical significance between two groups<sup>9</sup>.

Kawatra et al reported mean change in the air-bone gap was slightly higher in the group of myringoplasty with cortical mastoidectomy  $10.13 \pm 6.65$  as compared to group II of myringoplasty alone  $9.75 \pm 5.99$ <sup>15</sup>.

Agrawal et al stated that the hearing improvement was 12.5 dB in patients who underwent myringoplasty with cortical mastoidectomy and it was 9.41 dB in the group of patients who underwent myringoplasty alone<sup>16</sup>. Their result of hearing gain was lower than the present study.

Graft failure in our study was seen in 6 years 12%. the graft failure rate in group I was 4 (11.8%), whereas in

group II was 2 (12.5 %) but it is not significant. A study done by Tawabet al included 40 patients. The failure rate was 25% which was higher than ours, in a group of myringoplasty with cortical mastoidectomy failure rate was 4(20%) while 6(30%) in the group of myringoplasty alone. They emphasize that overall satisfactory hearing outcome with air-bone gap closure can be achieved irrespective of cortical mastoidectomy in the surgical treatment of tubotympanic disease<sup>17</sup>.

### Conclusion

The study showed that myringoplasty with and without cortical mastoidectomy carries similar surgical success, there was no significant difference between them. The hearing gain was significant for both myringoplasty with cortical mastoidectomy and myringoplasty alone and the differences between these two groups were not significant.

**Conflict of Interest:** None

**Ethical Clearance:** Informed written consent was obtained from all the participants in the study and the study and all its procedures were done in accordance with the Helsinki Declaration of 1975, as revised in 2000. The study was approved by the Iraqi Board of Medical Specializations.

# Determinants of Unmet Need for Family Planning among Married Women Age 15-49 in Sumatera Utara Province (Analysis of 2017 RPJMN Data)

Erna Mutiara<sup>1</sup>, Ancha Sitorus<sup>2</sup>, Sri Rahayu Novita<sup>3</sup>

<sup>1</sup>Senior Lecturer, Department of Population and Biostatistics, Faculty of Public Health Universitas Sumatera Utara, <sup>2</sup>National Population and Family Planning Board Representative Sumatera Utara Province, <sup>3</sup>Alumna, Department of Population and Biostatistics, Faculty of Public Health Universitas Sumatera Utara

## Abstract

Unmet need is still a serious problem that has relevance to development in the field of population. The Indonesian Demographic and Health survey shows the percentage of unmet need for family planning increased in 2017 by 11%. This analysis aims to find out the important determinants that contributed to unmet need for family planning in Sumatera Utara Province.

The analysis used secondary data from 2017 National Mid-Term Development Plan (RPJMN) Data carried out by National Population and Family Planning Board (BkkbN). The population in this analysis are all married women of childbearing age and the samples are married women of childbearing age who did not use contraception. The dependent variable is unmet need and determinant variables are socio-demographic characteristics (age, education, occupation, wealth quintile, number of living children and residence), knowledge of contraceptive method and service delivery factors namely exposure to family planning information and family planning officers visit.

There are 795 women childbearing age who do not use contraception as many as 37.5% have unmet need (9.6% of unmet need for spacing pregnancy, 27.9% of unmet need for limiting pregnancy). Thus, 1 out of 6 married women has unmet need. Variables of women's age, number of children still alive, knowledge, family planning officers visit are important determinants that contributed to unmet need for family planning in Sumatera Utara Province with the most contributed variable is age. Communication, Information and Education (IEC) efforts need to be improved on married women using mass media and family planning officers visit. Collaborating with local community and traditional leaders in the paradigm shift about the number of children are important part in reducing unmet need for family planning in Sumatera Utara Province.

**Keywords:** *Unmet need, married women, number of children, knowledge, officers visit.*

## Introduction

Sumatera Utara Province in 2017 has a population

of 14,262,147 and with the population growth during the period 2000-2010 is 1.22 percent per year<sup>1</sup>. The trend of the Total Fertility Rate (TFR) projection shows a decline from 3.00 in 2012 to 2.79 in 2017<sup>2</sup>. The results of the 2017 RPJMN survey report a TFR of 2.66 in Sumatera Utara Province and a prevalence of 52.3% in the use of contraceptive method among women of childbearing age, which do not meet the 2017 national target of 2.33 for TFR and 60.9% for contraceptive prevalence established by BkkbN<sup>3</sup>. The decrease in TFR is not followed by a significant decrease in unmet need,

---

e-mail: [erna3@usu.ac.id](mailto:erna3@usu.ac.id)

which actually increased from 10.2% in 2012 to 25.3% in 2017<sup>4</sup>.

Unmet need is a need for contraception that is not fulfilled. Women of childbearing age are said to be unmet need if they want to delay pregnancy or end pregnancy for the next two years but they do not use contraception<sup>5</sup>. The high number of unmet need influence the tight birth spacing and the high number of children born so that there is a high risk of maternal and infant mortality<sup>5</sup>.

The 2017 Indonesian Demographic and Health Survey (IDHS) of Sumatera Utara Province reports the level of unmet need for family planning decreased from 13% in 2012 to 11%. There are several different characteristics between provinces in Indonesia that affected the magnitude of unmet need for family planning<sup>5,6</sup>.

The high number and population growth will be a big problem if it is not addressed immediately. In 2015-2020 the population growth of Sumatera Utara Province is projected at 1.08%<sup>2</sup>. Such population growth is caused by the high rate of TFR. The 2017 IDHS includes Sumatera Utara's TFR of 2.9 children per woman during their lifetime. Even rural women have a higher TFR of 0.7 than women in urban areas<sup>6</sup>. The high TFR is caused by the high rate of unmet need for family planning in Sumatera Utara Province, 11% in 2017<sup>6</sup>. Besides being able to increase TFR, unmet need can result a decrease in contraceptive prevalence rate (CPR), which has risen only 3% from 2012-2017<sup>6</sup>. This analysis aims to understand the important determinants of unmet need for family planning in Sumatera Utara Province.

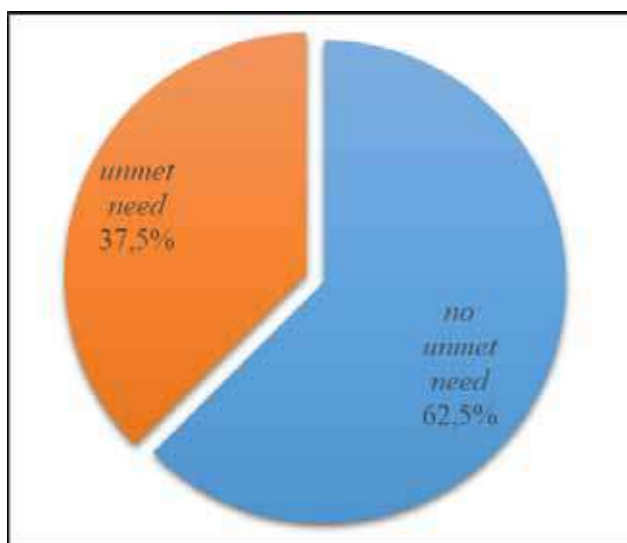

## Materials and Method

This survey uses a cross-sectional design. The population are married women who have given birth. The sample are women of childbearing age (WUS) 15-49 years old, married and designed to represent 33 districts/cities in Sumatera Utara Province. The sample size used is 795 married women of childbearing age (WUS) who do not use a contraceptive device in 78 clusters. The sample frame is a list of villages throughout Indonesia, equipped with urban/rural classification. The sampling design used is a two-stage sampling: Stage 1: A number of villages as clusters are selected by Proportional Probability to Size (PPS) sampling with the number of households. Stage 2: 35 households are selected by systematic random sampling. Data collection is carried out from April to June 2017.

Weight is calculated as a result of using the cluster sampling method at the time of the selection of research samples during data collection. Weight is normalized first so that the number of respondents analyzed do not experience swelling<sup>7</sup>.

## Result and Discussion

**Description of Unmet Need:** The analysis shows that of the 795 women of childbearing age (WUS) who do not use contraception as much as 37.5% experienced unmet need (Figure 1), 9.6% experienced unmet need for pregnancy spacing, 27.9% for pregnancy restriction. Thus, 1 out of 6 married women of childbearing age (WUS) experiences unmet need. Using a revised definition of unmet need, another analysis in Burundi in Central Africa also estimates unmet need at 32.4%<sup>8</sup>. This result is apparently greater than the national unmet need results of the 2017 IDHS results of around 11%<sup>6</sup>. The findings reveal that the number of unmet need for married women of childbearing aged 15-49 years in Sumatera Utara Province is lower than that of in Dang District of Nepal (49%), but higher than that of 26% in Klabang Sub-District Bondowoso Regency East Java and in the South Sulawesi Province at 14.3%<sup>9</sup>.

**Figure 1. Percentage of Unmet Need in Sumatera Utara Province in 2017**

**Cross tabulation of social demographic with unmet need:** As it is shown in Table 1, respondents aged 15-19 years have a risk of 2.78 times experienced unmet need greater than respondents who are > 35 years old. In Yogyakarta, respondents aged 16-34 years have a tendency of 1.626 times higher to experience unmet need compare to respondents aged 35-49 years. While in

Nusa Tenggara Timur (NTT), respondents aged 16-34 years have a tendency to 1,266 times higher to experience unmet need than respondents aged 35-49 years<sup>10</sup>.

Respondents who worked have a risk of 1.14 times greater to experience unmet. Consistent with the research conducted in West Padang<sup>11</sup>. Awareness of mothers who did not work for family planning is based on their low economy, so they think about regulating the number of births. The respondents with the fourth wealth quintile have a risk of 2.04 times greater to experience unmet need than the lowest respondents. Respondents have more than 2 children alive are 1.24 times more likely to experience unmet need. In Yogyakarta and NTT respondents with 3 children still alive or more, most experienced unmet need (respectively 1,848 times and 1,636 times)<sup>10</sup>. Same as the research conducted in Klabang District, women have 3-4 children are 5.4 times more at risk (95% CI: 0.99-29.60) to experience unmet need. The more children they have, the more likely a woman have exceeded her desired fertility preference, because she have unmet need<sup>9</sup>.

**Cross tabulation of knowledge about contraception with unmet need:** Respondents have poor knowledge are 1.69 times more likely to experience unmet need. A person's knowledge is the result of human sensation, or the result of knowing someone to a particular object through their senses (in this analysis in the form of a sense of hearing)<sup>10</sup>.

**Cross tabulation of contraceptive service providers with unmet need:** Respondents who are exposed to mass media have experienced 1.39 unmet need. Respondents visited by family planning officers are 3.03 times more likely to experience unmet need.

From Table 2 as a result of multivariate analysis, respondents aged 15-19 years have a tendency to experience unmet need 12.5 times higher than respondents aged 36-49 years after being controlled by number of children still alive, knowledge, media exposure and officer visits. Respondents aged 36-49 years will have the possibility of unmet need 0.08 times less than respondents aged 15-49 years. Consistent with the analysis in Burundi Central Africa showed the possibility of unmet need will decrease with increasing age<sup>8</sup>. The findings in Kenya also showed that respondents aged 35 years and over tend to experience unmet need 0.343 times less than respondents ages 15-19 years<sup>12</sup>. Respondents with the number of children 3 or more have a probability of 1.69 times unmet need. The analysis also

reveals that unmet need have a protective relationship with well-informed respondents [aOR = 0.47 (0.33 - 0.67)], respondents with poor knowledge have 2.13 times the possibility of unmet need.

Respondents who are exposed to the media have a 1.39 times unmet need. Respondents in Yogyakarta who are not exposed to mass media access and have poor knowledge tended to experience unmet need 3,640 times after being controlled by education, number of children still alive, female autonomy, media access, knowledge and age<sup>10</sup>.

The opportunity for unmet need for respondents who are not visited by Family Planning officers [aOR = 0.21 (0.13 - 0.35)] meant that respondents visited by officers have a 4.76 chance times unmet need. Relevant with findings in Ciawi Gebang, although the approach is different. Respondents received family planning counseling have 2.50 times unmet need after being controlled by the husband's knowledge and husband approval variables (95% CI 1.09 - 5.77)<sup>13</sup>.

Many factors associated with unmet need for family planning such as a lack of understanding of the risks of pregnancy, potential side effects and health concerns, lack of exposure to the risk of pregnancy, a prohibition on using contraception, did not want to be busy, also subjective experience that pregnancy would not occur without contraception<sup>14</sup>. Empirical evidence in Nusa Tenggara Barat showed that unmet need related to factors of age, parity, education, husband's education, economic status and family planning officers visit<sup>15</sup>.

Respondents who have 3 or more children tended to be 1.69 times higher to experience unmet need. The results indicated that the more children, the higher the unmet need. In Yogyakarta respondents who have 3 children or more tend to be 2.779 times higher to experience unmet need while in NTT tend to be 2.036 times<sup>15</sup>. The more the number of children alive, the more women tend to reach the desired family size and thus wish to limit further childbearing<sup>16,17</sup>.

Respondents with poor knowledge have greater unmet need events (2.13 times). In line with the results of the analysis of Putri (2013) and Hamid (2002) where respondents with poor knowledge are at greater risk of experiencing unmet need (respectively 1.59 times and 4.33 times)<sup>18,19</sup>. The research consistent with other studies from low-income countries such as West Bengal, India, Pakistan and Eritrea (a country located in northeastern Africa)<sup>20,21</sup>.

### Conclusion and Suggestion

**Conclusion:** The determinants of unmet need for married women who do not use contraception in Sumatera Utara Province are age, number of children still alive, knowledge and visits of officers. The most contribution determinant is age.

It suggested to improve Communication, Information and Education (IEC) efforts for married women by using mass media and family planning officers visit are expected to be very influential in increasing the knowledge of married women of childbearing age. Thus it is needed to increase the quality and quantity of Family Planning Field Officers (PLKB). Establishing cooperation with community leaders and local traditional leaders in the paradigm shift in the number of children is an important part in reducing unmet need in Sumatera Utara Province.

# Relationship between Effective Leadership and Decision Making on Patient Safety Culture

Endang Pertiwiwati<sup>1</sup>, Jajar Martono<sup>2</sup>

<sup>1</sup>Nursing Study Program, <sup>2</sup>Student of Nursing Study Program, Faculty of Medicine, Lambung Mangkurat University, Jl. A. Yani KM.36 Banjarbaru, 70714. Indonesia

## Abstract

**Background:** Patient safety culture is the value, belief, behavior adopted by individuals in an organization regarding safety that prioritizes and supports the improvement of safety in patients in the treatment process. The application of optimal culture in order to become a habit requires discipline from the leader to fit the stated goals. Purpose - This research aims to determine the relationship of effective leadership and decision making on patient safety culture in the nursing ward.

**Research Method:** This research is a quantitative non-experimental descriptive research with the collection of total sampling data in the form of a questionnaire to all nurses in the nursing ward with total number of 85 respondents.

**Results:** The results of the analysis of respondents in the study obtained results  $p = 0.931$  for effective leadership analysis of the patient safety culture., While for the analysis of decision making on patient safety culture obtained results  $p = 0.026$  and the pearson moment value obtained results 0.212.

**Conclusion:** Firm and systematic decision making is needed in the application of patient safety culture so meet the goals of professional service planning.

**Keyword:** *Decision Making, Nurse, Patient Safety Culture.*

## Introduction

The effort to improve service quality and patient safety in hospitals is now a necessity and a movement that is universalized by various parties. Developed countries have begun to make a paradigm shift in services that previously focused on quality towards the quality-safety paradigm. This indicates an increase not only in the service quality sector but more focused on maintaining patient safety consistently in the era of globalization<sup>1,2</sup>.

The current era of globalization in the ASEAN Economic Community MEA (MEA) has created challenges for all types of industries to compete, including the industry in the health services sector, this is encouraging the rapid growth of new hospitals to meet customer needs. Such business environment conditions require hospitals to improve the quality and quality of services in order to remain successful, both at the operational, managerial and strategic levels<sup>3</sup>.

The quality and service quality of a hospital as an institution that produces health care technology products certainly depends also on the quality of medical services and nursing services provided to patients to improve the quality of health services (Nursalam, 2015). The optimal role of nurses in developing nursing service quality has developed and leads to demands for adequate competencies to support the patient safety movement (Yulia, 2010). This statement is in line with Kohn (2000)

who establishes six dimensions in the quality of health services including those concerning patient safety<sup>4,5</sup>.

Safety culture is the values, beliefs, behaviors adopted by individuals in an organization regarding safety that prioritize and support improvement in safety. The patient safety culture is the values, attitudes, perceptions, competencies and patterns of individual and group behavior that determine organizational commitment and ways of patient safety<sup>6</sup>.

The patient safety culture consists of several elements. Elements in the patient safety culture include an open, fair (just), reporting, learning and informed. Being open and fair means sharing information openly and freely and fair treatment of staff when an incident occurs. Reporting culture is that nurses have confidence in the incident reporting system. Learning culture is committed to safety learning, communicating with others and always remembering them. Information culture means learning from past experience, being able to identify and reduce incidents in the future because of learning from events that have occurred<sup>7,8</sup>.

The patient safety culture is important. The patient safety culture will reduce adverse events (AE) so that hospital accountability in the eyes of patients and the community will increase.<sup>9</sup> The patient safety culture helps organizations develop clinical governance, organizations can be more aware of mistakes that have occurred, analyze and prevent harm or mistakes that will occur, reduce patient complications, recurring errors and resources needed to resolve complaints and demands<sup>7,9</sup>.

In the service room management system, it is needed a leader who has a leadership spirit and is able to deliver patient safety as a work culture in service and create a condition of patient safety culture or patient safety culture so that the quality of service and patient safety is maintained.

### Research Method

Research was conducted in the Ward Room of Ulin Banjarmasin Hospital with 85 respondents who worked in the treatment room. Sampling in this research using total sampling technique.

The type of research conducted by researchers is a non-experimental quantitative data approach, through quantitative descriptive analysis of variable components. Data collection is carried out with questionnaires as

primary data and analyzed by computer programs.

## Result

### Characteristics of Respondents:

**Table 1. Characteristic of respondent**

Characteristic	Respondent (n=85)	Percentage (%)
Gender	Male	24%
	Female	76%
Education	Vocation	90%
	Bachelor	10%
Training of Patient Safety	Ever been	97%
	Never	3%
Years of work in treatment room	>6 month	78%
	<6 month	22%

Based on the age analysis of respondents in the study ranged from 22-45 years and the average age of respondents was 29 years.

### Effective Leadership, Decision Making and Patient Safety Culture:

**Table 2. The results of the univariate analysis of effective leadership, decision making and patient safety culture in the study.**

Variable	Mean Median	SD	95% CI
Effective Leadership	82,46 80,00	8,302	80,67-84,25
Decision Making	14,12 15,00	1,601	13,77-14,47
Patient Safety Culture	100,89 102,00	7,706	99,23-102,56

### Bivariate Analysis of Effective Leadership and Decision Making on Patient Safety Culture:

**Table 3. Relationship between effective leadership and decision making towards patient safety culture.**

Variable	Application of Patient Safety Culture		
	N	Statistic test	Pearson Product
Effective Leadership	85	P = 0.931	-
Decision Making	85	P = 0.026	0.212*

## Discussion

**Patient Safety Leadership and Culture:** Effective leadership requires mastery of the leader in the existing

tasks and manpower, so the job satisfaction can be achieved. Based on the respondents' assessment of effective leadership in the high category, it can be said that effective leadership owned by the room supervisor from aspects of knowledge, self-awareness, communication, energy use, goal setting and action taking has been well implemented (Wardhani, 2013).

Effective leadership is the ability of leaders to influence subordinates in achieving an organizational goal. Effective leadership requires mastery of duties and professional staffing, so supervisors become role models and job satisfaction by implementing nurses can be achieved. A leader has a clear and appropriate target so that the achievement in the field of service in the treatment room can be conditioned properly and correctly.

However, based on the analysis conducted by researchers between effective leadership variables room supervisors with the application of patient safety culture there is no meaningful relationship. This happens because the management system of patient safety is not managed directly by the room supervisor, but is managed by a special commission in the Ulin Hospital Banjarmasin. So the discussion sessions and directives from the room supervisor to the implementing nurse are not optimal, become routine or become a habit. In line with the results obtained by researchers, Wardhani (2013) also revealed that there was no significant relationship between effective leadership and the application of patient safety culture ( $p = 0.406$ ). Although many references state that leadership is the first thing that must be considered in the development and application of patient safety culture, there are still many other variables which also have a strong influence and not become research variables<sup>10</sup>.

This is in accordance with the theory of Steven & John Jermier (1978) in Mulyadi (2005), that sometimes leadership is not something that is important in the success of a process. This is due to the factors of Leadership substitutes or neutralizer leadership, in the form of individual, occupational and organizational variables. According to Burke and Litwin, in addition to leadership factors, other factors that determine the success of implementing a patient safety culture include external environmental factors, structure and systems, individual knowledge and skills, work environment, needs and motivation<sup>11</sup>.

#### **Patient Safety Decision Making and Culture: An**

effective leader is leadership that is oriented towards determining rational and appropriate actions. The leader must be able to take action based on consideration of the effective leadership components described earlier. The action taken by a supervisor must pay attention to the ability-oriented leader before committing, no need to wait, take well-planned actions, cooperate with others in acting, act professionally, be able to make decisions, be able to give ideas, use leadership techniques in acting<sup>10</sup>.

The results of the analysis in the study of the effective leadership component of the room supervisor in the form of decision making with the application of patient safety culture there is a significant relationship with the value of  $p = 0.026$  ( $p < 0.05$ ). This is in accordance with Dwi Setiowati's (2010) study which states that there is a positive and weak strength relationship with the application of patient safety culture by implementing nurses. Marpaung (2005) also stated that there was a relationship between the action of the head of the room and the work culture of the nurse nurses ( $p$  value  $< 0.05$ ). However, Wardhani (2010) stated in his research the results of the test of the relationship between decision making and the application of a patient safety culture showed that there was no relationship between the actions taken by the head of the room with the application of a patient safety culture ( $p = 0.359$ ,  $p > 0.05$ ) in Unhas Hospital Makassar.

Decision making is part of the control function in nursing management (Dwi setiowati, 2010). Control in the patient safety culture is to provide feedback to staff, incident reporters, take actions for improvement and evaluation either post or before the event (Callahan & Ruchlin, 2003; Dwi setiowati, 2010). A leader needs to ensure that his subordinates' questions are answered with rational actions. The leader also needs to research and encourage critically and stay away from being skeptical of his staff.<sup>10,11</sup>

The above theory describes things that strengthen and can also be contrary to the results of research. Decision making by a supervisor must be appropriate and rational, so that every decision can be positively meaningful in implementing the application of patient safety culture in the form of reinforcement or rewarding staff in the service process.

#### **Conclusion**

The results of the final analysis revealed that effective leadership carried out by the head of the room

or supervisor in the room service was not related to patient safety culture, this indicates that there are other factors that might influence the application of patient safety culture in the room, one of them is individual factors from medical personnel who provide services there, the availability of facilities can also be a separate consideration.

Meanwhile, decision making is significantly related to the application of patient safety culture because firmness causes individuals to comply with existing regulations so that the goal of patient safety can be achieved by discipline and skill in work.

## Abstract

**Objective:** To examine the perception of telemedicine as a means to provide health services from the point of view of users of the health insurance system in the Municipality of Sonsón (Colombia).

**Materials and Method:** This qualitative study applied 16 interviews to key informants. The transcripts were later coded and analyzed adopting Strauss and Corbin's Grounded Theory, which resulted in an axial coding process.

**Results:** There is general rejection of telemedicine as a way to provide services because of its impersonal character and the limitation of the face-to-face contact with a health professional.

**Conclusions:** The implementation of telemedicine in the context of any health system should consider key social and cultural structural elements to ensure its acceptance by communities.

**Keywords:** Culture; health; health services; health systems; telemedicine; grounded theory.

## Introduction

The 1960's saw the beginning of the discussion about *connected societies* due to the emergence of Information and Communications Technologies (ICTs). Their impact on the social dynamics of human beings influenced economy, politics, culture and even public health<sup>1</sup>.

In the health sector, such technologies have improved the management efficiency of services

provided to the population with digital medical histories and novel diagnostic techniques that benefit the living conditions of people<sup>2,3</sup>.

Additionally, the relationship between technology and health sciences has led to consider different alternatives to overcome the barriers inherent to health service provision. For example, the geography of a territory may not enable to guarantee full access to specialized care. These situations caused the emergence of telemedicine<sup>4</sup>.

Besides, Internet is currently a key reference for health professionals; it has enabled to have more informed users and streamline many aspects of health care<sup>5</sup>.

Despite technological advances in this field, health care is still considered by many as a limited resource. According to estimates by the World Health Organization

e-mail: ciessalud3@escolme.edu.co

(WHO), between 2000 and 2009 there were 14 doctors for each 10,000 inhabitants worldwide, while in regions like Africa their number came down to just 2, which favors a wide gap in access depending on the context<sup>6</sup>.

In that sense, health systems should aim at preserving and maintaining the quality of life of all the population groups. In this regard, Colombia constitutes a point of reference in Latin America due to a series of health policy reforms that introduced an assurance model that seeks to guarantee coverage<sup>7,8</sup>.

However, little information on health care access in that country is available and it only refers to aspects such as the number of available hospital beds, physicians per people, or legal actions against insurance companies in case of failure to provide medical treatment. In spite of the efforts to improve access, the core problems of the system persist and the gap between urban and rural areas still is a latent barrier<sup>9</sup>.

For these reasons, a study was conducted to examine the perception of telemedicine of users in a relatively-remote municipality. Sonsón was selected because of its location: East of the Department of Antioquia and 3 hours by car from the capital (Medellín). Besides, in 2015 its population was mainly rural: 20,883 inhabitants compared to 15,221 in the urban area. Furthermore, this gap also translates into a territory still divided by socioeconomic factors<sup>10,11,12</sup>.

## Materials and Method

The goal of this year-long study was to understand the perceptions of telemedicine as a means to provide health services in 2016 from the perspective of users of the subsidized regime in the Colombian Health Insurance System living in Sonsón.

Therefore, qualitative research was conducted because, although it does not have a long history of applicability in health sciences (compared to epidemiological studies), its growing importance in recent years should be highlighted. This is due to the fact that it enables to obtain descriptive and interpretative data regarding behaviors observed in relation to the phenomenon under study from a holistic perspective. In this case, the adopted approach was historical-hermeneutical as it enables to acknowledge human beings as interpreters of their reality<sup>13,14,15</sup>.

Sixteen key informants participated in the process.

They met the inclusion criteria: they all were of legal age, enrolled in the Colombian Health Insurance System through the subsidized regime and living in Sonsón. An exclusion criterion was suffering from mental disorders that would prevent a voluntary and conscious participation in the study.

Regarding ethical considerations, elements from the Declaration of Helsinki were incorporated. Such instrument establishes the obligation to submit research projects to a committee that ensures the security of each participant. This was reflected in an informed consent based on the guidelines in Resolution 8430 of 1993 of the Colombian Ministry of Health<sup>16,17</sup>.

Therefore, the study was submitted to the Technical Committee of University Institution Escolme, who determined the study presented minimum risk as no physical, psychological, or social structures were modified in the informants.

Theoretical sampling was used to select the participants and ensure the widest possible diversity in variables such as age, gender, educational attainment and residence area (rural or urban), so that they were qualitatively representative of the population under study and connected by the health institutions in the municipality.

Semi-structured and in-depth interviews were used as the information collection instrument. They were later transcribed and coded based on Anselm Strauss and Juliet Corbin's Grounded Theory, understood as the process by which the collected data are fragmented, conceptualized and integrated to create a theory that explains the phenomenon under study<sup>18</sup>.

The first coding is referred to as *open* because it is a first approach by the researcher in terms of data, which results in descriptive categories. The second one is *axial* and it establishes associations between the first emergent categories to obtain more precise hypotheses that are validated by the informants in the study; thus, analytic categories emerge. During the third coding, called *selective*, a core category emerges and it enables to theorize the phenomenon under study by means of interpretative categories<sup>18</sup>.

Nevertheless, for time and budget reasons, this study reached as far as the *axial* stage of the coding process and produced the analytical categories found in Results.

The Grounded Theory was selected because of its scientific rigor in qualitative studies and since it enables health professionals in different fields to understand the subjective experiences of individuals regarding the problems under study<sup>19</sup>.

In addition, its symbolic interactionism enables to investigate aspects of human relationships with peers based on symbols and meanings that result from a social construct<sup>20</sup>.

**Findings:** Colombia is a country of contrasts not only because of its biodiversity, but also its traditions, culture and even the existing gaps caused by resource allocation. This situation has created a series of challenges in terms of development and public health plays a key role to overcome them.

Along with such differences in the social fabric, telemedicine emerges as an alternative that contributes to guarantee access to the health care system by population groups whose geographic location limits the type of health care they enjoy.

An exploration of the existing perceptions regarding telemedicine as an alternative to access health services in the Municipality of Sonsón revealed rejection among people. Although this alternative enables to access the system, in the users' opinion it does not provide the same satisfaction as direct care by health professionals. Such ideas are expressed by some of the informants in the study:

“This way of having a doctor see you personally and another physician through a device that helps the consultation doesn't seem trustworthy to me. It's not the same thing as being there with the specialist, because that way you can ask questions more easily; they check you and you feel satisfied. Maybe I don't believe in it because of my age.”

These arguments by the participants reveal a key element in health care: the trust built by the physician-patient relationship. This provides users with the confidence to clear up doubts regarding their treatment and other aspects related to their condition.

In the context of the Colombian health system, in addition to the factors related to people's perceptions and expectations regarding medical attention, there are administrative barriers for the dynamics of service provision.

These continuous limitations discourage users from accessing the services, moreover when they know they will be provided via telemedicine, which results in greater resistance. Thus, they decide on other alternatives, as some participants stated:

“They would tell you ‘come here’, ‘go there because the order is nowhere to be found’, ‘make copies of this’, ‘you're late’ and then you can't come from the farm because there's bad weather. An appointment via computer is useless; we'd better take our pill and we're under control.”

In this regard, the red tape imposed by the health system poses new challenges for stakeholders in society, especially those related to public health.

Different informants expressed disagreement with telemedicine because there is no direct contact with the health professional and, therefore, the trust that enables them to speak fluently and be satisfied is not built. Conversely, other interviewees maintained that they have no problem with this type of service:

“To me, it's a good mechanism in health services. Nowadays, technology is really advanced. Specialized attention is coming to remote areas where resources are limited or nonexistent and improves access and equality. Digital communication enables health information to be more comprehensive, up-to-date and accurate. Besides, the physician may have communication with the specialist at any time and that's an advantage.”

These testimonies provide an opportunity for the stakeholders that manage the Colombian health system to guarantee not only the efficiency of the operation but also greater acceptance of telemedicine and actually incorporate its benefits, thus improving the living conditions of the communities.

## **Discussion and Conclusions**

Telemedicine can be understood as the long-distance provision of health services associated with the rise of ICTs and globalization<sup>21</sup>. Its emergence has enabled efforts to overcome geographical barriers of access to health systems, particularly in communities in rural areas and developing countries<sup>22</sup>. Furthermore, it has become a key element to face the socioeconomic challenges that have been encountered since the 20th century<sup>23,24,25</sup>.

An example of the usefulness of telemedicine as a mechanism to reduce the barriers of access to health

services is the possibility of undocumented Mexican population in the United States to use resources in their country of origin, since they cannot access the benefits of the North American system because of their situation. Similarly, Salas, Salcedo and Aguilera (2013) list the advantages telemedicine offers in the context of Bogotá (Colombia) to guarantee the health care of patients with particular needs, even though the service is remotely provided<sup>26,27</sup>.

Nevertheless, in line with the results of this study, García and Rodas (2011) acknowledge some limitations associated with the implementation of telemedicine and highlight users' communication and information problems<sup>28</sup>. As indicated throughout this article, this situation does not only hinder its use but it also generates indifference and, therefore, poses new challenges in the field of public health<sup>29</sup>.

From this perspective, the study by Rubies et al. (2010) demonstrates the serious difficulties that underlie the implementation of telemedicine, not only because of the variables associated with the influence of people or organizations but also due to the obsolescence of technology<sup>30,31</sup>.

In light of this study, these difficulties gain traction largely because of the importance of the physician-patient relationship<sup>32</sup>. Furthermore, as stated in the study by Bermúdez (2016), the communication processes between these two parties are essential for users to adhere to the provided treatments<sup>33</sup>.

Notwithstanding, they are not the only elements to be considered when telemedicine is implemented because, as stated in this study, the red tape imposed by the Colombian health system constitutes a limitation in addition to users' social imaginaries and perceptions regarding this type of service provision, which leads to nonadherence to even necessary treatments<sup>34</sup>.

**Conflict of Interest:** The study does not present conflicts of interest with other authors or entities, it is an original production and it is approved by the authors of the article.

# Analysis of Public Value in Governmental Institution Cardiac Center as an Example

Sulaman Almesned<sup>1</sup>, Abdulrhman Almesned<sup>2</sup>

<sup>1</sup>Lecturer Department of Surgery, Medical College, Qassim University, Saudi Arabia, <sup>2</sup>Consultant Pediatric Cardiologist, University of Alberta Fellowship of Pediatric Cardiology and Center Director Prince Sultan Cardiac Center, Qassim, Saudi Arabia

## Abstract

This article deals with analysis of work environment in the lens of Public Value. A brief account of our organization, Prince Sultan Cardiac Center Qassim (PSCCQ), will be outlined along with its mission, vision and values.

This will be accompanied by a review of what we mean by Public Value, including an overview of the PSCCQ work environment in the public value perspective, with a discussion on opportunities and obstacles to the advancement of PSCCQ values and missions.

Finally, this article is an effort to introduce the culture of public value in health services in developing countries.

**Keywords:** *Public value, Analysis, Governmental institution, Developing country.*

## Introduction

This article deals with analysis of work environment in the lens of Public Value. A brief account of our organization, Prince Sultan Cardiac Center Qassim (PSCCQ), will be outlined along with its mission, vision and values.

This will be accompanied by a review of what we mean by Public Value, including an overview of the PSCCQ work environment in the public value perspective, with a discussion on opportunities and obstacles to the advancement of PSCCQ values and missions.

Finally, this article is an effort to introduce the culture of public value in health services in developing countries.

### Prince Sultan Cardiac Center Qassim:

**Overview:** Prince Sultan Cardiac Center Qassim is the only tertiary cardiac center in Qassim, a province in Saudi Arabia that serves heart disease patients of all ages.

It is a government cardiac center with its own Human Resources and Financial Department, allowing the center the flexibility needed to carry out its duties.

**Mission:** Our mission is to deliver an integrated Cardiovascular Healthcare System to serve people of all ages in Qassim Region and the nearby areas by offering a continuum of high-quality Medical and Surgical Services committed to Patient Safety, Medical Education & Training, Research and Community Service.

**Vision:** Our vision is to advance Excellence in Cardiovascular Medicine and Surgery as well as Medical Education & Training and Research at a National level.

**Values:** Our values are commitment to Professionalism, Safety, Care, Compassion and Quality.

**Public Value:** It's been about 30 years since the idea of public value first emerged and twenty-four years since Mark Moore published *Creating Public Value: Strategic Management in Government*<sup>1</sup>.

Let us first define what do we mean by VALUE?

*Value is “that property of a thing because of which it is esteemed, desirable or useful; worth, merit or importance”<sup>2</sup>.*

In an interview, Mark Moore defines PUBLIC VALUE as equivalent to shareholder value in public management, with the public sector acting in the best interests of the “collective”. The equality of the allocation of public benefits and the implementation of public duties is as critical as the achievement of social outcomes or the satisfaction of individual clients<sup>3</sup>.

With this brief explanation of what public value entails, a closer look at the working environment of our organization will be illustrated.

**PSCCQ Working Enviroment in the Lens of Public Value:** According to Moore<sup>4</sup>, philosophic, economic, technological and managerial work is needed to build a performance management system that helps the company to reflect on the principles it is meant to create.

Here, the four (4) activities will be identified and the analysis of the application of the PSCCQ will be shown. The following section will therefore try to answer the following question:

To what extent do PSCCQ invest in managerial, technical, political and philosophical work?

#### **Philosophical Work:**

*Philosophical work is “associated with naming and justifying the important public values to be achieved by a public agency (or reflected in its operations)”<sup>4</sup>.*

Philosophical work includes examining whether the principles or values of PSCCQ (Professionalism, Safety, Care, Compassion and Quality) are in the minds and hearts of its employees? Is the patient the focus of attention, or is the patient-centered care is an essential aspiration in the PSCCQ?

Only a proper survey can answer these questions in a reliable manner, but close attention may be paid to PSCCQ employees, which has shown that there is no clear understanding of PSCCQ values and they are not yet in the hearts of many employees .Hence, it is the responsibility of leaders to build awareness and belief towards the value of PSCCQ and to bring mission and

vision to the minds and hearts of PSCCQ employees. Management plays a vital role in developing dynamic ways to influence each employee in achieving PSCCQ values.

#### **Political Work:**

*Political work is “associated with building a broad, stable agreement about the important dimensions of value that those who can call the organization to account will use to evaluate agency performance”<sup>4</sup>.*

The PSCCQ reports to the Qassim cluster. Therefore, if we examine which value is being measured from the cluster, it will be QUALITY because PSCCQ has a quality team that has certain criteria where they are being tested for compliance.

PSCCQ has a department responsible for monitoring and evaluating the safety of patients and a physician responsible for investigating any Occurrence Variance Report (OVR) and sentinel events.

The PSCCQ must report the monthly OVR report to the cluster and the team of the designated department in the cluster will evaluate its performance.

#### **Technical Work:**

*Technical work is “associated with finding or developing empirical measures that can reliably capture the degree to which the nominated values are being realized (or reflected) in agency operations”<sup>4</sup>.*

Most of the performance indicators obtained in the PSCCQ rely on results (OUTPUTS) that are not measures (OUTCOMES), such as the number of patients admitted or treated or seen in the hospital.

Recently, attention to outcomes and to count what counts<sup>5</sup>.

The Patient Experience Department was opened, Special training was given on how to gather and assess what matters to PSCCQ patients. An important issue when implementing measurements is to decide what should be measured? More outcome indicators instead of output are collected, such as how many patients with heart failure are readmitted due to the complexity of measuring values.

In this implementation, a lot of work needs to be done to determine what really counts.

**Managerial Work:**

*Managerial work is “associated with linking a performance measurement system to a performance management system that can drive public efforts toward improved performance”<sup>4</sup>.*

There are no structured initiatives in PSCCQ to compensate or inspire workers to show and maintain public value, such efforts are actually dispersed and not coordinated, for instance, by providing a certification to nurses who record most of the OVRs

To conclude, it is clear that the combination of these four activities is the key to good management<sup>4</sup>. Nevertheless, in PSCCQ, these four activities, although available but not properly organized and reinforced by leaders and managers, call for urgent discussion and proper knowledge among all PSCCQ employees.

**Opportunities and barriers to the promotion of PSCCQ values and mission and hence the public value:** SWOT analysis was used to assess the opportunities and barriers to the promotion of PSCCQ values<sup>6</sup>.

SWOT analysis was developed in the 1960s by Albert Humphrey, a management consultant at the Stanford Research Institute. It is a technique used to determine and define the Strengths, Weaknesses, Opportunities and Threats – **SWOT**.

SWOT Analysis of PSCCQ:

**Strengths:**

- Highly qualified nursing staff
- Strong Leadership Commitment
- Good reputation among local community
- Realistic mission
- Strong support from cluster director
- PSCCQ manages its own budget

**Weaknesses:**

- Limited bed capacity
- Lack of separate building
- Strong resistance from many consultants
- Limited recruitment ability
- Some of Ministry of Health regulations

**Opportunities:**

- Vision 2030
- New trends in Ministry of Health
- Educational and training grants
- Health transformation
- Additional administrative and financial support for module of care
- New cluster administration
- New visa rules in kingdom of Saudi Arabia
- Social media

**Threats:**

- New stock management roles
- Rapid staff turn over
- Social media

**Conclusion**

An analysis of public value in any given organization is vital, as Richard Barrett, Founder of the Barrett Values Center, said: “When we work in an organization whose culture aligns with our personal values, we feel liberated. We are able to bring our full selves to work”<sup>7</sup>.

The concept of public value in Saudi Arabia is relatively new and the PSCCQ is no exception and this has been shown in developing countries<sup>8</sup>.

This analysis also highlighted how important it is for the PSCCQ to have legitimacy and support from the cluster to turn inputs into outcomes<sup>9</sup>.

Finally, the PSCCQ administration must organize structured efforts to understand, create and demonstrate public value among staff toward achieving valuable outcomes<sup>10</sup>.

**Conflict of Interest:** The authors declare that they have no conflict of interest.

**Informed Consent:** Did not require since there is no direct contact with the patients.

**Source of Funding:** Nil.

**Ethical Approval:** The article does not contain any studies with human participants or animal performed by any of the authors.

## Abstract

In our study, metal nanoparticles Ag, Cu, ZnO, CdO and Sn NPs were prepared by pulse laser ablation in liquid and characterized for investigation of reproductive toxicity in adult male rats. Thirty six healthy rats, two month age old and the rats weighing from 250-300 g, divided into six groups of six animals each (GAg, GCu, GZnO, GCdO and Sn) group which receive oral 0.3 ml dose of metal nanoparticles for 30 day. Blood samples were collected via cardiac puncture for serum collection. The formation Ag NPs, Cu NPs, ZnO NPs, CdO NPs, Sn NPs were shown through the x-ray diffraction pattern. AFM indicate to formation metal nanoparticles with diameter 61.36, 70.44, 66.82, 74.87 and 67.34 nm of Ag, Cu, ZnO, CdO and Sn NPs respectively. The results showed significant ( $P < 0.05$ ) elevation of luteinizing hormone (LH) for each metal nanoparticles except AgNPs non-significant. Each metal nanoparticle significant ( $P < 0.05$  and  $** p \leq 0.01$ ) of follicle-stimulating hormone (FSH), whereas in testosterone only Cu and Sn NPs significant ( $P < 0.05$ ).

**Keywords:** Metal nanoparticles, pulse laser ablation, testosterone, LH, FSH.

## Introduction

The application of nanomedicine is wide-ranging. One of nano-medicine's most significant problems is to comprehend its environmental efficacy and also to determine the possible toxicity of nano-scale materials. [1]The metallic nanoparticles (NPs) show distinct characteristics than they found at larger bulk size. These characteristics are accredited according to their smaller size and bigger area by volume ratio. [2] Nanoparticles of metal and metal oxide such as silver, zinc, gold, or titanium dioxide have been used as antimicrobial agents for over a century. The conduct of nanometals against pathogenic organisms at nanometric dimensions is currently being studied. [3]

The particle size is a significant nanomaterial characteristic that plays a main part in the characteristics of unique nanoparticles. The particle size may represent its physicochemical characteristics and enhance the ability to sorb and interact with biological tissues. [4,5] In reality, more research has been done on the size of nanoparticles than on other nano-scale properties. [6] Up

to now, results have shown that the use of nanomaterials increases biological activity as their size decreases. Today, multi-industry uses this science [7].

Nanoparticles and other cellular reactions toxicity relies on the nature of the material and doses were used. This showed that liver parenchyma cells play a significant part in eliminating nanoparticles from the blood. [8] Theoretically, nanoparticles may have some adverse effects on human health and the environment and their obvious effects on male reproductive function have not yet been clarified.

There are currently many techniques for generating suspended nanoparticles in aqueous solutions. Chemical techniques are the most frequently used because they are comparatively economical and the particle size can be easily controlled. Nevertheless, laser ablation in liquids has lately been shown to be a promising new method for obtaining metal colloids. [9-11] The aim of present study was to investigate the effects of metal nanoparticles toxicity on luteinizing hormone (LH), follicle-stimulating hormone (FSH) and testosterone.

## Experimental part:

**Preparation of metal nanoparticles:** Metal nanoparticles (Ag, Cu, Sn, ZnO and CdO) were produced by laser ablation of (Ag, Cu, Zn and Cd) targets (diameter = 1.5 mm, thickness = 0.6 mm, 99.99% immersed in a vessel filled with 3 mL of deionized water (DI) with power 500mJ and .The target irradiated vertically by a Q-switched Nd- YAG laser (DIAMOND-288 pattern EPLS), with wavelength ( $\lambda = 1064$  nm) duration time at 6 Hz. The laser beam was focused by a focal length 10cm), subsequently, we placed the pure metal solution and the pulsed Nd-YAG laser re-irradiates, the concentrated laser beam spot diameter was 4 mm.

**Experimental Model:** Suspensions of metal nanoparticles were administered to rats with 0.3 ml doses via oral gavage. Thirty six healthy rats and two months of age and rats weighing 250-300 g are all permitted to acclimatize in animal house conditions for one week ( $25 \pm 3^\circ\text{C}$ , 50-55 percent relative humidity and 12 hours light/dark cycle). The rats were divided into 6 groups in 6-rat capability cages made of plastic and sprinkled ground with sawdust, replaced every three days. The rats were fed a normal nutritionally balanced diet.

**Experimental Design:** Wistar male rats were divided into six groups of six individual animals.

- Control - Animals got (deionized water) only
- Ag- Animals got 0.3 ml/day of oral Ag NPs for 30 day.
- Cu- Animals got 0.3 ml/day of oral Cu NPs for 30 day.
- Sn- Animals got 0.3 ml/day of oral Sn NPs for 30 day.
- ZnO- Animals got 0.3 ml/day of oral ZnO NPs for 30 day.
- CdO- Animals got 0.3 ml/day of oral CdO NPs for 30 day.

**Blood Collection and Serum Separation:** At the end of the experimental period, blood collection 3ml per group was collected by heart puncture, Blood was gathered from each rat in the eppendorf tube. At  $30^\circ\text{C}$  and 3000 rpm for 15 min, eppendorf pipes were centrifuged. The blood sample was divided into two layers, the upper serum layer and the lower rejected layer and then Pasteur pipette pulled it. Till blood measurements, the serum layer from each rat was placed in freezing condition.

**Statistical Analysis:** Data is shown as the mean  $\pm$  SD. With Graphpad Prism 6.0 software, statistical analyzes were carried out using ANOVA one way. Means were used to compare untreated rats with distinct treated groups (\* $P \leq 0.05$ , \*\* $P \leq 0.01$ , \*\*\* $P \leq 0.001$ , \*\*\*\* $P \leq 0.0001$ ).

## Result and Discussion

**Structural and topography of nanoparticles:** Metal and oxide nanoparticle (Ag NPs, Cu NPs, ZnO NPs, CdO NPs) are formed by examining the x-ray, this is mentioned in my other paper.<sup>[12]</sup>

AFM imaging of metal nanoparticles was conducted on a smooth glass slide substrates by drop casting at heat 60. Film surface morphology was explored using AFM pictures, which at very elevated magnification generates topological surface pictures. AFM pictures as commonly recognized provide a helpful tool for unambiguously characterizing the order of magnitude and nanoparticle size distribution.

Figure (1) shows the morphology of dried colloids for Ag, Cu, Sn, ZnO and CdO NPs, 500 mJ/pulse and 500 pulses prepared by PLAL in DI. The images indicate that the MNPs have semi-sphere forms and we can see from graphic (2D) that the number and particle distribution of MNPs, note that the lowest size is Ag NPs and the bigger size is CdO NPs. Table (1) shows the average roughness value in DI at 500 laser energy and 500 pulses.

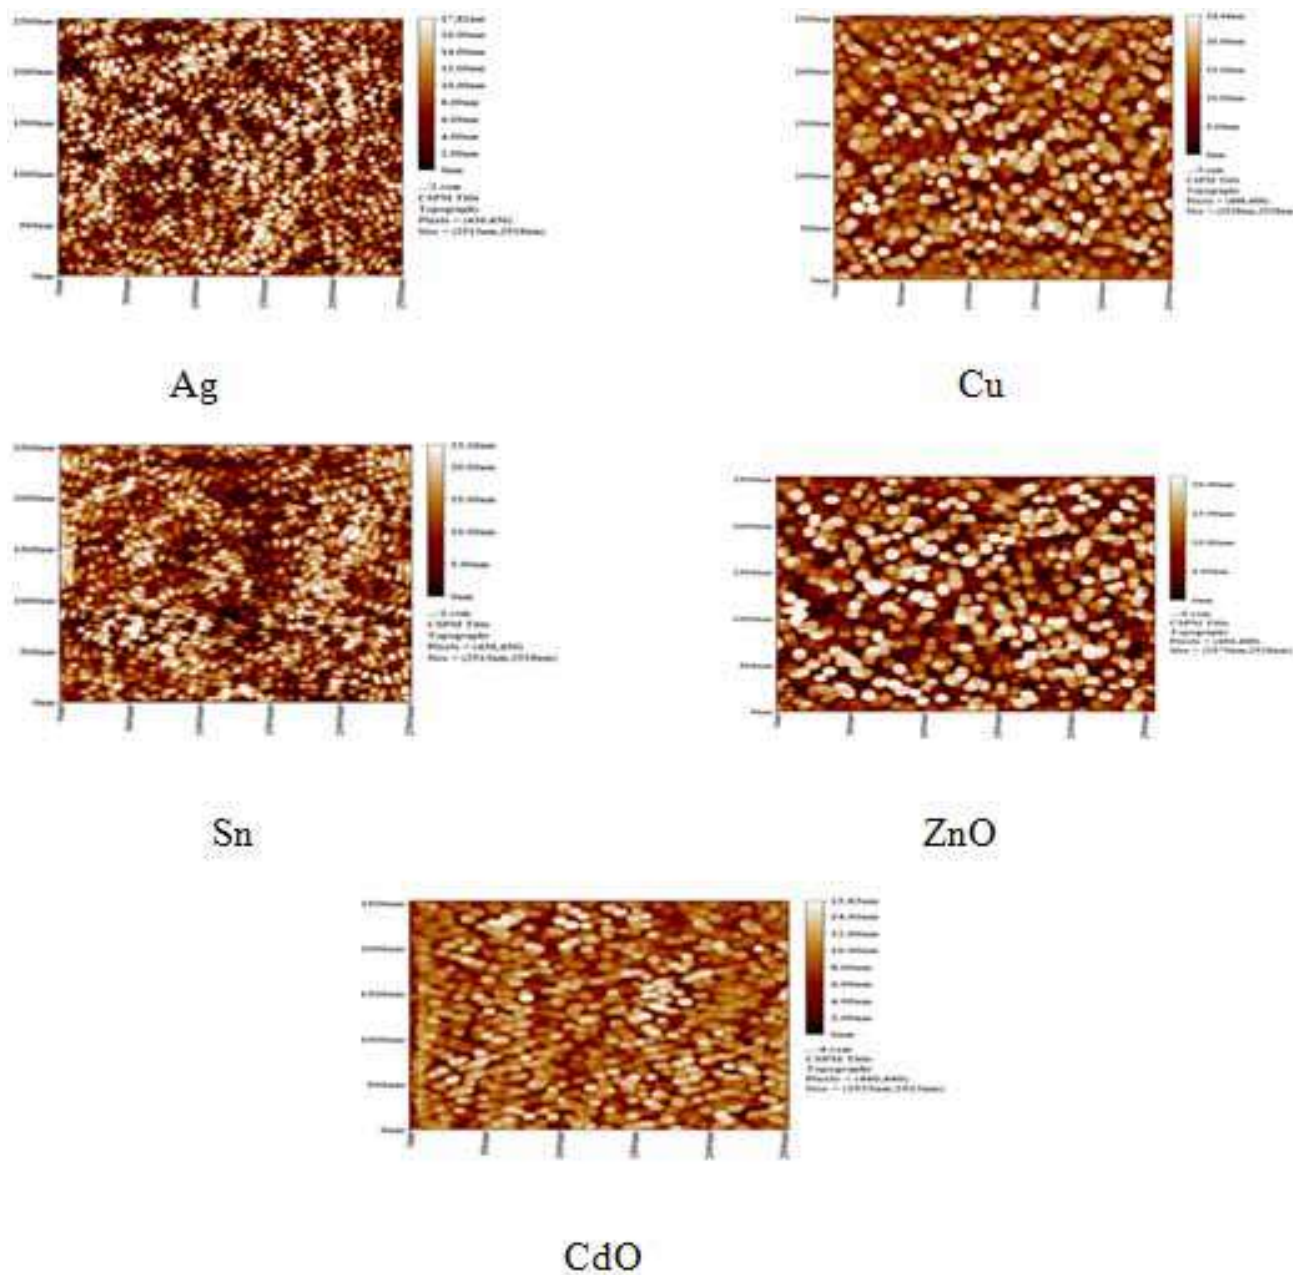

Figure (1): Typical 2DAFM image of Ag, Cu, Sn, ZnO and CdO nanoparticles prepared by PLAL by ablation of Sn target immersed in DI at 500 pulses constant, at 500mJ/pulse.

Table (1): Shows the values of roughness average and average diameter for MNPs in DI.

MNPs	Roughness Average (nm)	Average Diameter (nm)
Ag	4.23	61.36
Cu	4.44	70.44
ZnO	5.09	66.82
CdO	2.24	74.87
Sn	5.2	67.34

Atomic Absorption Spectrometer Analysis (AAS): The concentration of Ag, Cu, ZnO, CdO and Sn respectively, as in the table (2), prepared in PLAL has been determined by atomic absorption spectrometry.

**Table (2): Shows the concentration of MNPs with 500 mJ and 500 pulses.**

Metal Nanoparticles	Concentration (ppm)
Ag	40.4081
Cu	10.3758
ZnO	24.0768
CdO	0.027
Sn	53.45

**Effect Metal Nanoparticles on Sexual Hormones:**

Figure (2) indicate that the level of serum leutinizing hormone (LH) in male rats dosed with MNPs showed a significant rise ( $p \leq 0.05$ ) over control. High LH shows an original testis failure and may happen as a result of chromosomal disorders. With the exception of group Ag NPs, the non-significant note ( $p > 0.05$ ) in the LH corresponds to<sup>[13]</sup>.

**LH**

\* $p \leq 0.05$  and non-significant n.s

**Figure (2): The effect of MNPs on blood serum LH in male rats.**

Figure (3) indicate that the concentration of the Serum follicular stimulating hormone (FSH) showed a significant rise (\* $p \leq 0.05$  and \*\*  $p \leq 0.01$ ) in masculine rats dosed with MNPs compared to control, corresponding to.<sup>[14]</sup> This implies pituitary gland dysfunction, which can trigger reproduction of weaknesses.

**FSH**

\* $p \leq 0.05$  and \*\*  $p \leq 0.01$

**Figure (3): The effect of MNPs on blood serum FSH in male rats.**

Figure (4) indicate that the level of serum testosterone hormone in male rats dosed with Ag, ZnO and CdO is non-significant ( $p > 0.05$ ) This outcome corresponds to.<sup>[14,15]</sup> for male rats dosed with Ag, ZnO and CdO as opposed to control at this dose. In Cu NPs this outcome corresponds to<sup>[16]</sup>, low testosterone concentration suggests a hypothalamic issue, adrenal disease, pituitary disease, or liver disease, indicating that copper nanoparticles can be regarded a reproductive toxicant. Sn NPs demonstrate a significant rise in the concentration of serum testosterone hormone ( $p \leq 0.05$ ) elevated testosterone concentrations may indicate enlarged testis or adrenal glands.

**TESTOSTERONE**

\* $p \leq 0.05$  and non-significant n.s

**Figure (4): The effect of MNPs on blood serum testosterone in male rats.**

## Conclusions

In summary, oral administration of Ag, Cu, ZnO, CdO and Sn NPs prepared by PLAL in 500 mJ and 500 pulses, Zn and Cd metals transformation to ZnO and CdO nanoparticles prepared by PLAL. Indicate some of this metal (especially Cu and Sn NPs) have reproductive toxicity on male rats.

**Conflict of Interest:** There are no conflict of interest.

**Source of Funding:** Self Source funding.

**Ethical Clearance:** It is no behalf of authors certify the research conducted after being got official ethics clearance.

# Innovation of Jemawut Cookies (Foxtail Millet)-Tuna On Nutrition Status and Zinc Value for Children Aged 6-24 Months With Less Nutrition Status In Regency of Pacitan–Indonesia

Fibria Dhian Ikawati<sup>1</sup>, Diffah Hanim<sup>2</sup>, Harsono Salimo<sup>2</sup>

<sup>1</sup>Student, <sup>2</sup>Lecturer, Master of Nutrition Science Program, Sebelas Maret University, Surakarta, Indonesia

## Abstract

**Objective:** Indonesia provides support in preparing children as a nation's investment through the Scaling Up Nutrition (SUN) movement. The focus of the SUN movement is meeting the needs of 1000 FDL (First Day of Life) in order to reduce the number of malnutrition. Giving cookies Millet (foxtail millet) -tuna to children aged 6-24 months with under malnutrition status is one of the innovations in reducing malnutrition. The number of malnutrition children aged 6-24 months reaches 48% in region of Gemaharjo-Pacitan. This product contains 449.03 Kcal and 10.24 gr protein per 100 grams. It is hoped that the provision of these cookies combined with local food will improve nutritional status and zinc values in children aged 6-24 months with under malnutrition status.

**Method:** This study was experimental and conducted to 148 infants for 2 months and used a T-test. Results: Millet (foxtail millet)-tuna cookies increased nutritional status ( $p = 0,001$ ) and zinc value ( $p = 0.00$ ).

**Conclusion:** Cookies millet (foxtail millet) – tuna can improve nutritional status and zinc values in children aged 6-24 months of malnutrition in Pacitan - Indonesia.

**Keywords:** Millet-tuna cookies, nutritional status, zinc values, children aged 6-24 months.

## Introduction

According to the World Health Organization (WHO, 2014), 45% of under-five aged childrens' deaths are caused by malnutrition<sup>17</sup>. A Nutrition Status Assessment (NAS) conducted in Indonesia on 2017, shows that 11.3% of children aged 0-23 months are malnutrition (based on weight/age indicators)<sup>5</sup>. In Pacitan district alone there are 10.9% of children aged 0-23 months got malnutrition (Penilaian Status Gizi, 2018). The problem of malnutrition in children under two years is a problem

that needs to be addressed seriously<sup>4</sup>. The attention of developing countries is now shifting from breastfeeding to complementary food which side with breastmilk<sup>16</sup>. WHO recommends that supplementary feeding begin with 6 months with a gradual amount and form<sup>16</sup>.

The provision of Millet (foxtail millet) cookies for children aged 6-24, from local foodstuffs (barley and tuna) is expected to improve nutritional status (weight by age). Improvement of nutritional status according to age is also a priority in this intervention<sup>1</sup>. Body weight index according to age describes relative body weight compared to the age of children. This index is used to assess children who are underweight or severely under weight<sup>15</sup>. It is important to know that a child, whose weight is low according to age, may experience growth problems<sup>14</sup>. In addition to nutritional status, this intervention is expected to increase zinc value as one of the trace minerals or micro minerals that are important

---

Sebelas Maret University, Surakarta, Indonesia  
e-mail: fibria\_perfect@yahoo.com

for life. In children if the amount of zinc absorbed is very small, they will experience improperly growth<sup>3</sup>.

## Method

This research was conducted in Regency of Pacitan - Indonesia. The first phase was carried out by testing the Millet (Foxtail millet) -tuna) cookie product, in accordance to SNI (Indonesian National Standard) 2973: 2011 and Indonesian Ministry of Health's standard followed by the acceptability test. The targets in this study were children aged 6-24 months with malnutrition status who were joined in twenty "Breastmilk Village" groups, which had agreed to informed consent. The purpose of using the "Kampung ASI" group is to facilitate the level of obedience in providing interventions. The second phase of this experimental design was an experiment with randomized control (Randomized Controlled Trial/RCT)<sup>13</sup>. For sample calculation using  $G * Power (V.3.1.9.2)$ , the T-test statistic test obtained a minimum sample size of 19 children per group. From the screening results in August 2019 it was found that

48 children aged 6-24 months who were malnutrition, which in this experiment, 148 children aged 6-24 months were targeted for the study (additional samples were needed to anticipate the possibility of selected subjects dropping out, loss to follow-up, or disobedient subject). So that each group consist of 24 children aged 6-24 months with under malnutrition status (group 1 = the control group was given a biscuit intervention from the Ministry of Health and group 2 = the intervention group was given Millet (foxtail millet) -tuna cookies). This research has obtained information on ethical conduct under number 349/UN27.06/KEPK/EC/2019. The study was conducted for 60 days (October-December 2019), with 8 times nutritional education. The nutritional status and zinc values check up conducted before and after the intervention. The final goal in this study is to find out how the two intervention groups compare to their nutritional status and zinc values. In addition, to find out whether the provision of local food can increase nutritional status and zinc values in children aged 6-24 months with under malnutrition status.

## Result

**Table 1. Characteristics of research subjects**

Variabel	K (n=24) Before intervention	K (n=24) Afterintervention	I (n=24) Before intervention	I (n=24) Afterintervention
Age	16,75±3,124		18,71±4,154	
Weight (kg)	7,875±0,5439	8,237±0,6240	8,058±0,7751	8,688±0,7456
<b>Education</b>				
<b>Father's Education :</b>				
High School	18 (75%)		14 (58,33%)	
Middle School	6 (25%)		10 (41,67%)	
<b>Mother's Education</b>				
High school	9 (37,50%)		7 (29,17%)	
Middle school	15 (62,50%)		17 (70,83%)	
<b>Father's occupation</b>				
Farm worker	3 (12,50%)		5 (20,83%)	
Farmer	19 (79,16%)		16 (66,66%)	
Tradesman	2 (8,34%)		3 (12,51%)	
Government employee Etc.				
<b>Occupation</b>				
Farm worker	3 (12,50%)		4 (16,67%)	
Farmer	17 (70,83%)		16 (66,66%)	
Tradesman	4 (16,67%)		3 (12,50%)	
Government employee Etc.			1 (4,17%)	
<b>Family Income</b>				
< Rp. 2.000.000	21 (87,5%)		23 (95,83%)	
≥ Rp. 2.000.000	3 (12,5%)		1 (4,17%)	

From table 1 it can be seen that there was an increased body weight before and after the intervention of the two groups given the biscuit intervention from the Ministry of Health and the intervention of giving cookies Millet (foxtail millet) -tuna).

**Table 2. Test Results of Nutrition Value for Jemawut (Foxtail Millet)-Tuna Cookies**

Parameter	Unit	Result	Method
Calorific value	kcal/100 g	449,03	By Calculation
Protein	gr/100 g	10,24	SNI 2973-2011; point A.4
Fat	gr/100 g	15,3	SNI 01-2891-1992; point 8.1
Carbohydrate	gr/100 g	69	By Different

Source: SUCOFINDO Laboratory (2019)

Based on SNI 2973: 11 test, it can be seen that the nutritional content of foxtail millet-tuna is safe to be consumed chemically and biologically. Also the nutritional content between barley (foxtail millet) -tuna cookies and PMT (Supplementary Feeding) from the Ministry of Health for toddlers are compared. SNI and nutrient content test was conducted by the SUCOFINDO laboratory in Surabaya. Ingredients tested were Foxtail Millet-tuna cookies with 100 gr of barley and 50 gr of tuna.

**Table 3. The Comparison of Nutritional Value of Barley (foxtail millet) –Tuna Cookies with PMT (Supplementary Feeding) from the Ministry of Health per 100gr**

Nutritional Value	Barley (foxtail millet)-Tuna Cookies	Toddlers’ PMT from Ministry of Health	Gap
Energy (Kkal)	449,03	450	-0,97
Protein (gr)	10,24	10	0,24
Fat (gr)	15,3	15	0,3
Carbohydrate (gr)	69	70	-1

Source: SUCOFINDO Laboratory (2019) and Ministry of Health (2018)

The nutritional value of foxtail millet-tuna per 100 grams compared to toddler PMT from the Ministry of Health has a gap that can still be tolerated, which is for energy there is a gap (-0.97 Kcal), protein (0.24 gr), fat (0.3gr) and carbohydrates (-1gr). With nutritional values adjusted to the Ministry of Health standards, it is expected that the foxtail millet cookies which made from local food ingredients, has the same nutritional values which are in accordance to Ministry of Health standards and SNI 2973: 11.

**Table 4. T-test results for nutritional status (Weight/Age) in two intervention groups**

Group	n	Mean	SD	p
<b>Before:</b>				
Control	24	-2,31	0,27	0,959
Experiment	24	-2,31	0,24	
<b>Sesudah:</b>				
Control	24	-2,24	0,20	0,000
Experiment	24	-1,95	0,19	

Source: Stata 13 data (2019)

From table 4 it can be seen that the nutritional status (weight/age) for the experimental and control groups before the intervention did not differ significantly ( $p = 0.959$ ), it means that the two groups had almost the same intake before the intervention. However, with the

intervention (giving of foxtail millet-tuna and biscuits from the Ministry of Health) and nutritional education (eight times) for 60 days, there was a significant difference in nutritional status (weight/age) intake between the experimental and control groups ( $p = 0,000$ ).

**Table 5. T-test results for zinc values in two intervention groups**

Group	n	Mean	SD	p
<b>Before:</b>				
Control	24	52,75	6,73	0,398
Experiment	24	54,58	8,08	
<b>After:</b>				
Control	24	71,95	5,97	0,000
Experiment	24	92,75	4,98	

**Source:** Stata 13 data (2019)

From table 5 it can be seen that the zinc values for the experimental and control groups before the intervention did not differ significantly ( $p = 0.398$ ) it means that the two groups had almost the same intake before the intervention. However, with the intervention (giving of foxtail millet-tuna and biscuits from the Ministry of Health) and nutritional education (eight times) for 60 days, there was a significant difference in zinc values between the experimental and control groups ( $p = 0,000$ ).

Zinc is one of the micro minerals needed for every cell in the body. Adequacy of this mineral is important in maintaining optimal health. Zinc functions as a cofactor for various enzymes, cell structure and integration, DNA synthesis, hormonal storage and expenditure, immune-transmission and has a role in the immune system. Zinc deficiency can cause decreased appetite, dermatitis, slow growth and immunodeficiency<sup>7</sup>.

Hardinsyah (2014) suggests that pregnant women, breastfeeding mothers, children in their infancy and also parents, those are included in the range of zinc deficiency group. Zinc deficiency experienced by almost all respondents in this study could be caused by the lack of consumption of foods with high zinc content.

Based on laboratory results before and after the intervention, there was an increase with a significant average from 53.66 mg to an average of 82.5 mg of zinc value. Through this study, the administration of foxtail

millet-tuna and nutritional education for eight times, was able to increase the zinc value on average to 92.15 mg. For the intervention of barley cookies (foxtail millet)-tuna had added higher value than the intervention of biscuits from the Ministry of Health, this is because the zinc content in tuna flour affects the increases in zinc value. The acceptability of barley cookies (foxtail millet)-tuna as additional food is higher than the acceptability of biscuits from the Ministry of Health.

## Conclusion

Biscuit interventions from the Ministry of Health and Millet (foxtail millet) -tuna cookies (from local food) both improve nutritional status and zinc values in children aged 6-24 months with underweight nutritional status in Pacitan Indonesia. But cookies Millet (foxtail millet) -tuna from local food ingredients, with proper processing will increase the nutritional status and zinc value greater in infants aged 6-24 months with under malnutrition status.

**Conflict of Interest:** There is no conflict of interest in this study.

**Source of Funding:** Funding in this study as a whole is accounted on the researcher independently. There are no other funding sources.

<sup>1</sup>Assoc. Prof., Division of Exercise and Sport Sciences, Graduated School, <sup>2</sup>Assoc. Prof., <sup>3</sup>Assoc. Prof., Faculty of Nursing, Khon Kaen University, Thailand, Research and Training Center for Enhancing Quality of Life of Working Age People, Khon Kaen University, Thailand, <sup>4</sup>MD., Mahasarakham University Affairs Board, Mahasarakham University, Mahasarakham, Thailand, <sup>5</sup>Assoc. Prof., <sup>6</sup>Assoc. Prof., Faculty of Nursing, Khon Kaen University, Thailand

## Abstract

Renal failure is the deceleration of renal functions and the loss of renal cortex and medulla. Therefore, the exercise by the local dance training of the northeastern Thailand (Champa Sri local dance) may help improve glomerular filtration rate (GFR). This research is a quasi-experimental design with a control group. The objectives were as follows: 1) to compare the differences of the eGFR before and after the dancing training and 2) to compare the differences in the amount of product wastes caused by muscles and were excreted through the kidneys (creatinine) and blood urea nitrogen (BUN) before and after the dance training. The sample group was 60-69 year-old women who were healthy. They were divided into two groups: 35 women in an experimental group and 35 women in a control group. The research tools consisted of 1) the dancing DVD for training, 2) the dancing guideline and 3) the collection record of blood test. The dance training program takes 50 minutes a day, 3 days a week and lasts 16 weeks. The statistics used in the study are paired-t test, Independent T-test, Wilcoxon signed rank test and Mann Whitney U test. The study indicated that the differences of the eGFR and creatinine before and after the dance training between the experimental group and the control group were statistically significant ( $p < 0.05$ ). However, the BUN values before and after experiment of the dance training between the experimental group and the control group were no statistically significant difference. In conclusion, the native dance training of the Champa Sri helped increase the efficiency of the eGFR.

**Keywords:** *The Effectiveness, Local Dance, Glomerular Filtration Rate (GFR), Elderly Women.*

## Introduction

Kidneys are the two organs shaped like beans. The functions of kidneys are to excrete product wastes from

the body's metabolism. The functions are measured by the eGFR. The test of creatinine and BUN. If renal failure or renal function deterioration and the loss of renal cortex and medulla continue to severe symptoms, it will result in renal failure and other related complications. During 2015 to 2018, the patients in Maha Sarakham province who have had chronic kidney disease were increased from 11,365 to 21,419 or 88.46%<sup>1</sup>. Thus, the exercise training in healthy people can be useful for the prevention and reduction of acute kidney injuries<sup>2</sup>. Therefore, the local dance training of the northeastern

region of Thailand (Champa Sri local dance) may help increase the efficiency of the eGFR. The objectives of the study were as follows:

1. To compare the differences of the eGFR before and after the dancing training between groups.
2. To compare the differences in the amount of creatinine and BUN before and after the dance training between groups.

### Method

This research is a quasi-experimental design. The intervention of the research was “Champa Sri local dance” for 60-69 year-old women volunteers, who were healthy and were not recorded of nephrotic disease. The dance training program had started from week 1-16, 3 days per week for 50 minutes each, starting from 04.10 pm - 05.00 pm. The dance was performed on Wednesday, Thursday and Friday. Also, there was a control group in the study. Then, the calculation of the sample size was provided to compare the average scores between two groups of population<sup>3</sup>. The samples were divided into two groups including the experimental group and the control group. Each group consisted of 35 people, who voluntarily participated in the project. Then, the participants performed the simple randomization. The data of “Champa Sri local dance” in experimental group were collected from April – June 2018. It was divided into two periods including base line and 16 weeks. The data collection was taken at the same place as the dance practice, which was the meeting room of Nadun Sub-district Municipal. However, the data collection of the control group was taken at a meeting room, Khan Thararat Sub-district and Health Promotion Hospital, Kantharawichai district. The clinical examination was submitted to the clinical pathology laboratory at Mahasarakham Hospital. Additionally, the quality test of the tools including the clarification form, consent form and the record form were passed by three experts completely. Moreover, the compensation for female volunteers who participated in the dance training was received transportation fees for every trip of the dance training and every time of the collection of laboratory tests.

The test within the group used the pair t-test to analyze the differences for the data of normally distributed test. Then, Wilcoxon signed-rank tests were used for non-normally distributed tested data. The test between groups used the Independent T-test to analyze the differences when the data were normally distributed. Then, Mann Withney U test was used for the data of non-distributed test. The researcher evaluated volunteers with helping from the community leaders to clarify, persuade, volunteer and sign the consent form.

### RESULTS

1. There were 30 participants in the experimental group with the average age of 65.770 (SD = 2.12) and the control group were 30 participants with the average age of 64.87 (2.675). Five female volunteers participated in experimental group dropped out, control group as same as too.

#### The comparison of estimated eGFR:

- 1 The change of eGFR of the participants within the group before and after the dance training using pair t-test found that before and after the experiment in the experimental group were significantly different ( $p < 0.05$ ), control group as same as too. Also, the mean score of eGFR after the experiment was lower than the experimental group.
- 2 The change of eGFR between groups before and after the dance training using the Independent T-test showed that the percentage of eGFR in the experimental group's mean had a higher value (lower risk) and creatinine had a lower value (lower risk) than the control group. After the experiment of both groups, there was a significant difference in statistic ( $p < 0.05$ ), but the BUN values had no statistically significant differences ( $p > 0.05$ ) as showed in Table 1-2
- 3 The changes in physical activity and food dietary at home between groups before and after the experiment were not significantly different ( $p > 0.05$ ). Therefore, the study was indicated that the experimental and the control areas had similar living styles.

## Discussion

This was the first study to support novel evidence about the effects of moderate intensity aerobic exercise by using “Champa Sri local dance” in renal function parameters in healthy elderly female. The study indicated that the differences of the eGFR and creatinine before and after the dance training between the experimental and control groups were statistically significant ( $p < 0.05$ ) and the percentage of eGFR and creatinine in the experimental group's mean had a higher value (lower risk) than the control group.

1. To compare the differences in the amount of eGFR, creatinine and BUN before and after the dance training between groups. The eGFR's result had a higher value (lower risk) than control group. It was

consistent with eGFR's result by using duration of exercise training in large Chinese population<sup>4,9</sup> and aerobic exercise training in non-dialysis chronic kidney disease<sup>5</sup>. It helps improving the vascular function and maintain the function of the arteries. It also helps reducing renal arterial flow by means of the increased renal sympathetic nerve activity<sup>6</sup>. The strength and balance<sup>7,12</sup> of exercise resulted in increasing the values of eGFR, creatinine, creatine kinase<sup>12</sup> as well as correlating with the proportion of creatinine and weight. In addition, the 4-month period was considered to be appropriate<sup>9,11,12</sup> for training which can result in significant differences between the groups. Also, if the training has been done for 12 months, it may change inversely with pulse wave velocity<sup>10</sup>. This was good for blood

circulation. For the decrease of BUN values in this experimental group was similar to the results of the cycling exercise and the effects of exercise on laboratory test results<sup>12</sup>. However, the BUN values between the groups did not have the statistical difference as same as the moderate exercise intensity within 6 months<sup>8,14</sup>. This may be due to the increase or decrease of the BUN values which was correlated with muscle mass, dehydration<sup>16,17</sup>, uric acid quantity<sup>18,19</sup>, drug use and illness<sup>27</sup>, etc.

2. To compare the differences in the amount of CBC before and after the dance training between groups. The result of WBC, RBC, HGB showed a higher value than control group. It was because the regular and continuous exercise with the moderate intensity which will result in increasing of WBC, RBC, HGB and Hct. The platelets were decrease and the immune levels were balanced<sup>13,20,21,22,28</sup>. It also increased the circulation of immunoglobulins, neutrophils and natural killer cells<sup>23,28</sup>. However, the results of strength exercise which were compared with the aerobic exercise found that the values of RBC, HGB, Hct and mean Corpuscular Volume (MCV) were decreased, but the number of platelets was increased<sup>24</sup>. Anyhow, this may be related to Malnutrition<sup>25</sup> and dehydration<sup>26,27</sup> conditions as well as the decreased values of Hct may be related to the anemia condition. However, the values of HGB and MCV values for age and gender must be compared additionally<sup>29,30</sup>.

### Conclusion

The native dance training of the northeastern region of Thailand (Champa Sri local dance) helped increase the efficiency of the eGFR.

### Recommendation in this Research:

1. The duration of the dance training, the frequency and the number of days should be increased in order to check the differences in the change of the other related physical changes.
2. There should be more records of the use of modern and traditional medicines, or even the treatment with other alternative medicines which are available in the area.
3. The risks of diabetes and high blood pressure should be checked as it is one of the factors affecting the rate of renal filtration and other related physical changes.

### Recommendation for Further Studies:

1. The training of Champa Sri local dance in the next time should have activities to monitor and control food dietary and medicine. Also, the physical activities at home should be clearly determined together with the assessment of happiness in the activity participation.
2. The training of Champa Sri local dance next time should increase the skills of remembering details in the daily routine, physical activity, good dietary. Thus, the target group will be self-recorder.

**Conflict of Interest Statement:** No conflict of interest to declare.

**Source of Funding:** This study was supported by the Research and Training Center for Enhancing Quality of Life of Working Age People.

**Ethical Clearance:** It was taken from the office of Khon Kaen University Ethics Committee in human research. The project number is HE 602343.

# A 10-Year Follow-up of Rehabilitation of Severely Atrophied Edentulous Mandible with Implant Supported Over Denture: A Case Report

<sup>1</sup>Ajay Jain, <sup>2</sup>Chethan Hegde, <sup>3</sup>Sridevi Ugrappa

<sup>1</sup>Associate Professor, Faculty of Dentistry, AIMST Dental Institute, AIMST University, Semeling 08100 Bedong, Kedah, Malaysia, <sup>2</sup>Professor and Head, Department of Prosthodontics, A.B. Shetty Memorial Institute of Dental Sciences, Deralakatte, Mangalore, Karnataka, <sup>3</sup>Senior Lecturer, Faculty of Dentistry, AIMST Dental Institute, AIMST University, Semeling 08100 Bedong, Kedah, Malaysia

## Abstract

**Background:** Retention and support for the conventional complete dentures primarily dependent upon the residual alveolar ridge and mucosa. Patients with poor mandibular ridge foundation usually suffer from inadequate denture retention and stability. In such cases, implant-supported overdenture treatment provides improved prosthesis retention and support and thus greatly increasing patient's acceptance toward prosthesis as when compared to conventional dentures.

**Case Report:** The present case report describes a successful rehabilitation of resorbed mandibular ridge with an overdenture supported by two implants and 10 years of follow-up was performed and discussed.

**Conclusion:** Implant-supported overdenture provides a strong return for the investment in treatment time and expense. The clinical outcome of this treatment is significantly better than that achieved with conventional mandibular dentures, especially when patients are experiencing technical problems because of compromised prosthesis retention and stability.

**Keywords:** *Atrophied mandible, ball attachment, implant overdenture, follow-up, Dental Implants.*

## Introduction

Dental implants are tooth-root analogue devices inserted into the jaw-bone and have been increasingly used to support different types of dental prostheses such as fixed partial dentures, fixed complete dentures and removable complete dentures.<sup>1</sup> Implant dentistry has improved the patient's satisfaction by improving

the retention, stability, function, aesthetics and the same time preserving the residual bone, especially in the mandible. Implant-supported overdentures have expanded rapidly as a successful treatment modality to rehabilitate completely edentulous patients.<sup>2</sup>

Several studies have indicated that the employment of implant supported overdentures within the mandibular bone is an effective and efficient treatment modality<sup>3,4</sup> particularly in patients with excessive loss of residual bone.<sup>5</sup> The survival rate of implants in the front region of the mandibular bone is excellent and the rate of surgical complications is very low. Moreover, implants demonstrate a reduced rate of residual ridge reduction within the anterior mandibular jaw area.<sup>6</sup> The treatment selection depends on the patient's individual needs and treatment modalities along-side their monetary standing. Two dental implants are usually considered the minimal

number necessary for mandibular implant overdenture treatment.<sup>7</sup> In this case report, patient with resorbed edentulous mandible was successfully rehabilitated using two dental implants placed in the interforaminal region with ball abutments opposing conventional maxillary complete denture and 10 years of follow-up was performed and deliberated.

**Case Report:** A 54-year-old female patient reported with a chief complaint of loose acrylic complete dentures and difficulty in chewing in year 2010. Patient gave history of extraction 20 years back and since then she has been wearing the denture. The present denture, she is wearing; is her fifth denture. She was not happy with the retention of the denture as her complaint that the denture lifts up during eating and talking. Clinical and radiographic examination [Figure 1] revealed severe alveolar bone loss in the maxillary and mandibular residual ridges. There were no compromising systemic considerations. The blood reports of the patient were checked. The treatment plan was formulated, which comprised of mandibular implant-supported overdenture and conventional maxillary denture. The procedure was explained to the patient and informed consent was obtained. Two implants (A8, Ankylos C/X Implants, Dentsply, Sirona, US) of 3.5 mm diameter and 8 mm length was chosen according to the dimension of the bone. Under antibiotic prophylaxis and standard aseptic protocol, nerve block and infiltration anesthesia was administered. A full thickness crestal incision from first premolar to first premolar was given and muco-periosteal flap was reflected and osteotomy was performed in both the mandibular canine regions. [Figure 2] A paralleling tool was placed to check the implant parallelism and the implants were then threaded into position using a hand ratchet at 30 N cm countersinking the implant crest module at the crestal bone level and cover screw was placed and panoramic radiograph was taken [Figure 3]. On the 7th day of surgery, suture was removed and after 4 weeks the procedure of new complete denture began. Border molding, jaw relation record, try-in and denture delivery was completed [Figure 4, 5]. Twelve weeks postoperatively, osseointegration was evaluated clinically as well as radiographically using panoramic radiograph and both the implants were found to be rigidly fixed with an adequate zone of healthy, keratinized gingiva without any sign of crestal bone loss and the implants were ready to receive the prosthesis. The second-stage surgery was performed and the implants cover screws were removed and healing abutment were

screwed into the implant body [Figure 6]. The patient was recalled after two weeks, healing abutments were removed and a periodontal probe was used to measure the gingival cuff height at the right and left canine site implant position and ball abutments were tightened to the implants [Figure 7]. Self-cure acrylic was placed into the relieved space and denture was seated into patient's mouth and allowed to cure, when the patient was biting in centric relation [Figure 8]. After the acrylic is set, denture was removed and modified surface was finished and polished [Figure 9] and panoramic radiograph was taken post-operatively [Figure 10]. The patient was instructed for the use of soft brush and floss for maintenance of area around the implant ball abutments. The patient was recalled at one week, one month, three months and six months follow up appointments. The patient was delighted with the adequate retention, stability, comfort and function of the mandibular implant retained overdenture to her complete satisfaction. The occlusion was found stable; the denture and attachments were clean. The attachment system was devoid of any sign of wearing during the period.

In year 2020, the patient reported and mentioned that maxillary denture is fractured in the midline and mandibular denture was loose. She was not happy with the loose mandibular denture. On intra-oral examination, soft tissue covering (gingival cuff) around the implants was found to be healthy and attachment level was higher when compared with ten years ago photographs. There was slight plaque accumulation on ball abutments was noted. [Figure 11] On radiographic examination, there was minimal or no bone resorption noted around the implants when compared with ten years ago radiograph. The male attachments were evaluated and found to be loose and were not precisely fitting. The treatment planned was debridement of ball attachment, replace the male component and fabricate the metal based maxillary and mandibular dentures [Figure 12]. After the replacement with new dentures and attachments, patient was highly satisfied with the function and aesthetics.

## Discussion

Implant-supported overdenture provides many advantages over conventional denture therapy, like decreased bone resorption, reduced prosthesis movement, better esthetics, increased occlusal function and preservation of the occlusal vertical dimension etc. It is demonstrated that conventional mandibular complete denture produces significantly more patient problems

than maxillary complete dentures, primarily as a result of poor prosthesis retention.<sup>8</sup> Denture retention may be a major problem in patients with severely resorbed ridges, but placement of two or more implants allows optimal retention with patient satisfaction and performance. It has been reported that when implants are placed, the bone gets stimulated by the forces transmitted from implants; resulting minimal bone loss.<sup>9</sup> In the present case report, atrophied mandibular edentulous ridge was rehabilitated with overdenture supported with two implants and after ten years of follow up, minimal or no bone resorption was observed in comparison with the panoramic radiograph which was taken ten years ago. Although the support is shared by the tissues covered by the denture base, two implants usually provide sufficient stability in mandibular ridges.<sup>10</sup> Hygiene condition and residential maintenance procedures are improved with an overdenture.<sup>11</sup> For of these reasons, mandibular two implant overdenture has been described as a customary of take care for edentulous mandibles.<sup>12</sup> The two-implant overdenture therapy may be a consistent and reliable therapy for patients with an edentulous mandible. Many authors have hypothesized that it is appropriate to use two implants with an interconnector parallel to the hinge axis and a resilient overdenture on an ovoid or round bar.<sup>1,13</sup> Survival rates within the two implants supported overdenture groups compared with four-implant overdenture groups appear to be equivalent for patient satisfaction.<sup>14</sup> In the present case report author have placed two implants within the inter-foraminal region to provide retention and stability to the overdenture. The ball abutments were selected as they are cost effective and less technique sensitive, as compared to bar attachment which needs more inter-ridge space. Further, it has been reported that ball abutments are more advantageous with regard to optimizing stress and minimizing denture movement.<sup>15</sup> The anterior mandible has demonstrated a high predictability for implant-tissue integration and consequently, there's no use for planning the position of additional implants in anticipation of potential implant integration failure.<sup>16</sup>

### Conclusion

Implant-supported overdentures offer a strong return for the investment in treatment time and expense. The clinical outcome is significantly better than that achieved with conventional mandibular dentures, especially when patients are experiencing technical problems because of retention and stability of the compromised prosthesis. Patients with implant-supported overdentures are

highly satisfied with their dentures and show increased efficiency in mastication.

# Vascular Complications of Type 1 Diabetes among Indian Patients

Alma Baptist<sup>1</sup>, S. Salvi<sup>2</sup>, C.S. Yajnik<sup>3</sup>

<sup>1</sup>UGC-SRF, Inter-disciplinary School of Health Science, Savitribai Phule Pune University, Pune, <sup>2</sup>Director, Chest Research Foundation, Pune, <sup>3</sup>Professor & Director, Diabetes Unit, KEM Hospital Research Centre, Pune

## Abstract

Diabetes increases the risk of developing various irreversible complications. Demographics of Type 1 Diabetes (T1D) and its complications vary by country. Therefore, we need to examine data on Indian T1D patients and it is not enough to infer from international studies. This review aims to summarize the existing literature around micro and macro-vascular complications of T1D on Indian patients. We then discuss future directions and advocate more reports in this area on Indian T1D patients.

**Keywords:** Type 1 Diabetes, Indian Type 1 Diabetes patients, Diabetic Retinopathy, Diabetic Nephropathy, Diabetic Neuropathy.

## Introduction

Type 1 Diabetes (T1D) characterized by endogenous insulin deficiency, commonly occurs in children, although adults are also affected. According to International Diabetes Federation (IDF), globally newly diagnosed cases of T1D (0-14 years) have increased from 79,000 in 2013<sup>1</sup> to 96,100 in 2017<sup>2</sup>. Globally total number of children (0-14 years) with T1D were reported to be 5,86,000 in 2017<sup>2</sup> and from these 1,28,500 live in India, second highest in the world after the United States<sup>2</sup>. Estimates of the burden of T1D in India are few and have wide range, 3.8/1,00,000/year (1995-2008)<sup>3</sup> to 10.2/1,00,000/year (2008)<sup>4</sup>. In India T1D is one of the commonest endocrine and metabolic disease of childhood. However, in the absence of a nationwide registry, it is difficult to assess its true burden. Technological advancements in the management of T1D have improved the survival and lifespan of patients suffering this complex disease. Joslin Diabetes Center,

USA have reported thousands of people living with T1D for >50 years<sup>5</sup>. Early and long-term exposure to hyperglycemia in the presence of a significantly improved life span, increases the likelihood of these patients to develop complications which result in increased morbidity, treatment expenditure, hospital admissions and mortality. Thereby, lowering the quality of life, increasing burden of T1D and adversely affecting the economies of all countries, especially developing<sup>6</sup>.

Current understanding of the burden of these complications, come mainly from T1D cohorts of high-income countries (USA, Europe, Denmark, etc.) which highlight:

- a. Prevalence and incidence of complications of T1D vary hugely between countries<sup>7</sup>. Prevalence of DR among youth with T1D was 12% in Finland(2006-7)<sup>8</sup>, 17% in USA (2009-10)<sup>9</sup>, 0% in Philadelphia, USA (2009-13)<sup>10</sup>.
- b. There are ethnic disparities in diabetes-related outcomes among people with T1D. Higher numbers of diabetic ketoacidosis (DKA) and severe hypoglycemic events (SAE) have been reported in African Americans with T1D<sup>11</sup>.

A recent systematic review, highlighted that ethnic disparity in mortality is present in South Asians (SA)

patients with T1D<sup>12</sup>. Also, it is well established that Asians are at high risk of obesity, Metabolic Syndrome, coronary heart disease, etc. Whether this places SA T1D patients at higher risk of developing macro-vascular complications, needs further study. In the South East Asian Region (SEAR), India is the largest country and its data is often used to represent SEAR at the global level. This advocates for more studies on this matter from India.

This review aims to present a comprehensive report of studies from India on this matter. Studies that reported prevalence or incidence data on complications are included in Table 1, examined in detail and presented as a narrative with textual description by each complication.

### Diabetic Retinopathy (DR):

**Epidemiology:** The prevalence ranged from 5% to 62.5%. This wide-range could be attributed to factors such as duration of T1D, age of participants and different time-periods of the studies (Table 1). DR has been reported to be common cause of blindness among adults in the western world<sup>2</sup> and is often quoted as most common complication of diabetes. Reports on Indian T1D patients are contradictory. Multicenter survey of Early onset Diabetes in India (MEDI) study, is the only multi-clinic study on T1D patients from India. This was conducted at 7 endocrinology clinics of tertiary-care teaching hospitals across India in 2008. It reported retinopathy as the least prevalent<sup>13</sup> whereas, another study<sup>14</sup> reported retinopathy as the commonest (5% v/s 35.2%). This difference in prevalence of DR, even with similar mean age of participants in both studies (17.6±7.8 v/s 16.5±9.9 years), could be attributed to differences in inclusion criteria of study [age at diagnosis ( $\leq 20$  years versus  $\leq 25$  years)], multi-center versus single-center and time-period of study 2008 versus 1992-2008.

Age-gender adjusted prevalence of DR was reported by a single-center study in Chennai as 62.5%. This study also highlighted that sight threatening diabetic retinopathy (STDR) was seen more among patients with longer duration of T1D (>15yrs) than shorter duration ( $\leq 10$ yrs), 44.1% vs 0% respectively<sup>15</sup>.

Incidence of DR among Indian T1D patients, was reported as 7- 8% per year (77.4/1000 person years)<sup>16</sup>. Only one article reported on progression of DR and in their study of 4 years they found progression in 40% of T1D patients with DR<sup>17</sup>. However, their results need to be taken conservatively. As this study had small sample

size (n=40), details regarding participant recruitment, clinical characteristics of excluded patients was not mentioned<sup>17</sup>. Studies included in Table 1, used 4-7 field stereoscopic fundus photograph to diagnose DR, and grading these retinal images by Early Treatment Diabetic Retinopathy System (ETDRS).

**Risk factors for DR:** Among the studies reviewed, only few presented the association of risk-factors with DR. Duration of diabetes was the strongest independent risk factor (OR:3.9/year<sup>18</sup>, OR:1.99/5year<sup>15</sup>). More than 50% of patients with long duration T1D (> 15years) had DR<sup>18</sup>. HbA1c was found to be independently associated with DR (OR: 1.19) in one study<sup>18</sup> and not in others<sup>15</sup>. Whereas gender and age at diagnosis of T1D were not found to be associated<sup>13,15,17-21</sup>. T1D patients with DR when compared with those without DR were described as significantly older, with longer duration of diabetes DR (OR: 3.9/year<sup>18</sup>, OR:1.99 per 5year<sup>15</sup>), had higher BMI, waist circumference (OR:1.3) and BP (OR:1.4)<sup>15</sup>.

**Diabetic Nephropathy (DN): Epidemiology:** Prevalence of DN ranged (Table 1) from as high as 28.2% in 2002<sup>22</sup> to as low as 3% in 2019<sup>21</sup>. This cannot be interpreted as decline in prevalence of DN among Indian T1D patients, as these are reports from different clinic-based studies. Nephropathy was repeatedly stated as the 2<sup>nd</sup> most common microvascular complication of diabetes among Indian T1D patients<sup>16,13</sup>, occurring at the rate of 6.2% per year<sup>16</sup>. One report stated nephropathy to be the least common complication (6.8% prevalence)<sup>14</sup>. Prevalence of DN was seen slightly higher among males than females (8% v/s 6%, statistically non-significant). Age of development of DN was reported as 25.0 ± 6.0 years<sup>18</sup>. A study on South Indian T1D patients stated that age-gender adjusted prevalence of nephropathy was higher among T1D patients with Metabolic Syndrome (MetS) than without (51.3% versus 15.1%)<sup>20</sup>. Studies included in Table 1, assessed DN using Urine albumin excretion rate (UAE)<sup>20</sup> and defined nephropathy if urine protein excretion was >500mg/24h on more than two consecutive occasions<sup>16,14,20,13,18,22</sup>, after ruling out systemic or urinary tract infection.

**Risk factors of DN:** Duration of diabetes was the strongest independent risk factor for DN. However, for the same duration of T1D, prevalence of DN varied considerably by the studies. Duration of T1D  $\leq 5$  years: 10.3%<sup>22</sup>, 2%<sup>18</sup>, 0%<sup>14,19</sup>; >15years: 12.1%<sup>14</sup> to 22.2%<sup>18</sup>. Among other risk factors associated with DN, hypertension and MetS (OR: 4.92)<sup>20</sup> were reported to

have independent association, where as glycemetic control and age at diagnosis of T1D did not<sup>18</sup>. Prevalence of hypertension was 22.7% among T1D patients with microalbuminuria and only 1% among those with normoalbuminuria<sup>22</sup>.

Youngest age of development of DN among T1D patients was reported as 19 years<sup>19</sup>, irrespective of age at diagnosis of T1D and gender.

**Diabetic Neuropathy:** Diabetic neuropathy is commonly classified into two groups, peripheral and autonomic neuropathy. All the articles listed in Table 1 assessed Peripheral Neuropathy (PN) and did not report Autonomic Neuropathy (AN). Asevaluation of AN is difficult and requires sophisticated instruments. PN was diagnosed by bilateral absence of ankle jerks and/or bilateral distal sensory loss or any other severe form of neurological deficit<sup>18</sup> in studies before the year 2000. Recent studies have used biothesiometer and defined Vibratory Perception Threshold (VPT)  $\geq 20$  as PN<sup>20</sup>.

**Epidemiology:** Prevalence of PN ranged from 3.0% to 29.8% (Table 1). The extremely low prevalence (3%) was reported among south Indian T1D patients<sup>18</sup>. Other studies on south Indian T1D patients also reported similar prevalence (range upto 10%)<sup>3,14,20</sup>. Study that reported high prevalence of PN (29.8%), included T1D patients from one city of North India (Lucknow). This stark difference in prevalence of DN could be attributed to different assessment techniques and, different definitions of PN. There may also exist difference in available treatment, patient support or regional difference, which needs to be studied further.

Most studies reported PN as least common micro vascular complication of T1D among Indian patients but two studies found it to be the most common<sup>19,13</sup>. Prevalence of PN among T1D patients with MetS was 58.8% and those without MetS was 15.6% (age-gender adjusted)<sup>20</sup>. We did not come across articles that exclusively studied PN among Indian T1D patients or reported age-gender adjusted prevalence of PN.

**Risk factors of PN:** Slightly higher prevalence of PN was reported among males than females (3.7 v/s 2.4%), but statistically insignificant<sup>18</sup>. PN was found even in patients with shorter duration of T1D (<5 years): 29%<sup>19</sup>. With every year increase in duration of diabetes, the odds of PN were 2.3(1.5-3.7) independent of confounders<sup>18</sup>. Glycemic control was not found to be independently associated with PN. On comparing T1D

patients with and without MetS, the odds of developing PN were higher among those with MetS(OR: 3.65) adjusted for confounders<sup>20</sup>.

**Macro-Vascular complications:** Diabetes complications due to damage to larger blood vessels are the macro-vascular complications and include Coronary Heart Disease (CHD) and Peripheral Vascular Disease (PVD). These are common cause of mortality among T1D patients.

Only two articles, studied macro-vascular complications. They reported prevalence of CHD and PVD as 0.5% each<sup>18</sup> and incidence of CHD and PVD as 1.2 and 2.7/1000 person years, respectively<sup>16</sup>.

## Discussion

In the above section, we have presented a comprehensive report about chronic complications of T1D among Indian patients, based on studies from across India. As these studies were clinic-based and not at population level there by, prevalence or incidence reported in them are based on the total number of patients attending that particular clinic. Most of these clinics were tertiary-care referral center and cater to the city and nearby districts. Direct comparison of these studies with each other and with studies from other countries is difficult, as inclusion – exclusion criteria varied between the studies, different time-periods of study, use of secondary versus primary data and inconsistent definition of T1D across studies (antibody testing is still uncommon in routine clinical practice in India). Also, some articles, studied T1D under the umbrella of youth-onset diabetes<sup>13,17</sup> and not all reported prevalence of complications by type of Diabetes<sup>19</sup>. These reasons also resulted in widely varied estimates of prevalence of complications in these studies. Age-gender adjusted prevalence and incidence of complications was reported by only one study. Duration of diabetes and HbA1c, were consistently reported to be risk factors for vascular complications. Also, MetS was reported to increase odds for microvascular complications. Across all studies, prevalence of macro-vascular complications was reported as <5%.

The Diabetes Control and Complications Trial (DCCT) brought a paradigm shift in the treatment of T1D patients. Its follow-up study EDIC and other international cohorts such as EURODIAB, FINNDANE and T1D Exchange Clinic, have brought much insight about T1D and the daily life struggles of patients. There

exists a lack of understanding pertaining to quality of life of Indian T1D patients and real-world scenario of Indian T1D clinics (challenges, routine procedures, patient education, care giver knowledge, screening facilities and recommendations followed). This exists, due to following challenges in India:

1. In India current research studies and government programs pertaining to Diabetes are focused on T2D. And T1D is still fighting its place under the sun.
2. In India, doctor hopping is a common practice specially among patients with chronic conditions. This, results in poor follow up rates at the clinic and undermines the formation of a cohort, which can be invited for research.
3. Single center studies are more common in India. National-level registry of diseases both communicable and non-communicable are uncommon. The multicenter “Young Diabetes Registry” (7-sites) of Indian Council of Medical Research was launched with the purpose to study

diabetes among the young, addressing the issue of diversity in culture and environment.

A ‘Registry: network of all clinics treating T1D patients’ across India, is a simple solution to the above listed problems. It’ll enable clinics and hospitals across India, to extract meaningful information from their patient’s data. This information will aid to enhance awareness about T1D, advocacy for allocation of resources towards welfare of T1D patients, reinforce knowledge-sharing between health care teams and thereby improve standards of care.

### Conclusion

Micro-macro vascular complications increase the burden of T1D. Reports on this matter from India are few. The absence of data results in invisibility of patients and worsening of their condition. To have true understanding on this matter in a vast and diverse country like India, it has become increasingly important that we need more studies from different parts of India. Because such data will contribute to improve the treatment and healthcare planning for Indian T1D patients.

**Table 1: Reports of Complications in T1D from India [CA: Current Age, ADT: Age at diagnosis of T1D, DT: Duration of T1D, NM: Not mentioned]**

Reference	Participant description	Prevalence/Incidence

# Mental Health Among Orphan and Non-Orphan Adolescents in Delhi-NCR

Ashu Kumari<sup>1</sup>, Nudrat Jahan<sup>2</sup>

<sup>1</sup>Research Scholar, <sup>2</sup>Assistant Professor, Department of Clinical Psychology, SGT University, Gurugram

## Abstract

Mental health is defined as a state of happiness in which each person understands his or her own potential of handling challenges of life. A mentally healthy person can work effectively and joyfully and is able to make an influence on others. Stress coping mechanism largely depends on the upbringing pattern of the family. Orphan is a person who has lost both his parents and mostly learn to cope with the issues while experiencing life adversity. Aim: of the study is to study the mental health among orphan and non-orphan adolescents.

**Method:** 40 orphan adolescents were selected from the different orphanages of national capital region of India using purposive sampling method, similarly 40 non-orphan adolescents were selected from different schools. General health questionnaire- 28 was used to measure somatic, anxiety, social dysfunction and depression.

**Result:** Both the group were found significantly different on somatic ( $t= 10.30; p<.001$ ), anxiety ( $t= 10.30; p<.001$ ), social dysfunction ( $t= 10.30; p<.001$ ) and depression issues ( $t= 10.30; p<.001$ ).

**Conclusion:** Study shows that orphans mental health was poor than non-orphan adolescents.

**Keywords:** *Mental health, Orphan, non-orphan.*

## Introduction

Mental health comprises of our feelings, cognitive process and enlightenment. It effects our thinking, feeling, life processes and also effects our stress handling skills. Mental health is very important at every stage of life<sup>[1]</sup>. Many factors such as biological, brain chemistry genes, life experiences such as trauma or abuse and family history of mental health are causes of mental health problems. According to World Health Organization when children do not achieve social and behavioural potential then they lose their confidence and suffer from many mental health issues<sup>[2]</sup>.

Mental health play important role in Adolescent life and this is the significant period and crucial as the changing needs of the adolescents arise during this period. Adolescents are the future productive citizens of a country. Social problems like delinquency, crime, suicide, alcoholism, drug addiction, prejudice, under

achievement and dropping out of school are more sensitive problems in adolescent<sup>[3]</sup>. WHO says that worldwide 10-20% of adolescents experience mental health half of all mental illnesses begin in the age of 14 and two -quarters by mid20s. Therefore, Adolescents face major challenges like stigma, isolation and discrimination, as well as lack of access to health care and education facilities.

Recent studies have identified mental health problems - in particular depression, as the largest cause of the burden of disease among young people.

Poor mental health can have serious effects on the wider health and development of adolescents and association with several health and social outcomes such as higher alcohol, tobacco and illicit substances use, adolescent pregnancy, school dropout and delinquent behaviours. Parenting style refers to the way parents interact with each other and with children. Studied had

shown that parents -child interactions and relationships and parenting style affect mental health both in positive and negative ways<sup>[4]</sup>.

According to National Health Survey -3 which includes data from 2005 to 2006, 41 % of India's population is under 18 and It was also the largest child population in the world. According to the study, an additional 13 per cent of these children live in single-parent households, who are also socially and economically marginalized than that houses with the both parents. 85% children with single -parents are mostly living with their mothers and 4%of Indian population are orphans. However, challenges of mental health are different for orphans.

Orphan is defined as abandoned children, who has lost their parents. Studies reveals that India is home to 20 million orphans. states Uttar Pradesh, Madhya Pradesh, Chhattisgarh are home to billions of orphan children under age 18. This may rise up to 7.1 million and states in eastern region Bihar, Orisha, Jharkhand and west Bengal have up to 5.2 million till 2021. These states have double number of orphan children. Poverty has played a significant role to increase the number of abandoned and orphan children in these states. Military affected areas are also to be partially blamed. Importance is given to understand their physical states and mental health by several organizations all over the world. According to United Nations International Children's Emergency Fund (UNICEF), children those who have no parents or have a single parent, are malnourished and don't reach till their full potential of psychological and intellectual capabilities<sup>[5]</sup>. Another study in Tanzania, shows comparison of psychological health of orphans and non-orphans, originates wide evidence of reduced psychological wellbeing for orphans. This shows most orphans having psychological impairment, especially affected behaviour changes such as depression, anxiety and low self-esteem<sup>[6]</sup>. The world bank also says orphans have higher tendencies toward social disorganization than non-orphans<sup>[7]</sup>. To fulfil this gap present study was conducted with following objectives.

**Objectives:**

1. To study the somatic, social dysfunction, anxiety and depression issues among orphan and Non-orphan adolescents.
2. To study the difference in somatic, social dysfunction, anxiety and depression issues among orphan and Non-orphan adolescents.

**Hypothesis:**

1. There would be somatic, social dysfunction, anxiety and depression issues among orphan and Non-orphan adolescents.
2. There would be significant difference in somatic, social dysfunction, anxiety and depression issues among orphan and Non-orphan adolescents.

**Methodology**

**Design:** Descriptive correlational research design was used to conducted the study.

**Sampling:**

**Sampling technique:** Purposing sampling was used.

The samples were selected from 5 orphanage located in Delhi NCR. A total number of 40 orphan adolescent and 40 non-orphan adolescents were selected as per following inclusion and exclusion criteria's:

**Inclusion Criteria:**

- Age range 13 to 19 year only.
- English and Hindi speakers only.
- Minimum education Higher Secondary School.
- Orphans living in orphanage only.
- Non-orphans living with both the parents.

**Exclusion Criteria:**

- Subjects who were uninterested in study.
- Subjects who were suffering from any serious physical or mental issues.
- Physically handicapped subjects.
- Non-orphan living with single parent.

**Tools:**

**General health questionnaire 28:** The GHQ-28 was developed by Goldberg in 1978 and has since been translated into 38 languages. Developed as a screening tool to detect those likely to have or to be at risk of developing psychiatric disorders, the GHQ-28 is a 28-item measure of emotional distress in medical settings. Through factor analysis, the GHQ-28 has been divided into four subscales. These are: somatic symptoms (items

1–7); anxiety/insomnia (items 8–14); social dysfunction (items 15–21) and severe depression (items 22–28) It takes less than 5 minutes to complete<sup>[8]</sup>.

**Procedure:** To fulfil the objectives of the study, 31 orphanages located in Delhi-NCR were approached, among those 5 orphanages gave the permission to collect the data. 670 orphans living in orphanages were interviewed for their counselling needs. Duration was also used to identify the subject as per inclusion and exclusion criteria of the sample. 40 orphans were selected based on inclusion and exclusion criteria. Subject were

given detailed information about the study and consent was taken from the subject to use the data for research purpose. Data was collected by using GHQ.

## Results Analysis

In this study, the data obtained was analysed by using the Statistical Package for Social Sciences (SPSS) -21 version, paired sample t- test was calculated to see the difference between both the groups Obtained result is mention below.

**Table 1: Mean, S.D and t. test of General Health dimensions**

Variable	Orphan Mean	S.D.	Non-orphan mean	S.D.	t.
Somatic	6.47	4.02	2.15	1.79	6.2*
Social dysfunction	8.40	2.58	3.32	2.39	9.10*
Anxiety	7.27	3.92	2.07	2.54	7.0*
Depression	5.87	3.89	.55	.74	8.5*

**Note.** \* $p < .001$

The above result shows that in somatic complaints, there was significant difference among orphans and Non orphans ( $t = ; p < .001$ ). Similarly, anxiety in orphan adolescent was higher ( $M = 7.27$ ;  $SD = 3.92$ ) ( $M = 2.07$ ;  $SD = 2.54$ ) in Comparison with non-orphan adolescents. Social dysfunction was also higher in orphan adolescent ( $M = 8.40$ ;  $SD = 2.58$ ) ( $M = 3.32$ ;  $SD = 2.39$ ). compared to non-orphan adolescents. depression was higher in orphan adolescent ( $M = 5.87$ ;  $SD = 3.89$ ) ( $M = .55$ ;  $SD = .74$ ). compared to non-orphan adolescents. Result shows that there was significant difference in somatic, social dysfunction, anxiety and depression, demotion in orphan and non-orphan adolescents.

The result shows that orphan adolescent's mental health was very less rather than non-orphan. orphan children face many issues because of parenting lacking or others issues.

## Discussion

Mental health is a very important aspect for both groups. Mental health problem such as depression, anxiety, social dysfunction, stress somatic and other issues among adolescents and early adults are currently estimated to range from 5 to 80% in different populations worldwide<sup>[9]</sup>.

Orphan children suffer from many mental health problems because they don't have their parents or family, they have lack of confidence and their economic condition is very poor and their development is affected by various biological changes. They can't control their emotions any behaviour, therefore, they suffer from many mental health issues.

A similar study shows the psychosocial problems of orphans and non-orphans that prevalence of psychosocial problems (negative emotion, stigma, depression and behavioural problems) were higher among orphans than non-orphan adolescents<sup>[10]</sup>. Other study shows that the orphans are ill-treated by the society, which effects their mental health<sup>[11]</sup>. Because of the many tragedies such as loss of parent at in primary age has caused orphan adolescents loss of parental attachment in their lives. Living in orphanage, deprived orphan adolescents from their parent's attention and love. They face the different environment after the death of their parents<sup>[12]</sup>. These conditions influence orphan adolescents to experience such as depression anxiety, stress, social problem and somatic issues<sup>[13][14]</sup>.

We found in our study that orphan adolescent was highly suffered from mental health with caparison than

non-orphan's adolescents. Another study in Malaysia showed that orphan who are living in orphanage were more depressed and exposed to major depression disorder compared to that those are living with their family<sup>[15]</sup>.

In our study it was found that there was significant difference in somatic, anxiety, social dysfunction and depression among orphan and non-orphan adolescents at (p.001\*). Both hypotheses were accepted. Another finding describes ill-treatment and no counselling care are significantly associated with mental health among orphan and non-orphan's adolescents.

### Conclusion

According to our study there was significant difference in mental health of orphans rather than non-orphan adolescents. Due to lack of family and environment issues orphans suffers higher mental health issues in comparison with non-orphan adolescents.

**Conflict of Interest:** There was no conflict of interest in this study.

**Sources of Funding:** Study doesn't involve any funding since this was the part of SGT university project.

**Ethical Clearance:** Ethical clearance was obtained from SGT University Gurugram. We clearly explained aim of the study to the participants and information was collected after the consent form was filled from each participant. The rights were given to the study participants to discontinue participation at any time and participant name and other information were not used at the time of data collection and all personal information kept confidentially was assured at the study period.

**Acknowledgement:** I would like to thank my mentor dr. Nudrat Jahan who guided me always and special thanks to Hema ma'am and all my friends who supported me.

# A Study to Establish Correlation between Dermoscopic and Clinical Findings of Dermatophytosis

Asma Arif Hussain<sup>1</sup>, Namita D. Narkhede<sup>2</sup>

<sup>1</sup>Assistant Professor, Department of Dermatology, Skin OPD 29, <sup>2</sup>MD, Dermatology, Resident, Department of Dermatology, Krishna Institute of Medical Sciences and Deemed University (KIMSUDU), Malkapur, Karad, Satara, Maharashtra, India

## Abstract

**Background:** Dermatophytosis is a growing menace these days. Dermoscopy is a simple and non invasive diagnostic technique used in dermatology. But there are few studies on dermoscopy of dermatophytosis.

**Objective:** The present study aims to study the dermoscopic findings of dermatophytosis and to study its correlation with clinical and histopathological findings.

**Materials and Method:** It was a cross sectional study done over a period of 3 months. 100 patients with clinical diagnosis of any form of dermatophytosis, were included after taking an informed consent. Diagnosis of dermatophytosis was made clinically followed by KOH examination. Clinical examination, photographs and dermoscopy was done in all cases. Dermoscopy was taken by hand held dermoscope (Dermlite 4 gen DL4, California USA), with a magnification of 10x. Biopsy was done in selected patients.

**Results:** Out of 100 patients, male-to-female ratio was 1.5:1. Mean age was  $38 \pm 8.7$  years. Mean duration of disease was 3 months. Tinea corporis was the most common type, followed by tinea cruris and tinea facie. Dermoscopic findings of tinea corporis, cruris and facie were -peripherally distributed white scales, red to grey background, red to brownish black dots and globules at periphery, follicular micropustules and perifollicular scales. Tinea capitis showed black dots, broken hair and Morse code hair. Onychomycosis showed yellowish brown discoloration with subungual hyperkeratosis and jagging of free edge of nail plate.

**Conclusion:** In absence of adequate lab facilities, dermoscopy acts as a complementary tool to clinical diagnosis. Dermoscopy helps to initiate early treatment, thus helping to reduce tinea menace.

**Keywords:** Dermatophytosis, Dermoscopy, Tinea, Onychomycosis.

## Introduction

Dermoscopy is a simple, cost effective and non-invasive diagnostic technique used for many diseases

e-mail: drasmaarif.5aug@gmail.com

in dermatology. Its use as a diagnostic tool is spreading beyond the diagnosis of pigmentary disorders. Its usefulness is established in diagnosis of tinea capitis. It is also being utilised increasingly in diagnosing onychomycosis. Dermatophytosis is prevalent as an epidemic in our country and its menace is growing day by day. The diagnosis of dermatophytosis is generally clinical and aided by direct microscopic examination with potassium hydroxide and fungal culture. These conventional tools are time consuming, complex and require training and laboratory settings. There are few studies on dermoscopy of dermatophytosis. The present study aims to establish the dermoscopic findings of various dermatophytosis and to study its correlation

with clinical and histopathological features, thus helping in early diagnosis and early management of dermatophytosis and obviating the need of cumbersome lab procedures.

### Materials and Method

This was a cross-sectional study done over a period of 3 months from September 2019 to November 2019 in the out patient department of dermatology of Krishna institute of medical sciences, karad . One-hundred patients with clinical diagnosis of any form of dermatophytosis, who were willing to be a part of the study, were included.■

After taking ethical clearance and consent, One-hundred patients were included in the study. A relevant history was taken regarding the onset, duration, progression, recurrence and treatment modalities. Diagnosis of dermatophytosis was made by clinical examination which was confirmed with direct microscopic examination with KOH. Clinical photographs and dermoscopic examination were done in all cases. Dermoscopy was taken by a handheld dermoscope (Dermlite 4 gen DL4, California USA) with a magnification of 10x. The contact plate of dermoscope was cleaned with sanitizer to prevent contamination. Biopsy was done in selected patients only.

#### Inclusion Criteria:

1. New clinically diagnosed cases of dermatophytosis.
2. Patients of both genders
3. Patients of all ages.

#### Exclusion Criteria:

1. Patients not willing to give consent for study
3. Those with history of any topical or systemic antifungal treatment in last 3 months
4. Patients with any ongoing treatment with topical or oral antifungals
5. Patients with other comorbidities and immunosuppression.
6. Patients with tinea incognito.

### Results

Total 100 patients of dermatophytosis were included in the study. Out of 100, 60 were male and 40 were females with a male-to-female ratio of 1.5:1. Age of

patients ranged from 15 to 70 years, with a mean age of  $38 \pm 8.7$  years. In our study, median duration of disease was 3 months; it ranged from 15 days to 4 months. 74 patients had acute disease (< 6 weeks) while 26 patients had chronic disease (> 6 weeks). KOH examination was positive in all cases.

Different types of dermatophytosis that were detected in our study are shown (table 1), with tinea corporis (47 %) being the most common type, followed by tinea cruris (32 %) and tinea facie (6%).

**Table 1: Distribution of various types of dermatophytosis**

Sr.No.	Type of Dermatophytosis	Number of Patients/ Percentage
1	Tinea corporis	47
2	Tinea cruris	32
3	Tinea facie	6
4	Tinea capitis	3
5	Tinea mannum	3
6	Tinea pedis	4
7	Onychomycosis	5
<b>Total</b>		100

Dermoscopic findings are enlisted (Table 2). Peripherally distributed white scales was the most common feature seen in 100 % of cases followed by background color varied from red (74%) to grey (26 %). Red dots and globules were seen in 35% cases while brownish black dots and globules were noted in 21% cases. Perifollicular scales were noted in 54 % of cases. Follicular micropustules were seen in 5 cases.

**Table 2: Dermoscopic findings of dermatophytosis and onychomycosis**

Dermoscopic Findings	Number of Patients/Percentage
<b>Background color</b>	
Red	74
Grey	26
<b>Peripherally distributed white scales</b>	100
Moth eaten appearance	65
Bietts collaret like scale	35
<b>Dots and globules</b>	
Red	35
Brownish black	21
Excoriation marks	27
Micropustules	5
Perifollicular scales	54

Dermoscopic Findings	Number of Patients/Percentage
<b>Hair changes –</b>	
Morse code hair	38
Black dots	3
Broken hair	9
<b>Nail changes</b>	
Yellowish brown discoloration	5
Subungual hyperkeratosis	4
Jagged edge of nail plate	3
Onycholysis	3
Nail dystrophy	1

Dermoscopic findings noted in cases of tinea corporis included background diffuse erythema in 30 patients and grey background in 17 patients; brown spots surrounded by a white-yellowish halo (15 patients), follicular micropustules (3 patients); and morse code hair (20 patients). Whitish superficial thin scales were

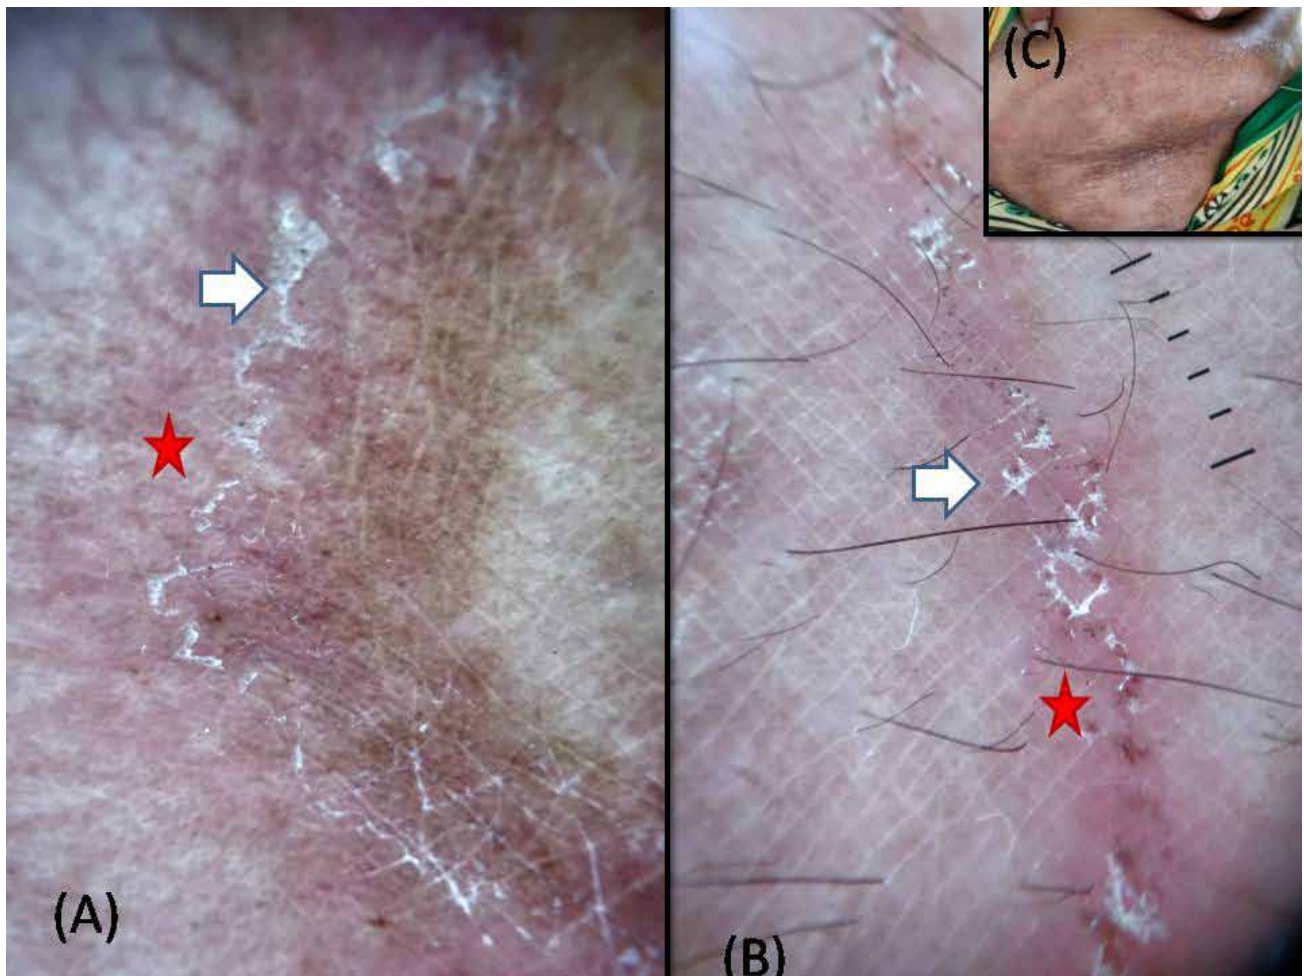

seen at the periphery of all the lesions. Scales were prominent along the skin creases. The vascular pattern is usually monomorphic, consisting of dotted vessels with mainly peripheral distribution. Hair changes included morse code hair (20 patients), broken hair (6 patients).

Dermoscopic findings of tinea cruris, tinea facie were similar to that of tinea corporis.

Dermoscopic findings of tinea manuum and pedis showed fine white scales within palmar and plantar creases with prominent surrounding erythema. Skin markings showed prominence.

3 patients of tinea capitis showed broken hair, black dots and morse code hair.

5 patients of onychomycosis showed yellowish brown discoloration with subungual hyperkeratosis, jagged nail plate edges, onycholysis with nail dystrophy.

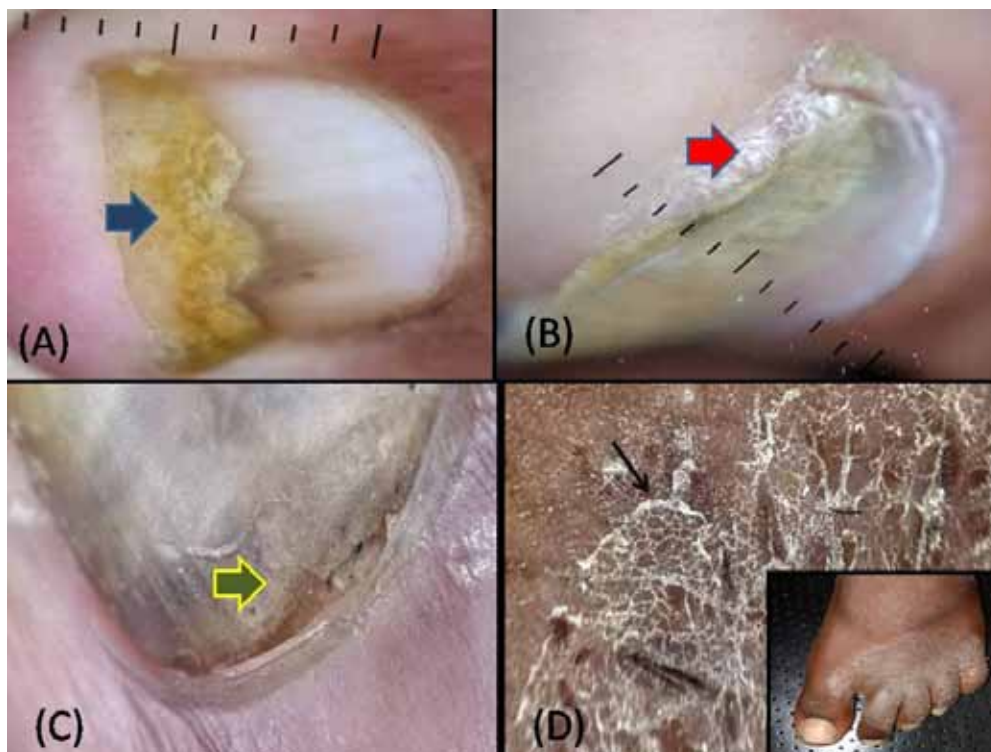

**Image 1: (White arrow) - Peripheral white scaling (A) shows continuous scales (B) Moth eaten appearance, (Red star)-background Erythema (C) clinical image of Tinea corporis**

**Image 2: Dermoscopic features of Tinea corporis. (A) Yellow arrow showing red grouped dots and globules. (B) Brown arrow showing brown dots and globules. (C) White arrow showing white scales with accentuation of skin markings. (D) Red circle showing white structureless areas corresponding to micropustules.**

**Image 3: Dermoscopic features of Onychomycosis and tinea pedis (A) Blue arrow showing Onycholysis and yellow discoloration (B) Red arrow showing Subungual Hyperkeratosis (C) Green arrow showing jagged nail plate and grey discoloration. (D) Dermoscopic features of Tinea pedis – showing white scales with accentuation of skin markings. Inset showing clinical image**

**Image 4: A, B-Dermoscopic features of Tinea capitis. (A) Purple arrow showing perifollicular scales. Inset shows clinical image of tinea capitis with facie. (B) Red circle shows medullated hair, Black circle shows Morse code (bar code) hair. (C) Histopathological (H & E) features of dermatophytosis – showing fungal hyphae in stratum corneum, spongiosis and hyperkeratosis (D) Showing PAS stain – fungal hyphae**

### Discussion

Clinical manifestations of tinea are similar irrespective of site of involvement. Tinea infections are easy to diagnose but may pose a diagnostic challenge to treating physician during partial treatment, steroid abuse or fungus invasion on other dermatoses. Dermoscopy of tinea of skin is uncommonly studied but the role of trichoscopy in dermatophytosis is well established in literature. Only few reports are present regarding the dermoscopy of other dermatophytosis. Hence present study was done.

Background color of most lesions is red due to inflammation in the early lesions while late lesions show greyish background corresponding to post inflammatory hyperpigmentation.

Peripherally distributed whitish scales are the hallmark of tinea corporis which was seen in 100 % of cases in our study. This finding is consistent with a study done by Bhat et al.<sup>1</sup>

Two types of scale distribution were noted –the outer border of the scales is typically sharply demarcated and focally might acquire a “moth-eaten appearance”.<sup>2</sup>

Multiple circular peripheral scales often coalesce to form larger multicyclic lesions. The so-called Biett’s collaret-like scaling refers to a continuous peripheral rim of scales, surrounded by an erythematous halo. These scales correspond to hyperkeratosis on histopathology.<sup>2</sup>

Scales are also focally noticed in perifollicular areas. Reddish Brown dots and globules are noticed at the periphery of the lesions. The color of these dots and

globules changes to black with the duration of the lesion. Reddish brown color is imparted by serum, RBCs and hemosiderin in the skin tissue secondary to intense scratching. These globules appear black due to melanin deposition in the epidermis due to post inflammatory hyperpigmentation.

Knöpfel et al<sup>3</sup> and Bhat et al<sup>1</sup> also described presence of brown spots surrounded by white yellowish halo.

Hair changes include translucent hair (possibly due to massive fungal invasion), broken hair, black dots.<sup>4</sup> Morse code-like hair or bar code-like hair, is defined as multiple white alternate bands across the hair shaft. These were described in tinea capitis<sup>5,6</sup> and in tinea of the vellus body hair as well.<sup>4,7</sup>

Fungal involvement of vellus hair indicates need of systemic therapy for complete cure.<sup>7,8</sup>

Follicular micropustules were seen in 5 cases. Similar findings are noted by Bhat et al<sup>1</sup>. Micropustules indicate neutrophilic micro abscesses around hair follicle. Excoriation marks denote denuded epidermis on histopathological examination due to scratching.

The dermoscopic findings in cases of onychomycosis reported in our study included yellow brown discoloration, subungual hyperkeratosis, jagging of the free edge of the nail plate and nail dystrophy. These findings are consistent with the findings of studies conducted by Piraccini *et al.*<sup>9</sup> and De Crignis *et al.*<sup>10</sup>

### Conclusion

As the lab facilities for diagnosing dermatophytosis are cumbersome and time consuming, dermoscopy acts as complementary tool to the clinical diagnosis. Thereby it guides to initiate early treatment and helps in the reduction of tinea menace.

**Conflict of Interest:** None

**Source of Funding:** Self

**Ethical Clearance:** Taken

# Normative Data of Trunk Muscle Endurance for Male Long-Distance Runners of Vadodara: An Observational Study

Bhura Paras A.<sup>1</sup>, Shah Sweety A.<sup>2</sup>, Bhura Camy P.<sup>3</sup>

<sup>1</sup>Ph.D. Scholar, Gujarat University, Assistant Professor, BITS Institute of Physiotherapy, <sup>2</sup>Ph.D. Guide, Gujarat University, Ahmedabad, <sup>3</sup>MPT, Assistant Professor, BITS Institute of Physiotherapy

## Abstract

**Introduction:** Over last two decades, Importance of trunk core muscle exercise has gain major interest in clinical as well as in profession athletes. Trunk muscle endurance and strength are routinely used measures in clinical evaluation, but lack of normative data is a limitation for measuring physical function of trunk in athletes.

**Aim:** Aim of the study is to find out normative data of trunk muscle endurance for male long-distance runners of Vadodara.

**Objectives:** To Establish normative data of Trunk flexors, extensors and side flexors endurance using McGill's Endurance Test.

**Methodology:** 80 male participants of 18-35 years were taken randomly from various sports ground of Vadodara. Study Design: Cross sectional Observation study. Outcome Measures: McGill's Endurance Test Procedure: Participants was selected based on Inclusion Criteria and McGill's Endurance test was used to examine trunk muscle endurance. These tests consist of four positions: 1) Trunk anterior flexor test, 2) Trunk posterior extensor test, 3) Latera side plank (Right) and 4) Lateral side plank (left). Statistical analysis: Descriptive statistics were used to summarise the data of all participants. Endurance levels between 25 and 50 consider low, between 50 and 75 consider medium and between 75 and 100 consider high.

**Result:** The mean value of trunk anterior flexor test was 148 sec, Trunk posterior extensor test was 108 sec, Lateral side plank (Right) was 83.2 sec and Lateral side plank (Left) was 81.5 sec.

**Conclusion:** This study was done to find out the normative data for endurance of trunk muscle in long distance runners of 18–35 age group. The reference value of trunk muscle endurance found in this study can be helpful for the quantitative evaluation, Rehabilitation programme and for the research purpose in the long-distance runners.

**Keywords:** *Trunk muscle endurance, Normative data, McGill's endurance test, Long distance runners.*

## Introduction

Good muscle Endurance is necessary to maintain postural control. Sustain postures require continuous, small adaptations in the stabilizing muscle to support the trunk against fluctuation forces. Large repetitive motions also require muscle to respond so as to control activity. In either case, as muscle fatigue, the mechanics of performance change and the load is shifted the inert tissue supporting the spine<sup>1</sup>. So, with poor muscular

support and sustained load on the inert supporting tissue, creep and distention occur, causing mechanical stress. In addition, injuries occur more frequently after a lot of repetitive activity or long periods of work and play when there is muscle fatigue. Core strengthening has play very important role in sports training as a method to condition athletes for the injury prevention to the spine and/or lower extremities. The main emphasis of core strengthening is focused on muscular stabilization of the

abdominal, Multifidus, paraspinal and gluteal muscles to provide better stability and control for activity of sports<sup>2</sup>. Past studies have shown the importance of pelvic stabilization in training the lumbar extensor muscles. Pollock et al. showed that resistance exercise training with pelvic stabilization improved development of lumbar extension strength<sup>3</sup>. Jeng et al. reported that the occurrence of LBP may be decreased by strengthening the back, legs and abdomen to improve muscular stabilization<sup>4</sup>.

Over last two decades, exercise and testing of trunk core muscle has gain major interest in the field of sports physiotherapy and professional athletes<sup>5,6</sup>. Injuries in the back muscle remains concern in professional athletes. The practice of measuring trunk muscle endurance has been widely used to identify athletes who may be at risk of muscle injuries, to evaluate rehabilitation outcomes and to enhance performance of athletes<sup>7</sup>. But still back literature contains limited normative data for trunk muscle endurance specially in the India. This lack of normative data is a limitation in the quantification of physical function of spine and is the impetus for this study.

When evaluating muscle performance in the trunk, an examiner can compare the normal and abnormal sides to quantify diminished muscle performance. This type of intrinsic control is not available for evaluation of the trunk muscle endurance. It is necessary to reference a normative data in order to find alternations of Trunk Musculature from Normal that is the main need of the study.

Core stability did not become popular in previous century, with the idea developing from the study of spinal stability by individuals, such as Punjabi<sup>8</sup>. Although lack of core stability associated with low back pain<sup>2</sup> and injuries<sup>9-10</sup>.

### Methodology

A total of 80 male participants of 18-35 years were taken from various sports ground of Vadodara. Verbal explanation of study was given to all participants and written consent was taken. Ethical clearance was taken from institutional ethical committee.

**Inclusion Criteria:** Healthy Male Timed Long-Distance Runners (10km, 21 km and 42.195 km), Age group 18 to 35 Years.

**Exclusion Criteria:** 1. Any Conditions affecting mobility or Balance 2. Any congenital and structural abnormalities 3. Any back, abdominal and lower limb surgical history, Hernia. 4. History of symptomatic low back pain within 6months of time.

**Procedure:** After taking informed consent participants' core endurance was examined using McGill's endurance test.<sup>11-13</sup>. Participants were advised to do trial and then ask to perform Actual test. Time was recorded in seconds per position where the participants could hold a static position of maximum seconds. Participant Begin and end the test with word start and stop and time was recorded with Stopwatch. 5 minutes of rest was given between each position to facilitate recovery. To maintain uniformity all participants were ask to perform test in same sequence. 1) Trunk anterior flexion test 2) trunk posterior Extension test 3) Lateral side plank (Right) and 4) Lateral side plank (Left).

**A. Trunk Anterior Flexor Test**

**B. Trunk Posterior Extensor Test**

**D. Lateral Side Plank (Left)**

**C. Lateral Side Plank (Right)**

**Statistical Analysis:** Descriptive statistics analysis was used to summarize the data of all participants using SPSS Software Version 22. Endurance levels were defined by using percentiles as low (between 25 and 50th), medium (between 50 and 75th), high (between 75 and 100th) respectively.

**Results**

Detail of all participants are given in table 1. Mean age is  $24.3 \pm 3.28$  Height is  $164 \pm 6.3$  cm, weight  $61 \pm 6.8$  kg and BMI are  $23 \pm 2.8$ kg/m<sup>2</sup>. The mean values for Trunk Flexors, extensors, Rt Lateral and Lt Lateral Plank are 148 Sec, 108 Sec, 81.5 Sec and 83.2 Sec respectively. Percentile data of four position of McGill’s Endurance Test for trunk Flexor and Extensor Test, right and left lateral Planks for all the participants are in table 3 respectively.

**Table 1: Detail of all participant**

S.No.	Variable	Mean	SD
1.	Age (Years)	24.3	3.28
2.	Height (cm)	164	6.3
3.	Weight (kg)	61	6.8
4.	BIM (kg/m <sup>2</sup> )	23	2.8

**Table 2: The mean data for all position of McGill’s endurance test**

S.No.	McGill’s Endurance Test	Mean	SD
1.	Trunk Anterior Flexor Test (sec)	148	14.3
2.	Left Lateral Plank (sec)	81.5	18.6
3.	Right Lateral Plank (sec)	83.2	21.8
4.	Trunk Posterior Extensor Test (sec)	108	26.3

**Table 3: Trunk muscle normative percentile data**

S.No.	McGill’s Endurance Test	25-50 %	50-75 %	75-100 %
1.	Trunk Anterior Flexor Test (sec)	78–128	128–151	151–212
2.	Trunk Posterior Extensor Test (sec)	75– 86	86– 118	118 – 149
3.	Left Lateral Plank (sec)	64.5– 72	72– 98	98 – 136
4.	Right Lateral Plank (sec)	65 - 76.5	76.5 – 113	113 -148

**Discussion**

Few studies have been done to find normative database for trunk flexor and extensor muscle endurance

in specific healthy individuals<sup>14-16</sup> and athletes.<sup>17,18</sup> A study done by Mbada et al (2010)<sup>19</sup> on normative values of static and dynamic abdominal muscles endurance in healthy Nigerians shows mean value 34.9 sec for static

endurance and 15.6 rep for dynamic endurance. McIntosh et al<sup>20</sup> had done study on trunk and lower extremity muscle endurance: They conclude that normative data for adults age group 19-29 years, who had endurance more than 75th percentile was 25% of male and female for dynamic chest raise, 18% male and 14% female for bilateral straight leg raise, 68% male and 62% female for static chest raise, 47% male and 46% female for prone bilateral straight leg raise.

The Values shown in table 3 suggest that 151-212 Sec., 118-149 Sec. consider as a good endurance, 128-151 Sec., 86-118 Sec. are fair and less than 128 Sec., 86 Sec. are considered as poor endurance for trunk flexors and extensors respectively. Th Value 98-136 Sec., 113-148 are good, 72-98 Sec., 76.5-113 Sec. are fair and less than 72 Sec., 76.5 Sec. are considered poor left lateral and right lateral plank endurance.

### Conclusion

This study was done to find out the normative data for endurance of trunk flexors, extensors and side flexors group of muscle in individuals of 18-35 years age group. Thus, the reference values in this study provide base for the rehabilitation program in runners and also as an outcome measure for quantitative improvement and can provide valuable insights for the other future researchers. Future Study can be performed with the larger sample size by including both male and female gender.

**Acknowledgement:** I would first like to thank my guide Dr. Sweety Shah madam for constant guidance and support. I am extremely grateful to Mr. Kamlesh Parmar and other participants who spare time from their busy schedules to participate in this study. I must express my very profound gratitude to my parents and to my wife Dr. Camy Bhura (PT) for providing me with unfailing support and continuous encouragement.

# Spatial Cluster Analysis as a Sampling Approach in Public Health Research

H. Gladius Jennifer<sup>1</sup>, M. Bagavan Das<sup>2</sup>

<sup>1</sup>Assistant Professor Biostatistics, Department of Community Medicine, Karpaga Vinayaga Institute of Medical Sciences, Chinnakolambakkam, Madhuranthakam, Tamilnadu, <sup>2</sup>Professor, School of Public Health, SRM University, Kattankulathur, Tamilnadu

## Abstract

**Introduction:** Sampling is the process of selecting unit from population of interest. Spatial cluster analysis is also a sampling strategy in large scale data on population/public health research; K Mean centroid is an exploratory tool to find the natural spatial clusters at focused level for both categorical and continues variables. Hence this study attempt.

**Objective:** The objective of the study was to develop a methodology for defining natural neighborhoods.

**Materials and Method:** The exploratory study was carried out during Nov 2016 to Dec 2017, using Primary Census Abstract of Kancheepuram district, Tamil Nadu issued from census 2011. Village data was extracted and the variables were made as domains by factor reduction and its scores were calculated by factor analysis. The villages were grouped with similar characteristics as clusters by K mean, Hierarchical and K Mean Centroid. The SPSS 16v, QGIS, GeoDa software were used.

**Results:** Out of 1020 villages 917 had selected after data mining and connectivity map was made. The census variables reduced as factors like Area, population, spatial distance, health facilities and recreation facilities by factor analysis. These factors scores were taken for the analysis after calculated weighted matrix. Villages were segregated as 5 clusters in every mapping, K Mean Centroid produced both clustering and significant map.

**Conclusion:** K Mean Centroid will give better understand about heterogeneity of large scale data. It helps us to select appropriate geographical locations to be sampled with existing data for further research.

**Keywords:** Factor scores, K mean, Hierarchical Cluster, K Mean Centroid, census.

## Introduction

Medical research aim to make general statement

based on certain observations about a wider set of subjects or variables. Defining appropriate sample size and choosing appropriate sampling techniques are mandatory in order to find precise results. There were many sampling techniques were available such as simple random sampling, stratified sampling, systematic sampling, convenient sampling, purposive sampling etc. these were mainly used when unit of subjects as individual. When unit of measurement were group/set of people cluster sampling, two stage, Multi stage samplings were appropriate. The purpose of cluster analysis is to identify homogeneous subgroups with similar characteristics. Hence the community based studies were used the above techniques.

Spatial research studies mainly focus on Physical, Environmental and social attributes which may require carefully designed strategy for collection of data.<sup>1,2</sup> The main aim of spatial sampling approaches will be calculating mean of given attribute in an area; to test the effects of difference between ecological conditions; to establish spatial investigation or describe spatial distribution.<sup>3</sup>

In recent years the concept of spatial association and prediction of variables were analyzed.<sup>2</sup> Spatial analysis is use to identify the spatial patterns, identification of disease clusters, explanation or prediction of disease risk in geographical data. In other words spatial clustering will identify homogeneous groups of objects based on values of their attributes/geographic space.<sup>2,4</sup> Usually to study Infectious spread of disease; Occurrence of disease vectors, clustering of risk factors/combination; Existence of potential health hazards; Localized pollution sources these spatial cluster analysis will be appropriate.<sup>2,4</sup>

The purpose of this paper is to introduce spatial cluster analysis as neighbourhood sampling technique for existing large data set like census data. This sampling approach will detect neighborhoods with similar attributes which will help investigator/researcher to identify homogeneous groups in large population studies.

The objective of the study was to develop a methodology for defining natural neighborhoods and establish natural neighborhood sampling approach with social and physical resources using 2011 census tract data. Hence this study attempt.

## Methodology

An exploratory study design was conducted in School of Public Health, SRM University, Kattankulathur, Tamilnadu; approximately one year from November 2016 – December 2017.

**Data Collection:** The primary data of census 2011, Kancheepuram district, Tamil Nadu was extracted from www.Census.gov.in website.<sup>5</sup> “Rural table for Chengai Anna district” and “Table for Kancheepuram district” were selected for this study.<sup>5,6</sup> The two sets data were merged by village code with name after checking duplication and spell checks for further analysis in SPSS 16v.

**Variables in census data:** The census data had

approximately three hundred and eighty variables describing codes and names of district and villages, area, total population, worker/non worker population, schools, colleges, health facilities, communication facilities, recreation facilities, transports their availabilities and their km in distance to travel; water, electricity, sanitation, drainage, waste disposal were available or not in each villages; land areas such as forest, irrigated un irrigated lands, river, pond, lake etc in sqm.<sup>2,5,7</sup>

These variables were segregated as domains by Factor analysis.<sup>7</sup> The factor scores were calculated for continuous and as well as categorical variables.<sup>7</sup> The factor scores were considered as continuous variables and the variables which rotated individually were taken with original values for cluster analysis.<sup>7</sup>

**Geo Coding:** The longitude and latitude of each villages in Kancheepuram district were collected and merged with data set by village codes.<sup>7</sup> These codes and data set were finally merged with base map of Kancheepuram district after checking for duplicates and missing data.<sup>7</sup>

**Statistical Software:** SPSS 16v, Q GIS, Geo Da

## Results

After calculating factor score the data was translated to spatial data by merging these attributes with base map of Kancheepuram district by using village code as indicator variable.<sup>7</sup> K Mean Cluster Analysis, Hierarchical Cluster analysis and K mean centroid cluster analysis were used to find homogeneous spatial clustering of given data.<sup>8</sup> The ratio of sum of squares was compared in order to choose the natural neighborhood or spatial cluster by physical and social amenities of villages.<sup>8</sup>

K mean cluster analysis use to create n data points in to k homogeneous clusters. It assess by calculating the ratio of the total between group-sum of squares with the total variance.<sup>8</sup> The higher the value of ratio will yield better separation of the clusters.<sup>8</sup>

In this study, k mean cluster analysis yield the ratio of between-sum of squares was 0.18. The total villages were clusters as five and as follows 1. Very poor amenities villages 376, 2. Average amenities villages 250, 3. Very good amenities villages 211, 4. Poor amenities villages 48, 5. Good amenities villages 32.

Hierarchical cluster analysis is classical type of clustering method; The clusters were built in step by step

process, either in top – down fashion or bottom – up.<sup>8</sup> It compute the distance between two existing clusters in order to decide how to group the closest two together.<sup>8</sup> It has there patterns of linkages: single linkage, complete linkage and average linkage.<sup>8</sup> Dentogram will give the pictorial representation of cluster tree in this method.<sup>8</sup> The significance assessed by ward’s method.<sup>8</sup>

In this study, the hierarchical cluster analysis yield the ratio of between-sum of squares 0.16. In hierarchical clustering the five clusters are as follows: 1. Very Poor amenities villages were 500, 2. Average amenities villages 302, 3. Very Good amenities villages 37, 4. Poor amenities 31 and 5. Good amenities villages were 47.

The k mean centroid method include geometric centroids of the observations as part of the optimization process.<sup>8</sup> The x and y coordinates are simply added as additional variables in the collection of attributes.<sup>8</sup> This approach will yield better ratio and significance maps; The only criteria will be the centroids should be there as attributes in data.<sup>8</sup>

In this current study, k mean centroid cluster analysis was 0.17. This method yield similar like k mean cluster analysis with few deviations; the five clusters were: 1. Very Poor amenities villages 365, 2. Average amenities villages 250, 3. Very Good amenities villages 224, 4. Poor amenities villages 46 and 5. Good amenities villages were 32.

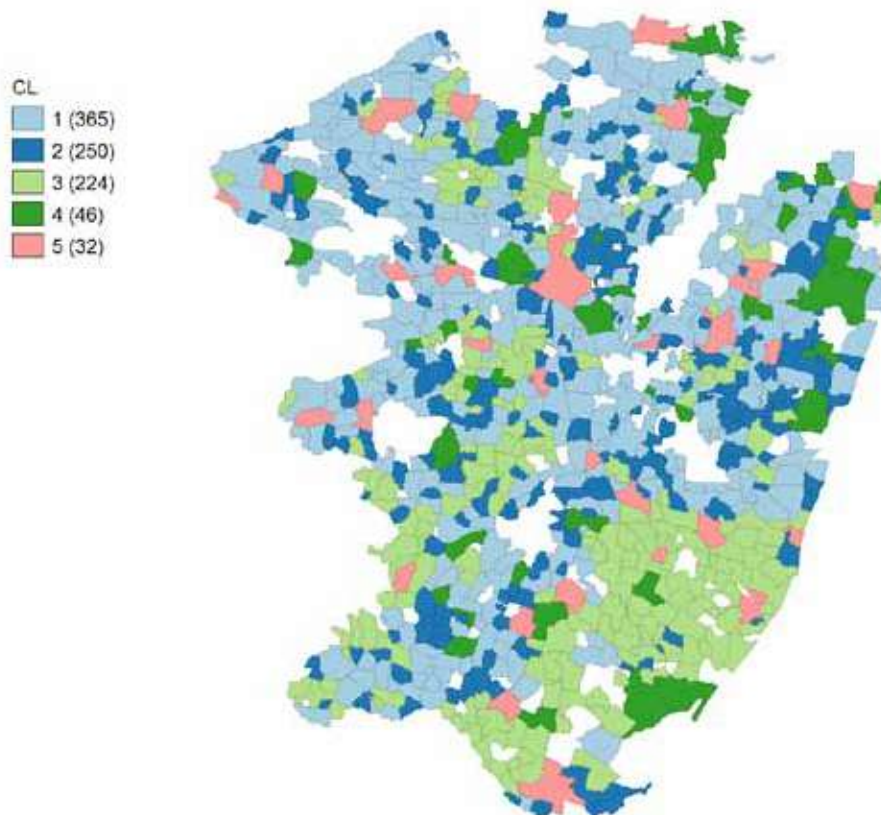

Figure 5: K Mean Centroid Cluster Analysis

## Discussion

There were various types of sampling procedures available for environmental studies.<sup>9,10</sup> The traditional sampling techniques were design based sampling which is based on either spatial autocorrelation or heterogeneity.<sup>9,10</sup> The other method was model based, adaptive sampling, spatially balanced sampling and kriging method.<sup>10</sup> These types of sampling procedures will be helpful to primary source of data collection process.

The present study explored a methodology that spatial cluster analysis as a sampling approach in biomedical or public health research. This spatial clustering would be very helpful sampling strategy for secondary source of data such as census tract data, sampling registration system etc. this study were assessed three different cluster analysis such as K mean, K mean Centroid and Hierarchical cluster analysis in order to define best fit of natural neighbourhood; and found K Mean centroid cluster analysis was appropriate method to detect the natural neighbourhood sampling strategy for any secondary source data such as census tract.

Adam et al conducted a study on socially based spatial boundaries in Canada by using census data and considered residential boundaries as natural neighbourhood.<sup>11</sup> They clustered one lakh population as homogeneous strata by using principle component analysis and Gi statistics for spatial dependence.<sup>11</sup> The residence, physical and land features such as roads, landscapes etc were used as indicators.

Similarly, Guo et al defined the concept of neighbourhood as residential location; they used hierarchical models in order to cluster the census data as homogeneous groups.<sup>12</sup> This study revealed that individual neighbourhood can be studied, he/she living on the boundary of a census area had more in common with residents of near area than with resident on the far.<sup>12</sup>

Study done by John RB, with the objective of whether neighborhood characteristics influences on symptoms of depression among elderly residents in New York city.<sup>13</sup> They used census cohort to assess the depression. The census variables were stratified as domains by factor analysis and then individual level survey had conducted.<sup>13</sup>

Luis DS et al studied intra-urban disparities in the quality of general population of Porto using census data.<sup>14</sup>

He assessed the spatial disparities of general population with two level such as territorial level and individual level survey.<sup>14</sup> Further the spatial dependence was determined with Moran I, Spatial Lag model and Spatial Error model.<sup>14</sup>

Basile et al conducted study to compare the spatial context with a multilevel perspective for neighbourhood research for mental health.<sup>15</sup> He used regional office survey data with 65830 study participants, Hierarchical spatial analysis was used to detect the disease clusters and he concluded that the neighborhood variations imply a significant impact between proximally closer neighborhoods.<sup>15</sup>

These literatures evident that, the spatial cluster analysis would be appropriate methodology to detect natural neighborhood or homogeneous spatial cluster groups, where to be sampled in environmental based research studies. The limitation of this study was, current study limited with the data set at district level, further studies will be required at higher level as well.

## Conclusion

The present study suggested that even though there were many types of sampling processes exists, spatial cluster analysis would be more appropriate method to detect the neighbourhood or homogeneous spatial clusters. However, the efficacy of spatial sampling may be increased if the investigator has prior knowledge about random field.

# Prevalence of Good Menstrual Hygiene Practices among Adolescent Girls in a Rural Area Kancheepuram District

M. Buvneshkumar<sup>1</sup>, P. Kaveri<sup>2</sup>, V. Ravivarman<sup>3</sup>

<sup>1</sup>Assistant Professor, Department of Community medicine, Chettinad Hospital and Research Institute, Affiliated to the Chettinad Academy of Research and Education (CARE), Chennai, Tamil Nadu, <sup>2</sup>Assistant Professor, Department of Community medicine, Melmaruvathur Adhiparasakthi Institute of Medical Sciences & Research, Affiliated to the Tamilnadu Dr. MGR Medical University, Chennai, <sup>3</sup>Professor, Department of Community medicine, Chettinad Hospital and Research Institute, Affiliated to Chettinad Academy of Research and Education (CARE), Chennai, Tamil Nadu, India

## Abstract

Adolescence is a transitional phase of childhood to becoming adults and encompasses several challenges with respect to physical, emotional, social and mental changes.<sup>2</sup> Education regarding healthy adolescence is crucial and of them all, understanding and practice of good menstrual .Therefore, it is important to assess the status of the menstrual hygiene practices among the adolescent girls particularly in undeveloped areas to address the lacunae, which helps to emphasize safe hygienic practices during menstruation.<sup>2</sup> A cross sectional study was conducted in field practice area, RHTC CHRI Kancheepuram. School going menarche attained adolescent girls in the age group from 10 to 19 years had been included .A total of 436 adolescent girls had been included using the multistage random sampling method and analysis was done using IBM SPSS 21 version. The mean age of the study population was 14.48 with standard deviation of 1.77. It has been evident that awareness of menstruation before menarche was only 14.7% and the first source of information about menstruation was found to be by their mothers followed by teachers. 77% of adolescent girls were using sanitary napkin and 23% of them were using cloth. In this study only 15% had good menstrual hygiene practice; there should be a need to educate the girls about menstruation, its importance and hygiene maintenance, to enable them to lead a healthy reproductive life in future.

**Keywords:** Adolescence, Good menstrual hygiene practice and Absorbent.

## Introduction

Adolescence is believed to be a vital phase of one's life, especially girls.<sup>1</sup> Adolescence is a transitional phase of childhood to becoming adults and encompasses several challenges with respect to physical, emotional,

social and mental changes.<sup>2</sup> Globally there were 1.2 billion adolescent girls in the year 2009 which forms 18% of the world's population.<sup>3</sup> According to census 2011 India has an adolescent population (both sexes) consisting of 19.6 percent and in Tamil Nadu, the total adolescent population (both sexes) constitute 17.2 percent.<sup>4</sup> Education regarding healthy adolescence is crucial and of them all, understanding and practice of good menstrual hygiene is of prime importance in our nation, especially when the rural population is concerned.<sup>5</sup>

Menstruation, the term signifies a physiological process from menarche (the first menstruation) to menopause (the last menstrual period) in a cyclical way; which requires appropriate knowledge and understanding

the practice of good menstrual hygiene will aid in the prevention of several undesirable consequences/complications in the future.<sup>6</sup> For example, there are evidences from studies suggesting that poor menstrual hygiene practices have been linked to possibilities of developing Reproductive Tract Infections (RTI),<sup>7</sup> Urinary Tract Infections (UTI),<sup>8</sup> and some long-term consequences such a cervical cancer and infertility, etc. India accounts for 27% of the world's cervical cancer deaths, according to World Health Organization data.<sup>9</sup> The incidence rate is almost twice the global average and doctors studying the disease say poor menstrual hygiene is partly to blame.<sup>9</sup> This explains the importance of good menstrual hygiene practice.

There are several aspects of good menstrual hygiene practice to be understood and several factors influencing the same should be addressed.<sup>6</sup> With regard to Good menstrual hygiene practices, there are studies discussing the effective types of absorbent sanitary materials used during menstruation, there are several aspects, which have been discussed in limited studies.<sup>6</sup> Disposable pads have been proven to have better outcomes and choice with evidence in several studies.<sup>6,10</sup> regarding good menstrual hygiene, whereas the reusable clothes which have not been cleaned properly have shown undesirable outcomes. Reusable clothes are proven to be not harmful, when it is washed properly and dried under sun, due to cultural taboos.<sup>10</sup> There are other measures of good menstrual hygiene practice, which include washing of genital regions appropriately, taking regular baths, using appropriate sanitary method and the knowledge about the disposal of the same, etc which have not been addressed.<sup>10,11</sup>

Nearly 72% of the adolescents have been residing in rural area,<sup>1</sup> which explains the challenges faced by the adolescent girls in seeking advice regarding menstrual hygiene practice or reproductive health unfortunately. The socioeconomic status influences in many ways such as access to disposable sanitary pads, in built toilets in households, proper sanitation facilities, all of which are seemingly unavailable or inappropriately maintained, in rural areas.<sup>11</sup> This again emphasizes the importance of educating the adolescent girls in knowing the practice of good menstrual hygiene.

In rural areas of India, menstruation has still been observed as a cultural taboo to be discussed about.<sup>12</sup> There are many issues being faced predominantly in women and adolescent girls residing in underdeveloped

areas during menstruation. Lack of awareness; lack of access to disposable absorbent material leading to use of alternatives such as old fabric cloths, rags, sand, ash, newspapers, dried leaves, hay and plastic; lack of proper toilet facilities at home and school level – altogether comprise the crux of menstrual hygiene related problems.<sup>5,13</sup> Social prohibitions, isolation and restrictions during the menstrual period from routine activities and the negative attitude of the parents for the open discussion on the related issues have blocked the way of the adolescent girls to right kind of information, especially in rural and tribal communities.<sup>14</sup> These issues lead to reproductive tract infections in 70% females using unhygienic material.<sup>13</sup> A woman throws away 125-150 kilograms of non-biodegradable absorbents used during menstruation in her lifetime lead to poor environment sustainability.

Majority of the schools do not support the adolescent girls or female teachers in managing menstrual hygiene with dignity.<sup>15,16</sup> Poor water and sanitation facilities will make them manage menstruation in a poor way and inappropriate sanitary protection materials can lead to blood-stained clothes causing them stress and embarrassment.<sup>15,16</sup> Therefore, failure to deliver appropriate menstrual hygiene facilities at home or at school reduces the level of having good menstrual hygiene practice among female students<sup>17</sup>. UNICEF states that 1 in 10 adolescent school age girls do not attend school during menstruation, which is similar to the world bank statistics, where the students have been absent from school 4 days every four weeks because of the menstruation.<sup>17</sup>

**Justification of the Study:** Good menstrual hygiene practices from the childhood may escalate safe practices which help in mitigating potentially possible infections in the future and also it promotes confident mental and physical health in young women, who would form the backbone of every society. Therefore, it is important to assess the status of the good menstrual hygiene practices among the adolescent girls particularly in rural areas to address the lacunae in practices. Studies related to menstrual hygiene are scarce that too in rural population.

**Objectives:** To estimate the prevalence of good menstrual hygiene practices among adolescent girls in field practice area of RHTC, CHRI.

## Material and Method

A Cross sectional study was conducted in Field

practice area of Rural Health & Training Centre, Chettinad Hospital and Research Institute from December 2016 to August 2017. The Study population was menarche attained School going adolescent girls in the age group of 10 to 19 years in the study area. Based on the study **article 45 %**<sup>19,20</sup> Assuming 95% confidence interval with a 5% allowable error. The sample size calculated with the formula,  $n=4 PQ/L^2$ , with 10% attrition rate the sample size was 436. The Multistage random sampling was adopted for choosing sample for the population.

**First stage:** The Rural Health and Training Center, Poonjeri, Chettinad Hospital and Research Institute, covers 12 villages. 6 villages have been chosen for the study by lottery method. **Second stage:** among them only 7 schools had adolescent age group (high school and higher secondary school). The list of schools was obtained from the respective authorities in the chosen geographical area. For feasibility with regards to time period among 7 schools by lottery method 3 schools were chosen randomly. **Third stage:** From the randomly chosen 3 schools, 839 adolescent girls who have attained menarche were enrolled. Among them 436 adolescent girls were selected through simple random sampling by lottery method.

**Study Tool:** Pretested Semi structured questionnaire and good menstrual hygiene (UNICEF guidance booklet).<sup>21</sup> was used.

**Ethical Committee:** Approval was obtained from Institutional Human Ethics Committee, CHRI Kelambakkam. Informed written consent was obtained from the parents or guardian of all participants after explaining the objective, risks and benefits involved in the study.

**Statistical Method:** Data of adolescents collected was coded and entered into Excel sheet. Statistical

analysis was done using statistical software IBM SPSS version 20. Descriptive analysis was carried by mean and standard deviation for continuous variables and chi square test for categorical variables, P value <0.05 was taken as significant.

## Results

The mean age of the study population was 14.48 ±1.77 years with the range from 11 to 18 years. Among the study population nearly 373 (85.6%) participants were from nuclear family. Most of the study participants' mothers were Illiterate 357 (81.9%). According to Modified BG Prasad's classification (2018) most of them 178 (41%) were from class III socioeconomic class followed by class IV 122 (28%) participants, then 80 (18%) participants from class II, 30 (7%) participants from class V and 26 (6%) participants. In the study population, 29.4% attained menarche at 11 years, 30.7% attained menarche at 12 years, 34.9% attained menarche at 13 years, 4.4% at 14 years and 0.7% at 15 years. Among the study participants only 15% had awareness regarding the menstruation before menarche. Among the study population majority 184 (42.2%) felt discomfort followed by some adolescent girls were scared 116 (26.6%) and a few of them were disgusted 98 (22.5%) towards menarche and only 38 participants (8.7%) were feeling normal during menarche. Among the study 303 (69%) reported that their routine work had been disturbed during menstruation while 133 (31%) revealed they didn't have any routine work disturbance during menstruation. Adolescent girls mother's education, Occupation and their socioeconomic status have highly been associated with good menstrual hygiene  $p < 0.001$ . This shows that we have to give more attention to the adolescent girls who belong to poor, illiterate and unemployed mothers.

**Table 1: Distribution of study participants by restriction during menstruation**

S.No.	Variable	Frequency	Percentage
1.	<b>Restriction to have certain food during the menstruation</b>		
	Yes	141	32.3
	No	295	67.7
2.	<b>Restriction to go to religious occasions</b>		
	Yes	287	65.8
	No	149	34.2
3.	<b>Restrictions not to attend school</b>		
	Yes	184	42.2
	No	252	57.8

S.No.	Variable	Frequency	Percentage
4	<b>Restriction not to do household</b>		
	Yes	110	25.2
	No	326	74.8
5	<b>Restriction to play</b>		
	Yes	86	19.7
	No	350	80.3

**Table 2: Factors affecting good menstrual hygiene**

Variables in the Equation									
		B	S.E.	Wald	df	P Value	Exp(B)	95% C.I.for EXP(B)	
								Lower	Upper
Step 1 <sup>a</sup>	Religion	1.905	.456	17.498	1	P<0.001v*	6.723	2.753	16.416
	Motherseducation	4.479	.483	85.957	1	P<0.001*	88.114	34.187	227.107
	Socioeconomicstatus	1.033	.236	19.068	1	P<0.001*	2.808	1.767	4.464

a. Variable(s) entered on step 1: Religion, Motherseducation, socioeconomicstatus.

After the univariate analysis of the demographic variable, multivariate analysis logistic regression was used to know whether good menstrual hygiene has been dependent on the demographic variables .The above table shows that mothers education, religion of the girl and socio economic status was significant. p<0.001

**Fig 1 : Distribution of study participants Absorbent used**

**Discussion**

The present study concludes that the first source of information regarding the menstrual hygiene was mother followed by the teacher. It is observed that, more than half of the respondents felt discomfort while experiencing menstruation. Furthermore, majority of the respondents claimed that they had negligent or very little information about menstruation before attaining menarche. Due to cultural expectations and restrictions many girls have not properly and adequately been informed about the realities of menstruation. As

a result, they feel subnormal, diseased, or traumatized. Unprepared girls have been frightened, confused and felt embarrassed by menarche and likely to develop negative attitudes towards menstruation.

In this study, it is observed that only a few participants have been practicing good menstrual hygiene. Major Lacunae was inner thigh area dry and properly disposal of absorbent. Regarding personal hygiene majority of them did not carry out hand wash after changing their napkins and/or did not shave their pubic hairs regularly. To overcome this problem school-level health policies

should be made by school management committee to promote and educate students regarding health and safety, to ensure adequate water and sanitation facilities and to protect girl students from bullying and sexual harassment.

In this study, it has been observed that only a few participants were practicing good menstrual hygiene. Certain ritual beliefs associated with menstruation like restriction to certain foods, isolation from religious occasions, restraint from school attendance, not allowing for play, have still been followed. In this study Good menstrual hygiene of the adolescent girls was depended on religion mothers education and socio economic status. Although most of the respondents used sanitary napkins during their menstrual periods, but not able to complete the good menstrual hygiene criteria. We should educate the girlst hose who using reusable cloth that it would be a misconception that washing and drying to be done secretly or in a hidden corner so that it cannot be seen by others. It has also been believed that menstrual fluids may be misused for black magic, so women should wash the wrapper/cloth during menses only at night when others were asleep. We should educate about menstrual health management and its link to their health. They should also make girl students aware of how to dispose of used menstrual products at home and in schools and about the consequences of throwing them in open or flushing them in toilets. Menstrual flow was seen as dirty, polluting and shameful, so women hide menstrual cloths for fear of being cursed.

### **Conclusion**

It is evident from the study that few of the participants used cloths as absorbent. In spite of cloth having its own advantage such as cheap, easy availability it could not be categorized as good menstrual practice because of difficulty in proper maintenance during menstruation. Although most of the respondents used sanitary napkins during their menstrual periods, most of them lacked in at least one or more hygienic practices like, keeping the inner thigh area dry, changing napkin regularly using mild soap and water for genital wash and proper disposal of sanitary pads/clothes during menstruation. The mothers' education, 'occupation and socioeconomic status of the respondents had a direct association with good menstrual hygiene. Certain ritual beliefs associated with menstruation like restriction to certain foods, isolation from religious occasions etcare still followed .In addition to that challenges concerned with respect to

sanitation issues in the schools like improper sanitary latrine facilities and continuous water supply, made it difficult to practice good menstrual hygiene. Teachers can make the school environment girl-friendly to manage menstruation with dignity. Sex education in schools helps adolescents to discover their sexual identity, to know physiological changes occurring in the body and how to take care of personal hygiene

## Abstract

**Introduction:** Mindfulness is the basic human ability to be fully aware of where we are and what we're doing. It is a special form of attention, a cognitive phenomenon that can increase awareness of internal pain or stress and help to cultivate habits of practicing self-care. Mindfulness is an attribute of consciousness long believed to promote well-being. This study was carried out to analyse the age and gender differences in assessment of mindfulness.

**Materials and Method:** This was a cross sectional study conducted in the Department of Physiology, VMCM, Karaikal over a period of three months. Mindfulness is assessed using Mindful Attention Awareness Scale (MAAS) It is a 15 item, Likert type 6 point scale with each having score ranging from low (1) to a high score (6) proportional to the degree of mindfulness. The structured questionnaire sent to subjects through the mail, WhatsApp in the form of google doc link. Individual responses received and the data analyzed.

**RESULT:** A total of 330 study participants were included in the study. Majority of study participants scored between 3-5 (70%) followed by >5 (17.8%). The mean score among females was higher compared to males. Using Independent t test the t value is -1.807 and the p value is 0.072. Interesting observation was made in the present study, as age advances there is a trend of increase in mindfulness score.

**Conclusion:** Our study conclude that there is trend that as age advances mindfulness increases and females show greater degree of mindfulness compared to males though statistically not significant.

**Keywords:** Mindfulness, Gender variation, Mindfulness attention awareness scale (MAAS).

## Introduction

Mindfulness can be defined as the degree of awareness that is achieved by purposefully paying attention to the present moment, without judging it.<sup>1</sup> Two components

are emphasized in defining mindfulness: self-regulation of attention and nurturing a non-judgmental orientation based on acceptance.<sup>2</sup>

Since the launch of the first empirical research conducted on this topic numerous studies have shown the positive effects of increased mindfulness - on life-satisfaction, vitality, self-esteem, empathy, optimism, integrity, or positive affect – and its contribution to reducing the difficulties with emotional dysregulation, depression, neuroticism, rumination, social anxiety and wandering thoughts. Mindfulness as a general concept and mindfulness meditation as a therapeutic method have become increasingly popular in the last decades

e-mail: thirumaran.dr@gmail.com

and the number of research papers on the subject has grown exponentially.<sup>3</sup>

Further, interest has developed regarding the human capacity for enhanced attention to and awareness of life’s experiences, which has been termed trait mindfulness. Trait mindfulness, also referred to in some literature as day-to-day mindfulness or dispositional mindfulness, is defined by Brown and Ryan as an inherent state of consciousness varying between and within humans that is characterized by the presence or absence of attention to or awareness of what is occurring in present experience.<sup>4</sup>

On reviewing the Indian literature with respect to the studies on assessment of mindfulness, surprisingly data is scanty. Hence the present study aimed at assessing the mindfulness and to analyse impact of age and gender on mindfulness.

**Materials and Method**

This was a cross sectional questionnaire based observational study conducted at the department of physiology, Vinayaka mission medical college after obtaining institutional ethical committee clearance. Consent was obtained from the participants. A total of 330 participants were included in the study. Convenience sampling technique was used. Mindfulness is assessed using Mindful Attention Awareness Scale (MAAS). It is a 15 item, Likert type 6 point scale with each having score ranging from low (1) to a high score (6) proportional to the degree of mindfulness. The structured questionnaire sent to subjects through the email, WhatsApp in the form of google doc link. Individual responses received and the data analyzed.

**The Mindful Attention Awareness Scale (MAAS):** The trait MAAS is a 15-item scale designed

to assess a core characteristic of mindfulness, namely, a receptive state of mind in which attention, informed by a sensitive awareness of what is occurring in the present, simply observes what is taking place. Instructions: Below is a collection of statements about your everyday experience. Using the 1-6 scale below, please indicate how frequently or infrequently you currently have each experience. Please answer according to what really reflects your experience rather than what you think your experience should be. Please treat each item separately from every other item.<sup>4</sup>

In collection of data we had assistance of medical undergraduate students who asked persons they know from general population (their friends, neighbours and family members) to complete MAAS.

**Inclusion criteria:** Both sexes in the age group of 18 yrs to 60 yrs were included.

**Exclusion Criteria:** Those who had severe neurological disorders.

**STATISTICAL ANALYSIS:** Descriptive analysis done with the interpretation of data. Age mean and score mean calculated with SD. Age Mean ± SD: 23.72 ± 7.76. Score Mean ± SD: 4.15 ± 0.92. For analytical purpose, age is subdivided into five class intervals: Less than 20, 20-29, 30-39, 40-49 and more than 50

**Results**

A total of 330 participants were included in the study. Majority of participants were belonged to age group less than 20 years which accounted for 55.6% followed by 20-29 years which accounted for 25.9%. Least number of participants were from the age group of >50 years which accounted for 0.9%. (Table. 1).

**Table 1: Age wise and mean score distribution of study participants.**

Age (Years)	No. of Counts	Percentage	Score Mean ± SD
<20	178	55.6%	4.05 ± 0.85
20 – 29	83	25.9%	4.25 ± 1.04
30 – 39	44	13.8%	4.12 ± 0.96
40 – 49	12	3.8%	4.61 ± 0.62
≥50	3	0.9%	5.31 ± 0.35
<b>Total</b>	<b>320</b>	<b>100%</b>	

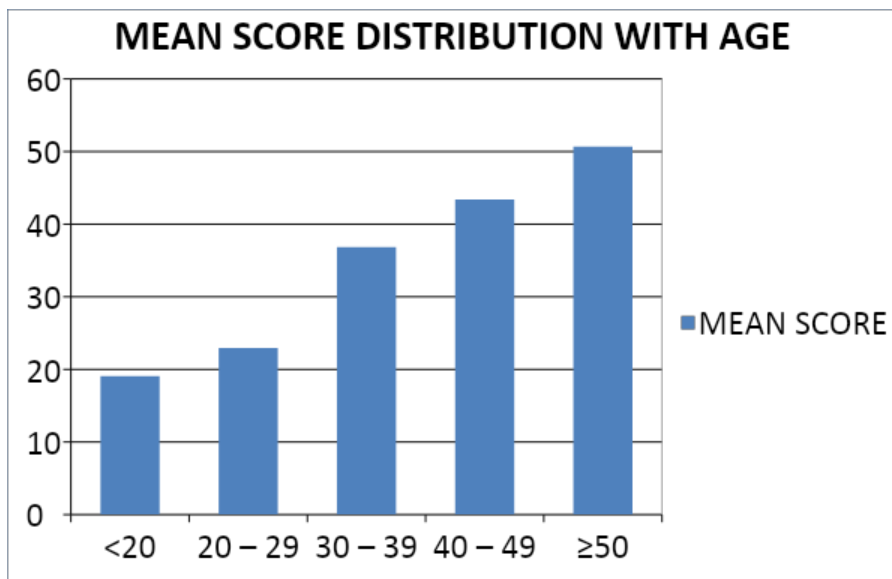

In our study, majority of study participants scored between 3-5 (70%) followed by >5 (17.8%). the mean score in females is higher compared to males. Using Independent t test the t value is -1.807 and the p value is 0.072.

**Table 2: Gender wise distribution of score**

Score Distribution	Male	Female	No. of Counts	Percentage
<3	25	14	39	12.2%
3 – 5	114	110	224	70%
>5	27	30	57	17.8%

Interesting observation was made in the present study, as age advances there is a trend of increase in mindfulness score.

**Fig. Mean score distribution with age**

**Discussion**

In the present study, age and gender were considered and assessed for mindfulness. In our study it was noticed that average mean score was high among females compared to males. Further, it was observed that, as age advances there is a trend of increase in mindfulness score. Majority of study participants were students. The mean score of mindfulness among students was found to be less compared to other higher age group participants. This low score could be due to weakness in organizational mindfulness and the role of the university as a new environment with its requirements and conditions. Undergraduate students in the first semester, who are new and unfamiliar members of this atmosphere, may be at high risk as a group for the disturbance of their mindfulness in parallel with other mental difficulties.<sup>5</sup> This is also in agreement with the studies conducted by Mogilner et al<sup>6</sup> and Sturgess .<sup>7</sup>

Among students, To bring mental processes under greater voluntary control, fostering general mental well-being and developing specific capacities such as calmness, concentration and training of attention and awareness skills are one of the solutions.<sup>8</sup> As per Charles et al, regarding the age contrasts is maturational change/ formative understanding which sets that as people age, they grow progressively adjust method for dealing with their feelings and in this way are less deciding about themselves as well as other people. It implies that more seasoned grown-ups can be progressively present “at this very moment”, since they are not hindered by force of their feelings. This is additionally upheld by the consequences of a longitudinal investigation of 2.704 members in four ages of families where they found that negative influence diminished with age and that more established individuals tended to control their feelings all the more viably.<sup>9</sup>

Drawing on the theoretical framework of potential mechanisms of mindfulness, as proposed by Hölzel et al.<sup>10</sup> research among experienced meditators Tran et al.<sup>11</sup> has shown that meditation experience and mindfulness are positively associated with indicators of all proposed mechanisms, i.e., attention regulation, body awareness, emotion regulation, and a change in perspective on the self. However, only improvements in emotion regulation and body awareness, but not in attention regulation and a less static perspective about the self explained the effects of trait mindfulness on mental health. Body awareness appeared to be a specific pathway for the effects of trait mindfulness on symptoms of anxiety, whereas non attachment (i.e., the relative absence of a fixation on ideas, images, or sensory objects, and of internal pressure to get, hold, avoid, or change circumstances or experiences; Sahdra et al.<sup>12</sup> for symptoms of depression.

The present study further aimed at determining the gender difference. There is almost no empirical work addressing gender differences on mindfulness in India to our knowledge. Mean scores among females were found to be high. But the difference was not statistically significant. In fact, most task-switching studies do not explore individual differences and accordingly are carried out with small samples. This is in agreement with the study conducted by Sabina Alispahic and Eneđina Hasanbegovic Anic.<sup>13</sup> As per their study, statistically significant gender difference for the subscales Observing, where females scored higher than men and Acting with awareness, where males had higher scores than their counterparts. Our observation with respect to gender is similar to the study conducted by Sturgess.<sup>7</sup>

Gender differences could be explained with different cognitive functioning of females and males. According to the previous research, women in general are much better in observing details than men and also in multitasking doing several things at the same time, while men in general having a tendency to focus on one task at the time and be more aware while doing it. Stoet et al.<sup>14</sup>

But there are a majority of research evidences from the past which contradict with the present findings and confirm gender differences on mindfulness and academic self-confidence.<sup>15,16</sup>

The present study has limitations. This study is limited in that it lacked multiple method to assess the MAAS, which did not allow for a formal multitrait-

multi method analysis of convergent/discriminant validity. Despite these limitations, it can be said that the MAAS has acceptable psychometric properties in the study population and is confident to measure mindfulness. This scale can also be used to evaluate the effectiveness of the mindfulness-based interventions. Further the limitation of the study was, reported results are based on self-reports throughout and thus potentially are prone to common-method variance effects and Study group is taken from a homogenous population.

## Conclusion

Our study was the empirical research about age and gender differences in mindfulness in this region. Our study conclude that there is trend that as age advances mindfulness increases (p value 0.133) and females show greater degree of mindfulness compared to males (p value 0.07) though statistically not significant. Further interventional studies can be carried out among youngsters to improve mindfulness.

# Association of Internet Addiction with Social Support, Loneliness And Stress: A Cross Sectional Study among Female College Students

Nitasha Khehra

*Assistant Professor, PG Department of Psychology, Mehr Chand Mahajan DAV College for Women, Sector 36 A, Chandigarh*

## Abstract

**Background:** Internet Addiction is a significant emerging mental health condition among Indian college students and cascading into a major public health concern. Internet addiction has witnessed an upsurge as a clinical phenomenon among young adults precipitated by new challenges specific to this developmental age and owing to its complexity resulting from multiple psychosocial factors which warrants the need for effective multi modal intervention due to high relapse rates and resistance to treatment.

**Aim:** The present investigation was aimed to evaluate the association of Internet Addiction with social support, loneliness and stress among female college students in Chandigarh.

**Methodology:** It was a cross sectional study among 200 undergraduate female students within the age range of 18-21 years, drawn from various colleges pertaining to Chandigarh region. Internet Addiction Test (Young, 1998) was employed as a screening instrument to identify internet dependence and other assessment tools administered include Perceived Stress Scale, Multidimensional Perceived Social Support scale and UCLA Loneliness Scale.

**Results:** Comparative Analysis revealed that there were significant differences between Internet Addiction and Non Internet Addiction groups of female college students in the areas of Stress, Loneliness and Family Support. Bivariate correlation analysis showed a positive relationship of Internet Addiction with Stress and Loneliness. However there emerged a negative correlation between Internet Addiction and Family Support.

**Conclusion:** Our study holds heuristic value for elucidating the potential impact of low family support and heightened stress due to plethora of reasons may increase vulnerability to Internet Addiction among female college students. We can conclude that young adults with insufficient or conflictual family interaction triggers emotional loneliness resulting in either social withdrawal or search for needed relationships in the Internet environment. Hence, family support is an important factor in treating and preventing Internet addiction.

**Keywords:** *Internet Addiction, Stress, Loneliness, Social Support, College Students.*

## Introduction

Internet Addiction (IA) refers to excessive or poorly controlled preoccupations, urges, or behaviors regarding Internet use, which eventually could lead to distress and functional impairment<sup>[1]</sup>. In the fifth edition of the DSM, Internet addiction is equated with the addiction to Internet games, although some research shows that

---

### Corresponding Author:

Assistant Professor, PG Department of Psychology,  
Mehr Chand Mahajan DAV College for Women,  
Chandigarh

they should be viewed as separate entities<sup>[2]</sup>. Internet addiction has been shown to be related to depression, anxiety, aggression, sleep disturbance, Attention Deficit Hyperactivity Disorder (ADHD) and alcohol dependence<sup>[3]</sup>. Compulsive Internet users show different activity patterns in regions of the brain that have been implicated in reward and emotion processing with decreased grey matter volume in several regions<sup>[4]</sup>.

Research on excessive internet use and associated behavioral problems has grown dramatically in the last few decades. A recent review of more than 103 studies found that over 12% of male students and 5% female students in China showed signs of Internet addiction<sup>[5]</sup>. In a study among 810 undergraduate Indian college students aged of 19 -21 years, reported the prevalence rate of IA as 8.8% (10.33% males and 6.87% females)<sup>[6]</sup>. Studies in different countries have generated widely different estimates owing to different study designs, varied diagnostic criteria, diverse assessment measures, cultural backgrounds and study samples.

Internet addiction is significantly associated with factors such as availability of own personal gadgets, use of smartphones, exposure to internet at a very young age, internet usage for the purpose of exploring new things and building new relationships online<sup>[7]</sup>. Adolescents have been identified as an at-risk population as they tend to be more prone to risky behavior and can indulge in addictive practices in order to cope with anxiety, frustration and failure or need for excitement, unrealistic optimism in relation to the feeling of invulnerability, or even the need to achieve their goals as a part of their transition into adult age<sup>[8]</sup>. Since most studies from India have reported higher prevalence of IA in males<sup>[9, 10]</sup>, so there are lacunae of studies examining this phenomenon exclusively in female students. It is pertinent to examine the association of Internet addiction and differential psychosocial correlates in this vulnerable developmental phase of young adulthood for the purpose of detecting early warning signs of underlying psychopathology and to formulate effective interventions.

### Objectives:

1. To identify possible differences between Internet Addiction and Non Internet Addiction groups on psychological variables of Social Support, Loneliness and Stress.
2. To study the relationship between Internet Addiction and the psychological variables of Social Support, Loneliness and Stress.

## Methodology

**Sample:** It was a cross sectional study and purposive sampling technique was used to select 200 undergraduate female students within the age range of 18-21 years drawn from colleges pertaining to Chandigarh region. The subjects belonging to nuclear families and middle income group in order to control the effect of socioeconomic variables.

**Procedure:** The testing schedule was started with participants filling details about their socio-demographic and Internet User characteristics after explaining the nature and purpose of the study. Written informed consent was taken from them and were conveyed that their participation was voluntary. The data gathered would be confidential to be used only for research purpose. Internet Addiction Test (IAT) was used as a screening measure to identify internet dependence. Data was collected from those college students using internet for at least since last 6 months. The selected sample comprised out of 100 dependent users and 100 non - dependent users of internet (as per Young's criteria of IA).

### Assessment Tools:

1. **Socio-Demographic Profile:** included questions on socio-demographic and Internet User characteristics of the participants such as age, marital status, educational qualifications, family type, family socioeconomic status, purpose of internet usage, age of internet usage initiation, time spent online per day and frequency of Internet use per week in days.
2. **Internet Addiction Test (IAT)**<sup>[11]</sup>: The IAT is a self-reported measure comprising 20 items rated on a 5-point scale determining the degree to which their Internet use affects their daily routine, social life, productivity, sleeping pattern and feelings. The IAT total score ranges from 20 to 100, with higher scores representing higher severity of Internet compulsivity and addiction. The participants were allocated into either the IA group (IAT score  $\geq 40$ ) or the Non IA group (IAT score  $< 40$ )<sup>[12]</sup>. Internal consistency (0.88), test-retest reliability (0.82) and bisection (0.72) are satisfactory.
3. **Perceived Stress Scale (PSS- 10)**<sup>[13]</sup>: The PSS consists of 10 items rated on a 5-point scale designed to measure the perception of stress and degree to which situations in one's life are appraised as stressful during the last month.

- 4. UCLA (University of California, Los Angeles) Loneliness Scale<sup>[14]</sup>:** The UCLA includes 20 statements rated on a 4-point Likert scale which reflects how lonely people define their lives. Cronbach’s alpha coefficient was found 0.90 in this study.
- 5. Multidimensional Perceived Social Support<sup>[15]</sup>:** The MSPSS is a 12-item scale that measures perceived support from three domains: Family (FA), Friends (FR) and a significant Other (SO) rated on a 7-point Likert-type scale. Cronbach’s alpha coefficients for FA, FR and SO were .82, .86 and .86, respectively.

**Statistical Analysis:** Considering the objectives of the study, descriptive analysis, Independent sample t-test and Pearson Product Moment Correlation was computed using SPSS Statistics Version 21.

**Results**

A descriptive analysis of the sociodemographic and Internet user’s characteristics revealed that the mean age of these students was 19.58 years(± 1.20) and all of them were unmarried. Majority of them primarily used the Internet for pleasure activities including social networking sites, entertainment, online shopping and online gaming. Pertinent findings in this study were earlier than expected age of internet usage initiation

was 13 years, time spent online per day was 4-6 hours, frequency of Internet use per week was everyday and 26-30 hours per week.

A perusal of Table 1 revealed a statistically significant difference between IA Group (N =100) and Non IA Group (N =100) in the areas of Stress (t = 2.82; p = 0.01) and Loneliness (t = 4.54; p = 0.01) with higher scores in IA Group and in the sub domain of Social Support, i.e., Family Support (t = 3.20; p = 0.01) with higher scores in Non IA Group. A perusal of Table 2 shows correlation analysis between Internet Addiction and the psychological variables. Correlation analysis showed a positive significant association between IA with Stress (r =0.417; p = 0.01) and IA with Loneliness (r =0.290; p = 0.01). However there emerged a negative significant correlation between IA and sub domains of Social Support, i.e., Family Support (r =-0.368; p=0.01). Results also showed a positive significant correlation between Stress and Loneliness (r = 0.215; p = 0.05) but a negative significant correlation between Stress and sub domains of Social Support, i.e., Family Support (r = -0.262; p = 0.01). As expected, there emerged a negative significant correlation between Loneliness and sub domains of Social Support, i.e., Significant Other (r = -0.339, p =0.01), Family Support (r = -0.289; p = 0.01), Friends (r = -0.432; p = 0.01) and total score of social support (r = -0.414; p = 0.01).

**Table 1: Shows descriptive analysis and comparative analysis of Internet Addiction and Non Internet Addiction groups on psychological variables of Social Support, Loneliness and Stress**

Variables	Internet Addiction Group (N = 100)	Non Internet Addiction Group (N = 100)	t-ratio

## Discussion

The present study aims to enhance our understanding of Internet Addiction (IA) among female college students and its relationship with psychosocial correlates of social support, stress and loneliness. Results revealed that Non IA group reported higher scores in the area of Family Support and a negative correlation exists between IA and Family Support. This crucial finding cannot be overlooked in this particular age group and gender specific research, that only lack of family support exacerbated Internet addiction among female college students which could be attributed to plethora of reasons such as inadequate emotional support, high discipline, intense conflicts, low expressiveness, maladaptive parental rearing styles, low family functionality<sup>[16]</sup>, low perceptions of social support from family, divorced families, low-income families, severely dysfunctional families<sup>[17]</sup>. Paradoxically with pre-existing problematic familial relations in these young adults would make treatment difficult. Another pertinent rationale for low family support provided to female young adults can be attributed to gender discrimination and rampant sexism in Punjab.

The present study also found that IA group reported higher scores in the area of Loneliness and a positive correlation exists between IA and Loneliness indicating that female young adults who are predisposed to or are engaged in addictive use of internet primarily to gain social approval, enhancement of self-esteem, overcoming feelings of loneliness, boredom, helplessness, anxiety and depression which can be achieved compensatively within online social environment. In a meta-analysis

examining 94 studies conducted in 22 countries also proved a correlation between depression, loneliness and Internet addiction<sup>[18]</sup>.

Our study revealed that IA group reported higher scores in the area of Stress and a positive correlation exists between IA and Stress. Besides numerous benefits of this ubiquitous technological tool, problematic Internet use is strongly associated with low impulse control and resulting in increased feelings of tension or arousal if there is lack of easy accessibility of computers or internet availability. Excessive Internet use is associated with a gamut of negative life consequences for college students undergoing major life changes and stressful life circumstances including low self esteem, relationship problems, lack of effective communication within family environment, academic stress<sup>[19]</sup> and social anxiety<sup>[20]</sup> and peer pressure, etc.

The present study reported a negative association of Loneliness with Social Support (Significant Other, Family Support, Friends); negative correlation between Stress and Family Support; and positive correlation between Stress and Loneliness. Loneliness is linked with Internet use due to the tendency for withdrawal from real life experiences since the individual might think that his current relationships do not meet his expectations<sup>[21]</sup>. Research evinces that people who were lonely with deficient social skills can develop compulsive Internet usage behaviors which prevents them from developing healthy social relationships in their daily life<sup>[22]</sup>. At this developmental stage, peer group becomes an important source of social support as they seek to individuate from family. But low social support from family decreases

a student's ability to proactively and reactively cope with the academic or other significant life stressors and can negatively impact their quality of life. Research suggests that compulsive Internet usage increased levels of depression, stress and loneliness<sup>[23]</sup>.

**Limitations:** The limitations include cross-sectional design which precludes making a causal link, purposive sampling technique, self report measures and gender specific sample (restricted to females) may limit generalization of findings. Longitudinal design based research can be conducted in future to formulate comprehensive preventive strategies.

### Conclusion

The present study holds significant heuristic value for future research by providing a comprehensive empirical research finding to understand the psychosocial underpinnings of Internet Addiction among female college students. A multidisciplinary team including social and mental health agencies must collaborate to provide a holistic management of IA and formulation of preventive measures remain critical to illuminate parents and educational institutions in curbing Internet-related problems early and effectively in college students.

**Conflicts of Interest:** Nil

**Financial Support and Sponsorship:** Nil

**Ethical Clearance:** There is no Institutional Ethics Committee. Written informed consent was taken from all students who participated in the study

# Effects of Dance and Movement Therapy (DMT) Versus Progressive Muscle Relaxation (PMR) on Quality of Life among Elderly Residing in Selected Old Age Homes of Haryana: A Quasi Experimental Study

Prakash Jha<sup>1</sup>, Srinivasan P.<sup>2</sup>, Uma J Deaver<sup>3</sup>, Jyoti Sarin<sup>4</sup>

<sup>1</sup>Nursing Tutor, Department of Mental Health Nursing, Maharishi Markandeshwar College of Nursing, Maharishi Markandeshwar (Deemed to be University), Mullana, Haryana, India, <sup>2</sup>Former Professor, HOD of Department of Mental Health Nursing, Maharishi Markandeshwar College of Nursing, Maharishi Markandeshwar (Deemed to be University), Mullana, Haryana, India/(Present Nursing Tutor at AIIMS Patna), <sup>3</sup>Professor, Department of Community Health Nursing, Maharishi Markandeshwar College of Nursing, Maharishi Markandeshwar (Deemed to be University), Mullana, Haryana, India, <sup>4</sup>Dean Principal, Maharishi Markandeshwar College of Nursing, Maharishi Markandeshwar (Deemed to be University), Mullana, Haryana, India

## Abstract

Elderly age group is a controversial issue as it is a natural process which presents a unique challenge for every individual in society. Thus it is being considered that quality of life among elderly is poor due to ignorance that is the vulnerable population. The objective of the study was to evaluate the quality of life among elderly before and after administration of dance and movement therapy and progressive muscle relaxation. Methodology: Quantitative research approach, quasi experimental non equivalent control group pretest post test design, with Purposive sampling technique. Data was collected by using Modified WHO-QOL Bref questionnaire for assessing quality of life. Thus findings of the study showed effectiveness of dance and movement therapy and progressive muscle relaxation on quality of life as the calculated Repeated Measure Anova F value (DMT  $F=1027.03$ ,  $p=0.00$  and PMRF= $496.31$ ,  $p=0.00$ ). Result also shows in PMR group quality of life among elderly was found to be statistically significant with source of income and history of chronic illness i.e ( $F=3.534$ ,  $p=0.02$ ) and ( $t=2.922$ ,  $p=0.00$ ) and in DMT group quality of life among elderly was found to be statistically significant with nature of previous occupation and history of chronic illness i.e ( $F=2.935$ ,  $p=0.05$ ) and ( $t=2.408$ ,  $p=0.02$ ). Conclusion: DMT and PMR was effective intervention given for 30 minutes at once daily for improving quality of life among elderly.

**Keywords:** *Quality of life, Dance and movement therapy (DMT), Progressive Muscle Relaxation (PMR), Elderly residing at old age homes.*

## Introduction

Elderly is unavoidable consequence of life. Every

individual who is born must grow older and eventually die.<sup>1</sup> Elderly is conventionally considered to be identical process that is shaping the physical and mental health. Ageing has considered itself an important public health challenge. Elderly has a distinct set of medical and social problems, which will become increasingly apparent in elderly.<sup>2</sup>

The world population is ageing and by 2025, the world's population is expected to include more than 830 million people at an age of 65 by 2030, the number of people in the world aged 60 years or over is projected to

---

Nursing Tutor, Mental Health Nursing, Maharishi Markandeshwar College of Nursing, Maharishi Markandeshwar (Deemed to be University), Mullana-133207, Ambala District, Haryana, India  
e-mail: jhap278@gmail.com

grow by 56 percent, from 434 million to 1.4 billion and by 2050 the global population of elderly is projected to reaching nearly 2.1 billion about 901 million.<sup>3,4</sup> Thus successfully ageing is dazzling the ability of elderly people to adapt to physical, social and emotional losses and to achieve satisfaction, security, safety and gratification.

A person with a depressed mood feels distressing, anxious, empty, desperate and powerless, worthless, blameworthy, short-tempered, or ashamed.<sup>5</sup> According to World Health Organization (WHO), the QOL is individual's insight of their situation in life in the perspective of customs and significance in which they survive and in relation to the objectives, opportunity, interactions and desires.<sup>6</sup>

Dance therapy effects changes in feelings, cognition, physical functioning and behavior.<sup>7</sup> Dance as psychotherapy has been used to recover from psychological and substantial well-being of a person.<sup>8</sup> Poco-Poco is the type of dance therapy which is used as the psychotherapy along with the music to relieve the mental illness.<sup>9</sup>

Progressive muscle relaxation is a psychotherapy that is used for relaxing mind and body by gradually tensing and soothing muscle of body.<sup>10</sup> Person will feels less pressure and have a good physical and emotional health. When the muscle is relaxed, the feelings of warmness and enormity are felt as a result.<sup>11</sup>

Elderly at the peak age feels impassiveness, worthlessness and insecurity, especially when living with these feelings in old age homes. It is very important to understand the factor which affects the quality of life of the elderly persons.<sup>12,13</sup> The quality of life also depends upon emotional interpretation that a person feels about life. Thus the quality of life is progressively more attributed as an estimation that is reliant on the person's prejudice.<sup>14</sup>

## Methodology

The study was conducted during the period from October 2017- November 2018 in the state of Haryana, India. A sample of 60 elderly participated in this quasi experimental study with the prior permission from concerned authority of old age homes. Quantitative research approach was considered to be the most appreciated approach to assess the effectiveness of dance and movement therapy and progressive muscle

relaxation on QOL among elderly with non equivalent control group pre-test post-test design.

**Inclusion Criteria:** Elderly aged 60 years and above, residing in old age homes, willing to participate in the study, alert, oriented and comprehend to respond, able to understand and speak Hindi and able to move without walking aids or any physical assistance.

**Procedure:** Screening was done on day 1 with selected variables and by Modified WHO-QOL Bref questionnaire for quality of life assessment with interview technique. Dance and movement therapy and progressive muscle relaxation was administered to elderly from 2<sup>nd</sup> day to 8<sup>th</sup> day as per intervention protocol. DMT contain 3 sessions i.e warm up session of 5 min duration followed by active session that involves all elderly to sit and do the chair step dance together for 20 min, further third session is for cooling or relaxing session for 5 min. Similarly Progressive muscle relaxation also include 3 sessions i.e warm up session that is done for 5 minutes followed by active sessions done for 20 minutes in this muscle are tensed for 5 seconds and relaxed for 20-30 seconds along with deep breathing and cooling session that is done for 5 minutes. Immediately after completion of 7 days intervention post test I was taken (day 8) and then after 1 week of post test I post test II was taken (day 16) for both DMT and PMR group.

## Data Analysis:

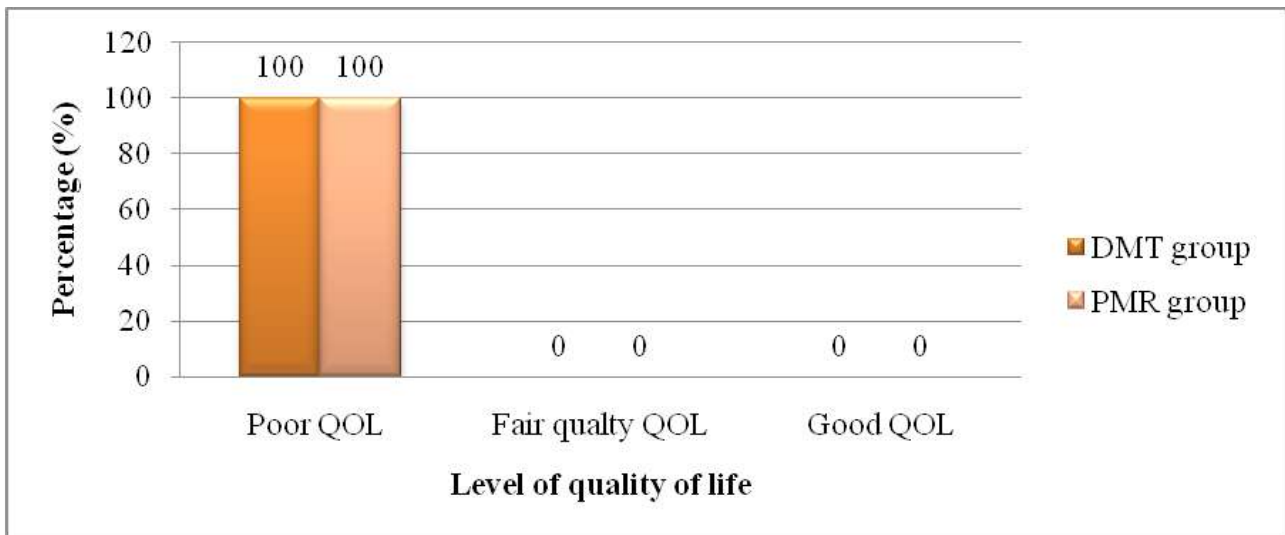

**Descriptive statistics:** Frequency, percentage distribution was used to describe selected variables, Chi-square was used to assess the homogeneity between two groups.

**Inferential Statistics:** Independent 't' test, Repeated measure ANOVA Spearman correlation, ANOVA and 't' test

## Results

Homogeneity was checked by  $\chi^2$  test was applied to compare the DMT and PMR group with respect to every selected variables. Hence both the group was homogenous except for gender ( $p=0.04$ ).

Percentage distribution of DMT and PMR in terms of quality of life among elderly before administration of intervention are shown in Figure 1. All the elderly in both DMT and PMR group (100%) were having poor quality of life.

**Figure 1: Quality of life before Administration of Dance and**

**Movement therapy and Progressive**

**Muscle Relaxation:** In terms of QOL, there was significant difference between DMT and PMR group found before administration of intervention as the calculated ‘t’ value was 7.60, p=0.001 with mean difference of 1.17 Mean score after administration

of intervention in DMT group was 99.33 and in PMR group was 98.57 with mean difference of 0.767. The calculated ‘t’ value was found to be 0.58, p= 0.56 in post-test I. In post-test II mean score after administration of intervention in DMT group was 96.57 and in PMR group was 96.97 with mean difference of 0.400. The calculated ‘t’ value was found to be 0.20, p=0.83.

**Table 1: Mean, mean difference, standard deviation of difference, Standard Error of Mean Difference and ‘t’ value of quality of life among elderly before and after DMT and PMR in DMT and PMR group N=60**

Observation	Group	Mean±S.D	M <sub>D</sub>	SE <sub>MD</sub>	‘t’ value	df	p value

NS -Not significant (p>0.05) t=58(2.00) \*- significant (p ≤ 0.05)

In DMT group the mean score of quality of life in pre test, post test I and post test II was 50.17, 99.33 and 96.57 respectively. Where the F value is 1027.03 with calculated p=0.00. Whereas in PMR group the mean

score of quality of life in pre test, post test I and post test II scores was 59.10, 98.57 and 96.97 respectively. Where F value is 496.31 with calculated p= 0.00.

**Table 2: Repeated measure ANOVA showing the significant difference within groups in terms of Quality of life in DMT group and PMR group N=60**

Groups	Test	Mean	F value	p value
DMT group (n=30)	Pre test	50.17	1027.03	0.00*
	Post test I	99.33		
	Post test II	96.57		
PMR group (n=30)	Pre test	59.10	496.31	0.00*
	Post test I	98.57		
	Post test II	96.97		

\*- significant (p ≤ 0.05)

In DMT group there was the predictability of nature of previous occupation in multiple correlation coefficient, the direction of predictability for the variable is as if chance of private service increases by 1 point, the quality of life get decreases by 8 points (-7.880). Similarly in second model if private service increases by 1 point then quality of life decreases by 12 points (-11.695) and if presence of history of chronic illness increase by 1 point then quality of life get decreases by 10 points (-9.538). In model three if private service increases by 1 point then quality of life decreases by 14 points (-13.873), if presence of history of chronic illness increase by 1 point then quality of life get decreases by

11 points (-11.051) and if no source of income increase by 1 point then quality of life get decreases by 8 points (-7.863). In final model if private service increases by 1 point then quality of life decreases by 14 points (-13.873), if presence of history of chronic illness increase by 1 point then quality of life get decreases by 11 points (-10.702), if no source of income increase by 1 point then quality of life get decreases by 7 points (-6.679) and if chance of Sikh religion increase by 1 point then quality of life get decreases by 3 points (-3.133). This infers that nature of previous occupation i.e private service among elderly had continuous prediction in negative direction throughout the models.

**Table 3: Step Wise Multiple Regression Showing Predictability of Individual Independent Variables on Quality of Life among Elderly in DMT Group (Regression Coefficient) in Post test II N=30**

Model	Unstandardized Coefficient		Standardized Coefficients Beta	t value	p value
	B Std.	Error			
(Constant)	97.880	1.232	-	79.442	0.00*
Nature of previous occupation (private)	-7.880	3.018	-0.442	-2.611	0.01*
(Constant)	95.972	1.020	-	94.048	0.00*
Nature of previous occupation (private)	-11.695	2.431	-0.657	-4.810	0.00*
History of chronic illness	-9.538	2.049	0.636	4.655	0.00*
(Constant)	97.242	0.862	-	112.818	0.00*
Nature of previous occupation (private)	-13.873	1.991	-0.779	-6.969	0.00*
History of chronic illness	-11.051	1.659	0.736	6.662	0.00*
Source of income (no source)	-7.863	1.891	-0.442	-4.157	0.00*
(Constant)	98.078	0.894	-	109.655	0.00*
Nature of previous occupation (private)	-13.873	1.863	-0.779	-7.446	0.00*
History of chronic illness	-10.702	1.561	0.713	6.857	0.00*
Source of income (no source)	-6.679	1.853	-0.375	-3.605	0.00*
Religion (Sikh)	-3.133	1.448	-0.216	-2.163	0.04*

\*- significant (p ≤ 0.05)

Presence of History of chronic illness having prediction with variability of R square = 15% (0.157) as calculated F value 5.210 which was significant at 0.05 level of significance which infers that the chance of fluctuation or change in R value is less than 0.03. Further when combined with Educational status – primary education (reference group- graduation and above) the

prediction with variability of R square= 28% (0.289) as calculated F value 5.492 which was significant at 0.05 level of significance which infers that the chance of fluctuation or change in R value is less than 0.01. This further infers that presence of history of chronic illness alone had higher predictability than the second model.

**Table 4: Step Wise Multiple Regression Showing Predictability of Multiple Independent Variables on Quality of Life among Elderly in PMR Group (Multiple Correlational Coefficient) in Post test II N=30**

Model	R Value	R square	Adjusted R square	Std. error of estimate	df	F value	p value
History of chronic illness	0.396	0.157	0.127	7.645	1/28	5.210	0.03*
History of chronic illness & Educational status (Primary)	0.528	0.289	0.237	7.148	2/27	5.492	0.01*

\*- significant (p ≤ 0.05)

### Discussion

In the present study, less than half of the elderly in DMT and PMR group were in the age group of 70-79 years of age i.e 13(43.3%) and 14(46.7%) respectively. More than half of elderly in DMT group were females 17 (56.7%) whereas in PMR group most of the elderly 22 (73.3 %) were males. More than half of elderly in DMT group were living in urban area 16(53.3%) whereas in PMR group two third of the elderly were living in urban area 18(60%). These findings are partially consistent and contradictory to a cross sectional study conducted by P. Gowthami B, Jayabharathi et al. (2016) on prevalence of depression and QOL among elderly where they found that less than half of the elderly 42 (32.3 %) belongs to the age group of 60-64 years and least no. of elderly 17 (13.1%) were in the age group of 70-74 and above 80 years. More than half of the elderly 73 (56.2 %) were males and less than half 57 (43.8%) were females and majority of elderly 130 (100.0%) were living in rural area.<sup>15</sup>

In the present study, it showed that all the elderly in both the groups (100%) were having poor quality of life in both DMT and PMR group before administration of intervention. These findings were contradictory to the various studies conducted by Abhay Mudey (2011), where it is found that 90% elderly were having fair quality of life and 85% were having good quality of life<sup>16</sup>.

### Conclusion

Dance and movement therapy and Progressive muscle relaxation was effective in improving quality of life among elderly.

**Acknowledgement:** The authors express their whole hearted thanks to all elderly people who participated in the study and made my research prosperous.

# Effects of Integrative Neuromuscular Training Combined with Yoga and Stretching Exercises on Abdominal Strength Endurance of Primary School Children

S. Malar<sup>1</sup>, D. Maniazhagu<sup>2</sup>

<sup>1</sup>Ph.D Scholar, <sup>2</sup>Assistant Professor, Department of Physical Education and Health Sciences, Alagappa University, Karaikudi, Tamilnadu

## Abstract

**Background:** Abdominal strength endurance is used to stabilizing the core muscles. Poor core muscle strength leads to the poor posture. It affects to the motor skills in children. The integrative neuromuscular training can enhance the abdominal muscle strength and used to avoid bad posture in children. This is a training to improve the physical fitness in children and lead them to live healthy life style.

**Purpose:** To know the sixteen weeks of training effects of integrative neuromuscular training combined with yoga and stretching exercises on abdominal strength endurance of primary school children.

**Method:** Sixty primary school children with the age of seven to ten years were selected as subjects from Alagappa Fitness Foundation, Karaikudi, Tamilnadu, India. They were randomly allocated to integrative neuromuscular training (n=15, INT), integrative neuromuscular training combined with yoga (n=15, INT-Y), integrative neuromuscular training combined with stretching exercises (n=15, INT-S) and control participants (n=15, CP). The subjects performed their scheduled training for the period of 16 weeks, three alternative days in a week. The three selected trainings were chosen as independent variables and abdominal strength endurance was chosen as a dependent variable. It was tested by sit up test, performance recorded in numbers.

**Results:** After the sixteen weeks training, the experimental groups showed that significant differences ( $p < 0.05$ ) on abdominal strength endurance. The control participants did not show any significant difference ( $p > 0.01$ ) on abdominal strength endurance.

**Conclusion:** The integrative neuromuscular training combined with yoga group produced greater improvement on abdominal strength endurance than the other trainings.

**Keywords:** *Neuromuscular, Training, Yoga, Stretching, Abdominal Strengthen durance.*

## Introduction

Physical activity is a behavior, whereas physical fitness is an attribute.<sup>1-3</sup> Physical activities that is planned, structured and repetitive bodily movement done to improve or maintain one or more components of physical fitness. Physical fitness is a groups of individual character attained from usual physical activity. These characteristics include cardio respiratory endurance, muscular endurance, muscular strength, body composition and flexibility.<sup>4-6</sup>

The growth prototype of a child is the consequence of

a constant interaction among the child's environment and genes. This comprises the socioeconomic surroundings of the family and school as well as the environmental of the district and country. Changes in the growth pattern, therefore, reflect changes in one or more of this factors.<sup>7</sup>

During infancy and preschool age, movement is an integral part of children's life. In the first six years of life, children discover themselves and the world through movement and captivate their surroundings, through their body and their sensations.<sup>8</sup> Thus, especially in that period of human life, the study of a child's motor performance can significantly contribute to the full

understanding of his/her entire personality.<sup>9</sup>

Physical activity in different forms is important to health and development during childhood.<sup>10</sup> Children need regular physical activity for normal growth and development, maintenance of good health and fitness and development of physical activity skills and behaviors that carry into adulthood.<sup>11</sup> Organs grow at different rates and these rates can differ from the growth rate of the human body as a whole.<sup>12-15</sup>

The integrative neuromuscular training (INT) is a conception to apply a versatile type activity which integrates specific (exercise targeted to motor control) and general (fundamental movement), strength and conditioning activities namely core focused strength, resistance dynamic stability, agility and plyometric. These are planned to improve a skill and health related fitness.<sup>16</sup> More recently, integrative neuromuscular training (INT) which includes general and specific physical activities that are intentionally designed to enhance both health (e.g., muscular strength and cardio respiratory endurance) and skill-related (e.g., agility and balance) components of physical fitness has been recognized as an innovative approach for school-age youth.<sup>17</sup>

Children and young people are now recommended to take part in at least 60 minutes of moderate to vigorous physical activity daily to promote and protect healthy heart function, increase bone and muscle strength, improve mood and lower the risk of depression and reduce the risks of obesity, osteoporosis and diabetes.<sup>18</sup> The abdominal muscles are made up of four layers of powerful elastic bands. These muscle fibers crisscross to form an anatomical girdle. They lie across each other at various angles. The abdominals work together as a unit to produce movement.<sup>19</sup> The abdominal muscle strength

provides core muscles stability to carry out daily work with minimum effort and avoid the strain in the body.

### Method

**Samples:** Sixty primary school children (N=60) with the age of 7-10 years were selected from Alagappa Fitness Foundation, Karaikudi, Tamilnadu, India. Features about the study were informed to the children’s parents and required to sign an informed consent form. The study protocol was approved by Departmental Research Committee of the Department of Physical Education and Health Sciences, Alagappa University.

**Training Approaches:** The chosen children were divided into four equal groups, i.e., three experimental and one control group. The experimental group-I practiced integrative neuromuscular training (INT), the experimental group-II practiced integrative neuromuscular training combined with yoga (INT-Y), the experimental group-III practiced integrative neuromuscular training combined with stretching exercises (INT-S) and group-4 acted as control participants, they did not practiced any particular training. The chosen subjects were participated in this study for the period of sixteen weeks i.e., three alternative days per week.

**Data Collection:** The abdominal strength endurance was tested before and after the 16 weeks of training program. It was tested by sit ups test and scored were recorded in numbers.

**Statistical Application:** To observe the pre and post test differences between the groups, the paired sample t test was applied. To find the adjusted post test mean differences among the group, the analysis of co variance was applied. The Scheffe’s Post Hoc Test was applied to find the pair wise comparisons between the groups.

### Results

#### Abdominal Strength Endurance:

**Table 1: Demonstrates the paired sample ‘t’ test on abdominal strength endurance (Measures in numbers)**

Group	Pre test (M±SD)	Post test (M±SD)	‘t’-Test	P Value
INT (n=15)	10.46±0.63	12.6±0.5	9.02*	0.00
INT-Y (n =15)	10.53±0.99	14.4±0.5	15.12*	0.00
INT-S (n =15)	10.4±0.73	13.46±0.63	10.8*	0.00
CP(n =15)	10.4±0.82	10.26±0.79	1.46	0.97

INT-Integrative neuromuscular training, INT-Y- Integrative neuromuscular training combined with yoga, INT-S- Integrative neuromuscular training with stretching, CP-Control participants, M-Mean, SD-Standard Deviation, \*- significant, Significant at p<0.01, Insignificant at p>0.05

Table-I shows the results of mean + standard deviation of abdominal strength endurance of integrative neuromuscular training (INT), integrative neuromuscular training with yoga (INT-Y), integrative neuromuscular training with stretching exercises (INT-S) and control participants. There was a significant increase ( $p < 0.01$ ) in abdominal strength endurance in INT, INT-Y and INT-S.

There was no significant increase ( $p > 0.05$ ) in abdominal strength endurance in control participants (CP). These results indicate that the sixteen weeks of training intervention produced improvement on abdominal strength endurance in experimental groups. In control participants, there were no significant improvement was found.

**Table 2: Demonstrates the analysis of covariance on abdominal strength endurance (Measures in numbers)**

	INT	INT-Y	INT-S	CP	F	p value
Adjusted post test Mean	12.59	14.38	13.47	10.28	125.05*	0.00

INT-Integrative neuromuscular training, INT-Y- Integrative neuromuscular training combined with yoga, INT-S- Integrative neuromuscular training with stretching, CP-Control participants, M-Mean, SD-Standard Deviation, \*- significant, Significant at  $p < 0.01$ , Insignificant at  $p > 0.05$

Table-2 shows the results of analysis of covariance on abdominal strength endurance of integrative neuromuscular training (INT), integrative neuromuscular training with yoga (INT-Y), integrative neuromuscular training with stretching exercises (INT-S) and control participants. There was a significant difference ( $p < 0.01$ ) in abdominal strength endurance among INT, INT-Y INT-S and control participants (CP).

of integrative neuromuscular training combined with yoga and stretching exercises have enhance the capacity of abdominal strength endurance. The integrative neuromuscular training combined with yoga (INT-Y) produced greater improvement on abdominal strength endurance than the other training groups. The control group did not show any significant improvement on criterion variable.

The superiority effects among the selected groups were found by the application of Scheffe’s Post Hoc Test. It is illustrated.

From the statistical end results we can confirm that, 16 weeks of integrative neuromuscular training combined with yoga and stretching exercises significantly enhanced the capacity of abdominal strength endurance in primary school children. The percentage of improvement on abdominal strength endurance of integrative neuromuscular training (INT), integrative neuromuscular training combined with yoga (INT-Y) and integrative neuromuscular training with stretching exercises (INT-S) were 20.45%, 36.75% and 29.42 %respectively. These results indicate that the INT-Y produced greater improvement on abdominal strength endurance than the other trainings. Hence, the integrative neuromuscular training with yoga is suitable for the development of abdominal strength endurance.

**Table 3: Pair wise comparisons on abdominal strength endurance**

Groups	Mean Differences	Scheffe’s (p value)
INT and INT-Y	1.78*	0.00
INT and INT-S	0.88*	0.00
INT and CP	2.32*	0.00
INT-Y and INT-S	0.9*	0.01
INT-Y and CP	4.1*	0.00
INT-S and CP	3.2*	0.00

The table-3 shows the pair wise comparisons on abdominal strength endurance of selected groups.

The present study findings were in line with certain results of earlier research, while slightly contrasting with other results of relevant studies. The integrative neuromuscular training is a time efficient and cost effective training. It improves the skill and health related fitness in children.<sup>20</sup>Integrative neuromuscular training is an effective and time-efficient addition to PE for enhancing motor skills and promoting physical activity

From the above table significant differences was found between the pairs were INT and INT-Y, INT and INT-S, INT and CP, INT-Y and INT-S, INT-Y and CP, INT-S and CP.

**Discussion on Findings**

After the completion of the sixteen weeks effects

in children.<sup>21</sup> The implication of plyometric training can improve strength among football players.<sup>22</sup> Plyometric training with resistance training is more beneficial than the resistance training with static stretching for improving upper and lower body strength in boys.<sup>23</sup> There was a significant improvement in health related physical fitness in students with intellectual impairment owing to the jump rope training.<sup>24</sup> The inclusion of rope-jump programs in physical education and sports lesson prospectus and in sports training intervention may give to the growth of children's motor skills and speed up the growth of the children.<sup>25</sup> There was a significant improvement in muscular strength due to the calisthenics, using different progressive variations.<sup>26</sup> Study findings from effects of strength training on speed leg explosive power and muscular endurance of college men students showed that speed, leg explosive power and muscular endurance were significantly improved due to the influence of strength training.<sup>27</sup> Twelve weeks of low intensity of land and aquatic plyometric training enhanced muscular endurance. Between the trainings the effect was similar on abdominal muscular endurance.<sup>28</sup>

### Conclusion

In conclusion, we compared the effects of integrative neuromuscular training combined with yoga and stretching exercises on abdominal strength endurance in primary school children. These training regimens appeared sufficient to enhance the abdominal strength endurance. The greatest improvement was found in integrative neuromuscular training with yoga than the other training groups.

The study protocol is most advantageous for primary school going children in the way to improving the health fitness. At this age, a children well adopted in healthy aspects it lead them to live healthy lifestyle and suitable for sporting performances in future.

# A Combination of Clinical Examination with Specific Biomarkers and Judicious Use of Imaging Modality can Reduce the Rates of Negative Appendicectomy

Satyendra Kumar Tiwary<sup>1</sup> Raghunath More<sup>2</sup>, Sandip Kumar<sup>3</sup>,  
Amit Nandan Dwivedi<sup>4</sup>, Jayant Maurya<sup>5</sup>, Satendra Kumar<sup>1</sup>

<sup>1</sup>Associate Professor, Department of General Surgery, <sup>2</sup>Associate Professor, Department of Anatomy, <sup>3</sup>Associate Professor, Department of Pathology, <sup>4</sup>Professor, Department of Radio Diagnosis and Imaging, <sup>5</sup>Junior Resident, Department of General Surgery, Institute of Medical Sciences, Banaras Hindu University, Varanasi

## Abstract

**Background:** Acute appendicitis is one of the most common surgical emergencies. Accurate diagnosis of acute appendicitis is based on careful history, physical examination and laboratory and imaging findings.

**Objective:** The primary aim is the correlation between clinical, biochemical and radiological assessment in patients of appendicitis and also to reduce the rates of negative appendicectomy.

**Method:** The study was carried out in Department of General Surgery, Sir Sunderlal Hospital, IMS and BHU from September 2015 to July 2017. Total 61 patients of age group 16-65 years and either sex were evaluated on the basis of predetermined proforma, which included a detailed history, clinical examination, laboratory investigations and high resolution sonography or CT and histopathology. Sensitivities, specificities, positive and negative predictive values of TLC, neutrophil percentage, Modified Alvarado Score, CRP, D-dimer, USG and CT scan were calculated in respect to histopathology finding as a gold standard.

**Results:** Modified Alvarado scoring (MAS 7-9: Appendicitis definitive) was present in 24 (39.3%) patients. Raised leucocyte count was present in 49 (80.32%) patients, while neutrophil count above 75% was present in 47 (77%) patients. Raised CRP was present in 55 (90.16%) patients with cut-off of >3 mg/l (normal range 1-3 mg/l) while D-dimer was elevated in 44 (72.13%) patients with cut-off of >5 mg/l. On ultrasonography, (77%) patients were diagnosed as acute appendicitis whereas (83.3%) had diagnosis of acute appendicitis in CECT abdomen. Histopathological examination was positive in 60 (98.4%) patients.

**Conclusion:** We concluded that combination of thorough clinical evaluation along with certain routine biochemical & specific markers and ultrasonography as the primary imaging modality is sufficient in establishing a diagnosis of acute appendicitis in more than 90% cases.

**Keywords:** Acute appendicitis, Histopathological examination, Rovsing's sign.

## Introduction

Abdominal pain is one of the most common reasons

---

for visits to the emergency room, comprising 7% of all visits<sup>1</sup>. In most of the patients, symptoms are benign and self-limited; a subset will be diagnosed with an "acute abdomen" as a result of serious intra-abdominal pathology necessitating emergency intervention. The incidence of acute appendicitis declines with age<sup>2-4</sup>. The incidence is highest among children aged 10-14 years. A declining incidence has been reported over the last decade<sup>5</sup>. Males are more commonly affected with male to female ratio of 1.4:1<sup>6,7</sup>. A three-fold risk

of appendicitis has been shown in patients with a family history of appendicitis, which also suggests the presence of genetic factors<sup>8</sup>. While the clinical diagnosis may be straightforward in patients who present with classic signs and symptoms, atypical presentations may result in diagnostic confusion and delay in treatment.

In many cases, the diagnosis of appendicitis is straightforward, however, the diagnosis can be challenging and despite advanced diagnostic imaging, rate of removal of healthy appendices in suspected cases of appendicitis remains high. During the past two decades, imaging techniques like ultrasonography and particularly computed tomography (CT) have allowed preoperative diagnosis of appendicitis to be more reliable<sup>9</sup>, related complications to be evaluated, the negative appendectomy rate and costs of caring to be lowered and differential diagnosis to be sought. Identifying perforated clinical appendicitis depends on clinical examination supported by raised inflammatory and biochemical markers. An early diagnosis of perforation improves outcomes, allowing the surgeon to prepare for a relatively difficult procedure<sup>10</sup>. The negative appendectomy and perforated appendicitis rates are both important quality measures of the treatment of acute appendicitis. There is an inverse relationship between these two measures<sup>11</sup>.

The primary aim of this study was to establish whether there is a correlation between clinical, biochemical and radiological parameters in patients of appendicitis. Also to explore the role of CT scan as complementary imaging tool in management of these patients.

## Method

This is a prospective hospital based observational study which was done after obtaining ethical approval from the Ethical Committee of Institute of Medical Sciences, Banaras Hindu University from September 2015 to June 2017. The study includes 61 patients who presented with peri-umbilical pain or pain in right iliac fossa was included in the study. Patients with age group <15 and >65 years, pregnant women and patients having history of previous abdominal surgery or diagnosis of appendicular lump or other abdominal conditions such as perforation peritonitis, ovarian malignancy, pancreatitis etc. where raised value of biochemical markers were excluded from the study.

Patients demographic profile was recorded clinically

followed by detailed history related to symptoms and their duration, presence or absence of similar complains in past, any history of diabetes or other co-morbidities, trauma, surgery, drug intake history were taken. A detailed abdominal examination to look for contour of abdomen (flat/distended/visible lump in right iliac fossa), local temperature, direct, indirect and rebound tenderness, lump in right iliac fossa, presence/absence of Rovsing's sign, Obturator sign and Psoas sign, presence of free fluid and bowel sound were also recorded.

Relevant hematological tests like complete blood count (CBC) with special test like serum C-reactive protein (CRP) and D-dimer was carried out. Soon after the report of CBC patients were graded according to Modified Alvarado Score. Further patients were subjected to high resolution sonography (HRS) at a frequency of 7.5 MHz where the points of interest were probe tenderness in RIF, visualization of appendix, mesenteric echogenicity and presence or absence of appendicitis. In case of discordance between clinical finding/scoring and ultrasonography patients were subjected to multidetector 128-slice CT scan abdomen where the points of interest were appendicular perforation, peri-appendiceal collection and presence or absence of dilated inflamed appendix. The patient was then subjected to laparoscopic/open appendectomy and the specimen was sent for histopathological examination.

Modified Alvarado scoring was done along with the biochemical, Ultrasound and CT scan findings, finally these were correlated with their histopathology report.

All these data were statistically analyzed using SPSS 16.0 software Windows version.

## Results and Discussion

Acute appendicitis the accuracy of the clinical diagnosis is approximately 80%, which corresponds to a negative appendectomy rate of around 20%<sup>12</sup>. 61 patients were suspected to have acute appendicitis. In 27 patients (44.3%) patients had Modified Alvarado scoring (MAS) 5-6 (Appendicitis possible) followed by MAS 7-9 (Appendicitis definitive) which was present in 24 (39.3%) patients. Raised leucocyte count 49 (80.32%) patients, neutrophil count above 75% was present in 47 (77%) patients. Raised CRP was present in 55 (90.16%) patients, D-dimer was elevated in 44 (72.13%) patients.

CECT abdomen was done in only 12 patients. 4 (33.3%) patients had appendicular perforation and 9

(75%) patients had peri appendigeal lymph node and dilated inflamed appendix (**Figure 1**) on CECT abdomen. Out of 12 patients, 10 (83.3%) had diagnosis of acute appendicitis in CECT abdomen. (**Figure 1**)HPE was positive in 60 (98.4%) patients.(**Table-1**) On correlating modified Alvarado score with TLS, neutrophil (%), lymphocyte (%), CRP (mg/l) and D-dimer (mg/l). Positive significant correlation was observed between MAS with TLC ( $r=0.514$ ,  $p<0.001$ ), CRP ( $r=0.613$ ,  $p<0.001$ ) and D-dimer ( $r=0.628$ ,  $p<0.001$ ) (Fig. 1-3). Negative significant correlation was observed only in MAS with lymphocyte ( $r= -0.438$ ,  $p<0.001$ ).(**Table 2**)

All clinically positive patients (n=55) had appendicitis on HPE, while in 6 patients having no clinical features of appendicitis, 5 were positive on histopathology and one had no appendicitis on HPE. So the sensitivity and specificity of clinical evaluation of our study is 91.67% and 100% respectively. The sensitivity of clinical assessment was almost equivalent with the results of the study conducted by MojcaGroselj-Grenc et al<sup>13</sup> which was 93.9%.

In present study, total leucocyte count was raised in 80.3% (n=49) patients while it was normal in the rest 19.7% (n=12). All patients having raised count were found to have appendicitis on HPE, while of 12 patients having normal TLC, 11 patients were positive on HPE and one had no appendicitis in histology. The sensitivity and specificity of total leucocyte count of the study was 81.67% and 100% respectively. This sensitivity was consistent with the study by Lau<sup>14</sup>.

In the present study, 77% (n=47) patients had neutrophil percentage above 75% and all these patients were positive on HPE. of 23% (n=14) cases having normal neutrophil percentage, 21.3% (n=13) had appendicitis on HPE while one was negative on histology. This gives sensitivity, specificity and accuracy of 78.33%, 100% and 78.69% respectively. This sensitivity was comparable to study by Sasso et al<sup>15</sup> In present study raised value of MAS (>4) was present in 83.6% (n=51) cases while in other 16.4% (n=10) MAS value was <4. In patients having raised MAS value, 50 cases were positive on HPE and one patient had no appendicitis on HPE. All the remaining 16.4% (n=10) cases having MAS<4 were histologically positive which makes sensitivity of 98% and specificity 0%. The sensitivity of studies by Ohle et al<sup>16</sup> and Musharraf Husain et al<sup>17</sup> had concordance to our study.

The preoperative serum C-reactive protein (CRP) levels were correlated with the histopathology. Out of 61 patients, 90.2% (n=55) cases had raised C-reactive protein level and all these patients were histologically found to have appendicitis. CRP level was normal in 9.8% (n=6) of which 8.2% (n=5) cases were having appendicitis while one patient had no features of appendicitis on HPE. In our study, sensitivity and specificity of C-reactive protein was 91.67% and 100% respectively. This result of Present study is in concordance with the study done by Wu et al<sup>18</sup>.

In our study D-Dimer was raised in 72.1% (n=44) patients while it was normal in 27.9% (n=17). All patients having raised value of D-Dimer had appendicitis on HPE while of the remaining 17 patients one had normal appendix and 26.23% (n=16) had appendicitis on histology. The sensitivity, specificity & accuracy in diagnosing appendicitis was 73.33%, 100% and 73.77% respectively which is much more than previous studies and is due to low cut-off D-dimer (>5mg/L taken as raised level). Our study was in concordance to Cayrol et al<sup>19</sup> which took D-dimer cut-off point of 0.230 mg/L. Combining the results of CRP and D-dimer improves the sensitivity value for diagnosing appendicitis. If we use both inflammatory marker (CRP & D-Dimer) we get a higher sensitivity value as 97%. The use of these biochemical tests is limited and so should only be used as a guide, with the wider clinical picture being of greatest importance rather than solely relying on the biochemical markers for a diagnosis.

In present study, USG suggested appendicitis in 80.33% (n=49) patients and all these patients had appendicitis on histopathological examination also. In other 19.7% (n=12) cases having no appendicitis on USG, 18% (n=11) had appendicitis on HPE while one patient was found to be negative on histology. Sensitivity, specificity and accuracy of High-resolution ultrasonography came out to be 81.67%, 100% and 81.97% respectively. Present study was also consistent with the study done by MojcaGroselj-Grenc et al<sup>12</sup> having sensitivity of 91% and specificity of 95% respectively. Accuracy of CT scan is higher as compared to USG for diagnosing acute appendicitis<sup>20</sup> but till today still there is utility of USG for the diagnosis of acute appendicitis particularly in pediatric cases<sup>21</sup>. CECT was not performed routinely in all patients but done only when there was discordance between clinical findings and Ultrasonography. In present study done in

only 12 cases out of 12 cases 83.33% (n=10) had acute appendicitis on CECT and HPE, one case was negative on CECT but positive in HPE and one had appendicitis neither on CECT nor in HPE. Sensitivity of CECT was 92.86%, while specificity 100% and accuracy 93.33%, positive predictive values of 100%. Similarly Lazarus et al<sup>22</sup> had sensitivity and specificity values in concordance to our study.

### Conclusion

The diagnosis of acute appendicitis is generally made on clinical grounds but on many occasions especially in children and female clinical findings alone cannot be used unequivocally for making treatment decisions. In our study we have shown that the combination of CRP & D-Dimer is a better predictor of acute appendicitis and complimentary to clinical diagnosis. A combination of thorough clinical evaluation along with routine biochemical & specific biomarkers and ultrasonography as the primary imaging modality is sufficient in establishing a diagnosis of acute appendicitis and reduce the rates of negative appendicectomy. Limited CECT abdomen can help in patients with discordant clinical and USG findings.

**Table 1: Ultrasonography, CECT abdomen and Histopathological finding**

Findings	Number (%)
<b>USG Finding (n=61)</b>	
Probe tenderness RIF	54 (88.5)
Appendix Visualisation	34 (55.7)
Periappendiceal Echogenicity	41 (67.2)
Acute appendicitis	47 (77.0)
Chronic appendicitis	1 (1.6)
Resolving appendicitis	2 (3.3)
<b>CECT Abdomen (n=12)</b>	
Appendicular perforation	4 (33.3)
Periappendiceal collection	9 (75.0)
Appendicitis	10 (83.3)
<b>Histopathology</b>	
No Appendicitis	1 (1.6)
Appendicitis	60 (98.4)
Reactive appendix	6 (9.8)
Acute aappendicitis	12 (19.7)
Acute on chronic appendicitis	7 (11.5)
Chronic appendicitis	31 (50.8)
Resolving appendicitis	4 (6.6)

**Table 2: The sensitivity, specificity, PPV, NPV and diagnostic accuracy of diagnostic variables with histopathological finding as gold standard**

	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)	Diagnostic Accuracy (%)
TLC	81.67	100	100	8.33	81.97
Neutrophil	78.33	100	100	7.14	78.69
MAS	98.04	0	83.33	0	81.97
CRP	91.67	100	100	16.67	91.8
D-dimer	73.33	100	100	5.88	73.77
USG	81.67	100	100	8.33	81.97
CECT	92.86	100	100	50	93.33
CRP plus D-Dimer	97.73	0	71.67	0	70.49

# Psychosocial Impact of Overactive Bladder Symptoms among Adults in a Selected Hospital at Mangaluru

Susamma Varughese<sup>1</sup>, Rajeev T.P.<sup>2</sup>, Devina E. Rodrigues<sup>3</sup>

<sup>1</sup>MSc Nursing, Assistant Professor, Department of Medical Surgical Nursing, Father Muller College of Nursing, Mangaluru and PhD Scholar, Nitte University Mangaluru, <sup>2</sup>MBBS, M.S., M.Ch, Professor & HOD, Department of Urology, K.S. Hegde Hospital, Mangaluru, <sup>3</sup>MSc (N), PhD in Nursing, Professor, Community Health Nursing, Father Muller College of Nursing, Mangaluru

## Abstract

**Introduction:** Overactive bladder symptoms (OABS) have a detrimental impact on mental health and social wellbeing. The apprehensions about frequent voiding, leakage and wetting, or unavailability of toilet facility which leads to embarrassment, anxiety, stress, social isolation and disrupts the daily activities of the people. Besides the psychosocial impact of OABS is seldom studied in south India. Understanding the impact on the psychosocial aspects among adults is vital in controlling and managing OABS. Therefore the aim of this study was to determine the psychosocial impact of overactive bladder symptoms among adults.

**Method:** An exploratory descriptive study design was adopted. The sample consisted of 142 male adults of 35-75 years of age recruited using purposive sampling from the department of Urology in selected Hospitals at Mangaluru. The subjects were interviewed for baseline Proforma, Overactive bladder symptom score (OABSS) and self reported questionnaire on Psychosocial impact of overactive bladder symptoms. The data was analysed using descriptive and inferential statistics.

**Results:** The subjects 52.8% had moderate and 31.0% had severe forms of OABS. Overall psychosocial impact was  $80 \pm 10.9$ , the Mean percentage 76.9 shows that OABS are severely affected the adults psychosocially. There was significant association between Psychosocial Impact of Overactive bladder symptoms and selected Demographic Variables such as age ( $p \leq 0.024$ ), Education ( $p \leq 0.03$ ) and Marital status ( $p \leq 0.02$ ) as well as there was a high positive correlation between OABS and Psychosocial impact of adults with OABS ( $r = 0.7$ .  $r^2$  value is 0.467).

**Conclusion:** The OABS have a major psychosocial impact in adult's life; the stress, frustration, hopelessness, uncomfortable to travel and attend social gathering and disturbed sleep.

**Keywords:** OABS; psychosocial impact; adults; OABSS.

## Introduction

The deliberate control of voiding is a necessity for the sense of normality. Overactive bladder syndrome is

a significant voiding condition which has a tremendous impact on mental health and social life of an individual. It impairs the self-esteem, independence, daily and social activities such as self care, work, exercise, travelling, shopping, sexual function and sleep. International continence society defines; "Overactive Bladder as a complex symptoms characterized by urinary urgency, with or without urge incontinence, usually with frequency and nocturia."<sup>1</sup> The embarrassment of urgency leads to social withdrawal and limits the normal activities. Furthermore it develops preoccupied thoughts such as "when I've got to go, I've got to go,

I have to rush because I think I may wet myself”<sup>2</sup> and anxiety which may lead to impairment of the emotional & psychological well being. Getting up many times at night and lack of sleep give rise to risk of fall, accidents, day time snap and irritability for simple matters etc. The OABS reduces the occupational productivity and people restrict or stop travelling, staying in relatives house and attending social and recreational functions due to worry about unavailability of toilet facilities. Moreover, the use, frequent change and disposal of sanitary pads generate the major stress among the affected. In spite of the negative impact on emotional and social well-being people do consider these conditions as normal as they get older. The mortification about being wet and the smell of urine restrict social interaction leading to social isolation. They develop a sense of hopelessness due to the thoughts of people avoiding them, neglected by family members, not able to play social and family role satisfactorily and becoming a burden to others due to illness. Though this condition has a severe impact on mental health and social life of the affected, OABS seldom received attention in the medical literature. Awareness of these issues among health care professionals is the prerequisite in the gentle management of the above discussed problems. Therefore the aim of this study was to find the psychosocial impact of overactive bladder symptoms among adults.

**Method**

An exploratory descriptive design was adopted in this study to assess the psychosocial impact of overactive bladder symptoms among adults. The institutional ethical clearance and permission to conduct the study was obtained from the concerned authority. The duration of the study was one year. The study was conducted among 142 male adults between the age group of 35 and 75 years. The formal consent from the subjects has been taken and conducted the structured interview. They were recruited using purposive sampling from the department of Urology of selected Hospital at Mangaluru. Those who have three symptoms of OABSS such as urgency,

frequency, nocturia and with or without leak of urine were recruited. The data was collected using Overactive bladder symptoms score (OABSS) (Homma et al)<sup>3</sup> and self reported questionnaire on psychosocial impact of overactive bladder symptoms. The severity of the symptom graded as Mild (0-7) moderate (8-12), severe (13-15).The reliability of the tool was obtained 0.75 by using Cronbach alpha method and validated in local languages. The data was analysed using descriptive and inferential statistics such as Frequency, percentage, Standard Error of Mean (SEM), Chi-square and Karl Pearson coefficient of correlation.

**Inclusion Criteria for Sampling:**

1. Male adults attending Urology OPD with the age group of 35 – 75 years.
2. Male adults will be selected based on the self reported symptom of overactive bladder not by the diagnosis.
3. The subjects will be selected based on OABSS screening and with or without treatment for overactive bladder symptoms

**Exclusion Criteria:** Adults with Neurogenic bladder and who are on urinary catheter

**Results**

**Baseline Characteristics of adults with Overactive Bladder Symptoms (OABS):** More than half of subjects 53(37.4%) were in the age group of 65-75 years. The mean age was 58±12.4. In the educational status 70 (49.3%) had primary education and only 5(3.5%) of them were graduate. The majority 132(93.0%) of them were married and 67(47.2%) subjects had 1-2 children with the mean 2.4±1.4. More than half of the subjects 80 (56.3%) were unskilled workers and 10(7.0%) of them were professional. The subjects 81(57.0%) had income between 5000 and 10000 with the mean 11897±5907. The majority 136 (95.8%) were consuming mixed diet.

**Frequency and percentage of Overactive Bladder Symptom Score:**

n=142

	OABS	Score	Frequency	Percentage
1.	<b>Frequency of urine</b>			
	≤7	0	4	2.8
	8-14	1	49	34.5
	≥15	2	89	62.7

	Once a week or more	2	1	.7
	About once a day	3	12	8.5
	2-4 times a day	4	36	25.4
	5 times a day or more	5	92	64.8
<b>4</b>	<b>Urge Incontinence</b>			
	Not at all	0	49	34.5
	Less than once a week	1	19	13.4
	Once a week or more	2	19	13.4
	About once a day	3	15	10.6
	2-4 times a day	4	17	12.0
	5 times a day or more	5	23	16.2

Table 1 reveals that 62.9% subjects had frequency of urine ≥15 times from waking in the morning until sleeping at night, 79.6% of them had nocturia ≥3 times, 64.8 % subjects had a sudden desire to urinate 5 times a day or more and 16.2 % of them had incontinence 5 times a day or more

**Severity of Overactive Bladder Symptoms:**

n=142

The figure 1 depicts more than half 75(52.8%) had moderate, 44(31.0%) severe and 23(16.2%) mild form of overactive bladder symptoms.

**Overall and component wise Mean, Standard deviation, Mean percentage, SEM and CI of psychosocial impact of OABS:**

n=142

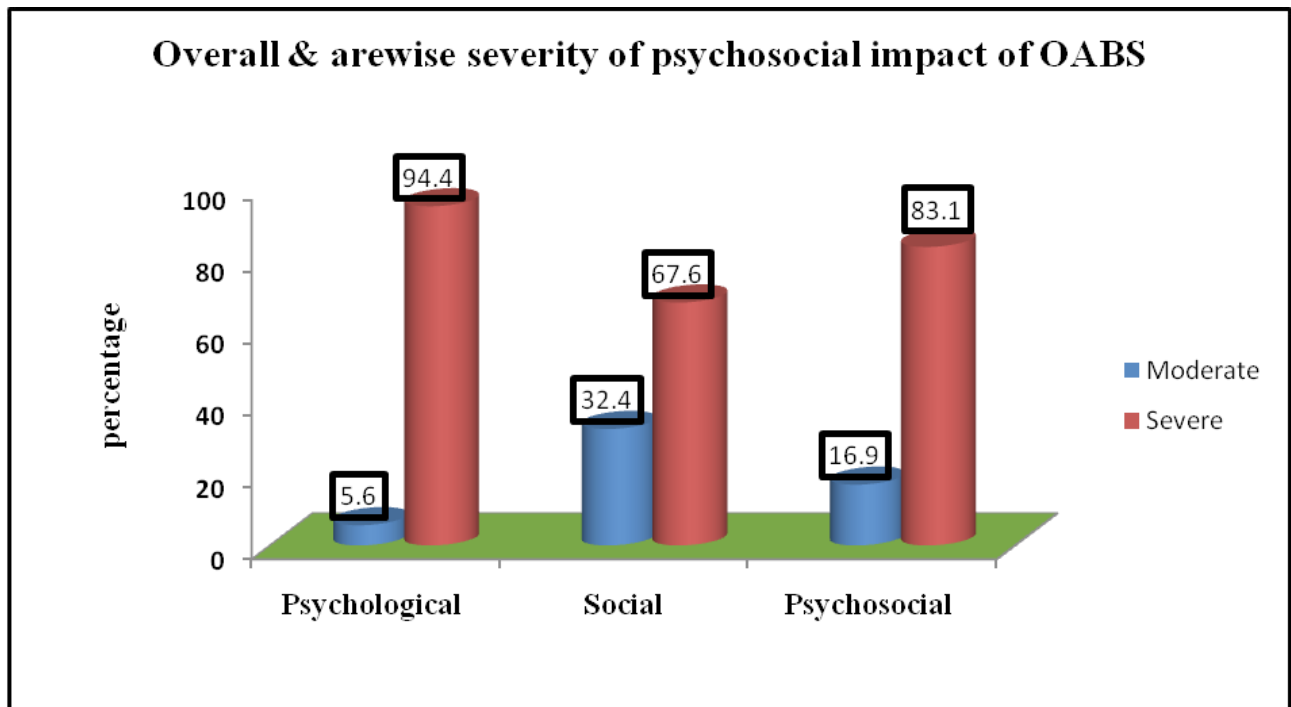

Components	Max.Score	Mean±SD	Mean Percentage	SEM	95% CI	
					Lower	Upper
Psychological impact	56	46.45±6.09	82.9%	0.51	45.45	47.44
Social impact	48	33.54±5.64	69.8%	0.47	32.61	34.46
Overall psychosocial impact	104	80±10.9	76.9%	0.92	78.20	81.80

**Table 2:** Among component wise psychosocial impact scores the highest mean percentage score was with Psychological impact (82.9%) which indicates that subjects had severe impact in this component. The least mean percentage was found in the Social impact (69.8%) but which also indicates that the subjects had high psychosocial impact in this component. The highest SD value was in the psychological impact (46.45±6.09) and found that the least SD value was in Social impact (33.54±5.64). However in component wise assessment, there is not much difference in range of SD value. Overall psychosocial impact was (80±10.9), with

Mean percentage 76.9 % which shows that OABS are severely affected the adults psychosocially. The SEM value in the both component and overall indicates there is less variability in these samples means (0.51, 0.47 and 0.92) respectively. The least variability was seen in the component related to social impact (SEM 0.47) Confidence Interval: In the component related to psychological impact 95% of the population mean was between 45.45 and 47.44. In the component related to social impact 95% of the population mean was between 32.6v and 34.96 as well as overall it found to be between 78.20 and 81.80.

**Frequency and Percentage, of Severity of Psychological, social and overall psychosocial impact of adults with OABS:**

n=142

**Figure 2:** On the observation of the data depicted shows that in the domain of psychological impact 134 (94.4%) subjects had severe, only eight (5.6 %) had moderate and none of them had mild psychological impact of OABS. In the domain of social impact 96 (67.6%) subjects had severe and, only 46(32.4 %) had moderate Social impact of OABS and in the overall area of psychosocial impact 118 (83.1%) subjects had severe and, only 24(16.9 %) had moderate impact of OABS.

**Association between the Psychosocial Impact of OABS among adults and selected Demographic Variables:** The Chi Square value shows that there was a significant association between Psychosocial Impact of

Overactive bladder symptoms and selected Demographic Variables such as age ( $p \leq 0.024$ ), education ( $p \leq 0.03$ ) and marital status ( $p \leq 0.02$ ). Therefore the Research Hypothesis is retained.

**Correlation between OABS and Psychosocial impact:** The calculated Karl Pearson correlation value was 0.7 and the ‘p’ values was  $< 0.001$ . Therefore there was a high positive correlation between OABS and Psychosocial impact of adults with OABS.  $r^2$  linear value was 0.467. It shows that out of thousand 467 subjects have correlation between OABS and Psychosocial impact.

**Correlation between severity of OABS and psychosocial impact among adults:**

n=142

**Figure 3:** The calculated Karl Pearson correlation value was 0.604 and the ‘p’ value is  $< 0.001$ . Therefore there was a positive moderate correlation between severity of OABS and Psychosocial impact of adults. ( $r^2$  square linear value was 0.365).

**Discussion**

**Demographic Variables:** In the current study 53(37.4%) were in the age group of 65-75 years with the mean age  $58 \pm 12.4$ . This finding consistent with the study conducted to determine Health-Related Quality of Life in Overactive Bladder shows that the mean age was 54.2

$\pm 16.4$  years<sup>4</sup>. In present study the subjects only 5(3.5%) of them were graduate. A previous study findings shows that 8.3 % of the subjects were graduate.<sup>4</sup> The majority 132(93.0%) of them were married and findings were consistent with other studies’ result was 54.7 and 59.2%<sup>4,5</sup>. In this study 80 (56.3%) were unskilled workers and 10(7.0%) of them were professional.

**Severity of OABSS:** Current study reveals that more than half 75(52.8%) have severe, 44(31.0%) moderate and 23(16.2%) mild form of overactive bladder symptoms. The findings supported by other studies observed that most participants reported moderate bladder problems (34.4%)<sup>4</sup> and among the OAB subjects, the most common severity of symptom was moderate (72.6%), followed by mild (21.2%) and severe (5.8%)<sup>6</sup>. Another study shows the incontinence was severe in 9% of the affected subjects<sup>7</sup>.

**Severity of psychosocial impact of OABS:** In the present study, overall area of psychosocial impact assessment showed that 118 (83.1%) subjects had severe and, only 24(16.9 %) had moderate impact of OABS. The findings were supported by the study conducted to identify the quality of life of incontinent men revealed that 50% moderately and 26% were extremely upset<sup>8</sup>

Among component wise psychosocial impact scores the highest mean percentage score was with Psychological impact (82.9%) and the lowest score was in the area of social impact with 69.8%, which indicates that subjects had severe impact in these components. This finding is consisted with similar study showed that the respondents scored lowest in the role physical domain and highest in the mental domain, with mean scores of 33.8 and 72.1, respectively<sup>9</sup>. In another study half of the incontinent subjects expressed social limitations and negative feelings related to incontinence and 21% expressed that incontinence negatively affected their life<sup>7</sup>. In current study the overall mean percentage score of psychosocial impact scores was 76.9%. The findings is supported another study shows that about 18% of persons with Urge Incontinence (UI) felt depressed or sad much of the time in the past year, whereas less than 10% of continent respondents felt the same way. Similarly, 17.7% of persons with UI had experienced depression for 2 or more years compared with 9.7% in the non-UI group<sup>10</sup>.

**Correlation of psychosocial impact and OABS:** In this study there was high positive correlation between OABS and Psychological impact of adults with OABS. This findings is consisted with similar study showed that the overactive bladder symptoms group presented a positive low correlation with anxiety symptoms ( $r=0.345$ )<sup>11</sup> and in another study 27.5 % of OAB patients had depression (HADS  $\geq 8$ ) and 12 % of OAB patients had moderate to severe depression (HADS-D  $\geq 11$ ). OAB patients with depression reported more severe

incontinence symptoms (ICIQ-UI), greater bother and more impact on quality of life (UDI-6, IIQ-7) compared to OAB patients without depression ( $p=0.001, 0.01, <0.001$ , respectively)<sup>12</sup>. Present study shows there was positive moderate correlation between severity of OABS and Psychosocial impact of adults. ( $r^2$  linear value was 0.365) .The current study findings are congruent with another study reveals that among OAB patients, there was a positive correlation between perceived stress levels and urinary incontinence symptoms (ICIQ-UI, Spearman's correlation coefficient= $0.39, p=0.007$ ) and impacts on quality of life (UDI-6, IIQ-7, OAB-q quality of life subscale; Spearman's correlation coefficient= $0.32, 0.31, 0.39$  and  $p=0.028, 0.005, 0.029$ , respectively)<sup>13</sup>.

**Strength and Limitations:** The study population were only males and the samples with OABS wet and dry were studied as combined were obvious limitations of the study. Similar studies could be conducted with the larger sample, different design and study would be done on OABS wet and dry separately. Since the present study has explored the severity of OABS and its psychosocial impact among adult male, it will facilitate the need to develop appropriate strategies and alternative therapies in the health care settings to manage OABS.

## Conclusion

The study reveals OABS severely affects the psychosocial life of adults. The effected individuals with OABS are embarrassed, worried, having feeling of low self confidence, sense of hopelessness, being neglected, disturbed and ashamed. These various aspects lead them to social isolation and unable to play a societal and family role satisfactorily; furthermore to an extend of interruption in family and societal relationship and ultimately being less productive. These factors suggest necessity for developing multiple alternative approaches including pharmacological treatment to handle this problem sensitively. Hence the awareness regarding psychosocial problems of OABS among healthcare professionals is necessary to provide appropriate care to manage such problems.

# Etiological Factors of Failure in Endonasal Dacryocystorhinostomy

Tripti<sup>1</sup>, Abhay D. Havle<sup>1</sup>, Ganesh M. Vihapure<sup>2</sup>, Swapna A. Shedge<sup>3</sup>

<sup>1</sup>Resident, <sup>2</sup>Asst. Professor, Department of Otorhinolaryngology, <sup>3</sup>Asst. Professor, Department of Anatomy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India

## Abstract

**Background:** External dacryocystorhinostomy was first performed by Addeo Toti in 1904. Before, in 1893 Caldwell did mention about endonasal approach in lacrimal surgery. In 1989, the first endonasal dacryocystorhinostomy (DCR) performed by McDonogh and Meiring. The knowledge about etiological factor of failure of DCR would immensely help in its prevention.

**Aim:** To find out the causes of failure of endonasal DCR.

**Materials and Method:** All the cases having epiphora following endonasal DCR surgery which completed minimum one year period irrespective of their gender were included in the study. A total of 50 cases from otorhinolaryngology and ophthalmology having epiphora were enrolled in the study. All cases were subjected to diagnostic as well as therapeutic endoscopy using '0' degree endoscope, causes like deviated nasal septum, intranasal synechia, cicatricial closure as well as inadequate size or non-dependant position of neo-ostium, inadequate sac marsupialization, etc. leading to failure were searched and corrected. All cases were followed for six months.

**Results:** There were 12 male and 38 female, epiphora was commonest symptom in all cases and the least common was redness and swelling of eyelid in 1. The most common etiological factor for failure of endonasal DCR was inadequate ostium size in 41, followed by inadequate sac marsupialization in 31, cicatricial closure of ostium in 26, intranasal synechia and ostium malposition in 18 each, ostium stenosis in 13, common canalicular obstruction in 11 and deviated nasal septum in 8 cases.

**Conclusion:** The most common aetiological factor responsible for failure of endonasal DCR was inadequate ostium size whereas; the least common was malpositioning of neoostium. The number of female having failed DCR was more than three times higher than male.

**Keywords:** Endoscopy, Lacrimal apparatus, Lacrimal duct obstruction.

## Introduction

Endonasal dacryocystorhinostomy (DCR) is

procedure for obstruction in lacrimal drainage system by way of nasal approach, with the help of a nasal endoscope. In 1904 the surgical modality by way of external dacryocystorhinostomy was first performed by Addeo Toti.<sup>[1]</sup> Before, in 1893 Caldwell mentioned endonasal approach in lacrimal surgery but due to narrowness of cavity it did not come in to practice.<sup>[2]</sup> With the development of the rigid fiberoptic endoscope the first modern endonasal endoscopic DCR procedure was described by McDonogh and Meiring in 1989.<sup>[3]</sup> Various causes of its failure are known like obstruction of the nasal ostium, canalicular obstruction, functional

epiphora, granuloma formation in the nasal ostium etc. The precise knowledge of such causes would immensely help in prevention of failure in endoscopic DCR.

**Objective:** To find out the causes of failure of endonasal DCR.

### Materials and Method

All the cases having epiphora following endonasal DCR surgery which completed minimum one year period, irrespective of their gender were included in the study. All pregnant or lactating mothers, previous nasal injury at ostium site, neoplastic lesions of nose and lacrimal apparatus and known cases of immunodeficiency were excluded from the study.

A total of 50 cases from otorhinolaryngology and ophthalmology OPD of tertiary care teaching hospital, as per set inclusion and exclusion criteria and willing to participate were enrolled in the study. In all cases demographic characteristics, clinical history and past medical history etc were recorded. The nose and eye examination for any obvious deformity, turbinate hypertrophy, nasal polyposis, watering or purulent discharge in the medial canthal area etc. was carried out in all cases. Regurgitation on pressure over lacrimal sac (ROPLAS) test was done in all cases for diagnosis of nasolacrimal duct (NLD) block. Also probing and syringing was carried out for testing the patency of tract. Further, all cases were subjected to imaging and laboratory tests like dacryocystography, CT-PNS and routine CBC, BT, CT, PT, urine, BUN, creatinine and blood sugar. Both diagnostic as well as therapeutic nasal endoscopy was performed under anaesthesia using '0' degree endoscope in every case. Diagnostic nasal endoscopy (DNE) was done to note various etiological factors in nasal cavity like, deviated nasal septum, intranasal synechia and non- dependant neo-ostium of previous surgery. At revision endoscopy as a part of corrective surgery additional causes like inadequate size of ostium, inadequate sac marsupialization, cicatricial closure of ostium etc. leading to failure were searched and corrected. After revision surgery during immediate follow up the crust were looked for and removed. Patency check of new stoma was made in all cases by syringing weekly for 1 month, monthly for 3 months and then at 6 month.

**Statistical Analysis:** Using statistical analysis the frequency distribution of collected data was obtained

with the help of SPSS (Statistical Packaging for Social Sciences) IBM, India software version 22.0.

### Observation and Results

Amongst 50 cases, there were 12 male (24%) and 38 female (76%) in the ratio of 1: 3.16. All study participants were between age group of 20-70 years (table-1). Most of the cases 15 (30%) were of age between 51-60 years and the least 5 (10 %) belonged to the age group of 20-30 years. Amongst all cases the commonest presenting symptom (table-2) was watering of eyes in 50 (100 %), followed by pain in lower corner of the eye in 38 (76 %), swelling at medial canthus in 33 (66 %) and lacrimal abscess in 2 (4%) cases, whereas the least common symptom was redness and swelling of eyelid consequent to preseptal cellulitis in 1 (2%) case. In all cases using dacryocystography and CT-PNS the cause of failure noted was common canalicular obstruction, deviated nasal septum in 11 (22%) and 8 (16%) cases respectively while in 31 it could not be ascertained. At DNE in all cases of revision endonasal DCR the most common etiological factor for failure noted was inadequate ostium size in 41 (82 %), followed by inadequate sac marsupialization in 31 (62 %), cicatricial closure of ostium in 26 (52 %), intranasal synechia and ostium malposition in 18 (36 %) each, ostium stenosis in 13 (26%) -(table-3). The mean duration between first surgery and revision surgery amongst all cases was 5.08 years  $\pm$  2.23 years. The mean duration of symptom free period between two surgeries was 8.42 months  $\pm$  3.38 months.

**Table 1: Age wise distribution of cases.**

Years of Age	Number of Subjects	Percent
20-30	5	10
31-40	9	18
41-50	10	20
51-60	15	30
61-70	11	22
<b>Total</b>	<b>50</b>	<b>100</b>

**Table 2: Distribution of cases according to their symptoms**

Signs and Symptoms	Number of Cases	Percent
Watering of eyes	50	100
Local pain	38	76
Swelling of medial canthus	33	66
Lacrimal abscess	2	4
Redness and swelling of eyelid	1	2

**Table 3: Distribution of cases according to Causes of failed DCR**

Causes of Failed DCR	Number of Subjects	Percent
Cicatricial closure of ostium	26	52
Common canalicular obstruction	11	22
Intranasal synechia	18	36
Ostium stenosis	13	26
Deviated nasal septum	8	16
Inadequate ostium size	41	82
Ostium malposition	18	36
Inadequate sac marsupialization	31	62

**Discussion**

This study of failed DCR cases stressed up on finding different etiological factors such as opening of ostium, site of ostium, various other intranasal and septal pathologies. In study by Dave TV et al the majority of the cases are females 66.6% and males 33.3%.<sup>[4]</sup> And in the study of Baek JS et al, out of the total 61 cases, 46 are female i.e. 75% of the sample and the overall mean age is 54 years.<sup>[5]</sup> The percentage of gender distribution of participants in this study was 24 and 76% amongst male and female respectively in the ratio of 1: 3.16. The majority of the study participants belonged to the age group of 51-60 years i.e. 15(30%) and the least in 20-30 years i.e. 5 (10%). Dacryocystitis is more common amongst females due to narrow lumen of the bony canal and it often results in partial or complete closure of the NLD.<sup>[6]</sup> Acute dacryocystitis is more common in 5th decade.<sup>[6]</sup> Acute dacryocystitis presents with complaints of local pain, watering and purulent discharge from eye, swelling of the lacrimal sac region and occasionally there may be pre septal cellulitis and lacrimal abscess. In the similar study by Dave et al the epiphora is commonest presentation in 100% of cases.<sup>[4]</sup> The study by Goyal R et al, persistent watering from affected eye in 44 cases, regurgitation of pus from sac in 34, mucocele in 18 and pyocele and fistula formation in 8 each.<sup>[7]</sup> In majority of the cases of this study the clinical presentation was epiphora in 50 (100%) and it was in accordance with above two studies, pain in lower corner of the eye in 38 (76%), swelling at medial canthus in 33 (66 %) and lacrimal abscess in 2 (4%) cases, whereas the least common was redness and swelling of eyelid consequent to preseptal cellulitis in 1 (2%) case. In study by Dave TV et al, majority of previous DCR cases are having inadequate ostium size (82%), commonest cause of failure is insufficient osteotomy 85.1% followed

by inadequate marsupialization of sac 77.7% and cicatricial closure of the ostium 55.5%.<sup>[4]</sup> In this study the causes leading to failure of DCR were inadequate ostium size in 41 (82 %) cases, followed by inadequate sac marsupialization 31 (62 %), cicatricial closure of ostium 26 (52 %) and it was in accordance with above two studies. Further, in this study the intranasal synechia and ostium malposition in 18 (36%) each, ostium stenosis 13 (26%), common canalicular obstruction 11 (22%) and deviated nasal septum 8 (16%) were the additional causes. The study conducted by Choussy et al revision endoscopic DCRs in 17 patients and reported ostium scarring in 13 (76.47%) patients and improper ostium site in 3 (17.64%) patients.<sup>[8]</sup> In this study the commonest cause of failure was inadequate ostium size in 41 (82%) cases. Hull et al in their study of failed endonasal DCR found 14 (74%) cases with failure due to ostium blockage as a result of scarring and the least common cause was high ostium 1(5%).<sup>[9]</sup>

In study by Goyal R et al, the patency of NLD is 85.10 %, whereas, partial block and clear fluid regurgitation in 06.38 % during 12 months follow up after surgery. In this study the NLD patency was confirmed by sac syringing at all follow ups after 1 week, 1 month and 3 months and 6 months post-operatively. Our findings was not in accordance with the study by Goyal R et al which could be due to almost double the period of follow up and sample size in their study.<sup>[7]</sup> In the study by Goyal R et al, during follow up over period of 1 year amongst their cases the complications are scarred and fibrosed ostium in 08, intranasal synechia formation in 07, ostium site granuloma with narrowing in 06, whereas common canalicular duct obstruction in 1.<sup>[7]</sup> Amongst all cases in this study, intra-operative complication were hemorrhage in 4 (8%), post-operative epistaxis 3 (6%) and local infection in 1(2%). However, no such complications mentioned by Goyal R et al were noted in this study.

Amongst 31 out of 50 cases of failed endonasal DCR in this study at dacryocystography and CT-PNS the cause of failure could not be ascertained whereas, the common canalicular obstruction, deviated nasal septum was found in 11 (22%) and 8 (16%) cases respectively.

**Conclusion**

The aetiological factors responsible for failure of endonasal DCR noted being many, the most common noted in this study during DNE was inadequate

ostium size in 41 (82 %) followed by inadequate marsupialization of sac 31 (62 %), cicatricial narrowing of ostium 26 (52%) and intranasal synechia and ostium malposition in 18 (36 %) each, ostium stenosis in 13 (26%). The pre-operative dacryocystography and CT-PNS per say in failed cases of DCR could not ascertain the cause for failure in 31 (62%) cases. The total number of female having failed DCR was more than three times higher than male (F: M -3.16 : 1).

**Summary:** The commonest aetiological factors for failure of endonasal DCR in this study was inadequate size of ostium followed by inadequate marsupialization of sac, cicatricial narrowing of ostium and intranasal synechia around ostium site whereas, the least common was malpositioning of neo ostium. The total number of female having failed DCR was more than three times higher than male. The findings of the present study suggests preoperative work up like paranasal sinus-CT scan and dacryocystography should be routinely undertaken for discovering the intranasal structural abnormalities so that the failure rate of endonasal DCR can be minimised. Meticulous endoscopic evaluation must be included as a part of preoperative work up in all cases for preventing failure of DCR.

**Acknowledgements:** We sincerely thank the departments of ophthalmology, radiology and anesthesiology for their cooperation during management of cases in this study. We are thankful to institutional research department for rendering financial support during the study.

**Conflict of Interest:** None.

This study was undertaken after prior ethical clearance from institutional ethics committee, vide letter No. KIMSDU/IEC/03/2017 dated 23/11/2017.

# Evaluation of Sensory Responsiveness in Children with Autism Spectrum Disorder

U. Ganapathy Sankar<sup>1</sup>, Monisha R.<sup>2</sup>

<sup>1</sup>Dean & Professor, <sup>2</sup>Ph.D. Scholar, SRM College of Occupational Therapy, SRMIST, Kattankulathur, Chennai

## Abstract

**Objective:** To identify the sensory responsiveness pattern using Dunn's Sensory Profile and severity of social impairment using Social Responsiveness Scale in children with Autism Spectrum Disorder.

**Methodology:** Cross sectional quantitative study design with convenient sampling was used. This study involved 20 children diagnosed with Autism Spectrum Disorder aged 5-6 from special School in and around Chennai. Caregiver's Sensory profile and social Responsiveness Scale was administered in order to quantify the severity and pattern of sensory responsiveness.

**Result:** Significant relation were found between social responsiveness scores and each of the six sensory system profile scores for children with Autism Spectrum Disorder

**Conclusion:** Atypical sensory responsiveness pattern is predominant in children with Autism Spectrum Disorder.

**Keywords:** Sensory responsiveness, Autism Spectrum Disorder, Primary schools, special schools.

## Introduction

Autism spectrum disorders (ASD) are complex neuro-developmental disorders that can cause problems with thinking, feeling, language and the ability to relate to others. The core feature includes persistent deficits in social communication and social interaction across multiple contexts, Restricted, repetitive patterns of behavior, interests, or activities which cannot be explained by intellectual disability and significantly impairs the functioning (DSM-5™ Diagnostic Criteria). Autism is known as a "spectrum" disorder because there is wide variation in the type and severity of symptoms people experience. ASD occurs in all ethnic, racial and economic groups. Although ASD can be a lifelong

disorder, treatments and services can improve a person's symptoms and ability to function<sup>1</sup>.

Abnormalities at the level of synapses, including newly described genetic perturbations and autism susceptibility genes, have been implicated in the pathogenesis of autism (Simone Khaliifeh et al 2016). Non-invasive modalities like Diffusion Tensor Magnetic Resonance Imaging have identified white matter tract involvement in the brains of autistic individuals and socio-emotional processing<sup>2</sup>.

Early and intensive intervention impact prognosis. Though no known medication relieves core symptoms of social and communication impairment, but fluoxetine is used to decrease anxiety and risperi done and aripiprazole are approved for irritability in autistic patient. Early identification and intervention with ABA(applied Behavior Analysis, speech, psychomotor and occupational therapies are crucial as is social integration. Early diagnosis and intervention with therapies remains the mainstay of insuring an improved outcomes and a better chance at full integration into society<sup>3</sup>.

The sensory systems are the sources for a living being to acquire information about the world, which support that being in successfully responding and adapting to the environmental demands (Claudia L. Hilton et al 2010). Sensory processing (SP) refers to the way that sensory information e.g. visual, auditory, vestibular or stimuli is processed and managed in the brain to generate adaptive responses to the environment and engagement in meaningful daily life activities (Johnson- Ecker & Parham 2000). SP theory suggests that optimal functioning in daily environments requires efficient reception and integration of incoming sensory stimuli and when this fails the individuals is unable to respond to sensory information with behavior that is regulated relative to the intensity of the input (Miller et al. 2007). Studies show that between 69% and 95% of individuals with an autism diagnosis experience sensory processing that is atypical (Ausderau, Baranek et al 2016). Sensory symptoms were first included as part of the ASD diagnosis in the most recent (2013) edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-5) and atypical sensory processing is now considered to be a core feature of Autism.

Dunn (1997) proposed a model for classifying patterns of dysfunction in SP according to individuals' behavioral response to stimuli and neurological thresholds, describing four patterns of SP dysfunction: Low Registration, Sensation Seeking, Sensory Sensitivity and Sensation Avoiding<sup>4</sup>. The most common atypical sensory processing that observed and studied in people on the autism spectrum are challenges with sensory modulation, where atypical responses to sensory stimuli make it difficult for the individual to function effectively within a particular environment (Hazen, Stornell et al 2014).

There are three types of atypical sensory modulation: (1). Sensory over- responsivity describes when an individual has an exaggerated negative response to sensory input, often leading to avoidance and hyper vigilance of the stimulus. (2). Sensory under-

responsivity describes when an individual may seem to be unaware of, or slow to respond to, a stimulus that would typically be expected to elicit a response. (3). Sensory-seeking behavior describes when an individual has an unusual craving for, or preoccupation with, certain sensory experiences. Many people on the autism spectrum experience a combination of sensory under- and over- responsivity (Baranek 2002). In addition, their sensory-seeking behaviors are associated with both under- and over- reactivity<sup>6,7</sup>. (Lane, Baker et al. 2010.). Abnormalities occurs across all sensory domains, including tactile, vestibular, auditory and visual (Harrison and Hare 2004, Rogers 1998) and in the absence of known peripheral dysfunction such as a visual or hearing loss (Baranek 2002).

## Methodology

Children diagnosed with Autism Spectrum Disorder aged 5-6 was selected from Child Therapy Service and special schools around Chennai. Twenty children diagnosed with ASD were recruited through the convenient sampling from there habilitation centers, hospitals and special schools in Chennai. All the participants were selected following physician diagnosis confirmed by the DSM-IV-TR criteria and Children with Intellectual Disability and other neuro development disorder, visual and hearing impairment were excluded. The purpose of the study was explained to the caregivers of the children with ASD. Written consent form was obtained from the caregivers and duly filled and signed demographic details were obtained. After obtaining the written consent the participants were administered sensory profile in order to quantify these verity of sensory issues

## Result

The Spearman rank correlation coefficient was used to compare the SP sensory raw scores with the SRS raw scores raw scores were also used to quantify the sensory responsiveness for each of the senses.

**Table 1: Demographic DATA**

S.No.	Demographic Variables	Class	No. of Children	Percentage
1	Age	5 Years	9	20.7%
		6 Years	11	79.3%
2	Gender	Male	15	76.7%
		Female	5	23.3%

**Table 2: Sensory profile score for children with Autism Spectrum Disorder based on gender**

S.No.	Domains Of Sensory Profile	Gender	Mean	SD
1	Auditory Processing	Male	20.11	5.122
		Female	35.13	5.555
2	Visual Processing	Male	32.40	4.233
		Female	34.15	4.532
3	Vestibular Processing	Male	40.12	3.747
		Female	43.11	3.847
4	Touch Processing	Male	72.21	18.748
		Female	70.22	14.384
5	Multi-Sensory	Male	22.35	4.648
		Female	25.34	4.748
6	Oral/Olfactory Sensory	Male	45.31	6.748
		Female	42.24	6.433

**Discussion**

Table 1 shows the characteristics of the participants based on the age and gender distribution. Most of the children were between the age of 5-6. Table 2 shows the mean scores of the following component of the sensory profile based on gender: auditory processing, visual processing, vestibular processing and touch processing, multi sensory and oral/olfactory processing. It displays the pattern of distribution of atypical sensory processing in various domains and shows very less difference in the scores between male and female children therefore indicating similar atypical sensory pattern in both the genders. Atypical sensory modulation is an important consideration in diagnosis and treatment of AS D. Difficulties in sensory responsiveness are often among the first indicators of autism noticed by parents and therefore, may be useful to facilitate early diagnosis and intervention (Bakeretal. 2008). The earlier ad is order is recognized, the earlier a child is able to receive help and the more effective outcomes of treatment can be achieved.

Additionally, there lationship between sensory modulation and other autistic traits seems more important than previously recognized and addressing sensory responsiveness issues in children with ASD may be more critical than previously understood. atypical scores from multi sensory responsiveness and responsiveness of the proximal senses of oral sensory/olfactory and touch as the strongest predictors of greater social impairment in the participants. This study would increase the understanding of OT practitioner on differential associations of sensory

responsiveness with autism and could contribute to development of intervention linking sensory processing with social, communication and language functioning in children with autism. It would help OT practitioner in assessing sensory processing patterns in young children with autism for earlier identification of children with a poor prognosis for later social and/or communicative competence. This may offer sensory implications for diagnosis and intervention addressing social issues in children with ASD for OTs.

**Conclusion**

Atypical sensory responsiveness is often one of the first signs that parents notice in their children with autism and therefore, may facilitate early diagnosis and intervention. Atypical responses to multi-sensory, touch and oral sensory/olfactory stimuli were identified as possible predictors of social severity.

## Abstract

**Introduction:** Diabetes is the chronic metabolic disease with rising prevalence in low and middle income countries. According to WHO diabetes is the seventh leading cause of death in 2016 and is major cause for complications like cardiovascular diseases and stroke. Hence, early identification of people at risk of diabetes is required to reduce the disease burden.

**Objectives:** To assess the diabetes risk among the adult population using Indian Diabetes Risk Score. To identify the factors associated with the diabetes risk score.

**Materials and Method:** A community based cross sectional study was done in an urban resettlement colony to identify the people at risk of developing type 2 diabetes. Indian Diabetes Risk Score was used to identify at risk individuals. The study subjects were categorized into low, medium, high risk groups based on IDRS scores. Random blood sugar levels of subjects were obtained at time of data collection after taking informed consent. The data was entered in Microsoft Excel and analyzed by using SPSS version 21. Chi square test was used to find any significant association between socio-demographic profile, RBS values and risk categories.

**Results:** In the study among 129 subjects, 64.3 % were males, 35.7% were females. IDRS scores indicate 12(9.3%) were in the low risk, 53(41%) were in medium risk and 64 (49.7%) were in high risk category. About 21.7% had Random blood sugar values  $\geq 200$ mg/dl at the time of study. There was significant association between RBS values and IDRS.

**Conclusion:** The present study showed that majority of subjects were in medium and high risk categories. Hence, the study recommended life style modification and further monitoring of blood glucose levels to prevent the risk of development of diabetes.

**Keywords:** Adult population, community, diabetes risk, Indian Diabetes risk score, Coastal Andhra Pradesh.

## Introduction

Non-communicable diseases (NCDs), including heart disease, stroke, cancer, diabetes and chronic lung disease, are collectively responsible for almost 70%

of all deaths worldwide. Almost three quarters of all NCD deaths and 82% of the 16 million people who died prematurely, or before reaching 70 years of age, occur in low- and middle-income countries.<sup>1</sup> The rise of NCDs has been driven by non-modifiable risk factors like age, gender, family history and modifiable risk factors tobacco use, physical inactivity, the harmful use of alcohol and unhealthy diets. Thus for NCD principles of primordial, primary prevention have to be applied for early detection of risk factors. These lead to identification

of “Risk Scores or Tests”. Several diabetic risk scores have been devised for the last decade for prevention programs in the USA, Scandinavia and U.K.<sup>2,3</sup>. All these scores are useful mass screening tools which are based on population based criteria from the respective countries. Mohan et al group from the Chennai Urban Rural Epidemiology Study (CURES) have attempted to develop a simple user friendly Indian Diabetes Risk Score.<sup>4</sup>

India currently represents 49% of the world’s diabetes burden, with an estimated 72 million cases in 2017, a figure expected to almost double to 134 million by 2025. Diabetes prevalence has increased by 64% across India.<sup>5,6</sup> Up to 2 % of women aged 15-19 years and 2.6 % aged 20-25 years had high or very high blood glucose levels. In men, this rose to 2.9 % and 3.7 %, respectively (NFHS 2015-16). Currently, 1 in 4 under age 25 years has adult-onset diabetes.<sup>7,8</sup> Challenges like early-onset diabetes, genetically predisposition, poverty, illiteracy, non-adherence to diabetic management etc indicate that diabetes must be carefully screened and monitored regardless of patient age within India.<sup>9,10</sup> About 66% of Indian Diabetics are not diagnosed as compared to 50% in Europe and 33% in USA. There is a need to unmask hidden burden of the disease. The IDRS has a sensitivity of 72.5% and specificity of 60.1% and is derived based on the largest population based study on diabetes in India CURES.<sup>11,12</sup> IDRS uses two modifiable risk factors (waist circumference and physical inactivity) and two non-modifiable risk factors (age and family history of diabetes), providing a clear message that if modifiable risk factors are altered, the risk score can be considerably reduced. This score may be incorporated into the proposed Indian National Diabetes Program and surveillance studies on NCD by WHO and ICMR.<sup>13</sup>. Hence the present study was conducted to assess risk for diabetes among adult population using IDRS.

### **Objectives:**

1. To assess the diabetes risk among the adult population using Indian Diabetes Risk Score.
2. To identify the factors associated with the diabetes risk score.

### **Materials and Method**

**Study Design:** A Community based cross-sectional study

**Study Setting:** Urban resettlement colony in the

urban field practice area of GITAM Institute of Medical Sciences and Research, Visakhapatnam, Coastal Andhra Pradesh.

**Study Period:** January- February 2019

**Sample Size:** 129

**Sampling Method:** Purposive sampling

**Procedure of data collection:** An urban resettlement colony was selected for the study in the urban field practice area of GITAM Institute of Medical Sciences and Research, Visakhapatnam. A regular free medical camp was conducted in the area in the month of January 2019. The study participants were selected from the population attending the camp based on inclusion and exclusion criteria. Data was collected using a Questionnaire including variables related to Socio-demographic profile and Indian Diabetes Risk Score (IDRS). The IDRS was based on four simple parameters namely age, abdominal obesity, family history of diabetes and physical activity. The information for these risk factors was obtained based on four simple questions and one anthropometric measurement namely waist circumference. Subjects with an IDRS value of  $\geq 60$  was categorized as high risk, 30-50 moderate and,  $< 30$  as low risk. The purpose of the study was explained and informed consent was taken from the subjects. Socio-economic status was assessed by using Modified kuppaswamy scale for 2019. The height, waist and hip circumference of the study subjects were measured in centimeters by using a non-stretchable measuring tape following WHO STEPS protocol.<sup>14</sup> The weight was measured in kilograms with the help of standardized weighing scale. BMI, WHR were calculated. The blood pressure of the participants was measured using a standardized sphygmomanometer in mmHg and BP  $\geq 140/90$  is considered as hypertensive according to JNC VII classification.<sup>15</sup> The levels of the Random blood sugar (RBS) of the participants were detected at the time of data collection by using standard glucometer.

### **Inclusion Criteria:**

1. All persons attending camp with age  $> 18$  years.
2. Those who are not clinically diagnosed as having diabetes.
3. Those who are willing to participate in the study.

### **Exclusion Criteria:**

1. Those who are already diagnosed to have diabetes.

2. Pregnant women, chronically ill patients.
3. Those who are not willing to participate in the study.

**Statistical Method:** Data was entered in Microsoft Excel and analyzed by using SPSS software version 21. Chi-square test was used to test the association between categorical variables and  $p < 0.05$  was taken significant.

### Results

About 129 subjects participated in the present study. **Table No. 1** represents the socio-demographic profile of the participants. The study subjects were in the age group of 22 to 65 years of age with mean age 39.71 years and  $SD = 12.211$ . Among the study participants 64.3 % were males, 35.7% were females. The distribution of participants based on education, occupation, socio-economic status is shown in **Table No. 2**.

The distribution of the subjects based on WHO cut off values (Asian standards) for BMI and anthropometry for men and women is represented in the **Table No. 3**. Among males ( $n = 83$ ), 62.66% had waist circumference  $\geq 90$  cm and 55.4% had waist hip ratio  $> 0.9$ . Among females ( $n = 46$ ), 82.6% had waist circumference  $\geq 80$  cm and 43.48% had waist hip ratio  $> 0.85$ . Among the participants 42.6% were obese based on BMI.

About 14.7% of the men were current smokers and 10.1% were current alcoholics. In the study participants 10.1 % were known hypertensive. About 14% of the individuals had blood pressure  $\geq 140/90$  and 21.7% had Random blood sugar values  $\geq 200$ mg/dl at the time of study as shown in **Table No. 4**.

The distribution of the study subjects into low, medium, high risk groups based on their IDRS scores is shown in **Figure no. 1**. Out of 129, 12(9.3%) were in the low risk, 53(41%) were in medium risk and 64 (49.7%) were in high risk category.

The study showed no significant association between socio-demographic variables and IDRS categories. The study participants were categorized into two categories based on their RBS values as individuals with  $RBS \geq 200$ mg/dl and others with  $\leq 200$ mg/dl. Chi-square test was done to find any significant association between RBS values and IDRS. The study showed a significant association between RBS values and IDRS as shown in **Table No. 5**.

## Discussion

The present study was done among 129 subjects to identify the risk of development of diabetes by using IDRS. Although various risk factor scoring systems (Ramachandran et al)<sup>16</sup> were developed previously, IDRS developed by Mohan *et al*<sup>4</sup> is considered simple, fast, inexpensive, non-invasive and reliable tool to identify individuals at high risk of type 2 diabetes which has been previously validated by other researchers in India. The IDRS scoring system clearly indicates that the risk of development of diabetes can be minimized by modifying the modifiable risk factors. In the study, out of 129, 12 (9.3%) were in the low risk, 53 (41%) were in medium risk and 64 (49.7%) were in high risk category. Similarly in the studies done by Mohan V et al<sup>4</sup> in Chennai city, Gupta et al<sup>17</sup> in urban Pondicherry, Nagalingam S<sup>18</sup> et al in semi urban area of Tamil Nadu the study subjects in high risk group were 43%, 31%, 37% respectively. In the studies done by Randip C et al<sup>19</sup> in rural West Bengal and Brinda P et al<sup>20</sup> in rural Karnataka the population in the high risk category were 31.5% and 25.7% respectively. The differences in the risk score among different studies might be due to differences in socio demographic profiles.

In the study, subjects were tested for RBS levels as it is the most convenient method and can be done in large scale at any time of the day depending on availability of the person and does not need venipuncture. In the present study 31.25% of the subjects in high risk group were having RBS  $\geq 200$ . Similarly in the studies done by Sumana M et al<sup>21</sup> and Arun A et al<sup>22</sup> 35% and 47% of the high risk group were having RBS  $\geq 200$  respectively. Thus validating IDRS. Various other studies were done (Vardhan A et al, Stanley JML et al, Adhikari P et al)<sup>23-25</sup> validating the IDRS score. Hence IDRS tool is cost effective in screening risk of type 2 diabetes in a developing country like India with rising burden of diabetes and where most of the people are unaware of their diabetes status.

## Conclusion

In the present study majority of the participants were in medium and high risk categories based on IDRS scores. The study showed significant association between RBS values and the IDRS. Hence the study showed that IDRS is a cost effective mass screening tool for early identification of people at the risk of developing diabetes.

**Recommendations:** All the subjects with RBS value more than the cut-off were advised to undergo further confirmatory test and follow up for diabetes. Those who belonged to IDRS moderate and high risk categories were advised lifestyle modifications and dietary changes. Those who were in the low risk category were advised health promotion activities.

# Passive Tobacco Exposure in School Age Children with Recurrent Respiratory Illness using Salivary Cotinine Assay

Vijay Simha, Ashwini P.S., UllalHarshini Devi<sup>1</sup>, Rathika D. Shenoy

<sup>1</sup>Junior Resident, <sup>2</sup>Senior Resident, <sup>3</sup>Professor, Department of Paediatrics, <sup>4</sup>Research Assistant, Central Research Laboratory, K.S. Hegde Medical Academy, Nitte (Deemed to be University), Mangalore

## Abstract

The micro (indoor) and macro (outdoor) environments play a significant role in recurrent respiratory illnesses in school-age children. Passive tobacco exposure is a leading underestimated cause of respiratory disease burden.

**Aim:** To assess passive tobacco exposure in school-age children with recurrent respiratory illness by measuring salivary cotinine.

**Method:** It is a cross-sectional study that included 160 children between 5 and 15 years with recurrent upper and lower respiratory illness. A validated questionnaire was administered for patterns of respiratory illness, socioeconomic status, micro and macro environment exposures with emphasis on tobacco. Salivary cotinine was measured by ELISA and value >10ng/ml was considered equivalent to passive tobacco exposure. Descriptive statistics were applied to compare tobacco exposed and unexposed groups. Chi-square test and binary logistic regression were used to calculate significance.

**Results:** History of exposure to ETS and/or tobacco dust within households was present in 30.6%. In 23.1%, bidi rolling was a family occupation. Passive tobacco exposure as determined by cotinine assay was present in 63.7%. Salivary cotinine levels ranged from none to 21.2ng/mL with a median of 12.04ng/mL. Among children with elevated cotinine, the history of tobacco exposure was present only in 38.2%. Residing in joint family was significant ( $p=0.009$ ) for elevated cotinine levels. There was no identifiable single significant risk factor including tobacco exposure for asthma.

**Conclusion:** Passive exposure to tobacco is an underestimated risk factor in childhood respiratory illness.

**Keywords:** Asthma; Bidi rolling; Environmental tobacco smoke; Nicotine.

## Introduction

**Background:** Childhood respiratory illness is a major cause of morbidity in low- and middle-income

countries.<sup>[1]</sup> Both the micro environment (housing characteristics) and the macro environment (outdoor air pollution) play a major role in childhood respiratory illnesses.<sup>[2]</sup> Recurrent childhood respiratory diseases especially asthma can be prevented or ameliorated by several basic measures and this includes improving living conditions, avoiding tobacco smoke exposure and reducing air pollution. Environmental tobacco smoke (ETS) is a leading cause of respiratory disease burden.<sup>[2-4]</sup> From side stream smoke, children are passively exposed to nicotine, sulfur dioxide and polycyclic aromatic hydrocarbons. It is estimated that globally, 40% of children are exposed to ETS within their households.<sup>[5]</sup>

Gupta et al. have shown a positive association between the prevalence of all respiratory symptoms and asthma in children with tobacco exposure.<sup>[2]</sup> Exposure to ETS is correlated with recurrent otitis media and tonsillitis as well.<sup>[3]</sup>

About 34% of smokers in India use bidis.<sup>[6]</sup> The content of tobacco and therefore nicotine is higher in a bidi than the conventional cigarette.<sup>[7]</sup> In addition, bidi rolling with exposure to tobacco dust is a traditional household occupation in most states of India.<sup>[6]</sup> Cotinine is a metabolite of nicotine and is a reliable biomarker for nicotine estimation and can be assayed from serum, saliva and urine. Salivary cotinine assay provides valid and quantitative measures of average ETS exposure.<sup>[8]</sup> Studies have used salivary cotinine assay as an objective measure to assess exposure to ETS in children with respiratory illness.<sup>[3,4,9,10]</sup> There are no Indian studies on cotinine estimation in childhood respiratory illness.

Children are vulnerable to adverse health effects because of the immature lung and immune system. We hypothesized that exposure to ETS by history alone would underestimate its contribution to recurrent respiratory illness. The contribution of bidi rolling practices to the micro environment is often overlooked. The aim of the present study was to establish the contribution of passive exposure to tobacco smoke and dust in school-age children with recurrent respiratory illness by history and quantitative estimation of salivary cotinine. We also looked at the contribution of individual factors in the persistence of asthma.

## Method

**Design:** It was a cross-sectional study done in rural outreach centers attached to a teaching hospital. School children, 160 in total, aged between 5 and 15 years with recurrent upper and lower respiratory illness with a history of at least one acute episode in the last six months were included. The sample size was calculated based on the formula:  $[(1.96)^2 \times p(1-p)]/d^2$ , where  $p$  is the prevalence (0.4),  $d$  is the precision (20% of  $p$ ).<sup>[11]</sup> Diagnosis of recurrent upper and recurrent lower respiratory illnesses were made using standard definitions.<sup>[11]</sup> Children with systemic conditions contributing to recurrent respiratory illnesses like congenital heart disease, gastroesophageal reflux, chronic systemic diseases and severe malnutrition were excluded.

**Demographic Data:** The questionnaire used in the study was adapted from the International Study of

Asthma and Allergies in Childhood. It consisted of three parts that included information on socio-demographic data, micro and macro environment exposures.<sup>[12]</sup> Socioeconomic status was assessed by the updated Kuppuswamy scale.<sup>[13]</sup> Exposure to tobacco dust through bidi rolling practices in the family was also ascertained. The questionnaire was validated before use and administered to either of the parent. All children were clinically examined and diagnosis documented.

**Lab:** A salivary sample of three ml was collected by asking the child to pool saliva in the mouth and then blow into the sterile container with a straw. The collected sample was stored at -80°C until analysis. Cotinine assay was done by enzyme-linked immunosorbent assay using a commercial kit (Calbiotech, USA). Salivary cotinine level >10ng/ml was considered equivalent to heavy passive exposure to tobacco.<sup>[14]</sup> The test was repeated twice for confirmation.

Institutional Ethical Committee approval was obtained prior to the initiation of the study. Written informed consent was obtained from a caregiver (either parent). For children  $\geq 12$  years an assent was taken along with parental consent.

**Statistical Analysis:** The software Statistical Package for Social Sciences version 20.0 (IBM SPSS, USA) was used for analysis. Demography, family reported exposures, pattern of respiratory illness and clinical data were expressed in percentages. Median with interquartile range (IQR) was used for central tendency. Based on the salivary cotinine level, children were categorized into those with and without heavy passive exposure to tobacco. Chi-square test ( $\chi^2$ ) was applied for the comparison of the two groups. Mann Whitney U test was used to compare the salivary cotinine values in those with and without the history of tobacco exposure. Binary logistic regression was used to assess the significance of tobacco exposure as a risk factor for asthma. A  $p$  value < 0.05 was considered significant.

## Results

The median age of the study population was 8 years (IQR 36 months). About two-thirds were boys (66%,  $n=106$ ). Table 1 gives the pattern of respiratory illness among the study population. The median age at onset of symptoms was 48 months (IQR 24 months). On average, children had six episodes of acute respiratory illness in a year. About 34% of had a prior hospital admission.

Table 2 gives the risk factors related to micro and macroenvironments in the study. Exposure to ETS and/or tobacco dust within households was present in 30.6% (n=49). Among them, the family occupation of bidi rolling was present in 23.1% (n=37). None committed to passive exposure in the school environment or neighborhood. Salivary cotinine levels ranged from none to 21.2ng/mL. Median salivary cotinine was 12.0ng/mL (IQR 4.9 ng/mL). A value >10ng/mL was seen in 63.7% (n=102). Nearly 81.6% residing in joint accommodation had elevated cotinine and this was statistically significant ( $\chi^2=6.85; p=0.009$ ). Among those with a history of household tobacco exposure (n=49), increased salivary cotinine was present in 75.5% (n=37). The median cotinine value in this group was 13.8 (IQR 5.5)ng/mL. Table 3 gives the median salivary cotinine for children with individual forms of tobacco exposure. Among children with elevated cotinine, there was no history of exposure to tobacco in 61.8% (n=63).

Table 4 shows the pattern of respiratory illness in children with a history of exposure to ETS and elevated cotinine. A comparison of measured salivary cotinine in those with and without a history of tobacco exposure showed that salivary cotinine in those children with a definite history of exposure was significantly higher than those with unknown source of exposure (U=3359 and p=0.018). There was no identifiable single significant risk factor including tobacco exposure for asthma.

Multiple	18 (36.7)	29 (28.4)

## Discussion

The airways of children are vulnerable to adverse micro and macroenvironment. The resting metabolic rate, oxygen consumption per unit body weight, oxygen demand, respiratory rates are higher in children and this with narrower airways makes them susceptible to allergens. Immunological and molecular influences can contribute to the infants propensity to wheeze which the children outgrow as they grow older.

In our study, exposure to ETS and/or tobacco dust within households was present in about one-third. These children had higher cotinine values than those without. Bidi rolling is an important home industry in the study area. The exposure to tobacco dust through bidi rolling was considerably higher than the exposure to tobacco smoke in our setting. The content of nicotine in a bidi and conventional cigarette is 2.4mg and 1 mg respectively.<sup>[7]</sup> Each bidi contains 0.2-0.3g of tobacco dust. With an average of 500-1000 bidis rolled per day per member of the family, children are exposed to 1.2-1.4g of nicotine in a day.<sup>[6]</sup> In households with bidi rolling, a week's requirement of tobacco is stored and women's family members get together to roll bidis. Children residing in joint families had significantly higher salivary cotinine values.

About 60% of children in our study had elevated cotinine and the source for exposure was not ascertained in the majority. Certain foods like potatoes, tomatoes, cauliflower and black tea contain nicotine. Dietary nicotine consumption accounts for only 10% of the total nicotine exposure experienced by a person with significant ETS exposure. Half-life of cotinine is 17 hours whereas nicotine half-life is 2-3 hours. The half-life of cotinine in children is reported to be 28 hours higher than that of adults.<sup>[15]</sup> In the questionnaire study

by Gupta et al., 30% of schoolchildren reported exposure to ETS within their households. Passive exposure was seen in 41% of asthmatics.<sup>[2]</sup> Kumar et al. found elevated salivary cotinine in 68.5% of children with persistent asthma; only 49.6% reported exposure.<sup>[4]</sup> A cotinine-validated exposure was seen in 45.6% of children with asthma in the study by Delpisheh et al.<sup>[9]</sup> About 30% of mothers and 28% of fathers reported smoking. The pattern of illness in children with elevated cotinine showed that tobacco exposure may be an important factor even in recurrent upper respiratory illness. Clark et al. found elevated cotinine in >50% of children undergoing surgery for tonsillectomy or middle ear disorders.<sup>[3]</sup> Nearly 47% of children including controls had objective evidence of ETS exposure in this study, though history was forthcoming only in 40%.

Analysis of other socio-demographic data suggested that prematurity, low birth weight and inadequate breastfeeding were not major risk factors in comparison to the micro and macroenvironment. Vedanthan et al. from southern India noted that 26% of children were not exclusively breastfed among children with respiratory illness.<sup>[16]</sup> Risk factors related to micro and macroenvironment were based on history and not by field survey and this would be a limitation of the study.

In conclusion, exposure of children to tobacco smoke and dust is an underestimated but an important contributing factor in childhood respiratory illness. Bidi rolling as a family occupation should be ascertained. Salivary cotinine estimation is a simple and useful test to establish exposure and will also help in quantifying the severity of exposure.

# A Retrospective Study on Most Common Symptoms in Dengue Viral Infection of Paediatric Age Group Presented in a Tertiary Care Hospital, Visakhapatnam

Yasaswini Sabbineni<sup>1</sup>, Pilli Hema Prakash Kumari<sup>2</sup>, Payala Vijayalakshmi<sup>3</sup>

<sup>1</sup>Assistant Professor, Dept. of Paediatrics, Gayatri Vidya Parishad Institute of Healthcare and Medical Technology, Maridi Valley, Marikavalasa Village, Madhurawada, <sup>2</sup>Professor and HOD, <sup>3</sup>Assistant Professor, Dept. of Microbiology, GITAM Institute of Medical sciences and Research, GITAM (Deemed to be University), Rushikonda, Visakhapatnam, India

## Abstract

**Background:** Dengue is a virus infection caused by four dengue virus serotypes (DENV1-DENV4). Children diagnosed with dengue virus have symptoms ranging from mild fever to dengue haemorrhagic shock. The present research is a retrospective analysis designed to determine the prevalence rate of dengue viral infection in pediatric cases with primarily gastrointestinal symptoms.

**Study Design:** It is a retrospective study.

**Method:** The study was conducted in the Department of Paediatrics at the Tertiary care Hospital, Visakhapatnam from June 2018 to October 2018. A maximum of 85 OPD/IPD cases have been registered in the study for a period of five months. The research examined clinical, laboratory, treatment and outcome data for 85 children (6 months to 14 years of age) admitted to hospital with fever and suspected dengue diagnosis. Full medical history of all dengue cases including signs and symptoms, method of diagnosis, management, length of stay and clinical outcomes are collected from patient information. Pan Bio ELISA was performed as a confirmatory test.

**Results:** Among the 85 suspected cases of dengue reported to OPD/IPD 65(76%) were confirmed as dengue positive and 20(24%) were found to be non-dengue cases with ELISA. Gender wise distribution of dengue positive cases, more cases were noticed in males 35(53%). Prevalence was more in the age group 5-11 years 24(37%). Among the 65 positive cases of dengue, more number of cases were supported with fever 65 (100%) followed by GI symptoms like vomiting 31(47%), nausea 26(40%) and diarrhoea with abdominal pain 29(44%).

**Conclusion:** This study will provide a clear insight into the prevalence of dengue in children, the symptoms of the disease and the outcome. The understanding of dengue in children, including its clinical manifestations, pathogenesis, diagnostic tests, management and prevention, is very important in reducing the mortality rate.

**Keywords:** Dengue, ELISA, Prevalence, Paediatric age group.

## Introduction

Dengue fever is one of the most prevalent infectious diseases in the world and is growing every year. The average seroprevalence of dengue viral infection in India is 48.7 per cent, rising from 28.3 per cent for children aged 5–8 years to 41.0 per cent for children aged 9–17 years and 56.2 per cent for individuals aged

18–45 years. Seroprevalence is high in the southern, western and northern regions of the country<sup>[1]</sup>. Dengue is a viral infection caused by four serotypes (DENV1-DENV4) of dengue virus belonging to the flaviviridae family. Individuals infected with any serotype will have long-term immunity from virus re-infection, but only partial protection against infection with another dengue virus serotype. Such infections with different serotypes often lead to severe clinical manifestation such as dengue haemorrhagic fever (DHF) and dengue shock syndrome (DSS). Other Arboviral diseases that are present in India, are Japanese encephalitis, West Nile viral disease, Chikungunya fever, Crimean-Congo hemorrhagic fever and Kyasanur forest disease<sup>[2]</sup>. This virus is spread by the mosquitoes *Aedes aegypti* and *Aedes albopictus*. Over the last 30 years, the spread of dengue and its vector has increased dramatically due to insufficient vector control, increased urbanization and air travel. In July 2017, in India, NVBDCP (National Vector Borne Disease Control and Prevention) reported about 28,702 cases of dengue dengue, with 46 deaths of dengue haemorrhagic fever reported as a major cause of death in children. Children infected with dengue virus present with symptoms ranging from mild fever to dengue haemorrhagic shock. Symptoms such as fever, myalgia, nausea, vomiting, rash, body aches and leukopenia include probable dengue symptoms. Warning signs include abdominal pain, persistent vomiting, fluid build-up and enlargement of the liver. In severe dengue shock, fluid accumulation and involvement of other organs is seen. Therefore, early prognostication of potentially severe dengue cases, especially in children, will aid in the timely and appropriate management and thereby improve the outcome. Cutaneous involvement can facilitate clinical diagnosis, however it is not present in all patients. There is no significant difference in complications and mortality in patients with DF with or without skin rash<sup>[3]</sup>. Rapid and accurate diagnosis of dengue in the acute phase of illness is important for initiation of therapy as well as for early enhancement of epidemic control measures especially in low endemic areas<sup>[4]</sup>. Diagnosis is done by detection of specific IgM antibody by ELISA which rise after 4-5 days of fever. Tests to detect NS1 antigen can also be performed but are less reliable<sup>[5-6]</sup>. The present investigation is a retrospective study designed to find out the prevalence rate of dengue viral infection in paediatric cases presented mainly with gastrointestinal symptoms.

## Materials and Method

**Study design:** It is a retrospective study conducted in the Department of Paediatrics in a Tertiary care hospital, Visakhapatnam from June 2018 to October 2018. This study was reviewed and approved by The Ethics Committee of GITAM Institute of Medical sciences and Research, Tertiary care hospital, GITAM (Deemed to be University).

### Inclusion Criteria:

- Age: varied from 6 months to 14 years
- Children presented with dengue fever to OPD and suspected cases of dengue

### Exclusion Criteria:

- Febrile cases with other proven etiology (malaria, typhoid upper respiratory tract infections)
- Negative cases for dengue serology.
- Cases with any co-morbidity that may alter the laboratory and/or clinical findings such as other viral infection.

**Study population:** A total of 85 recorded OPD/IPD cases were taken into the study for a period of five months. Data regarding most common clinical signs and symptoms like fever, arthralgia, myalgia, head-ache, body-aches, skin rash, bleeding manifestations and gastrointestinal (GI) symptoms like vomiting and pain abdomen were noted. The study reviewed the clinical, laboratory, treatment and outcome data of 85 children (6 months to 14 years of age) admitted to the hospital with fever and a suspected diagnosis of dengue. Complete medical record of all dengue cases which included signs and symptoms, method of diagnosis, management, duration of stay and clinical outcome was retrieved from patient's information reports. The study included children (<14 years of age) serologically diagnosed as dengue-positive at the time of admission using the dengue IgM specific antibodies ELISAs (Panbio® Dengue IgM capture ELISA, Alere™, Australia). According to the WHO recommendations (2009), all cases were classified clinically as severe dengue, DS and DWS. The Dengue IgM capture ELISA determines the level of IgM antibodies to dengue in a patient's serum. Children with confirmed dengue diagnosis (tested positive for IgM ELISA) were considered as dengue-positive group with IgMELISA titre value of >11 Pan-Bio Units (PBU), while the rest were grouped as non-dengue fever/other febrile illness (<9 PBU) and equivocal dengue (9-11

PBU). A positive result is indicative of either an active primary or secondary dengue infection.

Optical Density (OD) was measured at 450 nm using ELISA reader method at Department of Microbiology and test results were interpreted either positive or negative or equivocal according to manufacturers' instructions. The sensitivity and specificity of detection quoted by the manufacturer were 94.7% and 100%, respectively. This diagnostic kit provided qualitative detection of IgM antibodies specific to dengue virus in human serum, dependent on the following principle. IgM antibodies in patients' serum are captured by antihuman IgM ( $\mu$  chain specific) coated on to the solid surface (wells). In the next step, dengue antigen is added, which binds to capture human IgM in the sample. Unbound antigen is removed during the washing step. In the subsequent step, biotinylated flavivirus anti-DEN monoclonal antibodies are added followed by Avidin-HRP. Subsequently, chromogenic substrate (TMB/H<sub>2</sub>O<sub>2</sub>) is added. The reaction is stopped by 1N H<sub>2</sub>SO<sub>4</sub>. The optical density is measured at 450 nm.

Statistical analysis: The collected data was coded using Excel sheet (Window 2010) and analysis was done using software SPSS 24.0 version. Chi-square test was used to compare the categorical variables and  $p \leq 0.05$  was considered statistically significant.

## Results

After enrolment, baseline information including demographic characteristics, clinical history and examination findings was documented using a structured case report form. Among the 85 suspected cases of dengue reported to OPD/IPD 65 (76%) were confirmed as dengue positive and 20(24%) were found to be non-dengue cases. By studying the influence of demographic variable age on the prevalence of dengue viral infection it was observed that the prevalence was more in the age group 5-11 years with the total cases reported were 24(37%) followed by 1-5 years 21(32%) cases, 11-14 years age 17 (26%) and less than one year age 3 (5%). By Gender wise distribution of dengue positive cases, more cases were noticed in males 35(53%) than females 30(47%). Among the 65 positive cases of dengue, more number of cases were supported with fever 65(100%) followed by GI symptoms like vomiting 31(47%), nausea 26(40%) and diarrhoea with abdominal pain 29(44%). However very few cases were reported with headache 12(18%) and malaena 2(5%) (Table 1). The results also found that more number of dengue positive cases were reported from rural areas 36(55%) than urban areas 29(45%) (Table 2). By using gold standard method like ELISA, out of the 85 reported cases 65 were confirmed as dengue positive and 20 cases were found to be non-dengue. Majority of the reported cases at the time of admission have more than one lakh of platelet count and very few cases were recorded in the range of 21,000 to 1,00,000 platelet count (Table 3 and Figure 1). Platelet transfusion had been done in some reported cases.

**Table 1: Clinical characteristics of study cohort**

S.No.	Signs and Symptoms	Dengue (N=65)		Non-Dengue (N=20)	
		Positive	Negative	Positive	Negative
1.	Head-ache	12	53	05	10

## Discussion

Dengue has the most varied presentation, it can present as simple self-resolving fever or as dengue shock syndrome. Early detection and treatment reduce the associated morbidity and mortality. In this study the authors attempted to retrospectively analyze the various demographic and clinical parameters associated with dengue fever in children of ages varying from 6 months to 14 years. The authors found that the incidence of dengue in infants was less compared to other age groups. The incidence was highest in the 5 to 11 year age group, followed by the 11 to 14 year age group. These age groups are generally more exposed to the outside environment. However in the study conducted by Padmanabhan et al. 2018)<sup>[7]</sup>, the highest incidence was found in the 1 to 5 year age group followed by 11 to 14 year age group. Mital et al. 2016)<sup>[8]</sup> found that prevalence was highest in the 11 to 20 year age group. Vazhayil et al. 2017)<sup>[9]</sup> found highest prevalence in 11 to 15 year age group. In this study there was a male predominance in the incidence of dengue fever, 53% male to 47% female. Vazhayil et al. 2017)<sup>[9]</sup>, Rafique et al. 2015)<sup>[10]</sup> found that male predominance in the incidence of dengue fever in their study. However Padhiet al. 2014)<sup>[11]</sup> in their study observed that there was a female predominance in the occurrence of dengue. The classical clinical presentation of dengue is this is not always observed in the clinical practice. In the present study fever was present in all cases (100%) and vomiting was the most commonly associated symptom (47%), followed by nausea (40%), arthralgia (30%), myalgia (32%), rash (30%), head-ache (18%), diarrhea (15%), abdominal pain (12%) and malena (3%). In a study by Vazhayil et al. 2017)<sup>[9]</sup> fever was present in all cases and the following symptoms were associated in the decreasing order of incidence vomiting, headache, myalgia, abdominal pain, petechial rash and malena. In a study by Alok Kumar et al. 2017)<sup>[12]</sup> fever was present in all cases and the following symptoms were associated in the decreasing order of incidence vomiting, respiratory distress, weakness, pain abdomen, myalgia and rashes. In a study by Arunet al. 2017)<sup>[13]</sup> there was increased incidence of neurological manifestations, which were not seen in the present study. In this study dengue was more common in the monsoon period (July to September). The study conducted by Bandyopadhyay et al. 2013)<sup>[14]</sup> had proved that there was an increased prevalence of dengue viral infection in the monsoon and post monsoon period. In this study there is higher incidence of dengue fever in rural than urban populations. Diagnosis of dengue fever

can be done using ELISA for IgM, IgG. Detection of NS<sub>1</sub> antigen and RT-PCR techniques. Samples must be taken within 1–5 days after the onset of symptoms, to detect the antigen NS<sub>1</sub> protein), within 1–6 days to detect IgM antibodies for enzyme-linked immunosorbent assay (ELISA) or a rapid test after day 5 of starting the symptoms, within 1–5 to detect IgG. In this study diagnosis was done by using IgM ELISA as this is more sensitive and more easily available. Out of total 85 cases 65 were positive and 20 were negative and were treated as sero negative cases of dengue. Total positive ELISA cases with low platelet count were 31 and six cases were ELISA negative with low platelet count. Total count was supposed to be low in dengue cases but in our observation only 12 ELISA positive and 3 ELISA negative cases had a low total count. Development of a dengue vaccine is considered a high public health priority. A safe and efficacious dengue vaccine would also be important for travelers.

## Conclusion

Now-a-days dengue viral disease is a common disease in this part of the world and one of the dreaded fevers for the paediatric age group. The disease has various presentations and features, but early diagnosis and management can decrease the mortality rate significantly. The present study retrospectively analyzed all the typical and atypical presentations, epidemiological data and investigations of dengue in paediatric age group. This study will give a clear insight on the prevalence of dengue in children, about the disease symptoms and the outcome. Fever and GI symptoms are most commonly presented in the study population of the current study which is accordance to the results of past literature. Understanding of dengue in children, including its clinical manifestations, pathogenesis, diagnostic tests, management and prevention is very important to reduce the mortality rate.

**Institutional Review Board Statement:** This study was reviewed and approved by The Ethics Committee of GITAM Institute of Medical sciences and Research, Tertiary care hospital, GITAM (Deemed to be University), Visakhapatnam.

# Impact of Internal Branding on Employee Engagement: An Empirical Study Conducted among Medical Staff's Brand Supporting Behaviour in Indian Hospitals

Asha Binu Raj

*Assistant Professor-Organizational Behaviour, Human Resource Management, Department of Human Resource Management and Soft Skills, ICFAI Business School (IBS), Hyderabad, ICFAI Foundation for Higher Education (IFHE), (Declared as Deemed to be University u/s 3 of the UGC Act 1956), Hyderabad, Telangana, India*

## Abstract

Building an internal brand is a critical function of service organizations today. The employee's attitude and behaviour must represent the organization's brand, values and culture. Internal branding is highly relevant in healthcare, where it includes a range of strategies aimed at employees to help them deliver the desired service to patients. This empirical research paper focuses on the impact of internal branding dimensions on employee engagement among medical staff in select Indian hospitals. The analysis of the data collected from a sample of 176 respondents using structured questionnaires show that internal branding dimensions such as internal communication, HR processes during internal branding, brand focused training and leadership assist in engaging the medical staff while providing healthcare services. Considering social exchange theory (SET) as the theoretical foundation, the research indicates that medical staff show high level of engagement when hospitals implement internal branding programs.

**Keywords:** *Internal branding, employee engagement, employee behaviour, internal communication, HR processes, brand focused training, leadership, hospital.*

## Introduction

Employee engagement is a measurable degree of an employee's positive or negative emotional attachment to their job, colleagues and organization that influences their willingness to perform at work. It is defined as the "harnessing of organization members' selves to

their work roles"<sup>1</sup>. When engaged, employees express themselves cognitively, behaviourally and emotionally at work during role performance.<sup>1,2,3</sup>

Engaged employees often display positive emotional connection with their work and workplace and are likely to display high level of attentiveness and psychological involvement in their work.<sup>2</sup> They are more productive, better performers, satisfied, healthier and less likely to leave their employer.<sup>4,5</sup> To create a service delivery driven organization, it is important to equate employee engagement with both long term (relational) as well as short term (transactional) relationship with the organization. Some healthcare organizations highly focus on implementing employee oriented initiatives to reap the benefit of brand supporting behaviour of their staff. Past studies predict a deficiency of medical staff comprising of nursing staff, specialists, generalist physicians and other clinicians, which will hamper healthcare organizations' ability to deliver high-quality healthcare services in the coming decade. Hence to

enhance the healthcare productivity and patient safety through quality service delivery, employees need to be engaged and aligned with the hospital brand.

Internal branding is one such multidisciplinary practice which helps in aligning hospital's strategies and values with the employee's values, thus creating a brand which employees can trust. It provides a competitive advantage as it consists of activities which help employees feel connected to their hospital. Internal communications and involvement of HR during internal branding implementation, along with proper brand focused training give them a feeling of belongingness which is crucial in aligning the staff with the hospital.

**Literature Review:** The studies conducted by Punjaisri et. al.<sup>6,7</sup> in hospitality sector provide an extended view of the internal branding. Löhndorf & Diamantopoulos<sup>8</sup> suggested the link between social identity and internal branding leading to employee behaviour. These studies have indicated that there are many internal branding factors which lead to employee engagement. Although Lee et al.<sup>9</sup> suggested internal communication, training and reward as key factors of internal branding, they fail to explain the descriptive influence of these factors in detail as well as how they affect engagement. Asha<sup>10</sup> explained the role of internal branding resulting in employees' brand based outcomes such as employee engagement in services sector through employees' well-being. Similarly, Huang & Lai<sup>11</sup> showed that successful hospital brand management enables employees to understand the hospital's brand value which affect their behaviour and job performance. Internal brand expresses the hospital's ability to align its mission, vision, values and professional practices which support a consistent health service to patients.<sup>12</sup> Hence the first hypothesis is formulated based on the above rationale.

Hypothesis H1: Internal branding has a positive impact on employee engagement.

Internal branding is a means to create a powerful corporate brand.<sup>13,14</sup> While expecting an employees' brand supporting behaviour, hospitals need to communicate their brand message. Hence internal communications should be the first point of focus in an internal branding program aiming to secure people's commitment and encourage behavioural change to support patient orientation. It plays a significant role in internal branding as it influences employee's brand

knowledge, attitudes and behaviour in hospitality industry.<sup>13</sup> Based on these arguments, the second hypothesis was formulated.

Hypothesis H2: Internal communication during internal branding has a positive impact on employee engagement.

Involvement of HR in internal branding has been studied by de Chernatony et al.<sup>14</sup> who claim that HR plays a vital role in implementation of internal branding through recruitment, rewards and other practices aligned with the brand values. Hence HR department need to be aware of brand values and should help in instilling these values in daily operations.<sup>15</sup> This is because it is the responsibility of HR practices to create a work environment to induce engagement.<sup>16</sup> Hence the role of HR in engaging the employees while implementing internal branding initiatives is explicit. The third hypothesis was based on these arguments.

Hypothesis H3: HR practices during internal branding have a positive impact on employee engagement.

Using training programs for building an internal brand is also considered very effective by employees.<sup>17</sup> Unlike the traditional trainings, these programs must be focussed on instilling brand values among the employees, educating them about the importance of brand values and how to align their work with brand values, how to carry out their specific roles,<sup>16</sup> how to treat customers,<sup>18</sup> which further engages them with their work and workplace. This has provided a rationale for the fourth hypothesis.

Hypothesis H4: Brand focused training during internal branding has a positive impact on employee engagement.

Another variable, leadership was repeatedly mentioned in the services branding literature as a mechanism of motivating employees to "live the brand".<sup>19</sup> Research indicates that change oriented, dynamic and people oriented leadership style can induce engagement. Patient orientation and service delivery are also essentially affected by the way internal brand is managed by the leaders in hospitals. Therefore leaders have an inevitable role in developing an internal brand in hospitals, which employees can trust and finally represent during their on role performance and interactions with patients. The fourth hypothesis was based on this rationale.

Hypothesis H4: Leadership role during internal branding has a positive impact on employee engagement.

**Theoretical framework:**

**Social exchange theory:** One of the most influential theories for understanding workplace behaviour is social exchange theory (SET), which explains that parties dwell by certain reciprocity rule which is best known as an exchange rule.<sup>20</sup> It explains that people make social decisions based on perceived cost and benefits during their employment tenure leading to an economic and a social exchange relationship. Blau's<sup>21</sup> contribution outlined the impact of exchanged benefits on employees' attitude and behaviour such as commitment and engagement. Internal branding incorporates many programs which engage employees through various social exchange processes. Hence the present study has considered SET for developing the theoretical framework and further tried to analyse the questions like what is the impact of internal branding dimensions on employee engagement, viewing this relationship as an exchange process.

In hospitals, employee engagement underpins increased patient safety. Adoption of a comprehensive employee engagement strategy has a major impact on patient satisfaction. SET provides a valid rationale to discuss the same and how it is influenced by internal branding. The purpose of this study, therefore, is to empirically analyse the impact of dimensions of internal branding on employee engagement among the medical staff in Indian hospitals.

**Method**

**Sample Design:** The study was conducted among a sample of 176 medical staff in select private hospitals in India. All respondents selected through a criterion sampling took part in a structured survey. Approximately 290 questionnaires were distributed in hard copies as well as online forms, from which 189 responses were received. Only 176 questionnaires could be further considered for analysis. The sample consisted of 71% female employees and 29% male employees. The demographic distribution of the sample reflected 74% employees with an experience of 2 years to 8 years in their current hospital, 23% employees with an experience of 9 years to 15 years in their current hospital and 3% employees with an experience of more than 15 years in their current hospital.

**Data Collection:**

**Measures of variables**

**Perception of internal branding:** Internal branding was measured as a 3-dimensional construct comprising internal communication, brand focused training and HR involvement in internal branding. The measurement items were adapted from Aurand et al.<sup>15</sup> and Punjaisri, et al.<sup>6</sup> The reliability test has shown a Cronbach's alpha value of 0.81 for the adapted internal branding scale.

**Employee engagement construct:** The study used Soane et al.'s<sup>22</sup> ISA Engagement scale, which comprised of three components of engagement: intellectual, social and affective engagement. This instrument has three dimensions with three items each.

**Results**

**Table 1: Means, standard deviations and correlations among the variables in the study**

	Variable	1	2	3	4	5	M	SD
1	Internal Communication	-					4.06	.69
2	HR practices during internal branding	.63	-				4.19	.65
3	Brand focused training	.40	.42	-			4.01	.75
4	Leadership	.50	.63	.67	-		3.82	.69
5	Employee engagement	.66	.75	.60	.57	-	3.97	.70

**Note:** Correlations are significant at 0.01 level respectively. Correlation coefficients of 0.5 or greater are significant at p<.01, N= 176

As observed in table 1, descriptive statistics show that HR practices during internal branding have the maximum mean value (4.19) among all the variables and leadership has the minimum mean value of 3.82. Involvement of HR department in various brand building activities was the profound tool used in internal branding.

Table 1 also shows correlation between dimensions of internal branding and employee engagement. Involvement of HR, internal communication through various media and provision of necessary brand oriented training to the medical staff at all levels can help in stronger incorporation of brand message into operational activities. This would reinforce the brand values in medical staffs' attitude towards the brand. Leadership too moderately affects the effectiveness of implementation of these internal branding dimensions, facilitating the brand supporting behaviour, i.e., engagement. Results of table 1 provide support for all proposed hypotheses. This is further tested by regression analysis.

**Table 2: Model summary Regression of employee engagement on internal branding**

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
2	.823	.711	.701	.4023

According to the results of stepwise regression in table 2, model 2 is accepted according to which employee engagement in organizations depend on internal branding variables namely, internal communication, brand focused training and HR practices. Though leadership has implications on the successful implementation of internal branding and engaging the employees, but the direct impact of the same is not found to be very significant according to the present study results. Hence the accepted model has only three variables excluding leadership.

The next table shows the multiple linear regression estimates including the intercept and the significance levels.

**Table 3: Regression coefficients**

Model	Unstandardized Coefficients		Standardized Coefficients	t	Sig	Collinearity Statistics	
	B	Standard error	Beta			Tolerance	VIF
Constant	1.103	2.04	.61	.528	.501		
Internal communication	.008	.003	.357	.457	.018	.412	1.450
HR practices during internal branding	.019	.002	.426	.478	.125	.516	2.342
Brand focused training	.007	.001	.304	.347	.010	.432	1.376
Leadership	.002	.001	.256	.212	.000	.201	1.153

Table 3 shows that if all variables are forced into the multiple linear regression, it is found that only internal communication and HR practices during internal branding are significant predictors of employee engagement. As indicated by the results in table 3, HR occupies a unique position within hospitals as they link hospital's stakeholders with its service delivery objectives and medical staff.

Internal communication through various media ensures that employees understand the hospital's vision and mission statement and are aligned with the hospital's values. In addition, brand focused training instil brand values among employees and keep them informed and engaged, increasing the likelihood of them

becoming brand ambassadors. Medical staff are the major stakeholders to witness hospital's brand, values and objectives. They are also the ones that mainly communicate that experience through patient service. Supporting the previous researches, these findings provide evidence for accepting the first four research hypotheses. As observed in table 2, the three factor model consisting of internal communication, HR processes and brand based training is an effective indicator of employee engagement.

The information in the table 3 also allows to check for multicollinearity in the multiple linear regression model. Tolerance should be > 0.1 (or VIF < 10) for all variables, which is found to exist in the analysis.

**Figure 1: Plot of regression**

Figure 1 shows that when hospitals have better tools of internal communication, greater HR involvement and provisions for brand focused trainings, employees are more engaged. With an increase in the intensity of internal branding process and implementation, greater is the employee engagement.

**Practical implications:** Internal Branding is a corporate strategy which enables employees to not only understand the brand values and deliver on the brand promise but to also to 'live' it. It is particularly important in hospitality sector, where employees need to interact with customers directly and thereby exhibit brand supporting behaviour.<sup>6</sup> This is possible when the factors of internal branding help in creating an engaged workforce.

Employee engagement being one such behaviour, the same is empirically proven in the present study. Engagement of medical staff is positively related to hospital's internal communication, the extent to which HR involves in brand building process and the brand oriented trainings provided to the staff to align themselves with hospital's values and culture. Furthermore, though leadership has a correlation with employees' engagement, it reflects a partial role in the link between internal branding and engagement. The present research provides hospitals an insight to manage

their internal branding to align with the hospital's brand values and incorporate them primarily in their duties.

**Theoretical implications:** The present research has supported the existing literature in internal branding and provided a model showing internal branding factors enabling brand supporting employee behaviour leading to employee engagement. In alignment with the research studies done by Punjaisri et. al<sup>6,7</sup> the present research has added value to literature by testing the impact of internal branding factors in hospitals. Based on SET, the study adds to current body of knowledge how internal branding can impact employees' attitude and behaviours in alignment with the organization's brand through employee engagement.

**Limitations and scope for future research:** The present cross sectional study was conducted only in Indian hospitals, hence generalizability in sectors other than services might be difficult. There lies a future scope to analyse the same variables in other services sectors like telecommunication etc.

**Ethical Clearance:** Not applicable

**Source of Funding:** Not applicable

# Effectiveness of Health Education on Myths of Menstrual Hygiene among Adolescent Girls in Selected Rural Area in Andhra Pradesh, Vizianagaram District

Krishna Vaishnavi P.

*Professor, GITAM Institute of Nursing, GITAM, Visakhapatnam, Andhra Pradesh*

## Abstract

The main aim of this study was to find out the prevailing myths about menstrual hygiene among adolescent girls in selected high school and to find out the effectiveness of structured teaching program on menstrual hygiene. A quasi experimental study using one-group pre-test and post-test design was used with a sample size of 62 adolescent high school girls. The findings of the study revealed that the myths on menstruation were decreased after providing health education on menstruation. During post-test, 93.5% said that head bath during menstruation do not increase blood flow, 92% did not accept to avoid exercises during menstruation, 96.8% did not feel that there is a need to see a doctor always during menstruation, 95.5% did not accept that periods should exactly last for 1 week, 93.5% did not accept that touching pickles during menstruation spoils it, 93.5% felt that talking to mother during menstruation is good, 98.4% felt that touching animals like cow or sheep during menstruation is not impure, 95.1% felt that touching pregnant ladies during menstruation do not lead to fetal death, 93.5% felt that touching green plants during menstruation do not lead to plants death. There was significant association between class, source of health information and type of pads used and myths like "touching pickles during menstruation spoils it", "talking to mothers about menstruation is not good" and type of pads used at 0.05% significant level. The present study showed that the structured teaching program on menstrual hygiene changed the perceptual myths.

**Keywords:** *Menstruation, menstrual hygiene, myths, adolescent girls.*

## Introduction

WHO report (1999) stated that many mothers lack correct information and skills to communicate to their children about menstrual hygiene, leading to false attitudes, beliefs and practices<sup>1</sup>. Dhingra R and Kumar A reported that menstruation is still regarded as something unclean or dirty in Indian society and it is strongly related with misconceptions and cultural restrictions<sup>2</sup>. The myths about menstrual hygiene can be decreased

by providing knowledge and information on menstrual hygiene.

**Need for the Study:** There are unwritten rules imposed on menstruating women around the world surrounded by taboos, myths and unhygienic practices. In Bangladesh, women bury their clothes to prevent them being used by evil spirits<sup>3</sup>. Sarah et.al reported that due to these taboos, women and girls are excluded from social, cultural, sanitation and menstrual hygiene services<sup>4</sup>. In Tanzania, some believe that if a menstrual cloth is seen by others, the owner of the cloth may be cursed<sup>5</sup>.

In India, there are many taboos regarding menstruating women like preventing them to visit temple, to cook food, to attend weddings etc<sup>6</sup>. Harshad reported that correct knowledge will help them practice safe and hygienic menstrual practices and come out

of traditional beliefs, misconceptions and restrictions regarding menstruation<sup>7</sup>.

Some studies in India reported that there are restrictions ongoing to school, touching flowers and males during menstruation etc<sup>2</sup>. Even though the first menstruation is celebrated, many myths and taboos surround the practices of menstrual hygiene, causing psychological and physical trauma, affecting reproductive health<sup>8</sup>. These perceived myths can be changed by providing health education on menstrual hygiene.

#### **Objectives:**

- To compare the Pre-test and Post-test myths about menstrual hygiene among high school adolescent girls.
- To find out the effectiveness of structured teaching program on the myths about menstrual hygiene.
- To find out the association between selected demographic variables and pre-test myths.

#### **Limitations:**

- The study is limited to only high school adolescent girls
- The study is limited to only one school
- The study is limited to only rural school.

### **Methodology**

**Research Design:** A one-group pre-test and post-test research design was chosen.

**Sample:** The sampling technique used for the study was simple random sampling method. The present study included a sample of 62.

#### **Inclusion Criteria:**

- Adolescent girls studying in selected high school
- Subjects who can understand English and Telugu.

- Subjects who are willing to participate in the study.
- Subjects includes both who attained and did not attain menarche
- Students studying in 8<sup>th</sup>, 9<sup>th</sup> and 10<sup>th</sup> class.

#### **Exclusion Criteria:**

- Subjects who are not willing to participate in the study
- Subjects who are experiencing any severe health issues.

**Method of data Collection:** A questionnaire was prepared related to various myths that are prevalent among adolescent girls in consultation with subject experts and review of literature. The self-report questionnaire was used to collect pre-test and post-test information related to myths on menstrual hygiene. Structured health education program was conducted at high school using appropriate audio-visual media.

#### **Description of the Tool:**

**Section-1:** This section deals with information like age, class, attainment of menarche etc.

**Section-2:** This section includes 10 items of myths. The subjects need to tick one option of the response like 'yes' or 'no' response according to them for each item.

**Data Collection Procedure:** The permission to conduct study was obtained from the Principal of High School. Oral consent was obtained from the subjects. They were also informed that if they are not interested in the study they can withdraw from the study at any time. They were assured of their confidentiality.

**Data Analysis:** Frequency, percentage, chi-square test were used.

Chi-square was used to check the effectiveness of structured teaching program during pre-test and post-test. Chi-square is used to find the association between each myth and demographic variables.

## Results

**Table 1: Comparison of percentage of myths of adolescent girls about menstruation during Pre-test and Post-test (N=62)**

S.No.	Myths	Pre-Test				Post-Test			
		Yes		No		Yes		No	
		n	%	n	%	n	%	n	%
1.	Bath/Head bath during menstruation increases blood flow	30	48.4	32	51.6	4	6.5	58	93.5
2.	Avoid exercises during menstruation	51	82.3	11	17.8	5	8.1	57	91.9
3.	Always see a doctor during menstruation	43	69.4	19	30.6	2	3.2	60	96.8
4.	Periods should exactly last for 1 week	51	82.3	11	17.7	3	4.8	59	95.1
5.	If you touch pickles during menstruation, it gets spoiled	51	82.3	11	17.7	2	3.2	60	96.8
6.	Talking to mothers about menstruation is not good	51	82.2	11	17.7	4	6.5	58	93.5
7.	Touching the animals like cow or sheep during menstruation is bad	46	74.1	16	25.8	1	1.6	61	98.4
8.	Menstrual blood is impure	46	74.1	16	25.8	2	3.2	60	96.8
9.	During menstruation, pregnant ladies should not be touched at it causes fetal death	40	64.5	22	35.5	3	4.8	59	95.1
10.	Touching green plants during menstruation leads to death of plants	46	74.1	16	25.8	4	6.5	58	93.5

**Table-2: Effectiveness of structured teaching program on myths about menstrual hygiene (N=62)**

S.No.	Myths	Pre-test		Post-test		Chi-square	p-value
		Yes	No	Yes	No

### Discussion

In the present study, majority of students are adolescent girls 83.9% (52) are in the age group of 14-16 yrs, 43.5% (27) are studying 9<sup>th</sup> class, majority of girls 98.6% (61) attained menarche, 98.3% (61) had mother

as their source of information related to menstruation and 70.9% (44) used marked available pads.

The present study revealed interesting facts regarding myths of menstruation. After structured teaching program, subjects' perceptions regarding myths

were changed due to information that was statistically significant. In the present study, 48.4% had a myth that taking bath/head bath during menstruation increases blood flow during pre-test. This perception was changed among 93.5% (58) girls during post-test.

Some studies also show that there are restrictions related to activities. In a study conducted by Ishita et.al (2017), Restrictions practiced during menstruation among subjects are restrict sour foods (60.6%), religious activities (86.3%), restrict shampooing hair (63.5%), restrict wearing washed clean clothes 19 (61.9)<sup>9</sup>.

During pre-test 82.3% (51) had a myth that exercises should be avoided during menstruation. This myth was changed among 91.9 % (57) during post-test. As per Keerti et.al (2011), 78.99% girls were not allowed to attend religious occasions. 22.97% and 20.63% girls respectively were restricted from doing routine household work and playing<sup>10</sup>.

For the myth “always see a doctor during menstruation, during pre-test majority 69.4% (43) had myth and during post-test 96.8% changed their perception on this myth. Majority of students 82.3% (51), had a myth during pre-test that “period should exactly last for 1 week” which was changed among 95.1% (59) of adolescent girls during post-test. Similarly, the majority of myths during pre-test like “touching pickles during menstruation causes spoilage of pickles (96.8%), talking to mother about menstruation is not good (82.2%), touching animals like cow or sheep during menstruation is bad (74.1%), menstrual blood is impure (74.1%), pregnant ladies when touched during menstruation causes fetal death (64.5%) and touching green plants during menstruation leads to death of plants (74.1%)” could change their perception during post-test on the myths among majority of girls like 96.8% (60), 93.5% (58), 98.4% (61), 96.8% (60), 95.1% (59) and 93.5% (58) respectively.

The present study showed that the structured teaching program on menstrual hygiene was effective in changing their perception of all their myths during post-test compared to pre-test ( $p < 0.0000$ ) significant at 0.05 significant level.

The study also identified significant association between class, source of information and type of pads used and myth “touching pickles during menstruation spoils it” at 0.05 significant level. There was also significant association between the myth “talking to

mothers about menstruation is not good” and type of pads used.

In India, menstruation blood is considered as dirty and polluting. This was also reported that 63.4% of respondents had this misconception in the study conducted by Rajkumar Patil et.al<sup>11</sup>. In southern Africa, Kuper, reported about the perception that “menstrual blood of women is dangerous to men and also to the fertility of cattle and of crops”<sup>12</sup>.

**Conclusion:** As there are many myths among women regarding menstruation, nurses can implement health education program to women, thereby increasing quality of life.

### **Implications to Nursing:**

### **Implications to Nursing Practice:**

As many myths, taboos and restrictions are imparted on menstruating women, they are deprived of basic services like water and food for well being. Nurses working in community areas have an opportunity to provide health education on menstruation and can involve in changing the myths that are harmful to the well being of women. Even women need to be well informed about menstrual facts, to pass correct information and practices to their daughters, thereby helping them to adjust to the menstrual requirements.

**Nursing Research:** More research is required on the menstrual issues of women. Similar research can be conducted with large sample. Research is also needed in areas of issues related to factors contributing to the deprivation of health facilities. Further studies are required on involvement of health care personnel, teachers, friends in providing health information to adolescent girls and method of improving transmission of information to the target groups.

### **Conflict of Interest:** None

**Informed Consent:** Permission was obtained from the Principal of school. The participants were informed about the purpose of the study and were explained about the confidentiality and withdrawal anytime in due course of the study.

### **Source of Funding:** Self funding.

# Polymorphism in XRCC1, XRCC2, XRCC3 Genes and Risk of Gastrointestinal Cancer: A Case-Control Study from South-Western Maharashtra

Madhavi N. Patil<sup>1</sup>, Kailas D. Datkhile<sup>2</sup>, Anand Gudur<sup>3</sup>,  
Rashmi A. Gudur<sup>3</sup>, Satish V. Kakade<sup>4</sup>, Sandeep S. Kadam<sup>5</sup>

<sup>1</sup>Junior Research Officer, Department of Molecular Biology & Genetics, <sup>2</sup>Senior Research Officer, Department of Molecular Biology & Genetics, <sup>3</sup>Assistant Professor, Department of Oncology, <sup>4</sup>Associate Professor, Department of Preventive & Social Medicine, <sup>5</sup>Associate Professor, Apex Hospital, Kolhapur, MH, India

## Abstract

**Background:** Alarming increased incidence of gastrointestinal (GI) cancer in rural parts of Maharashtra intended us to elucidate association of polymorphism in DNA repair genes with GI cancer risk.

**Objective:** Hospital based case-control study designed to investigate association of polymorphisms in XRCC1, XRCC2, XRCC3 genes with risk of GI in Maharashtrian population.

**Method:** PCR-RFLP method was used to genotype polymorphisms in exon 6, 9 and 10 of XRCC1, exon 3 of XRCC2 and exon 7 of XRCC3 gene from 200 GI cancer patients and 300 controls.

**Results:** The genotypic frequency of variant allele His/His of cd280 of XRCC1 showed association with increased risk of GI cancer as compared to Arg/Arg genotype in rural population (OR = 14.04; 95% CI: 9.05-21.78,  $p < 0.0001$ ). The results of XRCC2 interpreted negative association (OR = 0.27; 95% CI: 0.10–0.73,  $p = 0.006$ ) and no association of XRCC3 (OR = 0.20; 95% CI: 0.08–0.53,  $p = 0.004$ ) with GI cancer.

**Conclusion:** The findings from this study revealed possible association of XRCC1 codon 280 polymorphism with increased risk of GI carcinogenesis in rural population of Maharashtra.

**Keywords:** Gastrointestinal cancer, PCR-RFLP, Genetic Polymorphism.

## Introduction

Gastrointestinal (GI) cancer is 4<sup>th</sup> most leading cancer and 2<sup>nd</sup> most common cause of cancer related deaths in India accounting 57,394 new cases in 2018 <sup>(1)</sup>. The etiology of GI Cancer is diverse and multifactorial where the presumed risk factors contributing to development and progression of GI cancer are related

to lifestyle factors including dietary habits, tobacco and alcohol consumption which have been considered to be associated with an increased risk<sup>(2,3)</sup>. Modulatory impact of environmental factors on genetic determinants may also be responsible for GI carcinogenesis<sup>(4)</sup>. However, exact means of GI cancer development has not been fully understood till date. It is evident from studies that the consequences of oxidative stress caused by multiple processes may damage cellular DNA which may contribute to promotion of carcinogenesis<sup>(5)</sup>. Multiple DNA repair pathways have been implicated in damaged DNA repair contributing to genetic stability<sup>(6)</sup>. XRCC1 is a major component of BER pathway important in repair of single strand breaks<sup>(7)</sup> where as XRCC2 and XRCC3 are DSB repair genes are key mediators in repair of double strand breaks<sup>(8)</sup>.

e-mail- hodgeneticslab@kimsuniversity.in

The single nucleotide polymorphisms (SNPs) in DNA repair genes are presumed to modulate DNA repair capacity and associated with altered cancer risk. Till date, 300 SNPs in XRCC genes, amongst which XRCC1 (rs1799782, rs25489, rs25487), XRCC2 (rs3218536) and XRCC3 (rs1799796, rs861539) are extensively investigated to explore their impact on cancer susceptibility. Recent years, number of studies illustrated association of SNPs in XRCC1 gene with breast<sup>(9)</sup> cervix<sup>(10)</sup> and head and neck cancer risk<sup>(11)</sup>. Similarly, association of XRCC2 and XRCC3 polymorphism with lung<sup>(12)</sup> and breast cancer<sup>(13)</sup> have been studied. However, findings from earlier studies continued with contradiction which failed to prove the association of SNPs in XRCC genes with risk of multiple cancers<sup>(14,15)</sup>. Number of studies demonstrated the pronounced susceptibility of gastric cancer in association with SNPs of XRCC genes<sup>(16, 17)</sup>. Few Indian studies also investigated the association between XRCC1 (Arg194Trp, Arg399Gln) polymorphisms and GI cancer<sup>(18, 19)</sup> but with incongruity, where Nisar et al 2018<sup>(20)</sup> reported no association of XRCC1 Arg399Gln with GI cancer in Kashmiri population. Also, polymorphisms of either XRCC2 (Arg188His) or XRCC3 Thr241Met did not show any relationship with GI cancer risk in any of Indian Population<sup>(21)</sup>.

Similarly, other researchers failed to prove significant association of polymorphism in XRCC2 (Arg188His) and XRCC3 (Thr241Met) with GI cancer risk in other population<sup>(22,23)</sup>. However, until now, no association of DNA repair gene polymorphisms with GI cancer is reported in rural population of Maharashtra. Therefore, present case-control study was aimed to investigate possible association of XRCC1 (*rs1799782*, *rs25489*, *rs25487*), XRCC2 (*rs3218536*) and XRCC3 (*rs861539*) genes with GI cancer risk, either autonomously or in relations with other demographic variables in rural population of Maharashtra.

## Materials and Method

**Study Subjects:** This case-control study included 200 histologically confirmed GI cancer patients and 300 healthy age and gender matched controls. All cases ranged in age from 20-75 years were enrolled immediately after being diagnosed during the year 2018-2019 from Krishna Hospital & Medical Research Centre. The demographic information including age, sex, place of residence, dietary habits, family history, tobacco and alcohol consumption status and other confounding risk

factors were collected from personal interviews in the form of structured questionnaire. Informed consent was obtained from all participants.

### Genomic DNA isolation from whole blood:

Genomic DNA extraction was carried out from 2-5 milliliter of whole blood samples of cases and controls as described earlier<sup>(10)</sup>. The DNA was used for further genotyping by polymerase chain reaction (PCR) and Restriction fragment Length Polymorphism (RFLP).

### Genotyping Assays:

Single nucleotide polymorphisms in XRCC1, XRCC2 and XRCC3 genes were studied by PCR-RFLP method. Each PCR reaction were carried separately in 20 microliter volume with 100 nanogram (ng) of purified genomic DNA template, 1X PCR buffer, 0.2 mM each dNTP, 1U Taq DNA polymerase and 10 picomole (pmol) primers described earlier<sup>(9, 10)</sup>. PCR amplification of 485bp codon 194 and 257 bp codon 280 of XRCC1 were carried out at annealing temperature 61°C with 30 cycles of 95°C- 30 seconds (sec), 61°C- 30 sec, 72°C- 30 sec. The codon 399 of XRCC1 (871bp) amplified with PCR conditions including initial denaturation at 95°C for 10 min followed by 30 cycles of 95°C- 20 sec, 56°C- 30 sec, 72°C- 20 sec and final extension at 72°C- 10 min. The PCR conditions for 290 bp XRCC2 codon 188 and 455bp sized codon 241 of XRCC3 were annealed at 58°C and 53°C for 30 sec respectively following 30 cycles of 95°C- 30 sec, 58/53°C- 30 sec, 72°C- 30 sec, 72°C- 10 min). After confirmation of PCR, each PCR product of XRCC1 exon 6, exon 9, exon 10, XRCC2 exon 3 and XRCC3 exon 7 were digested overnight at 37°C with 1 unit of restriction enzymes PvuII, RsaI, NciI, HphI and NlaII respectively. The restriction digestion products were separated on a 2-3% low EEO agarose (GeNei, Merck Biosciences) gel at 100 V for 30 min, stained with ethidium bromide (10mg/ml) and photographed with gel documentation system.

**Statistical Analysis:** The risk of GI cancer in association with XRCC1, XRCC2 and XRCC3 polymorphisms was studied by logistic regression model by calculating the odds ratio (OR) with 95% confidence intervals (CI) after adjustment of variables to determine the cancer risk associated with genotypes.

## Results

The mean age  $\pm$  SD of selected cases were 58.50  $\pm$  13.46 and controls were 53.13  $\pm$  12.55 who resided in the rural areas of south-western Maharashtra. Tobacco

chewing habit was prevalent in cases (66.80 %) than in controls (22.30%). The age and gender distributions were not different in cases than controls (Male: 56.9% and 62.7%); Female: 43.10% and 37.30%). Both cases and controls were educated and exhibited high non-vegetarian diet 82.2 % in cases and 73% in controls.

**Association of XRCC1, XRCC2, XRCC3 genotypes with GI cancer:** The genotype frequencies of detected XRCC1, XRCC2 and XRCC3 polymorphisms are summarized in table-1. The allele frequencies for XRCC1 cd 194 (C, 80.7%; T, 0%) in GI cancer cases were not much different from those of controls (C, 80.7%; 7.3%). The allele frequency of cd 280 of XRCC1 in cases of GI cancer (G, 28.20%; A, 71.80%) and controls (G, 84.70%; A, 15.30%) which found significantly different from each other. The genotypic frequency of homozygous variants of cd280 showing strong association with development of GI cancer in rural population (OR = 14.04; 95% CI: 9.05-21.78,  $p < 0.0001$ ). The wild type allele frequency of cd 399 of XRCC1 in GI cancer cases (G, 39.10%) and controls (G, 77.30%) which did not show much variation when

compared to variant allele A, (10%) in cases and 13.3% in controls. The results of XRCC2 interpreted negative association of XRCC2 (OR = 0.27; 95% CI: 0.10–0.73,  $p = 0.006$ ) with GI cancer in studied population. Similarly, we did not find any significant association of studied polymorphisms of XRCC3 (OR = 0.20; 95% CI: 0.08–0.53,  $p = 0.004$ ) with GI cancer.

**Interaction of demographic factors with XRCC1, XRCC2, XRCC3 genotypes and their association with GI Cancer:** We also considered the probable interaction of XRCC1, XRCC2 and XRCC3 gene polymorphisms with demographic risk factors. The analysis revealed that the Arg280His genotype in the exon 9 of XRCC1 and Gln399Arg genotype in exon 10 of XRCC1 associated with GI cancer when considered for mixed diet (OR = 13.26; 95% CI: 7.96–22.09,  $p < 0.0001$  for Arg280His genotype & OR = 6.54; 95% CI: 4.11–10.39,  $p < 0.0001$  for Gln399Arg genotype). Similarly high tobacco consumption is considered as significant risk factor for GI cancer when considered His/His homozygote variant genotype (OR = 19.53; 95% CI: 8.52–44.78,  $p < 0.0001$  of XRCC1 cd 280 of exon 9).

**Table: 1. The genotype frequencies of XRCC1, XRCC2 and XRCC3 gene polymorphisms in untreated GI cancer patients and controls**

GENE	Genotype	CASES (n= 200) (%)	CONTROL (n = 300) (%)	Odds' Ratio (95% CI)	P value	Adjusted Odds Ratio (95% CI)	P value

## Discussion

The emerging evidences implied that the SNPs of most common DNA repair genes are concerned with several infrequent cancers including GI cancer (24, 25). In present study, we discovered whether substitution in the XRCC1, XRCC2 and XRCC3 concerned with the advancement of GI cancer in rural population. Our results highlighted that epidemiological factors including diet, tobacco could promote GI cancer along with the polymorphisms of XRCC1 cd 280 of exon 9 and association of GI cancer was observed in this population. Results interestingly showed no association in genotypic frequencies of XRCC1 cd 194 and cd 399 of exon 6 and 10 polymorphisms between control and patient groups with GI cancer but cd 280 of exon 9 showed increased association with development of GI cancer. Thus our results seem to be in agreement with previous studies suggested that no association of XRCC1 cd 399 genotypes with GC cancer risk in Korean (26) Chinese (27) Brazilian population (28). Some researchers have summarized the association between SNPs in XRCC1 gene and clinical outcome of gastric cancer patients (29), however, results were not consistent. Some Indian studies proved association of XRCC 399 with gastric cancer development (30) but others failed to prove their association with GI cancer (20). Earlier studies demonstrated that XRCC1 gene polymorphism may modify risk of GI associated with low intake of fruits or vegetables. Secondly, food with high fat content associated with XRCC1 Arg/Arg genotype in relation with GI cancer risk. A study from Brazil revealed interaction between of XRCC1 399Gln with smoking, alcohol consumption in terms of gastric cancer (28). When considered XRCC2 Arg188His polymorphism in association with cancer development, some researchers found significant relationship of XRCC2 with GI cancer development but some are not in favor of proving susceptibility of other cancer with this polymorphism. Limited information on association of XRCC1, XRCC2 and XRCC3 polymorphisms with GI cancer susceptibility in rural Indian population challenged us to determine relationship of XRCC genes with risk of GI cancer. In answer to this, we depicted positive association of XRCC1 His 280 of exon 9 and negative association of either of XRCC2 (188His) and XRCC3 (241Met) with development of GI cancer in Maharashtrian population.

## Conclusion

Our study revealed that the *rs25489* polymorphisms of XRCC1 at cd 280 of exon 9 may associated with the GC risk in the rural population. Our results conferred negative association of XRCC2 and XRCC3 with development of GI cancer.

# Correlation of Anthropometric Parameters with Blood Pressure: An Anthropometric Study among Two Endogamous Groups of Haryana

Sandhya Singh<sup>1</sup>, Reena Singla<sup>2</sup>, Vishal Verma<sup>3</sup>

<sup>1</sup>Tutor, <sup>2</sup>Professor, <sup>3</sup>Assistant Professor, Department of Anatomy, MMIMSR, MMDU -Mullana, Ambala, India

## Abstract

**Background:** The present study is undertaken to study the correlation of anthropometric measurements with blood pressure in females and to find out effectiveness of anthropometric indicators as predictors to different grades of high blood pressure.

**Materials and Method:** A cross sectional study was conducted in 300 females aged 25-40 years belonging to two endogamous groups (baniya & jats) of haryana. various anthropometric measurements including height, weight, WC and HC were measured and derived anthropometric indices were calculated. Blood pressure including systolic and distolic was measured and data was statically analysed to find the prevalence of hypertension, to compare the correlation coefficient and to find the regression analysis of different anthropometric variables with BP(SBP, DBP) among the study group.

**Results:** . : Mean and standard deviation of weight, DBP, WC, HC and WHtR was more in Baniyas . p value was highly significant for age, height, WHR and significant for WC and HC. Among the study groups, prevalence of hypertension was 46%. A positive correlation of BP (SBP, DBP) was observed among all basic and derived anthropometric indices in both endogamous groups of Haryana and it was found to be highly significant. BMI and WC was found to be a better predictor for SBP and DBP in Haryanvi Baniyas with highly significant p value. WHR & BMI had a strongest predictability for SBP & DBP in Jat group .

**Conclusion:** To conclude, anthropometric parameters are strongly correlated and are good predictors of blood pressure in study population. Hence the present study recommends the screening programs and public awareness to detect the anthropometric parameters which can lead to prevalence of hypertension.

**Keywords:** *Anthropometry, Obesity, Haryanvi, Blood Pressure, baniya, Jats, Females.*

## Introduction

Anthropometric measurements are a set of non-invasive, quantitative techniques of determining an individual's body fat composition by measuring, recording and analyzing specific dimensions of the

body. Despite the modern techniques, anthropometric measurements such as height (HT), weight (WT), body mass index (BMI) and waist-hip circumference ratio (WHR) etc. are traditionally important method to study the genetic structure and prediction of risk factors of many complex diseases in human health.<sup>1</sup>

Body mass index (BMI), as an indicator of obesity, has been found to be consistently associated with increased risk of hypertension and other chronic diseases.<sup>2</sup>

BMI does not account for variation in body fat distribution and abdominal fat mass, which can differ

greatly across populations and can vary substantially within a narrow range of BMI<sup>3</sup>. Excess intra-abdominal fat is associated with greater risk of obesity-related morbidity than is overall adiposity and its association shows a significant gender difference.<sup>4</sup> Thus measurements of waist circumference and waist hip ratio (WHR) have been viewed as alternatives to BMI. Waist circumference has been shown to be the best simple measure of both intra-abdominal fat mass and total fat.<sup>5</sup>

WHO has opined that lower cut-off points than currently recommended should be used in some populations, especially in Asia, this is attributed to body fat distribution. Asian Indians tend to have more visceral adipose tissue despite having lean BMI.<sup>6</sup> Obesity and hypertension are on the rise in the world. Hypertension seems to be the most common obesity related health problem and visceral obesity seems to be the major culprit. Hypertension is an important public health problem in India. Various studies among Indians have shown a high prevalence of hypertension.<sup>7</sup>

Thus rapid urbanization, life style modification, demanding and stressful employment, sedentary life style and low rates of physical activity have increased the risk of obesity and hypertension in females. Therefore, it has become very important to screen the population at risk at an early age so as to apply preventive strategies. Hence the present study is undertaken to study the correlation of anthropometric measurements in females with blood pressure and to find out effectiveness of anthropometric indicators as predictors to different grades of high blood pressure.

## Material and Method

A cross sectional study in Department of Anatomy MMIMSR, Mullana - Ambala was conducted among 300 females (25-40 years of age) of known endogamous groups (baniyas & jats) of Haryana in the year (2012-2014). The subjects were taken from the urban and rural population of haryana. Persons with known hypertension, coronary artery disease, diabetes mellitus were excluded from the study. The study was approved by institutional ethical committee. The subjects were informed about the study, formal consent was taken, blood pressure was recorded and following anthropometric measurements were taken:

**1. Height:** Height in centimeters was measured (to the nearest 0.1 centimeter and then converted in meter by dividing the reading by 100) with a flexible

metallic measuring tape with the subject, standing barefooted in an erect position against an even wall or hard surface with the head positioned so that the top of the external auditory meatus in level with the inferior margin of the bony orbit.<sup>8</sup>

**2. Weight:** Weight in kilograms (to the nearest 0.5kg) was recorded with the subject standing motionless on the weighing scale, barefooted wearing minimum clothes and maintaining the privacy.

**3. Circumferences:** The waist and hip circumferences in centimeters were measured with a non-stretchable measuring tape. These circumferences were measured twice, to the nearest centimeter and the mean was used for subsequent analysis.

(i) Waist circumference (cms) was measured by using bone landmarks as references. The WHO guidelines recommend the measurement of waist circumference at the mid point between the lowest rib and the iliac crest (the highest point of the ilium)<sup>9</sup>

(ii) Hip circumference (cms) was measured at the level of the greater trochanters in centimeters. It should be taken around the widest portion of buttocks, with the tape parallel to the floor.

**Derived Anthropometric indices were calculated as follows:**

**1. Body Mass Index (BMI):** Weight (kgs)/height (m)<sup>2</sup>.

Asian Pacific classification for BMI was applied to classify the studied population into the following:

I. Underweight = <18.5 Kg/m<sup>2</sup>

II. Normal weight = 18.5 - 22.9 Kg/m<sup>2</sup>

III. Over weight = ≥ 23.0 Kg/m<sup>2</sup>

IV. At risk = 23.0-24.9 kg/m<sup>2</sup>

V. Obese I = 25.0-29.9 Kg/m<sup>2</sup>

VI. Obese II = > 30 Kg/m<sup>2</sup>

**Waist-Hip Ratio (WHR):** WHR = WC (cm)/ HC (cm)

Cut-off value used was 0.81<sup>6</sup>

**Waist-Height Ratio (WHtR):** WHtR = WC(cm)/ Height (cm)

The cut-off value used was 0.5<sup>10</sup>

**Blood Pressure:** As per JNC (Joint National Committee) guidelines<sup>11</sup>

Normal–Systolic and Diastolic < 120/80 mm Hg Prehypertension – Systolic 120-129; Diastolic 80-89mm of Hg Hypertension (stage -1) - Systolic 140-159;Diastolic 90-99 of mmHg (stage -2) - systolic > 160;diastolic>100 mm of Hg

For statistical analysis the data was imported in SPSS 20 software and was analysed for descriptive frequency of all variables. Pearson’s correlation coefficient were used to investigate the correlation between anthropometric indices and blood pressure among study groups. Regression analysis of different anthropometric variables with systolic and diastolic blood pressure was calculated in the study group.

**Results**

Mean and standard deviation of weight, DBP, WC, HC and WHtR was more in Baniyas . p value was highly significant for age, height, WHR and significant for WC and HC (Table-1). Overweight and obesity were seen in both groups. Derived anthropometric indices for example WC, WHtR and WHR were raised among both endogamous groups. Prevalence of hypertension was same in both endogamous groups (46%) (Table - 2).A positive correlation of BP (SBP, DBP) was observed among all basic and derived anthropometric indices in both endogamous groups of Haryana and it was found to be highly significant (Table – 3) . WHR & BMI had a strongest predictability for SBP & DBP in jat females. BMI & WC was found to be a better predictor for SBP & DBP in baniya females with highly significant p values. (Table-4,5).

## Discussion

BMI indicates general obesity whereas derived anthropometric indices for example WC, WHR and WHtR indicates central obesity. In the present study, mean and standard deviation of weight, DBP, WC, HC and WHtR was more in Baniyas. p value was highly significant for age, height, WHR and significant for WC and HC (Table-1). Derived anthropometric indices for example WC, WHtR and WHR were raised among both endogamous groups (Table 2). A similar study done by Khanna et al in which the elevated WHtR was showing significant p value. Various studies had concluded that WHtR was strongly associated with cardiovascular risk factors. WHtR is an important index of central obesity, which is free from any bias due to hip width changes along with waist circumference of short and tall subjects.<sup>12</sup> Unlike BMI, WHtR takes into account the distribution of body fat in the abdominal region which has been shown to be more associated with cardiovascular risks than body weight. WHtR is a better predictor of CVD risk primarily among Asian population.

The prevalence of hypertension was 46% in both endogamous groups (Table -2). Study done by Sidhu et al<sup>13</sup> showed the prevalence of hypertension to be highest among Baniya females (26.4%) followed by Jat Sikh (20.80%). The comparative profile of the incidence of hypertension among two endogamous groups indicates that the frequency of this silent killer i.e hypertension was maximum in both endogamous females. The possible reasons may include their higher socio-economic status, sedentary life style, changes in dietary practices and hereditary factors.

In the present study, a positive correlation of BP (SBP, DBP) was observed among all basic and derived anthropometric indices in both endogamous groups of Haryana and it was found to be highly significant. BMI, WHR, WC were found to be a better predictor for blood pressure in the study population. Similar study done by Badaruddoza et al<sup>14</sup> concluded that BMI and WHR are important indicators to predict the risk of CVD. A study done on Bengali kayastha population depicted strong correlation of BMI, WC and WHtR with DBP<sup>15</sup>. However WHR has shown better prediction power for cardiovascular disease among women. Dalton et al<sup>16</sup> advocated that WC as well as WHR have strongest relation with the elevation of BP in females. Waist and Hip circumferences are most important variables in women for obesity and BP. Study done by Deshmukh et al<sup>17</sup> reported BMI and WC had strong correlation with hypertension. In a study done by Bishnoi et al<sup>18</sup> on Bishnoi, Sikh and Hindu females, WC was found to be a significant predictor of CVD. Physical inactivity demonstrated a strong association with the elevation of CVD risk as seen in the present study. Hypertension was seen among study population due to their high socio-economic status, elevated anthropometric parameters i.e WC, WHR and WHtR, sedentary lifestyle and dietary modifications in the form of high salt and fat intake.

Therefore, generalised approach for all females including weight loss for overweight, regular physical activity, dietary modifications to reduce fat and sodium intake; increase intake of vitamins and fibres from food sources should be promoted to reduce the risk of hypertension.

**Ethical Clearance:** Taken from Institutional ethical committee.

# A Cross Sectional Study on Drug Adherence among Type 2 Diabetes Mellitus Patients Attending a Tertiary Care Hospital in Chennai

Srisanthana Krishnan V.<sup>1</sup>, Roselin V.<sup>1</sup>

<sup>1</sup>Assistant Professor, Department of Community Medicine

Sri Muthukumaran Medical College Hospital and Research Institute, Chikkarayapuram, Chennai

## Abstract

**Background:** Diabetes Mellitus (DM), pose a major public health problem. With the fact of increasing burden of DM and its complications, it is essential to take measures to control blood glucose levels among patients. Adherence to medicine plays a vital role in maintaining the blood glucose level, hence the study was planned to assess the drug adherence among type 2 DM patients attending a tertiary care hospital in Chennai and to assess the factors associated with non-adherence in these patients.

**Method:** Ninety three participants with Type 2 DM attending a tertiary care center were selected by systematic random sampling method. Type 1 DM and Gestational DM patients were excluded. A semi-structured interview with particulars about socio-demographic, clinical characteristics and adherence scores tool were used to collect the data. Data entry and analysis was done using SPSS version 20.

**Results:** Mean age of participants was  $54 \pm 8.5$  years. Sixty six percent of the participants were found to be adherent to their diabetic medications. Common reason for non-adherence was found to be forgetfulness 49.5%. Patients with DM for more than 5 years and patients not following regular physical activity were likely to be non adherent. Patients with family support were more adherent.

**Conclusion:** In spite of several public health measures, adherence level to medications was not satisfactory. The results emphasize the need to educate the patients about complications of DM and importance of adherence to medication. Further, programme should encourage family support by educating the family members during home visits by health workers.

**Keywords:** *Diabetes mellitus, Adherence, medication, factors, non- adherence.*

## Introduction

Diabetes Mellitus (DM), a common endocrine problem worldwide, which has serious economic and

medical consequences. The World Health Organization (WHO) estimated that the number of people living with diabetes and its prevalence are growing in all regions of the world. In 2014, 422 million adults<sup>1</sup> were estimated to have (8.5% of the population) diabetes, compared with 108 million (4.7%) in 1980. Across the South East Asian Region; approximately 72 million people were estimated to have diabetes in 2014, close to one fifth of all adults with diabetes in the world.<sup>2</sup>

Prevalence of diabetes in India among adults (20-79 years) was estimated to be 8.7% in 2015 as per International Diabetes Federation<sup>2</sup>. Though the burden

is high, Diabetes can be treated and its complications can be better prevented by lifestyle modifications and appropriate medical management. Appropriate medical management includes- choosing the right medication, advising on the importance of adherence to medication, patient adherence to the medicine and regular follow up.

In 2003, the WHO identified medication non-adherence as the leading cause of preventable morbidity, mortality and health care cost. Complex drug regimens make the patients difficult to follow the treatment. One of the major reasons for developing complications of DM is lack of adherence to medications<sup>3</sup>.

Ensuring that patients take oral anti-diabetic medications as prescribed and achieve near normal blood sugar control is the most challenge encountered by the health care providers. Hence, adherence assessment to the treatment should be considered in patients who do not reach the desired therapeutic goal.

Therefore it is important to break the barriers for non adherence, so that morbidity and mortality related to diabetes complications can be reduced. With this in view, this study was planned to know the drug adherence among diabetic patients and the factors associated with non-adherence.

**Objectives:** To assess the drug adherence among type 2 Diabetes Mellitus patients attending a tertiary care hospital in Chennai and to assess the factors associated with non-adherence in these patients.

## Materials and Method

The study was carried out among Type 2 Diabetes Mellitus (DM) patients attending the Non Communicable Disease (NCD) clinic in Sri Ramachandra Medical College and Research Institute, a tertiary care hospital in Chennai, during the month of January 2018. The NCD clinic is attached with the General Medicine Department and a separate register is maintained for these patients. On a daily basis around 300 patients visit the NCD out-patient department. They are prescribed free medicines for one month, blood sugar and urine sugar examination done once in three months and appropriate health education given on a regular basis.

Based on review literature, the non-adherence levels among diabetics were expected to be around 60%<sup>3</sup>. The minimum sample size calculated for a desired absolute precision of 10% and an  $\alpha$  of 5% was arrived to be

93. Participants were selected by systematic random sampling method from the NCD register.

All the patients with type 2 DM on medical management for at least 6 months were included in the study. Patients with type 1 DM and Gestational DM were excluded from the study.

**Study Tool:** A semi-structured interview schedule was used to obtain information from the participants. The questionnaire comprised of socio-demographic and clinical characteristics of the participants and the Adherence scores tool developed by Belayneh Kefale Gelaw et al, Adama, Ethiopia, 2014<sup>4</sup>. The adherence tool comprises of six questions with each question scored from 1 to 4 (1: daily 2: frequently 3: rarely 4: never) with higher scores favoring adherence. A score of 24 or 23 (with one point missed from question 1) were considered as adherent others as non adherent as per the adherence tool.

**Statistical Analysis:** Data entry and analysis was done using statistical package for social sciences (SPSS) version 20 software. Following a descriptive analyses, odd's ratio was computed to find out the association between risk factors & non-adherence. A p-value of < 0.05 was considered to be statistically significant.

**Ethical Issues:** The study was approved by the Institutional Ethics Committee of Sri Ramachandra Medical College and Research Institute (deemed to be university). Written informed consent was obtained from each participant.

## Results

The mean age of participants was 54 years (SD  $\pm$ 8.5 years) with a higher proportion being females (68.8%). There was no non-response rate in this study. Literacy level was found to be 78.5%. According to modified Prasad classification 64.5% of the participants were of socio-economic class I or II.

It was observed a large proportion (62.4%) of participants was diagnosed to have Diabetes Mellitus for less than 5 years. Around 41% of the participants were known hypertensive and 80.6% of the participants had tested their blood sugar level at least once in 3 months. In this study 93.5% of the participants were taking oral hypoglycemic drugs for their blood sugar control (Table 1).

**Table 1: Clinical profile of the participants**

Characteristic	Frequency (n)	Percentage (%)
<b>Duration of Diabetes Mellitus</b>		
1-5 years	58	62.4
5-10 years	22	23.7
>10 years	13	14.0
<b>Current medication taken by the participant</b>		
OHA	87	93.5
Insulin	02	2.2
Both	04	4.3
<b>Actual medicines taken</b>		
Metformin	90	96.8
Glipizide	46	49.5
Glibenclamide	09	9.7
Insulin	06	6.5
<b>Frequency of blood sugar monitoring</b>		
Once a month	18	19.4
Once in 3 months	75	80.6
<b>Consultation</b>		
Allopathy alone	88	94.6
Allopathy & Ayurveda	03	3.2
Allopathy & Unani	02	2.2
<b>Other known chronic illness</b>		
None	45	48.4
Hypertension	38	40.9
Heart disease	03	3.2

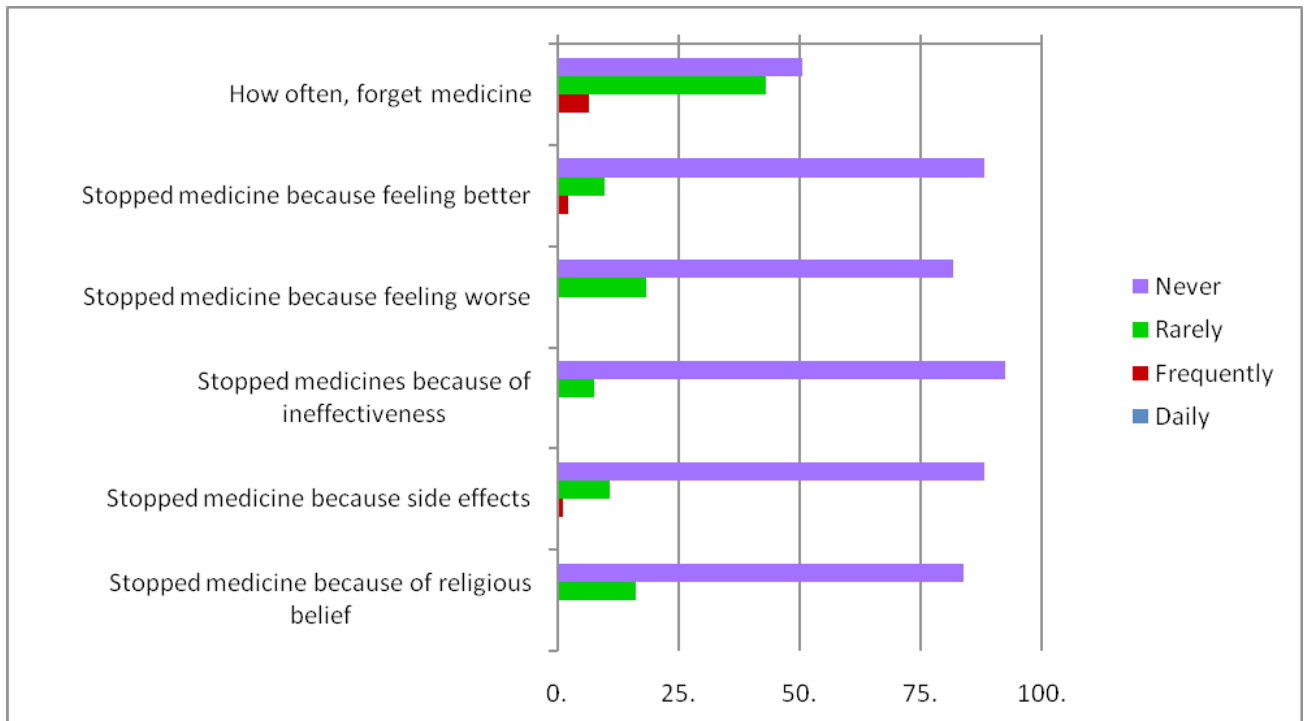

In this study 66% of the participants were found to be adherent to their medication (Figure 1). Most common reason for non-adherence in the present study was found to be forgetfulness 49.5% and 18.3% of the participants say that they stopped their medicines because they felt worse. Religious belief was also one of the factors found to be reason for non adherence (Figure 2).

Patients with DM for more than 5 years and patients not following regular physical activity were more likely to be non adherent and it was found to be statistically significant. Also, participants with more than 50 years of age, employed, travel time more than one hour, no family member support, lower educational status and participants who were not on proper diet were more likely to be non adherent to their medications. Participants who had an associated chronic illness were at lesser risk for non adherence, but it was found to be statistically not significant.

In our study it was found patients who experienced inability to purchase medicines due to cost reason were at greater risk for non adherence to medication. Participants who are on mono-therapy for Diabetes Mellitus were less adherent, compared to participants with poly drug therapy, but this was not found to be statistically significant. Participants who are not on regular physical activity were 3 times at higher risk of non adherence and it was found to be statistically significant (p value <0.01).

**Figure 1: Overall response to Adherence Scale**

**Figure 2 : Response to Medication Adherence Questionnaire**

**Discussion**

This study was done to find out the level of adherence and the risk factors associated with non-adherence. In this study, majority of the participants were in the age-group of 50-59 years, which is similar to studies by Ataur et al<sup>5</sup> and Bagonza et al<sup>6</sup>. The study group had more female participants, which was more likely due to the greater proportion of women attending the out-patient clinics. A simple tool was used to assess adherence in this study as it was easy to administer, less taxing on the participant and practically feasible compared to other. A review by Gonzalez et al<sup>7</sup> also supports the use of self-report in medications adherence.

The adherence level was found to be 66% in this study group. Similar results have been obtained in other parts of India<sup>8,9</sup>. A study done in Karnataka<sup>10</sup> in 2013 reported non-adherence of 54.6% and a study in Pondicherry<sup>11</sup> in 2010 demonstrated a non-adherence of 50.7%. A systematic review on the compliance to medication among diabetic patients showed that an average compliance to the oral hypoglycaemic agents ranged from 36% to 93%<sup>12</sup>. Studies done in Adama, Ethiopia<sup>4</sup> and UAE<sup>13</sup> report higher level of adherence of 72.2% and 84% respectively. This reveals

that adherence to medication is a challenge in many countries. The most common reason reported for non-adherence was forgetfulness. The same was observed in other studies<sup>4,13-15</sup>.

In this study the adherence level was better in those who were females, aged less than 50 years, literate, unemployed, family support and those belonging to the upper socio-economic class, but the differences were not statistically significant. A study in France also reported similar adherence levels among males and females<sup>16</sup>.

Participants diagnosed with Diabetes Mellitus within the last 5 years were more adherent to medications. Similar findings were reported by other studies<sup>4,8,13</sup>. The reason could be because of their concern of the disease and its complications. Participants who exercised regularly, followed diabetic diet and who had a co-existing chronic condition also were more adherent to medications, probably reflecting their concern on their own health. On the contrary a study done in 2012 by White et al demonstrated that those with a higher mean duration of Diabetes had more adherence. The effect of Diabetes related stress, perceived control and self efficacy on medication adherence is complex as described by Gonzalez et al<sup>17</sup>.

## Conclusion

This study was able to show adherence level to be 66% and the factors that undermine the outcomes of diabetes pharmacotherapy in diabetic patients. The main consequence of poor adherence to medications for glycemic control leads to the known complications of diabetes, including microvascular and macrovascular diseases and altered lipid metabolism.

So patients should be counseled on diabetic diet and regular physical activity as these can likely lead to good adherence. Adequate, information on diabetes and anti diabetic medications must be provided to all diabetic patients. The benefits of drug therapy and the factors related to non adherence must be stressed in health education session and measures like family support, daily reminder for medication must be made to reduce non adherence level.

Programme related modifiable factors like cost, availability of nearby health facility and ensuring availability of free drugs is important to strengthen the Non-Communicable disease programmes, based on the community needs.

Health programmes should be framed to deliver intensive education regarding the diabetes, its symptoms and various lifestyle modifications like change in dietary pattern, physical exercise, weight management, in order to control the sugar levels.

The role of health professionals is considerable in providing most effective health care. Patients should be encouraged to appropriately use anti diabetic drugs and regular awareness should be created regarding the benefits of using them, thereby preventing the non adherence.

**Acknowledgments:** Authors would like to thank all, who extended their knowledge and guidance to this study. Also, authors would like to acknowledge all their friends for their support. Last but not least author would like to thank study participants, without whom, this study would not have been possible.

Institute of Medical Sciences, Banaras Hindu University, Varanasi, India*

## Abstract

**Introduction:** Indian breast cancer patients usually present in advanced stage as compared to the western population. So the aim was to study the p53 mutation and c-erbB-2 expression in Indian breast cancer population.

**Method:** 200 patients of breast cancer were studied for p53 and c-erbB-2 expression by Immunohistochemical method by using NCL-CB11 from Novacastra laboratories for c-erbB-2 over expression and NCL-p53, clone D)-7 from Novacastra laboratories for p53 mutation.

**Results:** p53 was mutated in 16% cases and all tumors with p53 mutation had positive lymph nodes. c-erbB-2 was over expressed in 40% (80) cases. Out of these 80 cases, 44 cases (55%) were having grade 2+ staining. In the 32 comedo type of tumor, 24 cases (75%) were positive for c-erbB-2 while in other types it was positive in only 33.4% cases. In 80 cases of c-erbB-2 positive tumors, 32 cases were p53 positive while in 120 cases of c-erbB-2 negative tumors only 7% cases were p53 positive while rest were negative. There was no correlation between c-erbB2 and p53 mutation.

**Conclusion:** p53 mutation present in 16% cases was seen in only lymph node positive cases while c-erbB-2 over expressed in 40% of Indian breast cancer patients.

**Keywords:** Cancer, carcinoma, marker, neoplasm, proliferation, tumor.

## Introduction

In India, breast cancer is the second common cancer in female after carcinoma cervix and the incidence of advanced breast cancer is much more than early breast cancer probably because of illiteracy, unawareness, myth and neglect of the society. Current management

of primary breast cancer involves the need for prognostication. Most extensively studied prognostic markers are lymph node metastasis, tumour size, grade, vascular invasion, AgNOR counts etc. AgNORs are loops of DNA that transcribe ribosomal RNA and it measures the proliferative activity of cells. In many study AgNOR has been reported as prognostic marker in carcinoma breast.<sup>1,2,3</sup>

In recent years, additional biological and molecular parameters have become increasingly important as adjuncts to the standard histological and clinical assessment. p53 tumor suppressor gene and c-erbB-2 oncogene are most extensively studied biological markers in breast tumorigenesis till date.<sup>4,5</sup>

p53 is well known tumour suppresser gene aptly known as molecular policeman or guardian of genome.

---

Mutation of p53 gene is the most common genetic abnormality of human cancer. p53 protein is involved in several central cellular process that are critical for maintaining cellular homeostasis including gene transcription, DNA repair, cell cycling, senescence and apoptosis. Alteration in its function leads to more aggressive breast cancer and worse clinical outcome. Risk of cancer recurrence and death increase by 50% or more if p53 is mutated.<sup>5,6</sup> Immunocytochemical study of normal, benign and malignant breast tissue of different histological types revealed that p53 positive tumors are more aggressive and associated with poor prognosis.<sup>7</sup>

C-erbB-2 also known as HER2/neu is a member of type I epidermal growth factor receptor family of receptor tyrosine kinase. Members of this family have intrinsic tyrosine – kinase activity and are considered important mediator of cell growth, differentiation and survival. The protein product of HER/2 neu gene is 185 Kd surface membrane protein found in wide variety of tissues including epithelium of breast, ovary, endometrium, lung, kidney, GI tract and central nervous system.<sup>5</sup>

Paik et al (1990)<sup>8</sup> observed that c-erbB-2 over expression is second to node status in predicting the outcome in breast cancer patients. Winstanly et al (1991)<sup>9</sup> found that HER-2/neu over expression is independent predictor of overall survival. The objective of this study to find out the incidence of p53 mutation, c-erbB-2 over expression and their possible correlation with well established, clinico pathological markers like grade, tumour size, vascular invasion, lymph node status and AgNOR count in our Indian breast cancer patients.

## Material and Method

The study was conducted at University Hospital, Banaras Hindu University, India and included 200 patients of carcinoma breast. All patients underwent a detailed clinical history and thorough examination and necessary investigations were carried out for metastasis. Either Tru Cut needle biopsy specimen or specimen from operated samples were preserved for routine histology, AgNOR staining, c-erbB-2 staining and p53 staining.

Silver stained slides were examined using 1000 x magnification under oil immersion. AgNORs appeared as brown or black dots within yellowish background of nucleus. The number of dots was counted in 100 cells and the average was taken for each cell according to the method proposed by Giri et

al (1989).<sup>10</sup> **p53 Immunostaining was done by using primary antibody** (NCL-p53, clone DO-7) obtained from Novacastra laboratory using ABC technique and DAB and counter staining with haematoxylin while **c-erbB-2 Immunohistochemical Staining was done by using primary antibody** (NCL-CB 11) obtained from Novacastra laboratory using ABC technique and DAB and counterstaining with haematoxylin c-erbB-2 membrane staining was graded as grade 1+ to grade 3+.

**Grade 1+** = discontinuous membrane staining this low level staining pattern

**Grade 2+** = Continuous membrane staining involved 50% of the tumour

**Grade 3+** = Diffuse membrane staining involved 100% of tumour

**Statistical Analysis:** Statistical analysis was done using numeric and non-numeric variables. Parameter test like Pearson Chi Square Test, z test and student's 't' test, was applied. Results were referred as mean  $\pm$  SD and p value was considered significant at 5% level of significance.

## Results

Mean age for all patients was  $45.02 \pm 9.65$  yrs (range 30-70 years). Maximum numbers of patients were in stage III. Maximum patients had tumor size  $>5$  cm i.e. 132 cases (66%). Maximum number of cases had AgNOR count between 2-7/cell. Mean AgNOR/cell ranged from 2-20/cell with the mean of  $7.98 \pm 4.5$ .

c-erbB-2 expression (Table 2) was present in 80 cases (40%) and was absent in remaining 120 cases (60%). Out of these 80 cases, 44 cases (55%) were having grade 2+ staining. In the 32 comedo type of tumor, 24 cases(75%) were positive for c-erbB-2 while in other types it was positive in only 33.4% cases. p53 mutation was seen in 32 cases (16%) and was absent in remaining 168 cases (84%). 12% cases of p53 mutation showed strong staining and 4% cases showed equivocal staining .

p53 mutation showed statistically significant correlation ( $p < 0.001$ ) with lymph node metastasis. The tumour without lymph node involvement had not shown any p53 mutation while 32 cases of positive p53 mutation had lymph node metastasis. Mean tumour size  $6.25 \pm 0.886$  cm in p53 positive tumors and  $6.143 \pm 2.392$  cm in p53 negative tumor these value are also statistically not

significant. Out of total 32 cases of p53 positive tumors, 4 cases (50%) had vascular invasion on histology.

On correlation with lymph node to c-erbB-2 over expression, out of 80 tumors with c-erbB-2 positive, 52 (65.5%) cases had lymph node metastasis and 28 cases did not have lymph node metastasis (p<0.05).

Out of 80 c-erbB-2 positive cases 36 cases i.e. (45%) had vascular invasion. Mean tumour size was 6.214 ± 1.847 cm in c-erbB-2 positive cases and 6.139 ± 2.365 in c-erbB-2 negative cases.

Maximum number of c-erbB-2 positive tumor were in grade III i.e. 44 cases (64.7%) of cases of grade III tumor. 30% cases of grade II tumors had c-erbB-2 over expression. There is statistical significant correlation between grade of tumor and c-erbB-2 over expression (p<0.05).

In 80 cases of c-erbB-2 positive tumors (Table 2), 24 cases were p53 positive while in 120 cases of c-erbB-2 negative tumors only 7% cases were p53 positive while rests were negative. There was no correlation between c-erbB2 and p53 mutation. Mean AgNOR per cell in c-erbB-2 positive tumors was 10.02±4.05 and 7.08±4.40 in c-erbB-2 negative tumors which was statistically significant. Mean AgNOR per cell in p53 positive tumors were 8.75±4.27 and 7.83±4.58 in p53 negative tumors which was statistically not significant.

### Discussion

p 53 is a well known tumour suppressor gene known as guardian of genome. Elledge et al (1988)<sup>6</sup> observed that risk of cancer recurrence and death increased up to 50% or more if p53 mutated. Meenakshi et al (1999)<sup>7</sup> showed that p53 positive tumors are more aggressive and associated with poor prognosis. Meng et al (1999)<sup>11</sup> reported p53 mutation rate of 25-60% depending upon stage of disease and method of detection. Yokata T et al (1999)<sup>12</sup> showed that p53 mutation is associated with lymphatic invasion. Shrinivas P et al (2002)<sup>13</sup> found that p53 mutation is potential predictor of lymph node involvement. Khaliq T et al (2001)<sup>14</sup> has reported p53 mutation rate of 13.5% in Pakistani population. Iacopetta B et al (2000)<sup>15</sup> reported p53 mutation rate of 17% in case of invasive ductal carcinoma. Overgaard J et al (2000)<sup>16</sup> reported that p53 mutation is strong marker for prediction and disease free survival irrespective of nodal status and mutation is more frequent in ductal carcinoma, large size tumour, node positive and high grade tumour with detection rate of 23%.

In our study p53 mutation rate was found in 16% cases which are slightly more than p53 mutation reported by Khaliq T et al<sup>14</sup> from Pakistani population. All 32 cases of p53 positive tumor had lymph node metastasis while tumour without lymph node metastasis did not show any p53 mutation. Thus p53 mutation is significantly correlated with lymph node metastasis in our study similar to other studies.<sup>12,13</sup>

p53 mutation was present in 23.53% of grade III tumour, 10% cases of grade II tumor and 33.33% cases

of grade I tumor. This difference in positivity is due to number of cases as there are 12 cases in grade I tumor, 120 cases in grade II tumor and 68 cases in grade III tumour. Among 32 p53 positive cases 12.5% in grade I, 37.5% in grade II and 50% in grade III. Maximum number of cases is in grade III. There was no significant correlation between grade and p53 mutation.

Mean tumor size was  $6.25 \pm 0.88$  cm in p53 positive tumors and  $6.143 \pm 2.39$  cm in p53 negative tumors. There was no correlation found between p53 mutation and grade of tumour, tumour size and T-status similar to study by Shpitz B et al (2000).<sup>17</sup> Khaliq T et al (2001)<sup>14</sup> observed that there was no correlation between p53 positivity and tumor size, nodal status and histopathological diagnosis but in our study there was no correlation between tumour size, histopathology, but significant correlation between nodal status and p53 mutation. Mean AgNOR per cell in p53 positive tumors were  $8.75 \pm 4.27$  and  $7.83 \pm 4.58$  in p53 negative tumors which was statistically not significant.

Schmitt FC et al (1999) observed that c-erbB-2 was over expressed in 43.7% of but all cases of intraductal hyperplasia without atypia c-erbB-2 over expression was absent. c-erbB-2 oncoprotein overexpressed in 20-38 % of breast tumour.<sup>19,20,21,22</sup> Maximum positivity rate of c-erbB-2 has been reported in comedo carcinoma (~70%).<sup>20</sup> In our study c-erbB-2 over expressed in 40% cases of breast cancer almost similar to study by Imoto S et al (1999).<sup>22</sup> Out of 32 cases of comedocarcinoma, 24 cases (75%) are c-erbB-2 positive.

In our study 80 cases are c-erbB-2 positive. of these 65% patient had lymphatic invasion and 35% patient did not have lymphatic invasion. There is significant correlation between c-erbB-2 over expression and lymphatic invasion on histology. Studies by McGuire (1991),<sup>23</sup> Rilke et al (1991),<sup>24</sup> O'Reilly et al (1991),<sup>25</sup> Gusterson et al, (1992),<sup>26</sup> Erdem (2005)<sup>5</sup> have shown that c-erbB-2 over expression predicted outcome in node positive cases only and not in node negative cases. p 53 mutation has been linked to be associated with advanced breast cancer and resistance to chemotherapeutic agent adriamycin in a study by De Leo et al (2007).<sup>27</sup> Expression of growth factor and chemokine receptors is associated with inflammatory breast carcinoma and increased risk of recurrence and death in a study by Cabioglu A et al (2007).<sup>28</sup> In our study, 40% cases were c-erbB-2 positive and 16% cases were p53 positive. On correlating c-erbB-2 and p53, c-erbB-2 over expressed

in 80 cases (40%) out of them 24 cases (30%) was p53 positive whereas 56 cases (70%) were p53 negative. Whereas 60% of total cases were C-erbB-2 negative out of them 6.7% cases were p53 positive. There is no significant correlation found between p53 mutation and c-erbB-2 over expression.

# A Study of Internet Addiction and its Association with Big Five Personality Traits in Indian Adolescents

Shibani Julka<sup>1</sup>, Rajesh Upadhyay<sup>2</sup>

<sup>1</sup>Student, M.A. Clinical Psychology, Indira Gandhi National Open University, Maidan Garhi, New Delhi, India,

<sup>2</sup>Academic Counsellor, Indira Gandhi National Open University, Maidan Garhi, New Delhi

## Abstract

**Background:** Internet use has become an indispensable part of our lives. Adolescents are the ones who are particularly vulnerable to internet addiction. Problematic Internet use (PIU) or internet addiction is that manner of using internet which can lead to psychological, social, educational, or vocational problems in one's life. In today's world as computer and Internet use has become a staple of everyday life, there runs a risk of overuse and dependence, which has lead to addiction and moreover, may lead to personality problems and other psychopathologies.

**Method:** A non- experimental study was conducted among adolescents between the age of 15-17 years having access to internet facility in daily routine(n=100). Big Five Personality Inventory was administered to assess the personality and Young's Internet Addiction Test (IAT: Young, 1998) was self-administered by the students after being briefed with the instructions. Subjects were classified into mild users, moderate users and addicts for comparison. It was hypothesized that a significant negative correlation will exists between Internet addiction and Big Five Personality Traits.

**Result:** Approximately 40% of the students were found to be addicted, 25% were moderate users and 35% were mild users. Users found addicted scored poorly on the Big Five Personality Traits as hypothesized indicating negative correlation.

**Conclusion:** The findings from this study identified varied levels of internet usage among adolescents which could serve as a crucial factor in understanding its effects on the personality. The findings further imply that there is a need for early interventions such as setting boundaries or professional help in addition to detecting early warning signs of underlying psychopathologies.

**Keywords:** *Internet addiction, adolescents, personality traits, Internet Addiction Test, Big five personality inventory*

## Introduction

In the four decades since its inception, internet and its easy and wide accessibility has driven dramatic

change. It has enabled flow of information, including entertainment, news, financial, and academic material. It has brought people closer together by enabling various forms of interpersonal communication, notably e-mail, instant messaging, video conferencing and social networking. In a very short period, it has become the staple of everyday life and it is difficult for most of us to imagine a world without instant and continuous access to the internet. Since the number of internet users is on an exponential rise, the issues surrounding its excessive use and abuse by people has become a hot topic of research from varied scientific fields

e-mail: shibanijulka@gmail.com

including psychology, neuroscience and psychiatry. Internet addiction is characterized by excessive or poorly controlled preoccupation, urges, and/or behaviors regarding Internet use that lead to impairment or distress in several life domains.<sup>1</sup>

The term “internet addiction” was proposed by Dr. Ivan Goldberg in 1995 for pathological internet use.<sup>2</sup> However, the findings of Caplan indicated prominent role of social isolation in behavioural symptoms of pathological internet use. He therefore was of the opinion to replace the term pathological with problematic internet use.<sup>3</sup>

Internet Addiction is a problem akin to addiction of drugs, alcohol or gambling as some internet users were becoming addicted to the Internet in much the same way that others became addicted to drugs or alcohol and were even reported to have shown associated dysfunctions like increased aggression on withdrawal, increased irritation level, separation stress and anxiety etc.<sup>4</sup>

According to Young et.al. (2000) Internet addiction is a broad term covering a wide variety of behaviours and impulse control problems. The five subtypes of Internet addiction are as follows:

- Information overload.- Too much online surfing leads to decreased productivity at work and fewer interactions with family members.
- Compulsions.- Excessive time spent in online activities such as gaming, trading of stocks, gambling etc
- Cybersex addiction.- Too much surfing of porn sites often affects real-life relationships.
- Cyber-relationship addiction -. Excessive use of social networking sites to create relationships rather than spending time with family or friends may destroy real-life relationships.
- Cyber gaming addiction: obsession for online gaming.<sup>5</sup>

Griffith considered internet addiction as a subset of behavior addiction and any behavior that meets the 6 “core components” of addiction namely **salience** (*internet use becoming the most important activity that takes over thinking, feelings and behaviour of the user*) **mood modification** (*the positive subjective experiences as a consequence of engaging in Internet giving a feeling of high or a means of escape from the reality*) **tolerance**

(*the tendency to gradually increase the amount of time using internet in order to extend positive subjective experience*) **withdrawal symptoms** (*unpleasant feeling-states and/or physical effects which occur when Internet use is discontinued or suddenly reduced and might include impulsiveness, mood swings or irritability*) **conflict** (*interpersonal conflict, conflicts with other activities as academics, social life, other interests or intrapersonal conflicts*) **relapse** (*the tendency for or recurrence of prior behavioral patterns*).<sup>6</sup>

Given the present scenario the internet is actually burdening adolescent lives from gaming to sexual and emotional relationships. More and more people including adolescents are suffering from its consequences from having a negative impact on identity formation and negatively affecting the cognitive functioning causing neurological complications and social problems to poor academic performance and engaging in risky behaviour.<sup>7</sup>

In terms of prevalence the developing countries are not spared either due to extreme infiltration of technology even into the remotest corners.

There were about 42 million active internet users in urban India in 2008 as compared to 5 million in 2000.<sup>8</sup> In this exponentially growing population, youth and young adults occupy a significant number. It is estimated that in India, about 18 per 100 of the general population are active Internet users<sup>9</sup>. Surveys in the United States and Europe have also indicated alarming prevalence rates between 1.5 and 8.2%. Though it is much debated that internet has made lives of people easier but it has also inconspicuously added to the psychopathologies among its users.<sup>10</sup>

Although Internet addiction, specifically, has not been recognized as a disorder by the APA, it did recommend further research of overuse of the Internet and video games.<sup>11</sup>

## Method

A non- experimental study was conducted in a total of 100 school going adolescents of age between 15-17 years having regular access to internet . The school was selected purposively and for the sake of feasibility one section from each standard was selected randomly. Prior permission to conduct the study was sought from the concerned authorities of the school. Before initiation of the study the subjects were assured of the confidentiality. Subject consent was obtained as well as they were

informed about the purpose and nature of the study. The samples were selected using purposive sampling.

It was hypothesised that there will be a significant correlation between Internet addiction and Big Five Personality Traits

The tests administered were The Internet Addiction Test (IAT; Young, 1998) and The Big Five Inventory.

*The Internet Addiction Test* by Kimberly Young is a reliable and valid test<sup>12</sup> and is one of the most utilized diagnostic instruments for Internet addiction.<sup>1</sup>

It is a 20-item 5-point Likert scale that measures the self-reported compulsive use of the internet. Total internet addiction scores are calculated, with possible scores for the sum of 20 items ranging from 20 to 100 with a range from 20-49 (*normal*) indicating an average online user having full control over usage, 50-79 (*problematic*) indicating facing frequent problems due to excessive internet use and 80-100 (*significantly problematic*) suggesting no control at all over internet usage.<sup>1, 13</sup>

**English version of IAT is used in this study:** *The Big Five Inventory* is a 44-item inventory with a 5-point Likert scale that measures an individual on the Big Five Factors (dimensions) of personality i.e. **Openness** (traits like having wide interests, being imaginative, insightful, etc) **conscientiousness** (traits like organized, thorough, hardworking, responsible etc., **Agreeableness**, (traits like sympathetic, kind, affectionate, cooperative, cheerful, etc.) **Neuroticism and Extraversion**<sup>14</sup> to which the subject responds with degree of agreement or disagreement from 1 (*strongly disagree*) to 5 (*strongly agree*).<sup>15</sup>

Coefficient alphas and test-retest reliabilities suggests satisfactory reliability and validity.<sup>16</sup>

**Statistical Analysis:** *Pearson's correlation*

*coefficient* was used as a measure of the degree of linear dependence between the variables.<sup>17</sup>

Data was entered and analysed by SPSS program for Windows.

## Results

Mean age of the study subjects was 16.3 years. Of the 100 subjects approximately 66% were using internet on mobile phones and rest of them were using mobile and laptop or desktop interchangeably. The purpose of use comprised of entertainment, social networking, educational purpose and other uses. Majority of usage was for educational purpose comprising of 38%, social networking comprised of 27% and remaining 35% was for entertainment and general use.

When severity of internet usage using IAT was calculated it showed the following trend; 39% subjects fall under severe level users, moderate severity users comprised of 26% and 35% were among mild severity users.

Subjects who scored high on IAT scored low on Big Five Personality Trait Inventory. Pearson correlation test revealed that the personal trait of agreeableness, conscientiousness, extraversion and neuroticism have significant correlation with internet addiction level. Agreeableness, extraversion, openness and conscientiousness are negatively correlated with internet addiction level; however, neuroticism is positively associated with internet addiction level indicating poor management and control over emotions. The result of the study is shown in following Tables:

**Table 1: Internet addiction score**

Level (Score)	n	%
Mild level Users (20-49)	35	35
Moderate level Users (50-79)	26	26
Severe level Users (80-100)	39	39

**Table 2: Average scores on Big Five Personality Traits**

Traits	Mild Users (M.S) S.D	Moderate Users (M.S) S.D	Addicted Users (M.S) S.D
Extraversion	32.5 0.570	24.8 0.497	23.6 0.485
Agreeableness	33.8 0.581	25.6 0.505	23.2 0.481
Conscientiousness	33.9 0.582	25.8 0.507	24.3 0.492
Neuroticism	11 0.331	17 0.412	27.5 0.524
Openness	37.6 0.613	30.8 0.554	27.8 0.527

M.S- Mean score on each trait; S.D- Standard deviation

**Table 3: Pearson Product Moment Correlation**

Variables	Internet Addiction r p-value
Extraversion	-0.712 < 0.001
Agreeableness	-0.742 < 0.001
Conscientiousness	-0.668 < 0.001
Neuroticism	0.863 < 0.001
Openness	-0.451 < 0.001

r- Pearson Product Moment Correlation

## Discussion

A number of studies have been conducted across the world, especially among adolescents with respect to internet addiction.

In a study conducted by Syed Shah Alam et al. in 2013 showed impacts of excessive internet usages such as interpersonal problem, behavioural problem, physical problem, psychological problem, where an individual suffers from problematic personality as they are unable to control their emotions and the way of thinking and acting due to long hour use of the Internet. They tend to increase the net serving time and eliminate the set schedule indicating emotional instability and poor planning.<sup>18</sup>

Nalwa and Anand (2004) carried out a study in India among school children 16-18 years old. Dependents and non-dependents. Significant behavioural and socio occupational functional differences were revealed between the two groups. Dependents were found to have delays in the work at hand in order to spend time online. Loss of sleep due to compulsions of late night logins and feelings of boredom without internet reported by dependents were greater than those of non-dependents.<sup>19</sup>

Shapira et al. in 2003 found problematic internet use to be positively associated with subjective distress, functional impairment and Axis I psychiatric disorder.<sup>20</sup>

In the present study the severity of internet addiction and its relationship with personality traits was investigated. Individuals were able to meet a set of diagnostic criteria that show signs of impulse-control difficulty.

The findings of the study suggested nearly 40% subjects on a severe level of internet addiction while 35% and 26% came under the ambit of moderate and mild severity level respectively. The subjects who were found to be severely addicted to the internet scored poorly on

Big Five Personality Traits in comparison to the ones found on a moderate and mild level respectively.

Except for neuroticism which correlated positively with the internet addiction, rest of the traits correlate negatively with internet addiction.

Thus, the expected relationship between internet addiction and Big five personality traits was established.

Table 2 shows the average scores and standard deviation on each personality trait. The pattern of scores clearly indicates low scores on personality traits with increase in the severity level of internet addiction. Table 3 shows product moment correlation coefficient (r) of internet addiction vs Extraversion, agreeableness conscientiousness, neuroticism and openness to new experience. The r values of each trait viz - 0.712, -0.742, -0.668, 0.863 and -0.451 respectively at p-value of <0.001 indicates that the outcome value for each trait is significant.

Individuals scoring high on internet addiction have been found to have sceptical, impulsive and moody nature. Also such individuals tend to be disorganized and poor planners as per the studies done previously.

Neuroticism which correlated positively with internet addiction indicates a personality that is likely to experience negative emotions like depression anxiety, anger etc. readily, is emotionally unstable and moody. As reported by the subjects scoring high on internet addiction feelings of uneasiness and distress when not being able to use the internet. Some even reported anxiety and compulsiveness to use the social media so far so that disrupting their concentration on the task in hand, in their case, studies in addition to ruining the daily routine.

This study is just a preliminary step toward a deeper understanding of the relationship and implications of internet addiction on personality traits among adolescents.

## Conclusion

There is no way to stop science and technology development. The ever increasing need for high speed internet and its affordability has penetrated deep into our lives which has led to the emergence of internet addiction.

From the findings of previously conducted studies

as well as the current study it appears that Internet addiction can have a variety of detrimental outcomes for young people that may require professional intervention. In the fifth edition of the Diagnostic and Statistical Manual of Mental Disorders (DSM-V), the criteria for this condition are limited to “Internet Gaming Disorder” and do not include general use of the Internet, online gambling, or social media.<sup>21</sup>

There are certain limitations involved in this study which must be addressed. The sample size of 100 subjects is very small therefore, generalizability of the sample must be addressed with caution. Also present are some bias in terms of methodology by utilizing convenient purposive sampling technique.

This study is just a preliminary step and further research is required.

Albeit, on a smaller platform this study would definitely help to further strengthen the need for stringent discretion on the use of internet. Not only it would help to focus on this potential pathological condition but also on the need for preventive and interventional strategies to tackle this condition.

# Content Validation of Early Intervention Protocol for Preterm Infants in Indian Population

A. Rajarajeswari<sup>1</sup>, P. Ramachandran<sup>2</sup>, L.N. Padmasani<sup>2</sup>, Sailakshmi Ganesan<sup>3</sup>

<sup>1</sup>Associate Professor, Faculty of Physiotherapy, <sup>2</sup>Professor, Department of Paediatrics, Sri Ramachandra Institute of Higher Education & Research, Porur; <sup>3</sup>Head of Department, Department of Physiotherapy, The Spastics Society of Tamil Nadu, Taramani, Chennai, Tamil Nadu, India

## Abstract

**Background:** Preterm birth is defined as babies born alive at less than 37 weeks of gestation. Due to the lack of the in-vitro environment and their exposure to harmful environment of the NICU leads to the preterm infants having a long term disability. The awareness of environmental factors on development gave rise to the idea formation of various early intervention programs. The guidelines for early intervention progression should be tailored respecting the growing needs of preterm infants. Hence, the current literature states a need for a protocol with proper dosage in improving the motor outcomes.

**Objective:** The current study aimed to validate the content of early intervention protocol in Indian population.

**Materials and Method:** The process of content validation of early intervention protocol involved development stage and expert judgment stage. The early intervention protocol was designed into three stages with extensive review of literature. After designing the protocol, nine experts in field of paediatric & neurological physiotherapy performed the judgemental process. The process of validation includes rating of selected experts in a 5 point likert grading on two parameters namely relevance and ease of performance. Based on expert's inputs on early intervention protocol, the level of agreement, content validation index and kappa value was calculated.

**Results:** The three staged early intervention protocol almost exhibited an excellent agreement on all stages.

**Conclusion:** The structured early intervention protocol exhibited excellent content validity to its use in Indian population.

**Keywords:** Multimodal sensory stimulation, preterm infants, hammer smith neurological assessment scale, KMC.

## Introduction

WHO defined preterm birth as babies born alive at

less than 37 completed weeks of gestation. The highest incidence of preterm births (13.4%) occurs in southern and south-east Asia and India ranks first in yearly prevalence of preterm birth among the South Asian countries.<sup>1</sup>

During normal embryological development, developing brain is highly neuroplastic. The fetal development in the intra uterine environment provides an optimal surrounding for the formation and maturation of the neural synapses.<sup>2</sup>

e-mail: araji21@yahoo.com

Myelination of the central nervous system begins from 14 weeks of gestation and reaches a peak at 25-37 weeks.<sup>3</sup>

Gyrification process occurs from 10-28 weeks of gestation. The fetal brain develops from the lissencephalic structure to that of an adult brain with sulcus and gyri. Surface area of the cortical grey matter increases with more neurons in the cortex, which increases the ability of the cortex to process information.<sup>4,5</sup>

This process of normal development is altered in preterm infants, further worsened by the early exposure of the preterm to the harmful NICU environment.<sup>6</sup>

These studies suggest that the infants born as very and late preterm will have extended developmental, behavioural problems which needs early intervention to address these morbidities. 'Early intervention' means educational strategies and neuroprotection strategies aimed at enhancing brain development by promoting neural plasticity and neuro-protection at improving the environmental and neurological experiences of the preterm infant during the critical period of development.<sup>7,8</sup>

The CNS receives inputs from all the sensory pathways such as touch, vision, sound, and movement to explore the possibilities of neural connection and forms new synapses, which can be further trained to produce proper developmental outcomes.<sup>9</sup>

Despite the fact that intervention strategies are large in number, all have shown to improve cognitive function but neuromotor outcomes are not well established.<sup>10</sup>

Hence, the current literature states a need for early intervention protocol and ultimately result in improved functional outcomes. The designed early intervention protocol requires a validation process for its relevance and ease of performance.

Validity means to a test/protocol measuring what it intends to measure.<sup>11</sup> The content validity is similar to face validity using subjective judgement. Hence, an expert opinion is sorted to test the protocol for its intensions and practicality. The present study aimed to validate the content of early intervention protocol in Indian population.

## Materials and Method

The process of content validation involved development stage and expert judgment stage. The protocol was designed into three stages with extensive literature.<sup>12-15</sup> The staging of protocol is mannered in a progressive way, meeting the developmental needs of preterm infant. The early intervention protocol follows a set pattern of exercises including kangaroo mother care, tactile stimulation non weight bearing position followed by weight bearing exercises then with functional exercises. Totally ten experts were selected for the validation process but only nine experts in field of paediatric & neuro physiotherapy gave consent to participate in the study. This validation study was approved by the Institutional Ethics Committee of Sri Ramachandra University, Chennai, Tamilnadu, India.

**Procedure of Validation:** The primary investigator requested 10 independent experts with minimum 10 years of experience in paediatric & neuro physiotherapy to participate in the study. As per recommendations by Lynn MR<sup>16,17</sup>, a minimum of five and a maximum of 10 experts are required for the validation process. Out of 10, nine experts agreed to participate and were diversely placed in Southern parts of India. All experts were practicing paediatric & neuro physiotherapy including three professors, two associate professors and four senior physiotherapists. The process of validation included rating of experts selected in a 5 point likert grading on two parameters namely relevance and ease of performance. The scale was scored as 1=strongly disagree, 2=mildly disagree, 3=neutral, 4=agree, 5=strongly agree. The score 4 and 5 were acceptable for calculation, if scored less than 3, experts were requested for suggestions. The key exercise components were listed in three stage manner with likert scale being measured for its relevance and ease of performance. The prepared content was sent through electronic media and basic instructions were given. Based on expert's inputs on early intervention protocol, the level of agreement, content validation index and kappa value was calculated.

## Results and Discussion

Based on the reports of nine experts, the Content Validity Index (CVI) is tabulated in [Tab-1]. The protocol has eight components namely general, tactile, kinesthetic/proprioceptive, vestibular, visual, auditory stimulations with handling & parent education.

**Table 1: Content Validity Index (CVI) and kappa (K\*) of early intervention protocol**

Contents of early intervention protocol	Relevance		Ease of Performance	
	CVI	Kappa	CVI	Kappa
<b>General</b>				
Kangaroo mother care	100	1.00	100	1.00
<b>Tactile stimulation</b>				
Swaddling	89	0.89	89	0.89
Infant massage therapy	100	1.00	89	0.89
Gentle Human Touch	100	1.00	100	1.00
<b>Kinesthetic/Proprioceptive stimulation</b>				
Range of motion exercises	100	1.00	100	1.00
Gentle longitudinal compression of extremities	100	1.00	78	0.76
Infant positioning	100	1.00	100	1.00
Facilitation of head control	100	1.00	100	1.00
Assisted rolling using upper and lower extremities	100	1.00	100	1.00
Assisted kicking/reciprocal movements of legs	100	1.00	100	1.00
Facilitating hand to midline and mouth and legs hands together activities	89	0.89	78	0.76
Encouraging the development of head righting	100	1.00	100	1.00
Reaching in prone/supine	100	1.00	100	1.00
Encouraging creeping/crawling patterns	100	1.00	100	1.00
<b>Vestibular Stimulation</b>				
Cradled rocking	100	1.00	89	0.89
Visual stimulation	100	1.00	100	1.00
Promotion of eye following, to strengthen the eye and neck muscles, to promote head movement	100	1.00	100	1.00
Using Black and white objects	100	1.00	78	0.76
<b>Auditory stimulation</b>				
Maternal voice	89	0.89	100	1.00
Handling & Parent education	89	0.89	100	1.00

The content validation index was calculated by dividing number of experts who scored 4 or 5 by total number of experts participated in the validation process of early intervention protocol. The cut off level for acceptance if >0.78 as in accordance to a study [18], thus seven out of nine agree for an exercise. This further explains that if level of agreement is greater than 78%, the exercise is considered with good agreement among experts and to be included in protocol. A modified kappa was calculated to confirm the relevance of early intervention protocol. The interpretation of kappa values were taken as: fair= 0.40 to 0.60, good= 0.60 to 0.74 and excellent= 0.75 to 1.00.

The 19 item early intervention protocol was examined by all experts with good agreement among them. In tactile stimulation, swaddling & infant massage therapy,

Kappa values were moderate in ease of performance.<sup>12</sup> In vestibular stimulation, cradled rocking score showed minimal difficulty in ease of performance.<sup>13-15</sup> The main finding of the present study is that almost all components exhibited excellent agreement. Thus the early intervention protocol was well appreciated by majority of experts and was considered to be the most integral part of early intervention to preterm infants.

**Limitation:** Experts were recruited only from the Southern parts of India for the validation process.

**Conclusion**

The early intervention protocol exhibited excellent content validity to its use in Indian population. The protocol is safe and can be administered to infants.

**Ethical Clearance:** Taken from Institutional ethical committee, Sri Ramachandra Institute of Higher Education & Research, Porur, Chennai.

**Source of Funding:** Self funded

# Effect of Core Stability and Functional Mobility Exercises on Muscle Strength after Lumbar Spinal Cord Injury

Miss Neha Y. Kakade<sup>1</sup>, Suraj B. Kanase<sup>2</sup>

<sup>1</sup>Intern BPT, <sup>2</sup>Associate Professor, Department of Neurosciences Physiotherapy,  
Faculty of Physiotherapy, KIMSUDU, Karad, Maharashtra

## Abstract

**Background:** Many studies suggest that when people are confined to wheelchair, central neuropathies such as spinal cord injury usually reduce strength of core muscles and corresponding functional abilities for standing and reaching. Studies that have aimed to compare different strategies to improve functional capacity or stability have produced controversial results. Furthermore such studies have focused solely on individual component. In contrast, the present study describes the effect of core stability as well as functional mobility exercises on muscle strength after lumbar spinal cord injury.

**Aim:** To analyze the effect of core stability and functional mobility exercises on muscle strength after lumbar spinal cord injury.

**Methodology:** 25 patients with lumbar spinal cord injury were recruited on a volunteer basis. Ethics approval was obtained from Institutional ethical committee, KIMSUDU. The purpose and procedure of the study was explained to each participant before giving their consent to participate in the study. Neurological levels and impairment scales were determined according to the American Spinal Injury Association (ASIA) standards. Descriptive statistics such as percentages, mean, and standard deviation were used for data analysis.

**Result:** The p-value for each component is <0.0001 and is extremely significant. For each variable of the study (muscle groups) the post assessment values were more than pre assessment values. The intervention used in this study produced significant improvement in core strength and lower extremity strength of participants after lumbar spinal cord injury.

**Conclusion:** Core stability and functional mobility exercises improve muscle strength in lumbar spinal cord injury patients.

**Keywords:** Lumbar spinal cord injury, core stability, functional mobility, physiotherapy.

## Introduction

The spine is an inherently unstable structure as the osteoligamentous lumbar spine buckles under small compressive loading.<sup>1</sup> Paralysis of the muscles below

the level of the injury can lead to limited and altered mobility, self care, and ability to participate in valued social activities.<sup>2</sup> Disabilities related to spinal cord injury vary according to the degree of damage, and the damaged spinal segments or nerve fibers.<sup>3</sup> Mechanism of the injury that can cause damage to the vertebrae with a resultant damage to the cord is usually a hyper flexion with rotation movement. Extension with rotation is less likely to cause damage to the cord.<sup>4</sup> Injury to the lumbar spine usually results in paraplegia or paraparesis.<sup>5,6</sup> Spinal cord injuries are typically divided into 2 categories: complete injuries and incomplete injuries. The international standards for neurological

e-mail: drsurajkanase7@rediffmail.com

classification of spinal cord injury (ISNCSCI) defines a complete injury as having no sensory or motor function in the lowest sacral segments (S<sub>4</sub> and S<sub>5</sub>). An incomplete injury is classified as having no motor and/or sensory function below neurological level including sensory and/or motor function at S<sub>4</sub> and S<sub>5</sub>.<sup>7</sup>

Immediately following an acute injury to the spinal cord there is a stage of spinal shock. After the stage of spinal shock has passed the various neurological deficits starts manifesting which commonly consists of the following: motor and sensory deficits, spasticity usually increases during first six months after spinal injury and reaches a plateau by the end of first year.<sup>8</sup>

A critical role of spine musculature is to stiffen the spine in all potential modes of instability. Active control of spinal stability is achieved through the regulation of force in surrounding muscles. Trunk extensors, flexors, and lateral flexors provide spinal stability during every dynamic movement. So, there is an important need to have balanced muscular control.<sup>9</sup> Proper timing and coordinated efforts of these muscles are important for spinal stability.<sup>10</sup>

Core stability describes the ability to control the position and movement of the central portion of the body to allow optimum production, transfer and control of force and motion to the terminal segments in the integrated activities.<sup>11</sup> Functional capacity has been studied as one important aspect of activity of daily living. Different functional training method have been assessed for their effectiveness in improving functional capacity;<sup>12,13</sup> however, no definitive conclusions have been reached with regard to the type of functional training that is most effective.<sup>13</sup> Some studies have found that strength training can increase functional capacity,<sup>14,15</sup> even with only modest gains<sup>16</sup> or gains in a few measures.<sup>17</sup> Nevertheless, most studies that have been conducted focuses only on singular elements i.e. few studies that have been conducted focuses only on core stability while other studies focuses only on functional mobility for improving functional capacity in patients with spinal cord injury. Studying the effectiveness of combination of two elements i.e. core stability and functional mobility exercises in lumbar spinal cord injury patients could provide different interpretation about the utility

of core stability and functional mobility exercises to improve strength and functional capacity.<sup>18</sup> Therefore, the purpose of this study is to evaluate the effectiveness of core stability and functional mobility exercises on muscle strength in lumbar spinal cord injury patients.

## Material and Methodology

This study aimed to evaluate the effect of core stability and functional mobility exercises on muscle strength after lumbar spinal cord injury. This was an experimental study. The study was conducted in Krishna institute of medical sciences 'Deemed to be' University, Karad. 25 patients with lumbar spinal cord injury were recruited on a volunteer basis. Sample size was calculated with the help of formula  $N=4SD^2/(x \times \epsilon)^2$ . Ethics approval was obtained from Institutional ethical committee. The participants were recruited according to the inclusion and exclusion criteria. The criterion for inclusion in the study was 1. Patients with history of American spinal Injury impairment scale (AIS) grade C and D SCI. 2. Both male and female participants. The exclusion criterion from the study was neurological illness other than lumbar spinal cord lesion. A written consent was taken from each participant to voluntarily participate in the study. Each participant was explained about the purpose and procedures of the study. Once the informed consent was taken, detailed information was gathered, assessments were done with appropriate outcome measure and pre test was done. Depending on pre assessment evaluated strength, a six week core muscle strengthening exercise protocol was given and follow-up for progression was done after 2, 4 and 6 weeks. Later again post test was done and descriptive statistics such as percentages, mean, standard deviations and paired t test were used for data analysis and were recorded in order to derive the conclusion. All statistical analyses were performed with instat software.

## Statistical Analysis and Result

Descriptive statistics were performed for all variables (i.e., muscle strengths). Pre and post assessments of the selected participants were done. Arithmetic mean, standard deviations, paired t -test and p-value were calculated for each outcome measure.

**Table No. 1: Strength of muscle post intervention**

Sr.No.	Muscle Groups	Mean		SD		Paired t-value	p-value	Interference
		Pre	Post	Pre	Post			
1.	Hip flexors	2.280	4.440	0.8907	1.261	8.035	<0.0001	Extremely significant
2.	Hip extensors	2.480	3.920	1.112	1.288	4.793	<0.0001	
3.	Hip abductors	2.400	3.640	1.000	1.075	4.656	<0.0001	
4.	Hip adductors	2.480	3.920	0.8718	1.152	5.192	<0.0001	
5.	Knee flexors	3.200	4.560	0.8699	0.9129	5.283	<0.0001	
6.	Knee extensors	3.080	4.840	0.7024	0.9434	9.508	<0.0001	
7.	Ankle dorsiflexors	2.120	3.480	0.8327	0.9626	6.834	<0.0001	
8.	Ankle plantar flexors	2.680	3.800	0.4761	0.7071	7.716	<0.0001	
9.	Great toe extensors	2.160	3.520	0.8505	1.085	5.911	<0.0001	
10.	Trunk flexors	1.680	3.200	0.6272	0.7638	14.905	<0.0001	
11.	Trunk extensors	1.560	3.200	0.5066	0.7638	14.421	<0.0001	
12.	Side flexors	1.880	3.560	0.5831	0.6000	15.087	<0.0001	
13.	Trunk rotators	1.640	3.160	0.5686	0.6245	14.905	<0.0001	

The post assessment values of each study variable (muscle groups) are more than the pre assessment values. The mean difference of pre assessment values is -1.508. The mean difference of post assessment values is -0.172

**Table No. 2: Strength of lower extremity muscles and core muscles of body in male subjects.**

Males	Mean	SD	Paired t-value	p-value	Interference
Pre	2.098	0.2762	15.489	<0.0001	Extremely significant
Post	3.331	0.4612			

The post assessment values of mean and SD of overall core and lower extremity strength of male participants are more than the pre assessment values. The mean difference is -1.234.

**Table No. 3: strength of lower extremity muscles and core muscles of body in female subjects.**

Females	Mean	SD	Paired t-value	p-value	Interference
Pre	1.852	0.2969	6.891	<0.0001	Extremely significant
Post	3.409	0.6149			

The post assessment values of mean and SD of overall core and lower extremity strength of female participants are more than the pre assessment values. The mean difference is -1.558.

**Discussion**

This study aimed to analyze the effect of core stability and functional mobility exercises on muscle

strength after lumbar spinal cord injury. Core stability is the ability of lumbopelvic hip complex to prevent buckling and to return to equilibrium after perturbation.<sup>19</sup> Functional mobility is the manner in which people are able to move around in the environment in order to participate in the activities of daily living.<sup>20</sup> Weakness is the most obvious impairment that inhibits people with SCI from performing motor tasks.<sup>21</sup>

In this study 25 patients were recruited according to the inclusion and exclusion criteria, in which 13 were male participants and 12 were female participants. Manual muscle test was performed on each subject for thirteen muscle groups (hip flexors, hip extensors, hip abductors, hip adductors, knee flexors, knee extensors, ankle dorsiflexors, ankle plantar flexors, great toe extensor, trunk flexors, trunk extensors, side flexors and trunk rotators) in standardized position.<sup>22</sup> Muscle strength was graded on a scale from zero to five using six weeks of interval.<sup>23</sup> We evaluated the pre test and post test assessment values for manual muscle testing in the selected participants.

Depending on the pre assessment values a six week core stability and functional mobility exercise protocol was given and follow up for progression was done after 2, 4, 6 weeks interval. In the initial phase of treatment galvanic current was given to trunk and lower extremity muscles with the frequency as tolerated and passive range of motion exercises to trunk and lower extremity muscles which initiated flicker of contractions.<sup>24</sup> Denervated muscles are incapable of contraction except by direct stimulation of the muscle fibers by suitable electrical means.<sup>25</sup> Once the initiation of contractions was achieved electrical stimulation with the help of faradic current to motor nerves of spine and lower extremity was used. Innervated muscles contract in response to a demand for activity provided the demand is sufficient.<sup>24</sup> Once the patient was able to do active contractions, active assisted range of motion exercises were initiated. Once the power of contraction has been regained, the muscles were strengthened progressively until maximum function was obtained.<sup>25</sup> Strengthening of trunk and lower extremity muscles was done with isometric strengthening program. A person requires a progressive resistance training program in which the load is appropriately and progressively increased. Such training is often best performed within the context of a functional skill, provided the principles of progressive resistance training can be maintained.<sup>26</sup> Varieties of method which were used for providing resistance are pulleys, free weights, weight cuffs and theraband.<sup>25</sup> Resistance training increases muscle strength by making muscles work against a weight or force.<sup>27</sup> Bed mobility exercises were used to improve functional mobility of the participants.<sup>25</sup> After all this procedure the post test assessment values were evaluated.

Richardson et al. proposed that lumbar stabilization exercise increased the stability of the spine and posture

while performing functional postures and movements.<sup>28</sup> Panjabi reported that lumbar stabilization exercise, a muscle strengthening exercise for the deep muscle group, plays an important role in providing dynamic stabilization in the segments stability, and useful for decrease in spinal functional disorder.<sup>29</sup> Specific transverse abdominal muscle strengthening along with the conventional treatment shows speedy recovery than the only conventional therapy when given at the acute and sub-acute stages of traumatic spinal cord injury.<sup>30</sup> The present study also found improvements in lower extremity muscle strength as well as functional capacity after performing core stability and functional mobility exercises. The post test results derived that the stabilization exercises used in this study produced significant improvement in muscle strength in the lumbar area thereby improving functional capacity and muscle strength in the lower extremity.

## Conclusion

Core stability and functional mobility exercises improve muscle strength in lumbar spinal cord injury patients.

**Ethical Clearance:** Obtained from Institutional Ethical Committee, KIMSUDU, Karad..

**Source of Funding:** This project was funded by Krishna Institute of medical sciences deemed to be university, karad.

# Medicalization of Judicial Mode of Execution: A Critical Study in American Context

Author-Anjum Hassan<sup>1</sup>, Meenu Gupta<sup>2</sup>

<sup>1</sup>Ph.D. Scholar, <sup>2</sup>Ph.D. Guide, Amity Law School, I-2 Block, Sector 125, Noida Amity University Uttar Pradesh

## Abstract

Modes of judicial execution of death sentence have to be determined in light of various objective factors like prevailing atmosphere of the international opinion, international norms and standards, contemporary penological theories and ever progressing standards of human decency. Though it's essential to adapt the most civilized method of judicial execution, nevertheless, what is more important is how that civilized process of execution is carried out. History is witness to the fact that how medical professionals have made invaluable contributions to make the existing modes of execution more civilized, humane and efficient by playing the most pivotal role. Medicalization of the process of judicial execution through intravenous lethal injection is not novel. However, currently direct participation of physicians in the implementation of the death penalty through intravenous lethal injection has become an extremely controversial subject, initiating voluminous intellectual debate at global platforms. Hence, an appropriate contouring of such participation is increasingly coming under sharp scrutiny on ethical and legal grounds. The question arises, will the physicians not be guilty of gross professional misconduct by refusing to oversee the executions and taking care of the condemned persons in their last crucial hours, thereby neglecting their ethical responsibility to minimize the suffering and maximize the comfort. Physicians need to fulfill their role as caregivers by actively participating in the implementation and development of lethal injection as the most humane mode of judicial execution.

**Keywords:** Judicial execution, evolved standards, medicalization, physician, intravenous lethal injection.

## Introduction

*"The final cause of law is the welfare of society"*  
—Benjamin Cardozo<sup>1</sup>

Miles of distance have been crossed by man to transform the barbarian era to the current civilized society. Maturity, tolerance and understanding are all part and parcel of a civilization. History is witness to the fact that how medical professionals have helped in making the existing modes of execution more civilized, humane and efficient by playing the most pivotal role. To use a decapitating machine as a humane method of execution which later on was known as the guillotine, was first advocated and designed by Dr Joseph-Ignac Guillotine and Dr Antoine Louis, respectively. The electric chair, a method of execution that was considered 'more humane' for several years, was designed with the help of a dentist named Dr Alfred Southwick. To use gas chamber and even hanging as method of execution

was a valuable suggestion of Medical expertise only. It was Dr Stanley Deutsch, an anesthesiologist, who first conceived the idea of intravenous induction of general anesthesia through a lethal injection. In Texas in 1982, the first 'clinical trial' of the lethal injection was carried out on a 40-year-old African-American man as he was injected with anesthetic agents in the presence of two doctors. As a result, his death occurred within few minutes.<sup>2</sup>

America is one of the few countries to use Lethal Injection as a method of judicial execution. In this research paper we would be analyzing the participation of physicians in the implementation of the death penalty through lethal injection. And currently this is an extremely controversial subject, initiating voluminous intellectual debate at global platforms.<sup>3</sup> Social consensus on pressing issues like; whether physicians should be present at executions? Whether physicians should

supervise the execution process? Whether they should inject the lethal injections or just pronounce and certify death? is imperative in order to draft adequate legislation to ensure the most appropriate involvement of physicians in the entire execution process.<sup>4</sup>

The choice regarding participation of physicians in the entire execution process by intravenous lethal injections is made harder by the presence of distinct circumstances and undeniable arguments existing both for and against their participation in the said executions. In this research paper, scholar would critically examine the relevant ethical and legal arguments that bear on this decision.

**Physician's participation in mode of execution (intravenous lethal injection) of death sentence with special reference to America:** In United States of America, various acts currently applicable to medical practice make physicians liable for professional misconduct for participating in the execution process despite the fact that most death penalty statutes overtly not only provide for such participation but even require them to do so.<sup>5</sup> Although the method of judicial execution are becoming more and more medicalized, however, the negative effect of the threat of such sanctions and restrictions keeps on increasing. Now, it has become mandatory for the states to cure such statutory ambiguities, if physicians are required to contribute their part in the judicial executions.<sup>6</sup> Combination of both, permissive death penalty legislations allowing the participation of physicians in the execution process along with the medical practice acts protecting them from any kind of disciplinary action for such participation are required to resolve this disparity. These kinds of legislations will not only protect the medical profession as a whole but will also take care of the needs of condemned persons and the public, in best possible manner.<sup>7</sup>

**Arguments for and Against Physician Participation in Executions:** Significant arguments raised by the subject of physician's participation in the execution are analyzed here and clarity is sought through rational and pragmatic support on these issues.

**Ethical Arguments against Physician Participation:** Doctors being the healers, hence their active participation in the judicial execution process is completely irreconcilable with their basic ethical code, is the chief contention of the opponents of such participation of the physicians. Public strongly believe

and think that it's the inherent duty of the medical profession to use its skills and tools only and only for the betterment of the public health.<sup>8</sup> However, usage of such curative skills to act as the harbinger of death is completely in contravention of medicine's first and foremost goal, moreover it clearly violates a physician's fiduciary duty to serve the patient's interest in the best possible manner.<sup>9</sup>

In modern as well as ancient medical ethics, a substantial support exists for such a stand and position. Over 2000 years old, the Hippocratic Oath, still exists as the most potent weapon and repeatedly cited foundation of professional ideals for practicing physicians. Any action taken by the physician with intent of causing any direct or indirect harm or death is broadly condemned by the overt language of the oath. The relevant text reads as, "I will prescribe regimen for the good of my patients according to my ability and my judgment and never do harm to anyone. To please no one will I prescribe a deadly drug, nor give advice which may cause his death."<sup>10</sup>

The participation of physicians in some instances may help possibly reduce pain, but there exist many countervailing arguments as well. Firstly, the purpose of medical involvement through a physician should not be to reduce pain or suffering, but to help save life and humanity. Secondly, the presence of a physician also serves to give an aura of medical legality to the whole procedure of death penalty.<sup>11</sup> Thirdly, in a broader perspective, the physician is taking over some of the responsibility for executing the punishment, makes the physician handmaiden of the state as an executioner. The benefit for possible reduction of pain by the physician who is in fact acting under the control of the state, rather lawfully does harm.

**Ethical Arguments for Physician Participation:** The ethical ideal which should be aspired by physicians is; "The task of medicine is to cure sometimes, to relieve often, to comfort always."<sup>12</sup> Deepest obligation of physicians is to take utmost care of the interest and wishes of their patients. Although the preservation of life remains the supreme maxim of medical profession, however, as always, it's neither the chief ethical value nor in the best interest of the patients. Therefore, at times the preservation of life must give way to other goals of medical profession like the cure of extreme sufferings. This is the reasonable logic that backs the ethical approval to withhold and withdraw life-sustaining treatment in

order to relieve pain and suffering.<sup>13</sup> As a result, doing so does accelerate and questionably even results in death. However, the medical condition of some patient's is such that the only alternative in their best interest is to welcome death rather than to wait for a slowly deteriorating life of agony. By and large, the Double Effect Doctrine is sanctioned by both, medical ethics as well as contemporary legal theory, which contemplates that measures carried on for beneficial purposes, like minimizing the sufferings, may be allowed morally even if they foreseeably lead to death.<sup>14</sup>

Now considering this reality, vagueness still exists as to whether the physician participation in judicial execution is contrary to the doctor's ethical obligations imposed by the Hippocratic Oath or the interest of the patient. As is categorically stated by AMA that a physicians being components of a profession which is fully committed to save life whenever there exists hope of doing so, hence must forbid themselves from participating in any kind of judicial execution.<sup>15</sup> However, the situation is entirely different in case of a judicial execution, wherein the patient (convict) is surely going to die; hence, there exists no such hope of life. After exhaustion of last appeal by the convict, an execution date is assigned by the Court and it's only after that physicians are supposed to act in the actual execution process.

Physicians can not only ensure that the drugs are injected in the correct order but also prescribe and arrange a lethal pharmacological procedure which is in tune with the unique medical condition of the condemned, thus wiping out all possibilities of any unfortunate incident that could occur during the lethal injection procedure, like; the condemned may regain consciousness and undergo the unimaginable trauma of conscious asphyxiation.<sup>16</sup> The condemned will also not suffer the humiliation and pain as a result of multiple needle pricks by incompetent medical technicians as the physicians can insert the catheters correctly after locating the appropriate veins. Physician participation negates any irreversible brain damage condition by closely monitoring the vital signs during the entire procedure, thereby guaranteeing death.

**Legal Arguments against Physician Participation:** In some states medical practice acts may get violated by the participation of physicians in judicial execution process, is one of the chief legal arguments of the opponents. Various grounds are

established for physicians by the medical practice acts; to be either disciplined or de-licensed. "Dishonorable" or "unprofessional" conduct is time and again listed as a ground for professional sanction by these acts. Moreover, several medical practice acts incorporate actions, which are against the ethical norms existing within the profession, into their definitions of "unprofessional" or "dishonorable" conduct.<sup>17</sup> It's quite possible that various state medical boards may take disciplinary action against physicians for such judicial execution participation, as several medical lobbying groups have stood in opposition to such participation, including the AMA. Although, no such disciplinary action for defying these ethical norms has been undertaken by the state boards till date, however, the possibility still remains.

**Legal Arguments for Physician Participation:** Despite the fact that physician participation is strictly prohibited by several medical practice acts, the capital punishment statutes of most states either permit or call for some sort of such physician participation. It's worth mentioning that such physician participation is allowed by the federal execution protocol, however, the same is not called for by the protocol. Apparently, it seems that there exists a latent legislative disagreement between the capital punishment statutes and medical practice acts.<sup>18</sup> Established rules of interpretation and construction of statutes state and suggest that the medical practice acts should be superseded by the capital punishment statutes for two reasons.

Firstly, the rule of "last in time" is usually followed by the courts in case of conflicting statutes. In case of a conflict between two statutes, whether actual or perceived, the last enacted statute is allowed to override the one enacted earlier with respect to the conflicting provisions only, for the obvious and commonly accepted logic of being more accurate reflection and description of the prevailing will of people through the legislature. The ruling should definitely be in favour of the death penalty statutes being more recent in time as compared to the medical practice acts.<sup>19</sup>

Secondly, as per another rule of statutory construction, the statute which is specific in nature (deals directly with the subject matter) must prevail over the general one (does not deal with the subject matter directly), as the specific statutes provide more accurate and clear guidelines for the appropriate course of legal action. With regard to the present conflict, since the capital punishment statutes explicitly deal with the

issue by directly addressing the same, which the medical practice acts fail to do, hence the capital punishment statutes are bound to prevail over their corresponding medical acts.

Moreover, physician participation in judicial executions is possibly required by the American Constitution. Eighth Amendment to the Constitution has put an absolute bar on inflicting cruel and unusual punishments. The Supreme Court of America, in 1972, categorically declared and held certain executions unconstitutional on the basis of involved procedures and processes constituting unusual and cruel punishments.<sup>20</sup> On the other hand, in 1976, in Florida, Georgia, and Texas, in a series of cases, the Court upheld the imposition of capital punishment as constitutional, because these states had incorporated more humane modes of execution as contrary to the precious ones which comprised of cruel and unusual procedures. Now the obvious question arises, what constitutes unusual and cruel punishment? Is it the absence of supervision by physician that makes the execution method cruel and unusual?

Specifically in this context, for the Eighth Amendment purposes, the Court in *Trop v. Dulles* noted that what constitutes unusual and cruel punishment is entirely based on the ever evolving standards of human decency which ultimately mark the progress of a maturing society.<sup>21</sup>

### Conclusion

Taken as a whole, key ethical and legal arguments supporting and opposing the participation of trained physicians in intravenous lethal injection judicial executions; point towards a clear single conclusion that deliberations favoring the participation strongly overshadow the ones against it. By now, we are clear as to how the ethical arguments are wrongly based on mistaken belief as to the ethical role of physicians and the kind of mutual trust between the medical profession and public at large. In fact, physicians will be guilty of gross professional misconduct by refusing to oversee the executions and taking care of the condemned prisoners in their last crucial hours, thereby neglecting their ethical responsibility to minimize the suffering and maximize the comfort. Moreover, the legal questions raised by the medical practice acts are adequately invalidated by potential deliberations of Eighth Amendment and the legal rules of statutory construction.

Physicians need to fulfill their role as caregivers by actively participating in the implementation and development of lethal injection as the most humane mode of judicial execution. Additionally, prevailing ambiguity in medical statutes as to the physician participation must be removed by the competent legislatures, thereby, explicitly allowing physicians to supervise the whole execution procedure. Such rulings will not only benefit the convicts but the society at large. Supervision of judicial executions by competent medical professionals will not only ensure that the botched executions are minimized as much as possible but also protect the human rights of dying convicts by maintaining the standards of decency.

**Ethical Clearance:** Not Required

# A Cross Sectional Study to Evaluate Tree Plantation and Gardening as an Intergenerational Bonding Activity Amongst Geriatric Population

Rahul Netragaonkar<sup>1</sup>, Amrut Arun Swami<sup>2</sup>, Shruti Amrut Swami<sup>3</sup>

<sup>1</sup>Associate Professor, <sup>2</sup>Assistant Professor, Dept. of Community Medicine, DVVPF's Medical College, Ahmednagar, Maharashtra, <sup>3</sup>Assistant Professor, Dept. of Rasashastra & Bhaishajya Kalpana, Bidar Vidya Kendra R. Akka Mahadevi Ayurvedic Medical College, Bidar, Karnataka

## Abstract

**Background:** Life expectancy among the elderly has been improving for many decades all over world, the emotional and mental wellbeing of the geriatric people is at stake because of the younger people migrating to the urban areas or even abroad for work, and older people staying alone at their homes.

Few days can be spent by older–younger people together to plant trees. And this intergenerational bonding activity can give a sense of satisfaction and mental wellbeing to the older adults.

### Objectives:

1. To find out how older people spend time with younger generations
2. To evaluate if older people are interested in gardening and planting trees as an intergenerational activity.

**Method:** We conducted a survey on 120 older people in the community attached to our college, we enquired about the different means by which the older people spend time with the younger generations and if they will be interested in gardening or planting trees together with the younger generations.

**Results:** There were a total of 120 participants, 60 males and 60 females. Mean age was  $68.49 \pm 6.83$  years. Majority of them interacted with the younger generations daily (55.83%). Chit chatting, managing business and telling stories to children were the common things done together. Majority (70%) felt that they spent enough time with the younger people, while few were not spending time at all with their younger generations (5.83%). 79 participants never planted a single tree (65.83%). 107 participants felt that planting trees is necessary (89.17%) while 104 participants (86.67%) would like to do gardening or planting trees with their younger generations.

**Keywords:** *Intergenerational Activities, Geriatric Mental Health, Tree Plantation.*

## Introduction

Life expectancy among the elderly has been improving for many decades the reason being advancement of health sector and overall improvement in per capita income of the people all over world,<sup>[1]</sup> and there is evidence that the physical health of the elderly has also been improving with these advancement.<sup>[2-4]</sup>

The emotional and mental wellbeing of the geriatric people is at stake because of the increasing urbanization,

and younger people migrating to the urban areas or even abroad for work, and older people staying alone at their hometowns.

In the global Sustainable Development Goals<sup>[5]</sup>, goal 13 is Climate Action, “take urgent action to combat climate change and its impacts”. It’s a responsibility which is equally shared by the governments and all the people living on the earth. All the efforts how much ever minimal they may be should be counted as minute steps towards environmental betterment.

Planting and growing trees is one of the major responsibilities we have today on us.<sup>[6]</sup> All people should come together to help build our green zones inside and nearby cities and villages. Older people have much time left with them, younger people have energy. If all these generations spend some time together, then planting and growing trees can be easily done. People can maintain small gardens at home, every home can have a small nursery of its own where they can grow saplings of the common regional trees, even fruit trees like Mango, Papaya, Custard Apple, Guava. Weekends and few days in the vacations can be spent by older – younger people of the house together to plant these trees near to our houses, residential areas or near to cities. Planting trees have a large potential to conserve energy in urban areas.<sup>[7]</sup>

When the younger people who live in cities come to visit their parents in the villages, if they spend time together in planting these trees, it will be memories to cherish for both the generations. When the children are away, older parents can remember them while taking care of these trees, when the old people are dead, the children can remember them while eating fruits from these trees. And most importantly every tree that is planted and grown will be a one-step ahead on the path of environmental betterment.

We had conducted this study to see what things older people do with the younger generations and whether they will be interested in planting trees.

#### Literature review:

**AL Park et al<sup>[8]</sup>** studied the impact of intergenerational activities on general wellbeing of older adults. They suggested that geriatric people who are involved in intergenerational activities of any form are healthy both physically and mentally as compared to those people who are left to live alone. They concluded that the geriatric people should be involved in daily activities in home or in society to improve their overall wellbeing.

**CN Reisig et al<sup>[9]</sup>** studied the perception of geriatric people of wellbeing after intergenerational experiences with youth, they also concluded that the intergenerational activities are important for geriatric physical and mental health.

**Faer M et al<sup>[10]</sup>** conducted a large project on intergenerational activities between the adolescents,

young adults and older adults. They reported that not only the older people but also the adolescents and young adults are benefited from these intergenerational activities and they recommended different social and community activities to be planned and executed on a regular basis. Their project brought together different age-distinct, high risk, ethnically similar populations in an intergenerational, reciprocal support mechanism that addressed those negative factors that affect high-risk behaviour and decisional processes in adolescents and physical and mental functioning in the elderly.

Many authors have raised a concern about the mental and physical wellbeing of geriatric people. <sup>[11-13]</sup> Some of them suggested the importance of intergenerational activities in improving the overall health of the geriatric people.<sup>[14-17]</sup>

#### Objectives:

2. To find out how older people spend time with younger generations
3. To evaluate if older people are interested in gardening and planting trees as an intergenerational activity.

#### Method

We conducted a survey on 120 in the community attached to our parent medical college, where we enquired about the different means by which the older people spend time with the younger generations and if they will be interested in gardening or planting trees together with the younger generations.

Ethical Clearance for the institutional ethics committee has been taken to carry out this study.

#### Inclusion Criteria:

1. Old age people of both sexes and age more than 60 years
2. Residents of medical college and hospital area for more than 6 months

#### Exclusion Criteria:

1. Unmarried people
2. Those who are not willing to participate

**Sample Size:** According to a study conducted by GK Ingle et al<sup>[18]</sup> the proportion of old age people more than 60 years will be 7.7%,

So,  $p = 7.7\%$

Using formula for sample size (n) calculation,

$$n = 4 \times p \times q / e^2$$

Where,  $p = 7.7\% = 0.077$

$$q = 1 - p = 0.923$$

Taking e, absolute error of 5%,  $e = 0.05$

$$\text{So, } n = 4 \times 0.077 \times 0.923 / 0.05 \times 0.05$$

$$n = 113.71 \approx 114$$

A minimum of 113 patients will be included in the study, rounding it up to 120 patients.

**Sample size = n = 120**

**Sampling Technique:** Convenience Sampling

**Statistical method:** A simple questionnaire was prepared and a pilot study was conducted with 20 geriatric participants, the questionnaire along with the results were put forth the institutional research cell to validate the questionnaire. The validated questionnaire in google form format was used to collect the data from the geriatric people in the nearby community. Data was entered in Microsoft excel, qualitative data is shown in numbers and percentages and quantitative data in mean and SD. Charts and graphs are used to show the results.

### Results

There were a total of 120 study participants, 60 males and 60 females. Mean age was  $68.49 \pm 6.83$  years.

Majority of them interacted with the younger

generations daily (55.83%) followed by 3 to 4 days a week (30%).

**Table 1: Frequency of quality time spent with the younger generations**

Frequency of quality time spent	Number	%
Daily	67	55.83%
3 to 4 days a week	36	30.00%
1 to 2 days a week	9	7.50%
Once or twice a month or Less	8	6.67%
Total	120	100%

General chit chat (56.67%), managing family business and farms (35%) and telling stories to grandchildren (32.50%), doing Pooja – Bhajans (10%) were the common things done by the participants with their younger generations.

**Table 2: Common intergenerational activities done together**

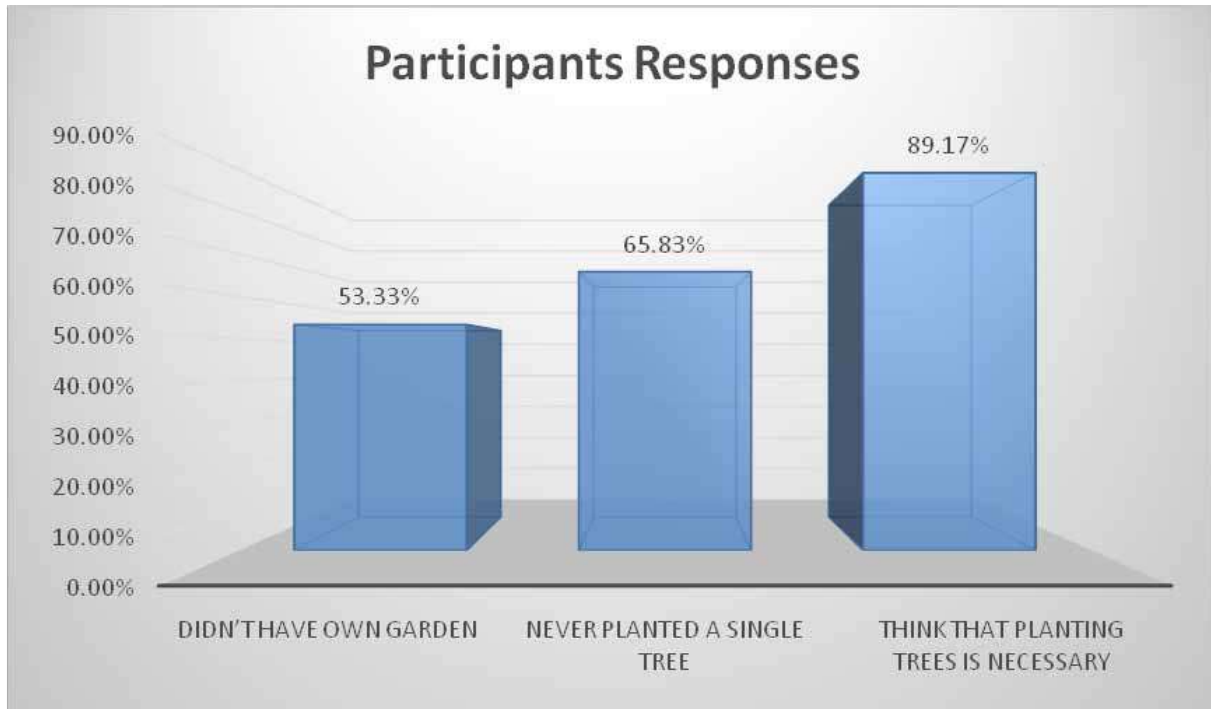

Common activities done together	Number	%
General chit chat	68	56.67
Managing family business/Farm	42	35.00
Telling stories to grandchildren	39	32.50
Pooja - Bhajan	12	10.00
Going for a walk	8	6.67
Gardening	4	3.33
Others	9	7.50

Majority (70%) felt that they spent enough time with the younger people, some felt that it was not enough (24.17%) while few were not spending time at all with their younger generations (5.83%).

**Fig 1: Opinion about younger people spending time with older people**

64 participants didn't have their own garden (53.33%), 79 participants never planted a single tree (65.83%). 107 participants felt that planting trees is necessary (89.17%)

**Fig 2: Participants response regarding gardening & tree plantation**

104 participants (86.67%) would like to do gardening or planting trees with their younger generations, 9 responded that they might do it (7.50%) while rest 7 showed no any interest (5.83%) in doing gardening or planting trees as an intergenerational activity. Upon one month follow up, we found that 16 families (13.33%) actually did the activity.

**Fig 3: Choosing gardening and tree plantation as an intergenerational activity**

## Discussion

Various intergenerational activities have different impact on the people. We may look to attitudinal and behavioural measures for indicators of intergenerational community solidarity. Attitudes of youth towards elders are heterogeneous and may be positively or negatively affected by familial and nonfamilial intergenerational contact.<sup>[19,20]</sup>

**Y Fujiwara et al<sup>[21]</sup>**, in their study launched a new intervention study called REPRINTS in which senior volunteers were engaged in an activity of reading picture books to children. At the follow-up, social network scores (frequency of contact with grandchildren and others around the neighbourhood) and self-rated health was improved for majority of the individuals who did this activity most intensively as compared to those who did not. They concluded that this specific intergenerational activity helped in improving the mental and physical health of the older adults.

**AL Park et al<sup>[8]</sup>** studied the impact of intergenerational activities on general wellbeing of older adults. They recommended intergenerational activities for better health of the elderly.

**CN Reisig et al<sup>[9]</sup>** studied the perception of geriatric people of wellbeing after intergenerational experiences with youth while **Faer M et al<sup>[10]</sup>** conducted a large project on intergenerational activities, both of them recommended there should be intergenerational activities to maintain the health and wellbeing of people, both young and old.

We found out that majority of the participants interacted with the younger generations daily (55.83%) followed by 3 to 4 days a week (30%). General chat (56.67%), managing family business and farms (35%) and telling stories to grandchildren (32.50%), doing pooja – Bhajans (10%) were the common things done by the participants with their younger generations.

With increased urbanization and globalization, there is a reduced contact and also a marked reduction in the intergenerational bonding activities due to the migration of younger people for jobs in other cities.<sup>[22]</sup>

Whatever time these older people get to spend with their younger generations, should be spent in memorable productive activities. What else can be more productive than planting trees together? The older generations can utilize their time in growing and nurturing saplings and

trees at and around home, the younger generations can contribute their energy to plant these saplings in nearby areas.

We found out that 64 participants didn't have their own garden (53.33%), 79 participants never planted a single tree (65.83%). 107 participants felt that planting trees is necessary (89.17%). This indicates that with a little motivation and dedication these people can get involved in gardening and planting trees, which is the most important thing in today's era.<sup>[23]</sup>

## Conclusion

Our study concludes that there are deficiencies in the intergenerational bonding activities. Various innovative and fruitful intergenerational activities should be developed, acted upon and followed to improve the physical, mental and social wellbeing of people from all the generations including old age people. Gardening and planting trees is one of such activity which people find important and are ready to follow.

**Limitations:** Being a time bound study, follow up was not possible to check how many participants are actually involved in gardening and tree plantation as an intergenerational activity. A prospective study should be done to evaluate the impact and acceptance of this activity for intergenerational bonding.

**Conflict of Interests:** None

**Source of Funding:** Self

# Misconceptions and Traditional Treatment Practices Regarding Childhood Epilepsy in Central Gujarat of India: A Community Perspective

Vipin Vageriya<sup>1</sup>, Anil Sharma<sup>2</sup>

<sup>1</sup>Assistant Professor, <sup>2</sup>Principal & Associate Professor, Manikaka Topawala Institute of Nursing–Charotar University of Science and Technology, Anand-Gujarat

## Abstract

**Background and Purpose:** There are various misconception are present in society about variety of diseases. This study was undertaken to determine the current misconception prevailing in society, community regarding people with epilepsy (PWE) and traditional treatment practices.

**Aims:** To determine the misconception and traditional treatment practices regarding epilepsy present in society

**Method:** Researcher collected data from 54 parents of epileptic patients who visited the outpatient clinic of selected hospital of Gujarat. The data were collected by using questionnaire.

**Results:** Over all it was observed that still people have various misconception towards epilepsy. The social acceptance of epileptic patient is also major challenge in some of the society.

**Conclusions:** A suitable educational intervention programs has to plan to prevent social stigma about epilepsy. Awareness is required among community people that epilepsy can be treated by using antiepileptic drug and other medial measures. People believe medication has poor recovery rate so some time traditional practices having good result in recovery.

**Keywords:** *Childhood epilepsy, traditional treatment, misconception, central Gujarat, Social stigma.*

## Introduction

**Background:** There are many causes of epilepsy which are misunderstood. The life style of today's children is quiet different from past children. People believe that epilepsy can be treated by practice of black magic. Various misconceptions are present in society regarding treatment and recovery of epilepsy. Few people consider epilepsy as sins committed by one's forefathers. It is further assumed that people are controlled by supernatural forces which unable to control their bodily functions and that the condition is transferable through bodily contact of sputum that comes out of a person's mouth during attack of seizures.<sup>1</sup>

The Result of a research study found that the Quality of life (QOL) in children with epilepsy is affected in terms

of physical control, poor self-esteem, and less energy levels. Cognitive functions, social communication and other activities are less affected.<sup>2</sup>

A study concluded that CWE(child with epilepsy) have poor quality of life as he is not able to control on his own body during episode of seizure. Researcher also suggested comprehensive care needs to go beyond the attempt of controlling seizures.<sup>3</sup>

Many people in developing countries still concern that epilepsy is a disease which can spread from one person to another organism(like communicable disease) by direct contact or via urine, saliva, stomach gas, and feces excreted during a epileptic seizure. This tendency has played a major role in people living with epilepsy being ostracized, stigmatized, and misunderstood.<sup>4</sup>

There are some reasons for accepting traditional practices. Indian villages are still in developing stage so it is difficult to get modern medicine from a small village. Another problem is traveling and transportation to reach neurologist which is expensive. Further, financial and economical condition of family. The traditional healers may also be preferred because they are easily approachable and some time they do not charge for treatment. This local practitioner does not require publicity because patients will come based on recommendations from other people who have been treated by traditional healers.<sup>5</sup>

Epilepsy is a group of neurological or brain disorders which is recognized by epileptic seizures. Epileptic seizures are episodes that can vary according to length of episode. During long episode (>5min) child vigorous shaking. These episodes can result in physical injuries, including occasionally broken bones.

Epilepsy is considered as neurological disorder, which affect physical, social, cognitive and emotional aspects of one's life. Epilepsy is characterized by recurrent seizures, which are brief episodes of involuntary movement that may involve a part of the body (partial) or the entire body (generalized). Sometime patient become unconscious during episode. The person feels lack of control of bowel or bladder function.

There are 50 million people living with epilepsy worldwide, and most of them reside in developing countries. About 10 million persons with epilepsy are there in India.<sup>6</sup>

The average incidence of epilepsy each year in the India is estimated at 48 for every 100,000 child. Prevalence is the number of people with epilepsy, using prevalence numbers, ranges from 1.3 million to 2.8 million ( 5 to 8.4 for every 1,000 people). Its prevalence is about 0.3% in our population. The prevalence is higher in the rural (1.9%) compared to urban population (0.6%).<sup>6</sup>

Epilepsy is very complicated situation for a client. During episode person is dependent on other. The date, time and frequency of episode is unpredictable. It is common neurological disorder worldwide. . Epilepsy directly affects around 50 million people, the majority of them (80-85%) stay in poor or developing countries. People with Epilepsy (PWE) and their families often face a very common aspect of epilepsy which is known as Epilepsy Stigma (ES). ES is considered to be one of

the most important factors that have a negative influence on PWE. It is a commonly encountered global issue among PWE in all cultures.<sup>7</sup>

**Need for Study:** In this scientific era, we are unfortunate that, still people believe in misunderstandings, discrimination and social stigma surrounding a person with epilepsy. The Researcher observed that educated people know very little about epilepsy. The society is faithful towards prejudice and stigma towards patients with epilepsy. Various types of misconception are present about causes and treatment of epilepsy. Each community has their own belief. Majority of misconception are found in rural people. It is also observed that traditional healers play a very strong influence on rural community, and they may play a huge role in reducing the stigma of epilepsy in the community

#### **Research Objectives:**

1. To determine the current misconception regarding epilepsy prevailing in society
2. To find out frequency of various traditional treatment practices for epilepsy

#### **Material and Method**

**Research Approach:** Quantitative

**Research Design:** Descriptive survey design

Setting: Out Patient Department (OPD) of selected hospitals of Central Gujarat

**Population:** The accessible population for study is the parents of epileptic child from OPD of selected hospitals of Central Gujarat.

**Sampling Procedure:** Non probability convenient sampling

**Sample Size:** Total number of parents were 54. Out of this 10 were female.

**Source of Data:** Data were collected from parents of epileptic child from OPD of selected hospitals.

**Delimitation:** The study was delimited to parents of epileptic children's those available in OPD of hospitals.

**Study Result:** Over all 54 parents undergone in study. Each parent has their own view about epilepsy. The interesting fact is that no parents accepted that epilepsy can be treated with antiepileptic drug. All

parents favor that traditional belief and practices helps in recovery of epileptic client. The study result divides into 2 sections. Section-I is about parent perception for

social stigma and section-II is about traditional practices used for treatment of epilepsy.

**Section-I:**

**Table 1: Perception about epilepsy stigma N=54**

Statements	Yes	No
1. People suffering from epilepsy are mentally challenged	43	11
2. Epilepsy is a revenge of past sin	48	6
3. Epilepsy can never be recovered.	51	3
4. Epilepsy can be controlled by black magic	50	4
5. Children with epilepsy are dull	47	7
6. Epilepsy spreads through touching or coughing	30	24
7. Life of a person with epilepsy is miserable	45	9
8. Marriage is a cure for epilepsy	28	26
9. Antiepileptic drug create side effect	53	1
10. Epilepsy makes people dependent on others.	50	4
11. Person with epilepsy become dies in next 5 years.	10	44
12. People with epilepsy are violent or crazy	35	19
13. Epilepsy is a curse or wrath of God	41	13
14. Epileptic child is paralytic.	12	42
15. Epilepsy makes people unfit for marriage.	39	15

The above table reflected that 99% of parents agreed that antiepileptic drug create adverse reaction. The majority of parents (82%) said that epileptic patient will not die within 5 years after epilepsy. 83% parent believed that Life of a person with epilepsy is miserable.

**Some of the other common stigmas towards epilepsy are:**

Myth 1: The child should not attend school if he had epilepsy.

Myth 2: There is separate school for epilepsy children

Myth 3: All epileptic attacks occur with convulsions.

Myth 4: Women with epilepsy cannot bear normal children

**Section-II:**

**Table 2: Traditional treatment practices- Epilepsy N=54**

Traditional practices		Yes		No	
		Frequency	Percentage	Frequency	Percentage
1	Motivate child to smell old shoes	45	84%	9	16%
2	Slapping the child at the time of episode	40	75%	14	25%
3	Application of mustard oil on eyes	28	52%	26	48%
4	Referring child immediately to temple/traditional healer	38	71%	16	29%
5	Making child to drink cows urine	14	26%	40	74%

Traditional practices		Yes		No	
		Frequency	Percentage	Frequency	Percentage
6	To please the God, sacred threads(Janeu) with lockets and idols are also worn,	20	37%	34	63%
7	Burning body part by sharp object	30	56%	24	44%
8	Practices such as tattooing and burning with leather objects	18	34%	36	66%
9	Restrain the child during episode	32	60%	22	40%
10	Shaking and arousing the child	36	67%	18	33%
11	Making the children to wear bangles of different metals	10	19%	44	81%
12	Use Ash Gourd (Petha)	25	47%	29	53%
13	Putting spoon in child's mouth	35	65%	19	35%
14	Making the child to hold a bunch of iron keys	30	56%	24	44%
15	Apply onion & garlic mixture on body	28	52%	26	48%
16	Pouring cold water on child's body	39	73%	15	27%
17	Provide Basil (tulsi juice) after seizure	23	43%	31	57%
18	Applying eucalyptus oil on child's body	27	50%	27	50%
19	Use Hing (Asafoetida) and sendha namak(rock salt) on body	22	41%	32	59%
20	Sucking the secretions from child's nose	12	23%	42	77%

The above table shows that most of parents (84%) agree that epileptic child should motivate to smell old shoes during epileptic attack. 73 % realized that Pouring cold water on child's body treat epilepsy.

Conclusion- Over all study concludes that a positive approach is required for preventing social stigma towards epilepsy. Investigator recommends that Epileptic Stigma (ES) is dissemination of accurate knowledge about epilepsy is the most important way to fight. This knowledge should be addressed to all individuals including the patients, health caretakers, families and friends of PWE, educators and the public at large. The association like Indian Epilepsy Association and epilepsy foundation can contribute to change the perception into the mind of common man.

Discussion-Study result reveal that majority of people still believe in traditional treatment and home remedies. Epilepsy is not a communicable disease. Epilepsy is a preventable and treatable condition, but still it remains a major public health problem due to high stigma, socioeconomic inequity among population, huge treatment gap, and the poor epilepsy healthcare delivery system in India. The psychosocial and economical aspects of epilepsy impact the patient and family more crucial. It is clearly mentioned that epilepsy is a complex public health problem which requires integrated multidisciplinary approach for treatment and team work. The time has been passed and rather than

focusing on pilot projects, a sustainable, cost effective, and comprehensive public health response is required to address the challenge of epilepsy in India. Neurologists, public health professionals, psychiatrists, psychiatric social worker, psychiatric nurse, and program managers need to join hands for prevention, improved care, and rehabilitation of PWE in India.

Gopalkrishna Gururaj and team conducted a study on topic "Epilepsy in India : Impact, burden, and need for a multisectoral public health response" in 2015. The study result concluded that there is no significant change in the perception, stigma, and discrimination of epilepsy across the country, despite improvement in educational and social parameters over the time. The huge treatment gap and poor quality of life is the big barrier to achieve the objective of treatment. Researcher strongly proved that a multidisciplinary response is required to address the burden, treatment and impact of epilepsy which calls for an integrated and multipronged approach for epilepsy care, prevention, and rehabilitation. Health care delivery, capacity building, mobilizing public support and increasing public awareness will be the vital sign of such an integrated approach in a public health model.<sup>8</sup>

At the end of study researcher will create awareness among rural people regarding prevention and mode of treatment of epilepsy through mass media, one to one interaction and family counseling.

**Ethical Clearance:** It is obtained from CHARUSAT ethical committee.

**Conflict of Interest:** Nil

**Source of Funding:** Nil

**Acknowledgement:** I am very thankful to all the nurses and staff who help in this study.

# Development of Job Design Indicators for Generation Y Nurses at Tertiary Level Hospitals under Ministry of Public Health in Thailand

Pornnipa Suparasri<sup>1</sup>, Netchanok Srithoomma<sup>2</sup>, Suchitra Luangamonlert<sup>2</sup>

<sup>1</sup>Ph. D. Candidate, Ph. D. in Nursing Management Program, Christian University of Thailand,

<sup>2</sup>Ph. D. in Nursing Management Program and College of Nursing, Christian University of Thailand

## Abstract

**Background:** Job design is an essential and integral part of human resource management that its effect in motivation Generation Y nurses to enhance and improve their performance. Job design is very important for nurses and the productivity of nursing organizations, while job design indicators remain unclear.

**Aim:** To develop job design indicators in addition to assessing and validating job design indicators for Generation Y nurses at tertiary level hospitals.

**Method:** The sample of this study was 360 Generation Y nurses in nursing units at tertiary level hospitals under Ministry of Public Health in Thailand. The scale development process applied the steps of scale development by DeVillis<sup>1</sup> as follows: 1) definition of operational terms; 2) creation of questions from the definition of terms; formation of 16 indicators of three components; 3) content validity testing by five experts with a CVI of 0.91; 4) determination of the internal consistency reliability with thirty Generation Y nurses in nursing units with a Cronbach's Alpha Coefficient of 0.85 and 5) testing of the construct validity by using confirmatory factor analysis.

**Results:** The research instrument for measuring job design for Generation Y nurses in nursing units at tertiary hospitals under Ministry of Public Health in Thailand consists of three components with 16 indicators: 1) job characteristics (factor loading .67) was composed of five indicators, 2) social interactions (factor loading .98) was composed of six indicators, and 3) growth and learning (factor loading .65) was composed of five indicators. The confirmatory factor analysis model of job design for Generation Y nurses in nursing units at tertiary hospitals was congruent with the empirical data (CMIN/df = 1.24, RMR=0.02, GFI=0.97, AGFI=0.94, RMSEA= 0.03, CFI=0.99).

**Conclusion:** The developed instrument should be used to measure job design for Generation Y nurses in nursing units and for policy formulation in redesigning jobs at tertiary hospitals under Ministry of Public Health in Thailand.

**Keywords:** Job design, Indicator, Generation Y nurses, Tertiary hospitals.

## Introduction

The 20-year Thai national strategy on public health includes strategies for action on the four issues: prevention promotion & protection excellence; service excellence; people excellence and governance excellence.<sup>2,3</sup> In addition to requirements for meeting service users' needs and the skills of professional nurses

---

### Corresponding Authors:

#### Dr. Netchanok Srithoomma

Assistant Professor, Ph. D. in Nursing Management Program and College of Nursing, Christian University of Thailand

e-mail: netchanok.srithoomma@alumni.griffithuni.edu.au

who are service providers and personnel structure changes, particularly among Generation Y professional nurses. Thus, job design is a challenge for administrators in building motivation and improving performance to enable personnel with generation differences especially nurses who have work attitudes aimed at achieving nursing organizational goals by allocating work suitable for personnel skills and needs.<sup>4,5</sup>

Therefore, organization job design is important and part of human resource management. Noe et al.<sup>5</sup> stated that current job design needs to adjust with the generation of personnel working in the organization to build motivation to work successfully by designing jobs based on job characteristics, to create social interactions among personnel and to build growth and learning at work. According to previous studies, nursing job design has been found to lack clarity of models and development of indicators consistent with nursing work system contexts. The characteristics of Generation Y nurses who need to provide holistic care with a higher ratio of patients than standard specifications due to staff shortages<sup>5, 6</sup>.

Currently the number of Generation Y nurses in tertiary hospitals under Ministry of Public Health in Thailand increased to 62.50 percent.<sup>7</sup> Generation Y nurses provide clinical care and have key roles in determining future nursing unit administrative directions in place of the old generation. Effective job design indicators for self-assessments by personnel will provide guidelines for managers to encourage employee interest in working while increasing job satisfaction thereby leading to high levels of nurses' performance and productivity.<sup>8</sup> Therefore the aim of this study to determine job design indicators for Generation Y nurses in the nursing organizational contexts.

**Research Objectives:** To develop job design indicators for Generation Y nurses at tertiary hospitals under Thailand's Ministry of Public Health.

## Method

**Selection and Description of Participants:** The population used in this research was Generation Y nurses in nursing units at 33 tertiary level hospitals. The sample size was set by calculating with the formula of Cochran<sup>9</sup> which determined the population representation at a 95 percent confidence level and a tolerance level of 0.05 percent to ensure complete information. The researchers then adjusted the size of the group according to the

formula of Gupta and colleagues<sup>10</sup> by calculating a dropout rate of 10 percent. Therefore, sample for this study was 360 Generation Y nurses with cluster and simple sampling.

**Scale Development:** The researcher developed and tested the quality of job design indicators for Generation Y nurses at tertiary level hospitals based on the concept of Noe, et al.,<sup>5</sup> and DeVellis's method<sup>1</sup> in eight steps of research tool development as follows:

- 1. Identifying the concepts of the variables:** The concept of Noe, et al.,<sup>5</sup> was used in selecting job design concepts that could be used in the research to build understanding about job design in nursing units.
- 2. Defining the concepts:** The individual components of job design in nursing units which were defined as follows: (1) job characteristics; (2) social interactions; and (3) growth and learning.
- 3. Designing a scale:** In designing a scale for considering each indicator of job design, a measurement scale was designed in the form of 5-point Likert scales ranging from "most real" to "least real".
- 4. Seeking item review:** Each item was reviewed by two nursing instructors with expertise in nursing administration and experience in academic work involving job design and three nursing administrators with expertise in the management of the nursing systems of Generation Y professional nursing working at tertiary hospitals. Thus the content validity index (CVI) was analyzed.
- 5. Conducting preliminary trials:** The research tried the items with 30 Generation Y nurses at tertiary hospitals. The data obtained were used to calculate the reliability of the indicators by using Cronbach's Alpha Coefficient to obtain internal consistency of the overall scales, individual component reliability, item-total correlations, item-item correlations and alpha-if-item deleted reliability coefficients.
- 6. Performing field tests:** As previously stated the sample in this study was composed of 360 Generation Y nurses in nursing units at tertiary hospitals based on the scale development concept of DeVellis.<sup>1</sup>
- 7. Conducting construct validity studies:** The data analysis was conducted by performing exploratory

factor analysis and confirmatory factor analysis.

- 8. Evaluating scale reliability:** The collected data were analyzed for reliability with Cronbach’s Alpha Coefficient.

**Statistical Analysis:** All statistical analysis was undertaken by using statistics computer programs. The types of statistical analysis were as follows: 1) descriptive statistic were used to determine mean and standard for individual items; 2) exploratory factor analysis was used to organize the components of job design and 3) confirmatory factor analysis was performed to test for the goodness of fit of the structural model of the factors and weights were assigned to construct the indicators and empirical data were used to determine the weights of the main variables used in constructing the indicators.

**Results**

Three hundred and sixty Generation Y nurses at tertiary hospitals responded with self-administered

questionnaires. Most of the participants were females (96.90%) and more than a half were aged 23-26 years (68.30%). Most had graduated with bachelor degrees (100%), had experience working in patient wards for one year and up (28.60%) and had had experience on the boards of directors at the nursing unit and nursing organization levels such as directors on nursing practice (99.40%), nursing quality assurance (64.40%), academics (31.90%) and special activities (11.10%). All of the participants had passed training in nursing practice (100%), nursing quality (100%) academics (60.60%) and special activities (8.60%).

The results of the exploratory factor analysis for indicators of job design returned to 16 indicators (KMO=.894, p<.001) of three components. Each of the components consisted of the following: 1) job characteristics (five indicators), 2) social interactions (six indicators), and 3) growth and learning (five indicators). These three components explained 56.45 percent of the observed variance (see Table 1).

**Table 1: Eigen Values, Percentage of Variance and Number of Indicators of Each Component of Job Design**

Component Name	Eigen Value	Percentage of Variance	Cumulative Percentage	Number of Indicators
1. Growth and Learning	6.17	36.30	19.62	5
2. Job Characteristics	2.18	12.80	38.33	5
3. Social Interactions	1.25	7.35	56.45	6

According to the mean scores for the job design indicators about most of the work performed, promoting organizational success had the highest score ( $\bar{X}$ = 4.69, SD=0.53) but the lowest score was work performed with a clear career path ( $\bar{X}$  = 3.38, SD=0.75). And the factor loading of each component, job characteristics, social

interactions and growth and learning were found factor loading within a range of .71-.77; .53-.72 and .64-.78 respectively. The growth and learning indicator, “You have developed yourself in line with plans for individual development performance,” had the highest factor loading value (factor loading=.78) (see Table 2).

**Table 2: Mean standard deviation and factor loadings of job design indicators for Generation Y nurses at tertiary hospitals under Ministry of Public Healthin Thailand**

No.	Indicators	Mean	SD	Factor Loading
<b>Job characteristic</b>				<b>0.67</b>
1.	The work you perform requires knowledge about health science and the nursing profession.	4.53	.57	.73
2.	The work you perform requires basic and special nursing skills.	4.57	.56	.75
3.	The work you perform corresponds with the law and professional nursing standards.	4.63	.54	.74
4.	The work you perform contributes to promoting organizational success.	4.69	.53	.77
5.	The work you perform has impact on the safety and lives of patients and their families.	4.48	.59	.71

No.	Indicators	Mean	SD	Factor Loading
<b>Social interaction</b>				<b>0.98</b>
6.	The work you perform requires nursing activity performance self-evaluation on every shift.	4.47	.58	.53
7.	The types of work you perform requires teamwork.	4.64	.55	.71
8.	The work you perform as a team goes well.	4.37	.62	.72
9.	The head nurse helps when you have problems performing work.	4.31	.67	.65
10.	Your colleagues help one another.	4.37	.62	.68
11.	The work you perform involves changes in information and knowledge for improvement.	4.43	.60	.58
<b>Growth and Learning</b>				<b>0.65</b>
12.	You participate in work scheduling on your own.	3.89	.91	.64
13.	The work you perform has a clear career path.	3.38	.75	.75
14.	You have made plans for developing your competencies and proficiency.	4.03	.64	.76
15.	You have developed yourself in line with plans for individual development performance.	3.98	.67	.78
16.	You have had opportunities to study work both inside and outside your unit.	3.82	.85	.73

The results of the confirmatory factor analysis for the indicators found that the job design model to be consistent with the evidence-based data as a perfect fit by considering chi-square statistics equal to .07 CMIN/df= 1.24, RMR=0.02, GFI= 0.97, AGFI = 0.94, RMSEA

=0.03, CFI = 0.99. The results of the factor scores found the three most important components to be social interactions, followed by job characteristics and growth and learning (see Table 3).

**Table 3: Statistics from the analysis of relationship between the variables of job design component models for Generation Y nurses at tertiary hospitals under Ministry of Public Health in Thailand**

Component	Component Factor	Factor Loading	R <sup>2</sup>
Social Interactions	6	0.98	.97
Job Characteristics	5	0.67	.46
Growth and Learning	5	0.65	.42

CMIN/df = 1.24, RMR=0 .02, GFI= 0.97, AGFI=0 .94, RMSEA= 0.03, CFI=0 .99

The data was tested by determining the internal consistency of 16 job design indicators for Generation Y nurses at tertiary hospitals and Cronbach’s Alpha Coefficient for the entire set after construct validity analysis was 0.85. Cronbach’s Alpha Coefficient for individual components was within a range of 0.81 – 0.87, while item analysis and inter-item correlation had values of 0.33 – 0.66. The corrected item–total correlation was within a range of 0.80 – 0.88.

### Discussion

This study of the development of job design indicators to build motivation for Generation Y nurses involved the following three components: job characteristics, social interactions, and growth and learning. Each components

has five, six and five indicators, respectively, for a total of 16 indicators. The results of this development of indicators correspond with the concept of Noe, et al.,<sup>5</sup> The motivational job design approach was composed of the following three components: 1) job characteristics with indicators involving skill/task variety, task significance, task identity, autonomy and feedback for a total of eight indicators; 2) social interactions with indicators involving positive working relationships with colleagues, teamwork and mutual assistance for a total of one indicator and 3) growth and learning with indicators involving the job allowing opportunities for learning and growth in competencies and proficiency (indicator) for a total of 11 indicators. The study of Al-Maabadi Rn, Aalem & Baddar<sup>12</sup> who studied the

relationships between job design and the satisfaction of 500 professional nurses working at university hospitals and hospitals under the Ministry of Public Health, involved 14 indicators. Furthermore the study of Morgeson & Humphrey,<sup>13</sup> who developed the Work Design Questionnaire (WDQ), offered the following four components: 1) task characteristics; 2) knowledge characteristics; 3) social characteristics and 4) work contexts with a total of 77 indicators. However the aforementioned study differed from the findings of a study by Teryima & Abubakar<sup>14</sup> who studied the impact of job design attributes on performance attainment in business organizations in a survey of deposit money banks in Nigeria that measured the job design component, job characteristics for a total of 11 indicators.

The job design indicators for Generation Y nurses at tertiary hospitals have acceptable levels of content trust and reliability. The results of the structural validity testing found that both components could explain the total variance of 56.45 percent. Social interactions, job characteristics and growth and learning were able to describe 97, 46 and 42 percent, respectively. As the previous studies the development of job design indicators involve measurements business and education<sup>4, 5, 13, 14</sup> which in nursing involves measurements concerned with job characteristics and does not cover Generation Y nurses who have to interact with personnel and the internal and external environments of nursing units, including perceptions about career advancement and learning in order to achieve competencies deemed adequate and fitting for service provision; thus this study was a first job design tool which modified the job design concept of Noe, et al.,<sup>5</sup> used in the roles of Generation Y nurses at tertiary hospitals.

### **Conclusion and Implementation**

Job design indicators of Generation Y nurses have structural accuracy accurate and consistent with the job design concept of Noe, et al.,<sup>5</sup> focuses on the factor loading of each component from the highest to the lowest, namely social interactions, job characteristics, and growth and learning consequently. This study reveals new knowledge of job design indicators for Generation Y nurses the head nurse of nursing units and nursing administrators should be imply job design assessment consistent with nursing unit contexts and have the job design polices of Generation Y professional nurses at tertiary hospitals.

**Source of Funding:** A part of the study was supported by Christian University of Thailand in 2019.

**Conflict of Interest:** The authors have no conflicts of interest.

**Ethical Clearance:** The Ethical Committee of Christian University of Thailand approved the research project (Registration No. N. 24/2561) on June 26, 2018 and the permission were obtained from the ethics committee on research involving human subjects at the selected tertiary hospitals where the research data were collected. The protected samples were obtained as personal information and ethical concerns which included informed-consent and maintaining confidentiality. They had the right to cancel participation in the study any time without any impact on participants.

# Why is Education Important to Prevent Cognitive Impairment? A Cross-Sectional Study in Jakarta Indonesia

Raden Siti Maryam<sup>1</sup>, Junaiti Sahar<sup>2</sup>, Kuntjoro Harimurti<sup>3</sup>, Sutanto Priyo Hastono<sup>4</sup>

<sup>1</sup>Doctoral Nursing Student, Faculty of Nursing, Universitas Indonesia, Departement of Nursing, Poltekkes Kemenkes Jakarta III, <sup>2</sup>Faculty of Nursing, Universitas Indonesia, <sup>3</sup>Faculty of Medicine, Universitas Indonesia, <sup>4</sup>Faculty of Public Health, Universitas Indonesia

## Abstract

**Background:** Cognitive impairment may lead to dementia, which can affect the elderly quality of life. Improving awareness and prevention of dementia risk factors become very essential to prevent cognitive impairment, and one of the effort is through.

**Objective:** This study aimed at observing the relationship between elderly characteristics as dementia risk factors with cognitive impairment incidence.

**Method:** Descriptive study with a cross-sectional approach was used. The population was elderly who resided in Special Capital Region of Jakarta, Indonesia. A sample of 341 elderlies, aged 60 years old or above was selected and screened through multistage random sampling. Chi-Square and Fisher's Exact tests used to analyze the data.

**Results:** The results of dementia screening using CDT found as much as 91.8 %elderly were suffered from cognitive impairments. There was a significant correlation between sex and educational background with cognitive impairment( $p=0.003$  and  $p=0.005$ ).

**Conclusions:** Educational background can affect individual's cognitive level. Elderly is expected to keep stimulating their cognitive, socializing, and maintaining their physical exercise.

**Keywords:** *Cognitive impairment, education, elderly, prevention, risk factor dementia*

## Introduction

The number of older people in Special Capital Region of Jakarta has been raising from 5.13% of a total 9.6 million of population during 2010, and is expected to keep raising to 16.39% of the total 11.5 million of population in 2035. Meanwhile, life expectancy in Jakarta in 2010—2015 is 71.6 years, and it will keep raising to 73.9 years in 2030—2035.<sup>1</sup> This data show that the raising of population is directly proportional with increasing age.

One of main common issues for older people, which also become the main cause of high demand in nursing care, around the globe with the prevalence of fifty million people is dementia or cognitive impairment.<sup>2</sup> The prevalence of dementia incidence in Indonesia

during 2015 has reached 1.2 million people. This data are predicted to keep increasing up to 1.9 million people in 2030 and almost hit four million people in 2050.<sup>3,4</sup>

Dementia or cognitive impairment is associated with lower life expectancy, and it is considered to be a terminal disease with mortality as the consequence of the main functional. This issue demonstrates on the increasing demand on palliative care for elderly with severe dementia.<sup>5</sup> Cognitive impairment can also affect the elderly's quality of life.<sup>6</sup> Prevention and caring strategy become crucial in decreasing nursing care demand and increasing health status as well as quality of life of the elderly.<sup>7,8</sup> which are common problems among the elderly people, account for a wide range of aging disorders. Group reminiscence can be used as a profitable therapeutic method for preventing cognitive-

behavioral disorders in older adults. Therefore, we aimed to investigate the effect of group reminiscence on the cognitive status of elderly people. **METHOD** This study was a non-blinded randomized controlled trial. We enrolled 100 elderly people who were under the support of Ilam Welfare Organization, western Iran in 2013. Balanced block randomization method was used to randomize the participants into intervention and control groups. Elderly people in the intervention group participated in a group reminiscence program consisted of two one-hour sessions per week for 8 consecutive weeks. Data were collected using Mini Mental State Examination (MMSE).

Factors in cognitive impairment prevention must be known in addition to dementia risk factors. One of the factor, which corresponds to cognitive performance, is a long-term formal education.<sup>5</sup> Low level of education is a strong predictor to the cause of dementia in the future.<sup>9</sup> Intervention, and care will vastly improve living and dying for individuals with dementia and their families, and in doing so, will transform the future for society. Dementia is the greatest global challenge for health and social care in the 21st century. It occurs mainly in people older than 65 years, so increases in numbers and costs are driven, worldwide, by increased longevity resulting from the welcome reduction in people dying prematurely. The Lancet Commission on Dementia Prevention, Intervention, and Care met to consolidate the huge strides that have been made and the emerging knowledge as to what we should do to prevent and manage dementia. Globally, about 47 million people were living with dementia in 2015, and this number is projected to triple by 2050. Dementia affects the individuals with the condition, who gradually lose their abilities, as well as their relatives and other supporters, who have to cope with seeing a family member or friend become ill and decline, while responding to their needs, such as increasing dependency and changes in behaviour. Additionally, it affects the wider society because people with dementia also require health and social care. The 2015 global cost of dementia was estimated to be US\$818 billion, and this figure will continue to increase as the number of people with dementia rises. Nearly 85% of costs are related to family and social, rather than medical, care. It might be that new medical care in the future, including public health measures, could replace and possibly reduce some of this cost. Dementia is by no means an inevitable consequence of reaching retirement age, or even of entering the ninth Key messages 1 The

number of people with dementia is increasing globally. Although incidence in some countries has decreased. **2 Be ambitious about prevention** We recommend active treatment of hypertension in middle aged (45-65 years). The ability of individuals in understanding and processing information can influence their health literacy in which it corresponds to literacy function and cognitive. However, health literacy concept is still wide and complex, which needs to be understood to decide on health caring, prevention, and health promotion in maintaining and improving the quality of life.<sup>10</sup>

According to some researches there are positive correlation between health literacy proficiency and cognitive function in older adult, yet the longitudinal relationship between level of education and cognitive impairment in Jakarta still remains unobserved. Therefore, this research attempted to observe the relationship between levels of education with cognitive impairment and how to prevent it.

## **Material and Method**

This study was a cross-sectional research conducted in five main regions of Jakarta, Indonesia, using a multistage random sampling. 341 subjects were selected through Rule of Thumbs, while there was a 10% of subject dropouts from the total of estimated sample. The inclusion criteria for the subjects were aged 60 years old or more, living with their family, and signing the informed consent. Subjects were excluded under the following circumstances: lack of communication skill, being critically ill or in bedrest condition, having impaired hearing, and unwilling to participate.

The protocol of this study was approved by the Ethics Committee of Faculty of Nursing, Universitas Indonesia, written in the approval letter number 46/UN2. F12. D/HKP.02.04/2018. The subjects were informed beforehand about the objectives and method of the study, and the written and signed informed consent was obtained from their caregivers.

The survey was conducted in residence of participants. Computer program was used for data entry and analysis. The demographic information was obtained from subjects and caregivers, including age, sex, education, history of smoking habit, social activity, and doing exercise were summarized using frequencies (percentages).

Tests and scales including Clock Drawing Test

(CDT) was used as dementia screening tests for elderly. CDT consists of 4 commands to draw a circular clock with numbers and hands completely.

**Funding:**

**Table 1. Elderlies characteristics distribution in Jakarta (N=341)**

Characteristic(s)	Frequency	Percent(%)
<b>Age</b>		
60 – 65 years old	156	45.7
≥ 66 years old	185	54.3
<b>Sex</b>		
Male	105	30.8
Female	236	69.2
<b>Educational Background</b>

<b>Physical Exercise</b>		
Yes	91	26.7
No	250	73.3
<b>Smoking Habit</b>		
Yes	38	11.1
No	303	88.9

A total of 341 elderlies who reside with their families participated in this research. Most of the elderlies are above 66 years old (54.3 %), female (69.2 %), are have only completed elementary schooling (87.1 %), did not doing routine physical exercise (73.3%), smoking habit (11.1 %), and are not involve in social activities (26.4 %). The demographic characteristic of respondents were showed in Table 1.

Community-based cross-sectional study was conducted to analyze relationship between elderly’s characteristic with cognitive impairment. Of the 354 subjects in the dataset, 326 subjects were identified as cognitive impairment. More detailed information about cognitive impairment can be seen in table 2.

<sup>a</sup> fishers Exact

The statistical test with CDT's screening tool shows the p-value for gender is 0.003, which means there is a significant correlation between gender and cognitive impairment. The analysis of the correlation between educational background and cognitive impairment shows that the proportion of elderlies with poor education have increased cognitive impairment compared to those who are well-educated. The result of the statistical test shows p-value= 0.005, which means there is a significant correlation between educational background and cognitive impairment.

The findings showed that 313 (91.8%) elderly had cognitive impairment. The impairment took form of changes in cognition, such as perception, counting ability, memory, verbal, executive function or problem-solving ability, and daily activity independency. This finding affected the needs of special caring for elderly.<sup>5</sup>Cognitive function also has a meaningful relationship with the quality of life of elderly.<sup>6</sup>

There are factors affecting cognitive function, which can be modified and left unmodified. For the modified factors, this study had proven that there was an insignificant relationship between smoking habits, social activity, and physical exercise with cognitive function. However the elderly with smoking habits have chances of cognitive impairment 0.4 times higher. Moreover, elderly who do not regularly socialize has a higher chance of cognitive impairment and 1.3 times higher chances of cognitive impairment for elderly who do not do physical exercise regularly. The finding in smoking habits with cognitive impairment is supported by previous research with the same topic of dementia.<sup>11</sup>Meanwhile, other researches show a meaningful relationship between physical exercise and social activity with cognitive impairment.<sup>12,13</sup>

Other factors, such as age and sex, cannot be modified. Moreover, this study has proven that there is a meaningless relationship between age and cognitive impairment. A theory says the aging process, which affects cognitive function, can be physiologic or pathologic in which a deep observation in physical changes, central nerve system, intelligence, memory, and psychologic changes corresponding to cognitive function and aging process.<sup>5</sup>In conclusion, age is not absolutely affecting cognitive function pathologically.

Other data show that the number of female elderly who experience cognitive impairment is 224 elderlies,

yet the number of male subjects is 89 elderlies. This data show female elderly outnumber the male subjects as the result of female higher life expectancy than male elderly.<sup>14</sup>This study explained the meaningful relationship between sex and cognitive impairment ( $p=0.003$ ). Sex types can affect cognitive function because of biological mechanisms such as genetic, different hormones, different brain cells, and external factors, like economic, social, as well as cultural factors.<sup>15</sup>This study is supported by previous research, which explains that female elderly have a chance of 1.158 times to get dementia higher than male elderly.<sup>11</sup>

Other than risk factors of dementia there is also a factor in preventing cognitive impairment. A factor, which continuously affects cognitive performance on the elderly is formal education.<sup>5</sup> Education is a process of learning, training, and educating to enhance knowledge and aptitude as well as to get experience in educating something.<sup>16</sup> Education aims to improve attitude and behavior, which include cognitive and affective aspects of individuals or group.<sup>17</sup>

Low levels of education can be a dominant predictor for the elderly in getting dementia or cognitive impairment.<sup>9</sup>intervention, and care will vastly improve living and dying for individuals with dementia and their families, and in doing so, will transform the future for society. Dementia is the greatest global challenge for health and social care in the 21st century. It occurs mainly in people older than 65 years, so increases in numbers and costs are driven, worldwide, by increased longevity resulting from the welcome reduction in people dying prematurely. The Lancet Commission on Dementia Prevention, Intervention, and Care met to consolidate the huge strides that have been made and the emerging knowledge as to what we should do to prevent and manage dementia. Globally, about 47 million people were living with dementia in 2015, and this number is projected to triple by 2050. Dementia affects the individuals with the condition, who gradually lose their abilities, as well as their relatives and other supporters, who have to cope with seeing a family member or friend become ill and decline, while responding to their needs, such as increasing dependency and changes in behaviour. Additionally, it affects the wider society because people with dementia also require health and social care. The 2015 global cost of dementia was estimated to be US\$818 billion, and this figure will continue to increase as the number of people with dementia rises. Nearly 85% of costs are related to family and social, rather than

medical, care. It might be that new medical care in the future, including public health measures, could replace and possibly reduce some of this cost. Dementia is by no means an inevitable consequence of reaching retirement age, or even of entering the ninth Key messages 1 The number of people with dementia is increasing globally Although incidence in some countries has decreased. 2 Be ambitious about prevention We recommend active treatment of hypertension in middle aged (45-65 years. The data showed a meaningful relationship between levels of education with cognitive impairment for *p-value* 0.005. This is supported by a previous study with the same topic, which showed *p-value* 0.012, that the elderly with a low level of education is 10.831 times higher in getting dementia.<sup>11</sup> Other researches also described education as a risk factor that had a meaningful relationship with cognitive function ( $p=0.017$ ). The number of elderly who suffers from cognitive impairment reached 75% of elderlies.<sup>18</sup>

A concept of cognitive reserve is assumed to be a healing factor in decreasing the risk of dementia as well as cognitive impairment.<sup>19</sup> Cognitive reserve is defined as the mind's resistance to damage the nerve or neuro-pathologic.<sup>20</sup> Cognitive activities can stimulate cognitive reserve and buffer effect in preventing quick cognitive impairment.<sup>21</sup> individual caregivers, health care professionals and on the use of resources. Existing therapeutic interventions can only help control or reduce symptoms, and slow the disease's progression. Identifying protective factors or effective prevention strategies would result in considerable benefits. Participation in cognitive leisure activities has been implicated as a possible prevention strategy. OBJECTIVE The objective of the review was to establish best practice in relation to cognitive leisure activities in preventing dementia among older adults. INCLUSION CRITERIA Randomised controlled trials (RCTs) Cognitive stimulation can delay or even prevent impairment as a result of the aging process, Alzheimer-dementia, or MCI.<sup>22</sup> Besides the WHO has recommended cognitive stimulation for older people, whether they already have cognitive impairment or have not yet.<sup>23</sup>

Many studies have proven the link between the level of education with dementia. Exposure to modifiable risk factors such as education levels starting from childhood to old age can reduce the occurrence of cognitive impairment. It can also strengthen the capacity of individuals and populations to be able to make healthier life decisions, adopt healthier lifestyles, and improve

health status.<sup>13</sup> This is supported by research there is correlation between information support, appreciation, and emotional support with the activities of elderly hypertension.<sup>24</sup>

## Conclusion

Risk factors for cognitive disorders such as age, sex, education, social activities, sports, and smoking should be a concern for the elderly and their accompanying family. For its members to stay active and productive by continuing to do cognitive stimulation, social activities, and exercise according to ability. For families who still have children to make their children pursue the highest level of education, both formal and informal.

# Breast Cancer: Self-Concept and Quality of Life for Patients in Wahidin Sudiro Husodo Hospital Makassar City, Indonesia

Rahman<sup>1</sup>, Naharia Laubo<sup>1</sup>, Baharuddin K<sup>1</sup>, Rudy Hartono<sup>2</sup>

<sup>1</sup>Lecturer in The Department of Nursing, <sup>2</sup>Associate Professor in The Department of Nutrition, Makassar Health Polytechnic, Indonesia

## Abstract

Breast cancer (*carcinoma mammae*) is a malignant neoplasm derived from the parenchyma group. Purpose of this study to analyze relationships self-concept with quality of life in breast cancer patients at wahidin central public hospital sudirohusodo Makassar. This study used an study design *observational analytic* with approach *cross sectional*. The population in this study were breast cancer patients at the general hospital center. Wahidin Sudirohusodo Makassar amounted to 174 people the sample was drawn by *purposive sampling technique*, a sample of 32 people. Data collection is done using a questionnaire. The results showed that self-concept was significantly associated with quality of life ( $p= 0.022$ ). There is a relationship between self-concept and quality of life based on marital status ( $p= 0.022$ ). There is a relationship between self-concept and quality of life working as civil servants (PNS) ( $p= 0.053$ ). Conclusion: self-concept is related to quality of life based on marital status and employment in breast cancer patients. It is expected that the results of this study can be taken into consideration in increasing bio.psoio and spiritual nursing care services so that it can help clients choose adaptive coping.

**Keywords:** *Self-concept, quality of life, Breast Cancer.*

## Introduction

Breast cancer is a disease that occurs due to excessive growth or uncontrolled development of cells or breast tissue<sup>1</sup>. Risk factors that can cause breast cancer include reproductive factors, endocrine factors, diet and genetics or family history. Breast cancer is one of the health problems of women in Indonesia (also in the world), breast cancer is also influenced by an increase in life expectancy, lifestyle which is detrimental to health, environmental conditions. Cancer is a disease that is very feared by the community because of the high mortality rate. Cancer prevalence throughout the world continues to increase, both in western countries and

Asian countries. The Report *World Cancer* estimates that the incidence of cancer will increase to 15 million new cases by 2020<sup>3</sup>.

WHO data (*World Health Organization*) shows that there are 458,000 annual deaths due to breast cancer in women<sup>7</sup>. The number of breast cancer sufferers in the United States and several other developed countries ranks first in non-communicable diseases<sup>17</sup>. Cases of breast cancer in the United States recorded nearly 200,000 women diagnosed each year there are more than 40,000 die from this disease<sup>4</sup>. Basic Health Research Results (Riskesdas) in 2013 and data in hospitals in Indonesia showed that breast cancer cases were the highest, 1.4 per 1000 residents or around 330,000 people. Cancer is the seventh cause of death in Indonesia. Breast cancer and uterine cancer<sup>14</sup>.

Based on data obtained from the Hospital Information System (SIRS) in 2007, breast cancer ranked first in hospitalized patients in all hospitals in Indonesia (16.85%), followed by cervical cancer (11.78%)<sup>18</sup>. Data on breast cancer patients at the Central General Hospital.

Dr. Wahidin Sudiro Husodo in 2015 The number of breast cancer patients was 161 people from January to December and in 2016 there were 174 breast cancer patients from January to December.

Breast cancer occurs due to disruption of the cell growth system in the breast tissue. There are several factors that become the risk of breast cancer, namely a family history of breast cancer, early menstruation, advanced menopause, hormone replacement therapy, radiation, alcohol consumption<sup>18</sup>. According to Hartati, (2008). The results of the study can be seen that more than half (53.4%) of breast cancer patients have negative self-concept and some other studies show negative self-concept of up to 87.9%. Therefore it is recommended that the implementation of educational and psychological programs to reduce the consequences of poor quality of life. Family support is very important for self-concept of breast cancer sufferers because the family is the closest person to the respondent so that any form of illness suffered by family members or breast cancer that can affect self-concept, will always be accepted by the family will give the best for family members. If an individual gets moderate to low social support, individuals will experience negative experiences, reduce self-confidence and not be able to control changes in their environment such as feeling ignored<sup>27</sup>. Cancer patients also extend self-actualization and support from the government<sup>28</sup>.

Based on this study the quality of life of patients with breast cancer undergoing chemotherapy in the Chemotherapy Room at AM Parikesit Tenggarong Hospital was obtained from the estimated interval on quality of life believed that 95% of the median value 59.30 was in the range of 58.69-67.07 with a value the highest quality of life is 51.00. The suffering experienced by a cancer sufferer is understood as a process of personal maturation. There is a personal change towards the positive that cancer sufferers experience in their struggle for survival<sup>23</sup>.

Based on the description above the researcher is interested in conducting research to find out the relationship between self-concept and quality of life in breast cancer patients with guidelines on self-concept of breast cancer patients including body image, self-ideal, self-esteem, role appearance, and self-identity later on quality Breast cancer patients include physical aspects, social aspects, psychological aspects, and environmental aspects.

## Material and Method

Type of research used in this study was *observational analytic* with design *cross sectional*. This study aims to determine the relationship between self-concept and quality of life in breast cancer patients in the Polyclinic of the Central Hospital General Dr. Wahidin Sudirohusodo Makassar.

This research was conducted at the Central General Hospital. Wahidin Sudirohusodo Makassar. The location of this researcher was chosen because it included type A hospitals which were estimated to be able to meet the desired sample size. The number of samples in this study were 32 breast cancer patients from 174 population data. The data used were primary data, namely data obtained directly at the location of the study with the questionnaire method by distributing questions in writing in the form of questionnaires directly given to respondents. Data obtained at the polyclinic of the Dr. Central General Hospital Wahidin Sudirohusodo Makassar regarding the number of patients with breast cancer as a whole.

**Findings:** Results of this study were carried out at the Polyclinic Center General Hospital Dr. Wahidin Sudirohusodo Makassar from June 5 2017 to June 8, 2017 with a total of 32 respondents. The research method used in this study was *observational analytic* with design *cross sectional*. The results of data processing that has been done is presented as follows

Knowing yourself is very important in an effort to develop yourself, meaning that it is impossible for personal development to occur without first recognizing weaknesses and excellence in him. This means that the individual has the ability to determine what is best in itself in order to improve the quality of his life<sup>8,9,10</sup>.

The results of this study also showed that there was a significant relationship between the self-concept of former lepers through personal communication in the Makassar area. The formation of self-concept through interpersonal communication is the way a person views himself through interaction with others. Even self-concept tends to give a picture and assessment of oneself based on the relationship with the people around him. This tendency is indicated by the ability to think and judge someone either himself or someone else or give the perception of others by trying to give an assessment<sup>23</sup>

**Table 1. Relations Self Concept Quality of Life in Patients with Breast Cancer at Polyclinic General Hospital Center Dr. Wahidin Sudirohusodo Makassar**

Self Concept	Life quality						ρ
	Good		Less		Amount		
	n	%	n	%	N	%	
Positive	17	70.8	2	25.0	19	59.4	0.022

Total	24	75.0	8	25.0	32	100.0	

**Table 2: Relationship Self Concept Quality of Life in Patients With Breast Cancer Based Marital Status at Polyclinic of General Hospital Center Dr. Wahidin Sudirohusodo Makassar**

Marital status	Self Concept	Quality of life						ρ
		Good		Less		Total		
		n	%	n	%	n	%	
Married	Positive	17	53.1	2	6.2	19	59.4	0.022
	Negative	7	21.9	6	18.8	13	40.6	
	Total	24	75.0	8	25.0	32	100.0	

**Table 3: Relationship of Self Concepts with Quality of Life in Breast Cancer Patients Based on Occupation at Polyclinic of General Hospital Center Wahidin Sudirohusodo Makassar**

Work	Self Concepts	Quality of Life						ρ
		Good		Less		Total		
		n	%	n	%	n	%	
Wokers	Positive	4	57.1	0	0	4	47.1	0.053
	Negative	1	14.3	2	28.6	3	42.9	
	Total	5	71.4	2	28.6	7	100.0	
Entrepreneur	Positive	2	50.0	0	0	2	50.0	0.248
	Negative	1	25.0	1	25.0	2	50.0	
	Total	3	75.0	1	25.0	4	100.0	
Hourse Wives	Positive	11	52.4	2	9.5	13	61.9	0.248
	Negative	5	23.8	3	14.3	8	38.1	
	Total	16	76.2	5	23.8	21	100.0	

This is in accordance with the theory of explaining that self-concept is a very decisive factor in interpersonal relationships, because each person will behave according to the self-concept of a positive person will tend to develop positive attitudes about himself, such as good self-confidence and the ability to see and judge positively. Individuals with positive self-concepts tend to be able to cause good behavioral adjustments to the social environment<sup>12</sup>.

The results of the show that self-confidence is one component of self-concept which will increase when patients can ensure that their shortcomings will not provide any obstacles in their work. In addition,

in providing advanced communication can increase a person’s confidence<sup>18</sup>.

**Discussion**

**Relationship between self-concept and quality of life based on marital status:** From the results of this study indicate that self-concept has a relationship between quality of life and marital status, where breast cancer patients need family support they get also keeps them motivated to live their daily lives from her husband or children in the treatment and rehabilitation of her illness.

This is in accordance with the theory put forward by Nofitri (2010), that married individuals have a higher quality of life compared to individuals who are not married, divorced or widowed as a result of the spouse's death. can be one of the reasons they endure treatment routinely, because the presence of a partner during treatment will also help them feel they can get full support and enthusiasm until the role of the husband at this time also greatly affects them<sup>16,19,20,21</sup>.

This was strengthened by research by Ketut NM (2013) with the relationship of the characteristics and attitudes of women of fertile age couples with Pap Smear examination at Sukawati II health center. Denpasar stated that there is a link between marital status and the incidence of breast cancer because in married women there will be reproductive activity during pregnancy or hormone lactation. It is known that breast differentiation is protective to be ineffective. In addition the lactation process will continue to work until the time the process will decrease and decrease by itself. So that if the mother does not understand how the process of breastfeeding properly and correctly will result in the dam of milk and emptying of the alveoli ducts that are not perfect and this can be one of the risk factors for breast cancer<sup>11,12,15</sup>.

According to Kusmiran (2012) stated that there is a link between marital status and the incidence of breast cancer because in married women there will be reproductive activity during pregnancy or hormone lactation. It is known that breast differentiation is protective to be ineffective. In addition the lactation process will continue to work until the time the process will decrease and decrease by itself. So that if the mother does not understand how the process of breastfeeding properly and correctly will result in the dam of milk and emptying of the alveoli ducts that are not perfect and this can be one of the risk factors for breast cancer<sup>6,7</sup>.

Family support is very important for self-concept of breast cancer sufferers because the family is the closest person to the respondent so that any form of illness suffered by family members or breast cancer that can affect self-concept, will always be accepted by the family will give the best for family members. If an individual gets moderate to low social support, individuals will experience negative experiences, reduce self-confidence and not be able to control changes in their environment such as feeling ignored<sup>27</sup>.

### **The relationship between self-concept and**

**quality of life based on work status:** Based on the results of the characteristics of the respondents seen from the work the highest proportion were respondents who were employed by civil servants where there was a relationship between self-concept and quality of life in respondents who worked as civil servants with a specific value ( $p = 0.053$ ). The results of the research above show that workers with civil servants have a quality of life with good self-concept because they have the ease of getting information about the illness, how to treat their illness and have health insurance that makes it easier for the client self-examination and the higher the level of one's education will be more anticipatory so that the handling of the disease can be done<sup>3</sup>.

This also relates to acceptance of themselves. Women who work have a different pattern of thinking than women who don't work because women who work have higher independence than women who don't work, women who work don't have to depend on men in terms of income.

That independence can influence one's self-concept. A woman who has a job to be trained to be more independent will bring confidence and positive self-concept.

This is reinforced by research According<sup>5,2</sup> shows that, women who work have higher self-acceptance than women who do not work tend to be more numerous and this shows a connection with their quality of life, especially in accepting themselves when they are first diagnosed with breast cancer until the treatment they have to undergo all this time undergoing routine as well as the side effects they have had during chemotherapy<sup>22,23,25,29</sup>.

## **Conclusion**

**Based on the research results it can be concluded that:**

- a. Self-concept is related to quality of life in breast cancer patients in the polyclinic of the Center General Hospital. Wahidin Sudirohusodo Makassar.
- b. Self-concept is related to quality of life in breast cancer patients in the polyclinic of the Center General Hospital. Wahidin Sudirohusodo Makassar based on marital status.
- c. Self-concept is related to quality of life in breast cancer patients in the polyclinic of the Center General Hospital. Wahidin Sudirohusodo Makassar

**Conflict of Interest Statement:** Between subjects and researchers there is no conflict of interest.

**Source of Funding:** This research was funded independently by researchers, because they did not get sponsorship from other institutions

**Ethical Clearance:** Research ethics were obtained from the Health Ministry Ethics Health Research Ethics Commission Makassar No. 376/KEPK-PTKMKS/VII/2017.

# Risk Communication in the Air Pollution

Rahmi Amir<sup>1</sup>, Anwar Daud<sup>2</sup>, Indar<sup>3</sup>, Furqan Naeim<sup>4</sup>

<sup>1</sup>Faculty of Public Health Hasanudin University, <sup>2</sup>Department of Environmental Health, <sup>3</sup>Department of Health Policy and Administration, <sup>4</sup>Department of Occupational Health and Safety, Faculty of Public Health Hasanuddin University, Makassar, Indonesia

## Abstract

**Background:** Air pollution is the leading cause of death, cognitive impairment, and work productivity so that it inhibits domestic investment and economic growth. Emissions of transportation activities, fuel use household and industry are the biggest sources of pollutants that require a strategy and action plan holistically, to deal with the environmental crisis that is the cause decrease in air quality in Indonesia.

**Material and Method:** Literature review sources come from an online journal database published by PubMed, Proquest, Google Scholar, and other sources such as the report on air pollution. Data of all documents collected manually and systematically.

**Findings and Discussion:** Communicating air pollution is very important as a warning of its effects and also carries out risk management and prioritizes and mitigates risks in public and environmental health decision-making spaces. a review of published studies spanning impact on your health suggests that strategies for preventing the effects of air pollution. However the evidence is base on the studies that are methodologically weak and have little or no underlying theory.

**Conclusion:** The paper concludes with a call for more regions studies to evaluate the role of risk management strategy (with or without improved technologies) to reduce air pollution and burden disease in developing countries as well as interventions that n draw more strongly on existing risk environment theory and practice.

**Keywords:** *Air Pollution, Health Impact, Risk Communication.*

## Introduction

Pollution and its harmful effects on people is health the environment, and the planet have been neglected both by governments and the international development community. Pollution is the largest environmental cause of disease and death in the world today, responsible for an estimated 9 million premature deaths in 2015. 92% of all pollution-related mortality is seen in low-income and middle-income countries. A new *Lancet* Commission on

pollution and health aims to confront and overturn this urgent predicament. The substantial health and economic costs of pollution globally can no longer be ignored<sup>1</sup>.

Approximately half the past decade, awareness about air pollution exposure and its significance for human health has increased. With growing attention on vulnerable populations, increasing environmental diseases caused by pollution according to 2015 data announce that pollution is the cause 9 million premature deaths or nearly 16% causes death in the world<sup>2</sup>. The impact of climate change, exposure, and vulnerability to extreme heat will continue to increase from 1990 onward region, 157 million people were affected by the wave in 2017, compared to the previous year and with an average person experiencing an additional 1-4 days of heat waves per year in the same period<sup>3</sup>.

---

**Rahmi Amir**

Faculty of Public Health Hasanudin University,  
Makassar, Indonesia

e-mail: ammiandjala@gmail.com

For the national economy there are 153 billion hours of work lost in 2017 due to heat. There has been an increase of more than 62 billion per hour since 2000. The direct effects of climate change are expanding in 2017, found a total of 712 extreme weather events which resulted in economic losses of US \$ 326 billion, almost three times the total loss in 2016<sup>4</sup> and choice of, energy technology-*ie*, fuel-stove combinations-and energy-related behaviours. Therefore, whilst health constitutes the largest consequence of solid-fuel use, large-scale intervention programmes will require links to many other sectors, such as energy, rural development, and finance. Complete transitions to electricity or petroleum-based fuels, such as natural gas and kerosene, will certainly provide substantial health gains.<sup>5,6</sup> (Although kerosene has several hazards, such as increased risk of poisoning or burns these hazards have not been quantified systematically, and are probably smaller than the benefits of kerosene from reducing pollution..

Air pollution is damage to components air due to air density and emissions tall one by industrial activities or transportation activities which disturbs the ecological balance and negative effect in human life<sup>5</sup>. Motor vehicles produce emissions whose concentration depends on the year of the vehicle and type of fuel used. Vehicles that are manufactured with longer manufacturing will emit higher emissions compared to new vehicles. in addition, vehicles that use gasoline will produce different types of emissions from diesel-fueled vehicles<sup>6</sup>.

Risk communication includes the range of communication capacities required through the preparedness, response and recovery phases of a serious public health, risk communication is recognised as the multi-directional communication. However populations so that they can take informed decisions to protect themselves and their loved ones. The goals of risk communication are to share information vital, minimizing harm to self and others, and o change beliefs or to change behavior<sup>7,8</sup> Risk communication is a form of exchange of information and perspectives or views, along with factors, factors relating to risk among risk reviewers, risk managers, consumers and other interested parties. We adopt the definition of risk communication<sup>9</sup>.

The extensive list demonstrates the variety of goals and objectives that can be associated with risk communication programs. Increasing trust and credibility may be one major objective, but certainly is not the sole objective of risk communication. But many objectives,

such as behavioral changes or fair participation, rely on a minimum of trust among the communicators in order to be effective.<sup>10</sup>

Many of the global environmental problems that we are now facing have their precedence and causes in the cities and urban areas we live in. Lessons in understanding urban risk are now emerging – urban hazards and risk are predominantly human-induced, and exacerbate natural events. Various economic, social, and economic aspects compound the risks that urban residents face. Urban lifestyles and resource consumptions can be directly or indirectly attributed to the many environmental consequences that we are seeing – both within the city, as well as the entire hinterland or urban watershed that it is located in<sup>11</sup>.

Some risk communication problem derive from mistaken beliefs about scientific research on the nature of how risk are assessed and managed and on risk communication itself. scientific information for example can not be expected to resolve all important risk issue<sup>12</sup>.

## Materials and Method

The author conducted a review of accessible literature published over the last 30 years our main objective was to provide evidence of the role chemical component of air pollution of adverse health effects in humans. We commenced a PubMed database search using the “risk communication”, “air pollution”, “environmental health”, “risk assessment “health issue” “climate change”. The Literature was also from other scientific databases including ProQuest and science direct online database search. The article was selected upon by author based on relevance and usefulness.

## Findings and Discussion

**Problem of risk communication:** Two major types problem in risk communication problem deriving from instutional and political system for which little can be done. several kinds of legal considerations,including statutory, mandates, liability and informed consent influences the options available to risk management<sup>12</sup>.

Communication with citicent about risk can increase their desire to participate in or otherwise influences decisions about the control of those risks, threby making risk management even more cumbersome. The interest of citizens an their motivation to participate in the politycal process can introduce difficult chalenges

when that implementation of risk control measures is necessarily decentralized and local preferences.

Risk communication is successful to the extent that it raises the level of understanding of relevant issues or actions and satisfies those involved that they are adequately informed within the limits of available knowledge. Risk communication can also be used as a form of prevention. The first form of prevention is precautionary communication that is communication made to people who don't care and don't want to listen to risk. The second is outrage management, which is

communication that is done to reduce anger or worry about a condition that is actually not too dangerous<sup>7,13</sup>.

Furthermore, in a climate of general distrust toward social organizations, it is helpful to accept countervailing powers and public control and to provide public access to all relevant information. On the basis of these structural opportunities for public involvement and control, specific communication programs can be designed that include elements of successful persuasion. How can one make a message attractive provided that the information given is accurate, complete, and honest?

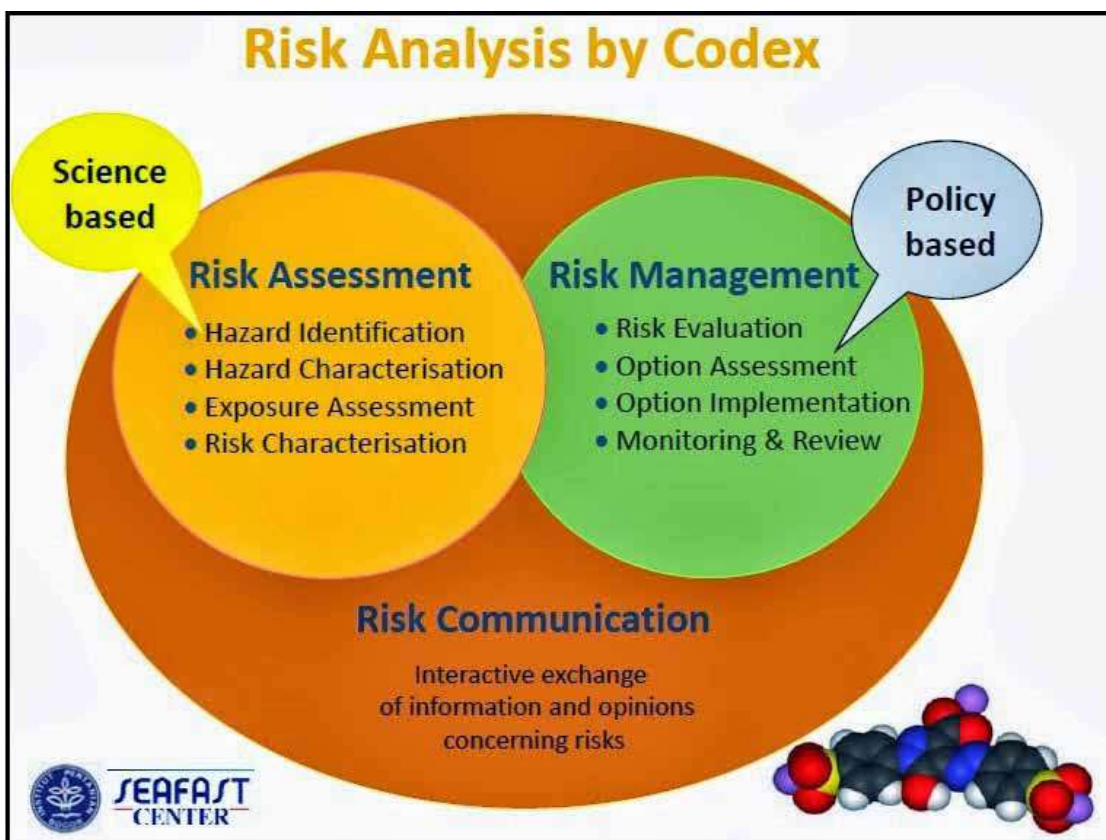

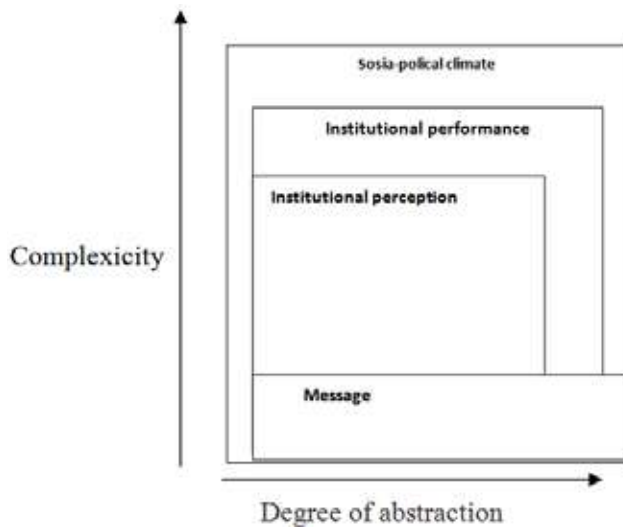

Figure 1 : Risk assessment or chemical contamination.

**Trust in information:** Political science and risk communication scholars have identified a number of factors that relate to trust, including confidence in the government's preparedness, honesty, willingness to disclose information, dedication and caring. Personal experience informs perceptions of trust and which organizations the public deems trustworthy. These factors can be divided into three broad categories: (1) Public perceptions of the government; (2) Personal experience and (3) Trustworthy organizations.

**Risk analysis and action planning:** Risk assessment consisting of hazard analysis and vulnerability analysis is a basic instrument of DRM that is used to study the factors of disaster risk and provides the basis for planning and implementing measures to reduce risks and impacts of disasters. Action Planning is the follow-up process that engages with the local stakeholders and leads to actionable plans that are based on the assessed risk and focus to reduce it, and that are more dependent on local aspirations and capacities than external support<sup>14</sup>.

**Figure 2 : The five levels of analyzing trust :** illustrates the cumulative nature of these five levels. The figure is simple illustration of the interrelations among the five levels . Each level is embedded in the next higher level.

Finally, implementation management is the key process that translates the plans into ground reality, and needs to be founded on principles that are in tandem with those of action planning so as to ensure implementation that is true to the essence of local plans and is sustainable beyond project durations. This chapter will focus on the concepts of risk analysis (RA), action planning, and implementation management from the point of view of urban disaster risk. RA is used here to refer to a method of determining the quantitative or qualitative degree of risk. The terms “risk analysis,” “action planning” and “implementation management” have the underlying concept of “participative approaches.” This means that the affected target population is involved in the various stages of all of these processes.<sup>15</sup>

**International Impacts on Local and Regional Air Pollution:** Many types of air pollutants have been observed. including primary pollutants that are emitted directly like soot particles from a diesel vehicle, dust blowing in the wind from the desert or degraded agricultural land, mercury from coal-fired power plants, pesticides from agricultural operations, and nitrogen oxides from motor vehicles. They also include secondary pollutants that are made in the atmosphere by chemical reactions<sup>16</sup>

Increasing vehicle speed will result in lower emissions of carbon monoxide and hydrocarbons per vehicle-mile, while oxide emissions from nitrogen will

increase per vehicle-mile as speed increases. Because the three types of pollutants above are completely undesirable there is no general rule regarding the best speed from an air quality perspective. The same thing has been proven in modeling Padang City’s air quality. In another study of the comparison of several models to calculate pollutant concentrations, CO concentrations were obtained proportional to the increase in traffic volume and decrease in vehicle speed<sup>17,18</sup>.

**Health Benefits from Air Pollution:** The traditional understanding of environmental policy, reflected in the language of the U.S. Clean Air Act, holds that the marginal health benefits associated with abatement become smaller as the air becomes cleaner. Recent research results, which suggest that the C-R function for PM2.5 may in fact be supralinear at levels of air pollution prevalent in low and middle-income countries such as China and India, suggest that the traditional understanding of policy may be incorrect. A supralinear C-R function, if correct, would imply that the percentage reduction in mortality per unit of abatement would be lower at the higher air pollution levels currently found in India and China than in the United States. This implies then that considerable improvements in air quality will be required to achieve substantial reductions disease burden. However the marginal benefits associated with pollution control policies depend also upon the size of the exposed population, baseline death rates, and the value attached to reductions in mortality risks. Therefore, even incremental improvements could confer important public health benefits. This is the view embodied in the World Health Organization’s (WHO) world air quality guidelines, which include interim targets in addition to the much lower air quality guideline itself<sup>16,19</sup>.

**Contemporary environmental issues and climate change:** Climate change is one of the natural phenomena that has occurred for a long time, however, this issue will be of concern to the global community with the IPCC study which states that global warming will occur closely with human activities since the mid-20th century<sup>20</sup>.

Global warming has become an indisputable fact about current livelihoods. Environmental problems make us vulnerable to disasters and tragedies, we are in a planetary emergency with problems that are piled high around us unless we take these issues seriously and need immediate attention Impact of air pollution on human health<sup>21</sup>.

Known health effects in the population are divided into two categories: mortality and morbidity. The number of people who are exposed to chemical contaminants in the air at low levels, far greater than the number of exposed at high enough levels to produce a clear response. Subsequent low levels of exposure are often repeated over a period of years, and the frequency of chronic diseases that are also present in the exposed population. For example any small increase in the incidence of heart disease or lung cancer caused by exposure to certain chemicals will be difficult to detect, because this disease is present at high levels in the exposed population<sup>22</sup>.

### Conclusion

In conclusion, as the atmospheric environment is a complex system. There are many factors affecting the quality of the atmospheric environment and the relationship between them is complicated. Therefore air pollution forecasting based on the area and different pollutants should choose different forecasting risk analysis. Moreover there is one best approach to make the most accurate forecast.

# HIV/AIDS Awareness of People Who Work at Barbershops and Beauty Salons at Al-Nasiriya City in Iraq

Rawaa Kamel Abd<sup>1</sup>, Tareq Al-Qassab<sup>2</sup>, Vinoth Raman<sup>3</sup>

<sup>1</sup>Assistant Lecturer, <sup>2</sup>Lecturer, Department of Community Health Techniques, Kut Technical Institute, Middle Technical University, Baghdad, Iraq, <sup>3</sup>Assistant Professor, Quality Measurement and Evaluation Department, Deanship of Quality and Academic Accreditation, Imam Abdulrahman Bin Fisal University, P.O. Box 1982, Dammam 31441, Saudi Arabia

## Abstract

**Context:** Barbers and beauty salons are cosmetic staff undertaking skin piercing practices involving reusable sharp instruments, which present risks for transmission of HIV and alternative blood-borne pathogens.

**Aim:** Assess the level of awareness on HIV/AIDS and its risk factors, attitude towards HIV/AIDS and to spot high risk behaviors related to HIV/AIDS among a person who uses Barbershops and beauty salons at Nasiriya City in Iraq.

**Methodology:** A cross sectional study was conducted to assess knowledge attitude and practice with respect to the transmission and prevention of HIV/AIDS among barbers and beauty salons in Nasiriya city in Iraq.

**Results:** A total of 107 Barbers and Beauty salons participated in the age groups were 16% below 20 years, 42% 21-30 years, 27% 31-40 years, 13% 41-50 years and 2% above 50 years (Barbershops) and followed by Beauty salons were in the age group of 5% below 20 years, 58% 21-30 years, 32% 31-40 years and 5% 41 to 50 years. Among the participants, 82% were male and 18% were female.

**Conclusions:** Participants have a good knowledge regarding HIV/AIDS. Health strategies such as support supervision and training are needed to facilitate effective preventive measures against HIV disease among beauty salon and barbers workers.

**Keywords:** HIV/AIDS; Awareness; Barbers and Beauty Salons; Nasiriya City.

## Introduction

HIV/AIDS could be a major medical, public health still as a grave socioeconomic challenge to the world. HIV disease continues to be a serious global public

health issue. Inadequate Knowledge, negative Attitudes and risky practices are major obstacles to prevent the spread of HIV.<sup>[1]</sup> Skin is one of the natural, barriers for pathogens to enter and used as protecting the organ. Its integrity is responsible for prevention of infection like HIV/AIDS.<sup>[2]</sup> Barber's shop could be a source of infections agents each blood-borne and different infestation and the sure way to prevent this can be through instrument sterilization after every customer.<sup>[3]</sup> The zone of the Middle East is foremost among the regions within the world with the rapidly growing epidemic of HIV. During this situation, serious and powerlessness are rise because the epidemic is on the increase with proof showing significantly elevating HIV prevalence, new HIV infections, and AIDS-related deaths (Dalia).<sup>[4]</sup>

A study from Nasiriyaon the knowledge and practice of sterilization of instruments by barbers showed that 93.9% weren't aware of the necessity and method of sterilization.<sup>[5]</sup> This means that almost all the consumers were in danger of contracting these deadly however preventable diseases. Certainly, infection acquired from barbing saloon sometimes results in serious complication because individuals infected with these diseases are not aware until laboratory investigation reveals it. Report from previous research finding revealed that the infectious diseases have high prevalence rate and are being rapidly transmitted to people in non sexual routes such as barbering as well as sexual routes in both developed developing countries with prevalence rates are as follows: HIV 2.2% to 28%, HBV 6.826%, and HCV 2.2 to 4.8%.<sup>[6]</sup> The objective of this study were to evaluate the extent of awareness on HIV/AIDS and its risk factors, angle towards HIV/AIDS and to spot high risk behaviors related to HIV/AIDS among someone World Health Organization uses Barbershops and wonder salons at Nasiriya city in Iraq.

**Materials and Method**

A cross-sectional study, approach been carried out to find the awareness of HIV/AIDS and its risk factors. Approach concerning HIV/AIDS and to classify high-

risk activities related to HIV/AIDS between a person who uses Barbershops and Beauty salons at Nasiriya city in Iraq. The data will be collected from 107 Barbers and Beauty salons participated in the age group 20-60 years. It was carried out over 4 months a time period starting from first March till June 2019 after verbal approval was taken from each person participated in the study. It includes research approach, research design, and population. Study settings, sample size and sampling technique, development, and description of tools, data collection method, and plan for data analysis. The collected information is organized, tabulated, analyzed and interpreted using descriptive and inferential statistics. The data were analyzed by using Statistical Package for Social Science (SPSS) version 20 with both descriptive and inferential statistics. The results were expressed as mean and standard deviation. The data were analyzed by analysis of variance (ANOVA). A probability level (p-value) of less than 0.05 was considered statistically significant.

**Results**

The study involved samples (n=107) who fulfilled the inclusion criteria. The source of previous knowledge of HIV/AIDS is shown in Fig. 1.

**Table 1: Knowledge concerning HIV/AIDS in the study population**

Knowledge	Study Population N=107		Barbershops (N=88)	Beauty Salons (N=19)	Mean ± SD	'p' value
<b>Blood related transmission</b>						
HIV can be transmitted from mother to child	Yes	104	86	18	52±48.08	0.000 (S)

**Fig. 1: Source of HIV information.**

## Discussion

**Knowledge about HIV/AIDS:** Knowledge observed that all respondents represent by blood-related transmission, sex-related transmission and other modes of transmission in barbershops and beauty salons (Table 1). Most of the peoples in both (97.5%) have a good level of knowledge.<sup>[7]</sup> More than 97% of peoples know HIV might be spread via transmitted from mother to child [52±48.08]<sup>[8]</sup>, transmitted by sharing a needle or a syringe [52.5±48.79]<sup>[9]</sup> and transmitted by blood transfusion [53±49.5; p=0.000]. A similar result was reported by Kiran *et al*<sup>[10]</sup> study in whom, 94.12% were aware regarding contaminated needles and syringes, 95.09% on blood transfusion. 3% of peoples have a negative response to the knowledge of HIV/AIDS [1.5±0.71]. 94% of peoples have a positive response about HIV/AIDS knowledge could be transmitted by sexual intercourse [50.5±50.2]. 99% believed the use of a condom can stop HIV spread through sexual intercourse [53±48.08] and 100% of respondents by transmission can be prevented by pre-marital blood testing [53.5±48.79; p=0.000].<sup>[11]</sup> In other modes of transmission, 87% [46.5±44.55] thought HIV through cannot be transmitted by shaking hands, 95% thought HIV through cannot be transmitted by eating and drinking from the same plate or cup of an infected person [51±50.91]. 96% assumed one can get HIV through mosquito bite [51.5±48.79; p=0.000].<sup>[12]</sup>

**Attitude towards HIV/AIDS:** The majority of 96% of respondents confirmed a positive attitude concerning HIV/AIDS<sup>[13]</sup> and 4% has a negative attitude know that one of your clients infected with the disease did shaving to him (Table 2). 99% of peoples have a positive attitude about the disease is transmitted to you as soon as you shake hands with him, HIV can be prevented by not sharing the needle and HIV transmission can be avoided through a single partner.<sup>[14]</sup> Most people have a positive attitude towards HIV know that they think there is a need to isolate a person infected with the disease. The media has an impact on the definition of the disease and ways of prevention. The minority 3% of peoples have negative attitudes towards HIV/AIDS.

**Practices regarding HIV/AIDS:** Table 3 shows that the majority 92% of all the peoples had practice towards HIV/AIDS and handle with pruning tools (needles and other sharp cutting tools) and dispose of them as soon as they are used [49±46.67].<sup>[15]</sup> 99% of peoples had wash hands before and after any operation with practice towards HIV/AIDS [53±48.08]. The

testing practice positive response (100%) had washing tools and sterilization between the customer and another [53.5±48.79]. 98% of the peoples have used protective barriers such as gloves when dealing directly with blood [52.5±48.79]. 82% [44.5±47.38] of peoples had you ask your client before dealing with him whether he has a contagious disease with practices regarding HIV/AIDS.<sup>[16]</sup> 89% of peoples had tests to make sure you are safe from a transitional disease [47.5±51.62; p=0.000] and 11% [4.5±2.12] of peoples have negative test practice towards HIV/AIDS.<sup>[17]</sup> Most of the peoples (95%) have practice towards HIV/AIDS and 5% of peoples have not to practice. Practices regarding HIV/AIDS. The present study is conducted to find out the awareness, attitude, and practice of HIV/AIDS among the peoples who use Barbershops and Beauty salons at Nasiriya city in Iraq. Among the 107 people were studied in the age group of 20–60 years. 88 (82%) males were used in Barbershops and 19 (18%) females were used in Beauty salons.

## Conclusion

The study revealed that the knowledge, attitude, and prevention of HIV/AIDS among, Barbers and Beauty salons. Participants have good knowledge about HIV/AIDS. There are significant gender and urban-rural differentials in Nasiriya in terms of knowledge, attitude, and practices in HIV/AIDS. Continuous such surveys at regular intervals would further help to assess the level of awareness and attitude towards HIV/AIDS for designing future educative programs also there should be rules and regulations from the ministry of health regarding the sterilization and disposal of sharp equipment in barbershops. It is suggested that focusing on interventions programs which helps them in understanding the disease.

## Abstract

Pneumonia is the biggest cause of mortality among under-five children in the world, including Indonesia. However, counter actions in Indonesia is taking form of limited studies that observed pneumonia comprehensively. This review aimed to obtain a comprehensive view of Pneumonia among children under-five in Indonesia. The review applied Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) guidelines. Databases were PubMed, CINAHL, Medline, and SINTA to overview risk factors of Childhood Pneumonia in Indonesia. Other databases were official websites of Indonesia government and International health organization websites to search Pneumonia programs, guidelines, and statistical data. Various datasets from different sources are integrated in to the findings. The review found the coverage of the new case findings of pneumonia children under-fives was low. Limited report and valid data of childhood pneumonia. Many factors identified as risk factors of Childhood Pneumonia. Pneumonia control guidelines have been developed by the Indonesian Ministry of health. However, programs' implementation report and the involvement of social component is minimal. Enhancing civil society roles, comprehensive approaches, and inter-professional collaboration in childhood pneumonia programs would be impacted in preventing pneumonia among under-five children.

**Keywords:** *Cases, programs, pneumonia, risk factors, under-five children.*

## Introduction

Children under-five years are part of a population that is of a considerably higher risk of developing severe diseases, including Pneumonia. Pneumonia is the main cause of mortality among under-five children in the world, including in Indonesia<sup>(1,2)</sup>. Pneumonia is caused by a bacterial, viral, or fungal infection that affects lungs, particularly the alveoli. The alveoli are small sacs in the lungs that, in the event of infection,

fill with pus or fluid resulting in difficulties in breathing, painful breathing, and limited oxygen intake—all of which may lead to death<sup>(1)</sup>. In Indonesia the definition of pneumonia is similar to the WHO definition. Pneumonia is categorized as an Acute Respiratory Infection (ARI). ARIs are the most cited causes of visit to Public Health Centers (40%-60%) and hospitals (15%-30%) among Indonesian children.

The high mortality rate caused by pneumonia in the world encouraged international institutions such as WHO, UNICEF, and Save the Children to develop guidelines that focus on prevention, protection, and treatment of pneumonia<sup>(2-5)</sup>. Since 1984 the Ministry of Health of the Republic of Indonesia has developed programs that focus on family-based promotion and prevention, and the strengthening of pneumonia management, including diagnosis and treatment<sup>(5)</sup>. The *Integrated Management of Childhood Illness* (IMCI) exists to guide screenings

for childhood pneumonia. Hence, program report and monitoring are limited. Despite prevention efforts, pneumonia prevalence remains high in Indonesia with 20 out of 34 provinces having a prevalence higher than the national average.

Limited studies in Indonesia have presented childhood Pneumonia from many different aspects and analyzed them comprehensively. The aim this review was to provide a comprehensive view of Pneumonia among under-five children situations in Indonesia, including the relevant data, risk factors, programs, and policies.

### Materials and Method

This review applied Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) guidelines <sup>(6)</sup>. This approach is suitable to achieve the aims of this study that needs a clear question and uses systematic processes the data processes are integrated into the findings in a final report. The steps of this PRISMA include identification of the relevant data bases and other sources, screening, assessing eligibility, and deciding studies that include in analysis. The steps were determining the literature topic which is prevalence of Pneumonia, surveillance data and reports, health surveys, country policies and guidelines, and gaps in the implementation.

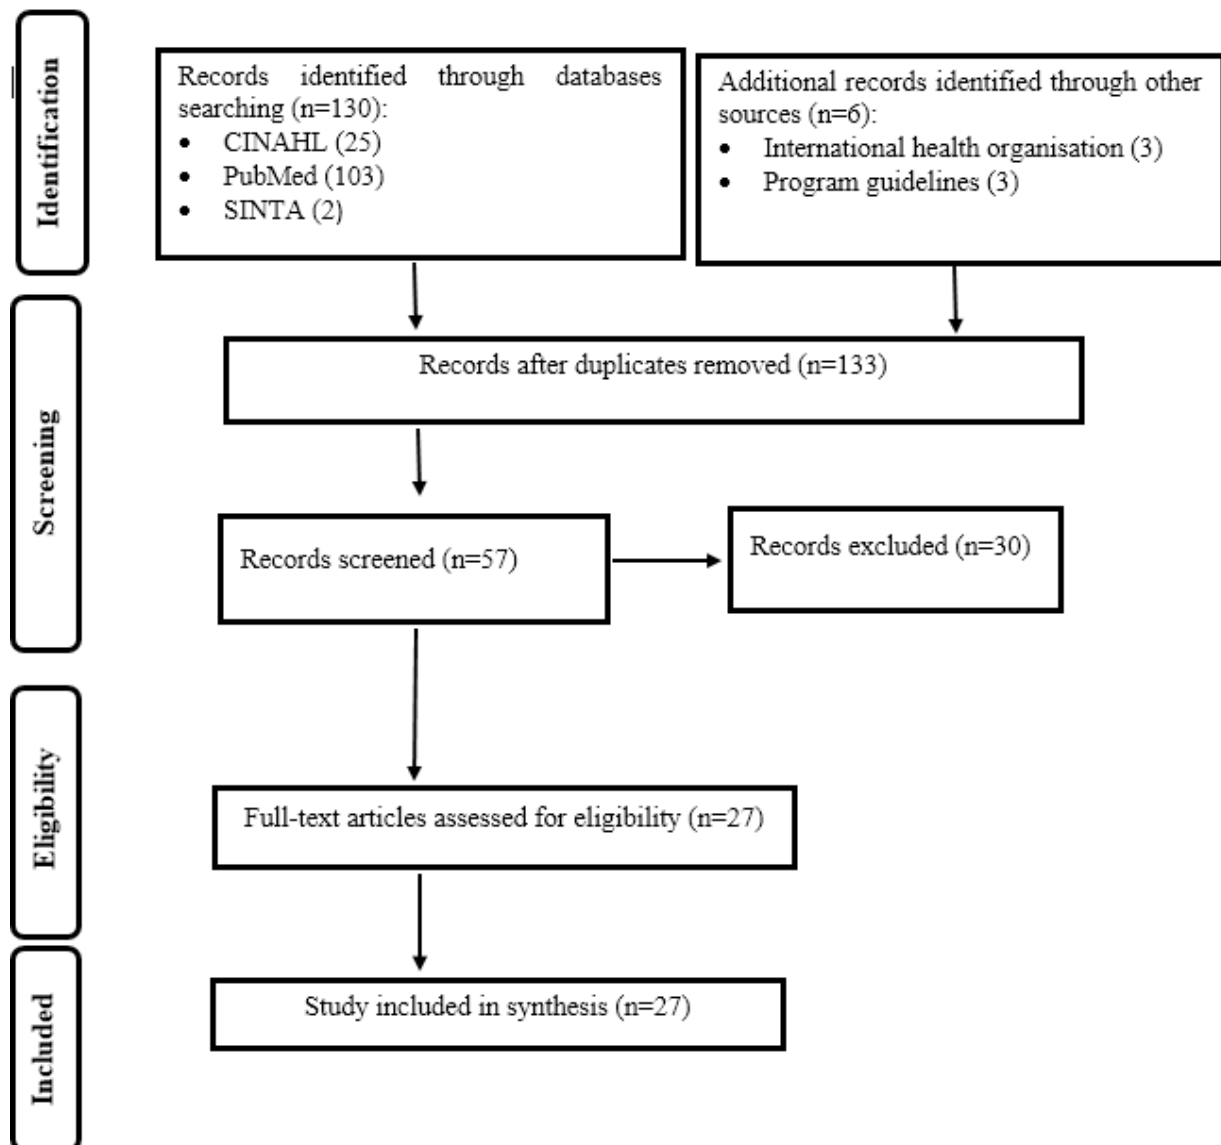

Figure 1: PRISMA flow diagram

The online sources were the Ministry of Health office, local district government reports and data, hospital reports, policy and programs in the local government the National Statistical Bureau, and various databases including PubMed, CINAHL, Medline, and SINTA. Lastly, organizing and analyzing Indonesian literature and comparing the findings with other countries' studies' findings and International guidelines. This review covers information on mortality and morbidity, risks factors, and programs of the Indonesian ministry of health in dealing with and controlling pneumonia.

## Results

**Mortality and Morbidity of Pneumonia in Indonesia:** Pneumonia is also the second leading cause of under-five children mortality after diarrhoea (15.5%) in Indonesia. Pneumonia case rates have increased from 2007 to 2013 (2.1%, to 2.7%). 20 out of 34 provinces in Indonesia had higher pneumonia prevalence compared to the national prevalence, including Aceh, Bangka Belitung, and East Nusa Tenggara. The East Nusa Tenggara (ENT) province has the highest incidence and prevalence of pneumonia in Indonesia (38.5%). The pneumonia prevalence in ENT was twice that of the national prevalence. However, ENT had a very low percentage of coverage of new cases findings in certain districts, including the Sumba Barat district the coverage fluctuated. It was 18% in 2011, slightly increased to 19.2% and 19.3% in 2012 and 2013, and significantly decreased to 4.94% in 2015. None of the reports found established a cause of the changing coverage rates. While the national coverage target of Acute Respiratory Infection Prevention and Control (P2-ISPA) program in 2016 was 90% of number under-five children<sup>(5)</sup>.

**Risk factors of Pneumonia:** Studies identified risk factors of childhood Pneumonia including nutritional status, exclusive breastfeeding, environmental factors, poverty, access to health services, and health knowledge.

- a. **Nutritional status:** A study in Indonesia confirmed that under-fives with poor nutritional status have a 6.52 greater chance of contracting pneumonia compared to under-fives with good nutritional status<sup>(7)</sup>. Another study in Indonesia found that nutritional status is also influenced by parenting, social, and culture, for example children only eat rice<sup>(8)</sup>. Sufficient nutrition supply hinders under-fives from infection disease especially pneumonia.
- b. **Exclusive Breastfeeding:** A study in Indonesia

revealed that breastfeeding decreased pneumonia cases among under-fives<sup>(7)</sup>. In addition, length and duration of exclusive breastfeeding correspond to pneumonia cases among infants<sup>(9)</sup>.

- c. **Environmental factors:** Environment is considered as a pneumonia factor among under-fives. This includes indoor<sup>(10)</sup> and outdoor air pollution<sup>(11)</sup>, cigarette smoke exposure<sup>(12, 13)</sup>, overcrowding<sup>(14)</sup> and bad sanitation<sup>(15)</sup>.
- d. **Conditions of poverty:** Poverty does not always mean the lack of income to afford sufficient quantity and quality of food, leading to malnutrition and inability to access health services that prevent treatment for children; poverty-related situations like low education, lack of knowledge, improper housing and sanitation, lack of access to clean water, and crowded housing also increase the risk of child pneumonia<sup>(16-18)</sup>.
- e. **Access to health facilities:** Access to health facilities is a key factor in preventing and treating childhood pneumonia. Studies found that access to health facilities was a strong determinant of health seeking behavior. When health facilities are not easily accessible the parents or families are discouraged to bring sick children to hospitals or primary health care centers, thus resulting in delayed treatment<sup>(19)</sup>.
- f. **Knowledge, attitudes and practice toward pneumonia:** Knowledge, attitudes and practice surrounding childhood pneumonia affect the occurrence and severity of child pneumonia. The inability to detect the signs of pneumonia and inappropriate or harmful health practices may prevent proper health care seeking behaviour<sup>(20)</sup>, and mother's perception of pneumonia severity was associated with the seeking health care.

**Programs in Preventing and Controlling Pneumonia among Under-Five in Indonesia:** Pneumonia control guidelines in Indonesia have been developed since 1984 as part of the Infection Control program of ARIs. The latest revision was released in 2016<sup>(5)</sup>. The main content of the ARI control program in Indonesia focuses on two specific approaches of family and health service-strengthening.

The Indonesian pneumonia control program involves cross-sectoral collaboration among health services, regional health offices, communities, and NGOs. The roles of each component are described as 52 activities

outlined in the ARI guidebook<sup>(21)</sup>. The activities largely cover the roles of health services and regional health offices, while the involvement of societal components such as communities and NGOs is limited. The roles of communities and NGOs were very general compared to health services' and government officials' roles.

The Indonesian Ministry of Health (MoH) via the Directorate General of Disease Control and Environmental Health (P2PL) has published a module of Standard Management of Pneumonia since 2010<sup>(21, 22)</sup>. The module described in detail actions to prevent and treat pneumonia especially in the community and PHC services. They also have strengthened the Pneumonia guidelines by realising policies and regulations that legally authorized by the President of Indonesia or MoH. The legal policies and regulations were related to the responsibilities, roles and functions of health services, government, and society in prevention of Pneumonia and the risk factors. The Minimum Health Service Standards is regulated in the MoH regulation No. 43 released by 2016, Exclusive Breastfeeding is specified in the government regulation No. 33 released by 2012, and Community Empowerment and Participation in Health development is regulated in the MoH regulation No. 65 released by 2013 (others government policies and regulations attached). The Indonesian MoH have produced various policies and regulations that proven by legislative to protect health activities legally. However, those regulations have not been maximally socialized to society, resulting in limitations of society's participation in health development.

## **Discussion**

Pneumonia is the most leading cause of mortality among under-five children in the world, including Indonesia. The Indonesian government has intensified programs to decrease the pneumonia incidence in Indonesia since 2011<sup>(5)</sup>, but it has become evident that not all parts of Indonesia have been reached equally. The coverage of Pneumonia new cases was less than the national target. However there was not clear explanations about causes of this issue. This may be due to a lack of reporting and valid data either from PHCs or hospital on childhood pneumonia in Indonesia. Several actions were established to improve the reported data of pneumonia among under-fives, however the health data—especially the latest update of the health situation—were either difficult to access, inaccessible, or none were provided. There is a need for comprehensive data on childhood

pneumonia and accessible data.

This review found several risk factors of Pneumonia among under-five children such as nutritional status, breastfeeding, environment, poverty, accessibility, and knowledge. Children with poor nutrition had risk of many infection disease including Pneumonia. Low nutrition status engenders inflammatory response disorder, immune, and disturbs metabolism as well as expose flawed tissue for infection<sup>(23)</sup>. Social, economic and cultural factors contribute in their own way as well. Those aspects coexist in a diverse place like Indonesia, making it difficult to detach nutritional status from parenting and the aforementioned factors that play into it. Low breastfeeding rates contribute to pneumonia cases<sup>(9)</sup>. Breast milk contains immunoglobulin which protects infants from bacteria and viruses. Next the environmental factor has a huge effect on under-fives' health. Under-fives, frail and with imperfect immune systems, are at high risk of diseases like pneumonia.

Social economic status of the family is one environmental factor that has been consistently regarded as a significant predictor of child pneumonia. Available studies vary in defining low economic status or poverty, which potentially leads to finding biases. In many developing countries where a large amount of the population relies on subsistence agriculture or less formal livelihood, objective and reliable measures of income is not always available. Therefore, in addition to income the use other indicators including household possession, dwelling site or service areas could be better in measuring the conditions of poverty<sup>(24)</sup>.

Referring to the context of low-income countries where health facilities are often inadequate, studies suggested improved utilization of skilled community health workers as a means to increase access to health care—especially in the prevention and early treatment of child pneumonia. Empowerment and capacity building of community health personnel should be given consideration as well<sup>(19,25,26)</sup>. Meanwhile, comprehensive child health care such as monitoring of nutrition status, immunization, pre-natal care, and care for prevalent illness can play important roles in reducing hospitalization from pneumonia<sup>(27)</sup>.

The Indonesian government provides comprehensive guidelines to deal with childhood Pneumonia. However the guidelines had limited information about the involvement of other societal components such as health

professional organizations, universities or professional health schools, families, and health volunteers in pneumonia prevention programs. This may lead to limited roles and participation of society in preventing pneumonia and might also affect their awareness of the disease. As a result the study that assessed society's roles in preventing pneumonia is limited despite how societal components have the potential to assist the government in reducing pneumonia mortality and morbidity.

### Conclusion

The updated data related to mortality, prevalence and incidence of child pneumonia in Indonesia are limited. There is an urgent need for comprehensive and accessible data of pneumonia. Nutritional status, environmental factors, social and economic conditions, women's empowerment, knowledge, attitudes and practice toward pneumonia and access to health care are among key risk factors of pneumonia among under 5 years old children. Nevertheless, existing studies were predominantly clinical and quantitative in nature, thus more qualitative studies are needed especially in explaining non-clinical factors associated with the disease. Comprehensive approaches and inter-professional collaboration are needed in dealing with Pneumonia among under-five children in Indonesia.

# Health Risks of People Living Close Cipayung Depok Landfill Due to Hydrogen Sulfide Exposure: Respiratory Problems and Malodor Peceptions

Rima Maulida Hidayati<sup>1</sup>, Suyud Warno Utomo<sup>2</sup>, Haryoto Kusnoputranto<sup>3</sup>

<sup>1</sup>Faculty of Public Health-Universitas Indonesia, <sup>2</sup>Department of Environmental Health, Faculty of Public Health and School of Environmental Science, Environmental Studies Program, Universitas Indonesia, <sup>3</sup>Department of Environmental Health, Faculty of Public Health

## Abstract

**Background:** Cipayung Landfill operating with open dumping system which exceeded its capacity. The waste which enters the landfill is 800 tons/day and the height of the waste heap reaches 30 meters.

**Objectives:** This study aims to analyze the risk level of H<sub>2</sub>S and to identify respiratory problems and malodor peceptions in people living around the landfill.

**Method:** This study uses the method of descriptive quantitative with analysis health risk approach. H<sub>2</sub>S sampling was carried out at 2 points around the Cipayung landfill closest to resident areas. The number of samples in the study is 100 people who are in Hamlet 07, Cipayung Urban Village. Data collected uses three parts questionnaire consist; general characteristic of respondents, respiratory problems, and malodor perceptions.

**Results:** The highest measurement result of H<sub>2</sub>S is 0.021mg/m<sup>3</sup> with RQ value calculation is 2.98 . Out of 100 respondents, 81% had suffered respiratory problems during living near the landfill the most frequent symptom of respiratory problems in the last 2 weeks was coughing (25%).All respondents (100%) smell foul of the landfill, with the majority saying that the smell disturbs daily activities (70%) and causes unhealthy effects (75%).

**Conclusion:** The RQ value >1 which means people living close to the landfill are at risk of non-carcinogenic effects in the next 30 years. Respiratory problems and malodor perceptions in people living close the landfill indicate that health effects have arisen from the potential hazards of H<sub>2</sub>S. Recommendation: It needs amelioration of processing system and other efforts by the stakeholders to decrease the risk of health and environment problems caused by H<sub>2</sub>S from Cipayung Landfill.

**Keywords:** *Environmental Risk, Landfill, Hydrogen Sulfide, Respiratory Problems, Malodor Perceptions.*

## Introduction

Landfill is the way to manage domestic and industrial wastes in many developed and developing

countries. If landfill not managed properly it can lead to environmental degradation by releasing various contaminants such as groundwater contaminations and odor emissions<sup>1</sup>. There are some bad things that are caused by landfills: Toxins, leachete, and greemhouse gasses. Toxic substances are derived from waste like televisions, and other electronic appliances which contain hazardous substances (mercury, arsenic, PVC), lama kelamaan dapat menyerap ke soil and groundwater, and become environmental hazards. Leachate is highly

---

**Rima Maulida Hidayati**

Faculty of Public Health-Universitas Indonesia

e-mail: suyud.ui@ui.ac.id

toxic that can pollute the land and ground water. And greenhouse gasses removes the oxygen and causes it to break down in an anaerobic process<sup>2</sup>.

Landfills in the decomposition process can produce harmful gases that can caused health problems. One of the gases produced at the landfill is H<sub>2</sub>S<sup>3</sup>. The respiratory tract and nervous system are the most sensitive organs when exposed to H<sub>2</sub>S exposure. H<sub>2</sub>S at high concentrations can cause someone to lose their ability to smell, so it is wrong to think that H<sub>2</sub>S is no longer available even though it still exists. This can increase the risk of exposure to air levels which can cause serious health effects<sup>4</sup>. Most health effects are respiratory disorders. Complaints of breathing can be coughing, coughing up phlegm, breathing sounds/wheezing, shortness of breath, breathing sound/wheezing accompanied by shortness of breath, chest pain, flu and coughing with flu<sup>5</sup>. Peoples living near the landfill are directly exposing to volatile H<sub>2</sub>S compounds. Long-term exposure to this compound is associated with potential health risks, such as respiratory irritation, cancer and even damage to the central nervous system<sup>6</sup>.

Cipayung Landfill which began operating in 1984, is located in Cipayung Village, Depok City. Cipayung Landfill is a waste collection place originating from 11 subdistricts in Depok City with an area of 10.8 hectares. The area of the Cipayung landfill is categorized as overload with the amount of garbage entering 800 tons per day and will continue to increase with the height of 30 meters of waste generated<sup>7</sup>. The air quality around Cipayung Landfill for H<sub>2</sub>S parameters is 0.14 mg/m<sup>3</sup> (converted to 0.1 ppm) which means it passes the odor threshold value based on the Decree of the Minister of Environment of the Republic of Indonesia Number 50 of 1996 which is 0.02 ppm<sup>8</sup>. Preliminary studies have been carried out by conducting observations and direct interviews with people who live close the Cipayung landfill. It is found that 15 people who have lived more than 15 years mentioned having experienced respiratory complaints such as coughing, chest pain, and most often is a sore throat due to the stench. from landfill. Based on observations obtained smells like rotten eggs smelled quite strong even from a distance of 1 km and smelled stronger when the wind blew.

Despite of the harmful effects caused by landfill there are not previous research on health and environmental impacts on the residents living closer to Cipayung landfill. Therefore this research was conducted to be able

to find out the health risks, respiratory problems and odor problems in people who live close the Cipayung landfill.

## Materials and Method

**Data sources and Study Population:** This study uses primary data derived from data collected using questionnaire and measurement of ambient H<sub>2</sub>S around Cipayung landfill. The population in this study were all residents of hamlet 07, Cipayung Urban Village, which is the closest settlement to the landfill. Based on the sample size, 100 people became the study samples. The inclusion criteria determined are people aged ≥ 18 years based on anthropometric uniformity.

**Measurements:** Measurements were made using a questionnaire divided into 3 parts, consisting of the characteristics of respondents (age, sex, length of stay, and distance of the house from the landfill as measured by researchers using the Google Maps), malodor perceptions, and respiratory problems. And measurement for level ambient of H<sub>2</sub>S using a spectrophotometer with the methylene blue method.

**Data Analysis:** Descriptive statistics generated for the questionnaire using SPSS Software Version 20.0. Risk level of H<sub>2</sub>S exposed obtained by calculations using the Louvard formula from the measurement results of ambient H<sub>2</sub>S concentration.

## Results and Discussions

**General Characteristic of People Living Close Landfill:** Table 1 shows that there were more female than male respondents in this study. In terms of age group the 18-45 years old range was the highest represented with 68%. Majority of duration of time living close the landfill was >20 years (61%). Most of the respondents live with a distance of <300 meters from the landfill which is 76%.

The existence of a landfill in an area can have an impact on the peoples who live around it<sup>9</sup>. Therefore the distance between the landfill site and the nearest residential area is a crucial thing. The majority of respondents in the study were respondents whose home distance from the landfill was less than 300 meters with the nearest distance of only 120 meters. This distance is not by the recommended distance between the landfill site and the residential area. Some recommendation about the distances; 1) Regulation of the Minister of Public

Works of the Republic of Indonesia the recommended distance is at least 1 kilometer<sup>10</sup>, 2) International Solid Waste Association the recommended minimum distance is 500 meters<sup>11</sup>, 3) Standards and Regulations of British Columbia in Canada recommend a distance of at least 300 meters<sup>12</sup>. The recommended distance is a consideration for the exposure of the community to pollution caused by the landfill (leachate pollution, air pollution, odor, disease vector spread). Previous research found that residential houses with short distances (<124.94 meters) with landfill have higher air pollutant yields compared to

those far away<sup>13</sup>. In line with the results from the study by Njoku showed that seventy eight percent of participants lived closer to the landfill site (100-500 meters) indicated serious contamination of air quality evident from bad odors linked to the landfill site<sup>14</sup>. Furthermore the results of a study conducted by Singga on scavengers at the Kupang Alak landfill found an association between the distance of the residence of the scavengers and health problems experienced by scavengers<sup>15</sup>.

**Table 1. General Characteristic of Respondents**

	Number	Percentage (%)	Min-Max	Mean
<b>Gender</b>				
Male	23	23	-	-
Female	77	77	-	-
<b>Total</b>	<b>100</b>	<b>100</b>		
<b>Age</b>				
18-45 years	68	68	19-74 years	41.26 years
> 45 years	32	32		
<b>Total</b>	<b>100</b>	<b>100</b>		
<b>Duration of time living close the landfill</b>				
9-20 years	39	39	9-74 years	28.62 years
> 20 years	61	61		
<b>Total</b>	<b>100</b>	<b>100</b>		
<b>Distances from landfill</b>				
< 300 meters	76	76	120-600 meters	275.0 meters
≥ 300 meters	24	24		
<b>Total</b>	<b>100</b>	<b>100</b>		

**Level and Risk Quotient of H<sub>2</sub>S Ambient in Around Cipayung Landfill:** H<sub>2</sub>S concentrations based on the results of measurements made at 2 points around the Cipayung landfill are 0.015 ppm (0.021 mg/m<sup>3</sup>) and 0.012 ppm (0.017 mg/m<sup>3</sup>). The H<sub>2</sub>S concentration exceeds the normal H<sub>2</sub>S concentration that comes from

natural sources that is 0.00011-0.00033 ppm<sup>4</sup>. The Risk Quotient (RQ) lifetime value calculated from the highest H<sub>2</sub>S concentration was 2.98. The RQ value >1 which means people living close to the Cipayung landfill are at risk of noncarcinogenic effects in the next 30 years.

**Table 2. Perception of malodor (smells like rotten eggs) coming from the landfill**

	Yes		No		Total	
	N	%	N	%	n	%
The smell disturbs daily activities	70	70	30	30	100	100
The smell has an unhealthy effect	75	75	25	25	100	100

Previous research by Faisya et al. regarding health risks due to H<sub>2</sub>S exposure to communities around the Sukawinatan Landfill Palembang showed that in the next 30 years duration of exposure respondents would have noncarcinogenic risk (RQ> 1) of 1.48<sup>16</sup>. The risk of health problems appears more quickly in the results of a study by Rifai et al. The noncarcinogenic RQ value for the next 5 years is 1.13 (RQ> 1)<sup>17</sup>.

**Malodor Perceptions of People Living Close Cipayung Landfill:** In this research, shows that most respondents perceived that the smell like rotten eggs disrupts daily activities which are about 70%. And then complained that the smell like rotten eggs caused an unhealthy effect that is equal to 75% (Table 2).

Cipayung landfill which has established for more than 35 years still operates with an open dumping system. Open dumping systems that are used can have bad impacts on both the environment and human health, including causing air contamination and odor pollutions<sup>18</sup>. This is worsened by the situation where the

landfill waste heap passed the maximum capacity, which reached 30 meters from the ground.

Based on the results of this study it was found that all respondents (100%) claimed to have smelled like rotten eggs originating from landfill, consider the odor to disturb with their daily activities are 70% and consider the odor to have an unhealthy effect on them by 75%. This is in line with the survey found that 75% strongly agree living close to a landfill raises concern for them, with the majority of reasons worrying, is due to health<sup>19</sup>. And then, previous research conducted by Sakawi et al. showed that 83.7% of respondents living close to landfill felt the bad odor had affected the tranquility and quality of life, and 80.5% of respondents agreed that the foul smell was associated with their health effects<sup>20</sup>.

The smell like rotten eggs (malodor) is most often smelled by people living close landfills during afternoon which is 56%, followed at evening which is 19%, almost all day is 15%, and morning is 10% (Figure 1).

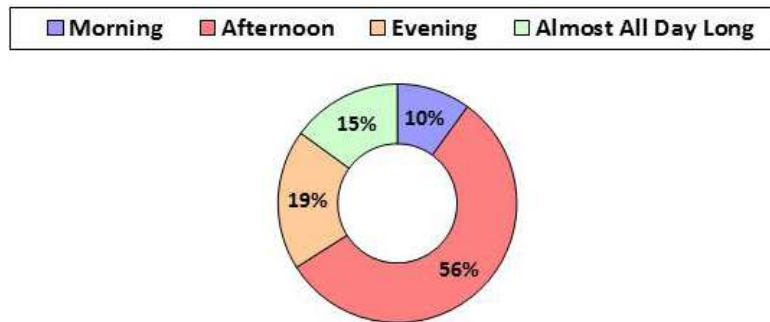

Figure 1. When it smells like rotten eggs (H<sub>2</sub>S)

**Respiratory Problems in People Living Close Cipayung Landfill:** Result of this study shows that majority stated that they had experienced respiratory problems during living near Cipayung Landfill (81%) (Figure 2). Symptoms of respiratory problems that are often complained of in the last 2 weeks are cough by 25% (figure 3).

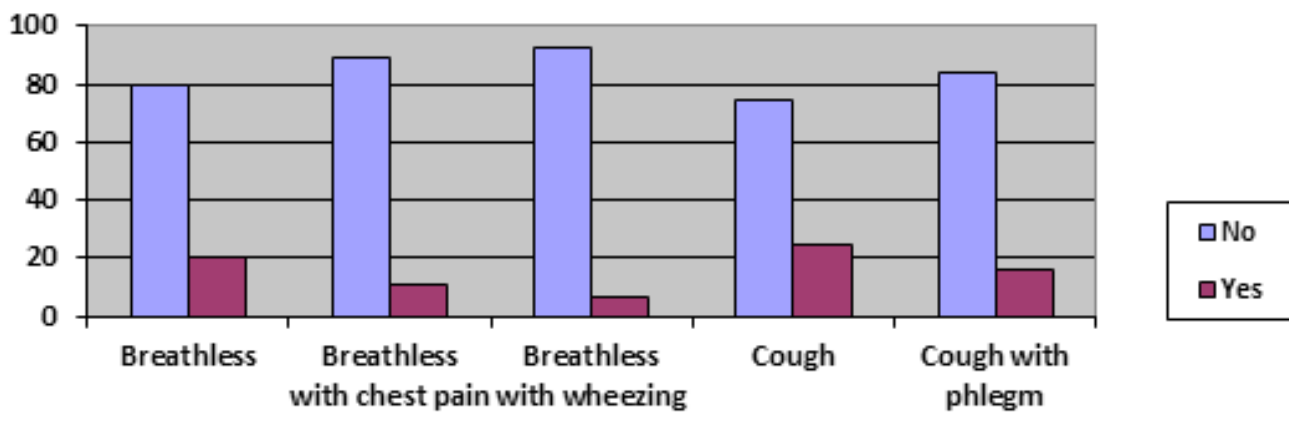

Figure 2. Have experienced respiratory problems (shortness of breath, chest pain, coughing, coughing with phlegm) during living close the Cipayung Landfill

**Figure 3. Respiratory problems that have been experienced in the last 2 weeks by peoples who live close the Cipayung landfill**

H<sub>2</sub>S can be smelled by humans at low concentrations in the air, ranging from 0,0005 to 0.3 ppm. Humans can be exposed to H<sub>2</sub>S mainly through inhalation and can be quickly absorbed by the lungs. If H<sub>2</sub>S is repeatedly or prolonged exposure can cause some symptoms of health problems such as irritation of the nose, throat and eyes, headaches, difficulty breathing in asthma patients, fatigue and loss of body balance<sup>4</sup>. The most common health effect caused by H<sub>2</sub>S exposure is respiratory disorders. Problems of breathing can be coughing, coughing up phlegm, breathing sounds or wheezing, shortness of breath, breathing sounds or wheezing accompanied by shortness of breath, chest pain, flu and cough accompanied by flu<sup>3,5</sup>.

Based on the results of this study, it was found that the majority of respondents (81%) stated that they had experienced breathing problems while living near the Cipayung landfill with symptoms including shortness of breath, coughing, coughing with phlegm, shortness of breath accompanied by chest pain, and breathing sounds. This result of study in line with the research conducted by Njoku the results showed that residents who live close to the landfill experience breathing disorder while living near the landfill<sup>14</sup>. Then the results of a cohort study also showed an association between living close to a landfill and damage to the respiratory system, and symptoms of respiratory disorders among residents living near landfills<sup>21</sup>. And then, a previous study by Putri conducted on workers at the Super Depo Sutorejo landfill showed that 76.2% of workers had experienced respiratory complaints while working at the landfill<sup>22</sup>.

### Conclusion

This study evaluates the health risks, respiratory problems and odor problems in people who live close the Cipayung Landfill. This study concludes that people who live close the Cipayung landfill have risk of noncarcinogenic health disorder within the next 30 years (RQ = 2.98). This study is an important and early effort to understand the issues related to respiratory problems and malodor that emanate from Cipayung landfill. With this research, it is expected that the responsible stakeholders can make a comprehensive effort, including repairs, supervision and monitoring to reduce the health and environmental impacts caused by H<sub>2</sub>S originating from the landfill.

# Influenza Vaccine and The Frequency of Acute Respiratory Tract Infection of West Java's Pilgrims-Indonesia: Is there any Correlations Between? (An Analysis of Siskohatkes Indonesian Hajj Data 2018)

Risma Yustiani Syarif<sup>1</sup>, Syahrizal Syarif<sup>1</sup>, Tri Yunis Miko Wahyono<sup>1</sup>

<sup>1</sup>Department of Epidemiology, Faculty of Public Health, University of Indonesia

## Abstract

**Background:** Acute Respiratory Tract Infection (ARTI) stand as infectious disease that cause the highest mortality globally<sup>(1)</sup>. In 2010, 150.523 Indonesian pilgrims diagnosed as ARTI, 53.027 diagnosed as influenza and 10.572 diagnosed as Pneumonia<sup>(2)</sup>. The Kingdom of Saudi Arabia (KSA) and Indonesian Ministry of Health has recommend Influenza Vaccination for Pilgrimage<sup>(3)</sup>. This study aim to find the correlation between influenza vaccination and the frequency of ARTI of West Java's Pilgrims 2018.

**Method:** A Cross-sectional study design of Siskohatkes data; an integrated Indonesian Hajj Application that computerize all health assesment of pilgrims in Hajj Mass Gathering. Total sample is 374 West Java's Pilgrims in 2018 with complete data recorded. Influenza vaccinationstatus, ARTI's events and covariates are extracted and combined from Impor pages, Vaccination section, Health Assesment Section 1,2,3 and Medical Record . This study applied multivariate cox regression analysis andthe correlation effect expressed by prevalence oddratio (POR) with p value 0.05 and 95% confident interval (CI).

**Result:** The prevalence of ARTI in West Java's Pilgrim-Indonesia at Hajj Mass Gathering 2018 is 71.85%. Pilgrims that take influenza vaccination is 34.32%. Cox regression test results of the correlation is POR 0.99 (0.61 -1.61) with p-value 0.98, which means the Pilgrims with influenza vaccination is at 0.99 risk of ARTI events compare to those without influenza vaccination after being controlled by Age, Education, and Diabetes.

**Conclusion:** This study revealed that influenza vaccination doesn't have protective effect to frequency of ARTI in West Java's Pilgrims 2018. There was effect modification by age (p-value 0,03<0,05). Implementing vaccination in high risk indications pilgrims e.g elderly and Diabetes may prevent higher frequency of ARTI.Appropriate informationabout the role of vaccination the risks of ARTI andit's alternative prevention to Pilgrims is needed.

## Introduction

ARTI syndrome is a complex clinical condition

---

### Corresponding Author:

Department of Epidemiology, Faculty of Public Health,  
University of Indonesia

e-mail: Triyunis@yahoo.com

of varying etiology and severity which classified into Acute Upper Respiratory Infection (AURI) and Acute Lower Respiratory Infection (ALRI), depending on the main organ affected. AURI are generally mild symptoms categorized as Common Cold (CC) and Influenza Like Illnesses (ILI). Most of the fatalities and episodes of severe illness in ARTI are caused by ALRI, mainly due to Pneumonia and Severe Acute Respiratory Infection (SARI)<sup>(4)</sup>. Influenza also threatening because its rapid

transmission trigger unpredictable and recurring pandemics event with consequences on human health and impact on world economic conditions, so planning and preparedness is very important to mitigate the impact of the pandemic<sup>(5-6)</sup>. Factors that are assumed theoretically related to ARTI events are gender, age, education, occupation, comorbidities, influenza vaccination, clean living behavior (using masks and washing hands), smoking, direct contact, travel week, wave of departure and city of study<sup>(7)</sup>.

Hajj Mass Gathering has been associated with the risk of communicable disease, particularly respiratory infection that increased by long and arduous journey, severe crowding the weather and the stress of Hajj rituals<sup>(8-9)</sup>. Indonesia as the biggest muslims country, annually send their pilgrims to Kingdom of Saudi Arabia (KSA) to perform Hajj. In 2018 there was 2.371.675 pilgrims from all over the world, 203.351 within from Indonesia including 38.567 pilgrims from West Java<sup>(10)</sup>. These crowd definitely related to higher risk of ARTI of Pilgrims in Hajj Season.

Respiratory diseases found as the most common cause of outpatient department visits during the hajj, accounting for 41-60.8% of visits<sup>(11-12)</sup>. In Hajj 2017, a total of 289 influenza-related SARI cases, including 11 deaths, were reported in Makkah City. All cases of deaths occurred among international Hajjis with 44% cases from South East Asia<sup>(13)</sup>. In 2017, acute nasopharyngitis accounting for 19% visits of all outpatient Indonesian Pilgrims. In 2018, 5 diagnosis of ARTI become top 10 disease in Indonesian Pilgrims with Common Cold ranked no. 1<sup>(14)</sup>. Over 70 tons of medicine prepared by Indonesian Ministry of Health to serve their pilgrims, mostly consist drugs for ARTI<sup>(15)</sup>.

Influenza vaccination is a key element of a global strategy to minimize the risk of an influenza pandemic<sup>(16)</sup>. Recommended influenza vaccines for pilgrims are Trivalent Inactivated Vaccine (TIV) and Live attenuated Influenza Virus (LAIV). TIV derived from influenza A and B virus derivatives with the composition of virus A (H3N2), virus A (H1N1) and virus B. Indications of influenza vaccine in hajj pilgrims are: children aged 6 months to 18 years, elderly adults  $\geq$  50 years, sufferers of chronic diseases such as heart disease, chronic lung disease, diabetes, kidney dysfunction, hemoglobinopathy or immunosuppression, pregnant women trimester 2 or 3 during influenza season, people with high risk of exposure (congregation, health worker). The antibody

response obtained from the vaccine will occur after 2 weeks and this immune system lasts up to 2 years<sup>(17)</sup>.

The KSA has recommended influenza vaccines for those at risk since 2005, but this has not been a requirement for entry into the country and pilgrims who use them are still low<sup>(18-20)</sup>. In Indonesia, influenza vaccination became a recommendation for Hajj, but unsubsidized by the government. Not every Indonesian pilgrims take the vaccination. These health and economic burden of ARTI, its potential risk to become a pandemic, awareness of emerging disease disaster (SARS, MERS-CoV) needs to be considered. This study is highly recommended to revealed those facts in Indonesia.

## Method

A Cross-sectional design using data from Siskohatkes (Sistem Komputerisasi Haji Terpadu Kesehatan) 2018, conducted from July to September 2019 with permission from West Java Provincial Health Office and the Hajj Health Center – Indonesian Ministry of Health. The confidentiality and Informed consent was guaranteed. West Java Province was chosen because it sent the most pilgrims from Indonesia in 2018 and represent the characteristics of Indonesian pilgrims. Study population are amounted to 38,567 peoples<sup>(10)</sup>. The sample was pilgrims from West Java Province 2018 with influenza vaccination that experienced or not experienced ARTI, selected by non-consecutive sampling technique, randomly probability proportional to size (Lemeshow formula) and carried out in 27 Clusters (regency-city) of West Java. At 90% power, alpha value 5%, resulting of 372 participants.

The inclusion criteria: West Java's Hajj pilgrims of JKS embarkation of Hajj season 2018 with complete data recorded in Siskohatkes and having medical contact of ARTI while in Saudi Arabia. Pilgrims who don't meet health requirements, provision of influenza vaccination  $\leq$  10 days before departure to hajj, experienced ARTI according to ICD 10<sup>th</sup> diagnosis code with any severity degree of ARTI at  $\leq$  14 days after influenza vaccination, registered as tanazul pilgrims or Hajj safari participants will be excluded<sup>(21)</sup>.

The dependent variable is frequency of ARTI; define as every pilgrim whom experienced ARTI (with syndrom of signs fever, cough, cold, sorethroat, myalgia, malaise) in  $\geq$  14 days after vaccination diagnosed by the doctor as J00-J06, J09-J18, J20-J22, and J40 based on ICD 10<sup>th</sup>. The independent variable is influenza vaccination.

Covariates are age (>54 years old and ≤54 years old), sex, education (University, Senior High School and ≤Junior High School), occupation classified as Formal Worker (BUMN/BUMD employees, PNS, TNI, Polri), Informal Worker (Traders, private employees, farmers) or Not Worker (Housewife, retired, students), Obesity (BMI ≥30), Diabetes Mellitus (DM), Heart Disease, Chronic Obstructive Pulmonary Disease (COPD), Chronic Kidney Disease (CKD). The diagnosis standard of covariates are based on the consensus of the Executive Board of the Association of Indonesian Internal Medicine Experts (PB-PAPDI), related guidelines and World Health Organization (WHO).

Data downloaded from Siskohatkes by entering portion number of each sample. Identity of Pilgrims, Diagnosis and history of ARTI, Influenza Vaccination status and covariates taken from Impor page, Health Assessment Section 1,2,3, Vaccination Section and Medical Record. Those data were combined, cleaned, edited and coded. Data analysis was performed using the Stata program (v.13, StataCorp). The correlation between dependent and independent variables using multivariate Cox regression analysis. Interpretation of effect is expressed by POR, p value <0.05 and Confidence Interval of 95%.

## Results

Table 1 showed characteristic of study samples. The proportion of Pilgrims suffering ARTI was 71.85%, while Pilgrims not suffering ARTI was 28.15%. The proportion of Pilgrims taking Influenza Vaccination was 34.32%, while Pilgrims not taking Influenza Vaccination was 65.68%. Total samples became 373 since one pilgrim passed away. COPD and CKD variables being omitted because sample with those diagnosis were less than 4 Pilgrims and can't be continued in analysis.

<b>CKD</b>							
Yes	3	100	0	0	-	-	-
No	265	71.62	105	28.38			

Table 2 showed that influenza vaccine’s variable POR value 0.96 with p-value 0.81 > 0.05 (95% CI 0.70 - 1.31) which means the incidence of ARTI in pilgrims who is not taking vaccination is 0.96 at risk than those taking vaccination. There are no protective effect and no

significant relationship between influenza vaccination and the frequency of ARTI in West Java Pilgrims. The POR and p-value of CKD cannot be assessed because the samples were too low (only 3 pilgrims).

**Table 3. Multivariate Analysis of Influenza Vaccination and ARTI frequency in West Java's Pilgrims 2018**

Variable	POR	95% CI	P-value
Influenza Vaccine	0.99	0.61 -1.61	0.98
Age (> 54 y.o)	1.38	0.85 - 2.24	0.18
Education (Senior High School)	1.01	0.76 - 1.32	0.94
Diabetes Melitus	1.18	0.55 - 2.52	0.66

Table 3 showed the final multivariate model to assess correlation between influenza vaccination and ARTI frequency by controlling other covariates with Cox Regression test. The result of POR is 0,99 (95% CI 0.61-1.61), which means that the Pilgrims that not having influenza vaccination is at risk ARTI incidences in Hajj as much as 0,99 compare to those whose having influenza vaccination after being controlled by the variable Age (more than 54 y.o), Education (Senior High School) and DM.

### Discussion

This cross-sectional study evaluated that there were no protective effect of Influenza Vaccination with ARTI frequency in West Java's Pilgrim 2018 after being controlled by Age (more than 45 years old), Education degrees (Senior High School) and Diabetes Mellitus, according to result of final model in multivariate analysis POR 0.99 (95% CI 0.61-1.61) p value <0.05. The result is in line with research in Iran and Malaysia that found that effectiveness of Influenza vaccines in their pilgrims is contradictory<sup>(22-24)</sup>.

Our study showed that influenza vaccines might be useful for elderly (age  $\geq$  54 y.o) and DM. Both variables are confounding by indication for influenza vaccination. The immune system that naturally decreases in the elderly and immunosuppressed conditions in people with DM causes those pilgrims more susceptible to infection. TIV in elderly result significant reduction in all cause mortality and pneumonia related mortality as well as hospitalization rate. It reduce complications, less hospitalizations and reduced mortality in DM patient<sup>(13,25)</sup>.

The level of education is assumed to be related with ARTI prevention understanding, commitment of influenza vaccination and healthy behaviour. Future research with wider population and economic review is recommend.

### Conclusions

There is no protective effect of influenza vaccination and ARTI frequency in this study. We found effect modification between those variables after stratified by age based on Homogeneity test p value  $0,03 < 0,05$ . Implementing influenza vaccination for high risk indication pilgrims in combine with other strategy will optimize prevention of ARTI in Hajj season. Vaccine's cost might be a problem for vaccine fulfillment. It is very important for Pilgrims to get appropriate information about health strategy preventing ARTI in Hajj.

**Ethical Considerations:** This study was approved by The Research and Community Engagement Ethical Committee Faculty of Public Health Indonesia University (Ket-716/UN2. F10. D11/PPM.00.02/2019).

# The Increasing Obedience and Changes in Blood Pressure Through Family Empowerment Model in Elderly People with Hypertension

Risna Damayanti<sup>1</sup>, Abdul Aziz Alimul Hidayat<sup>2</sup>, Nurhayati<sup>3</sup>

<sup>1</sup>Lecturer, Department of Nursing, University of Megarezky Makassar, Indonesia, <sup>2</sup>Associate Professor, Department of Nursing, University of Muhammadiyah Surabaya, 60113, Indonesia, Jl. Sutorejo No. 59 Surabaya, (031) 3813096, <sup>3</sup>Associate Professor, Department of Nursing, University of Muhammadiyah Jakarta, Indonesia

## Abstract

**Background:** The implementation of program to handle hypertension requires support from all sides, especially family. Optimization of family empowerment depends on the model that serves as a reference for nursing services, assisting families and patients.

**Purpose:** This research aims to analyze the effect of family empowerment model on obedience and changes in blood pressure in elderly people with hypertension.

**Method:** This research used a pre-experimental design with a one group pretest-posttest design approach with 21 elderly people diagnosed with hypertension, selected by purposive sampling. The research instrument for the obedience used a diet obedience questionnaire of 19 questions using a Likert scale of as always = 4, often = 3, sometimes = 2, never = 1. The blood pressure used observation sheets and tensimeter.

**Results:** The results of the Paired T Test showed an increasing diet obedience after the intervention with P value = 0.007 ( $p < 0.05$ ), while a decreasing in systolic blood pressure with P value = 0.005 ( $p < 0.05$ ), and diastolic blood pressure with P value = 0.023 ( $p < 0.05$ ). can be improved by family empowerment.

**Keywords:** *Elderly, Hypertension, Obedience, Blood Pressure, Family Empowerment.*

## Introduction

The prevalence of hypertension globally, according to the World Health Organization (WHO) is around 22% for the population aged  $\geq 18$  in 2014, estimated to increase to 29.2% by 2025. The prevalence of national hypertension in 2013 is 28.1%, increases by 3.58% in 2018 (from 28.1% to 31.68%). In South Sulawesi the

number of hypertension sufferers in 2013 was 25.8% and increased by 8.3% in 2018 (from 25.8% to 34.15%)<sup>1</sup>.

In general the treatment of hypertension can be divided to two approaches, namely pharmacological and non-pharmacological approaches. The efforts developed in the non-pharmacological approach to hypertension include lifestyle modification, weight loss, regular physical/exercise exercises, smoking cessation, increasing the fruit and vegetable intake, alcohol reduction, sodium intake control and potassium supplements<sup>2</sup>.

The implementation of program to deal with hypertension requires support from all sides, especially the family role. The Ministry of Health has a program that sets the operational strategy for health development through Healthy Indonesia Program with the Family

Approach (PIS-PK) to increase health promotion and community empowerment, in this case family empowerment<sup>3</sup>. Families are the smallest part of society which plays a role in improving the health of their families<sup>4</sup>.

Family empowerment is an effort to increase knowledge, awareness and desires of the family to improve health status. Optimization of family empowerment depends on a model that will serve as a reference for nursing services. A model will produce a positive impact if the model can be developed according to the needs of providers and users of health services, such as nurses, communities and families. The family empowerment model which is often used is health education, counseling, and assistance to families and patients<sup>5</sup>.

Health education is the provision of information to improve knowledge and abilities through learning techniques or instructions to influence human behavior<sup>5</sup> and providing health education can help families in controlling blood pressure<sup>6</sup>. Assistance is giving help to raise awareness about the importance of health and problem solving, and assistance provided to families to prepare menus or foods for hypertensive diet.

For this reason, this research will analyze the effect of family empowerment model in increasing obedience and blood pressure improvement in hypertensive elderly patients.

### Method

This research used a pre-experimental design with one group of pretest-posttest design. The research was conducted in March to May, 2019 in Parangbanoa Village, involving 21 respondents using purposive sampling with inclusion criteria: 1. families who have elderly people with hypertension with systolic blood pressure between 140-179 mmHg, diastolic 90-119

mmHg, 2. The age of elderly people were  $\geq 60$  years, 3. no taking antihypertensive medicine, and 4. willing to be a respondent.

This research used diet obedience questionnaires of 19 questions in Likert scale with answers 1 = never, 2 = sometimes, 3 = often, 4 = always and observation sheets for blood pressure measurements. The activities were conducted in the first week (pretest) and the eighth week (posttest). The intervention was conducted for 4 weeks. Data analysis to determine the effect of family empowerment model on obedience and changes in blood pressure were using paired T test with  $P < 0.05$ .

### Results

**Table 1: Distribution of Frequency Characteristics of Elderly People with Hypertension**

Variable	Frequency	Percentage (%)
<b>Age</b>		
60-62	11	52,4
63-65	3	14,3
66-68	1	4,8
69-71	3	14,3
72-74	3	14,3
<b>Gender</b>		
Male	3	14,3
Female	18	85,7
<b>Duration</b>		
$\leq 1$ tahun	12	57,1
$> 1$ tahun	9	42,9
<b>Family History</b>		
No	8	38,1
Yes	13	61,9

Based on table 1, most of the respondents were 60-62 years old (52.4%) and most of them were women (85.7%). Based on the duration of suffering, most of them had hypertension  $\leq 1$  year (57.1%) and had a family history of hypertension (61.9%).

**Table 2: Effects of the Family Empowerment Model on Obedience and Changes in Blood Pressure**

Variable of Obedience	Pre Intervention		Post Intervention		P Value
	Mean	SD	Mean	SD	
Obedience	48,86	4,163	50,90	4,369	0,007
<b>Variable of Blood Pressure</b>					
Systolic Blood Pressure	151,43	9,500	144,29	12,479	0,005
Diastolic Blood Pressure	93,10	4,323	89,76	5,585	0,023

The results of the Paired T Test on obedience were obtained such as P value = 0.007 ( $p < 0.05$ ), systolic blood pressure was obtained as P value = 0.005 ( $p < 0.05$ ) and diastolic blood pressure was P = 0.023 ( $p < 0.05$ ). The results showed that there was an influence of family empowerment models on obedience and changes in blood pressure in elderly people with hypertension.

## Discussion

Research has shown an increasing diet obedience and changes in blood pressure after intervention in family empowerment models implementation due to the role and support of the family of the elderly people, including education and assistance for the implementation of a healthy lifestyle by improving diet, doing physical activity diligently, adequate rest and being able to manage stress.

Theoretically the food eaten affects the stability of blood pressure. Nutrient content such as fat and sodium have a close relationship with hypertension. The implementation of a regular diet can normalize hypertension, such as by reducing foods with high salt, fatty foods, eating high fiber foods and doing sports activities <sup>7</sup>.

Gusmira's research (2012) stated that treatment and diet are needed to control blood pressure, and patients need to understand that as much as hypertension cannot be cured, it can be controlled by changing lifestyle and obedience to diet (low diets salt, caffeine, saturated fat)<sup>8</sup>.

Family support is important to determine the beliefs, health values, treatment and care programs. Support from health personnel is also needed to increase the level of obedience<sup>9</sup>.

This is in line with the research conducted by Arista Novian (2013) which shows a relationship between hypertension diet obedience and family roles where the P value was (0.008) < of the alpha value (0.05) the family can be a support system for assistance<sup>10</sup>.

The results of Fitri's research, Dachriyanus (2016) stated that the family support has a very strong relationship with obedience and there is a unidirectional relationship; the higher the family support is the higher obedience will be<sup>11</sup>.

Educational empowerment is provided to clients with a client-focused empowerment approach or collaborative care where health care providers and

patients make joint decisions<sup>12</sup>. Family knowledge, both cognitive and behavioral in improving health status, overcoming health problems, and helping the recovery process, form family empowerment. The outcome expected is for the family to be independent and skilled in caring for the hypertensive family members.

The mechanism causing changes in the family, which has a positive effect on every family-focused treatment as well as suitable promotive actions with cultural status of the community, influences nursing actions and treatments developed in the family<sup>13</sup>.

The results of the research of Sri, Herman, and Mudatsir (2016) prove the influence of health education on family health tasks on hypertension diet obedience in the working area of Blang Mangat Health Center in Lhokseumawe City <sup>11</sup>.

Meanwhile, Mery, Oktaviani and Patriani (2017) shows the influence of education with the theoretical approach of the Dorothy E. Johnson's behavioral system model towards changes in blood pressure in hypertensive patients with P value of systolic blood pressure: 0.001 and P value of diastolic = 0.007 (Solon, Putri, & Naing, 2018).

Heni and Supriyah (2019) proves the influence of family assistance in self-care for the blood pressure stability in hypertensive patients <sup>14</sup>. Based on the research of M. Isra et al (2017), respondents who have high family support tend to have a low degree of hypertension<sup>15</sup>.

Meanwhile the research of Novita, Asti and Mamat stated that there is an effectiveness in providing salt diet to the stability of elderly people's blood pressure with hypertension in Purwoyoso village in Semarang with P value of systolic blood pressure: 0.008 and P value of diastolic: 0,0001 <sup>16</sup>.

## Conclusion

Family empowerment is one of the interventions that empowers families in controlling hypertension. In this research there were significant differences before and after intervention of the family empowerment model implementation.

**Recommendation:** The family empowerment can be used as an intervention to control hypertension.

Relevance of Research: This research has highlighted

the problem of family empowerment where the families have not understood hypertension and its treatment well, and lack of attention, support and motivation to the elderly people regarding their condition, causing no improvement in blood pressure.

# Risk Factor of Hypertension among Adolescence: A Literature Review

Riza Fikriana<sup>1,2</sup>, Nursalam<sup>3</sup>, Shrimarti Rukmini Devy<sup>4</sup>, Ahsan<sup>5</sup>, Al Afik<sup>6</sup>

<sup>1</sup>Doctoral Program of Public Health, University of Airlangga, Surabaya, Indonesia, <sup>2</sup>Nursing Major, STIKes Kepanjen Malang, Indonesia, <sup>3</sup>Faculty of Nursing, University of Airlangga, Surabaya, Indonesia, <sup>4</sup>Faculty of Public Health, University of Airlangga, Surabaya, Indonesia, <sup>5</sup>Nursing Major, Faculty of Medicine, University of Brawijaya, Malang, Indonesia, <sup>6</sup>Faculty of Medicine and Health Science, University of Muhammadiyah Yogyakarta, Indonesia

## Abstract

Hypertension is one of the non-communicable diseases whose numbers continue to increase in both developed and developing countries. This increase in prevalence will increase the risk of cardiovascular disease. Current developments, hypertension can also occur in the teen age group. The purpose of this study was to analyze the risk factors for hypertension that occur in adolescence. A literature review was conducted from 55 references sources and 10 article was eligible to this study. Data source using Science Direct, Proquest, SAGE dan Springer Link which published since 2007 until 2017. The results of the analysis of hypertension risk factors in adolescents showed that groups of adolescents with overweight and obesity had a higher risk of developing hypertension. Family history, high consumption of salt, consumption of cigarettes and low physical activity also increase the risk of hypertension. The development of adolescent hypertension can also be predicted through wrist circumferences, high waist circumference and high levels of fat in the blood. Overweight and obesity in adolescents characterized by an increase in body mass index are the most common risk factors for hypertension in adolescents. These risk factors can be reduced through efforts to lose weight and make modifications to healthy lifestyles such as consuming healthy foods, increasing physical activity and preventing smoking cigarettes.

**Keywords:** Hypertension, adolescence, overweight, obesity, body mass index.

## Introduction

Current disease developments have shown the epidemiology transition from infectious diseases to non-communicable diseases. The increase in non-communicable diseases does not only occur in developed countries, but also increases significantly in developing countries. The development of non-communicable diseases is multifactorial and this will have an impact on increasing non-communicable diseases such as high

blood pressure, high cholesterol and an increase in blood glucose<sup>29</sup>. The current development of hypertension does not only affect adults and the elderly. Teenagers also have a risk for hypertension. In the last two decades it was found that hypertension tends to continue to increase and threaten since a young age<sup>13</sup>. The Basic Health Research Results conducted by the Ministry of Health of the Republic of Indonesia in 2013 showed that the national prevalence of hypertension in adolescents aged 15-17 was 5.3% with a distribution of 6% in male adolescents and 4.7% in adolescents women. Based on regional distribution, adolescent hypertension was higher in rural areas (5.6%) compared to urban areas (5.1%)<sup>12</sup>.

Hypertension is a disease that involves the interaction of genetic, demographic, comorbid and

environmental influences and become a risk factor for the occurrence of heart disease.<sup>24,28</sup> If hypertension is uncontrolled there will be a risk of complications such as coronary heart disease, stroke and chronic kidney failure<sup>2, 3, 30</sup>. The results of the study show that deaths in patients with heart disease, by 30%, have a history of hypertension. Any increase of 20/10 mmHg in systolic/diastolic pressure, will increase by 20% the risk of death in heart disease<sup>27</sup>.

The prevalence of hypertension in adolescents is certainly at risk of experiencing an increase if maximum prevention efforts are not carried out. Based on the expert panel conducted and published by the American Academy of Pediatrics, it was reported that according to the results of an epidemiological survey in the last 20 years there has been an increase in the prevalence of adolescents who experience prehypertension and hypertension. The development of hypertension in each year, estimated at 7% of prehypertensive teens develop hypertension. The purpose of this paper is to describe the risk factors for hypertension in adolescents.

### Method

This study was used literature review of articles that published from 2007 to 2017 from the database of Science Direct, Proquest, SAGE and SpringerLink. The inclusion criteria from the selection of articles that have been published is discussing the prevalence of hypertension in adolescents and risk factors for the incidence of adolescent hypertension. Based on the literature review of 55 articles that discussing hypertension in adolescents, 10 articles that met the requirements of the specified inclusion criteria were selected, which discussed the prevalence of hypertension and risk factors that increase the occurrence of adolescent hypertension.

### Result

Analysis of the research method used by the ten articles reviewed has found that the entire article uses quantitative research method. As many as 9 articles the research design used was using a cross sectional study approach, while 1 other article used a cohort study approach. The instruments used were questionnaires, anthropometry measurement and mercury sphygmomanometer or digital sphygmomanometer.

The results of the analysis of 10 reviewed articles show that as many as 90% of articles describe adolescents with overweight and obesity are risk factors that are

often associated with the occurrence of hypertension in adolescents. A total of 2 articles showed the development of adolescent hypertension can also be identified from the measurement results of wrist circumferences and high waist circumference. For risk factors associated with adolescent hypertension, others include family history of hypertension, consumption of high salt foods, consumption of cigarettes, lack of physical activity and high levels of fat in the blood.

### Discussion

The results of article review shown that overweight and obesity in adolescents as indicated by an increase in body mass index were the most common risk factors for hypertension in the teen age group<sup>1,8,10,16,17,18,23,25,26</sup>. Risk factors for hypertension in adolescents can be seen based on anthropometry, kidney and electrolyte function, innervation mechanism, stress response, hyperdynamic circulation, influence of insulin on hemodynamics, gout, family history, genetic influence, and birth weight<sup>7</sup>. The results of the other study, show that adolescents with overweight are directly proportional to the occurrence of hypertension in adolescents, where 30.33% of overweight adolescents have prehypertension and 13.93% of overweight adolescents have hypertension<sup>26</sup>. The results of other studies showed that in overweight adolescents, 16% had prehypertension and 45% had hypertension. In obese adolescents, 23% had prehypertension and 45% had hypertension<sup>25</sup>. Not only that study, other research show that the Incidence Rate (IR) development of adolescent hypertension was 0.5% - 0.8% per year. In obese adolescents there are a significant increase in the development of hypertension. On the first visit, obese adolescents who had blood pressure > 120/80 mmHg were 31.3%; the second visit was 29.3%; the third visit was 59.3%<sup>23</sup>. Other factors associated with the incidence of prehypertension and hypertension in adolescents include history, consumption of cigarettes, lack of physical activity, consumption of foods high in salt and increased levels of fat in the blood<sup>8,9,25</sup>.

Increased sedentary lifestyles cause overweight and obesity and this will have an impact on increasing high blood pressure<sup>29</sup>. In addition, adolescent behavior in carrying out unhealthy lifestyles such as lack of physical activity, high sedentary activities, low consumption of high fiber and smoking behavior are closely related to the incidence of overweight in adolescents<sup>32</sup>. This is in accordance with the results of this literature review which shows that low physical activity, unhealthy food

consumption and cigarette consumption are also risk factors for hypertension in adolescents.

To reduce the risk of hypertension in adolescent groups, it is very necessary for adolescents to make behavioral changes towards healthy lifestyles such as regulating diet by limiting fat consumption, regulating body weight by seeking weight loss, actively exercising regularly and regularly, preventing smoking and blood pressure monitoring. Setting diet and increasing physical activity are very important for overweight adolescents with the aim of proper energy balance<sup>6,19</sup>. Efforts to prevent hypertension in overweight adolescents through optimizing health promotion and specific protection are very important. A healthy lifestyle campaign is a form of health education that aims to reduce unhealthy behavior that can increase the risk of hypertension. One form that can be done is peer health education. Peer health education is able to change one's lifestyle so that this will have an impact on controlling blood pressure and reducing the risk of cardiovascular disease<sup>5</sup>. In addition, it also activates non-communicable disease health services in schools with the aim of screening risk factors and early detection of hypertension<sup>13</sup>. In addition to health education, mentoring can also be used as an effort to prevent hypertension early in overweight adolescents. Mentoring is effectively used to manage body weight and increase self-esteem in obese individuals<sup>14</sup>. Assistance is carried out, so that youth involvement will begin early in terms of planning and controlling actions. Action planning and action control are mediators in the intention and formation of one's behavior<sup>31</sup>. Planning will influence the control of actions which can ultimately affect behavior<sup>4</sup>.

### Conclusion

Overweight and obesity are risk factors that can increase the occurrence of adolescent hypertension. Other risk factors are family history, high salt consumption, cigarette consumption and low physical activity. To reduce these risk factors, efforts to lose weight and make a healthy lifestyle such as consuming healthy foods, increasing physical activity and preventing consumption of cigarettes are very important things.

# The Influences of Coping Strategies on Emotional Well-Being Victims of Verbal Bullying in Senior High School 11 Surabaya

Rosdiana Mahardika Putri<sup>1</sup>, M. Bagus Qomaruddin<sup>2</sup>, Rachmat Hargono<sup>2</sup>

<sup>1</sup>Health Promotion and Behavioral Sciences, Master Program of Public Health Sciences, <sup>2</sup>Department of Health Promotion and Behavioral Sciences, Faculty of Public Health, Airlangga University, Surabaya, Indonesia

## Abstract

**Background:** Bullying problem which happened to students in schools continues occur and increasing every year throughout the world. Bullying is unpleasant behavior with intentional to hurt others and occurs repeatedly and it shows difference power between bullied and victims. Bullying can cause feelings of stress which victims experienced the most. Victim of bullying can overcome feelings of depression by coping strategies. Adaptive coping strategies can contribute to generating positive emotional well-being for victims of bullying at school. Bullying happened at Senior High School 11 Surabaya can cause emotional problems in students. This study aims to analyze the influences of coping strategies on emotional well-being of victims of verbal bullying in Senior High School 11 Surabaya.

**Material and Method:** This type of research was observational analytic with cross sectional design and used a quantitative approach. The sample of the study was 94 students who were victims of verbal bullying in Senior High School 11 Surabaya. The sampling technique was used proportional stratified random sampling method. Data analysis was used logistic regression test.

**Result:** Coping strategies were significantly influence on emotional well-being victims of verbal bullying in Senior High School 11 Surabaya were dispositional coping style ( $p = 0.017$ ), positive reappraisal ( $p = 0.022$ ), and positive events ( $p = 0.040$ ).

**Conclusion:** The conclusion of the study showed that emotional well-being of victims of verbal bullying in SMA Senior High School 11 Surabaya influenced by dispositional coping style, positive reappraisal, and positive events that are carried out as coping strategies in overcoming the verbal bullying behaviors. Teenagers can use coping strategies in dealing with life stressors to prevent adverse effects on emotional well-being.

**Keywords:** *Bullying, Emotional Well-Being, Victims of Verbal Bullying.*

## Introduction

Bullying is an aggressive behavior with intentional to repeated this action from time to time, and combined

with power aggression to hurt others<sup>1</sup>. Bullying is a serious topic of concern to the government and the general public<sup>2</sup>. UNICEF U-Report was reported that two-thirds of 100,000 young people in 18 countries have been victims of bullying. GSHS was reported that the percentage of students aged 13 to 17 have been victims of bullying were 20.6%. The Center for Urban Education Success was reported that the prevalence of students involved in bullying, which were as a perpetrator, victim or perpetrator as well as a victim were 20-29% per year.

UNICEF was reported that the prevalence of children in Indonesia aged 13 to 15 years who have been

victims of bullying in schools were 50%. KPAI was reported that the amount of educational cases happened until 30 May 2018 in Indonesia were 161 cases including 23 cases of victims of brawls, 31 cases of brawls and 36 cases of victims of violence and bullying, 41 cases of violence and bullying children and 41 cases of policy victims such as illegal levies, expelled from school, not allowed to take the exam, and 30 cases of dropped out of school.

The results of previous studies showed that bullying in Senior High School 11 Surabaya happened in four forms, which were physical, verbal, social and cyberbullying<sup>3</sup>. Victims of bullying were generally adherent and unconfident teens<sup>4</sup>, physically weak, and rejected by peers<sup>5</sup>. Adolescents who have experienced bullying were 1.5 times more likely to experienced depression compared to adolescents who did not experience bullying<sup>6</sup>.

Victims of bullying were often feeling insecure and unhappy at school, which causes victims of bullying experienced difficulty concentrating, regulating attention that affects academic achievements, and tend to absent from school, and dropped out of school<sup>7</sup>. Victims of bullying were associated with various interpersonal difficulties such as refusal of friends, low friend acceptance, few or no friends, and negative friendship quality<sup>8</sup>.

Bullying in schools have been associated with poor student well-being and had an effect on student education, which were decreased academic grades, and can cause mental health problems such as symptoms of depression, anxiety, internalization, loneliness and withdrawal from the social environment, had suicidal thoughts, self-harm, and violent behavior in adulthood<sup>9</sup>. Victims of verbal and physical bullying were more likely to engage in maladaptive behavior and experienced internal pressure<sup>9</sup>.

Students who were faced bullying adopted different coping strategies depends on age and gender<sup>10</sup>. Coping strategies are the processes to reduce stress by using all efforts and self-regulation in order to influence stressors, which are considered as burdens that exceed the ability of individuals. Coping strategies aim to reduce the impact of stressful situations or increase resources and efforts to deal with stress.

The results of previous studies showed that the sefive coping strategies were the most often used by students

in the UK aged 13 to 16 years, including discussing the experienced of bullying with someone, ignoring the problem with experienced of bullying, defending themselves, avoiding or moving away from bullies and make many friends<sup>11</sup>.

The results of previous longitudinal studies showed that support from peers and family have been associated with decreased depression while firm coping strategies such as meeting or contacting bullies has been associated with increased depression<sup>12</sup>. The aim of the study was to analyze the influences of coping strategies on emotional well-being of victims of verbal bullying in Senior High School 11 Surabaya.

## Materials and Method

This research was an observational analytic study with cross sectional design and used a quantitative approach. The research was conducted in August, 2019. The research sample were 94 students who were victims of verbal bullying in Senior High School 11 Surabaya. The sampling technique was used proportional stratified random sampling method. Data collection techniques was used primary data from questionnaire results. Data processing was used SPSS software. Data analysis techniques was used logistic regression test.

### Findings:

**Table 1. Frequency distribution of coping strategies in Senior High School 11 Surabaya**

Coping Strategies	N	%
<b>Problem management</b>		
Good	63	67,0
Poor	31	33,0
<b>Dispositional Coping Style</b>		
Good	57	60,6
Poor	37	39,4
<b>Social Support</b>		
Good	54	57,4
Poor	40	42,6
<b>Positive Reappraisal</b>		
Good	56	59,6
Poor	38	40,4
<b>Positive Events</b>		
Good	53	56,4
Poor	41	43,6

Table 1 showed that the majority of victims of verbal bullying had good coping strategies in overcoming verbal

bullying behaviors at school. The majority of victims of verbal bullying had good problem management were 67%, good dispositional coping style were 60.6%, good social support were 57.4%, good positive reappraisal were 59.6%, and good positive events were 56.4%.

**Table 2. Frequency distribution of emotional well-being in Senior High School 11 Surabaya**

Emotional Well-Being	N	%
Good	43	45,7
Poor	51	54,3

Table 2 showed that the majority of victims of verbal bullying had poor emotional well-being were 54.3% due to experienced verbal bullying behaviors at school.

**Table 3. The results from logistic regression analysis of the influences of coping strategies on emotional well-being of victims of verbal bullying in Senior High School 11 Surabaya**

Variable	Sig.	Details
Problem management	0,142	Not significant
Dispositional Coping Style	0,017	Significant
Social Support	0,086	Not significant
Positive Reappraisal	0,022	Significant
Positive events	0,040	Significant

Table 3 showed that coping strategies that had significant influence on emotional well-being were dispositional coping style (0.017), positive reappraisal (0.022), positive events (0.040). Whereas the problem management and social support did not have significantly influence on emotional well-being of victims of bullying.

### Discussion

Emotional well-being is an emotional quality of individual’s daily experience which characterized by the frequency and intensity of an individual experiencing feelings of sadness, anxiety, anxiety, happiness, depression, anger, cheerfulness, and affection that make an individual’s life pleasant or unpleasant<sup>13</sup>.

The results of logistic regression analysis showed that dispositional coping style, positive reappraisal, and positive events had significant influenced on emotional well-being. This is consistent with previous research showed that students who have dispositional resilience with good positive attitudes had the state good psychological well-being in almost alldimensions<sup>14</sup>. Victims of verbal bullying tend to prefer the optimistic

on performed dispositional coping styles to produce good emotional well-being. Optimism is a cognitive construct that has been linked with motivation, so individual who have an optimistic will exert effort to get the desired results<sup>15</sup>.

The results showed a positive reappraisal have been influences on emotional well-being of victims of verbal bullying. This is consistent with previous research that showed positive reappraisal used by caregivers to create positive emotional feelings in dealing with difficult situations to resolve and it significantly correlates with positive influence in interpreting the experience of caring for a sick partner and facing the death of a partner being treated<sup>16</sup>. Positive reappraisal encourages victims of verbal bullying to interprets the experience of verbal bullying behaviors at school as a lesson to improve the ability to deal with difficult situations which can contributes to creating positive emotions that will influences on emotional well-being of victims of verbal bullying.

The results also showed that positive events have been influences on emotional well-being of victims of verbal bullying. This is consistent with previous research showed that positive events influence individual to produce positive feelings and it significantly correlates with increased well-being<sup>17</sup>. Positive events contribute to creating emotional well-being can be caused because victims of verbal bullying were more likely to be active in carrying out positive activities in accordance with their passion that causes feelings of happiness.

The results of logistic regression analysis showed that the problem management and social support variables were not significantly influences on emotional well-being. This is in accordance with previous research which showed that seeking for social support and convincing thoughts and perceived sense of control, and expressing emotions were not significantly associated with psychological well-being<sup>18</sup>. While problem management were not significantly influence on emotional well-being can be caused by victims of verbal bullying prefer problem solving by seeking social support from family, friends or teachers to help victims in obtaining information about solutions to overcome the problems encountered.

### Conclusion

The conclusion of the study showed that emotional well-being of victims of verbal bullying in SMA Senior

High School 11 Surabaya influenced by dispositional coping style, positive reappraisal, and positive events that are carried out as coping strategies in overcoming the verbal bullying behaviors. Teenagers can use coping strategies in dealing with life stressors to prevent adverse effects on emotional well-being.

**Suggestion:** Teenagers can produce good emotional well-being by using adaptive and positive coping strategies to facing bullying at school.

**Acknowledgements:** On this occasion the author would like to thank the respondents who honestly filled out the questionnaire that had been given.

# The Role of the School's Health Clinic Teacher on Clean and Healthy Life Behavior in Elementary School Students in the South Ternate City

Rusny Muhammad<sup>1</sup>, Kartini M. Ali<sup>1</sup>

<sup>1</sup>Lecturer of Department of Nursing, Health Polytechnic of Ternate, Indonesia

## Abstract

Clean living behavior and health in schools is a set of behaviors that are practiced by students, teachers and the school community based on awareness so that they are independently able to prevent disease, improve their health, and play an active role in creating a healthy environment. The purpose of this study was to analyze the role of the school's health clinic teacher on a clean and healthy life behavior in elementary school students in South Ternate City. This research is *pre-experimental* with method *one group pre-post test design*. The unit of analysis in this study was all grade 4 and 5 elementary schools in South Ternate City, with a sample size of 269 students. The sampling technique is done by *stratified random sampling*. This analysis used *paired sample t test*. The results showed that the teacher's role in the respondent's knowledge ( $p=0,000$ ) the attitude ( $p=0.000$ ) and the skills of the respondent ( $p=0.002$ ). This mean that there are significant differences between the pretest and posttest groups. The conclusion in this study is that there is an effect of the role of the teacher School's Health Clinic on clean and healthy behavior in students in the South Ternate City Elementary School.

**Keywords:** *Role of Teachers School's Health Clinic, Clean and Healthy Living Behaviors, Elementary Schools, South Ternate City.*

## Introduction

Indonesian health status is strongly influenced by clean and healthy living behavior. This program should be implemented from school age so that healthy lifestyle practices can persist into adulthood<sup>(1)</sup>. One of the efforts in health development is through the application of Clean and Healthy Behavior. Clean and healthy living behavior is a set of behaviors that is practiced based on awareness as a result of learning, which makes individuals, families, groups or communities able to help themselves (independent) in the health sector and play an active role in realizing the public health<sup>(2)</sup>.

Implementation of a clean and healthy lifestyle that is not good can cause school-age children (6-10 years) more easily experience various diseases, such as diarrhea, intestinal worms, dental caries/cavities, nutritional problems (malnutrition, poor nutrition, over-nutrition, anemia), problems related to risk factors (drug abuse, free sex, sexually transmitted infections including HIV/AIDS, reproductive tract infections) and health problems related to basic sanitation (clean water, latrines/toilets, and wastewater disposal) who lack health requirements such as typhus, cholera, dysentery<sup>(3)</sup>.

Health problems in school-age children are influenced by the environment and personal hygiene behavior. Based on Riskesdas data (2018), around 23.1% of children in Indonesia first smoke at the age of 10-14 years. The prevalence of smoking habits increased from 1.4% to 2.1% and the prevalence of children lacking in physical activity increased from 26.1% to 33.5%. The proportion of correct bowel behavior at  $\geq 10$  years is 87.3% and 43% is correct in hand washing. Around

---

### Corresponding Author:

**Rusny Muhammad**

Lecturer of Department of Nursing, Health Polytechnic of Ternate, Jalan Cempaka, District Kota Ternate Selatan, Indonesia

e-mail: rusny.muhammad@gmail.com

31.8% of children aged 10-14 years in North Maluku Province have behaved correctly in washing their hands, but this proportion has decreased from the proportion in 2013 which was 59.5%.

Efforts have been made to create clean and healthy life behavior in schools through the School's Health Clinic activities. School's Health Clinic is an effort to foster and develop healthy habits and behavior in school-age students which are carried out thoroughly and in an integrated manner<sup>(4)</sup>. Clean and healthy life behavior in schools needs to be endeavored, especially to increase self-awareness of school residents. Self-awareness arises through school education programs. The impact of the implementation of the School's Health Clinic program can improve the health status of school residents with indicators of decreasing student and teacher absenteeism due to illness, decreasing cases of malnutrition, decreasing the number of students who need P3K handling, students achieving normal weight and height, and improving personal hygiene students<sup>(5)</sup>.

The program activities School's Health Clinic has not been able to be implemented properly if the teachers' School's Health Clinic does not carry out their roles to the full. Teacher School's Health Clinic as the executor of the School's Health Clinic program acts as an educator, controller (supervisor) and provides a good example or example to their students<sup>(6)</sup>. The role of the teacher School's Health Clinic is very important in health education especially applying clean and healthy behavior in the school environment<sup>(7)</sup>. Based on this the researcher conducted training on clean and healthy behavior of school children to teachers School's Health Clinic, so that the health status of school children can be increased through the role of the teacher. The evaluation was carried out by surveying the clean and healthy behavior of elementary school children.

**Method**

This research is pre-experimental using method one group pre-post test design. The study was conducted in 10 elementary schools in South Ternate City. The sample size is 269 students in grades 4 and 5. The collected data is then processed using the SPSS 25.0 program with the Paired t test. Data collection techniques are done by filling out questionnaires and sheets checklist.

**Findings:**

**Characteristics of Respondents:**

**Table. 1 Characteristic of Respondents**

No.	Variable	n	%
1.	Age (Year)		
	8 – 9	120	44.6
	10 – 11	149	55.4
2.	Sex		
	Man	130	48.3
	Female	139	51.7
	Total	269	100

Table 1 showed that most respondents aged 10-11 years were 149 (55.4%), and males were 139 (51.7%).

**Knowledge, behavior, and skill before and after applying clean healthy life behavior by the school health clinic teacher:** Table 2 showed the differences in the average value of knowledge before (63.31) and after (70.33) interventions with an increase of 7.02. Paired t-test results showed the p value = 0.000, <0.05 which means that the difference is significant. There are differences in the average value of behavior before (66.54) and after (69.23) intervention with an increase of 2.69. Paired t-test results showed the p value=0.000, <0.05 which means that the difference is significant. There is a difference in the average score of skills before (27.48) and after (28.32) interventions with an increase of 0.84. Paired t-test results showed the p value = 0.002, <0.05 which means that the difference is significant.

**Table 2. Knowledge, behavior, and skill before and after applying clean healthy life behavior by the school health clinic teacher**

Group	Average	Difference	p value
<b>Knowledge</b>			
Pretest	63.31	7.02	0.000
Posttest	70.33		
<b>Behavior</b>			
Pretest	66.54	2.69	0.000
Posttest	69.23		
<b>Skills</b>			
Pretest	27.48	0.84	0.002
Posttest	28.32		

**Discussions**

**Effect Role of Teachers School's Health Clinic Against Knowledge Students about Behavior of Living Healthy:** According to Notoatmodjo<sup>(8)</sup> knowledge is the result of knowing after someone in sensing a certain object. There is an increase in knowledge of

respondents after the application of clean and healthy living behaviors through the role of the School's Health Clinic Teacher in Elementary Schools in South Ternate City. This study is in line with research conducted by Chandra, Fauzan<sup>(9)</sup> that there is a significant relationship between the variable knowledge with the variable clean and healthy life behavior in primary school students in Ceribon District. This is in line with the results of research conducted by Rorimpandey, Rattu<sup>(10)</sup> which examines the factors associated with clean and healthy living behaviors (clean and healthy living behavior) at SMP Negeri 2 Tompaso students.

Following other studies also, that there are differences before and after being given peer education interventions on the knowledge of respondents<sup>(11)</sup>. Based on the results of a further analysis it can be concluded that there are significant differences in respondents' knowledge about clean and healthy life behavior after being given education better than before education was given to the intervention group. The teacher's role is the most dominant factor with clean and healthy life behavior in the school setting. So that through the role of the School's Health Clinic Teacher, a healthy lifestyle will be formed for students in the School.

The results of this study indicate that the school's health clinic teacher plays a very important role in the behavior of students including clean and healthy living behaviors (clean and healthy behavior) in the school setting, thus forming a healthy lifestyle in the school through increasing student knowledge. This statement was also stated by Pratama<sup>(12)</sup> where clean and healthy living behavior is an effort to provide learning experiences or create conditions for individuals, families, groups, and communities, by opening communication channels, providing information, and conducting education to improve knowledge. The introduction of health to students is sought by elementary schools in the city of South Ternate through the school's health clinic teachers. This is as suggested in the research of Arifin, Heriyani<sup>(13)</sup> which states that the need for government policy support to improve the implementation of clean and healthy living behavior in the form of regulations, decrees, and instructions in the program implementation of clean and healthy living behavior.

**The Effect Of The School's Health Clinic Teacher's Role on Student Behavior:** Behaviors are reactions or responses that are still closed from someone to a stimulus or object<sup>(14)</sup>. The attitude clearly shows the

connotation of the suitability of the reaction to certain stimuli which in everyday life are emotional reactions to social stimuli. School's health clinic teachers provide health education to respondents using demonstration method with the help of posters and video media. This is to support changes in student behavior. There is an increase in changes in positive behavior of respondents after the application of clean and healthy living behaviors (clean and healthy behavior) through the role of the School's Health Clinic Teacher in Elementary Schools in South Ternate City.

The results of the pre-test of respondents who had a negative attitude turned positive after being intervened through the role of the school's health clinic teacher using the demonstration method with the help of poster and video media and health education. This is statistically significant so that it is obtained that health education through the role of the school's health clinic teacher influences the attitude of elementary school students in the city of south ternate about behavior and healthy behavior before and after the intervention. It was similarly stated by Maimun and Erawan<sup>(15)</sup> that there was an influence of public health practitioner kids on improving the attitude of fifth-grade elementary school students about clean and healthy behavior before and after the intervention in Poasia State Elementary School, Kendari City 2016. The study Gomo, Umbuh<sup>(16)</sup> in Manado with the results of the study showed that the knowledge of acceleration students in Manado was good enough where 90.4% of students knew about clean and healthy behavior in schools with 68% of students practicing their knowledge. Raharjo and Indarjo<sup>(17)</sup> states that there is a relationship between attitudes and the application of clean and healthy life behavior to dispose of waste in its place after being given the facility of garbage bins in schools.

The role of the school's health clinic teacher is very capable to assist students in determining attitudes so that most of the students can respond and appreciate what is taught by the school's health clinic behavior about clean and healthy living behavior. For example, some students have applied several indicators of clean and healthy life behavior such as washing hands with soap in running water, taking out the trash in place, taking part in sports, choosing healthy foods cleaning toilets, cutting nails, and weighing weight in the room school's health clinic. This is as said by Harahap, Saefuddin<sup>(18)</sup> that the clean school environment has a significant influence on students' clean lifestyle behavior. Teacher's behavior

on a clean lifestyle also has a great impact on students' clean lifestyle behavior and makes the clean school environment the impact on student behavior becomes stronger.

**Effect of the School's Health Clinic Teacher's Role on Students' Skills:** There is an increase skills (real actions) of respondents after the application of clean and healthy living behaviors through the role of the School's Health Clinic Teacher in Elementary Schools in South Ternate. This study is in line with research conducted by Maimun and Erawan <sup>(15)</sup> that there are significant differences in the actions of respondents after being given better education than before being given education in the intervention group, so it can be concluded that there is an influence of public health practitioner kids to increase respondent's actions regarding clean and healthy life behavior.

The results of this study are supported by the results of monitoring and evaluating activities of clean and healthy life behavior at the School, where elementary school students in the city of South Ternate demonstrate washing their hands with soap in running water when they finish picking up trash, seen buying nutritious snacks in the canteen, defecate/urinate in the school bathroom, doing sports at school once a week, taking out the trash in its place, and showering and brushing teeth every morning and before going to bed. Supporting facilities for the application of clean and healthy life behavior have also been provided by the school in such as the availability of handwashing areas using soap the existence of a healthy canteen at school, weight measuring devices, proper latrines, trash bins, posters of handwashing steps the dangers of smoking and Throw garbage in its place.

Theoretically, behavioral factors contribute to 30-35% to health status. Because the impact of behavior on health status is quite large, efforts are needed to change unhealthy behaviors into healthy ones. The healthy paradigm is elaborated and operationalized among others in the form of clean and healthy life behavior Citrawathi, Adnyana <sup>(19)</sup>. To that end, by providing information about healthy and clean living through the role of the School's Health Clinic Teacher, by providing health education, demonstrations or modeling in the form of behavior (concrete actions) it is hoped that students will be able to form a habit of clean and healthy life behavior. However, facilities and infrastructure alone are not enough to support an attitude that will manifest in the

form of action. Policies and regulations made by the principal will help in turning an attitude into a behavior.

## Conclusions

There is an increase in knowledge, changes in positive behavior and increased skills (real actions) of respondents after the application of clean and healthy living behaviors (clean and healthy behavior) through the role of the School's Health Clinic Teacher in Elementary Schools in South Ternate City. There is an influence of the role of the school's health clinic teacher on the behavior of clean and healthy living (Clean And Healthy Behavior) elementary school students in the City of South Ternate.

**Conflict of Interest:** The authors declare there is no conflict of interest.

**Source of Funding:** Research funding comes from the Budget Implementation Entry List Health Polytechnic of Ternate.

**Ethical Clearance:** Taken from Health Research Ethics Committee Health Polytechnic Of Tanjungkarang Number 257/EA/KEPK-TJK/IX/2019.

# Correlation between Plasma Sex Hormones Levels and Hepatitis C Infection in Some Iraqi Male

Sabah Saad Abdulsahib<sup>1</sup>, Ammar Basim Al-Assadi<sup>2</sup>, Kadhim Ibrahim<sup>3</sup>

<sup>1</sup>Department of Biomedical Engineering, University of Technology, Baghdad, Iraq, <sup>2</sup>College of Biotechnology, Al-Nahrain University, Baghdad, Iraq, <sup>3</sup>Nursing Home Hospital in Medical City of Baghdad, Iraq

## Abstract

Hepatitis C virus (HCV) is an infectious agent which is responsible for hepatic illness, cirrhosis and hepatocellular carcinoma. The present work was designed to find out the correlation between sex hormones (Testosterone, Estradiol E2 and Progesterone) and its prevalence. Infection with HCV was diagnosed with Sacace HCV Genotype Plus Real-TM kit and plasma levels of sex hormones were measured by Roche Elecsys and cobas e analyzers. The two of three studied hormones showed alteration in the patients in comparison with the controls. The plasma Testosterone and Estradiol mean level was increased significantly in male patients with HCV infection in compared with healthy control there is no significant difference between patients and control in progesterone plasma level. There is no significant correlation between HCV viral load mean results and the mean levels of Testosterone and Estradiol while there is significant correlation with Progesterone mean levels.

**Keywords:** Hepatitis, HCV, Testosterone, Estradiol, E2, Progesterone, Sex Hormone.

## Introduction

Hepatitis C virus (HCV) infection is an important worldwide public health trouble. Most HCV cases turn into chronic hepatitis C (CHC), which may progress to liver fibrosis, cirrhosis, and hepatocellular carcinoma. The global prevalence of HCV infection is estimated at more than 170 million people, and some studies estimate that mortality related to HCV infection (death from liver failure or hepatocellular carcinoma) will continue to increase over the next two decades<sup>1</sup>.

HCV is an enveloped RNA virus, classified as a separate genus (*Hepacivirus*) of the *Flaviviridae* family. The genome of HCV is a 9.6 kb single-stranded RNA of positive polarity with a 5' untranslated region (UTR)

that works as an internal ribosome site of entry, a single long open reading frame encoding a polyprotein of approximately 3,000 amino acids (aa) and a 3' UTR<sup>2</sup>. HCV is classified into six main genotypes (1-6) and subdivided into various subtypes named in alphabetical order from a to z. Currently, sequencing of HCV isolates has identified more than 83 subtypes from the six genotypes<sup>3</sup>. The distribution and prevalence of HCV genotypes depend on geographical location. Three broad patterns of genotype distribution have been identified to date. One pattern, characterized by high genetic diversity, involves geographically discrete areas of West Africa with types 1 and 2, Central Africa with type 4 and Asia with types 3 and 6. This pattern is suggestive of a long period of endemic infection. Another pattern involves areas with a few subtypes circulating in specific risk groups, e.g., subtype 3a in drug addicts. The third pattern involves areas where a single subtype is present, such as in Egypt with subtype 4a and South Africa with subtype 5a<sup>4</sup>.

The largest rate of infection with HCV in the general population (10-20%) has been reported in Egypt. It can differ from 5.3% in parts of Africa to about 2.2%

e-mail: ammarbio\_88@yahoo.com

in South East Asia, 1.7% in North America, and 1% in Europe. There is wide alteration within the Asia-Pacific region too: Western Pacific (3.9%), Thailand (1.5%), China (1.3%), Japan (1.1%), Taiwan (1.0%) and Korea (0.6%). Emerging data from the rest of Asia too suggests a wide variation in prevalence rates. In India the seroprevalence rate was 1.85% of blood donors. Through the general population it has been studied that 4.57% in Pakistan, 1.8% in Saudi Arabia and 2.1% in Yemen have been recorded as being infected with the disease<sup>5</sup>.

Males have strikingly raised risk of advanced liver illness (cirrhosis and HCC) across diverse disease etiologies, including HCV, so supporting the potential roles for gender-associated differences in risk factor exposures as well as sex-based biological variances in disease progression<sup>6</sup>. Females are more likely than males to clear HCV in the acute phase of infection, even within a little month after infection. These notes imply the possibility that female hormones inhibit the infection with HCV, either at the levels of virus attachment/entry, virus RNA replication, virus protein synthesis or production of infectious virus particles (virions)<sup>7</sup>.

Antiviral drugs typically used to fight hepatitis C may cause sexual dysfunction (SD) and decreased libido. SD is the most frequently executed side effect of many antidepressant medications used to treat the reduction and anxiety connected with HCV combination treatment. Sexual dysfunction was reported to be more common in patients with chronic hepatitis C than in individuals without known liver illness<sup>8</sup>.

### Patients and Method

In this study, thirty blood samples were taken from male patients with hepatitis C virus infection were diagnosed by real time PCR by using Sacace HCV Genotype Plus Real-TM kit, attending the Nursing Home Hospital in Medical City of Baghdad during the period from September to December 2018, and thirty blood samples were collected from apparently healthy individual (control). The age of patients was between 21 – 63 years with the mean age at presentation being 39.23 years and from 20 to 58 years with the mean age 44.4 years for healthy control. Plasma levels of Testosterone (TES), Estradiol (E2) and Progesterone (PPOGES) were detected for patients and control by using Roche Elecsys and cobas e analyzers.

Statistical Analysis: The Statistical Analysis System- SAS (2012)<sup>9</sup> program was used to effect of

difference groups in study parameters. T-Test was used to significant compare between means variables. Estimate of correlation coefficient between parameters in this study.

### Results and Discussion

The statistical analysis for results of HCV PCR results for patients and control were shown in Table 1. The mean results of HCV PCR load for patients  $13248092.80 \pm 4905056.25$  IU/ml ( $57389739.67 \pm 21651522.21$  copy/ml) was significantly higher than healthy control  $0.00 \pm 0.00$  IU/ml ( $0.00 \pm 0.00$  copy/ml).

The plasma Testosterone mean level in male patients with HCV infection ( $7.091 \pm 0.55$  ng/mL) was significantly higher than healthy control ( $5.592 \pm 0.43$  ng/mL). (Table 2).

This result agreed with El-Serafi *et al.* who reported that testosterone was found to be significantly increased in the patients with HCV infection above that found in healthy control<sup>10</sup>. Total serum testosterone is associated with an elevated risk of both progressive hepatic fibrosis and progressive hepatic inflammatory activity in infected men with HCV. Testosterone may be very important in the pathogenesis of HCV-related advanced liver illness in males<sup>6</sup>. Active HCV infection was described by higher level of total testosterone compared with participants who accomplished HCV viral clearance the relationships among hepatic function impairment, testosterone and chronic viral infection are complex. Active HCV infection and accompanying impaired liver function are celebrated as risk factors for hypogonadism also changed in semen production. Hypogonadism is also a recognized complication of end stage hepatic disease, which was observed to improve after orthotropic liver transplant<sup>11</sup>. Testosterone is primarily metabolized by the liver, and the metabolic clearance of testosterone is decreased in severe hepatic disease<sup>12</sup>.

Experimental study elucidated that the Hepatitis C virus also augments AR signaling. The AR, whose preponderant ligand is testosterone, is a nuclear hormone receptor expressed in liver. In addition to regulating genes implicated in sexual dimorphism the AR regulates/co-regulates abundant other genes involved in diverse cellular processes of relevance to liver illness, including differentiation, cellular proliferation, inflammatory response and apoptosis (e.g. phosphate and tensin homolog, epidermal growth factor receptor, interleukin-6 signal transducer and tumor protein p53)<sup>13</sup>.

While Nguyen *et al.* reported that Hepatitis C Virus infection modulates androgen status indirectly via elevated Sex hormone binding globulin (SHBG). Screening for androgen deficiency in the context of HCV infection should selectively target males with more severe liver illness or documented higher grade fibrosis<sup>14</sup>.

The plasma Estradiol mean level in patients with HCV ( $55.33 \pm 3.01$  Pg/mL) was significantly higher than healthy control ( $32.99 \pm 2.05$  Pg/mL) (Table 2).

This result agreed with Wang *et al.* who reported that male patients with Hepatitis C infection showed significantly higher E2 concentrations than healthy males<sup>15</sup>. Farnetti *et al.* studied expression of estrogen receptors, type of estrogen receptors and oxidative DNA in patients with HBV and HCV-related chronic liver diseases, indicating that positivity in the liver for an estrogen receptor variant could result in elevated genomic harm and greater rates of cytoproliferation and carcinogenesis<sup>16</sup>.

It was noted that, owing to elevated aromatase activity the peripheral conversion of androgens to estrogen improved. The conversion of adrenal androstenedione to estrone in cirrhotic patients was also reported<sup>17</sup>. As a result of these data and research, our patient group's comparable elevated estradiol concentration was consistent with prior research. Iyer *et al.* also reported that Wild estrogen receptor (ER $\alpha$ ) basal expression in the liver is greater in men than in women. In addition the enhanced subcellular expression of ER subtypes found in diseased livers correlates with the expression of oncogenic and inflammatory markers. During pathogenesis of HCV, this modified expression of ER subtypes in the liver can lead to the progression of cirrhosis and cancer<sup>18</sup>.

The liver receptors of estradiol and estrogen safeguard hepatocytes from oxidative stress, inflammatory injury, and cell death, all contributing to fibrosis. As a result of the general slower development of liver disease and reduced viral clearance in females the disease burden resulting from HCV infection is mainly discovered in males<sup>19</sup>.

Estradiol (E2) may play a positive role in permanent liver injury by stopping the accumulation of monocyte-

macrophages and inhibiting the development of inflammatory cytokines<sup>20</sup>.

The plasma Progesterone mean level in male patients with HCV infection ( $0.624 \pm 0.04$  ng/mL) showed no significant difference with healthy control ( $0.693 \pm 0.05$  ng/mL) (Table 2).

This results were disagreed with the study done by Ahmed *et al.* who showed that progesterone serum levels were elevated in female patients with HCV in compare with healthy control<sup>21</sup>. Yuan *et al.* reported that Progesterone can counteract these beneficial E2 impacts by increasing the accumulation and cytokine output of inflammatory cells by means of progesterone receptor PR<sup>20</sup>.

Table 3 showed there is negative relation between HCV PCR load and the levels of Testosterone and Estradiol but it was not significant while there is a significant correlation with Progesterone level.

Wang *et al.* reported that men with high concentrations of serum testosterone had the smallest concentrations of antibodies and inflammatory cytokines after viral infection<sup>15</sup>. Each 1 ng/ml rise in total serum testosterone was correlated with a 27% rise in the danger of advanced fibrosis and a 16% boost in the danger of advanced inflammatory activity among males infected with HCV<sup>6</sup>. One possible explanation for testosterone's < proviral < consequences is that it alters the development of lipoprotein in a manner that encourages replication of HCV. Another chance that is demonstrated by this research is that testosterone inhibits immune responses to HCV infection<sup>22</sup>. Testosterone inhibits immune responses to HCV infection<sup>15</sup>.

## Conclusion

We concluded that plasma Testosterone and Estradiol mean level was increased significantly in male patients with HCV infection in compared with healthy control and there is no significant difference between patients and control in progesterone mean level also there is no significant correlation between HCV viral load mean results and the mean levels of Testosterone and Estradiol while there is significant correlation with Progesterone mean levels.

# Impact of Discharge Educational Program on Preterm Infants' Mothers' Knowledge and Practice

Samar M. Mohamed El-Hadary<sup>1</sup>, Soheir A. Dabash<sup>2</sup>, Hanan M. Rashad<sup>2</sup>, Zahraa E. Osman<sup>3</sup>

*1Assistant Lecturer, Pediatric Nursing, 2Assistant Professor, Pediatric Nursing, Faculty of Nursing, 3Professor, Pediatric Medicine, Faculty of Medicine, Cairo University*

## Abstract

Preterm infant discharge educational program ensure best practice and help guide the mothers to appropriate level of care following birth. The aim of the current study was to evaluate the impact of discharge educational program on preterm infant mothers' knowledge and practice. A multiple time series quasi-experimental research design was utilized. Between March 2018–February 2019, a convenient sample of sixty mothers of preterm infants was recruited from neonatal intensive care unit of El-Monira Pediatric Hospital-Cairo University. These mothers were assigned equally to either the study or control group. Mothers in the study group received four educational sessions along with hospital routine care; mothers in the control group only received hospital routine care. Mother's knowledge and practice were assessed during preterm infant hospitalization and post discharge three times using structured interview sheet and observational checklist. Results revealed that mothers' knowledge and practice about preterm infant was in the unsatisfactory level for both groups before the program intervention. Mothers' knowledge and practice total mean scores in the three times post intervention were significantly higher for study group than those in the control group. Conclusion: Discharge educational program can improve mothers' knowledge and practice to take care of their preterm infant.

**Keywords:** *Discharge Educational Program, Preterm Infants Mothers, knowledge, practice.*

## Introduction

Discharge of a premature infant is a stressful experience for parents because they will be engaged in full responsibility for their child care for the first time<sup>(1)</sup>. Another reason is that most parents lack discharge preparation and the confidence to take care of their neonate at home<sup>(2)</sup>. Previous studies suggested that parental knowledge and practice were significantly correlated with preterm infant safety, parent satisfaction and physical, emotional, psychological and social well-

being of the family<sup>(3)</sup>. It is essential that parents have acquired adequate knowledge and skills to take care of their child before discharge home.

Early discharge programs facilitate the transition to the home and have beneficial effects on both the parents and children. However, only a few studies have been conducted to identify the real needs of parents of preterm infants and to determine whether early discharge programs meet such needs<sup>(4)</sup>. Health education could increase mothers' knowledge, care abilities and self-confidence, which will subsequently assist them in handling the pressures of caring for a fragile infant at home<sup>(2)</sup>.

Prematurity is of great relevance, due to its social impact, economic costs, and effect on quality of life, as well the health consequences for premature infants<sup>(5)</sup>. Discharge education is a primary means to help parents get ready for caring for their child at home<sup>(6)</sup>. Previous

---

Mobile Phone: 01090665019

studies found that providing information and support for parents during hospitalization could impact parental confidence, parenting behavior and family wellbeing at home <sup>(7)</sup>. Parental discharge education usually begins while the infants are in NICUs, aiming at providing anticipatory guidance and information to help parents successfully care for the infant at home <sup>(8)</sup>. Meanwhile, many strategies have been established to improve the effectiveness of discharge education programs <sup>(9)</sup>, researchers found that education programs for parents of preterm infants during the hospitalization period contributed to higher levels of parental knowledge of parenting infants, more parental satisfaction with nursing service <sup>(10)</sup>, lower infant morbidity after discharge <sup>(11)</sup> and lower readmission rates <sup>(12)</sup>.

Despite receiving training by neonatal nurses, mothers of preterm infants encounter difficulties at home, hospital readmission rates increase and family life is disrupted <sup>(13)</sup>. The majority of governmental pediatric hospitals in Egypt prohibit mothers from providing care in NICUs, where the preterm infants are hospitalized due to care safety and survival concerns. However, few studies in Egypt examined the effect of education programs on mothers' knowledge and practice for their preterm infant discharge from NICUs. The interactions between healthcare practitioners and parents of preterm infants are limited in Egypt NICUs.

**Aim of the study:** To evaluate the impact of discharge educational program on preterm infants' mothers' knowledge and practice.

**Hypotheses:** Mothers who received the discharge educational program about their preterm infants will have higher mean knowledge and practice scores than those not received.

## Material and Method

**Research Design:** A multiple time series quasi-experimental research design was utilized.

**Participants:** A convenience sampling of mothers of preterm infants in NICU was recruited from Elmonira Pediatric Hospital, Cairo University. The inclusion criteria of mothers of premature infants were: 1) age of 18 years or above; 2) primary caregiver of the premature infant after discharge; 3) and their preterm infants gestational age ranged between 32 - <37 weeks of gestation. Mothers of preterm infants were excluded if their child experienced surgery; had a congenital

malformation; or was abandoned, readmitted or deceased. A total of 60 mothers were recruited in this study and assigned to either the control group (N = 30) or the study group (N = 30).

### Tools of Data Collection:

1. **A structured interview sheet:** It was developed and conducted by the research investigators and included two main parts:

**Part I (Mothers' personal data):** involved questions related to personal characteristics of mothers such as, age, level of education, occupation, place of residence and other data related to maternal history.

**Part II:** Mothers' knowledge and practice sheet (pre & post-test): included 65 questions to assess mothers' knowledge about preterm infants; it covered areas of preterm infants criteria, needs of preterm infants, warming, sleeping, feeding, skin care, prevention of infection, Kangaroo mother care, vaccination, management of some preterm infants problems and follow up.

2. **Observational Checklist:** It designed by research investigators and involved 109 questions divided to 10 procedures was used to evaluate mothers practice regarding "mothers' practice related to breast feeding, expression of breast milk, cup feeding, bottle feeding, cord care, eye care, sponge bathing, table tub bathing, diaper care and kangaroo mother care".

**Tool Validity and Reliability:** Data collection tools were submitted to three experts in the field to test the content validity. Reliability was done by cronbach's alpha test and the result of knowledge was 0.78 and practice 0.75.

**Procedure:** After the Ethical Committee approval was obtained the potential mothers were contacted to provide a detailed explanation of the study and also obtain written informed consent. All the participating mothers were asked to complete the demographic data. Mothers were assigned to either the study or control groups. The content of discharge education in this study was based on the baseline assessment for mothers' needs which were assessed individualized for each mother by pretest and used as baseline data for educational program. The discharge educational program was based on small groups (three- five mothers) and was delivered in the teaching rooms of the NICU. The discharge education

program included four sessions and each session lasted maximum 60 minutes about preterm infants criteria, needs of preterm infants, warming, sleeping, feeding, hygienic care, prevention of infection, Kangaroo mother care, vaccination, management of some preterm infants problems and follow up. Teaching approaches were a question/answer; a lecture discussion, videos, computer, power point data show demonstration-redemonstration of procedures and illustrated Arabic booklet.

The program was provided after preterm infant admitted to NICU and before infant discharge. For the study group, a prior appointment was made with mothers to decide when and where to initiate the discharge education. After finishing the four education sessions, each mother received Arabic booklet containing the discussed information.

All mothers of preterm infants in the two groups were asked to complete the post-test three times after their preterm infants discharge from NICU at the 2<sup>nd</sup>, 4<sup>th</sup> and 8<sup>th</sup> weeks follows up. All the data were collected from March 2018–February 2019.

**Statistical Analysis:** Data were statistically described in terms of mean ± standard deviation and percentages when appropriate. Data distribution was tested using Kolmogorov Smirnov test. Comparison of numerical variables between the study groups was done using Student *t* test for independent samples in comparing two groups of normally distributed data and Mann Whitney *U* test for independent samples for comparing not-normal data. Within group comparison of numerical variables was done using paired *t* test in comparing two groups when normally distributed and Wilcoxon signed rank test for paired (matched) samples when not normally distributed. For comparing categorical data, Chi-square (*c*<sup>2</sup>) test was performed. Two sided *p* values less than 0.05 was considered statistically significant.

All statistical calculations were done using computer program IBM SPSS 22.

## Results

**Table (1): Mothers’ characteristics of both groups in percentage distribution (n=60).**

Mothers’ characteristics	Groups				P
	Control (n. 30)		Study (n. 30)		
	N	%	N	%	
<b>Age/year:</b>					
• <20	3	10.00	3	10.00	0.557
• 20 - <25	5	16.666	5	16.666	
• 25 - <30	9	30.00	10	33.333	
• 30 - <35	8	26.666	8	26.666	
• ≥ 35	5	16.666	4	13.333	
Mean ± SD	28.83 ± 6.597		27.87 ± 6.084		
<b>Educational level:</b>					
• Can’t read & write	2	6.7	8	26.7	0.186
• Basic education	12	40.0	7	23.3	
• Secondary	10	33.3	10	33.3	
• University	6	20.0	5	16.7	
<b>Job:</b>					
• House wife	26	86.7	28	93.3	0.915
• Working	4	13.3	2	6.7	
<b>Place of residence:</b>					
• Urban	25	83.3	25	83.3	1.000
• Rural	5	16.7	5	16.7	
<b>Parity:</b>					
• Primi	10	33.3	7	23.3	0.390
• Multi	20	66.7	23	76.7	

Table (1) No significant differences were found between the study and control groups with regard to mothers’ characteristics (i.e. age, education level, place of residence and parity).

**Table (2): Comparison of total mean mothers’ knowledge and practice of both groups in pre/post-tests.**

Mothers’ Knowledge & Practice	Tests							
	Pre		1 <sup>st</sup> Post		2 <sup>nd</sup> Post		3 <sup>rd</sup> Post	
	Mean±SD	P	Mean±SD	P	Mean±SD	P	Mean±SD	P
<b>Knowledge:</b>								
Control Group	21.10±8.54	0.021	27.15±8.35	0.000	29.09±7.09	0.000	30.35±6.21	0.000
Study Group	16.50±6.27		61.30±2.45		60.77±3.29		58.79±2.24	
<b>Practice:</b>								
Control Group	25.00±11.09	0.261	33.42±9.26		35.57±9.81		35.50±11.75	
Study Group	27.93±8.80		100.00±6.30	0.000	98.10±6.49	0.000	96.86±6.64	0.000

Results showed that the mean score of total knowledge in the control group was significantly higher than the corresponding mean scores in the study group ( $p = 0.021$ ), while no significant difference was found

for practice ( $P = 0.261$ ) between the two groups in pretest. Post-test the mean scores of total knowledge and practice were significantly differed (Table 2).

**Table (3): Relation between mothers’ knowledge and practice level of both groups in pre/post-tests.**

Mothers’ Knowledge & Practice	Tests																			
	Pre					1 <sup>st</sup> Post					2 <sup>nd</sup> Post					3 <sup>rd</sup> Post				
	Control (n. 30)		Study (n. 30)		p	Control (n. 26)		Study (n.30)		p	Control (n.23)		Study (n.30)		p	Control (n.20)		Study (n.29)		p
	N	%	N	%		N	%	N	%		N	%	N	%		N	%	N	%	
<b>Knowledge:</b>																				
• Unsatisfactory	28	93.3	30	100.0	0.150	23	88.5	---	---	0.000	21	91.3	---	---	0.000	17	85	---	---	0.000
• Satisfactory	2	6.7	---	---		3	11.5	30	100.0		2	8.7	30	100		3	15	29	100	
<b>Practice:</b>																				
• Unsatisfactory	30	100	30	100		26	100.0	---	---	0.000	23	100	---	---	0.000	20	100	---	---	0.000
• Satisfactory	---	---	---	---		---	---	30	100		---	---	30	100		---	---	29	100	

Results illustrated that mothers of both groups had unsatisfactory knowledge and practice level with no significant relation in pretest, while a significant relations were found in the 1<sup>st</sup>, 2<sup>nd</sup> & 3<sup>rd</sup> post-tests.

**Discussion**

The current study evaluated the impact of discharge educational program on knowledge and practice among the mothers of preterm infants. After implementation of the discharge educational program mothers in the study group reported a higher satisfaction level of knowledge and practice about how to care for their preterm infants than those in the control group. The discharge education program as a nursing therapeutic intervention was significantly improved knowledge and practice of mothers about how to care for their preterm infants at home. This may be attributed to several causes: First the study group received four sessions of discharge education that provided basic knowledge about caring for their preterm infants after discharge which met mothers’ needs, second, after participating in the discharge education, mothers might feel supported by healthcare providers <sup>(14)</sup> so that they have more confidence and excitement after discharge <sup>(2)</sup> and third, because the education program used small groups (one-four mothers), mothers had more chances to exchange experience with each other and to receive support from buddy mothers <sup>(15)</sup>.

The findings of the current study denoted the positive effects of education on knowledge and practice among the mothers of preterm infants, this in consistent with <sup>(16)</sup> study. Similarly, a study conducted by <sup>(14)</sup> reported that mothers involved in the education program had increased knowledge and skills about how to care for their preterm infants. Another study <sup>(17)</sup> reported that an improvement was observed in mothers’ knowledge and skills on post-test and the experimental group showed greater improvement than the control group, with statistical significant in both groups. However the current study findings contradicted with <sup>(5)</sup> showed that interventions were not effective for mothers in caring for their preterm infants at home.

At present there are no standardized protocols about hospital discharge and follow-up care of premature infants in Egypt. Consequently, premature infants may leave the hospital without adequate discharge and follow-up care plans to ensure appropriate and adequate care at home. Based on the results in this study, it is recommended that discharge education program for mothers about caring for their preterm infants should be included in clinical routine care and clinical care policy should be established to support the use of discharge education program so as to benefit premature infants and their families.

## Conclusion

Mothers who received the discharge educational program about their preterm infants had higher mean knowledge and practice scores than those not received.

**Ethical Clearance:** Approvals were obtained from research ethical committee at faculty of nursing, - Cairo University. All mothers who participated in the study were informed about the aim, procedure, benefits, and nature of the study. A written consent was obtained from mothers. The anonymity and confidentiality issues of information were assured and the mothers had the right to refuse or withdraw from the study at any time during the study without any effect on the care provided to their preterm neonates.

**Conflict of Interest:** There is no conflict of interest.

**Source of Funding:** The fund was partially covered by the Faculty of Nursing.

## Abstract

Developmental dysplasia of the hip (DDH) is a common pediatric orthopedic condition. DDH is an abnormal development of the hip joint. The aim of the current study was to evaluate the effect of protocol of care for mothers on postoperative outcomes among their children with developmental dysplasia of hip. Time series quasi-experimental research design was utilized. A convenient sample of 60 children with DDH was recruited. The study findings revealed that mothers who received protocol of care had a higher mean score of knowledge and practice regarding care of their children with DDH than those in control group. There were highly statistical significance correlations between children's improved postoperative outcomes and mothers knowledge and reported practice after implementation of protocol of care. The study concluded that application of protocol of care for mothers' of children with DDH has a positive effect in improve postoperative outcomes. It is recommended that protocol of DDH care should be available at orthopedic department and designing suitable booklet about proper care, follow up and complication of DDH. In-service education for nurses may refresh their knowledge regarding DDH and nursing management of the orthopedic children.

**Keywords:** Protocol of care, Postoperative outcomes, Mothers of children with DDH and children with DDH.

## Introduction

Developmental dysplasia of the hip (DDH) is a common pediatric orthopedic condition. In spite of recent advances in the understanding of DDH the precise definition of DDH itself is controversial. It represents a broad spectrum of conditions affecting the proximal femur and acetabulum, in which the femoral head and the acetabulum are not aligned and do not develop proportionately<sup>1</sup>. The incidence of DDH varies greatly with nations and continents, but around the world

incidence of DDH ranges from 1 to 34 cases per 1000 births<sup>2</sup>.

Eight in ten cases are females; roughly 6 in 10 children occur in the first born children. Furthermore, ultrasound studies have demonstrated hip instability in up to 15% of all newborn<sup>3</sup>. Numerous factors can lead to DDH which includes several mechanical, hormonal, genetic and environmental factors. Early finding and management offers the best possible result. Hip dysplasia into teens and later life may result in irregular gait, reduced the strength and generate many hip and knee disease<sup>4</sup>. The final outcome of DDH depends on the age of child the severity of child's condition and the response to treatment such as (a special brace or harness, casting, surgery). After surgery child will be put into a hip spica cast for a minimum of 6 weeks<sup>5</sup>.

Families, especially mothers, can suffer

psychological and social problems such as anxiety, guilt, fatigue, depression, and social isolation during home care. All of the parents had problems with care giving activities in the home, especially toileting, cast care, and skin care, pain, feeding and personal hygiene<sup>6</sup>.

Protocols of care are instruments that can reduce the variability of conduct among the professionals involved in health care, to promote greater security for the patient and for the professional, to allow process and outcome indicators to be developed, to improve the quality of care and the rational use of resources<sup>7</sup>.

Nurses play a significant role in identifying signs of DDH in new born. The primary goals in caring for a child at the hospital pre & post-operative care is followed by caring for a child in cast to maintain the position of the hip joint. Moreover, prevent complications and provide stimulation necessary for the developing child. As early as possible, involve parents in caring for their children to build confidence in their ability and provide home care<sup>8</sup>.

#### Hypotheses:

1. Mothers who will receive the protocol of care will have higher mean score of knowledge and practice related to care of children with DDH than those who don't.
2. Children of the mothers who will receive the protocol of care will have better postoperative outcomes than those who don't.

#### Material and Method

**Participants:** A convenient sample of 60 mothers of children with DDH was participated in the study.

**Setting:** The study was conducted at pediatric orthopedic surgical unit and in the pediatric orthopedic surgical outpatient clinic at Cairo-University Specialized Pediatric Hospital, Cairo, Egypt.

#### Data Collection Tools:

1. A structured interview sheet: It included child and mothers' personal data as child age, gender, rank, mothers' age, level of education and child's past and present medical history.
2. Postoperative Outcomes Recording Sheet: It was developed by the researchers to assess the children during postoperative period. It included established child postoperative outcomes criteria related to vital signs, intensity of pain, status of cast, skin integrity,

occurrence of complications of immobilization, child's appetite, occurrence of potential injuries, as well as positioning.

3. Pre/Post Test: it was developed by the researcher to assess mothers' knowledge regarding DDH such as definition of DDH, causes, types and plan of treatment. Observation Checklists evaluate the mothers' practice regarding care of children with DDH. it was modified and simplified by the researcher<sup>7</sup>.ory, to fit the capabilities of mothers. Observation checklists was involve measurement of skin and hygienic care, cast care, care of immobilized child, protect from potential injury.
4. Pain Rating Scales: It was used to assess the intensity of postoperative pain among children with DDH it was include:
  - A. The Face, Legs, Activity, Cry, Consolability scale (FLACC) to assess pain for children between the ages of 2 months and 7 years or children. The scale is scored in a range of 0–10 with 0 representing no pain.
  - B. Faces Pain Rating Scale to assess pain intensity among children aged more than three years of age. The scale is treated as a 5 level Likert scale with scores ranging from 0 (no pain) to 5 (worst pain).

**Tool Validity and Reliability:** The tools was submitted by three experts in pediatric surgery nursing, and pediatric orthopedic surgery to test the content validity of the tools to ensure the content validity. Reliability of tools was performed to confirm its consistency and was calculated statistically.

**Procedure:** Written consent was obtained from caregivers and oral acceptance from the children after description of the aim and nature of the study. The researcher attended to orthopedic surgical unit and outpatient orthopedic clinic. Through an individual interview with each child and mother the researcher provided completed data about the child, parents' personal data and child history. The researcher conducted preoperative teaching for mothers having children with DDH about postoperative care. Before teaching sessions the mothers were exposed to pre-test to assess their knowledge about care should be given to children with DDH. Then the research investigator explained teaching through two educational sessions the first session provided the mothers knowledge about definition of

DDH, predisposing factors, symptoms, orthopedic operation for those children. The second session was focused on care should be given by the mothers such as reducing child's pain, skin and hygienic care, cast care, care of immobilize child, protection from potential injuries, enhance appetite of the child and positioning. These activities were applied through demonstration and re-demonstration through simulation. The implementation on the child of the protocol took place during the first week after orthopedic operation through re-demonstration of care for child by the mothers guided by research investigator. To evaluate the mother's care giving activities regarding care of children with DDH was taken place using modified and simplified observational check lists and postoperative outcomes recording sheet will be assessed. They would be assessed three times; the first time immediate postoperative of orthopedic surgery for DDH children in the orthopedic surgery department the second time after two weeks and then the third one

after one month of the orthopedic surgery in orthopedic outpatient clinic.

**Statistical Analysis:** The collected data was tabulated, and summarized. Data was computerized and analyzed using appropriate descriptive and inferential statistical tests to test the research hypothesis (SPSS) program version 21 were used. Level of significance was set at  $P < 0.05$ .

**Findings:** Table (1) indicated that the highest percentages of children in both groups (60% & 56.7% respectively) aged less than 3 years. The mean age of children in the study group was  $3.5 \pm 2.48$  years and it was  $2.8 \pm 1.71$  years for children in control group. Two fifths and more than half (40% & 56.7% in order) of children in both groups were ranked as first child in their families. The majority of children in study and control groups (63.3% & 73.35 correspondingly) didn't enter school.

**Table (1): Percentage Distribution of Children' Personal Characteristics (n=60).**

Children' Characteristics	Study Group (n=30)		Control Group (n=30)		$\chi^2$	p-value
	No.	%	No.	%		
<b>Age/Years</b>						
<3	18	60.0	17	56.7	4	0.13
3-<6	7	23.3	12	40.0		
6-<10	5	16.7	1	3.3		
X $\pm$ SD	3.5 $\pm$ 2.48		2.8 $\pm$ 1.71			
<b>Child Rank</b>						
First	12	40.0	17	56.7	1.7	0.63
Second	7	23.3	5	16.7		
Third	6	20.0	4	13.3		
More than third	5	16.7	4	13.3		
<b>Education</b>						
Did not enter school	19	63.3	22	73.3	1.5	0.47
Nursery	6	20.0	6	20.0		
Primary	5	16.7	2	6.7		

\*Significant at p-value<0.05.

Figure (1) proved that more than three quarters and less than two thirds (76.7% & 60% correspondingly) of children with DDH in the study and control groups were females.

Figure (1): Percentage Distribution of Children's Gender in the Study and Control Group (n=60).

In relation to mothers knowledge outcomes table (2) proved that all of mothers (100%) of the study groups had satisfactory knowledge out comes compared with mothers in the control group still had unsatisfactory

knowledge out comes (86.7%, 66.7 & 50% in order). There were statistical significance difference between mothers in study and control group related to knowledge outcomes (p>0.05).

Table (2) Comparison between Outcomes of Knowledge Related to Postoperative Care of Their Children in Study and Control Groups.

Knowledge Outcomes	Study Group (n=30)		Control Group (n=30)		$\chi^2$	P-value
	N	%	N	%		
<b>Immediate Postoperative</b>						
Satisfactory	30	100	4	13.3	21.37	0.041*
Unsatisfactory	0	0	26	86.7		
<b>After 2 Weeks</b>						
Satisfactory	30	100	10	33.3	10.01	0.002*
Unsatisfactory	0	0	20	66.7		
<b>After 1 Month</b>						
Satisfactory	30	100	15	50	5.00	0.025*
Unsatisfactory	0	0	15	50		

\*Significant at p-value < 0.05.

Table (3) illustrated that there was no statistical significant correlation between children improve postoperative outcomes and mothers' reported practice in pretest (r= 0.190, p>0.05). There were statistical significant correlations between children improved postoperative outcomes and mothers reported practice in immediate postoperative, two weeks after surgery and one month after surgery (r = 0.190, p<0.05, r = 3.86, p < 0.05, r = 2.8, p < 0.05 & r = 0.26, p < 0.05).

Table (3) Correlations between mothers Reported practice and Improved Postoperative Outcomes (n=60).

Improved Postoperative Outcomes	Mothers' Reported Practice	
	r	P
Before the surgery	0.190	0.146
Immediate after surgery	3.86	0.012*
Two weeks after surgery	2.8	0.049*
One month after surgery	0.26	0.043*

\*Significant at p-value<0.05

It was evident from table (4) that there were highly statistical significant correlations between children improved postoperative outcomes and mothers knowledge and reported practice ( $r = 0.98$ ,  $p < 0.05$ ,  $r = 0.94$ ,  $p < 0.05$  in order).

**Table (4) Correlation between Knowledge and Reported Practice of Mothers and Improve Postoperative outcomes.**

Variables	Improve postoperative outcome	
	r	P
Level of knowledge of mothers	0.98	0.0001*
Reported practice of mothers	0.94	0.0001*

\*Significant at p-value  $< 0.05$ .

### Discussion

Based on the result of the current study the highest percentages of children in both groups aged less than 3 years. On the same line with this findings of a study done by<sup>9</sup> who indicated that repeated, carefully performed clinical examinations of the pediatric hip from newborn to walking age remain the best method for early detection of DDH. Regarding the child's rank the highest percentages of children in both groups ranked as first child in their families. This finding is in agreement with a study carried out by<sup>10</sup> who found that; first-born children were associated significantly with an increased risk of DDH.

The results of this study indicated that more than three quarters and less than two thirds of children with DDH in the study and control groups were females. This result was in the same line with<sup>3</sup> which reported that 8/10 of children are females. In addition other studies by<sup>11</sup>,<sup>12</sup> and<sup>10</sup> were also supported that the female sex had a significantly high prevalence among the children with DDH.

Concerning mothers' knowledge about postoperative care provided for their children after DDH surgery the results of the study highlighted that all of mothers of the study groups had satisfactory knowledge outcomes compared with mothers in the control group still had unsatisfactory knowledge outcomes<sup>13</sup> are agreed with the results as they found that, Improper postoperative care can lead to unplanned, increased morbidity and complication, use of appropriate education materials teaching method, caregivers will gain an improved comfort level and increased knowledge base. This will

translate to better children care and more complete caregiver education for home.<sup>8</sup> endorsed that educational programs should be provided about suitable nursing interventions for children with DDH.

The existing study showed that there were no statistical significant correlations between children improved postoperative outcomes and mothers reported practice in pretest. There were statistical significant correlations between children improved postoperative outcomes and mothers reported practice in immediate postoperative, two weeks after surgery and one month after surgery. The foregoing result supported by<sup>14</sup> who illustrated that application of standard operation procedure for perioperative nursing increased the completeness of preoperative preparation, decreased the incidence of postoperative complications, and the parental satisfaction was greatly improved.<sup>15</sup> who proved that implementation of quality improvement program resulted in a shift toward fewer cast complications, leading to overall improved patient care.

The current study clarified that there were statistical significant correlations between children improved postoperative outcomes and mothers' knowledge and reported practice after administration of the protocol of care. These results were in accordance with<sup>16</sup> who found that there was a highly statistical significant positive correlation between the studied mothers' total knowledge score and total practices score regarding shunt infection. This may be because of the increasing knowledge of mothers, leading to improved care and practices for their children.

### Conclusion

Protocol of care for children with DDH improves knowledge and practice of mothers' related to care of children with DDH as well as postoperative outcomes.

#### The study recommended the following:

- Protocol of DDH care can be used and integrated with the routine care for children with DDH with emphasize to be performed at home to improve postoperative outcomes.
- Designing suitable booklet about proper care, follow up and complication of DDH.
- In-service education for nurses may refresh their knowledge regarding DDH and nursing management of the orthopedic children.

**Ethical Clearance:** A written approval was obtained from the ethics and research committee of the Faculty of Nursing-Cairo University. Written informed consent was obtained from the caregivers and oral acceptance from children was confirmed after explaining the purpose, nature and benefits of the study. Children were informed that participation in the study was voluntary; anonymity and confidentiality of the data were assured.

**Conflict of Interest:** The authors declare that there is no conflict of interest.

**Source of Funding:** The fund was partially covered by the Faculty of Nursing.

# The Temporal Pattern of Ambient PM<sub>2.5</sub> and Health Risk Assessment in Thailand

Samart Prasertsin<sup>1</sup>, Ganjana Nathapindhu<sup>2</sup>

<sup>1</sup>Student of Doctoral Program of Public Health, <sup>2</sup>Department of Environmental Health Occupational Health and Safety, Faculty of Public Health, Khon Kaen University, Khon Kaen, Thailand

## Abstract

This study aims to investigate the distribution pattern and the health risk assessment of PM<sub>2.5</sub> in the Thailand atmosphere. Data used from initially PM<sub>2.5</sub> monitoring station of 5 cities in Thailand that different major source of polluted PM<sub>2.5</sub> recorded data during January 2014 to December 2017 were observed. The findings shown that average concentration ranged from 1 µg/m<sup>3</sup> to 247 µg/m<sup>3</sup>, highest in Saraburi. The diurnal patterns shown highest peak concentrations at 08.00 – 09.00 am and lowest at 02.00 - 04.00 pm. Due to weekly pattern the concentrations in weekday were likely more than weekend. The seasonal patterns comparison was highest in winter and lowest in rainy. For the potential health risk analysis the population were divided into four age group (children 1-5 years, children 6–11 years, children 12–19 years and adults 20 and over). The health risk analysis was considered age-specific respiratory rates and body weights for different age group. There were shown that negative health effect for all age group, especially cement plant area (Saraburi), urban (Khon Kaen), coal power plant (Mae-Moh), industrial area (Rayong) and Moon soon area (Hat-Yai) respectively. The children 1-5 years group had the highest health risk, children 6-11 years, children 12-19 years and adults respectively. This study concluded that PM<sub>2.5</sub> is still a challenging environmental health problem for Thailand and is a risk to public health. Knowing the distribution patterns helps policymakers to plan solutions.

**Keywords:** PM<sub>2.5</sub>; Health risk; Air pollution.

## Introduction

Air pollution has become environmental health problem in Thailand a past decade, due to economic growth and air pollutions has decreasing also. The rapid urbanization led to numerous of air pollution source including, building construction, mobile exhausts, heating combustion and resuspended dust form road. Throughout the 25 years (1990-2015) air pollution is one of the environmental risks for global burden of disease, especially in South East Asia, chronic obstructive

pulmonary disease is associated with a 700 - 800 DALYs per 100,000 and 30 - 40 deaths per 100,000<sup>(1)</sup>.

Thailand has experienced about air pollution over the past decades. There are efforts to solve the air pollution by driving the legal mechanism and installation of an air quality station for surveillance. Due to hard work, many air pollutants were maintained good standard in most areas. However, Thailand is still experiencing the problem of inhalable dust over the guideline in many areas. For instance the PM<sub>2.5</sub> that is getting attention in the past 2-3 years due to PM<sub>2.5</sub> can enter the lower respiratory tract and cause short-term and long-term health effects <sup>(2)</sup>. Moreover the proportion of disease burden attributable of PM<sub>2.5</sub> for lung cancer and cardiovascular disease were 16.8% and 14.6% respectively and mortality attributable to PM<sub>10</sub> was 3.4% for all-causes mortality, 1.7% for respiratory and 3.8% for cardiovascular mortality<sup>(3)</sup>.

Previous studies of Thailand ambient fine particulate matter were conducted in high risk areas such as the haze episode phenomenon in the north the heavy traffic roads, open burning area and industrial areas (4)(5)(6)(7)(8)(9)(10). However, to collect ambient air particulate matter samples, it is necessary to use special tools that are still limited in Thailand because these tools must be imported from abroad and are expensive. For this reason, in the long-term study of changes in order to see the pattern of distribution of ambient dust is difficult because of the high budget required. In the long-term studies, most of the time, data is often used from air quality monitoring stations. In the past, Thailand has only monitored and monitored on total suspended particulate matter and PM10. PM2.5 monitoring stations in Thailand began to be installed and measured in 2014, making the study of PM2.5 in Thailand is still limited. Thailand is a tropical country, which is different from the research that is widely distributed in America, Europe and China. The study of the distribution pattern of PM2.5 could provide the consistency of the quantity in each period and area of which will be the informatics solutions to the PM2.5 problem in Thailand.

Therefore, this study aims to investigate the distribution pattern of PM2.5 over time and assess the health risk from exposure in each age group in the Thailand atmosphere.

### Material and Method

**Ambient PM2.5 Data:** Air quality monitoring stations in Thailand are set up to monitor the concentration of 6 air parameters, consisting of PM10, PM2.5, CO, NO<sub>2</sub>, SO<sub>2</sub>, and O<sub>3</sub>. Measurement and reporting results are based on standards of United States Environmental Protection Agency (US-EPA). Air pollutants concentrations were reported every 1 hour and collected in the Thailand air pollution database of Pollution Control Department (PCD). In this study, selected hourly PM2.5 concentration data from January 1, 2014 to December 31, 2017 (4 year) from 5 stations with completed data that different regions of Thailand and the characteristics of the main sources of pollution are different, namely Khon Kaen, Saraburi, Mae Moh, Rayong and Hat Yai, that be representative, namely

urban areas, cement industries, petrochemical industry zone and tropical monsoon zones, respectively.

Concentration data will be compared the average for each hour of the day and analyzed mean difference by linear regression model in daytime-nighttime, weekday-weekend and season. Stata version 13 was used to analyze in this study.

**Health Risks Assessment:** To investigate the potential health risk of population exposed to PM2.5 were applied to calculate the total daily respiratory intake. The pathway of health risk to population's exposure was assessed using the hazard quotient (HQ). This study was analyzed by age group consisting of children 1-5 years, children 6-11 years, children 12-19 years and adults 20 years and older that followed to the exposure factors calculated by the US-EPA (2009)<sup>(11)</sup>. The procedure for calculating health risk was shown in figure 2.

The description of the steps of health risk assessment to PM2.5 are followed below:

1. Identification of the potential health risk substance. In this study assessed potential risk by ambient PM2.5 concentration.
2. Assessment of PM2.5 population exposure rate (ER). The equation is described below,

$$ER = (C_{PM2.5} \times IR \times FR \times FA \times EF \times ED) \times (BW \times AT)^{-1}$$

Were;  $C_{PM2.5}$  is the average hourly concentrations of PM2.5 ( $\mu\text{g}/\text{m}^3$ ); IR is inhalation rate ( $\text{m}^3/\text{day}$ ); FR Factor of Retention; FA Factor of Absorption; ET Exposure Time (hrs/day); EF Exposure Frequency (days/year); ED Exposure Duration (year); BW is body weight (kg); AT Average Time of Exposure (day). The exposure factors used in this study shown in table 1.

3. Toxicity assessment, in this study, calculated from RfC. based on de Oliveira et al., 2012<sup>(12)</sup>.

$$RfD = RfC \times (IR \times BW)^{-1}$$

4. The health risk characteristic will be assessed by the hazard quotient (HQ), if  $HQ > 1$  there were potential adverse health.

$$HQ = ER \times RfD^{-1}$$

**Table 1: The health risk assessment parameters and value of parameters**

Exposure Factors	Adult	Children		
	≥20 Year	1-5 Year	6-11 Year	12-19 Year
IR; inhalation rate (m <sup>3</sup> /day)	13	7.6	11	14
FR; Factor of Retention	1	1	1	1
FA; Factor of Absorption	1	1	1	1
ET; Exposure Time (hrs/day)	24	24	24	24
EF; Exposure Frequency (days/year)	365	365	365	365
ED; Exposure Duration (year)	30	2	3	3.5
BW; body weight (kg)	65	16	29	52
AT; Average Time of Exposure (day)	30×365	2×365	3×365	3.5×365
RfD; Reference dose (µg/kg.day)	0.006	0.041	0.016	0.007

**Result**

**Ambient PM2.5 concentration:** The concentration of PM2.5 in all cities, maximum peaks were observed in cities with the largest cement industrial in Thailand–Saraburi, exceeds annual WHO guideline (20 µg/m<sup>3</sup>) by 9 times (mean 41 µg/m<sup>3</sup>, min 1 µg/m<sup>3</sup>, max 247 µg/m<sup>3</sup>). The diurnal cycle there are two valleys in whole day, it is highest value around 7:00-9:00 and lowest around 14.00 – 16.00 and rising again around 18.00 – 21.00 after that there are decrease for the second time around 1.00 – 5.00, this pattern shown in all stations.

The weekly cycle shown that there are downward trends in weekend, especially Saraburi, Sunday is lower than other days obviously.

The annual examination results that Saraburi, Mae Moh, Rayong and Khon -Kaen shown similar pattern, all peak around February – Mar and lowest around June–August. In other hand, Hat-Yai, mass concentrations do

not vary different throughout the year there are minor rise around June and October.

The analyzing of mean different by multiple linear regression, in this study, use nighttime, weekday and rainy season as a reference parameter and controlling the confounding factor with meteorological factors such as wind speed, wind direction, temperature and rainfall. The study indicated that most of the daytime had a higher concentration than nighttime, except for Rayong which had lower daytime than nighttime and Saraburi with no significant differences. When comparing between weekends and weekdays, it was found that all stations had a significantly lower average on weekends than weekday. As for the season, it is found that most of the winter and summer that dry season are higher than the rainy season, except for Hat Yai station in the tropical monsoon zone, which makes this station different from others. The study results are shown in Table 2.

**Table 2: The comparison of the average concentration of PM2.5 between daytime-nighttime, weekday-weekend and season.**

Station	Daytime	Weekend	Winter	Summer
	Mean dif. (95% CI.)			
Saraburi	-0.241 (-0.841, 0.358)	-0.689* (-1.257, -0.122)	24.162* (23.486, 24.838)	14.002* (13.341, 14.663)
Rayong	-5.479* (-5.886, -5.073)	-0.576* (-0.992, -0.160)	9.878* (9.398, 10.359)	11.830* (11.323, 12.338)
Mae-Moh	1.338* (0.863, 1.812)	-1.438* (-1.917, -0.958)	45.442* (44.889, 45.996)	12.185* (11.633, 12.737)
Hat-Yai	1.996* (1.689, 2.304)	-0.089* (-0.396, 0.220)	-0.892* (-1.256, -0.523)	-3.991* (-4.349, -3.633)
Khon Kaen	0.646* (0.136, 1.155)	-1.391* (-1.909, -0.874)	35.842* (35.252, 36.432)	17.923* (17.313, 18.532)

\* significant value (P-value <0.05)

**Table 3: The hazard quotients values of different age groups**

Station	Hazard quotients (HQ (sd.))			
	Adult (≥20 years)	Children (1-5 years)	(6-11 years)	(12-19 years)
Saraburi	1.171(0.703)	19.010(11.407)	5.924(3.555)	1.840(1.104)
Rayong	0.654(0.577)	10.619(9.359)	3.309(2.915)	1,028(0.906)
Mae Moh	0.788(0.795)	12.784(12.900)	3.984(4.020)	1.237(1.248)
Hat Yai	0.505(0.313)	8.199(5.082)	2.555(1.584)	0.793(0.492)
Khon Kaen	0.947(0.716)	15.377(11.624)	4.792(3.622)	1.488(1.125)

**Health Risk Assessment:** Hazard quotients for the 5 cities in Thailand are show that the potential health risks of PM2.5 exposure for children age groups were highest in Saraburi, followed by Khon Kaen, Mae Moh, Rayong and Hat Yai, respectively. Comparing by age range, found that children 1-5 years are the

group that has the highest risk of exposure to PM2.5, at Saraburi Station, which has the highest PM2.5 concentration. Children aged 1-5 years have a higher Hazard quotient than adults and children 12-19 years to 19 times. The level of health risk of each age range in each station is shown in Table 3.

**Discussion**

The results show that PM2.5 is a significant environmental health problem in Thailand due to the concentration exceeding the WHO guideline (20 µg/m<sup>3</sup>) and exceeding the Thailand air quality standard (25 µg/m<sup>3</sup>), especially in cement industry area that must be given priority in finding the instrumentality of controlling, from the production process, transportation process that requires large numbers of trucks, must have standards to measure the pollution level emitted from the transportation process. The results show that the average daily concentration of PM2.5 is highest during rush hour, which is the period of heavy traffic, consistent with the study in 6 major cities in South East Asia. Including Bangkok, Beijing, Sennai, Bandung, Manila and Hanoi, where traffic is considered the main source of pollution in urban areas<sup>(13)</sup>. After that the concentration level is the lowest of the day in the afternoon. Because the sun causes the temperature to increase the low air pressure and the air rises, leading to the spread of PM2.5. This meteorological phenomenon is consistent with the studies of Barmpadimos et al., In 2012 and Vu et al., In 2015. The considering of PM2.5 level in each month of the year, it was found that the dry season month is more concentrated than the wet season due to the

relative humidity and rainwater, eliminating dust in the atmosphere<sup>(14)(15)</sup>.

Health risk assessments show that people are at risk of exposure to PM2.5 exposure, especially among children aged 1-5 years and children 6-11 years old, consistent with the study of de Oliveira et al. In 2012, it was found that children between the ages of 2 - 12 years had a higher risk than children older than 12 years and adults<sup>(12)</sup>. The child is more likely to be at a higher risk because the child has a respiratory rate to weight more than adults in the same amount of exposure to PM2.5, children have a higher risk. The risk level depends on the amount of exposure, causing the risk level to vary with the concentration of PM2.5 in the atmosphere. In this study, it is shown that the change in the level of PM2.5 in the air in diurnal circle and each season is different. Allowing people, especially children 1-11 years, to reduce or avoid exposure to pollutants during times of high risk, which can reduce the risk of public health.

**Conclusion**

This study provides the assessment of the ambient PM2.5 concentration and health risks in the 5 different background of Thailand. The daily average PM2.5 mass concentrations in the previous 4 years (2014 – 2017), all stations exceed WHO air quality guideline, especially Saraburi, mass concentrations exceed 9 times, which indicated an overall improvement of the air quality in Thailand. PM2.5 mass was decrease 2 periods around 8.00 – 9.00 and 19.00 – 21.00 and are likely rise in weekday. Due to annual cycle the concentration highest in winter and summer month, with lowest concentrations in rainy. The risk analysis shows that the potential health risks are highest in cement plant background, followed by urban and coal power plant. Winter and summer conditions are more serious for inhalable particles health risk. The hazard quotient shown the public health risk especially children.

The results of the present study can contribute to policy making by the set-up authorities to control or elimination of the pollutants and the risk to public health.

# Psychological Wellness of Early Childhood Educators Inventory: A Reliability Analysis Study

Samsiah Mohd Jais<sup>1</sup>, Mohammad Nasir Bistamam<sup>1</sup>, Mohammad Aziz Shah Mohammed Arip<sup>1</sup>,  
Pau Kee<sup>1</sup>, Amelia Mohd Noor<sup>1</sup>, Md Azman Shahadan<sup>1</sup>

<sup>1</sup>Lecturer in Department of Psychology & Counselling, Sultan Idris Education University

## Abstract

The aim of this paper is to determine the reliability index of Psychological Wellness of Early Childhood Educators Inventory (PWECEI) that was developed by Jais et al. (2019) that consists of 163 items in total. This inventory consists of five domain which are Career Interest, Personality, Psychological Well-Being, Basis Knowledge, and Ethics and Regulation. Total of 191 early childhood educators that participate in Nursing and Early Education Courses (male:11, female:180) were involved in pilot study. The internal consistency reliability analysis was conducted and results revealed that overall the Cronbach Alpha value for this inventory was .86 which shows that PWECEI has acceptable reliability value to measure early childhood educators' wellness in Malaysia. Further studies are needed to validate this variable across different population, culture, and with higher number of samples by using confirmatory factor analysis (CFA).

**Keywords:** Caregivers; Psychological Wellness; Career Interest; Personality; Psychological Well-Being; Basis Knowledge; Ethics and Regulation.

## Introduction

**Problem Statement:** Education in Malaysia is an on-going effort towards further developing the potential of individuals in a holistic and integrated manner, so as to produce individuals who are intellectually, spiritually, emotionally and physically balanced and harmonious, based on a firm belief in and devotion to God. Such an effort is designed to produce Malaysian citizens who are knowledgeable and competent, who possess high moral standards, and who are responsible and capable of achieving high level of personal well-being as well as being able to contribute to the harmony and betterment of the family the society and the nation at large <sup>[1]</sup>.

In the pursuit of achieving this, early childhood educators have been proven to be one of the most

important factors responsible to the success of the initial education program aimed at building the basis of stable children's emotional and mental development. However the country is often shocked by the news of abusive and abusive baby sitting. The issue of baby and toddler abuse by baby sitters and children either in the registered care centre or in the home is endless as it appears on a daily basis in local newspapers.

Usually parents who send their children to a day care center expressed concern and encourage every teacher and caregiver to undergo a mental health screening to avoid cases of repeated abuse<sup>[2]</sup>. Although they find it difficult to do so they feel it is one of the ways to reduce child abuse cases in nursery or kindergarten. Some of the nursery owner also agree that every employer needs to screen caregivers who want to be taken seriously.

In addition to aspects of psychological well-being, criminogenic elements also need to be filtered to identify pro-violence or pro-crime background and stance. This is emphasized by Dr Geshina Ayu Mat Saat from the University of Science Malaysia who is also a psychologist. She proposed that the government

enforced individuals who involved in childcare services to undergo periodic psychokinetic profiling to prevent repeated child abuse cases<sup>[3]</sup>.

In addition, a press release reports that the tragedy of a five-month-old baby boy was found in a fridge caused many people to express dissatisfaction and even dared to criticize the care of the victim who was also the accused in the case<sup>[4]</sup>. They also question the credibility of the babysitter and the appropriate actions that need to be taken to prevent such cases from happening again. Undoubtedly the incident involving Adam certainly caused trauma to the community, especially to parents who sent their children to a daycare center.

Associate Prof Dr Balan Rathakrishnan emphasized that parents should take into account the mental health aspects of caregivers before deciding to send children to caregivers. In his opinion, in the case of Adam the accused may have suffered from a mental health condition that prompted him to commit such cruel acts. According to him, a caregiver may be subjected to excessive pressure and may cause them to sometimes act outside their sanity. This is because they may look normal, but if there is a trigger their actions can reach an unexpected level. In addition, past history can also encourage the accused to look for something weak to release anger and self-gratification<sup>[4]</sup>.

In addition, Metro Daily reported on average cases of negligent caregivers are over unregistered and caregivers with no training and accreditation from the Social Welfare Department (JKM)<sup>[5]</sup>. The main quality to look for in caregivers is patience and they have undergone stress-free courses. In KAP there is a unit for the ethics and professionalism of caregivers, but the authorities want caregivers out there to uphold this profession as a professional. This is because caregivers sometimes need to be nurses, doctors, cooks and many more.

They also recommend that the JKM refer to and apply Rule 3 (2) of the TPA Act as it is provided that any person passing the KAP must register as a registered nurse with the JKM with the doctor's report previously required. They also requested that Ministry of Health be able to continue this provision to ensure registered nurse record statistics. Many do not do this. There are still many caregivers refuse to register. One recommendation they have made to the ministry in the past is for caregivers to have a board of trustees release an identity or list of caregivers' names in the portal

for easy review using their identity card numbers so that they can review background, work ethic, criminal record, abuse and more<sup>[5]</sup>.

**Literature Review:** Emotional well-being includes the ability to cope with stress such as being flexible and compromising to solve problems in which it involves building awareness and accepting others' feelings<sup>[6]</sup>. According to Goleman<sup>[7]</sup>, emotional well-being is the ability of a person to manage his emotional well-being, maintain harmony and express emotions through skills of self-awareness, self-control, self-motivation, empathy and social skills.

Spiritual well-being involves the exploration of meaning and purpose in human life and individuals with spiritual well-being can be identified through basic characteristics such as feelings of meaningful life and direction and relationship with their Creator<sup>[6]</sup>. Spiritual well-being has a significant relationship with an individual's mental health. This finding is supported by the findings of Shima<sup>[8]</sup> in which she found that individuals with spiritual well-being are at lower risk for mental health problems such as anxiety, and depression.

Physical well-being is the ability of the body to perform activities as well as refrain from substance abuse activities and individuals who achieve good physical health have resistance to any diseases that may affect their functioning<sup>[9]</sup>. Well-being enables the development of one's potential to live and work effectively and to make significant contributions to society. Therefore, physical well-being is very important to ensure that you work well and optimally.

The well-being of the environment is described in a manner that respects mutual respect and in harmony with the environment in which individuals who have a good environmental well-being choose to live by protecting the environment around them<sup>[6]</sup>. Financial well-being is a relatively new dimension and is generally adopted as the eighth welfare dimension after the effects of the Depression that lasted from December 2007 to June 2008<sup>[6]</sup>. Joo<sup>[10]</sup> states that financial well-being is a healthy, happy and free financial condition based on subjective assessment of financial condition. The lack of finances can lead to conflicts with family members and can also lead to social problems as a result of having to find resources to meet family needs.

Job well-being is described by Sha'ari, Rajjah, Rames and Rosnida<sup>[6]</sup> as routine demands combined

with new and uncertain challenges that make a job enjoyable, meaningful and rewarding. There have been studies that found that a poor work environment can affect caregiver satisfaction and commitment. For example, limited promotion opportunities [11], low salaries [12], high childcare ratio [13-15] and long working days (typically between 6.30am and 6.30pm) were the main reasons for their departure.

Sha'ari, Raijah, Rames and Rosnida [6] state that social well-being refers to the ability to communicate and connect with others with positive self-image (confident, friendly, and caring towards others). According to Deming and Kahn [16], among the criteria that factor into a high wage earner and good job performance are the social and cognitive well-being of individuals involved in relation to experience, education and writing levels.

**Methodology**

**Sample:** This current study uses a quantitative method to find the reliability of the Psychological Wellness of Early Childhood Educators Inventory

(PWECEI). To measure the reliability of this inventory, this pilot study recruited 191 early childhood caregivers from eight areas in Malaysia that participated in Nursing and Early Education Courses.

**Procedure:** Researcher explained about any benefits or harm that participants will get from this study before the data collection process conducted. After that, if they agree to participated in this study they were asked to fill up the consent form first before proceed to the inventory part. This inventory took up around 20 minutes to be completed by the participants.

**Measure:** Table 1 shows that this inventory consists of five domain that represented by 16 different sub-domain. PWECEI was developed by Jaiset al. [17] to measure the psychological wellness among caregivers of early childhood in Malaysia. This self-reported inventory was developed in Malay language and consists of five point Likert scale comprise of positive and negative items. The positive, negative and total number of items in each constructs before and after the reliability analysis has been conducted can be seen in Table 1.

**Table 1: Domain and Construct in PWECEI**

Domain/Construct		Item		
		Positive	Negative	Total
<b>Career Interest</b>				
1.	a. Social	All positive item	-	16
	b. Artistic	All positive item	-	17
2.	Personality	All positive item	-	10
<b>Psychological Well-Being</b>				
3.	a. Emotional	All positive item	-	10
	b. Spiritual	1,2,3,4,6,7,8	5	8
	c. Physical	All positive item	-	3
	d. Environment	1,2,3,5	4,6	6

<b>Ethics and Regulation</b>				
5.	a. Ethics	2,3,4,6,7,10,11	1,5,8,9,12	12
	b. Regulation	All positive item	-	8
<b>Total</b>		<b>152</b>	<b>11</b>	<b>163</b>

### Result

Overall the internal consistency of this inventory after internal consistency reliability analysis had been conducted is .86 range from .58 to .96 and the mean of inter-item correlation is .45. According to Table 2 the total number of items in this inventory was 204, but after conducted reliability analysis (internal consistency) the total number of items become 163 with total number of items been removed was 53. The Cronbach alpha value before removing the item was .82, but after some of the items have been removed the Cronbach alpha value increase to .86 which shows a good reliability value according to DeVellis<sup>[18]</sup>. The general rule of thumb suggested ideal Cronbach alpha value is above .70 (good), .80 (better) and .90 (best) <sup>[18]</sup>.

Some of the construct and sub-construct have fewer items that is below than 10 items have a quite low Cronbach alpha value as it is quite sensitive to the number of items in the scale<sup>[19]</sup>. So, Pallant <sup>[19]</sup> suggest that it would be more appropriate to report the mean inter-item correlation value for the items. BrckaLorenz, Chiang, and Nelson <sup>[20]</sup> recommend optimal range for inter-item correlation is between .15 to .85 while optimal mean inter-item correlation is between .15 to .50. In this study the inter-item correlation varies between .23 to .64 with total average inter-item correlation value is .45 that shows an acceptable value.

**Table 2: Outcome from Reliability Analysis of PWECEI**

Domain/Construct		Number of Item		Reliability Value (α)		Mean Inter-Item Correlation	
		Before	After	Before	After	Before	After
1.	<b>Career Interest</b>						
	a. Social	20	16	.91	.92	.36	.41
	b. Artistic	20	17	.91	.92	.36	.40
2.	Personality	24	10	.73	.87	.12	.39
3.	<b>Psychological Well-Being</b>

### Discussion

The aim of this paper is to determine the reliability of Psychological Wellness of Early Childhood Educators Inventory (PWECEI) that was developed by

Jais et al.<sup>[17]</sup>. Reliability define as the extent to which a research instrument consistently has the same results if it is used in the same situation on repeated occasions<sup>[21]</sup>. In this study the type of reliability that being used in this

study is internal consistency by using Cronbach' Alpha test which in this test the average of all correlations in every combination of split-halves is determined. The Cronbach's  $\alpha$  result is a number between 0 and 1. An acceptable reliability score is one that is 0.7 and higher<sup>[22]</sup>.

Finding from this study shows that this PWECEI has an acceptable and good reliability value ( $\alpha = .86$ ). As finding shows that this inventory has an acceptable reliability value, this inventory can be used as an early step to measure psychological wellness of early childhood educators before they been hired by the related party. This can help government, especially the Ministry of Women, Family and Community Development to plan appropriate action plans. Further studies are necessary to revalidate PWECEI across different population, culture, and with higher number of samples by using confirmatory factor analysis (CFA).

**Ethical Clearance:** The inform consent was acquired from the participant who agreed to participate in this study.

**Conflict of Interest:** There is no conflict of interest in this research.

**Source of Funding:** This study was funded by the Psycotest Consultance Service through External Research Grant 2019(2019-0041-106-29) in collaboration with lecturers from Psychology and Counselling Department of Sultan Idris Education University.

# The Correlation Factors on Epilepsy Stigma amongst People in Indonesia

Saniya Ashilah Rabbani<sup>1</sup>, Joseph Ekowahono R<sup>2</sup>, Viskasari P. Kalanjati<sup>3</sup>

<sup>1</sup>Clinical Students at Faculty of Medicine, <sup>2</sup>Lecturer at Department of Neurology, <sup>3</sup>Lecturer at Department of Anatomy and Histology, General Hospital of dr. Soetomo, Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia

## Abstract

**Background:** Epilepsy is a recurrent attack or seizure disorder more than twice for no reason derived from cerebral cortical cerebral neurons, and sometimes accompanied by a decrease in consciousness, both motor and sensory and behavioral or emotional intermittent and stereotyped behavioral or emotional. Until now the etiology of epilepsy is still not known with certainty and multifactorial nature of this matter that raises many wrong assumptions and views of some Indonesian people about epilepsy disease. The study was conducted to find out the correlation between social factors background (domicile, age and occupation as well as education) and stigma towards people with epilepsy in the community.

**Method:** This study was an observational analytic study by observing domicile, age, occupation, last education, and knowledge of epilepsy in society and analyzing the relationship between age, domicile, occupation and education of respondents with stigma against epilepsy patients. The method used is cross sectional data collection through a modified questionnaire from Knowledge, Attitudes, and Practice towards Epilepsy Survey (KAPE) which has passed the validation stage of previous research. The data taken were analyzed descriptively and tested by *chi-square* test using SPSS.

**Result:** With a total of 127 respondents based on domicile got significant correlation, based on last education level also got significant relation with p value is  $0,028 < 0,05$  whereas no correlation on age variable with stigma where p value is  $0.834 > 0.05$  and there is no significant correlation between occupation with stigma where p value is  $0.730 > 0.05$ .

**Conclusion:** There is correlation between domicile and education level with stigma to epilepsy patient.

**Keywords:** Epilepsy; Stigma; Knowledge, Attitudes, and Practice.

## Introduction

Epilepsy is a brain disease that define by conditions occurring at least two attacks without symptom (or

reflex) by a distance of more than 24 hours. Epilepsy consider treatable for individuals having epilepsy, but they are having no seizures for the past 10 years, and without seizure drugs for the past 5 years<sup>1</sup>. Epilepsy is the second chronic neurological disease which is often faced by neurologists and affects nearly fifty million people worldwide<sup>2</sup> while the patient's seizure-free condition were taken from medical records. Then quality of life of seizure-free temporal lobe epilepsy patients were compared with not seizure-free patients after amygdalohippocampectomy. The statistical tests used were unpaired t-test if the data was distributed normally, and Mann-Whitney test if the data was not distributed

---

normally. Results: 31 patients, 21 were seizure free (Engel 1. In developed countries, it is estimated that every year 30 to 50 new cases occur from 1,000 people in the general population, whereas in developing countries it can reach double<sup>3</sup> hypopharynx cancers account for a small proportion of the head and neck cancer workload in the UK, and thus suffer from the lack of high level evidence. This paper discusses the evidence base pertaining to the management of hypopharyngeal cancer and provides recommendations on management for this group of patients receiving cancer care. Recommendations \* Cross-sectional imaging with computed tomography of the head, neck and chest is necessary for all patients; magnetic resonance imaging of the primary site is useful particularly in advanced disease; and computed tomography and positron emission tomography to look for distant disease. (R. There are around 1.5 million sufferers of epilepsy in Indonesia the prevalence of 0.5-0.6%<sup>4</sup>.

Stigma is all forms of physical and social attributes that reduce a person's identity<sup>5</sup>. Stigma is usually associated with health problems or illness as a social process characterized by rejection, reproach, or exclusion of certain individuals or groups<sup>6</sup>. In Indonesia the stigma about epilepsy is rather high, many assumptions and wrong point of views to Indonesian regarding epilepsy. Most Indonesian consider that epilepsy is a contagious hereditary disease and curse. This assumption causes suffering to sufferers because in addition to having to bear the weight of suffering at the time of the coming attack the sufferer is sometimes cleansed by the community. This can affect the quality of life of epilepsy patients<sup>7</sup>.

Many factors influence the emergence of wrong views about the disease epilepsy, namely knowledge of health, education level, and culture. Many inconsistencies in the results of a treatment due to the influence of ethnic and socio-economic cultural factors. This is also due to differences in understanding and perception at the time of receiving information, daily lifestyle and adherence to treatment<sup>8</sup>. Data on public perceptions about epilepsy sufferers in Indonesia has not been widely reported.

This study aimed to determine the correlation between social factors background (domicile, age and occupation as well as education) and stigma towards people with epilepsy in the community.

## Method

This study is an observational analysis of data

from a questionnaire sheet modified from Knowledge, Attitudes, and Practice towards epilepsy survey (KAPE) 9 with a cross sectional case study.

**Sample:** The research sample was taken using the simple random sampling method where a minimum quota was determined in each sampling area consisting of, 50 people from Surabaya and 50 people from Mataram and the surrounding area. With the following details, 25 who live in urban areas of Surabaya, 25 people who live in rural areas of Surabaya, 25 people who live in urban areas of Mataram and surrounding areas and 25 people who live in rural areas of Mataram and surrounding areas. With a minimum total of 100 samples.

**Time and Place:** This research was conducted in 2 cities, Surabaya City (the working area of Pacar Keling Health Center and East Silver Health Center) and Mataram City (working area of Pagesangan Health Center and Tanjungkarang Health Center). The period was conducted on 1 September 2016 - 1 October 2017 based on questionnaire sheet data.

**Data Analysis:** Data from the questionnaire sheets analyzed with frequency and chi-square with SPSS 19.0 (SPSS.Inc., Chicago, IL). Significant level was reached when  $p < 0.05$ . Odd ratio calculation was used to calculate the ratio of differences between groups of stigma against patients with epilepsy.

## Result

**Behaviors and Actions (Stigma) of Respondents Against Patients with Epilepsy:** Based on stigma of respondents towards people with epilepsy, it said that stigma are severe when answering  $> 75\%$  ( $> 2$  of the stigma questions, Score = 0-6) and to be mild stigma if answering  $\leq 25\%$  ( $\leq 2$  of the questions) stigma, Score = 7-9). (Table 1)

**Analysis of Factors of Domicile, Age, Occupation, Education with Stigma Against People with Epilepsy:** There was a difference shown by the statistics of the domicile of respondents in the city and in the village. The value of  $p = 0.001$  with an odd ratio of 6,300 (95% CI 2,100 - 18,903) which shows that respondents who live in Surabaya City or in the City Matrix have severe stigma against those who live in Surabaya Desa or Mataram Desa. (Table 2)

While for the age factor, it can be seen that from 127 respondents found stigma against patients with epilepsy, were at least in the age group 65-74 years

with a total of 2 respondents (50%). Likewise, stigma to the most severe patients with epilepsy were found in the 18-24 age group with 22 respondents (44.9%). Mild and severe stigma towards patients with epilepsy are dominated by the 18-24 age group because the most respondents obtained from the 18-24 age group with a total of 49 respondents. This difference was not statistically significant with a value of  $p = 0.834$ . (Table 2).

The type of respondent's occupation with severe stigma towards epilepsy sufferers was at least in the type of occupation as a farmer with 2 respondents (33.3%), besides the most severe stigma towards epilepsy sufferers were found in the type of occupation as a housewife with 20 respondents (37%). Each of the severe and mild stigma was dominated by the type of housewife's work because the largest number of respondents comes from the type of work as a housewife. P Chi-square value of  $p = 0.730$  obtained where the value was not statistically significant. (Table 2).

The results showed that there were more people who had behaviors and actions towards patients with mild epilepsy (stigma) against sufferers of epilepsy in the amount of 58.3%. While people who have behaviors and actions towards patients with severe epilepsy (stigma) against epilepsy in the community category based on recent education were only 41.7%, and the difference was statistically significant with a  $p$  value = 0.028. (Table 2).

Respondents who have good knowledge about epilepsy with severe stigma categories were 13 people (32.5%) and the difference was not statistically significant with  $p = 0.153$ . an odd ratio value of 1.768 (CI 95% 0.807 -3,874) shown that respondents with less knowledge have a tendency to be 1,768 times more likely to have severe stigma towards sufferers of epilepsy compared to respondents who have good knowledge. (Table 2).

**The correlation between the respondent's education level category and stigma of epilepsy sufferers:** Out of the 127 respondents obtained stigma

towards patients with severe epilepsy in the last education under primary school as many as 9 respondents (29%), while the stigma in the last education higher than elementary school were 44 respondents (45.8 %) and the difference was not statistically significant with  $p = 0.099$  and an odd ratio of 2.068 (95% CI 0.864-4953). Respondents with more than elementary school education have a tendency to have 2 times more severe behavior and actions (stigma) compared to respondents with education below elementary school.

Comparison of the latest education under junior high school and more than junior high school shown that from 127 respondents found the stigma in the last education less than junior high school were 12 respondents (26.1%), while the behavior and stigma in the last education higher than junior high school as many as 41 respondents (50.6%). The difference was statistically significant with  $p = 0.007$  and an odd ratio of 2.904 (95% CI 2.904-6.394). It is obtained where respondents with education more than junior high has a tendency to have stigmatized compared to respondents with education below junior high. (Table 3).

**Table 1: Distribution of respondents based on domicile and stigma level**

Stigma		Respondents (n)	Total
Mild	Surabaya City	10	74(58.3%)
	Surabaya Village	24	
	Mataram City	17	
	Mataram Village	23	
Severe	Surabaya City	21	53(41.7%)
	Surabaya Village	8	
	Mataram City	13	
	Mataram Village	11	
Total	Surabaya City	31	127(100%)
	Surabaya Village	32	
	Mataram City	30	
	Mataram Village	34

## Discussion

Compared to respondents who live in rural areas, Respondents who live in urban areas experience stigma and get a p value smaller. As a result, it can be concluded that there is a significant correlation between domicile and stigma against patients with epilepsy. This trend is caused by people from rural areas tend to live in village-type communities and were closer to the tendency to offer support to one another. People in rural areas were more receptive to disease.<sup>10</sup> Geographical regions with strong cultural perceptions of diseases that rely on non-scientific explanations, such as Asia and Africa have a worse attitude towards epilepsy as evidenced by the misunderstanding of epilepsy as an infectious disease caused by spiritual science<sup>11</sup>

For the results of processing the correlation between age and stigma there is no significant correlation between it. Increased levels of stigma in the elderly age group shown differences in choosing social networks based on increasing age. With increasing age the perception of time constraints leads to psychological needs so as to produce smaller social networks with increased emotional ties. In general there is no correlation between age and community stigma against people with epilepsy.<sup>12</sup>

From the chi square results, it can be concluded that there is no significant correlation between work and stigma for patients with epilepsy. Based on previous research there was also no significant correlation between work status and the stigma, such as people who do not work, work part-time or work full day. Those all do not have a correlation with negative behavior or discrimination against epilepsy<sup>12</sup>. Similarly, research conducted in the western world many people with epilepsy found working as employees and found no discrimination against epilepsy sufferers who work<sup>13</sup>cross-sectional epidemiologic study of 241 persons with epilepsy identified from an at-risk population of 24,130 individuals (64.7% from urban and 35.3% from rural areas.

The wrong view of epilepsy was also influenced by the level of education. Several studies have shown that a better level of education will provide an attitude towards epilepsy<sup>14</sup>. However, this opinion has not in line with the results of research conducted. Mild stigma was found at all levels of education except in the bachelor. There were more respondents who have severe stigma than mild stigma. The results of the chi square value indicated a

significant correlation. The level of education did not guarantee that a person does not have discrimination against sufferers with epilepsy. In a study from Thailand, 38% of elementary school teachers never heard or read about epilepsy and 15% preferred to find all children with epilepsy in a special class.<sup>15</sup> Saudi Arabia included private/public schools designated for male and female students. A structured 37-item questionnaire was used to examine their demographics, knowledge, attitudes, and experience with epilepsy. Results Six hundred and twenty primary school teachers working in public (58%.

From the research conducted there were no significant correlation between the knowledge variables with stigma against patients with epilepsy. The data obtained respondents who have both of less knowledge and good knowledge have the amount of mild stigma more than severe stigma. Someone who has heard, obtained information and known about epilepsy tends to behave positively and does not discriminate against someone with epilepsy<sup>14</sup>.

**Limitation:** This research does not explain the factors that influence the presence of severe stigma in urban areas.

## Conclusion

There is a significant correlation between the domicile (city or village) and the last education of the respondent and stigma towards sufferers of epilepsy.

**Conflic of Interest:** The authors declare that they have no competing interests.

**Source of Funding:** The authors declare that this study have self-funding

**Ethical Clearance:** This study received a certificate of ethical clearance no. 015/EC/KEPK/FKUA/2017 from ethical commission of Faculty of Medicine, Universitas Airlangga Indonesia.

# Effect of a Learning Activity Package on Improving Awareness about Liver Fluke Prevention and Control for Secondary School Students in Northeastern Thailand

Saowalux Khatchamart<sup>1</sup>, Suchada Paileeklee<sup>2</sup>, Ariyaporn Kuroda<sup>3</sup>,  
Teerachai Nethanomsak<sup>4</sup>, Narong Khuntikeo<sup>5</sup>

<sup>1</sup>Doctoral Student of Community Health Development Program, Faculty of Medicine, <sup>2</sup>Assistant Prof., Department of Community Medicine, <sup>3</sup>Lecturer, Faculty of Education, <sup>4</sup>Assistant Prof., Faculty of Education, <sup>5</sup>Associate Prof., Department of Surgery, Khon Kaen University, Thailand

## Abstract

**Background:** Liver fluke has long affected the health of Thai people, particularly those who live in the Northeast Region. It is a major cause of Cholangiocarcinoma (CCA), which is one of the important causes of mortality affecting people in this region. The national helminth prevalence survey also reported that children were infected by *Opisthorchis viverrini* (OV).

**Objectives:** To evaluate the effects of “The Learning Activity Package (LAP) on Improving Awareness of Liver Fluke Prevention and Control” for secondary school students.

**Methodology:** This quasi-experimental study primarily focused on improving awareness of liver fluke prevention and control among secondary school students in Grade 7, with three components, attitude, acceptance and giving value, as well as consciousness of responsibility at individual, family and community level. The LAP was implemented for 8 weeks in 6 schools at Don-Chan District, Kalasin Province, Thailand. Data collection used a questionnaire and data analysis used descriptive statistics, paired t-test, and Wilcoxon signed-rank test.

**Results:** After the LAP intervention implementation among 121 students, this study showed a significant increase in all awareness components. The mean of the post-test awareness scores increased from baseline to 45.01 points (95 % CI =42.66 - 47.35 points,  $p < 0.001$ ), reflecting a large effect. (Cohen’s  $d=3.45$ )

**Conclusion:** This LAP intervention is an effective and beneficial school-based program to impact liver fluke infection prevention and control behavior among secondary school students at individual, family and community level.

**Keywords:** Awareness, Liver Fluke, Secondary School Student.

## Introduction

Liver cancer is one of the leading causes of health

problems worldwide. Reports on liver cancer mostly indicate it to result from hepatocellular carcinoma and CCA.<sup>1</sup> CCA is the most reported liver cancer (82.0-89.0%) in Thailand.<sup>2-4</sup> Particularly in the Northeast Region, it is mostly found to be caused by OV. In the past decade, OV infection was estimated to affect population 10 million worldwide, with 80 % in Thailand.<sup>5</sup> Results from the 2009 Helminths and Protozoa Infections National Survey (HPINS) by the Department of Disease Control indicated that the overall OV infection rate

---

Tel: 66 (0) 43 363588; Fax: 66 (0) 43 202488

among the Thai population was 8.7%, with the highest rate of 18.6% found in the Northeast Region.<sup>6</sup>

In the past the Ministry of Public Health of Thailand has implemented a national control strategy to alleviate OV infection using three main approaches: 1) stool examination and treatment; 2) health education and campaigning about OV infection preventive strategies and 3) promoting community participation.<sup>7</sup> Even though the strategies have been implemented the OV infection prevalence among adults remains. In addition, results from the 2009 HPINS reported that OV infection also affects children. The same survey noted that for children infected with OV in the Northeast Region the youngest was 7 years. Such a pattern suggests that OV infection increases among children as they grow up.<sup>6</sup> This agrees with the study in 1983-1994, in which a prevalence of liver fluke caused by OV was also reported among school children thereby increasing the need to provide health education among this population group in a school setting.<sup>8</sup> Consequently, this current study put more emphasis on young adolescents aged 12-14 years for their energetic and readily exploring nature, and keenness to learn new information. It is expected that they could benefit highly from the OV preventive strategies and intervention that is directly provided to them. It is notable that the intervention under focus in this study could serve as a new group approach. The focus has long been on the traditional target group of adults whose behaviors are ingrained, since they have long been grounded in their sociocultural and environmental context, so that it is hard to change.

Don-Chan District, Kalasin Province has the highest liver fluke prevalence rate.<sup>9</sup> In addition, Don-Chan has many such as 23 natural water reservoirs, which serve widely for sources of fresh water fishes, including cyprinid fishes, known as the intermediate host of the OV infective stage in humans.

LAP was developed from Contemplative Practices Theory<sup>10</sup>, because this theory suggests that transformative learning can create a change from the inside, creating a new paradigm, changing mind sets and bringing about change in cognitive, affective and psychomotor domains, in line with this study intent to improve awareness at individual, family and community level. It is expected that it could be highly beneficial for OV preventive strategies and interventions that directly related to them. It is notable that the intervention under focus on this study could serve as a new group approach.

It has shifted the focus to the younger group from the traditional target group of adults, whose behaviors are ingrained from their sociocultural and environmental context making it hard to change.

This study aims to evaluate the effects of the "Learning Activities Package (LAP)" on improving awareness of liver fluke prevention and control among grade 7 of secondary school students.

## Materials and Method

A quasi-experimental study with pre/post-test design was conducted in Don-Chan District, Kalasin Province, Thailand. This study purposively selected 6 secondary schools. The target population was 158 grade 7 studying students. The exclusion criteria were students who had (a) a long sickness or (b) a learning disorder. The students were recruited voluntarily from each school.

**Sample Size:** Since this study aimed to evaluate the effect of the LAP, it was decided to include all 158 of the voluntary students in 6 secondary schools.

**Intervention:** The 8-week intervention called the LAP was designed to improve the awareness about liver fluke prevention and control among secondary school students. The awareness comprised of three components, including attitude, acceptance and giving value, as well as consciousness of responsibility at individual, family and community levels. Before proceeding with the intervention the standardized teachers in each target school were improved their knowledge and contemplative teaching for the target students<sup>[11]</sup>. The training program for the teachers included knowledge of liver fluke infection, contemplative practices and teaching skills. In addition, lesson plans and the objectives of LAP was created by experts and stakeholders, which given to trained teachers for standardization for teaching and teaching planed.

**Measurement:** The measurement tool was a self-administrated questionnaire which comprises 2 parts: (1) general information and (2) awareness that has three components. First, attitude towards prevention and control of liver fluke infection (items 1-15) with a rating score of 1-4 points (Strongly Disagree =1, Disagree =2, Agree=3, Strongly Agree =4 points). Second, acceptance and giving value to problems of liver fluke infection (items 16-21), with a rating score of 1-5 points, (Very Little=1, Little=2, Moderate=3, Much=4, Very Much=5). Third, consciousness of responsibility at the

individual level (items 22-28), family level (items 29-35) and community level (items 36-42) of prevention and control of liver fluke infection, with a rating score of 1-4 points (Never=1, Rarely=2, Sometimes=3, Often=4).

For the part of awareness towards prevention and control of liver fluke infection developed by the researchers the validity was confirmed by three specialists (education, helminths and methodology) and a Cronbach’s alpha coefficient for the present sample of 0.86 was found.

Measurements were taken at baseline among 158 students at 6 schools before the LAP intervention, and again after these groups had completed the intervention at the eighth week.

**Data Collection:** The questionnaires were given to the students in their classrooms. The data abstraction was checked for completeness, and the data double entry technique was used to ensure the accuracy of the data entry process and transferal of data for analysis in the SPSS program with Khon Kaen University license. The statistics used were frequency, percentage, percentile, median, mean and standard deviation, paired t-test and Wilcoxon Signed-Rank test. Additionally, Cohen’s d was used to indicate the effect size of the LAP intervention<sup>[12]</sup>.

This study was reviewed and approved by the Ethics Committee for Research on Human Subjects, Khon Kaen University, Thailand. (HE601240).

**Results**

The number of students at the beginning of the study was 158 students, but only 121 participated for the full period of program. Their average age+SD was 12.72+0.5 years and 56.20 % were girls.

**Effects of the LAP:** After completing the LAP implementation the mean score of all components significantly increased and the highest mean score difference was the component of the acceptance and giving value, while the second highest mean score was the component of being conscious of taking responsibility at the community level. The total mean score of awareness difference within the group was statistically significant at 45.01 points (95 % CI, 42.66-47.35). The Cohen’s d found a large effect for the intervention(Table).

**Comparisons of median and percentile score by awareness items:** This part aims to check the score difference of the students before and after the intervention. This study found the median scores changed for 37 items (20 items changed a lot) from 42 items. There were 5 items (items of 1. Liver fluke infection is an important problem. 3. Liver fluke infection is not a severe health problem. 5. Consumption of raw fish makes strong health (Negative statement).14. Food vendors selling raw fish dishes in the community cause more LFI affected community members. 15. Traditional ceremonies which serve raw fish dishes cause more LFI affected persons.) that did not change but items 3, 5 and 14 moved to better quartiles. Items 1 and 15 didnot change both the median scores and quartiles, because they had a high score.

**Table : Mean scores of awareness of liver fluke infection prevention and control by components**

Awareness components	Baseline		Post-test		Mean Difference	SD	p-value
	Mean	SD	Mean	SD			
Awareness (174 points)	97.95	10.97	142.96	10.28	45.01	13.03	<0.001*
(1) Attitude (60 points)	45.11	4.12	51.84	4.39	6.74	5.48	<0.001**
(2) Acceptance and giving value (30 points)	11.27	3.12	24.74	2.78	13.47	3.67	<0.001**
(3) Consciousness of responsibility							
- Individual level (28 points)	17.68	4.09	24.38	2.91	6.70	4.34	<0.001**
- Family level (28 points)	13.94	4.23	22.22	3.24	8.29	4.79	<0.001**
- Community level (28 points)	9.97	2.96	19.78	3.01	9.81	3.76	<0.001**
Cohen’sd = 3.45							

P-value test by \*Paired t-test/\*\*Wilcoxon signed rank test

## Discussions

This research study examined the effects of the “LAP” on improving awareness of liver fluke infection prevention and control with the application of contemplative practices, based on the situation context and health behavior especially for the study area. This study found the mean score of awareness was different among the students before and after the intervention. From the contemplative theory<sup>13</sup> the LAP transferred knowledge and awareness using the students self-regulation, understanding themselves better and increasing the capacity of their minds<sup>14-16</sup>. In addition the contemplative teaching by the teacher can improve the classroom climate to support the development of inside attention, emotion, self-regulation, empathy, compassion for self and others, and action in order to encourage and transform self-learning among the students<sup>11</sup>.

To evaluate the effect of LAP, this study used a Quasi Experimental design with the appropriate intervention evaluation in students by purposive school. However the limitation was not randomly allocated therefore, this study results may be used only for schools with similar context. In addition the target students dropped out at 23.0%, and most students come from one school, because of a no fixed classroom for learning, and some students had gone to participate often in social activities outside the school. In addition, some students were still regularly absent in other subjects too. As a result the students who completed period participating in this full were 121 students.

## Conclusions

This LAP intervention is an effective and beneficial school-based program to impact a liver fluke infection prevention and control behavior among secondary school students at individual, family and community levels.

# Protective Effect of Ethanolic Extract of *Zingiber Officinale* Against Mercuric Chloride Induced Renal Toxicity In Rats

Sawsan A. Ali<sup>1</sup>, Mariam A. Kadhem<sup>2</sup>, Hameed A. Ali<sup>3</sup>

<sup>1</sup>Lecturer in Histology, Department of Anatomy and Histology, College of Veterinary Medicine, University of Basra, Basra, Iraq, <sup>2</sup>Assistant professor of Pharmacology and Toxicology, Department of Physiology and Pharmacology, College of Veterinary Medicine, University of Basra, Basra, Iraq, <sup>3</sup>Assistant Professor of Medical Microbiology Department of Microbiology, Alzahra College of Medicine, University of Basra, Iraq

## Abstract

The current study was designed to investigate the possible protective effects of ethanolic extract of *Zingiber officinale* on renal damage induced by mercuric chloride intoxication in rats. Forty albino adult rats (180±10g, n=10 per group) were administered HgCl<sub>2</sub> (3mg/kg, Ip, 3 times weekly). The treatment of *Z. officinale* extract (200 mg orally for 8 weeks. HgCl<sub>2</sub> administration altered the body weight, kidney weight, chemical parameters of creatinine, urea, and MDA. Body, kidney weight the biochemical and histopathological findings of this study significantly (P≤0.05) showed a protective effect of a *Z. officinale* extract against HgCl<sub>2</sub> intoxication. In conclusion, *Z. officinale* extracts may be an ideal choice against kidney damage induced by HgCl<sub>2</sub>.

**Keywords:** mercuric chloride, *Zingiber* extract, histopathology, kidney.

## Introduction

Mercuric chloride accumulates mostly in rat liver and kidney as these organs involved in the detoxification and excretion of foreign materials<sup>1</sup>. Mercury contamination of the environment continues to be a concern and a major source of this contamination is from human activities by industrial waste which releases mercury into the environment<sup>2</sup>. The renal cortex and liver are considered to be the most susceptible organs affected which leads to functional impairment (3). Several studies were focused on the role of free radicals and oxidants due to mercuric toxicity affect the proximal convoluted tubules injury, which suggests that the nephron plays an important role in the active transport of this heavy metal<sup>3,4,5,6,7,8,9</sup>

Natural herbaceous plant *Zingiber officinale* Roscoe is one of the most common food-flavoring spices used worldwide<sup>7</sup>. For many years, several pharmacological properties of ginger, such as anti-inflammatory, analgesic, gastrointestinal regulating agent, antioxidant and antimicrobial properties have been identified<sup>8,9,10</sup>. Efforts are now being directed in obtaining drugs with different chemical features since many modern drugs originated from plants the investigation of the chemical composition of traditional medicinal plants could lead to the development of new drugs. The study therefore, investigated the possibility of utilizing the ethanolic extract of *Z. officinale* in the treatment of HgCl<sub>2</sub> induced nephrotoxicity.

## Method

**Experimental Design:** Forty healthy adult albino rats 180±19g, were separated into four groups of ten rats for each group. eight weeks the animals kept in suitable cages and was feeder standard diet and water ad libitum. The control group received distilled water (10ml/kg/ intraperitoneal (Ip) the second group-administered three times per week (ip) injection of HgCl<sub>2</sub> at a dose of 3mg/

kg. Third group, treated with [HgCl<sub>2</sub>(3mg/kg) plus (200mg/daily orally)] of *Z officinale* extract, and the fourth group treated with *Z officinale* extract (200mg/daily orally).

**Sample Preparation:** At the end of 8 weeks, all animals were scarified the body and kidney weight is measured. Clear sera were collected and stored at -20°C for biochemical assay. The kidneys was rapidly excised and stored in 10% formalin solution and processed for histological examination.

**Determination of biochemical and histomorphometric parameters:** Serum creatinine, urea and lipid peroxide contents were measured in all rats involved in this study using standard laboratory method.

Body and kidney weights were estimated at the end of 8 weeks. Under light microscopy the number and the diameter of (pct) were measured beside the histological examination.

**Statistical Analysis:** The data were expressed as means ± standard deviation (X ± SD). ANOVA (analysis of variance) to compare between more than two groups of numerical (parametric) data followed by post hoc Tukey test. A P value <0.05 was considered statistically significant.

**Results**

**Effect of Zingiber officinale extract treatment on body and kidney weights:** Table 1 showed a significant decrease in (b.w) and a significant increase in (k.w) of the rats among the HgCl<sub>2</sub> group(P≤0.05). While the (k.w) of the rats treated with extract of *Z officinale* showed a significant decrease when compared with rats among the HgCl<sub>2</sub> group(P≤0.05). No significant difference in the body and kidney weight between (*Z officinale* + HgCl<sub>2</sub>) group and the control group.

**Effect of Zingiber officinale extract treatment on the diameter and number of (pct):** Means diameter of

(pct) shows a significant increase in HgCl<sub>2</sub> treated group compared with other groups (P≤0.05), while the number of (pct) showed a significant decrease in HgCl<sub>2</sub> compared with other treated groups (P≤0.05). Table 3 showed a significant decrease in the diameter of (pct) among rats treated with *Z officinale* + HgCl<sub>2</sub> group (P≤0.05), also showed a significant increase in the number of the (pct) of *Z officinale* + Hgcl<sub>2</sub> group(P≤0.05). No significant difference in the diameter of (pct), and the number of (pct) of the *Z officinale* extract and control group.

**Table 1: Effect of Zingiber officinale extract treatment on body and kidney weights**

Groups	Bodyweight (gm)	Kidney Weight (gm)
Control	190.50±6.123 (A)	1.397±0.013 (C)
HgCl <sub>2</sub>	157.83±2.041 (C)	4.055±0.181 (A)
HgCl <sub>2</sub> +Z officinale	171.50±5.205 (B)	2.220±0.216 (B)
Z officinale	189.67±5.887 (A)	1.406±0.019 (C)

Values are expressed as mean± SD of 10 rats in each group. Significantly different from Group HgCl<sub>2</sub> (P≤ 0.05). Capital letters denote differences between the groups.

**Table 3: Effect of Zingiber officinale extract treatment on the diameter and number of (pct)**

Groups	The Diameter of (pct)	No. of (pct)
Control	41.373±0.329 (C)	17.728±0.746 (A)
HgCl <sub>2</sub>	53.353±0.654 (A)	14.725±0.502 (C)
Z officinale + HgCl <sub>2</sub>	44.893±1.0731 (B)	16.415±0.521 (B)
Z officinale	41.165±0.245 (C)	18.036±0.934 (A)

Values are expressed as mean± SD of 10 rats in each group. Significantly different in Group Hgcl<sub>2</sub>, (P≤ 0.05). Capital letters denote differences between the groups, P≤0.05 vs. control.

**Effect of Zingiber officinale extract treatment on creatinine, urea and MDA levels:** Creatinine, urea and MDA levels shows significant elevate in the HgCl<sub>2</sub> group of rats compared with the control group (p < 0.05). While the *Z officinale* + HgCl<sub>2</sub> group rats shows a significant reduction in the serum creatinine and urea levels (P≤ 0.05) (table 2).

**Table 2: Effect of Zingiber officinale extract treatment on creatinine, urea and MDA levels**

Groups	Creatinine	Urea	MDA
Control	127.96±0.076 (C)	58.045±1.413 (C)	4.365±0.199 (C)
HgCl <sub>2</sub>	437.77±24.013 (A)	149.08±1.652 (A)	7.908±0.263 (A)
HgCl <sub>2</sub> +Z officinale	244.67±14.684 (B)	87.848±1.889 (B)	5.063±0.398 (B)
Z officinale	123.77±0.537 (C)	55.400±0.530 (C)	4.410±0.197 (C)

Values are expressed as mean± SD of 10 rats in each group. Significantly different from Group HgCl<sub>2</sub> (P≤ 0.05). Capital letters denote differences between groups.

**Morphological Examination:** The kidneys of rats of the *Z officinale* extract, *Z officinale* + HgCl<sub>2</sub> groups showed bean-shaped, reddish-brown in color with smooth and possess convex and concave borders nearly normal (fig. 1a,b & d), while the kidney of rats of the HgCl<sub>2</sub> group was pale, swollen and enlarged (fig.1c).

**Histological Examination:** Figure 2a: show histopathological findings from H & E stained kidney sections. In the control group rats, no glomerular or pathological abnormalities. However, HgCl<sub>2</sub> group rats showed multiple pathological changes, which include dilated of Bowman’s capsules, atrophy glomerulus tuft, vacuolated of epithelial cells and cast formation with the presence of interstitial exudates. Also, a glomerular cell cast of renal tubules proximal dense nuclear of epithelial cell, hyper atrophy of other cells, a hemorrhagic area with a mild aggregation of some inflammatory cells beside a swelling of epithelial cells as shown in (fig. 2b). Rat kidneys treated with *Z officinale* + HgCl<sub>2</sub> group showed normal renal tubules and nearly normal epithelial cells, with very mild degeneration, while normal kidney tissues appear in (fig. 2c) rats.

**Fig. 1: a, c & d. (normal, *Z officinale* & HgCl<sub>2</sub> + *Z officinale* extract groups) showed normal gross appearance kidney. b, HgCl<sub>2</sub> group showing pale and swollen kidney.**

**Fig. 2:a. Control group, showing normal glomeruli (G) and normal renal tubules (RT). b, HgCl<sub>2</sub> group showing dilated of Bowman’s capsules (D), glomeruli tuft atrophy (→) vacuolated of epithelial cells (V) and glomerulus cells cast of renal tubules (C), hemorrhagic area (H). c, Zingiber officinale + HgCl<sub>2</sub> group showed nearly normal renal tubules with normal epithelial cells, and very mild degeneration(D). d, Zingiber officinale group showed normal glomerulus tuft, normal renal tubules and normal glomeruli of Bowman capsule H & E400X.**

## Discussion

The pathogenesis of nephrotoxicity of mercury is due to binding of mercuric ions with sulfur, like a thiol group of amino acids, which transfer mercury ion via sodium ion channels to the kidney tubules, causing in accumulation in the renal proximal tubular cells and increasing free radicals formation and damaging renal tubules<sup>4,11,12</sup>. So the current study was undertaken to determine whether Zingiber can reduce or prevent HgCl<sub>2</sub> induced renal damage by examining different biochemical and histological parameters related to kidney function of intoxicated and treated rats.

Reduce of the body weight may be resulting from being an interruption of HgCl<sub>2</sub> in the absorption and metabolism of feed nutrients essential for health<sup>13</sup>. Mercury is capable of damaging the organism in many ways because of its high affinity to various tissues and its tendency to accumulates<sup>14,15,16</sup> the result of the present study is inconsistent with other findings<sup>12,16,17</sup>. The biological effects ascribed to Zingiber include induction of endogenous antioxidants in rat tissue organs, scavenged free radicals by giving electron(s) to them, protecting cells from oxidative stress and increased detoxification of foreign compounds<sup>18</sup>.

Serum Creatinine and urea are the most sensitive biochemical marker used in the assessment of renal tissue damage because the creatinine and urea are excreted through kidney therefore, in cellular damage there is retention of creatinine, urea in the blood<sup>19</sup>. Many previous studies reported that proteinuria from mercuric toxicity is due to disorders in the glomerular filtration barrier which resulted from damage in podocytes, and decreased reabsorption of filtered protein<sup>16,20</sup>. The significant increase in serum creatinine level is evidence of the reduced ability of the renal tubules to excrete and creatinine from the blood of the HgCl<sub>2</sub> group rats, a reality that was also supported by the photomicrographs of the kidney tissue. Creatinine and urea levels

return to nearly normal levels in the (*Z officinale* + HgCl<sub>2</sub>) group that give an indication that Zingiber has protective and ameliorative effects on HgCl<sub>2</sub> induced kidney damage (table 2). These results are inconsistent with a previous explanation that the zingiber contains a high concentration of flavonoids and alkaloids<sup>21,22</sup> and acts as an antioxidant and/or free radical scavenging activity. Also the present study showed that treated of rats with the HgCl<sub>2</sub>, markedly induced elevation in malondialdehyde (MDA) due to the induction of free

radical generation and stimulation of lipid peroxidation. Treatment of rats with Zingiber significantly reduces MDA level, due to Ginger compounds like gingerols, shagols, and ketone they have the capacity to reduce the free radical capacity<sup>22,23</sup>.

The epithelium of (pct) is the most sensitive part of the kidney to the toxic effects of mercuric chloride due to their enzymatic activity<sup>4,24</sup>. In a histomorphometric study the diameter of (pct) in the treated HgCl<sub>2</sub> group was significantly increased (P≤0.05) as compared with other experimental groups, this an agreement with previous results<sup>4,25,26</sup>. One of the reasons for the increase in the diameter of (pct) is loss of brush border due to oxidative stress produced by HgCl<sub>2</sub><sup>21,22</sup>. A significant decrease in the number of (pct) of the HgCl<sub>2</sub> reflects oxidative stress-induced necrosis and apoptosis<sup>27,28</sup>. In the present study the maintenance of the diameter of (pct) in the (*Z officinale* + HgCl<sub>2</sub>) group indicates the antioxidant and anti-inflammatory effects of Zingiber, as reported previously by<sup>26,29,30</sup>.

Figure 2 shows that the HgCl<sub>2</sub> causes pathological changes and, On another side the morphological picture of *Z officinale* + HgCl<sub>2</sub> rat kidney group shows nearly normal tissue architecture with very few degenerative changes. These results were consistent with previously published articles<sup>4,24</sup>. The result of the present study confirms the role of Zingiber in improving tissue damages by reducing/inhibit the number of pct and pathological changes induced by a toxic dose of HgCl<sub>2</sub>.

## Conclusion

*Z officinale* has an antioxidant effect and able to retard the progression of renal tubular pathological changes induced by HgCl<sub>2</sub>.

## Abstract

Diabetic neuropathy (DN) is one of the microvascular complications of diabetes. Marked increase in oxygen free radicals (OFR) results in oxidative stress that leads to development of DN. Antioxidant enzymes play a major role in protection against progression of DN, by reducing OFR. This study aimed to investigate the association between superoxide dismutase 2 *SOD2*:p.(Ala16Val) and superoxide dismutase 3 *SOD3*:p.(Arg213Gly) genetic variants and the risk of neuropathy in Type 1 Diabetes children and adolescent. The study included 80 children with type 1 diabetes divided into 2 groups, group 1 of 40 patients with clinical DN and group 2 of 40 patients without DN. HbA1c levels were measured and genetic variants of *SOD2*:p.(Ala16Val) and *SOD3*:p.(Arg213Gly) were assessed by Taqman Real time Polymerase Chain Reaction (PCR) for both groups. The frequency of Ala/Ala genotype (OR=0.28 with 95% CI of 0.11-0.71) and Ala allele (OR=0.33 with 95% CI of 0.17-0.65) of *SOD2*:p.(Ala16Val) were significantly lower in group 1 (27.5%, 50% respectively) than group 2 (57.5%, 75% respectively) (p=0.007, p=0.001 respectively). In contrast the frequency of Val/Val genotype (OR=4.68 with 95% CI of 1.19-18.3) and Val allele (OR=3 with 95% CI of 1.54-5.86) were significantly higher in group 1 (27.5%, 50% respectively) than group 2 (7.5%, 25% respectively) (p=0.019 and p=0.001 respectively). Regarding *SOD3*:p.(Arg213Gly) gene variants the frequency of Arg/Arg genotype and Arg allele were higher in group 1 (100%,100% respectively) than group 2 (90%,95% respectively) but with statistical insignificance (P=0.06, P=0.058 respectively), however the frequency of Arg/Gly genotype and Gly allele were higher in group 2 (10%, 5% respectively) than group 1 (0%, 0% respectively) but also with no statistical significance (P=0.058 and P=0.06 respectively). There is a possible association between *SOD2*:p.(Ala16Val), but not with *SOD3*:p.(Arg213Gly) genetic variants and the occurrence of DN in patients with type 1 diabetes mellitus.

**Keywords:** Type 1 diabetes- neuropathy- *SOD2* gene- *SOD3* gene- Real Time PCR.

## Introduction

Diabetes Mellitus (DM) is a collection of metabolic abnormalities characterized by hyperglycemia which

results from defects in insulin secretion, insulin action or both.<sup>1</sup> Diabetes Mellitus Type 1 is caused by destruction of the insulin-producing beta cells in the pancreas<sup>2</sup> and can lead to microvascular complications as DN, affecting somatic and/or autonomic nervous system.<sup>3</sup> About 20% of patients with diabetes will develop clinically significant neuropathy within 10 years of diabetes onset<sup>4</sup> the molecular mechanisms involved in development of diabetic peripheral neuropathy (DPN) is complex process that includes over activation of polyol pathway and protein kinase C in presence of

hyperglycemia, increase of free radical and oxidative stress are incriminated in the pathogenesis of DPN<sup>5</sup>, also genetic factors such as single nucleotide polymorphism (SNP) in the superoxide dismutase and catalase gene may be a risk factor for DN.<sup>6</sup> Superoxide dismutases are the primary antioxidant defense system, catalyzing dismutation of superoxids into O<sub>2</sub> and H<sub>2</sub>O<sub>2</sub>. In mammals there are cytosolic (SOD1), mitochondrial (SOD2) and extracellular (SOD3) isoforms that are all products of distinct genes.<sup>7,8</sup> Mitochondrial SOD2 gene is located on the chromosome 6q25.3, it contains five exons, coding for 223 amino acids which undergo post translational modifications via the mitochondrial translocases to facilitate the import process in the mitochondria.<sup>9</sup> The rs 4880 of *SOD2* p. (Ala-9Val) or p.(Ala16Val) is the most studied variant in exon 2 of *SOD2* gene<sup>10</sup> the replacement of alanine to valine affects the  $\alpha$ -helix configuration in the mitochondrial targeting sequence (MTS) affecting the influx to mitochondria causing enzyme degradation and decrease enzyme activity.<sup>11</sup> Extracellular superoxide dismutase 3 gene lies on chromosome 4p15.2, it contains 3 exons. The entire 720bp coding region lies within exon 3.<sup>12</sup> The rs 1799895 (Arg213Gly) is present in exon3 of *SOD3* gene at codon 213. SOD3 with Gly-213 inhibits ionic interactions between heparin and SOD3 enzyme so it binds less tightly to the plasma membrane, and its serum concentration is about nine times or more that of the isoenzyme with Arg-213.<sup>13</sup> This study aimed to investigate the association between *SOD2*:p.(Ala16Val) and *SOD3*:p.(Arg213Gly) genetic variants and the risk of peripheral neuropathy in Type 1 Diabetes children and adolescents with more advanced method than the one used by ElMasry et al. (2005), which was Real time PCR using Taqman probes. Moreover the present study targeted a younger age group with neuropathy with short duration of diabetes compared to that done by El Masry et al. (2005).<sup>14</sup>

## Method

This case control study was conducted on 80 patients with T1DM, diagnosed according to American Diabetes Association (ADA) criteria 2018<sup>1</sup> that were recruited from outpatient clinic of the Diabetes, Endocrine and Metabolism Pediatric Unit (DEMPU), at Children Hospital, Cairo University in the period from January 2018 to December 2018.

We divided 80 patients into two groups, group 1 consisted of 40 Type 1 diabetes patients with clinical DN, diagnosed on basis of symptomatic symmetrical distal

neuropathy (reduced or absent ankle reflexes, vibration sense at the medial malleolus and/or reduced sense of position with one or more typical symptoms, such as burning sensation, cramps, parasthesia or numbness) using scores for neuropathy symptoms and neuropathy examination regardless of age, or degree of glycemic control, with diabetes duration of 5 years or less.

Group 2 included 40 patients (age and sex matched to group 1 with diabetes duration of more than 5 years regardless of degree of glycemic control without any symptom of neuropathy as a control group. Patients with type 2 diabetes or those with any other cause of neuropathy were excluded from the study. All participants in this study were informed and consents were taken from their parents. All subjects were subjected to thorough history taking including: age of onset of symptoms and duration of diabetes. Full clinical assessment was done.

Four milliliters of blood were collected from each participant and divided into 2 tubes: one EDTA tube for measurement of Glycated Hemoglobin (HbA1c) and another EDTA tube for DNA isolation and PCR procedure. Glycated Hemoglobin (HbA1c) Assay: Withdrawn samples were assayed immediately after collection on Dimension clinical chemistry system using FDA approved kits supplied by Siemens healthneers\*®.

\*Dimension (Siemens): Siemens Healthcare Diagnostics Inc. 511 Benedict Ave/Tarrytown, NY 10591 Phone: +1 914 631-8000).

The HbA1c measurement was based on a turbidimetric inhibition immunoassay (TINIA) principle which is NGSP certified as traceable on the DCCT.<sup>15</sup> Determination of *SOD2*:p.(Ala16Val) (rs4880) and *SOD3*:p.(Arg213Gly) (rs1799895) gene variants by Taqman Real Time Polymerase Chain Reaction included two steps: Extraction of genomic DNA from peripheral blood leucocytes of EDTA anticoagulated blood using QIAamp DNA blood Mini kit (Qiagen) by spin columns,<sup>16</sup> then, amplification of extracted DNA and analysis of gene variants by real time PCR technique using TaqMan single nucleotide polymorphism (SNP) genotyping assay (Applied Biosystems) performed on Step One™ Real Time PCR System (Applied Biosystems). The reaction volume was 20 $\mu$ l/well, and the thermal cycler was adjusted for initial step for activation of AmpliTaq Gold DNA polymerase enzyme, by adjusting temperature at 95°C for 10 minutes followed by 40 PCR cycles; each cycle of PCR consisted of 3 steps: denaturation step at 92°C for 15 seconds, annealing step reaction mixture was cooled to 60°C for 30 seconds, extension reaction,

done at 60°C for 30 seconds. After PCR amplification, an endpoint plate read was performed using Step One™ Real Time PCR System (Applied Biosystems). The Sequence Detection System (SDS). Software used the fluorescence measurements made during the plate read to plot fluorescence (Rn) values based on the signals from each well. The plotted fluorescence signals indicated which alleles were in each sample and alleles were converted to genotypes.

Data obtained from the study was coded and entered using the software SPSS (Statistical package for social science) version 17(Chicago,IL,USA). Parametric data was summarized using mean and standard deviation. Frequency and percentages were used for qualitative variables. Comparison between groups was done using Chi square and Fischer exact test for qualitative variable. Student's t test was used to compare two groups. The odds ratio (OR) and their 95% confidence intervals (CI) were calculated to estimate the strength of the association between each of genotypes and alleles and patients and controls. P-value is considered significant if <0.05.<sup>17</sup>

## Results

The baseline clinical, demographic features and genetic variant analysis of SOD2 and SOD3 genes of

both studied groups are showed in (Table 1).

There was no statistically significant difference as regards the age of participants, or their HbA1c levels (P=0.12, and P=0.92 respectively), but there was a statistically significant difference regarding diabetes duration among the studied groups (P=<0.0001).

The frequency of Ala/Ala genotype (OR=0.28 with 95% CI of 0.11-0.71) and Ala allele (OR=0.33 with 95% CI of 0.17-0.65) of SOD2:p.(Ala16Val) were significantly lower in group 1 than group 2 (P=0.007 and P=0.001 respectively). In contrast the frequency of Val/Val genotype (OR=4.68 with 95% CI of 1.19-18.3) and Val allele (OR=3 with 95% CI of 1.54-5.86) were significantly higher in group 1 than group 2 (P=0.019 and P=0.001 respectively).

Regarding SOD3:p.(Arg213Gly) genetic variants the frequency of Arg/Arg genotype and Arg allele were higher in group 1 than group 2 but with statistical insignificance (P=0.058 and P=0.06 respectively). However the frequency of Arg/Gly genotype and Gly allele were higher in group 2 than group 1, but also with no statistical significance (P=0.058 and P=0.06 respectively (Table 1).

**Table 1: Baseline, demographic, biochemical data and univariate analysis of factors with SOD**

Variables	Group 1 (n= 40)	Group 2 (n= 40)	P- value
Age (Years) mean ± SD	13.45(±2.64)	12.67(±1.75)	0.12
Sex (male/female)	27/13	22/18	0.25
Diabetes duration (Years) mean ± SD	3.75 (±1.07)	7.75 (±1.03)	<0.0001
HbA1c (%) mean ± SD	8.86 (±0.97)	8.84 (±0.91)	0.92

SOD3Gly allele (%) n= 80	0 (0)	4 (5)	0.06

P-value is considered significant if <0.05

## Discussion

The current study threw the light on different genotypes of Superoxide dismutase 2 and 3 in type 1 diabetes children and aimed at finding an association between the different genotypes and the risk of diabetic neuropathy.

Genotypic analysis of *SOD2*:p.(Ala16Val) gene variant revealed that the frequency of homozygous Val/Val genotype and Val allele of *SOD2* was significantly increased in DN patients (27.5%, 50%) than in those without neuropathy (7.5%,25%) (P=0.019).

Val/Val genotype was found to be a significant risk factor for developing peripheral neuropathy in a diabetes patient, (OR=4.68 with 95% CI of (1.9-18.3), P= 0.019). So this genetic variation tend to be the main risk factor for diabetic neuropathy regardless the glycemic control which was comparable between our two groups and regardless the duration of diabetes which was intended to be more than 5 years in patients without neuropathy and 5 years or less in patients with neuropathy to identify the impact of genetic variation on the development of diabetic neuropathy.

It was also found that the frequency of Ala/Ala genotype was significantly lower in patients with DN (27.5%) compared to those without neuropathy (57.5%) (OR=0.28 with 95%CI of (1.9-18.3), P = 0.007). Hence this genotype was associated with lower risk of DN.

In agreement with these results, Stokov et al. (2003)<sup>6</sup> and Zotova et al. (2003)<sup>18</sup> showed that *SOD2*:p.(Ala16Val) gene variant in a Russian population was associated with a high risk of the development of neuropathy in type 1 diabetic patients they stated that Val/Val genotype was more common in diabetic neuropathy patients (18.6%,20.4% respectively) than in diabetic patients without neuropathy (5.4%,5.6 respectively) (P=0.009, P=0.02 respectively). Regarding Ala/Ala genotypes, it was found that, it was significantly more common in diabetic patients without neuropathy (P=0.03,P=0.03 respectively).

These observations are also consistent with the findings of El Masry et al. (2005),<sup>14</sup> who demonstrated that Val/Val genotype of *SOD2* (rs4880) was a significant risk factor in diabetes patients with neuropathy but not nephropathy and the Ala/Ala genotype was more common in diabetes patients without neuropathy or other microangiopathic complications than those having neuropathy.

On the contrary, in 2015 a study on the Polish population which was done by, Wegner et al. (2015)<sup>19</sup> found that, Val/Val genotype of *SOD2* (rs4880) did not increase the risk of T1DM or chronic diabetes complications in Polish T1DM patients (P= 0.761, OR= 0.407). This discrepancy may relate to different genetic background in sample selection.

Regarding rs1799895 of *SOD3*:p.(Arg213Gly) gene variants, our current study revealed that the frequency of Arg/Arg genotype and Arg allele were higher in group 1 (100%,100% respectively) than group 2 (90%,95% respectively) but with statistical insignificance (P=0.058, P=0.06 respectively), however the frequency of Arg/Gly genotype and Gly allele were higher in group 2(10%,5% respectively) than group 1(0%,0% respectively) but also with no statistical significance (P=0.058 and P=0.06 respectively). In harmony with our results, Zhai and his coworkers on 2017<sup>20</sup> declared that no significant association was found between *SOD3*:p.(Arg213Gly) genetic variants and development of type 2 diabetes mellitus and its complications in Chinese population (P=0.66). On other hand, Zotova et al. (2003)<sup>18</sup> reported that the *SOD3*:p.(Arg213Gly) genetic variant was significantly associated with the development of diabetic polyneuropathy in T1DM patients in a Russian population. This was attributed to significantly higher frequency of homozygous wild Arg/Arg genotype in diabetic neuropathy patients (27.9%) than the diabetic patients without neuropathy (9.7%) (P=0.002). It is recommended that the results obtained by this study would be confirmed on larger studies on wider scale including other microvascular complications as nephropathy and retinopathy and its relation to glycemic variability.

## Conclusion

This study suggested the presence of a possible association between the *SOD2*:p.(Ala16Val) (rs4880), but not *SOD3*:p.(Arg213Gly) (rs1799895) gene variants and the susceptibility of diabetic polyneuropathy in children and adolescents with type 1 diabetes mellitus. This susceptibility is independent of glycemic control or diabetes duration.

## Abstract

HCV constitutes a significant health burden worldwide. Hepatitis C is a disease with significant global impact. Egypt has a high prevalence of HCV worldwide (>10%) . In Africa and the western Pacific the prevalence ( $\geq 3\%$ ) is significantly higher than in North America and Europe (<2%). In general, everyone with chronic HCV should receive antiviral therapy. This is because patients who are cured of their HCV infection benefit from reduction in the risk of hepatocellular carcinoma, liver related mortality and even all-cause mortality. In general, everyone with chronic HCV should receive antiviral therapy, treatment should be given first to patients with advanced fibrosis and high risk for liver-related complications. Also, patients with severe extrahepatic HCV manifestations should be given high priority. The timing of treatment in patients with mild liver disease can be individualized. This review provides insight into clinical studies of NS3/4A protease inhibitors, NS5B viral polymerase inhibitor (nucleotide and non-nucleotide), and NS5A inhibitors, alone and in combination.

**Keywords:** Direct-acting antiviral agents (DAAs); Hepatitis C virus; Side effects.

## Introduction

HCV constitutes a significant health burden worldwide. Indeed, this virus has a high propensity for establishing a chronic infection. In the long-term lead to advanced fibrosis, cirrhosis and hepatocellular carcinoma (HCC) <sup>(1)</sup>.

Hepatitis C is a disease with significant global impact. According to the World Health Organization (WHO) 2014 there are 130 - 150 million people chronically infected with HCV, corresponding to 2-2.5%

of the world's total population. There are considerable regional differences. Egypt has a high prevalence of HCV worldwide (>10%) . In Africa and the western Pacific the prevalence ( $\geq 3\%$ ) is significantly higher than in North America and Europe (<2%)<sup>(2)</sup>.

HCV has seven main genotypes (1–7) with multiple subtypes based on the sequence heterogeneity of HCV genome. Genotyping is important for planning of HCV treatment and helps to identify cure rate. Genotype 1a is predominantly located in North Europe and North America, whereas genotype 1b is predominantly found in southern and Eastern Europe and Japan. Genotype 2 is found more frequently in Europe than in North America. Genotype 3 is endemic to South-East Asia. Genotype 5 is almost exclusively found in South Africa. Genotype 6 is primarily distributed in Asia. Genotype 7 is identified in patients originating from the Democratic Republic of Congo. HCV genotype 4 is the cause of about 20% of the 170 million cases of hepatitis C in the world. In Middle East and Africa, it causes more than 80% of

HCV infections. Egypt has the highest frequency of HCV-4 that is responsible for almost 90% of infections and a major cause of chronic hepatitis, liver cirrhosis (LC), HCC and liver transplantation<sup>(3)</sup>.

In general, everyone with chronic HCV should receive antiviral therapy.

This is because patients who are cured of their HCV infection benefit from reduction in the risk of hepatocellular carcinoma, liver related mortality and even all-cause mortality<sup>(4)</sup>.

**Treatment Indication:** In general, everyone with chronic HCV should receive antiviral therapy.

This is because patients who are cured of their HCV infection benefit from reduction in the risk of hepatocellular carcinoma, liver related mortality and even all-cause mortality<sup>(4)</sup>. DAA regimens, ideally IFN-free, should be preferred<sup>(5)</sup>. However, if resources are limited and DAA therapies are not easily accessible, treatment should be given first to patients with advanced fibrosis and high risk for liver-related complications. Also, patients with severe extrahepatic HCV manifestations should be given high priority for immediate treatment. The timing of treatment in patients with mild liver disease can be individualised; waiting for IFN-free therapies with low risk of side effects should be considered<sup>(5)</sup>.

#### **Direct Acting Antivirals (DAAs):**

**Sofosbuvir:** Sofosbuvir (SOF) is a pyrimidine nucleotide analog inhibitor of NS5B, indicated in the treatment for HCV genotypes 1a, 1b, 2, 3, and 4 as a component of a combination antiviral treatment regimen.<sup>(6)</sup>

Sofosbuvir is phosphorylated within the cell, incorporates itself into the growing viral RNA strand, and terminates HCV RNA strand synthesis prematurely.<sup>(7)</sup>

SOF confers an excellent genetic barrier to resistance; among several clinical trials, resistance has been reported in just one patient, when it was utilized as a monotherapy.<sup>(8)</sup>

Sofosbuvir is activated in the liver by its phosphorylation to its triphosphate nucleoside analog, which is then dephosphorylated to the inactive GS-331007. Peak plasma concentrations (C<sub>max</sub>) of SOF is attained in 0.5–2 h and 2–4 h, while its terminal half-

life is 0.5 h and that of GS-331007 is 27 h. SOF can be administered with/without food; no gender or race difference has been reported with its use. Following a single 400 mg oral dose, most of the drug was eliminated in the urine (a little amount as the parent drug and the major as GS-331007). No dosage adjustments are recommended for hepatic or mild-to-moderate renal impairment.<sup>(6)</sup>

The most common side effects encountered for SOF was reported, when it was used in combination with IFN, and/or with longer (24 vs. 12 weeks) treatment. The adverse effects were fatigue, headache, nausea, insomnia, pruritus, irritability anemia, asthenia, and diarrhea. When it was combined with RBV and IFN the adverse effects were decreased appetite, influenza like illness, pyrexia, chills, neutropenia and myalgia.<sup>(7,8)</sup>

**Ledipasvir:** Ledipasvir (LDV) is an NS5A inhibitor and is currently available only as ledipasvir/sofosbuvir fixed-dose combination tablet for genotype 1a, 1b hepatitis C. LDV has shown efficacy to treat HCV patients without PEGinterferon or ribavirin. Natural resistance can emerge quickly against HCV NS5A, with suboptimal therapy. Patients with mutation in Y93H and Q30K are typically more susceptible to develop such resistance, a condition that may be minimized by the use of a combination treatment.<sup>(9)</sup>

Ledipasvir undergoes oxidative metabolism by unknown mechanism, and is excreted mainly through the biliary tract, while less than 1% in the urine. The parent drug accounts for about 70% of the excreted dose. The terminal half-life of LDV is 47 h.<sup>(10)</sup>

Ledipasvir has demonstrated a high efficacy as a combination with SOF in treating HCV 1 patients, with or without RBV. Moreover, it provides better sustained virological response in relapsing cases from RBV/SOF combination. The current recommendation for LDV use suggests there is no need to combine LDV/SOF with RBV or to prolong the treatment duration for more than 12 weeks.<sup>(11)</sup>

The most common side effects reported for LDV are diarrhea, nausea, fatigue, headache, insomnia and elevations in both bilirubin and lipase elevations. These side effects are more common with a longer duration of treatment (24 weeks) or concomitant RBV therapy.<sup>(12)</sup>

**Velpatasvir:** Velpatasvir is an inhibitor of viral NS5A was approved for the treatment of adult patients

with chronic HCV genotype 1, 2, 3, 4, 5 or 6 infection. A fixed dose combination of velpatasvir 100 mg and sofosbuvir 400 mg is to be taken orally once daily with or without food. The combination of velpatasvir/sofosbuvir being pan-genotypic has clinical importance as it cover HCV patients will all 6 genotypes and it may not be necessary to perform genotype testing. Velpatasvir/Sofosbuvir combination is indicated for chronic HCV patients without cirrhosis or with compensated cirrhosis. For indicated patients with decompensated cirrhosis the regimen should include ribavirin.<sup>(13)</sup>

Velpatasvir is subjected to metabolism via the CYP2B6, CYP2C8, and CYP3A4 pathways, and most of the dose is excreted in feces, primarily via biliary excretion of the parent drug.<sup>(14)</sup>

The commonly reported adverse events were headache, fatigue and nausea. As with other sofosbuvir-containing regimens.<sup>(13)</sup>

**Voxilaprevir:** Voxilaprevir (VOX) is an HCV NS3/4A protease inhibitor. Voxilaprevir is metabolised in vitro by CYP3A4, with the vast majority of drug in plasma being the parent drug. Velpatasvir and voxilaprevir are both inhibitors of drug transporters P-gp, BCRP, OATP1B1 and OATP1B3. Biliary excretion is the major route of elimination. The median terminal half-life of voxilaprevir is approximately 33 h<sup>(15)</sup>.

Sofosbuvir, velpatasvir and voxilaprevir are available in a three drug fixed-dose combination containing 400 mg of sofosbuvir, 100 mg of velpatasvir and 100 mg of voxilaprevir in a single tablet. The recommended dose of the combination is one tablet taken orally once daily with food<sup>(15)</sup>.

Child-Pugh A cirrhosis had no dose adjustment. The combination is not recommended in patients with moderate hepatic impairment (Child-Pugh B) and contraindicated in those with severe hepatic impairment (Child-Pugh C)<sup>(15)</sup>.

**Ritonavir-boosted paritaprevir:** Paritaprevir is an inhibitor of the HCV NS3/4A protease, has activities against genotypes 1a and 1b with good activities against genotypes 4a and 6a, whereas it is less active against genotype 2A and 3a. Ritonavir is an HIV-1 protease inhibitor that acts as a pharmacokinetic booster of paritaprevir.<sup>(16)</sup>

**Ombitasvir:** Ombitasvir is an inhibitor of HCV

NS5A with pangenotypic efficacy. ombitasvir is metabolized by amide hydrolysis and is highly bound to plasma proteins. It can be given with meals.<sup>(17)</sup>

**Dasabuvir:** Dasabuvir is a non-nucleoside inhibitor of NS5B RNA dependent RNA polymerase acting as an allosteric inhibitor of the palm domain of NS5B. Dasabuvir is active against replicons of genotypes 1a and 1b, whereas it has a reduced activity in the genotypes 2a, 2b, 3a, and 4a.<sup>(18)</sup>

All-oral Paritaprevir / Ritonavir / Ombitasvir plus Dasabuvir regimen is given with meals and is recommended for the treatment of genotypes 1a, 1b, and 4 with or without ribavirin. The All-oral regimen has high rates of SVR in treatment of both naïve and experienced patients with best outcome in non-cirrhotic patients with genotype 1b infections.<sup>(16)</sup>

The all-oral members are highly bound to plasma proteins, and apart from ombitasvir, which is metabolized by amide hydrolysis they are metabolized through hepatic CYP450 enzymes. Because non-renal mechanisms accounted for the elimination of all-oral regimen, renal impairment may not require specific recommendation and not recommended for patients with moderate hepatic impairment and is contraindicated in those with severe hepatic impairment. The adverse effects are nausea, pruritus, insomnia and asthenia.<sup>(19)</sup>

**Grazoprevir and elbasvir:** Elbasvir is an inhibitor of NS5A, whereas grazoprevir is an NS3/4A protease inhibitor. The combination of elbasvir and grazoprevir was approved with or without ribavirin for treating adult patients with chronic HCV genotype 1 or 4. A fixed-dose combination of elbasvir 50 mg and grazoprevir 100 mg is to be taken orally once daily without regard to meals. Genetic assessment for patients of genotype 1a is recommended to determine if the patient is NS5A resistant before the initial treatment, in order to determine the combination with ribavirin in regimen and the duration of therapy. Both elbasvir and grazoprevir undergo metabolism via the CYP3A pathway, and most of the dose is eliminated in the feces with little amount in urine. Subjects receiving Elbasvir/Grazoprevir for 12 weeks, most complained of fatigue, headache, and nausea as the common adverse reactions. In subjects receiving Elbasvir/Grazoprevir with ribavirin for 16 weeks the most often reported adverse reactions were anemia and headache.<sup>(20)</sup>

No dosage adjustment of Elbasvir/Grazoprevir

is recommended in patients with renal impairment, including patients on dialysis. No dosage adjustment of Elbasvir/Grazoprevir is recommended in patients with mild hepatic impairment. However, Elbasvir/Grazoprevir is contraindicated in patients with moderate or severe hepatic impairment.

**Daclatasvir:** Daclatasvir inhibits both viral RNA replication and virion assembly by binding to the N-terminus of NS5A causing structural distortions that interfere with NS5A functions. Daclatasvir is given once daily in oral dose (60 mg/day). It is well absorbed after oral administration with peak plasma concentrations occurring within 2 hours post dose; a high-fat, diet decreases daclatasvir bioavailability when compared with fasted conditions. There is no effect on daclatasvir bioavailability with normal diet. It binds to plasma protein by approximately 99%.<sup>(21)</sup>

Daclatasvir is metabolized by the liver with CYP3A4. The majority of the drug is eliminated in the feces and about 7% of the dose was excreted in the urine (primarily as unchanged daclatasvir). Its elimination half-life is about 13 hours and its clearance equals 4.2L/h. The most common reported adverse reaction are headache, fatigue, nausea and diarrhea. Daclatasvir is contraindicated with strong CYP 3A inducers. Consider the benefits and risks when prescribing daclatasvir to a pregnant woman. No data is available regarding the presence of daclatasvir in human milk. Benefit/risk patients should be considered in administering daclatasvir to lactating mothers. No dosage adjustment with renal impairment or any degree of hepatic impairment.<sup>(22)</sup>

**Simeprevir:** Simeprevir (SIM) is an NS3/4A protease inhibitor, its efficacy has been reported against HCV genotypes 1a and 1b. SIM has proven efficacy in non-responders from IFN-RBV treatment when it is combined with SOF in a daily dose of 150 mg with/without RBV for only 12 weeks schedule therapy<sup>(23)</sup>

SIM has demonstrated a higher genetic barrier to resistance. SIM reaches C<sub>max</sub> after 4–6 h. It is advisable to take SIM with food. It is metabolized by CYP3A family. Because of the intestinal CYP3A4 and p-glycoprotein inhibition, a careful monitoring for drug interactions is a mandatory precaution.<sup>(24)</sup>

Most of the drug is recovered in the feces. The terminal half-life reaches up to 41 hours. No dose adjustment is required in renal and mild hepatic impairment. Simeprevir is a well-tolerated drug. Most

of the reported side effects are known to result from the concomitantly taken medication. The side effects reported when it is combined with RBV/IFN are nausea, myalgia, rash, photosensitivity, pruritus and dyspnea. In other studies, when IFN is not included the side effects were nausea and headache. In the absence of IFN and RBV the reported adverse effects for SIM/SOF were rash, photosensitivity and pruritus<sup>(23)</sup>

## Conclusions

IFN-free antiviral treatment is safe and well tolerated. Patients can be treated almost independently of liver function or concomitant disease. Viral eradication is associated with reduced morbidity and mortality and better quality of life.

**Ethical Considerations:** The study protocol was approved by the ethical committee of the Internal Medicine Dept. at faculty of Medicine, Minia University.

**Source of Funding:** None

**Conflict of Interest:** None.

# Evaluation of Implant Stability after Application of Platelet Rich Fibrin in Mandibular Posterior Ridge Splitting and Simultaneous Implant Placement Versus Xenograft Application: A Randomized Clinical Trial

Shymaa M. El-Halawany<sup>1</sup>, Takek El-Ghareeb<sup>2</sup>, Elzahra FELbagoury<sup>3</sup>

<sup>1</sup>Assistant Lecturer Oral and Maxillofacial Surgery Department Faculty of Dentistry Fayoum University in Egypt

<sup>2</sup>Assistant Professor, <sup>3</sup>Professor, Oral and Maxillofacial Surgery Department Faculty of Dentistry, Cairo University

## Abstract

**Aim of the Study:** The purpose of this study aimed to answer a clinical question whether the use of platelet rich fibrin after ridge splitting with simultaneous implant placement will enhance implant stability in comparison with xenograft or not.

**Materials and Method:** sixteen patients were divided into 2 equal groups (Group I & Group II). Patients in both groups underwent surgical ridge splitting for narrow edentulous posterior mandibular ridge with simultaneous implant placement. In Group I, platelet rich fibrin used as a graft material around the implant in between buccal and lingual cortices. In Group II, Tutogen® xenograft used as a graft material around the implant in between buccal and lingual cortices.. Each patient was assessed for implant stability measured by Osstell™ by means of resonance frequency analysis (RFA) which is recorded as Implant Stability Quotient (ISQ) values first intraoperative then at intervals 3 months, 6 months and 9 months postoperatively. Moreover the bone relative density has been evaluated by cone beam computed tomography (CBCT) immediate postoperative and 6 months later.

**Results:** A higher mean value of ISQ was recorded in Group II than in Group I with no statistically significant difference ( $p=0.246$ ). In addition a higher mean value of bone density was recorded in Group I than in Group II with no statistically significant difference ( $p=0.601$ ).

**Conclusion:** Platelet rich fibrin could be used as grafting material from natural source, non-immunogenic, without xenopathy after ridge splitting in posterior mandibular region as a technique with time and cost saving with least morbidity.

**Keywords:** Platelet rich fibrin, xenograft, alveolar ridge splitting.

## Introduction

Bone loss presented as an ongoing process following tooth loss affecting the mandible four times more than the maxilla. Horizontal bone loss occurred faster and to

a greater extent than vertical bone loss, Deficiencies of alveolar bone constitute an obstacle for implant surgery in the oral and maxillofacial area, as a certain amount of supporting bone is necessary for dental implants.<sup>(1)</sup>

A variety of augmentation procedure as onlay bone grafts, horizontal guided bone regeneration, and ridge splitting techniques could be used which indicated mainly in cases with sufficient bone height but inadequate thickness. Use of ridge splitting technique allows implant placement simultaneously thereby treatment time is shortened.<sup>(2)</sup>

Xenograft is a common graft material which has osteoconductive characteristics but lacks an osteogenic property. High survival and success rate of implant placed in xenograft is documented.<sup>(3)</sup>

Platelet-rich fibrin (PRF) is a second generation PRP and has an advantage of accelerating the healing of soft and hard tissue. The known significant role of platelets and leukocyte as biomaterial is synergized by fibrin matrix supporting them and harmony between cytokines and their supporting fibrin matrix give PRF unique importance than any other platelet derivative.<sup>(4)</sup>

The presented study is to compare between platelet rich fibrin application after ridge splitting with simultaneous implant placement and xenograft application in enhancement of implant stability by time.

## Materials and Method

### Materials:

**Group I:** Surgical ridge splitting was performed for narrow edentulous posterior mandibular ridge with immediate implant placement and use of platelet rich fibrin as a graft material around the implant in between buccal and lingual cortices.

**Group II:** Surgical ridge splitting was performed for narrow edentulous posterior mandibular ridge with immediate implant placement and use of Tutogen xenograft as a graft material around the implant in between buccal and lingual cortices.

**Fig. 1: Implant placement after ridge splitting.**

**Study Population:** 16 patients were selected suffering from mandibular posterior horizontal alveolar ridge deficiency with sufficient alveolar bone height and seeking for fixed prosthetic rehabilitation by implant placement. Full medical history had been recorded for every participant patient. Fabrication of study casts and radiographic stents was done also.

**Clinical Examination:** Careful examination of surrounding teeth, occlusion, soft tissue and bone was performed.

**Radiographic Examination:** Patients of both groups have been subjected to standard panoramic digital radiographs.

Implant stability has been measured in two planes perpendicular to each other: mesiodistal and buccolingual. The four readings summed and the average was considered. The readings have been recorded at intervals first intraoperative then 3 months, 6 months and 9 months postoperatively. The values were expressed as numbers between 1-100 ISQ.

Cone beam computed tomography (CBCT) was performed preoperatively for measuring the available bone width, length, inferior alveolar nerve tracing and bone density

## Results

All patients were females with average age group of 36 years (range 26-52 years).

**Clinical Results:** The early postoperative period for all patients went uneventful with no significant complications. All patients showed postoperative edema with variable degrees.

**Surgical Results:** In this study the following complications were encountered.

Numbness had occurred after ridge splitting and implant placement on one case in group I. The neurosensory testing was performed for this case by subjective patient assessment with visual analog scale for the follow up period. The patient reported gradual decrease in numbness sensation and reach normal sensation about 2 months after the surgery.

Seepage of implant down of its place in group II due to incomplete fracture of buccal cortical plate during ridge splitting.

**Implant Stability Assessment:** At 9 months a higher mean value of ISQ was recorded in xenograft II than in PRF group I with no statistically significant difference (p=0.246) Table (1).

**Bone Density:** Six months post-operative, a higher mean value of bone density was recorded in PRF group I than in xenograft group II with no statistically significant difference (p=0.601) Table (2).

**Discussion**

In the present study 24 implants were inserted in 16 patients where ridge split technique was used for widening of horizontally deficient posterior mandibular alveolar ridge with immediate implant placement. Two different grafting techniques were used to fill the gap created after ridge splitting, and evaluation of implant stability over time was performed to compare between the used grafting materials.

All patients in both groups were subjected to surgical

operation of ridge splitting and immediate implant placement under local anesthesia without unpleasant experience for the patients.

However, Penarrocha et al reported that patients in his study expressed discomfort during the surgical procedure, because energy required to split and expand the ridge is dissipated throughout the maxillofacial region and he recommended that split procedure preferable be done under sedation or general anesthesia.<sup>(5)</sup>

The average ridge width in the present study

groups was 4mm this was according to Scipioni et al recommendation who suggested that wherever dental implants were placed, a minimal thickness of 1 to 1.5 mm of bone should remain on both the buccal and the lingual/palatal aspects of the implants. <sup>(6)</sup>

This also was in accordance with Simion et al who reported that ridge splitting technique was useful in managing narrow edentulous ridges for implant placement, and this technique was indicated when a standard osteotomy could not be created because of a crest width of 4 mm or less. <sup>(6)</sup>

In the present surgical technique after implant placement filling of the gap with either of the used materials was performed and the surgical site was tightly closed with intact mucoperiosteum. This was also advocated in an experimental study by Botticelli et al who studied healing that occurred adjacent to implants placed in recipient sites with a wide marginal defect and compared effects of bone grafting material and a collagen membrane, he concluded that if defects around implants were grafted or covered with collagen membranes, a higher percentage of bone to implant contact was obtained and marginal bone loss was avoided. <sup>(7)</sup>

This was also in a line with the conclusion of Han et al on his experimental study in dogs, who assessed the effects of bone grafting material and a collagen membrane after the ridge splitting technique and immediate implant placement and he reported that space created after ridge splitting could be filled with autologous/heterologous graft or application of platelets concentrates such as PRP or PRF that seemed to accelerate the healing of hard and soft tissues for higher success rate in ridge splitting technique with simultaneous implant placement. And also better for the prevention of marginal bone loss after ridge splitting procedures. And also he showed that the group which used no graft revealed a significantly lower percentage of bone to implant contact and most prominent marginal bone loss. <sup>(8)</sup>

However, this was in difference with Scipioni et al in his experimental study, where he evaluated healing at implants with and without primary bone contact and reported that gap created after ridge splitting could be filled with a blood clot, which in turn organizes and replaced with woven bone, and matured into load bearing lamellar bone at the implant interface. <sup>(9)</sup>

In the case which complained of numbness postoperatively the post-operative CBCT showed

approximation of placed implant to inferior alveolar nerve. This could explain numbness which had occurred, as ridge splitting maneuver was too near from mandibular canal and the dental implant was too close to the mandibular canal with subsequent formation of an adjacent hematoma that pressed against the nerve causing IAN compression. This was as reported by Khawaja and Renton that “cracking” of the IAN canal roof by its close proximity to preparation of the implant bed (millimetres) may cause haemorrhage into the canal or deposition of debris which may compress and cause ischemia of the nerve. <sup>(10)</sup>

Sohn et al reported that unwanted fracture of buccal cortical plate occurred in five patients among the 23 patients who underwent immediate lateral ridge expansion. <sup>(11)</sup> This goes in accordance with the case which encountered fracture of buccal cortical plate in this study.

The same complications were reported by Elian et al who reported that mandibles were at risk of malfracture in the osteomized segment because the mandibular bone had less flexibility and a thicker cortical plate during ridge expansion with simultaneous implant placement. <sup>(12)</sup>

In the current research results of implant stability after nine months revealed higher mean values in xenograft group. However the mean values of density, immediately post operatively, were higher in PRF group six months post operatively.

It could be elicited from results of this study that no correlation between the bone density values obtained by CBCT and implant stability. This is in a line with several studies such as the clinical study made by Roze et al who inserted twenty two implants into the maxillae and mandibles of human cadavers, and no correlations were found between (ISQ) values and bone density. Also, similar findings were documented in the clinical study by Huwiler et al on resonance frequency analysis in relation to jawbone characteristics. He reported that no relation was found between bone density and values of implant stability. <sup>(13,14)</sup>

In other hand, this could be possibly explained as PRF composed of densely thick fibrin networks with densely packed activated platelets meshed among the fibrins which act as natural matrix scaffold for the recruitment and attachment of tissue cells and also inducement of angiogenesis and also provide sustain release of growth factors into the wound area as reported by Dohan et al. <sup>(4)</sup>

Therefore the slow and continuous release of growth factors and the good characteristics of fibrin structure are the two essential factors to initiate and enhance bone regeneration in any condition even in the empty defect, so PRF alone could bridge the bone defects Kazakos et al. which accelerate new bone formation. However, xenograft undergo slow resorption as documented by clinical biopsies in another study Hallman et al. which in turn led to slow substitution of the newly formed bone. The slow resorption rate of xenograft provide extended stability and that could explain the higher implant stability in xenograft group.<sup>(16,17)</sup>

Based on the fore mentioned results, we can use the advantages of PRF being simple, natural inexpensive, affordable and easy prepared biomaterial as a favorable matrix for the development of a coherent healing without inflammatory excess for bone healing stimulation. Moreover this may overcome drawbacks of xenograft such as risk of cross contamination with bovine spongiform encephalopathy, its immunogenicity, financial ramifications and patient specific consent considerations based on religious, social issues associated with biologic tissues.

**Funding:** The study was self-funded.

**Competing Interests:** No conflict of interest.

**Ethical Approval:** The Ethics and research committee, Faculty of Dentistry, Cairo University approved the study and patients' consent was obtained.

# The Influence of Age, Work Period, Distance of Residence, and Midwife's Intention to Behavior in Recording and Reporting Routine Immunization

Sindy Aziza Hermanuya<sup>1</sup>, Sri Widati<sup>2</sup>, Oedojo Soedirham<sup>2</sup>

<sup>1</sup>Health Promotion and Behavioral Science, Master Program of Public Health Science, <sup>2</sup>Departement of Health Promotion and Behavioral Science, Faculty of Public Health, Airlangga University, Indonesia

## Abstract

One of the most critical issues in immunization recording and reporting is the validity of immunization coverage data, so the quality of immunization recording and reporting has a vital role in producing quality immunization coverage. The over report immunization report data is evidence that midwives are not compliant in carrying out recording and reporting. The behavior of midwives in carrying out routine immunization recording and reporting can be determined by intention or intention and several other factors. The purpose of this study was to analyze the influence of age, work period, distance of residence, and midwife's intentions on the behavior of implementing routine immunization recording and reporting. This research method included observational research with a cross-sectional design with primary data through interviews using a questionnaire that was read to midwives (n=110) and document studies using the Rapid Convenience Assessment (RCA) form in the community. The results showed that the behavior of midwives in carrying out routine immunization recording and reporting was influenced by the work period (p=0.011) and intention (p=0.031). Conclusion: There is a significant relationship between the length of work and the intention of the midwife towards the behavior of implementing routine immunization recording and reporting.

**Keywords:** *Recording and Reporting Routine Immunization, Midwives, and Behavior.*

## Introduction

WHO data in 2014 showed a significant decrease in mortality in children under five years old. This can be seen from the number of child deaths under five years in 1990 (12.6 million children) and 2013 (6.3 million children). The target of child mortality below five years in 2015 is estimated at two-thirds between 1990 and 2015, so it can be said to be still relatively high<sup>1</sup>. According to the Ministry of Health of the Republic of

Indonesia in 2015 the provision of immunization is one of the most effective efforts in reducing child mortality. Immunization should be able to reduce child mortality due to PD3I through increased coverage of complete immunization. However, in reality, around 22 million babies in the world do not get complete immunization and 9.5 million are in South East Asia, including children in Indonesia<sup>2</sup>. Based on the Indonesian Health Profile the success of the immunization program in infants aged 0-11 months is measured through indicators of complete primary immunization. The achievement of this indicator in Indonesia in 2015 was 86.24%. This figure has not yet reached the 2015 Strategic Plan target of 91%<sup>3</sup>.

East Java Province is a contributor to the highest number of cases of Extraordinary Events in Indonesia, such as Diphtheria outbreaks that occurred in 2011, 2012, and 2017. One of the factors causing the high number of Diphtheria cases in East Java in 2017 is a

decrease in the number of babies age from 11 to 11 months which is not fully immunized basic in the last two years. The highest number of positive diphtheria cases were in Sampang Regency, ten positive cases, Pasuruan Regency 7 positive cases and Tuban Regency 3 positive cases<sup>4</sup>. It illustrates the problem, even though the achievement of complete primary immunization in 2016 in the Sampang Regency has reached the national target of 91.68%, but the number of diphtheria cases in the Sampang Regency remains high.

Various things can cause the low behavior of midwives in carrying out routine immunization recording and reporting. Research by Hargono et al. In 2012 states that one of the causes of the emergence of diseases that can be prevented by immunization is the low quality of recording and reporting of immunization programs. One of the most critical issues is the validity of immunization coverage data, so the quality of immunization recording and reporting has a vital role in producing quality immunization coverage<sup>5</sup>. The over report immunization report data is evidence that midwives are not compliant in carrying out routine immunization recording and reporting. The most important determining factor in someone's behavior is the intention or intention (intention). According to Ajzen (1991), individual behavior is strongly influenced by the individual's own intention (behavioral intention) towards certain behaviors<sup>6</sup>.

This study aims to analyze the influence of age, work period, distance of residence, and intention of midwives on the behavior of implementing routine immunization recording and reporting.

## Materials and Method

This cross-sectional study is a research carried out at a time and is not limited to when it has been completed<sup>7</sup>. This study was conducted to determine the effect of age, work period, distance of residence, and intention of midwives on the behavior of implementing routine

immunization recording and reporting. This research was conducted in 21 Puskesmas in Sampang Regency.

In this study the sample is a midwife who has inclusion criteria which have worked for at least two years in the area, legally has a Registration Certificate and Work Permit there is no Independent Practice Midwife in her work area, and is willing to be a sample in this study voluntarily.

The sampling technique used in this study is proportionate stratified random sampling. Based on sample calculations, a minimum sample of 110 midwives was obtained. In this study the dependent variable is behavior and the independent variables are age, work period, residence, and intention.

Data collection techniques in this study were data collection in the field carried out using a questionnaire that was read to the midwife by visiting 'polindes,' or while attending the 'Posyandu' toddlers activities after that, a document study was conducted using the RCA form by comparing immunization records recorded in the MCH book owned by the community with recording immunization in a baby cohort book owned by a midwife.

Analysis of the data used logistic regression with the backward method to find out whether there is a relationship between the two variables studied. The significance test is done by comparing the significance value obtained with  $\alpha$ ; if  $p < \alpha$  ( $\alpha = 0.05$ ) there is a significant relationship.

## Results

Table 1 shows that respondents with age less than 30 years do not record and report routine immunizations in their cohort book following the community's MCH handbook. Statistical test results showed no significant effect between the age variables of midwives on the behavior in carrying out routine immunization recording and reporting.

**Table 1. Influence of midwife age on behavior**

Age	Behavior				Total (N = 110)		P-value
	Following the MCH Handbook		Not following the MCH Handbook		N	%	
	N	%	N	%			
<30 years	0	0,0	4	100	4	100	0.280
30 – 45 years	6	6,7	83	93.3	89	100	
>45 years	2	11.8	15	88.2	17	100	
<b>Total</b>	<b>8</b>	<b>7.3</b>	<b>102</b>	<b>92.7</b>	<b>110</b>	<b>100</b>	

**Table 2. Influence of midwives’ work period on behavior**

Work Period	Behavior				Total (N = 110)		P-value
	Following the MCH Handbook		Not following the MCH Handbook				
	N	%	N	%	N	%	
<6years	0	0,0	7	100	7	100	0.011
6 –10years	3	7.7	36	92.3	39	100	
>10 years	5	7.8	59	92.2	64	100	
<b>Total</b>	<b>8</b>	<b>7.3</b>	<b>102</b>	<b>92.7</b>	<b>110</b>	<b>100</b>	

Table 2 shows that respondents whose work period is <6 years do not record and report routine immunizations in their cohort book following the community’s MCH handbook. It supported by the results of statistical tests

showing a significant effect between the variable work period of midwives on the behavior in carrying out recording and reporting routine immunizations.

**Table 3. Influence of distance of residence midwives on behavior**

Distance of Residence	Behavior				Total (N = 110)		P-value
	Following the MCH Handbook		Not following the MCH Handbook				
	N	%	N	%	N	%	
0-2 km	8	10.7	67	89.3	75	100	0.996
2-4 km	0	0.0	11	100	11	100	
4-6 km	0	0.0	9	100	9	100	
6-8 km	0	0.0	7	100	7	100	
>8 km	0	0.0	8	100	8	100	
<b>Total</b>	<b>8</b>	<b>7.3</b>	<b>102</b>	<b>92.7</b>	<b>110</b>	<b>100</b>	

Based on table 3, respondents with a place to live (distance) more than two km all record and report routine immunizations in their cohort book following the community’s MCH handbook. Statistical test results

that showed no significant effect between the distance variables of the midwife’s residence to the behavior in implementing routine immunization recording and reporting.

**Table 4. Influence of Midwives’ Intention on Behavior**

Intention	Behavior				Total (N = 110)		P-value
	Following the MCH Handbook		Not following the MCH Handbook				
	N	%	N	%	N	%	
Lemah	1	12.5	7	87.5	8	100	0.031
Kuat	7	6.9	95	93.1	102	100	
<b>Total</b>	<b>8</b>	<b>7.3</b>	<b>102</b>	<b>92.7</b>	<b>110</b>	<b>100</b>	

Based on table 4, respondents who have strong intentions mostly record and report routine immunizations in their cohort books that are following the community's MCH handbook. Statistical test results show a significant effect between the intention variables of midwives on the behavior in recording and reporting routine immunizations.

## Discussion

The results showed that the length of the service variable had a significant effect on the behavior variable because officers with long working periods already have much experience and understand the impact if they do not do routine immunization recording and reporting on time and there is a high potential for errors which will result in an Extraordinary Event of immunization and others which are then implemented in the form of behavior by recording on time and following established procedures. The results of this study are not in line with the results of Nuraini's research in 2018, saying that the village midwife's tenure does not affect the intention of achieving the program<sup>8</sup>.

Behavior is an action. Attitudes toward actions are related to their impacts, values related to actions, ethics and traditions<sup>9</sup>. Behavior (behavior) is done because individuals have the interest or desire to do so<sup>10</sup>. It is in line with the results of Agus Suprpto's research in 2016 which states that the variable of the length of service and employment status both individually and together have an influence on midwife behavior in providing antenatal services with  $p$  values  $<0.05$ <sup>11</sup>.

The results of this study indicate that the majority of respondents intend to carry out recording and reporting of routine immunization programs following established standards. While the results of the logistic regression analysis of the intention variable affect the behavior variable of midwives, it is in line with the theory proposed by Ajzen in 2005, that intention will positively influence the implementation of a behavior. Where the higher or increasing one's intention will affect the implementation of behavior<sup>12</sup>.

The results of this study are also following the opinion that states the intention to perform a behavior is a person's tendency to choose to do or not do an action. Intentions are also determined by the extent to which individuals have positive attitudes towards certain behaviors and the extent to which a person chooses to do certain behaviors has the support of people who are

influential in his life, and individuals can overcome perceived behavioral control. The implementation of recording and reporting routine immunizations carried out by midwives begins with the intention or desire to do so but due to the lack of a sustainable monitoring system and the commitment of the leadership.

A person's actions can be determined from his intention so that the intention of the midwife very much determines the decision to record and report routine immunization programs in accordance with the standards. The intention according to Fishbein and Ajzen in 1975, is a probability or possibility that is subjective, namely someone's estimate of how likely it is to do something<sup>13</sup>.

## Conclusion

There is a significant influence between the work period and the intention of the midwife on the behavior of implementing routine immunization recording and reporting. Actions to record and report routine over-reporting immunizations are not only preceded by an intention or desire to record and report routine immunizations that are not following procedures, but also because of an unsustainable monitoring system from the leadership. As a suggestion, it is essential to pay attention to the factors and intention and behavior of midwives in recording and reporting routine immunizations. The Head of the Puskesmas must conduct a quality integrated monitoring and evaluation system as a behavioral control for midwives in carrying out routine immunization recording and reporting.

**Acknowledgments:** On this occasion the author would like to thank the respondents who honestly filled out the questionnaire that had been given.

**Conflict of Interest:** The author states that there is no conflict of interest regarding the publication of this article.

**Source of Funding:** The personal fund used in this research.

# Decreasing Blood Sugar Levels Through Modification of Diabetes Exercise and Peer Group Support

Siti Rahmani<sup>1</sup>, Abdul Aziz Alimul Hidayat<sup>2</sup>, Nurhayati<sup>3</sup>

<sup>1</sup>Lecturer, Departement of Nursing, University of Megarezky Makassar, Indonesia, <sup>2</sup>Associate Professor, Departement of Nursing, University of Muhammadiyah Surabaya, 60113, Indonesia, Jl. Sutorejo No. 59 Surabaya, <sup>3</sup>Associate Professor, Departement of Nursing, University of Muhammadiyah Jakarta, Indonesia

## Abstract

**Background:** The efforts to handle patients with type 2 diabetes mellitus need to consider both the physical and psychological aspects. A physical activity that can be done is diabetes exercise. To do this exercise regularly.

**Purpose:** This study aims to analyze the effect of modified diabetes exercise and peer group support in decreasing blood sugar levels in patients with type 2 diabetes mellitus.

**Method:** This study used a quasi-experimental design with a pre-test and post-test with 38 respondents, which consisted of 19 respondents for the intervention group and 19 respondents for the control group. They were selected by purposive sampling. Data was collected using aglucometer, observation sheets with a Standard Operating Procedure (SOP).

**Results:** The results of the paired t test showed decreasing blood sugar levels after modified diabetes exercise and peer group support in the intervention group with p value as much as  $0.001 < 0.05$ . Meanwhile, in the control group there was no decrease in blood sugar levels, with results of the paired t test with p value of  $0.453 > 0.05$ .

**Conclusion:** To control blood sugar levels through modified diabetes exercise and peer group support.

**Keywords:** *Diabetes Mellitus, Diabetes Exercise, Peer Group Support, Blood Sugar Levels.*

## Introduction

Diabetes mellitus is the inability of the body to metabolize carbohydrates, fats and proteins which leads to hyperglycemia (high blood glucose levels) which is a progressive chronic disease<sup>1</sup>. According to WHO data the number of diabetes mellitus cases in 2015 was 415 million. In 2040, it is estimated that the number will be 642 million. The prevalence of Diabetes Mellitus based on a doctor's diagnosis in residents aged  $\geq 15$  years old in South Sulawesi, Indonesia in 2013 was 1.6% and increased to 1.7% in 2018 which showed a 0.1% increase based on a doctor's diagnosis<sup>2</sup>. Based on this, blood sugar level problems need to be addressed.

Diabetes mellitus can be managed non-pharmacologically through meals' planning and physical

activities. There are 4 main pillars in the management of diabetes mellitus, namely meal planning, physical exercise, hypoglycemic efficacy drugs and counseling<sup>3</sup>. A physical activity that diabetics can do is diabetes exercise.

Diabetes exercise is a way to reduce blood glucose levels in people with diabetes mellitus, because during physical exercise such as diabetes exercise increases blood flow, making more insulin receptors available. This increase is caused by more capillary nets opening, and receptors becoming active that will decrease blood glucose levels in patients with type 2 diabetes mellitus<sup>4</sup>. Sharoh & Salmiyati (2019) stated that diabetes exercise influenced blood sugar levels in patients with type 2 diabetes mellitus. 10 out of 12 participants in their

intervention group experienced lower blood sugar levels compared to 2 participants who experienced increased blood sugar level after diabetes exercise<sup>5</sup>.

People with diabetes mellitus are affected by various psychological factors such as motivation, habits, goals and awareness when they undergo either pharmacological and/or non-pharmacological treatments. One way to make patients more enthusiastic to receive either treatment is getting social support from partners, families, as well as health workers and communities with diabetes mellitus.

Patients with diabetes mellitus can get support and assistance from various sources, one of them is peer group<sup>6</sup>. Peer group support provides an opportunity for people with the same painful experience to share knowledge and experience with others that cannot be obtained from health workers or family<sup>7</sup>. Doing activities together can increase motivation and foster interests and attitudes in managing diabetes, one activity being through physical exercise/diabetes exercise. Patients with type 2 diabetes mellitus may feel compelled to exercise because they are connected to social groups that are ready to listen to their complaints and share strategies to solve problems related to the illness<sup>8</sup>.

Aty (2014) researched the aerobic capacity of respondents that exercised less than 3 times/week for less than 30 minutes before peer group support. With peer group support the aerobic capacity of the majority of respondents increased. The respondents exercised between 4-6 times/week for 45-60 minutes<sup>9</sup>. This study tries to analyze the effect of modifying diabetes exercise and peer group support on decreasing blood sugar levels in patients with type 2 diabetes mellitus.

**Method**

This research used a quasi-experimental design with a pre-test and post-test with 38 respondents, with consisted of 19 respondents for the intervention group and 19 respondents for the control group which were selected using purposive sampling. The data was collected using a glucometer and observation.

The researchers used observation sheets for both the intervention group and the control group. The researchers measured blood sugar levels using a glucometer. The intervention group participated in physical exercise/diabetes exercise followed by peer group support for approximately 2 hours for 3 consecutive days. Their blood sugar levels were measured post-intervention (15 minutes after intervention).

The data was analyzed to determine the effect of modifying diabetes exercise with peer group support on decreasing blood sugar levels usingpaired t test with p <0.05.

**Results**

**Table 1. Characteristics of Frequency Distribution DM Type 2**

Variables	(n)	(%)
<b>Age</b>		
≤ 50	13	34.2
51 – 53	5	13.2
54 – 56	12	31.6
>57	8	21.1
<b>Gender</b>		
Male	7	18.4
Female	31	81.6
<b>Education</b>		
Low Education	30	78.9
Middle Education	6	15.8
High Education	2	5.3
<b>The Use of Oral Hypoglycemic Medicine</b>		
Consuming	13	34.2
Not Consuming	25	65.8
<b>Obedience to Taking Medicine</b>		
Low Obedience	7	53.8
High Obedience	3	23.1
Middle Obedience	3	23.1

Table 1 shows the characteristics of the respondents. 34.2% were less than 50 years old, 81.6% were women and in term of education, 78.9% had poor education. 65.8% did not consume oral hypoglycemic medicine, and for the ones who consumed medication, 53.8%had low obedience in term of taking medication.

**Table 2. Effect of Modifying Diabetes Exercise and Peer Group Support on Decreasing Blood Sugar Levels**

Variable of Blood Sugar Levels	Pre Intervention		Post Intervention		pvalue
	Mean	SD	Mean	SD	
Group of diabetes exercise modification and peer group support	284.4	99.8	239.8	94.7	0;001
Group of control	231.2	62.2	238.4	60.7	0.453

There were differences in blood sugar levels before and after intervention by modifying diabetes exercises and peer group support the paired t test results with p value (0.001).

## Discussion

The decrease in blood sugar levels after intervention via diabetes exercise and peer group support was caused by the respondents' motivations to take part in the exercises with peer group support. Bandura's social learning theory (2004) explained these results; the theory stated that if someone wants to act there must be motivation and encouragement from the environment. Here the motivation came from peers with the same disease<sup>10</sup>.

The difficulty of motivating respondents to participate in diabetes exercise was overcome by peer group support. Peer group activities affect both the group and individuals in the group. This is in accordance with Sarason (1994) who stated that the strategies to improve obedience include the support of health professionals, social support, health behaviors, and provision of information<sup>11</sup>.

Peer group members can share, exchange ideas, listen to suggestions or experiences from others and discuss various points of views. This helps them to understand each other's feelings, especially those who are struggling with the same problems, with similar emotions, and the same thoughts regarding the disease. Peer groups help the participants to increase their self-esteem and respect for each other. Peer groups encourage members to be more open to express their problems, it is a more practical and comfortable place to give and receive emotional support and can be an effective place to exchange information<sup>8</sup>.

The results of this research are supported by other research<sup>12</sup>. The research stated that patients who had peer group support achieved a more significant decrease in blood sugar levels due to increased knowledge related to insulin use and increased self-management abilities. Kusnanto (2009) stated that there was a significant difference between the treatment group and the control group that showed the influence of peer group support to increase exercise obedience in people with diabetes mellitus<sup>8</sup>. Yin et al. (2015) stated that diabetes mellitus patients with peer group support were better in terms of self-management and also more regularly checked their blood sugar levels over a period of 4 years<sup>13</sup>.

Peer groups make clients feel that they have a group that is ready to listen to complaints, and remind them to exercise regularly<sup>8</sup>. Feeling well and regular exercise help to increase blood flow to the muscles by opening the capillaries of small blood vessels to the muscles. Physical activity can control blood sugar levels since glucose will be converted into energy. Physical activity increases the production of insulin, which decreases blood sugar levels. People who lack exercise have difficulty to burn food that remains in the body as fat and sugar. If insulin is insufficient to convert glucose into energy, this may cause type 2 diabetes mellitus<sup>14</sup>.

This result is in line with Yulianto's (2015) research that showed decrease in blood sugar levels in the intervention group<sup>15</sup>. Hastuti W, Sonhaji, Abdillah Y (2017) stated that diabetes exercise had an effect on blood sugar levels in patients with type 2 diabetes mellitus<sup>16</sup>. Nugraha et al. (2016) showed that there were differences in blood sugar levels before and after diabetes exercise<sup>17</sup>.

## Conclusion

Blood sugar levels can be controlled by paying attention to physical and psychological aspects. The intervention group that implemented modification of diabetes exercise and peer group support showed decreasing blood sugar levels compared to the control group. There was a significant difference between blood sugar levels in the intervention group and the control group.

**Recommendation:** Modification of diabetes exercise and peer group support can be used as a non-pharmacological therapy in an effort to reduce blood sugar levels in patients with type 2 diabetes mellitus.

**Relevance of the Research:** This study highlighted the problem faced by diabetes mellitus patients of lack of motivation to exercise. Hence the modification of diabetes exercise and peer group support can increase their motivation to join diabetes mellitus handling programs.

**Acknowledgements:** We would like to express our deepest gratitude to University Muhammadiyah of Jakarta for its kind support.

**Ethical Clearance:** Received from Institutional Ethical Committee.

**Conflict of Interest:** Nil.

# Pre-Marriage Course Regarding Health Reproductive: Knowledge and Attitude of Bride and Groom Candidate in Preparing Health Status before Pregnant in Grobogan Regency

Achadi Nugraheni<sup>1</sup>, Cahya Tri Purnami<sup>1</sup>, Atik Mawarni<sup>1</sup>,  
Winarni M.<sup>1</sup>, Apoina Kartini<sup>1</sup>, Septo Pawelas Arso<sup>1</sup>, Alfi Fairuz Asna<sup>1</sup>

<sup>1</sup>Faculty of Public Health, Diponegoro University, Jl. Prof. Soedharto SH, Tembalang, Semarang, Central Java, Indonesia

## Abstract

**Background:** Maternal mortality, children mortality, stunting, and other health problems are still high in the world. One strategic to prevent this problem is to increase health knowledge in preparing for pregnancy to brides and grooms candidate. The aim of the study was to analyze differences in knowledge and attitudes of the brides and grooms candidate related to reproductive health before and after being given an intervention in Grobogan Regency.

**Method:** The quasi-experimental research with one group pre and posttest design was used to analyzed 31 bridegrooms as subject in the area of Grobogan Regency. The bridegrooms were given an intervention in the form of one-day pre-marriage course for 6-7 hours, wich is given by KUA officers (Office of Religious Affairs) and Health Service officers who have been trained. Knowledge and attitude were measured before and after a given intervention using a structured questionnaire and data gathered were analyzed using Wilcoxon Signed Rank Test.

**Result:** The results showed there was an effect of pre-marriage course intervention on knowledge ( $p=0.001$ ) but does not have a significant effect on the attitude of the bride and groom ( $p=0.209$ ).

**Conclusion:** One-day pre-marriage course can increase knowledge the brides and grooms candidate while the attitude doesn't.

**Keyword:** Knowledge, attitude, bride and groom candidate, pre-marriage course.

## Introduction

One of the development agendas of National Midterm Development Plan of Indonesia (RJPMN) 2020 - 2024 is to improve the quality and competitiveness of

human resources. Among the targeted development in 2015 – 2019 is the decreased prevalence of stunting (short and very short) of toddlers from 37.2% (2013) to 30.8% (2018), yet the anemia prevalence in pregnant women increased from 37.1% (2013) to 48.95% (2018) according to Indonesian Basic Health Research<sup>(1)</sup>. In fact, one of the policy guidelines listed in National Midterm Development Plan of Indonesia (RPJMN) 2020 - 2024 is the improved health of mother and child, family planning, and reproductive health, all of which include improving nutrition of adolescent girls and pregnant women, expanding access and quality services of family planning and reproductive health according to regional characteristics by optimizing the roles of private sectors and local governments through advocating information,

education, communication (IEC) and counseling on population control, family planning and reproductive health, as well as increasing knowledge and access to health reproductive services for adolescent in a gender responsive cross-sector.<sup>(2)</sup>

According to Indonesian Demographic and Health Survey (SDKI) in 2012, maternal mortality rate (MMR) was relatively high; 359 per 100,000 live births. The higher number of the MMR suggests that the quality of the reproductive health and the ability to develop human resources of a country is still low.<sup>(3)</sup> Ministry of Health Republic of Indonesia, 2017). In this case, Indonesia is dealing with many problems and challenges in relation to providing reproductive health services and fulfilling reproductive rights, as the MMR, 305 per 100,000 live births, and the infant mortality rate (IMR), 22.23 per 1000 live births, are relatively high while the health status of women and children is still low.<sup>(4)</sup>

According to Indonesian Basic Health Research (Riskesmas) 2018, 30.8% of infants suffer from stunting, 36.3% of women aged 15-19 years and 17.3% of pregnant women suffer from chronic energy deficiency. Meanwhile, anemia in adolescent girls aged 13-18 years, pregnant women, and women of childbearing aged 15-49 remains to be the health problem in the community; besides, teenaged marriage and pregnancy are still relatively high. (1) Furthermore, SDKI 2017 reported that 10.5% of women aged 15-19 are married, 7% of women under 20 have become mothers or are pregnant for their first child, and teen pregnancy rate aged 15-19 years is 36 per 1,000 pregnancies. Apart from these problems, infectious and non-communicable diseases being considered as a special concern in the reproductive age group, especially women, are tuberculosis, hypertension, diabetes mellitus, and IMS including HIV AIDS.<sup>(5)</sup>

The higher number of the Maternal Mortality Rate (MMR) and all problems involved might be caused by lack of reproductive health education. As a matter of fact, reproductive health education has existed in various programs; such as, Youth Care Health Services (PKPR) program that contributes to knowledge, attitudes, and activities in maintaining reproductive health in Buleleng District.<sup>(6)</sup>

Moreover, young couples need sufficient information about various aspects of reproductive health early in their married life. For example, information about high-risk pregnancies the importance of family planning method

as well as the selection of appropriate method to prevent pregnancy in the early years of married life the use of genetic counseling to prevent genetic diseases are the main health problems in the early years of married life. Therefore, conducting pre-marriage counseling classes by experts is one of the important health services. The counseling program helps couples to get information about reproductive health issues and build their marriage on the right basis.<sup>(7)</sup>

In 2015, Ansah, *et al* pointed out that attending pre-marital counseling classes reduced risks of marital failure.<sup>(8)</sup> Couples attending counseling classes dealt with lower risks of marital problems and have a better marriage (In 2017, Parhizgar, *et al* found that premarital counseling increased marital satisfaction.<sup>(9)</sup> Therefore, an innovative premarital course is a form of a strategic intervention that has a significant influence to increase knowledge and attitudes of the bridegroom in order to reduce MMR, CMR, stunting, and other health problems.

Given this explanation the aim of this study was to analyze the differences in knowledge and attitudes of the bride and groom related to reproductive health before and after being given an intervention in Grobogan Regency.

## Method

This study applied a pre and posttest quasi-experimental research design in one group. The pre-marriage course discussing reproductive health as the intervention was conducted in one day for 6-7 hours at Office of Religious Affairs (KUA). The variables of knowledge and attitude of the subjects were measured before and after intervention using a structured questionnaire.

The sample was 31 bridegrooms of both the brides and the grooms registered at the Religious Affairs Office (KUA) in Grobogan Regency in January-July 2019. Samples were selected following the inclusion criteria, based on which the brides and the grooms were in the working area of the community health center (Puskesmas) of Grobogan District from January to July 2019 and willing to be the respondents. Data were collected by interviews using a set of questionnaire that its validity and reliability had been tested. Bivariate data analysis in this study was Wilcoxon Signed Rank-Test. Subjects' participation was voluntary proven by signing of informed consent.

## Results and Discussion

The characteristic of the sample, bridegrooms registered at KUA Grobogan Regency in January - July 2019, is presented in table 1. Most respondents are male (61.3%) the age of the bride and groom is in between 21 and 35 years (80.4%) the last education of the couples is junior high (35.5%), and the job of the bride and groom is mostly private sectors (54.5%).

**Table 1. Characteristics of respondents**

Characteristic	Newlyweds	
	n	%

### Differences in Knowledge and Attitudes before and After the Intervention:

**1. Knowledge:** The Wilcoxon test showed that there was no significant differences in knowledge between before and after the intervention on premarital activities ( $p = 0.191$ ), while there were significant differences in knowledge between before and after the intervention on pregnancy planning ( $p = 0.001$ ), infant nutrition ( $p = 0.007$ ), disease prevention ( $p = 0.002$ ), and there was significant difference in knowledge between before and after the intervention on the total score of knowledge ( $p = 0.001$ ).

**Table 2. Difference Scores of Knowledge Regarding Premarital Activities, Pregnancy Planning, Infant Nutrition, Disease Prevention, and Total Knowledge Before and After Intervention of Newlyweds**

Knowledge	Newlyweds	
	Mean ± SD	Min-Max
<b>Premarital Activities</b>		
Pre test	3.03±1.16	0-4
Post test	3.41±1.32	0-4
p value	0.191 <sup>a</sup>	
<b>Pregnancy Planning</b>		
Pre test	13.42±3.20	3-18
Post test	15.87±3.22	6-18
p value	0.001 <sup>a</sup>	
<b>Infant Nutrition</b>		
Pre test	4.06±1.09	1-5
Post test	4.74±0.51	3-5
p value	0.007 <sup>a</sup>	
<b>Disease Prevention</b>		
Pre test	2.77±1.14	0-4
Post test	3.70±0.90	1-4
p value	0.002 <sup>a</sup>	
<b>Total Knowledge</b>		
Pre test	23.77±4.11	14-31
Post test	27.74±5.02	16-31
p value	0.001 <sup>a</sup>	

a = Wilcoxon Test

Table 2 shows that there is a significant increase in the knowledge score of the bridegroom, especially regarding pregnancy planning, infant nutrition, disease prevention and the total score of knowledge.

**2. Attitude:** The result of the normality test of the newlyweds showed significance value of 0.001 for the pretest and of 0.002 for the post test; thus, it could be concluded that the value was not normally distributed for both before (pretest) and after (posttest) intervention.

Table 3 presents the results of different test between pre-test and post-test of attitudes using Wilcoxon test. The result showed that there was no significant differences in attitude between before and after the intervention on premarital activities ( $p = 0.133$ ), pregnancy planning ( $p = 0.076$ ), infant nutrition ( $p = 0.594$ ), disease prevention ( $p = 0.298$ ), and there was no significant difference in the total score of the attitude ( $p = 0.209$ ).

**Table 3. Difference Scores in Attitude Regarding Premarital Activities, Pregnancy Planning, Infant Nutrition, Disease Prevention, and Total Attitudes Before and After Intervention of Newlyweds**

Attitude	Newlyweds	
	Mean±SD	Min-Max
<b>Premarital Activities</b>		
Pre test	10.65±2.44	2-14
Post test	11.54±2.12	8-14
p value	0.133 <sup>a</sup>	
<b>Pregnancy Planning</b>		
Pre test	9.87±3.01	1-14
Post test	11.03±2.41	6-14
p value	0.076 <sup>a</sup>	
<b>Mother and Infant Nutrition</b>		
Pre test	3.94±0.77	1-5
Post test	3.80±0.90	2-5
p value	0.594 <sup>a</sup>	
<b>Disease Prevention</b>

Post test	29.25±5.11	21-37
p value	0.209 <sup>a</sup>	

a = Wilcoxon Test

### Discussion

**1. Knowledge:** Bivariate analysis showed that there were significant differences in knowledge regarding pregnancy planning, infant nutrition, disease prevention, and total knowledge of the newlyweds before and after pre-marriage guidance intervention regarding reproductive health. However, statistical analysis showed that there was no significant difference in knowledge regarding premarital activities for newlyweds before and after intervention ( $p > 0.05$ ), meaning that the knowledge of the newlyweds increased after being treated with an intervention.

This result was in line with the one stated that premarital education/course can increase knowledge related to reproductive health<sup>(7,10,11)</sup>. As the knowledge of the respondents about pregnancy planning and infant nutrition increased the future generation would be expected to be having high quality considering the quality of health during 1000 First Day of Life is the

key to achieve optimal nutritional status in the next life cycle.<sup>(2)</sup>

The result of this study showed that the average score of knowledge increased by 4 points before and after the intervention. The knowledge of the bridegrooms was categorized into premarital activities, pregnancy planning, maternal and infant nutrition, and disease prevention. Researchers believed that premarital counseling has a significant influence on reproductive health and sexual health behaviors for adolescent/bridegrooms.<sup>(12-14)</sup>

**2. Attitude:** Statistical analysis showed that there was no significant relationship in the attitude of the bride and groom before and after the intervention, while the average score of the total attitudes did not increase significantly. Most respondents had a positive attitude (agree) regarding premarital activities, pregnancy planning, maternal and infant nutrition, and disease prevention. This finding was not in line with one of the research conducted on newlyweds in Brebes district concluded that there was a significant difference in attitude before and after the intervention was given.<sup>(15)</sup>

The low impact of the premarital counseling classes was caused by, among others, mixed participants in the training class, limited number of experts to review the educational content, inadequacy of time for question and answer, and speech emphasizing process as a method of education/one-way communication. Therefore, it is recommended that in addition to conducting counseling classes, more attention is given to class disaggregation by gender, using group discussion method, and educational films for active participation of the couples.<sup>(7)</sup>

### Conclusion

Premarital course interventions significantly affects the increased knowledge of both the bride and groom, but it does not have a significant effect on the attitude of the bride and groom. Further the increased knowledge of the bride and groom is expected to reduce indirectly the maternal and child mortality rates and improve the quality of the family health.

# Correlation between 25-Hydroxyvitamin D Serum Levels with Telomere Length in Premenopausal Minangkabau Ethnicity Women

Sri Nani Jelmila<sup>1</sup>, Delmi Sulastr<sup>2</sup>, Yuniar Lestari<sup>3</sup>

<sup>1</sup>Postgraduate Biomedical Science, Faculty of Medical, University of Andalas, Padang, Indonesia, <sup>2</sup>Department of Nutrition, Faculty of Medical, University of Andalas, Padang, Indonesia, <sup>3</sup>Department of Public Health, Faculty of Medical, University of Andalas, Padang, Indonesia

## Abstract

**Background:** Aging is associated with an increased prevalence of non-communicable diseases. Premenopause is a phase in aging characterized by reducing the biological functions of cells. Aging can be measured by cell biomarker, namely telomeres. Telomere length can be influenced by various factors including vitamin D. Vitamin D acts as an anti-proliferation and anti-inflammatory cell. This study aimed to examine the relationship between 25-hydroxy vitamin D serum levels with telomere length of Minangkabau premenopausal women in Padang city.

**Method:** This cross-sectional study was recruited ninety-three Minangkabau premenopausal women in Padang city. The recruitment subject was using a multistage random sampling technique. 25-hydroxy vitamin D serum levels were measured by the ELISA method. Telomeres length was measured by qPCR using O'Challagan & Fennech method. The analysis was carried out by univariate and bivariate with Pearson correlation.

**Results:** The average serum 25-hydroxy vitamin D levels were  $27.79 \pm 1.38$  ng/ml. The average telomere length was  $474.13 \pm 2.02$  bp. There was a correlation between 25-hydroxy vitamin D serum levels with telomere length ( $r = 0.267$ ,  $p = 0.01$ ).

**Conclusion:** This study concluded that there was a correlation between 25-hydroxy vitamin D serum levels with telomere length of Minangkabau premenopausal women in Padang city. An increase of 1 ng/ml 25-hydroxy vitamin D serum levels slowed down telomere shortening 0,583 bp.

**Keywords:** *Vitamin D, Telomere, Premenopause, Minangkabau.*

## Introduction

Non-communicable diseases are a global and national problem faced today. Data from the World

Health Organization (WHO) Global Report on Non-Communicable Disease in 2017 states that non-communicable diseases cause 40 million deaths per year or around 70% of deaths worldwide. This figure is expected to increase to around 52 million deaths per year in 2030. More than 9 million of all deaths from non-communicable diseases occur at the age of 40 years and over<sup>1</sup>.

Data Riskesdas in 2013 showed an increase in the prevalence of non-communicable diseases from the previous year. Non-communicable diseases suffered

Tel: +6285263828800

by many people aged 40 years and over. Around 47% of the death rates due to noncommunicable disease in Indonesia are women<sup>2</sup>.

Pre-menopause is a phase in the aging process, which is a transition from reproductive to non-reproductive periods that occur at the age of 40-55 years. During this time biological and endocrine changes such as the occurrence of estrogen hormone fluctuations that affect the menstrual cycle<sup>3</sup>. The hormone estrogen has a role as an antioxidant and increases telomerase activity. Low estrogen levels at the end of pre-menopause will increase the risk of non-communicable diseases that will be encountered when entering menopause in the next 5 until 10 years<sup>4</sup>.

Aging at the cellular level can be measured by examining telomeres, which are cell aging biomarkers. Telomeres are structures that play a role in protecting and preventing the fusion and degradation of chromosomes located at the ends of chromosomes<sup>5</sup>. Telomeres experience a shortening of around 24.8-27.7 base pairs per year. This shortening process is in line with increasing age. Progressive shortening of telomeres causes aging, apoptosis or oncogenetic transformation of somatic cells<sup>6</sup>.

Telomere length can be influenced by various factors, including body mass index, hormone therapy, antioxidant intake, chronic diseases, multivitamins, minerals and sex. One vitamin that has a role in maintaining telomere length is vitamin D. Vitamin D is a fat-soluble vitamin that acts as a steroid hormone that has many vital roles in mineral metabolism, bone health, proliferation, cell differentiation and apoptosis as well as anti-inflammatory properties. Research shows that vitamin D plays a role in maintaining genomic and telomere stability. Vitamin D levels can affect telomere length through anti-inflammatory mechanisms and controlling the rate of cell proliferation<sup>7,8</sup>.

Indonesia is a tropical country that receives sun exposure throughout the year. Even though they are exposed to sunlight throughout the year the prevalence of vitamin D deficiency in Indonesia tends to be high at 50% in women aged 45-55 years<sup>9</sup>, and 35.5% in women aged 60-75 years<sup>10</sup>.

The high prevalence of vitamin D deficiency is associated with lifestyle and environmental factors, including the lifestyle of Indonesian women who tend to avoid sunlight, spend more time indoors, use of

sunscreen and low intake of food sources of vitamin D<sup>11</sup>. Besides, older women are more at risk of vitamin D deficiency because of the reduced ability of the skin to synthesize vitamin D<sup>12</sup>.

Vitamin D deficiency is associated with telomere shortening. This deficiency is related to the function of vitamin D in maintaining genomic stability<sup>13</sup>. However the effect of vitamin D on telomeres is still controversial. The purpose of this study was to examine the relationship between serum 25 (OH) D levels and telomere length of the Minangkabau premenopausal women.

## Material and Method

This research is a cross-sectional study of 93 ethnic Minangkabau premenopausal women aged 40-55 years. Subjects were selected by multistage random sampling. The inclusion criteria in this study were willing to enter the study by signing an informed consent, aged 40-55 years, Minangkabau ethnic, having menstrual disorders and not using hormonal contraception. The exclusion criteria in this study were not coming and not being found when collecting research data, suffering from chronic diseases such as diabetes mellitus, hypertension, cancer (obtained from anamnesis). This research has obtained approval from the Andalas University Ethics Committee.

Telomere length is measured using the O'Callaghan and Fenech method. Venous blood was taken in 5cc cubital fossa then stored in a vacutainer. Blood samples were carried out by DNA isolation in the Biomedical Laboratory of the Faculty of Medicine, Andalas University, Padang. Following procedures in the Pure Link genomic DNA isolation kit. The isolation process consists of blood lysis, DNA binding, washing and eluting. The DNA concentration was measured using nano drops. Examination of 25-hydroxy vitamin D serum levels was carried out according to the procedure using an ELISA kit from DBC Canada. Data were analyzed using Pearson correlation parametric analysis. Abnormal data were transformed into Log 10. Significant correlation if  $p < 0.01$ . Data analysis using SPSS 20.

## Results

The results of this study are shown in table 1. The average age of respondents was  $46.52 \pm 1.08$  years, with a minimum age of 40 years and a maximum age of 54 years. The mean serum 25 (OH) D level was  $27.79 \pm 1.38$  ng/ml with a minimum value of 10.96 ng/ml and a

maximum value of 58.88 ng/ml. The average telomere length was  $474.13 \pm 2.02$  bp with a minimum telomere length of 102.32 bp and a maximum of 2041 bp.

**Table 1. Average of Age, 25-Hydroxyvitamin D Serum and Telomere Length**

Variables	Mean $\pm$ SD	Minimal value	Maximal Value
Age (year)	46,52 $\pm$ 1,08	40	54
25(OH)D Serum (ng/ml)	27,79 $\pm$ 1,38	10,96	58,88
Telomere Length (bp)	474,13 $\pm$ 2,02	102,32	2041

**Table 2. Regression Model for 25-Hydroxyvitamin D Serum and Telomere Length**

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	1,833	,320		5,736	,000
	25(OH)D Serum	,583	,220	,267	2,648	,010

**Figure 1. Correlation between 25-Hydroxyvitamin D Serum levels and Telomere Length**

Figure 1 showed a significant correlation between serum 25 (OH) D levels and telomere length ( $p = 0.01$ ,  $r = 0.267$ ).  $R^2 = 0.072$  indicates that serum 25 (OH)

D levels affect telomere length by 7%. Regression prediction equation in this study obtained  $Y = 1.833 + 0.583 X$  or telomere length =  $1.833 + 0.583$  levels 25

(OH) D (ng/ml). This means that every 1 ng/ml increase in serum 25 (OH) D levels slows shortening of telomere 0.583 bp (table 2).

## Discussion

Telomeres are nucleoprotein structures at the ends of chromosomes that play a role in maintaining genomic stability and preventing fusion and degradation of chromosomes during the process of cell division. Telomeres consist of a sequence of 6 TTAGGG hexanucleotide base pairs that repeat hundreds or even thousands of times. Telomeres will experience a shortening with age. The length of human telomeres ranges from 4-15 kbp. Telomeres will experience a shortening of around 24.8-27.7 base pairs per year. Telomere length can be influenced by various factors, including body mass index, antioxidant intake, chronic diseases, physical activity and gender. Progressive shortening of telomeres will result in cell aging and an increased risk of degenerative diseases<sup>6,14</sup>.

This study found that the length of telomeres of premenopausal women of Minangkabau ethnicity with an age range of 40-55 years ranged from 102.32 bp to 2041 bp with an average of  $474.13 \pm 2.02$  bp. This study analyzes the telomere length using the O'Challagan & Fenech method, which measures the absolute length of the telomere. This result is lower than the results of a study by Dalgard in the Danish National Twin Registry of 405 women aged 18-64.3 years getting an average telomere length result of  $7,010 \pm 30$  bp<sup>15</sup>. The study of Shin on 54 middle-aged obese women in Korea also obtained longer telomeres with an average of 8,290  $\pm$  1970 bp in premenopausal women<sup>16</sup>. Richards's study obtained a mean telomere length in women in the United Kingdom of  $7,000 \pm 700$  bp<sup>13</sup>. Different telomere lengths can be caused by differences in telomere length at birth, different measurement method used, age, race, diet, physical activity, estrogen levels and body mass index<sup>17,18</sup>.

Serum 25 (OH) D levels are the best indicator of vitamin D status<sup>12</sup>. The results showed that serum 25 (OH) D levels of premenopausal women of Minangkabau ethnicity ranged from 10.96 ng/ml to 58.88 ng/ml with a mean of  $27, 79 \pm 1.38$  ng/ml. The results showed that the average Minangkabau premenopausal woman experienced vitamin D insufficiency. Vitamin D insufficiency was based on classification by the Endocrine Society if serum 25 (OH) D levels were

obtained between 21-29 ng/ml<sup>12</sup>. The research data showed that respondents who experienced vitamin D deficiency (level 25 (OH) D <20 ng/ml) were 18.3%, vitamin D insufficiency (levels 25 (OH) D 21-29 ng/ml) were 39.8 % and deficiency (25 (OH) D levels 30-100ng/ml) as much as 41.9%.

The results of this study are higher than the results of research conducted by Mazidi in 4347 participants in the National Health and Nutrition Examination Survey (NHANES) with an average level of 25 (OH) D  $23.3 \pm 9.4$  ng/ml on female subjects. This difference in results can be caused by differences in climate and exposure to sunlight, race and different method used in the measurement<sup>19</sup>.

25 (OH) D serum levels are related to telomere length. In this study the results obtained were significant and positive patterns with  $r = 0.267$  and  $p = 0.01$ . This result is in line with research by Richards of 2160 women in the United States with an average age of 49.4 years. Research by Beilfuss also shows a relationship between serum 25 (OH) D levels and telomere length. This study analyzed data from the National Health and Nutrition Examination Survey (NHANES) 2001-2002 involving 11,039 respondents who found an association of each increase of 10 nmol/L levels of 25 (OH) D increasing telomere length by 0.03 kbp in women aged 45-59 years<sup>20</sup>. Liu conducted a Nurse Health Study study of 1337 white women with an average age of 59 years also found the relationship between serum 25 (OH) D levels with telomere length with a  $p$ -value = 0.02<sup>21</sup>.

Williams in the Northern Finland Birth Cohort of 5096 respondents with an average age of 31 years, found no relationship between 25 (OH) D levels and telomere length<sup>22</sup>. Cassidy's studied also found no relationship between serum 25 (OH) D levels with telomere length. The difference in the results of this study can be due to differences in respondent's characteristics in terms of age, race, body mass index, intake and lifestyle patterns and climate conditions related to the amount of sun exposure<sup>17</sup>.

The mechanism of the relationship between vitamin D levels and telomere length can occur through anti-inflammatory and anti-proliferation mechanisms<sup>19</sup>. Vitamin D in its active form, decreases the number of systemic inflammatory mediators such as interleukin-2 and tumor necrosis factor. Reduced systemic inflammation can result in reduced reactive oxygen

species (ROS) production to prevent telomere erosion<sup>13</sup>. Vitamin D plays a role in reducing the rate of cell proliferation, especially for cells that have the potential for mutations such as cancer cells. Besides, vitamin D can increase telomerase activity which is an enzyme that plays a role in maintaining telomere length<sup>23</sup>.

### Conclusion and Suggestion

The conclusion from the results of this study there is a relationship between serum 25 (OH) D levels with the telomere length of the Minangkabau ethnic premenopausal women. Every 1 ng/ml increase in serum 25 (OH) D levels slowed the telomere shortening to 0.583 bp. Women should increase their serum 25 (OH) D levels to slowed the telomere shortening.

# The Dynamics of Budget Fulfillment Policy in the Implementation of Minimum Service Standards in the Health Sector at Community Health Centers (Case Study in Sleman and Magelang Regencies, Indonesia)

Sunarto<sup>1</sup>, Mukti, A.G<sup>2</sup>, Pramusinto A.<sup>3</sup>

<sup>1</sup>Students of Doctoral Study Program Faculty of Medicine, Public Health and Nursing Gadjah Mada University (UGM), Yogyakarta, Indonesia, <sup>2</sup>Department of public health, Faculty of Medicine, Public Health and Nursing UGM, Yogyakarta, Indonesia, <sup>3</sup>Department of Management and Public Policy, Faculty of Social and Political Sciences UGM, Yogyakarta

## Abstract

**Background:** Health is a basic need of every individual that must be met. The government is responsible for meeting the needs of public health services. Health service programs require adequate budget support. Central government budget policies tend to have differences in implementation between regions in implementing the Minimum Service Standards for Health Sector (MSS-HS) program.

**Research Objectives:** To determine the dynamics of budget fulfillment policies in the implementation of the MSS-HS in Sleman and Magelang Regencies.

**Research Method:** This research is qualitative research with a case study approach. Informants consist of officials or staff of local government who control information or influence policy making. Data collection techniques sourced from the study of policy documents, in-depth interviews, observation and focus group discussions by conducting triangulation. Results: Health budget policies in Sleman and Magelang districts were relatively similar, but differed in responding to regulations from the centre. The funding sources for the Community Health Centers (CHCs) in the two districts are different. CHCs in Sleman Regency come from Regional Public Service Agency (RPSA) funds, Health Operational Assistance and CHCs Operational Subsidies, while CHCs in Magelang District come from Health Operational Assistance and RPSA.

**Conclusion:** The implementation of the MSS-HS at the CHCs in Sleman and Magelang, in general there were no funding problems.

**Keywords:** Budget Policy, Minimum Service Standards for Health Sector, Local Government.

## Introduction

Health is a state of well-being that includes physical, mental and social as a whole, and not only free from

disease or weakness so that health is an important part of life<sup>[1]</sup>. Every Indonesian citizen has the right to receive health services<sup>[2]</sup>. The right to the highest health basis can be achieved based on a transparent, participatory, fair and balanced health system and attention to aspects of human rights<sup>[3]</sup>. Republic of Indonesia Law No. 23/2014 concerning Regional Government states that, among the six mandatory functions for Regional Government is health. Republic of Indonesia Law No. 36/2009 concerning Health confirms that efforts to implement health are based on the Minimum Service Standards in the Health Sector (MSS-HS). The law also stipulates

that the central government health budget is allocated at 5% of the APBN Expenditure outside the region and at 10% of the Regional Revenue Expenditures excluding salaries, and at least 2/3 of the health budget is used for public services.

Sleman and Magelang districts are districts in Java, Indonesia. At the time of this study, two districts in implementing health services in the Community Health Center (CHC) were guided by Minister of Health Regulation No. 43 of 2016 concerning MSS-HS. Each district/city has its own uniqueness and problems to meet the needs of public health services. Local governments use district head regulations that govern implementation to complement the 12 MSS-HS indicators regulated by the central government.

CHC is a technical implementation unit of the district health office that has the responsibility for health development in the sub-district area so that it becomes CHC. The implementation of health services in CHC is guided by MSS-HS which is set by the central government as the minimum standard of service obtained by the community. Implementation of health services in community health centers requires adequate budget support, to achieve the target indicators of success for SPM-HS<sup>[5]</sup>. Based on this background, researchers are interested in knowing the dynamics of the SPM-HS budget policy in Sleman and Magelang Regencies.

### **Research Method**

This research uses a qualitative method with a case study approach. This case study approach focuses on one particular object that is raised as a case to be explored in depth to open the reality behind the phenomenon<sup>[6]</sup>. This research was carried out in early to mid-2019 at several CHCs located in Sleman and Magelang Regencies. The data used are primary and secondary. Selection of informants in this study using purposive sampling. The informants were determined based on criteria, namely those who were more in control of information and authority in the policy of fulfilling the MSS-HS in Sleman and Magelang Regencies. Policymaking and design of budget fulfilment MSS-HS to achieve performance MSS-HS is a collective process that involves many parties (complex responsive process) so that the method chosen is qualitative and participatory because it is expected to understand the ongoing process in organizations involved in the budget process and the implementation of regulations on MSS-HS for

Health<sup>[7]</sup>. Secondary data of this study were taken from various documents from the CHCs. The data collection techniques include documentation for the same data source simultaneously and observation of passive participation, in-depth interviews and or FGD.

### **Research Result**

The health budget exceeds 10%, Sleman regency began in 2016 and Magelang since 2017. There was a significant increase compared to previous years. The financing of regional health services comes from various sources, including from (1) the State Revenue and Expenditure Budget (SREB); (2) District and provincial Regional Revenue and Expenditures Budgets (RREB); (3) deconcentration, and (4) other legitimate sources. The RREB is the annual financial plan of the regional government which is discussed and approved jointly by the regional government the Regional House of Representatives, and determined by regional regulations.

The sources of the health budget can be classified into four, namely: (1) special allocation funds (2) health operational assistance, (3) operational subsidies for CHCs, and (4) revenue funds for CHCs. Data on budget sources in Sleman and Magelang Regencies, in this report the researchers took the most complete information from the Gamping and Salaman CHCs. Based on this research it is known that the public health centre budget source is not much different, namely: Revenue Budget and State expenditures received annually in the form of health operational assistance obtained from genuine income from public health centres. CHCs in Sleman receive additional regional income and expenditure in the form of operational subsidies for CHCs. The Gamping CHCs is in accordance with the following informants.

“If there are three sources of funds here. Namely the RPSA the and the HOA. The CHCs Operasional Subsies are from the RREB ... Revenue or the RPSA then regional revenue or the CHCs Operasional Subsies or the Regional Expenditure Budget ... Then from the HOA “(Resource person).

CHCs in Magelang, another budget source CHCs that come from the RREB are not used for the development of CHCs but are given directly to civil servants CHCs staff as monthly salaries. The results of this study note that the largest budget source for public health centres comes from the RPSA. In 2018 the Gamping CHCs received a budget from the Health Operational Assistance (HOA) 19% the Operational subsidies for CHCs (8%),

and the RPSA (72%). In 2018 the Salaman CHCs the source of the budget consists of revenue from HOA (10%) and RPSA (90%). The Gamping CHCs receives revenue from the RPSA from the capitation of the Social Security Organizing Agency (SSOA), non-public social

security administering bodies, internships, bank interest, competition prizes and research. Whereas the Salaman CHCs receives a RPSA budget from the capitation of the SSOA, non-capitation and public services as well as inpatients for patients not registered with the SSOA.

Source: CHCs of Gamping and Salaman, 2019

Graph 1. Comparison of CHCs Revenues

Source of Gamping CHCs budget obtained from the operational subsidies for CHCs, HOA and RPSA, while Salaman CHCs budget comes from HOA and RPSA, both have increased every year. Each increased sharply when starting the national health insurance policy in 2014. Based on the amount of revenue the Gamping and Salaman CHCs have differences. The total income of the Salaman CHCs is greater than the Gamping. CHCs. This is because the Salaman CHCs is CHCs that has a larger capitation amount and is an inpatient CHCs.

CHCs allocates 14% the Salaman CHCs allocates 26% of the total MSS-HS program.

### Discussion

**General Health Budget Policy:** Implementing a MSS-HS policy requires adequate funding. Law of the Republic of Indonesia No. 23/2014 concerning Regional Government states that regional expenditure is prioritized to fund Mandatory Government Affairs related to basic services determined by MSS-HS<sup>[4]</sup>. Law of the Republic of Indonesia No. 25/2009 concerning Public Services states that the organizer is entitled to get a budget allocation in accordance with the level of service needs. The state must allocate an adequate budget through the State SREB or RREB.

Based on the use and allocation of the budget, it shows the different formats of budget policy and the concentration of budgeting. The format of the Gamping CHCs uses broad budgetary allocations the CHCs Salaman with more detailed allocations in each indicator. The concentration of the use of the second budget CHCs show a striking difference. In the indicator group of maternal and child health services the Gamping CHCs allocates 38%, while Salaman allocates 59% of all MSS programs. In the indicator group for elderly and mental disorders the Gamping CHCs allocates 27%, while Salaman allocates 1%. In the indicator group of basic and productive age education services the Gamping

Some health budget sources, namely: first is a special allocation fund. Special allocation funds are funds allocated by the government at 5% of the SREB for health sector development. The 2016 special health allocation fund consists of physical special allocation funds used to increase access to basic health services, referral health services, and pharmaceutical services.

And non-physical specific allocations used to fund HOA, drugs and logistics, Family Planning programs, CHCs accreditation, hospital accreditation, and Delivery Assurance. The special allocation fund in the field of health is not the main fund in the implementation of health development in the regions.

The second source of the budget is the HOA fund. HOA is part of the special non-physical allocation fund in the health sector that funds priority programs in the health sector, using a minimum of 60% of the total HOA fund allocation for CHCs and other health programs. Where as the management of CHCs uses a maximum of 40% of the total allocation of funds for the operations of the CHCs for public health. The third is the source of operational subsidies for CHCs, originating from the RREB which is lowered by the regional government used to finance Public Health Efforts activities to strengthen the promotive and preventive sides.

The fourth source of funding is income from the CHCs in the form of capitation funds. According to the Minister of Health Regulation No. 21/2016 concerning the use of the national health insurance capitation fund, it is stated that capitation funds are monthly payment amounts paid in advance to first level health facilities based on the number of registered participants regardless of the type and number of health services provided. All capitation funds are used to pay for health services at least 60% and support operational costs for health services up to 40%. More capitation funds are used for efforts to improve individual health services.

The national health insurance for Indonesian people implemented a tiered health service system. This tiered health service system causes the decentralization of health services so that health services are concentrated in primary services such as CHCs and family doctors. This has resulted in a significant increase in the number of patients visiting primary care centres such as CHCs. The challenges in changing the health system include the decentralization of services that led to the need for the development of Human Resources to fill new posts in health care<sup>[8]</sup>. In research related to health care reform in the UK the decentralization of health services can lead to increased data requirements and labour costs<sup>[9]</sup>. In the era of National Health Insurance, synergy is needed related to financing and human resources.

RPSA is a regional apparatus work unit formed in regional governments to provide services to the

community in the form of goods and or services without expecting profit and in carrying out their duties upholding efficiency and productivity. Financial management patterns of RPSA are management patterns that provide flexibility in the form of flexibility to implement sound business practices to improve services to the community to advance public welfare and educate the nation's life as an exception to the provisions of regional financial management in general<sup>[8]</sup>. The Government of Sleman and Magelang Regencies have implemented the RPSA system so that the public health centres in both districts have their authority in managing their finances. The management of the system of RPSA in Sleman and Magelang Regencies is regulated in Regulations of the Regent<sup>[8][9]</sup>.

According to research in Pekalongan, it is known that the advantage of using the RPSA system is that the CHCs can independently manage the management system so that it can develop according to the characteristics of the region<sup>[10]</sup>. The concept of independence in the management of the CHCs RPSA for the better. The research has similarities with CHCs in the two districts which are the CHCs of the RPSA.

The HOA budget is used for activities that are community health efforts so that the allocation of HOA funds to the CHCs is mostly for the MSS-HC Program. In this study, it is seen that the comparison of budget allocations for HOA in the two CHCs the indicators of maternal and child health programs get the highest budget allocation, 38% and 33% while the indicators of health services for people with Tuberculosis and HIV have a low allocation of 6%-9% of the total budget allocation for MSS-HC. The amount of budget allocation can affect the achievement of the MSS-HC program indicators. If the budget allocation is adequate the implementation of the MSS-HC program will be more optimal which will impact on the achievement of the target indicators for the MSS-HC standard. Low budget allocation for indicators of health services for people with tuberculosis and HIV can be a factor in the low achievement of these indicators.

**Achievement of MSS-HC Indicators of CHCs:**  
To define the successes and failures of policy, several components are needed, among others, first the evaluation of policies to measure program achievements with initial targets. Second, related to public values that emphasize the role of bureaucracy. Third the process of policymaking and management must be done well.

Fourth, related to political aspects and fifth, an explicit treatment of policies that can determine whether policies will succeed or fail<sup>[11]</sup>.

Both districts have implemented a MSS-HC development policy. This shows that the decentralization of health services has paid attention to aspects of regional health security. Based on field data the two CHCs show that the results indicators with high achievements according to the target of 100% are indicators of maternal and child health and health services of people with severe mental disorders. While indicators that have low performance are health services for people with TB, 46% and 37.78%, respectively. Based on the allocation and achievement of the indicators, it shows that the budget is quite influential on the success of program outcome indicators. One parameter for assessing the success of a policy is to assess the success of the program through its indicators, such as. operational indicators, outcome indicators, resource indicators, and actor indicators<sup>[12]</sup>.

### Conclusion

The dynamics of budget policies to meet the needs of MSS-HC standards can affect the success or failure of the achievement of each indicator. After decentralization the fulfilment of the health budget depends on the policies of each region. The Sleman district government has allocated operational subsidies for the CHCs to support the achievement of minimum service targets in the CHCs, Magelang district. Since the national health insurance came into effect the revenue of the CHCs has risen sharply. In the MSS-HC, adjustments are made to budget allocations at the local level or CHCs.

## Abstract

The aerobic dance leaders who high level of knowledge are very important to encourage and support people to be able to do aerobic dance continuously. Therefore the aerobic dance leaders should advise people on how to do aerobic dance correctly according to the principles of exercise. However, some aerobic dance leaders had insufficient knowledge on aerobic dance. The purpose of this research was to develop of aerobic dance leaders training program and to evaluate the effectiveness of the training program. The volunteers 30 people. It is action research including: phase 1 the development of aerobic dance leaders training program, phase 2 the training program for aerobic dance leaders, and phase 3 the aerobic dance leading in communities for 8 weeks. It found that phase 1 the development of aerobic dance leaders training program had CVI is 0.93. Phase 2 the knowledge in aerobic dance of participants has been increased the aerobic dance leadership the self-efficacy and outcome expectations were also increased. Phase 3 the overall physical fitness of male and female participants in aerobic dance was better the self-efficacy and outcome expectations were also increased and ability to be aerobic dance leaders in overall is at a very good level. Conclusion the training program for aerobic dance leaders was able to develop people who have never been aerobic dance leaders before to be aerobic dance leaders in the communit.

**Keywords:** Aerobic dance leaders training program, aerobic dance leadership, self-efficacy, outcome expectations.

## Introduction

If people do not have enough physical activities, it would be the main cause of death from non-communicable diseases.<sup>1</sup> Not having enough physical activities was a risk factor for deaths and incurred health expenses.<sup>2</sup> Over the past 10 years, one in three of Thai people have had insufficient physical activities. Aerobic dance exercise that is very popular. In Thailand, many organizations have campaigns for people to pay attention to their health with aerobic dance exercise such as department stores, and parks or even in the government and private sectors.

The good exercise leaders should inform knowledge in exercise to people properly according to the principles of exercise. However, it found that aerobic dance leaders in the community studied and learned aerobic dance from the purchased videotape by themselves<sup>3</sup>, so there is the raising of questions on what the quality of aerobic dance leaders is.

The purpose of this study was to develop the aerobic dance leaders training program, assess knowledge and ability to be aerobic dance leaders, self-efficacy and outcome expectations of being aerobic dance leaders. It also included follow up on the results of being aerobic dance leaders in the community by evaluating knowledge and ability of being a dance leader, physical fitness, self-efficacy, and outcome expectations for aerobic dance of the people who came to aerobic dance.

## Method

This research is the action research which is divided into 3 phases below.

**Phase 1: The development of the aerobic dance leaders training program:** The researcher submitted the aerobic dance leaders training program to 3 experts in order to evaluate the content validity index (CVI). The research consisted of two main tools including the questionnaire for participants in the aerobic dance leaders training program (aerobic dance leadership, self-efficacy and outcome expectations, evaluation test on knowledge) and the questionnaire for participants in aerobic dance (aerobic dance leadership, self-efficacy and outcome expectations, physical fitness tests).

**Phase 2: The aerobic dance leaders training program:** The sample group was the undergraduate students from 3 departments including sport sciences, public health, and physical education at Roi Et Rajabhat University for 30 people calculated using WINPEPI Course Version 11.65 and added the size of sample for 20% to protect the withdrawal of sample group during the experiment. The inclusion criteria was that the participants haven't been aerobic dance leaders before, and the exclusion criteria was that the participants couldn't attend the research study as the schedule. Before and after training the sample answer questionnaire on aerobic dance leadership, self-efficacy and outcome expectations and evaluation test on knowledge in aerobic dance. The sample group attended the aerobic dance leaders training program for 20 hours.

**Phase 3: The aerobic dance leading in community:** The who passed the aerobic dance leaders training program will lead aerobic dance to people in the community. Before and after training the participants will be tested for physical fitness from the lecturer team from the Department of Sports Science, Roi Et Rajabhat University and answer questionnaires on self-efficacy, outcome expectations, and aerobic dance leadership. The aerobic dance leaders will lead aerobic dance to people in the community for an hour per day, 3 days per week within 8 weeks.

**Statistics:** Testing the differences within the group by analyzing the differences, using a pair t-test by SPSS Statistics 19.0 for Windows.

### Results

**Phase 1: The development of aerobic dance leaders training program:** The inspection results of the aerobic dance leaders training program outline were found that the CVI was 0.93.

**Phase 2: The aerobic dance leaders training program:** It was found that the trainees increased knowledge in aerobic dance ( $p < .000$ ), increased ability to be an aerobic dance leader ( $p < .001$ ), and increased self-efficacy ( $p < .002$ ) and outcome expectations ( $p < .000$ ) as shown in table 1.

**Table 1: The evaluation analysis of the aerobic dance leaders training program.**

Variables	$\bar{X}$	S.D.	95%CI	t	p-value
<b>Knowledge of dance aerobics</b>					
Pre-test	16.37	2.03	-3.89 to -2.25	-7.65	<.001***
Post-test	19.43	2.31			
<b>Ability to be an aerobic dance leader</b>					
Pre-test	3.33	.72	-.87 to -.35	-4.74	.001**
Post-test	3.94	.42			
<b>Self-efficacy</b>					
Pre-test	3.70	.58	-.57 to -.15	-3.50	.002**
Post-test	4.07	.40			
<b>Outcome Expectation</b>					
Pre-test	3.38	.58	-.91 to -.45	-6.07	<.001***
Post-test	4.06	.39			

**Note:** P-values are results of pair t-test for variables of knowledge of dance aerobics, ability to be an aerobic dance leader, self-efficacy, and outcome expectation. \*  $p < .05$ ., \*\*  $p < .01$ ., \*\*\*  $p < .001$ .

**Table 2: The evaluation analysis of people who came to do aerobic dance.**

Variables	$\bar{X}$	S. D.	95%CI	t	p-value
<b>Self-efficacy</b>					
Pre-test	42	3.7	-1.48 to -.37	-3.26	.001**
Post-test	42.92	3.57			
<b>Outcome Expectation</b>					
Pre-test	42.16	3.20	-1.60 to -.67	-4.79	<.001***

## Discussion and Conclusion

**Phase 1: The development of the aerobic dance leaders training program:** It was found that the content validity in CVI is 0.93. It shows that the components, principles and reasons, objectives, content, measurement and evaluation activities of the program outline are appropriate and passed all components. After the training program, had theoretical knowledge and practice. There is also an exchange of learning experience of aerobic dance leaders in order to encourage learners to have more experiences and support the trainees to apply the theoretical knowledge into the practice. Which the program should be designed by the participants themselves so that the program will be in line with the needs of the trainees and have training in the things that they can actually apply.<sup>4,5,6,7,8</sup>

**Phase 2: The aerobic dance leaders training program:**

- 2.1 The knowledge in aerobic dance, it was found that after the training program had more knowledge in aerobic dance with the statistical significance. The developed training program helped the trainees have knowledge and understand about dancing and aerobic dance leadership as well as movement skills and aerobic dance. However the exercise leaders should have knowledge about the test of physical fitness and suggest method and techniques for proper exercise to prevent injuries that may occur.<sup>9</sup>
- 2.2 The aerobic dance leadership, it was found that after the training program had more aerobic dance leadership with the statistical significance as the trainees participated and performed various activities by participatory training and from follow-up after training. Which the exercise and sports leaders promoted greater participation in sports and exercise which had an effect on the members' health.<sup>10,11</sup>
- 2.3 The self-efficacy, it was found that after the training program had more self-efficacy with the statistical significance. The trainees in the aerobic dance leaders training program received of the development of self-efficacy according to Bandura's concept.<sup>12</sup> This method will result in the changes of behaviors positively and determines the exercise goals and increase exercise.<sup>13</sup>
- 2.4 The outcome expectations, it was found that after the training program had more outcome expectations

with the statistical significance. In this research the trainees had high self-efficacy this also leads to increase the outcome expectations.<sup>14,15</sup> It's due to the training program for aerobic dance leaders provided knowledge, advice about aerobic dance leaders and exchanged learning together. There was practical training to gain confidence and able to be an aerobic dance leader.

**Phase 3: The aerobic dance leading in communities:**

- 3.1 The physical fitness of the people who came to aerobic dance, found that all lists of physical fitness test have been improved after training in which female participants. For male, found that the VO<sub>2</sub>max was increased, grip strengths and leg strengths as well as vital capacity higher than before aerobic dance. It shows that the results were caused by the aerobic dance that uses energy, and there are movements for both the upper and lower parts of the body. Which, it increases the heart rate and muscle functions and the subcutaneous fat was reduced, so it increases the endurance performance of the respiratory and circulatory systems, this may be a result of increased nervous system function. Therefore, aerobic dance program as a suitable program for losing weight and the development of aerobic abilities.<sup>19</sup>
- 3.2 The self-efficacy, it was found that after aerobic dance had more self-efficacy with the statistical significance. It may be the results used method of the development of self-efficacy according to Bandura's concept as follow:<sup>12</sup> used inspirational and persuasive words to show that everyone can be an aerobic dance leader, see other people's experiences by the role model from the people who came to aerobic dance, used emotional stimulation by talking to reduce anxiety and use simulation scenarios to reduce their stress,<sup>20</sup> and use of successful experiences. These method will result in the changes of behaviors positively.<sup>21</sup>
- 3.3 The outcome expectations, it was found that after aerobic dance had more outcome expectations with the statistical significance. It can be seen that the aerobic dance people knew the positive effects of aerobic dance and increased self-efficacy in exercise, so it is the factor that encouraged aerobic people to expect the outcome of aerobic dance increasingly.<sup>15, 22</sup> The outcome expectations in aerobic dance can

explain exercise behaviors. It also included a short-term goals such as doing aerobic dance will help you have better health with a better shape or weight loss in order to encourage people who came to exercise can do aerobic exercise regularly and sustainably.

3.4 The who passed the aerobic dance leaders training program had knowledge and can be an aerobic dance leaders in their community, it was found that had aerobic dance leaders at a very good level. Being a good aerobic dance leader the dance leaders should have basic knowledge of correct aerobic dance, be able to provide first aid and be a good example of health care.<sup>11</sup> This is for the benefits and safety of those who do exercise.<sup>23</sup>

### Conclusion

It can be seen that the tools for the training program the researcher have created can be used as the aerobic dance leaders training program and the trainees who passed the training course have the ability to be aerobic dance leaders.

## Abstract

The purpose of this pilot study is to investigate the impact of sport centre facilities (teamsport) usage towards mental health among university's students. Fifty-nine students from different majors have participated in this study. This study adopted a quantitative approach using the survey for collecting data. The data was analyzed using SPSS 23.0. Analyses involved frequency, percentage, score level, correlation and regression. The results demonstrated that the reliability test for Sport Centre Facilities Inventory ( $\alpha = 0.722$ ) and Mental Health Scale ( $\alpha = 0.831$ ) were acceptable. The level score of satisfaction for sport centre facilities among students showed that more than 50% (37 participants) considered the facilities provided by sport centre were moderate. The level of mental health found high. There was a positive correlation between the quantity of the facilities for teamsport ( $r=0.284$ ,  $p<0.05$ ) and mental health. However there were no significant relationships between variety of the facilities for teamsport and mental health. The regression analysis showed that the contribution of teamsport facilities on mental health student was 18.5% ( $R^2 = 0.185$ ). The findings have implications for future research regarding the instrumentation and the usage enhancement of facilities for the better results of mental health of students.

**Keywords:** *Teamsport, mental health, student, sport facilities.*

## Introduction

In the university, Sports Centre is a unit entrusted to enhance the level of health and wellbeing of students<sup>12</sup>. The Sports Centre usually provides facilities for a variety of sports such as individual sports and teamsport. The current study is focusing on teamsport which can be defined as a sport that involves two or more players and shares the same goal<sup>1</sup>. It is believed that with adequate facilities, students can fulfil their leisure time and improve their physical, emotional and mental

health<sup>8</sup>. Further, teamsport is a good alternative among most fitness exercises because of its extensive health effects such as improving cardiac health and reducing blood pressure<sup>7</sup>. In addition to physical health effects, teamsport activities can also help overcome mental health problems such as loneliness or lack of socializing skills. For example, teamsport such as a tennis game can assist in controlling the feeling of anger and disappointment<sup>10</sup>. Besides the research also found that taking part in sport activities led to a physiological adaptation such as respiratory adaptation, musculoskeletal, cardiovascular and hormone so as to encourage individual capability in increasing physical and mental tolerance and eventually prevents the occurrence of mental disorder<sup>8</sup>. Research also showed the direct association of sports benefits to mental health among students where there is consistent evidence that participation in teamsport can enhance social and psychological health<sup>3</sup>. However, recent studies found that university students were riskier with mental health problems than those in the general population or

e-mail: suzyla@uum.edu.my

other individual groups<sup>4</sup>. The study report also showed the probability of graduate students suffering from depression and panic were six times higher than the general population. Therefore, this study attempts to investigate whether involvement in teamsport have any impact towards mental health.

## Method

This is a quantitative study that involved survey using questionnaires. The following is the description of the methodology of this study.

**Participants:** The participants of the study were opportunity sample, which consisted of students in Universiti Utara Malaysia (UUM). In order to be eligible to participate in this study the participants must be involved in at least one of the teamsport activities at the UUM Sports Centre.

**Sample:** The pilot test involved 59 undergraduate and postgraduate students that have used the teamsport facilities in UUM's Sport Centre. The sample of this study also focused on student's involvement in team sports such as hockey, softball, futsal, and basketball.

**Instruments:** All the measures in the questionnaire used two versions; Malay and English. The questionnaire is divided into three parts; A, B and C. Part A was focusing on personal information, such as age, gender and types of teamsport activities involved. Part B contained five items about the usage of teamsport facilities, for example, "*Variety of the facilities for teamsport are well adequate at the Sport Center*" in five points scale from strongly disagree to strongly agree. Higher score in these items indicated higher levels of satisfaction towards team sports facilities. This instrument was adapted from the questionnaire of the use of sports facilities by Hong Kong University of Science and Technology. The reliability of this instrument was satisfactory with 0.72. Part C contained twelve items adapted from the General Health Questionnaire (GHQ-12)<sup>5</sup>. This instrument measured the wellness of psychological and to identify individuals with higher risk of developing psychiatric disorders, such as particular symptom and behaviour they experienced recently. This also includes psychological problems of depression, anxiety and social withdrawal. The example of these items was "*able to concentrate*" and "*losing confidence*". Each item was rated on a five-point scale from strongly disagree to strongly agree. The total score of GHQ-12 was 60 with higher score indicates greater psychological problems. The reliability

of this instrument is 0.83 Cronbach Alpha.

Since there were no available Malay version of the usage of teamsport facilities and GHQ-12, this pilot study applied a back-to-back translation procedure from English-Malay-English for both instruments. Two independent language professionals first translated this questionnaire into Malay. Then, another two independent translators subsequently back translated all the items into English. The original and the back-translated English version were compared to identify any differences of items before finally providing a final version.

**Procedure:** This study used cross-sectional and correlational design. All the data in this study was collected in April 2019 at UUM Sport Centre. The data collection was conducted by a trained research assistant (RA), who was then distributed packs of questionnaires to the teamsport participants. The RA then waited for the participants to complete the questionnaires and attended any questions from the participants.

**Data Analysis:** The data from 59 respondents was analyzed using Statistical Package for Social Sciences (23.0). We first used mean score to examine the participants' information. Cronbach's alpha coefficients were then calculated to examine the internal consistency of two questionnaires. Moreover, this study conducted two main analyses; correlation and regression. Correlation was conducted to observe the relationships between the usage of teamsport facilities and mental health while regression was done to examine the impact of usage of team sports facilities towards mental health.

## Results

**Reliability of the Instruments:** The reliability test for all scales were acceptable as shown in Table 1.

**Table 1: Result of reliability test for the research instruments**

Instrument	Cronbach Alpha Value ( $\alpha$ )
Sport Centre Facilities	0.722
Mental Health	0.831

**Demographic Data of Participants:** The demographic information was presented in Table 2. Overall there were 24 males (40.7 %) and 35 females (59.3 %). Most of the participants were aged between 21 to 25 years old (55 participants) and only 3 participants aged between 17 to 20 years old. Participants in this study consists of 57 undergraduate students (96.6 %)

and 2 post-graduate students (0.4 %). There were four types of teamsport involved which were hockey - 25 students (42.4%), softball - 15 students (25.4%), futsal - 10 students (16.9%) and basketball - 9 students (15.3%).

**Table 2: Demographic Information of the Participants**

Demographic Information		Frequency (f)	Percentage (%)
Gender	Male	24	40.7
	Female	35	59.3
Age	17-20	3	5.1
	21-25	55	93.2
	26-30	0	0
	31-35	0	0
	36-40	1	1.7
Teamsport	Hockey	25	42.4
	Softball	15	25.4
	Basketball	9	15.3
	Futsal	10	16.9
Types of Student	Undergraduate	57	96.6
	Post-graduate	2	3.4

**Level of Sport Centre Facilities and Mental Health:**

**a. Level of sport centre facilities satisfaction:** The findings revealed that the level of sport centre facilities were low and moderate. More than 50% (37 participants) considered the facilities provided by sport centre as moderate. The summary of the result was depicted in Table 3.

**Table 3: Level of sport centre facilities satisfaction**

Level of Sport Centre Facilities	f	Percent (%)
Low	22	37.3
Moderate	37	62.7
High	0	0
<b>Total</b>	<b>59</b>	<b>100</b>

**b. Level of Mental Health:** Table 4 displayed percentage of participants found with high level of mental health. Only 10 participants were identified at the moderate level.

**Table 4: Level of Mental Health**

Level of Mental Health	f	Percent (%)
Low	0	0
Moderate	10	16.9
High	49	83.1
<b>Total</b>	<b>59</b>	<b>100</b>

**The relationship between sport centre facilities and mental health:** Table 5 displayed the correlation between sport centre facilities and mental health among participants in this study. Mean scores found to be moderate on the quantity of the facilities for teamsport, variety of the facilities for team sports, lighting glare, toilet and changing room and the services provided by staff at sports centre. There was a positive relationship between quantity of the facilities for teamsport ( $r=0.284$ ,  $p<0.05$ ), cleanliness of toilet and changing room (0.271,  $p<0.05$ ) the services given by the staffs (0.273,  $p<0.05$ ) and mental health. However there was no significant relationship between variety of the facilities for teamsport and mental health. Results also found that there were no significant relationships between the lighting glare at the sport centre and mental health. Overall the results in this study showed positive correlation between sport centre facilities and mental health levels.

**Table 5: Correlation between sport centre facilities and mental health**

No.	Variables	Mean	SD	Mental Health (r)	Sig.
1	Quantity of the facilities for teamsport are well adequate at the Sport Center	3.4237	0.98617	0.284*	0.029
2	Variety of the facilities for teamsport are well adequate at the Sport Center	3.4237	0.87501	0.004	0.976
3	Lighting glare at the Sport Center are satisfied	3.6271	0.90779	0.006	0.963
4	Toilet and changing rooms cleanness are satisfied	3.8814	0.69691	0.271*	0.038
5	The services given by the staff at the Sport Center are good	3.8814	0.74475	0.273*	0.037

\*Correlation is significant at the 0.05 level (2-tailed).

**Effect of sport centre facilities on mental health levels:** The linear regression was used to identify the effect of sport centre facilities on mental health among students. The results in Table 6 demonstrated five dimensions of teamsport facilities that could contribute

to the mental health among participants. The regression analysis showed that the value of r square was 0.185 which indicated that the contribution of teamsport facilities on mental health was 18.5%.

**Table 6: The effect of sport centre facilities on mental health**

Variables	Standardized coefficients Beta (β)	Sig.	R <sup>2</sup>
Quantity of the facilities for teamsport are well adequate at the Sport Center	0.274	0.150	0.185
Variety of the facilities for teamsport are well adequate at the Sport Center	-0.222	0.150	
Lighting glare at the Sport Center are satisfied	-0.150	0.275	
Toilet and changing rooms cleanliness are satisfied	0.236	0.089	
The services given by the staff at the Sport Center are good	0.166	0.336	

### Discussion

According to the results, it is shown that the new version of the instruments demonstrated a high internal consistency. Both instruments have strong reliability in the range of 0.70 to 0.80. The study has established a psychometrically sound measure for Malaysian in regards to the use of sport facilities and mental health for university student’s population. Both instruments were well-translated from English into Malay Language which employed a back-to back translation procedure. It is valid and reliable measure to use in the future studies. Also, it was a breakthrough study with all items in Malay Language that can be used particularly in the area of teamsport and mental health at the university. In addition these instruments may be used for some South East Asian Countries such as Singapore, Indonesian, Brunei and Timor Leste. These countries are normally using Malay language as a medium of communication

with the community and it is understandable to them. The new Malay Version instruments can be used as tools for future studies to measure the students’ satisfaction in sport activity and college mental health across the region.

Moreover the students which participated in teamsport at university sports centre showed a good standing mental health levels and a moderate level of students that used sport facilities at the university. However the results displayed a moderate relationship between the two variables the value is still acceptable to observe and discuss the connections between the usage of the facilities and mental health dimensions. In other words, if students were actively participating the teamsport activities, it may result the good levels of psychological well-being of the students. To sustain psychological wellbeing of the students, this potentially could be a reason for the university administrations to

make extra efforts on encouraging sport events, especially teamsport games at the university and improving sport facilities and engagements with students. It is worth to discuss in further since the involvement in sports and recreational activities has numerous positive effects on emotional wellbeing among teenager groups<sup>11</sup>. Some studies have proved that when people always engaging to sports and physical activities, it may help people to control emotions, manage dysfunctional behaviors and reduce suicidal thoughts<sup>2,9</sup>. It makes this topic invaluable to study as it is certainly show unique relations to the human awareness to stay healthy.

In addition to the study the effects between the use of sports center and mental health among UUM students demonstrated a very small effect. The result is not quite promising and it may cause due to other personal factors such as the students' intention to sporting the frequency of attending the sport centre, and talent and interest in one particular teamsport. It may produce different results if the students are attending the sport center for the purpose of socializing, coping with stress, and improving self-confidence. For future studies, it is desirable to investigate about the human motivation and emotion when participating in the teamsports as a preferable choice for their recreational pursuits. Many people are unaware that physical activity during sports may amplify the aspects of psychosocial health, especially on the teamsport which involve group work in the game. Certainly, joint activity and work together as a group or team members could promote a better way to get healthier than individual activities while considering the nature of the social participation<sup>3</sup>. A mutual participation in the team members will encourage the sport spirits, commitment and attitude to win the game than individual participation which focuses on personal goals with no interactions during the game<sup>1</sup>. Surprisingly, participation in teamsport activities were associated with a good intervention to control substance and alcohol addictions<sup>6</sup>. Attending sport activity is exceptional for university students to prevent them from the addiction behaviors which may lead them to poor academic performances and dropout from the schools.

In conclusion, this pilot study provides some directions and information for future studies. It is also an effort to link between students who are engaged with teamsports and their coping strategies to predict from mental health issues. It is hope that students will engage more in the teamsport as their coping strategies to avert them from the illnesses. In the future the researchers

suggested that more studies could be conducted to bridge the gaps between sports facilities, particularly in teamsport in relation to university students' mental health. Also, it will develop effective strategies and approaches to motivate university students for participating in the teamsport at the university levels.

**Conflict of Interest Statement:** The authors declare that they have no conflict of interest.

**Source of Funding:** This paper was supported by Development and Ecosystem Research Grant Scheme (DEcoR) Universiti Utara Malaysia, Sintok, Kedah, Malaysia.

**Ethical Clearance:** Research committee approval was obtained.

# The Relationship between Adolescent Pregnancy and Stunting among Toddlers Aged 12-36 Months in Bogor District, Indonesia

Syamsul Ma'arif<sup>1</sup>, Ratna Djuwita<sup>1</sup>

<sup>1</sup>*Department of Epidemiology, Faculty of Public Health, University of Indonesia*

## Abstract

**Background:** Stunting is a serious problem that needs to be handled both in Indonesia and globally. Approximately 151 million, or 22.2%, of toddlers in the world are currently stunted. The purpose of this study is to assess the relationship between adolescent pregnancy and stunting in toddlers aged 12-36 months in Bogor District, Indonesia.

**Method:** A cross-sectional study design was employed, with primary data from a total sample of 500 toddlers in the District. Stunting status was assessed based on the height-for-age indicator  $<-2$  z-score, while the categorization of adolescent pregnancies related to pregnant women age  $<20$  years. The analysis of the relationship between adolescent pregnancies and stunting applied multivariate Cox regression analysis and the effect is expressed by the prevalence ratio (PR) with a 95% confidence interval (CI).

**Result:** Our study shows that the prevalence of stunting in toddlers aged 12-36 months in Bogor District is 39.2%. The Cox regression test results of the relationship between adolescent pregnancy and stunting show a PR of 1.42 (95% CI: 1.01-1.98), which means that pregnant women who are still teenagers ( $<20$  years) display a prevalence of stunted toddlers 1.4 times higher than those who are adult ( $\geq 20$  years), after being controlled by the “mother’s education” and “mother’s parenting pattern” variables.

**Conclusion:** Stunting can be prevented by raising the maternal gestational age by increasing the minimum marriage age in accordance with Indonesian marriage law limitations at age of 19 years and get first time pregnant at age of 20 years.

**Keywords:** *Stunting, 12–36 months, Toddlers, Adolescent Pregnancy, Bogor District Indonesia.*

## Introduction

Stunting is a problem that must be prevented given its very broad impact. The most serious impacts are a decrease in children’s intelligence level, vulnerability to disease, a decline in productivity and reduced economic growth, which ultimately increase poverty in Indonesia<sup>1</sup>. In more detail the impacts of stunting are divided into

short- and long-term effects. Short-term impacts include decreased cognitive abilities, motor skills and language development, as well as increased morbidity and mortality, while examples of long-term ones are declining reproductive health, small stature when adult, obesity, decreased learning ability and reduced productivity and work capacity<sup>2</sup>. Stunting in toddlers is a serious problem in Indonesia. The prevalence of stunting in the world in children aged below five has reached 22.2%, or about 151 million toddlers<sup>3</sup>. Basic Health Research 2018 reported that the prevalence of stunting in toddlers in Indonesia in 2018 had reached 30.8%<sup>4</sup>. Similar results from the Monitoring Nutritional Status (PSG) survey conducted by the Director of Public Nutrition of the Indonesian

---

University of Indonesia

e-mail: djuwita257@gmail.com

Ministry of Health show that the prevalence of stunting in Indonesia increased from 29% in 2015 and 27.5% in 2016, to 29.6% in 2017<sup>5,6,7</sup>. One of the provinces in Indonesia that has a high prevalence of stunting is West Java, with a significant increase in cases from 25.1% in 2016 to 29.2% in 2017<sup>6,7</sup>. One District in West Java with a high number of stunting cases is Bogor, at 28.5%<sup>7</sup>.

Factors causing stunting are grouped into three categories: immediate causes, underlying causes and basic causes. Basic causes are a result of aspects of the quantity and quality of human resources, such as caregiver education, social economic status and adolescent pregnancy<sup>8</sup>. Adolescent pregnancy has adverse effects on the mother's reproductive health; the nutritional adequacy condition of mothers who are still teenagers is not optimal to deal with pregnancy, leading to the risk of higher anthropometric failure, such as stunted growth of the child at birth<sup>8,9</sup>. Teenagers are at a vulnerable age in terms of education level, knowledge and the parenting of mothers of their children. A lack of these skills can lead to insufficient nutritional intake amongst toddlers and ultimately result in stunting. This study is highly recommended to look at the relationship between adolescent pregnancy and stunting among toddlers and to reach important conclusions in the efforts to reduce stunting in Indonesia.

## Method

The type of research is a cross sectional design<sup>10</sup>, using primary data taken from Tamansari District, Bogor District, Indonesia which was chosen as one of the districts with the highest prevalence of stunting. Tamansari has three community health centers, with 111 posyandu (integrated service posts)<sup>11</sup>. 46 of these were selected as sampling locations because of their active and routine carrying out of activities compared to other posyandu<sup>12</sup>. The study population was 10,447 toddlers aged 12-36 months<sup>12</sup>, and the research sample 500 toddlers aged 12-36 months from 46 posyandu in Tamansari district, that were randomly probability proportional to size (PPS). The inclusion criteria were the availability of complete data according to the variables to be studied, that the toddlers lived with their parents, and had lived at the research area for at least one year. We excluded toddlers with abnormalities (disabilities), which hampered the process of anthropometric measurement, and mothers who refused to participate. Data collection was conducted from 2 to 18 July 2019 using questionnaires and by recruiting trained enumerators from Nutrition and Epidemiology Master's students. The data collected were

verified by checking the instrument that has been filled in. The dependent variable was stunting status, while the independent variable was adolescent pregnancy, with the birth weight of toddlers, parents' income, mother's education, mother's parenting pattern, body mass index, and calorie and protein intake covariate. Anthropometric data for toddler height were measured using a Length Measuring Board (LMB) for those aged 12-24 months, and a microtoise for those aged 25-36 months. Toddlers' age data were obtained by checking birth certificates or maternal and child health books (MCH), while calorie intake data were based on a 24 hour recall questionnaire. Data on the age of adolescent pregnant mothers were obtained from the MCH handbook. Other data for the covariate variables were obtained from interviews using questionnaires. Data analysis was performed using the Stata program (v.13, StataCorp). Determination of stunting status was based on height-for-age z-scores using WHO Anthro software; calorie and protein intake status was based on Nutrisurvey software; and data on adolescent pregnancy variables were grouped into two categories, namely adult pregnancy if pregnant at age  $\geq 20$  years, and adolescent pregnancy if pregnant at age  $< 20$  years. Relationship analysis of the independent and dependent variables employed multivariate Cox regression analysis, and the interpretation of the effects was expressed by PR and a confidence interval of 95%<sup>13</sup>.

## Results

**Table 1. Characteristics of the study sample**

Variable	Frekuensi n=500	Proportion (%)
<b>Stunting Status</b>		
Stunting	196	39.2
Normal	304	60.8
<b>Adolescent Pregnancy</b>		
Adolescent Pregnancy (age <20 years)	81	16.2
Adult Pregnancy (age $\geq 20$ years)	419	83.8
<b>Toddler's Birth Weight</b>		
LBW	49	9.80
Normal	451	90.2
<b>Parents' Income</b>		
Low (<2 million rupiah)	177	35.4
High ( $\geq 2$ million rupiah)	323	64.6
<b>Mother's Education</b>		
Elementary School	262	52.4
Junior High School	114	22.8
Senior High School	115	23.0
University or College	9	1.8

Variable	Frekuensi n=500	Proportion (%)
<b>Mother's Parenting Pattern</b>		
Bad	277	55.4
Good	223	44.6
<b>Maternal Body Mass Index</b>		
Underweight (BMI <17.0)	54	10.8
Normal (BMI 18.5.0-25.0)	295	59.0
Overweight (BMI >25.0)	151	30.2
<b>Toddler's Calorie Intake</b>		
Poor	287	57.4
Satisfactory	213	42.6

Variable	Frekuensi n=500	Proportion (%)
<b>Toddler's Protein Intake</b>		
Poor	293	58.6
Satisfactory	207	41.4

The study involved 500 participants from Taman Sari District, Bogor District, Indonesia. Table 1 shows a description of the characteristics of some of the variables. The proportion of stunted toddlers aged 12-36 months was 39.20%, while the proportion of mothers who became pregnant in their teens was 16.20%.

**Table 2. Bivariate analysis of adolescent pregnancy with stunting in toddlers aged 12-36 months**

Variable	Stunting		Normal		Total	PR	95%CI	P-value
	n=500	%	n=500	%				
<b>Adolescent Pregnancy</b>								
Adolescent Pregnancy (age <20)	47	58.02	34	41.98	81	1.63	(1.30-2.04)	0.0002*
Adult Pregnancy (age ≥20)	149	35.56	270	64.44	419	[ref]		

**Note:** PR = Prevalence Ratio; \*significant statistic  $p < 0.05$

Table 2 shows the bivariate analysis of adolescent pregnancy and stunting. The prevalence of mothers who had teenage pregnancies and stunted toddlers was 58.02%, while those without stunted toddlers was 41.98%. In comparison, adult pregnancies resulting in stunted toddlers was 35.56%, while those without

stunting was 64.44%. From the bivariate analysis the results have a PR value of 1.63, with p-value of  $0.0002 < 0.05$  (95% CI 1.30 – 2.04), which means that the prevalence of stunting in toddlers resulting from teenage pregnancies was 1.63 times higher than from adult pregnancies.

**Table 3. Full multivariate model**

Stunting Risk Factors	PR	95%CI	P-Value
Adolescent Pregnancy	1.41	1.00 – 1.98	0.048*
Parents' Income	1.28	0.95 – 1.71	0.099
Mother's Education	1.46	0.98 – 2.16	0.058
Toddler's Birth weight	1.41	0.94 – 2.11	0.090
Mother's Parenting pattern	1.41	1.04 – 1.90	0.025
Maternal Body Mass Index	1.14	0.90 – 0.44	0.254
Calorie Intake	1.02	0.68 – 1.51	0.911
Protein Intake	0.85	0.57 – 1.27	0.447

**Note:** PR = Prevalence Ratio; \*significant statistic  $p < 0.05$

Table 3 shows the full multivariate model consisting of the main variables, namely adolescent pregnancy and

the other covariate variables that have the potential to be confounders.

**Table 4. Final multivariate model**

Stunting Risk Factors	PR	95%CI	P-Value
Adolescent Pregnancy	1.42	1.01 – 1.98	0.042*
Mother's Education	1.53	1.04 – 2.25	0.031*
Mother's Parenting Pattern	1.42	1.05 – 1.91	0.021*

**Note:** PR = Prevalence Ratio; \*significant statistic  $p < 0.05$

The final multivariate model can be seen in Table 4 the PR result is 1.42 (95% CI 1.01-1.98), which means that the prevalence of stunting resulting from adolescent pregnancy is 1.42 times higher than that from adult pregnancy, after being controlled by the “mother’s education” and “mother’s parenting pattern” variables.

### Discussion

From this cross-sectional study, we have evaluated that adolescent pregnancies, controlled by mother’s education and parenting pattern, pose a significant risk of stunting in Bogor District, West Java, Indonesia, with a result of 1.42 (95% CI 1.01-1.98). This is in line with research in Nepal, which found that teenage mothers had a prevalence of stunted toddlers 2.12 times higher than adult mothers (POR = 2.12 95% CI 1.01-4.44)<sup>14</sup>. In Indonesia, 54.01% of women pregnant for the first time are older than 20, but the remainder are under 20. This shows that half of the women who have been pregnant in Indonesia experience their first pregnancy at the age of <20 years<sup>15</sup>. Adolescent pregnancy is also inseparable from the high level of child marriage among adolescents in Indonesia. Early marriage in West Java is 30.5%. This makes West Java the province with the highest prevalence of early marriage on the island of Java and is ranked ninth nationally, while Tamansari, as the research location, is one of seven sub-districts in Bogor District which has a high prevalence of early marriage in West Java<sup>16</sup>. Research in India concluded that the prevalence of stunted toddlers with mothers who married at the age of <18 was 1.2 times higher than adult mothers (POR = 1.22 95% CI 1.12-1.33)<sup>17</sup>, while research at Tamale Metropolis, Ghana, also concluded that mothers who were married at the age of > 18 years had a stunting prevalence 0.76 times higher than those aged <18 (POR = 0.76 95% CI 0.59-0.99)<sup>18</sup>. Adolescent pregnancy causes adverse effects on reproductive health and mothers are at great risk of giving birth to babies with a stunting condition. Maternal nutrition at that age (<20 years) has not developed optimally, and if it is

forced nutrition it will result in higher anthropometric failures later, such as stunted growth of the child’s body. Teenage pregnancy also has the potential to lead to babies with a low birth weight (LBW), which accounts for around 20% of stunting<sup>15</sup>.

In this study, two confounder variables cause stunting: mother’s education and mother’s parenting pattern. Educational factors play a major role amongst mothers in terms of fulfillment of toddler nutrition intake during the growth process. Mothers with a low education are also at risk of having stunted children due to their lack of experience and correct knowledge about feeding intake. Studies in Brazil concluded that mothers with low education (<9 years) had a prevalence of stunted toddlers 1.7 times higher than mothers with higher education ( $\geq 9$  years) (PR = 1.77 95% CI 1.10-2.86)<sup>19</sup>. In other studies in Rwanda, it was concluded that mothers with poor education had a prevalence of stunted toddlers 1.7 times higher than mothers with higher education (POR = 1.71 95% CI 1.25-2.34)<sup>20</sup>. while mothers’ parenting patterns played an important role in terms of toddlers’ food intake, personal hygiene practices and the environment; seeking treatment was also very relevant when associated with stunting<sup>21</sup>. Research in West Nusa Tenggara (NTB), Indonesia, concluded that mothers who had poor knowledge of malnutrition had a prevalence of stunted toddlers 2.2 times higher than those with good knowledge (p value = 0.001 PR = 2.28), and that children raised by two parents had a prevalence of stunted toddlers 1.6 times higher than those raised by big families (p value = 0.003 PR = 1.64)<sup>22</sup>.

These overall results indicate that there are interrelated variables between adolescent pregnancy, education and mothers’ parenting pattern. Promotes a woman to get pregnant for the first time in adulthood will open up opportunities for adolescents to study at a higher level. This is what will ultimately increase the knowledge and parenting of mothers related to toddlers. For further research, it would be beneficial to add other

variables related to wider maternal characteristics, such as the length of the mother's marriage, status of the mother's occupation, mother's height and mother's knowledge of how to care for toddlers. In addition, we recommend that future research be conducted on a wider population, not limited to the District.

### Conclusions

Based on the results of the study, stunting can be prevented by increasing the maternal gestational age by raising the minimum age of marriage in accordance with Indonesian marriage law limitations at age of 19 years<sup>23</sup> and get first time pregnant at age of 20 years, because from this study there are still 16.2% of mothers who are pregnant aged <20 years. Moreover, it is also necessary to improve the education of adolescent girls, giving them knowledge about proper parenting before they get married and become pregnant.

**Ethical Considerations:** This study was approved by The Research and Community Engagement Ethical Committee Faculty of Public Health Universitas Indonesia (Ket-560/UN2. F10/PPM.00.02/2019).

## Abstract

Acute diarrhoea is a major public health problem and is the second leading cause of death in children. It has implications in terms of morbidity and mortality especially in the under five years old age group. The purpose of this study was to determine the factors associated with acute diarrhoea among children under 5 years old in Sabah. This was a case-control study involving 584 samples in four districts in Sabah. Analysis with multiple logistic regression discovered the associated factors of acute diarrhoea among under 5 years old were child's age, single parents aOR5.209 (95%CI 1.09-25.01), Peribumi Sabah mother aOR1.542 (95%CI 1.01-2.34), unemployed mother aOR1.783 (95%CI 1.16-2.75), less than RM2,000 monthly household income aOR1.643 (95%CI 1.08-2.49), no garbage collection aOR1.923 (95%CI 1.24-2.98), adjacent open garbage aOR1.888 (95%CI 1.23-2.91), average rainfall of 151mm or more aOR1.768 (95%CI 1.22-2.56) and less than 1 year of breastfeeding aOR1.685 (95%CI 1.11-2.55). The study has revealed the need to improve the overall level of hygiene and sanitation in the population.

**Keywords:** *Diarrhoea, children, Sabah, factors, case-control.*

## Introduction

Diarrhoea is still a major public health problem, causing notable numbers of morbidity and mortality worldwide. It is the second leading cause of death in children under five years old. Around 1.8 million people die each year from diarrhoeal disease, with 90% are children who are under 5 years old from developing countries<sup>1</sup>. The outcome of the infection may have effects in electrolyte loss, dehydration, shock and sometimes

death. Diarrhoea has morbidity effects, which include stunting of growth, delay in neurological development, concomitant infections, diarrhoea recurrence and failure to thrive<sup>2</sup> worldwide. The present study was undertaken to further define research priorities for the prevention and treatment of diarrhoea in low and middle income countries. We used the Child Health and Nutrition Research Initiative (CHNRI).

In Malaysia, diarrhoea persistently contributes to the national's public health issue, with at least 13 million episodes of acute diarrhoea occurring annually. Acute diarrhoea is under reported with only less than 0.1% of cases actually being captured by the national surveillance program. Gastrointestinal infection is the second most common cause for hospital admissions to public hospitals and with more hospitalizations; there is a significant burden placed on health care costs. For example the cost for inpatient care of childhood rotavirus

diarrhoea alone in Malaysia was estimated to be up to US\$1.8 million annually<sup>3</sup>.

Hospitalizations for acute diarrhoea were found to be higher in East Malaysia and were particularly high in the indigenous minority. It may represent a true prevalence of hospitalization but in East Malaysia there is proportionately less access to private medical facilities and a higher preference to hospitalize patients because of the patients' travel distances. Besides that, many children who have mild illnesses do not seek medical treatment and this can indicate that thousands more in Malaysia are unreported<sup>4</sup>. This study was conducted to determine the factors associated with acute diarrhoea among those under 5 years old in four districts of Sabah.

### Material and Method

This study was conducted in four districts of Sabah which are Kota Kinabalu, Penampang, Putatan and Papar. The major ethnic groups here are Kadazan/Dusun, Bajau, Murut, Malay, Chinese, Indian and other Bumiputera. This is a case-control study involving 584 respondents, which consisted of 292 in each group of case and control. The cases were children under 5 years old with acute diarrhoea selected randomly from public health centres in the four districts of Sabah over the period of 11 months. Acute diarrhoea is defined as having three or more episodes of loose stools in any 24-hour period within the past four weeks (28 days) before the interview. The controls were respondents under 5 years old who attended the same health care centres for problems other than gastrointestinal diseases.

A questionnaire was adapted and then modified to suit the local context with permission from authors in a previous study done in Brazil, which looked at risk factors for diarrhoea in a middle income country<sup>5</sup>. It underwent forward translation to Malay and was

reviewed by experts for content and language. A pre-test was conducted, and the comments and discussion were taken into account for the final adjustments in the questionnaire. The questionnaire incorporates demographic, socioeconomic, food preparation, disease contact and environmental variables. The data was analysed with SPSS 20.0 for bivariate analysis then with logistic regression. Respondents who voluntarily agreed to take part had to give their written consent and they were given full information regarding the research. There were no invasive procedures involved.

**Findings:** There were 614 respondents interviewed and 30 were rejected. Out of the rejected respondents, 18 did not have a complete address or had missing data while 12 attended the health centres but did not originally stay in the four districts. The final sample size were 584 respondents, which consisted of 292 in each group of case and control. A total of 584 samples, which were 292 cases and 292 controls which included from Kota Kinabalu with 182 (62.3%) respondents, 48 (16.4%) from Penampang, 53 (18.2%) from Putatan and 9 (3.1%) from Papar for each case and control group. In terms of the child's age the mean age was 2 years old for cases and 1 year 8 months for controls. The variables were then analysed with multiple logistic regression.

The main factors that influence acute diarrhoea among those under 5 years old were child's age, single parents aOR5.209 (95%CI 1.09-25.01), Peribumi Sabah mother aOR1.542 (95%CI 1.01-2.34), unemployed mother aOR1.783 (95%CI 1.16-2.75), less than RM2,000 monthly household income aOR1.643 (95%CI 1.08-2.49), no garbage collection aOR1.923 (95%CI 1.24-2.98), adjacent open garbage aOR1.888 (95%CI 1.23-2.91), average rainfall of 151mm or more aOR1.768 (95%CI 1.22-2.56) and less than 1 year of breastfeeding aOR1.685 (95%CI 1.11-2.55).
