Abstract

The number of Low Birth Weight (LBW) in Indonesia is still high because of, among others, the lack of mothers' knowledge to prevent LBW case. The solution proposed is to encourage *Dasa Wisma (Dawis)* activists to assist pregnant women as one of the strategic actions. The aim of the research was to analyze the effect of assistance training towards the knowledge and practices of *Dawis* activists related to the prevention of LBW case in pregnant women. Method of this research was pretest and posttest without control group design of Quasi-experimental were applied. The population sampled using purposive random sampling was 37 *Dawis* activists in Tlogosari Wetan District, Semarang. The distance between pretest and posttest was approximately one month. Test result of Wilcoxon Match Paired test revealed that there were significant differences in the knowledge ($p < 0.05$) and practices ($p < 0.05$) of *Dawis* Activists before and after the intervention of assistance training. In the end of this research, the knowledge of *Dawis* Activists increased 5.97 points, while their practices increased 3.97 points. The recommendation from this research is that assistance training for *Dawis* Activists is necessary, even if it is only for a day, in order to increase the competence of *Dawis* Activists in assisting pregnant women to prevent Low Birth Weight case in one month.

Keywords: *Training, Knowledge, Dasa Wiswa Assistance, Pregnant Woman, Birth Weight.*

Introduction

The number of Low Birth Weight (LBW) case in Indonesia is still high. LBW has been considered the primary factors in the increasing number of mortality and morbidity of neonatal, infants, and children, which may lead to long-term effects in the future[1]. In Indonesia, the high rate of malnutrition cases in pregnant women contributed to that of LBW case, which was estimated to be more than 350.000 infants per annum, and it has been predicted that 17 million LBW babies per annum might also be exposed to. Meanwhile, in Central Java, the percentage of LBW tended to be increasing since 2012 to 2015, and it decreased in 2016[2]. According to the report of the Health Office of Semarang City in 2016, there were 506 infants (1.9%) of LBW infants in 2016, consisted of 260 male infants and 249 female infants[3]. One of the districts identified to be low nutrition infants and toddlers was Tlogosari Wetan District. Realizing the possible danger of LBW, several strategies have been implemented to reduce LBW cases, yet, the results have not been maximum. Meanwhile, the government has not prioritized community empowerment programs.

Cadres, the closest persons to the community and pregnant women, have been empowered to be able to assist pregnant women for the last few years. In addition to the cadres, some people may voluntarily assist pregnant women, such as the *Dasa Wisma* (*Dawis*) activists. Until recently, *Dawis* activists have not joined such training regarding their function to assist pregnant women within their area. The assistance of *Dawis* activists to pregnant

Corresponding Author:

e-mail: nugraheni.sa.undip@gmail.com

women is one of the strategic moves that significantly leverage in solving LBW problems. The general purpose of this research was to analyze the changing paradigm from PLC to CLC with evidence-based proof that the *Dawis* activists could be educated with the prevention of LBW through assistance training, in order to raise their confidence and possess sufficient knowledge as pregnant women assistant.

Method

This was quasi-experimental research, with pre and posttest without control group design. The population of this research was the *Dawis* Activists in the working area of PHC Tlogosari Wetan, Semarang City, especially in Kecamatan Tlogosari Wetan. The sampling method has been done through purposive random sampling to 37 *Dawis* Activists.

Intervention in this research was through a training for a whole day, led by an expert in Mothers and Child Health from the Faculty of Public Health Diponegoro University, as a provision for the *Dawis* Activists to assist pregnant women related to LBW prevention. Data about the knowledge and practices was obtained from a structured interview by trained enumerators. Data analysis used Wilcoxon Match Paired test (data obtained distributed abnormally) to analyze the difference or alteration in the result in the knowledge and practices of the *Dawis* Activists before and after intervention.

Results and Discussions

According to distribution table from the *Dawis* Activists, all 37 participants in this research were females (100%) with following composition: 75% of participants were above 35 year old including four 50 year old participants. Most of them has been joining *Dawis* for 10 years or less (84%), which the biggest population were 5 years and 10 years' experience as *Dawis* members (5 people in each population). The latest education was mostly Senior High School or equal (56%) with following professions: 54% housewives, 54% private sector workers as tailors, entrepreneurs, and company workers.

The Knowledge of *Dawis* Activists: The table 1 showed the increase and decrease number of participants who understand the knowledge related to maternal and child health.

Table. 1 The difference of participants' knowledge before and after intervention

Table. 2 The score difference of participants' knowledge

Participants knowledge related to LBW prevention	Before intervention		After intervention	
	N	%	N	%
Give 75% or less right answers	27	73.0	1	2.7
Give more than 75% right answers	10	27.0	36	97.3
Total score	37	100.0	37	100.0
Mean	10.62		13.51	
Wilcoxon test	p= 0.001 (p < 0.05)			

This study showed that intervention through the *Dawis* Activists as an action to prevent obstetric outcomes of LWB, then after the *Dawis* Activists implemented pregnant women assistance, it showed a significant result. Difference test used Wilcoxon test showed significant difference of knowledge during before and after intervention (p=0.001). The result of normality test showed irregular distribution pretest variables (p=0.020) and irregular distribution posttest variables (p=0.002), thus Wilcoxon test was selected. From the results of difference test using Wilcoxon test, it showed a significant difference of knowledge in before and after intervention (p=0.001).

This result was in accordance with the previous study in Australia, which shows that 70% - 97% participants achieve an increasing rate of confidence through training and 83% - 91% participants achieve an increasing rate of knowledge in mothers and children health topic from pre-training score 11 to post-training score 15[4]. Another literature shows that output targets from the training in health program counselor communication techniques, it increases the confidence of participants who have limitations in delivering health information[5,6]. The keys of success in health training are delivering health education with confidence, good communication techniques, giving positive stigma, and educate people naturally for counselors[7].

These results corresponded with the result of a research in rural India, which shows that anemia maternal incident during 3 – 5 months of gestation period significantly related to the high LBW tendency (OR: 0.34, 95% Cl: 0.13-0.92, p=0.03). Approximately 30% of participants experience unplanned pregnancy, thus, it raises the risk of LBW. Therefore, pregnant women need to be provided with nutrition plan education and healthy lifestyle during their pregnancy[8].

Another important subject that should be informed by the *Dawis* Activists to pregnant women was the restriction on consuming medicines. Bocca, et al, stated on the research that Extremely LBW with < 1500 grams birth weight happened because of drugs exposure, which then caused element deficiency or toxicity that affected fetus development, obstructed the absorption of uteroplacental nutrition circulation, and increased oxidative stress[9].

The Practice of *Dawis* Activists in PHC Tlogosari Wetan Working Area: The following table showed the increasing and decreasing number of participants who implemented pregnant women assistance practices.

Table. 3 Practice Differences of the Participants before and after intervention

No	Statement	Before intervention				After intervention			
		Do		Don't		Do		Don't	
		n	%	N	%	n	%	n	%
1	Pregnancy Test	36	97.3	1	2.7	33	89.2	4	10.8
2	Pregnancy Signs	29	78.4	8	21.6	31	83.8	6	16.2
3	Pregnancy check in health facility	22	59.5	15	40.5	35	94.6	2	5.4
4	Pregnant women carry heavy load	23	62.2	14	37.8	36	97.3	1	2.7
5	Resting and small activities for pregnant women	23	62.2	14	37.8	33	89.2	4	10.8

15	Sports for pregnant women	26	70.3	11	29.7	32	86.5	5	13.5

Table.4 The score difference of participants' practices

Participants practices related to LBW prevention	Before intervention		After intervention	
	N	%	N	%
Give 75% or less right answers	30	81.1	9	24.3
Give more than 75% right answer	7	18.9	28	75.7
Total score	37	100.0	37	100.0
Mean	9.70		13.02	
Wilcoxon test	p= 0.001 (p < 0.05)			

The result of normality test showed irregular distribution pretest variables (p=0.001) and irregular distribution posttest variables (p=0.001), thus Wilcoxon test was selected. From the results of difference test using Wilcoxon test, it showed a significant difference of practice in before and after intervention (p=0.001). This study showed that there was a significant practices change in before and after intervention as the result of comparative test used Wilcoxon test (p=0.001).

The material conveyed by the *Dawis* Activists stated that pregnant women must avoid cigarette smokes is in line with the literature which stated that smoking causes toxicity trace element that could disrupt uteroplacental circulation and increase oxidative stress[9]. In another literature, it shows that cigarette smokes exposure during pregnancy would increase the risk of LBW and premature birth[10–13], and inducing labor in 37 – 38 weeks gestation[14].

This research also in accordance with following literatures, that LBW case prevention could be implemented through prenatal care program evaluation, pregnant women mapping, assistance, education, and elevate the knowledge about mother and children health[15]. Implementation of the *Dawis* Activists assistance to pregnant women through education and motivation is flexibly conducted based on the activities of the *Dawis* Activists and pregnant women, including home visit. This could be optimized according to the research from Krans, et al. in the United States, which states that optimum prenatal check for LBW prevention through education and home visit which is the fittest model for pregnant women because of its flexibility[16].

Home visitation in New York according to Lee, et al. is conducted as pregnant women service strategy, including in the case of teenage pregnancy which has limited social and family support[17–19]. Furthermore, home visit program becomes the core program that has a significant impact to decrease the risk of pregnancy complication, including LBW[20].

Conclusions

The result of this study shows that there are differences in the knowledge of the *Dawis* Activists before and after intervention regarding the training on LBW prevention in pregnancy with p=0.001 and the average increasing point is 3.11 point. There are also differences in the practices of the *Dawis* Activists before and after intervention regarding the training on LBW prevention in pregnancy with p=0.001 and the average increasing point is 3.32 point.

The role of the *Dawis* Activists is also crucial to convey information and to monitor public health level by monitoring pregnant women health. Also, PHC needs to assign more active programs and activities to the *Dawis* Activists under its working area to provide monitoring and information regarding health issues, especially for pregnant women.

Conflict of Interest: The authors declare that they have no conflict of interest within this research.

Acknowledgements: The writers send gratitude to the Heath Department of Semarang, the staff of Tlogosari Wetan PHC, the *Dawis* Activists from Pedurungan sub-district, Tlogosari Wetan District, and all participants who help the authors completing this research. Our highest gratitude to the Faculty of Public Health Diponegoro University and the Directorate General of Public Health the Indonesian Ministry of Health, specifically the Directorate of Public Nutrition and all its ranks.

Ethical Clearence: This research has been approved by the Health Research Ethics Committee Faculty of Public Health Diponegoro University Number 046/EC/FKM/2018 on 25th April 2018.

Risk Factors of Pregnancy Incidence before 20 Years Old in Indonesia in 2016

Djoko Nugroho[1], SriWinarni[1], Farid Agushybana[1], Najib[2], Undari Nurkalis[1]

[1]Department of Biostatistics and Population Studies, Faculty of Public Health, Diponegoro University, [2]Research and Development of National Family Planning Coordinating Board of Central Java Province, Semarang, Indonesia

Abstract

Young age pregnancy is an important public health problem, due to its high association with mortality and morbidity for both mother and the child and also reflect the country's welfare. Teenage mother often have problems related to labor or postpartum period. Lack of knowledge can be caused by low education, which create barrier upon receiving message. Highly educated people tend to have more information, from other people as well as press, and they're also more open to new value compared to less educated people. Marriage below 20 years increase the odd of pregnancy before 20 years. Knowledge about contraceptives is crucial and related to Maturing Age of Marriage programe. Problems in Maturing Age of Marriageprograme will increase pregnancy below 20 years rate. Descriptive analysis related to pregnancy risk factors below 20 years old is needed throughout Indonesia.

Keywords: *Marriage age <20 years; contraceptives knowledge; pregnancy <20 years.*

Introduction

Children quality reflect country's welfare. Maternal and child mortality reflect people health status and welfare.[1] Based on the Indonesian Demographic and Health Survey 2012, maternal mortality rate associated with pregnancy and childbirth accounted for 259 per 100,000 live births. Maternal factor that affects the health status of children and mothers is age during pregnancy and childbirth.[2,3]

Maternal age at the time of pregnancy affects the mother's pregnancy because it is related to the maturity of reproductive organs and mother's psychological condition to receive pregnancy. Young age pregnancy (less than 20 years) is one of 4T criteria of high risk pregnancy.[4,5]

Corresponding Author:

Based on riskesdas (Basic National health research) 2013 on women aged 10-54 years, 2.6 percent first marriage occurs at age less than 15 years and 23.9 percent married at age 15-19 years.[6] The result of Indonesia Demographic and Health Survey in 2012, median age of first marriage of Indonesian women was 20,1 years; while the Indonesian Demographic and Health Survey 2007 showed the median age of first marriage was at the age of 19.8 years and the results of the 2002-2003 Indonesian Demographic and Health Survey showed 19.2 years. This shows increasing trend of the median age of first marriage within the last 10 years although not yet in accordance with the expected target of 21 years.[2]

Early marriage that causes young pregnancy often occurs due to parents factor. They often think that girls is an economic burden and marriage is one of the attempt to maintain family life.[7] The younger the marriage age, the lower the level of education achieved by the child because of the responsibilities of being a wife and expectant mother.[8] Teenagers in rural areas are more likely to be mothers compared to urban area.[2]

Age Specific Fertility Rate (ASFR) for the age 15-19 years describes the number of pregnancies in adolescents aged 15-19 years. Results of the Indonesian Demographic

and Health Survey 2012, ASFR for 15-19 year olds were 48 per 1,000 women aged 15-19 years while the target expected in 2015 was 30 per 1,000 women aged 15-19 years.[2] Younger the marriage age means longer time span of reproduction.[2] Riskesdas 2013 showed the pregnancy rate at age less than 15 years old was 0,02 percent, while pregnancy rate in adolescence (15-19 years old) was 1,97 percent. Pregnancy regulation is crucial because it affects the fertility rate in Indonesia.[2]

Pregnancy below 20 years of age is influenced by education, contraceptive knowledge, contraceptive behaviour, culture, adolescent/dating behavior, health care, providers and income. Teenage women, at age of 15-19 years, responsible for 15 million birth each year. According to the data from Central Bureau of Statistics, teenage marriage rate in Indonesia was 8.8%. In developing country, 1 to 4.4 million teenagers have a miscarriage; and most procedures are performed under unsafe conditions. Complications of pregnancy and childbirth are the leading causes of death between the ages of 15-19. Limited knowledge or limited access to health care systems was the leading factors for pregnancy complications.[9]

Lack of knowlegde can be caused by low education, which will create barrier upon receiving message or information.[10] In the other hand, higher education means it easier to receive the information.[11]

Data from Central Java showed that women who married before 21 years are 54.67%. The highest percentage of marriage before 21 years are in Rembang (72.17%). In the other hand, there are 13.82% men who married under 25 years, with highest percentage in Banjarnegara (23.59%). Underage marriage will lead to pregnancy under <21 years of age. This also happened in several provinces throughout Indonesia.

From data above, we decided to create a descriptive study to find risk factors related to high number of parity before 20 years old throughout Indonesia.

Method

A descriptive, cross sectional study was conducted to describe several factors related to teenage pregnancy: maternal education, marriage age, contraceptive knowledge and the age of first childbirth.

Target population were Indonesian woman who pregnant before 20 years old. The sample of this study were 456,686 Indonesian woman who were pregnant before 20 years 2016. Univariate and bivariate data analysis were provided in this

Results and Discussions

Characteristics of subject are shown in Table 1.

Table 1.Univariate analysis of education level, married age, contraceptive knowledge, first birth and pregnancy <20 years

Variable	f	%
Education Level

First Birth		
20-35 years	33,429	73,36
< 20 years	12,140	26,64
Pregnancy < 20 years		
No	33,429	73,36
Yes	12,140	26,64

Based on table 1.1, the highest education of Indonesian fertile women is elementary school (33.18%) and graduated from junior high school (30.57%). As many as 59.05% of sample married at 20-35 years, and 99.75% of them know about contraception. There are 73.36% women who not pregnant before 20 years

In our study, majority of childbearing age women have low education level, which consisted of primary school education and junior high school, 38.13% and 30.57% respectively. Unicef (2008) mentioned that factors contributing to teenage pregnancy are lack of education and information about sexual health especially from parents.

Table 2. Frequency distribution of level education on teenage pregnancy in Indonesia 2016

Pregnancy < 20 years	Education Level										Total	
	No Formal School		Elementary, Graduated		Junior High, Graduated		Senior High, Graduated		University / Academy			
	f	%	f	%	f	%	f	%	f	%	f	%
No	500	1,50	10.307	30,83	10,669	31,92	7.529	22,52	4.424	13,23	33.429	100,00
Yes	454	3,74	7.070	58,24	3.260	26,85	1.153	9,59	203	1,67	12.140	100,00

The results also showed that the teenage pregnancies were more prevalent among childbearing age women who did not go to school and graduated from elementary school, 3.74% and 58.24% respectively. Childbearing age women with higher education have lower teenage preganancy incidence (graduated from junior high school, graduated from senior high school, and PT / academy; 31,92%, 22.52% and 13.25% respectively). Childbearing age women with low education have difficulty to digest messages or information conveyed and hamper their development and attitudes toward newly introduced values.

As for childbearing age women with junior high school, senior high school and PT / academy education are known to have a smaller percentage of teenage pregnancy; this result showed that highly educated women tend to get more information either from other people or from press.

Tabel 3. Frequency distribution of marriage age on teenage pregnancy in Indonesia 2016

Pregnancy < 20 years	Marriage Age				Total	
	20 – 35 years		<20 years			
	f	%	f	%	f	%
No	26.546	79,41	6.883	20,59	33.429	100,00
Yes	361	2,97	11.779	97,03	12.140	100,00

The results showed more than half of reproductive age women married at age 20 - 35 years with a percentage of 59.05%. From the study, it is known that women who married at the age of 20-35 years did not experience teenage pregnancy (79.41%). In the other hand, almost all women who married before 20 years old have pregnancy under the age of 20 years with a percentage of 97.03%. Unicef (2008) mentions that the factors contribute to teenage pregnancy are traditions that lead to early marriage (developing countries) and lack of access to tools that prevent pregnancy. The statement is in accordance with our results in which women who married at the age of less than 20 years tend to have a pregnancy under the age of 20 years. In the reproductive period, under 20 years of age is the recommended age for delaying marriage and pregnancy.[12] Pregnancy under the age of 20 is said to be risky, with mortality rate 2-4 times higher than healthy reproduction.

Table 4. Frequency distribution of contraceptive knowledge on teenage pregnancy in Indonesia 2016

Pregnancy < 20 years	Contraceptive knowledge				Total	
	No		Yes			
	f	%	f	%	f	%
No	80	0.24	33,349	99.76	33.429	100,00
Yes	36	0.30	12,104	99.70	12.140	100,00

Majority of Indonesian childbearing age women already known about the contraception type with a percentage of 99.75%. Knowledge is obtained after the person senses a particular object. Sensing occurs through the five senses of the human senses: sight, hearing, smell, taste and touch. Most of the knowledge is obtained through the eyes and ears. Knowledge is a very important factor for a person's behavior.

In our study, the number of childbearing age women

who have and do not have knowledge about contraception were almost the same percentage to have a teenage pregnancy, where tenage pregnancy in women without contraceptive knowledge is slightly higher (0.30%) and women have contraception knowledge have a slightly greater percentage (99.76%) in terms of pregnancy after 20 years. Changing a person's health behavior can be done by providing health education.[13,14] Lack of knowledge about high-risk pregnancies is influenced by education. Women of childbearing age who have low education will find it difficult to digest messages or information conveyed and hamper their development and attitudes towards newly introduced values.[13,15]

Table 5. Frequency distribution of age of first time give birth of <20 years old reproductive age women in Indonesia 2016

Pregnan-cy< 20 years	First Birth				Total	
	20 – 35 years		<20 years			
	f	%	F	%	f	%
No	33,429	100,0	0	0.0	33,429	100.0
Yes	0	0.0	12,140	100.0	12,140	100.0

From our study, it is known that childbearing age women who first gave birth in the age range 20-35 years was 73.36%. Teenage pregnancy has a higher pregnancy, delivery and post partum complication compared to healthy reproductive individual (age 20-35 years). It is caused by immature reproductive organs to conceive, which can harm the mother's health, development and growth of the fetus. In addition, teenage pregnancy can cause other problems due to imperfect body growth, socioeconomically disadvantages, difficulty in childbirth, or not ready to perform the mother role.

Conclusions

Indonesian childbearing age women in 2016 have a low level of education, which is elementary and junior high by 38.13% and 30.57% respectively. Childbearing age women who do not receive formal education and have primary school education have a greater percentage of pregnancies under the age of 20 with a percentage of 3.74% and 58.24% respectively.

Indonesian childbearing age women in 2016 are known to have contraceptive knowledge with percentage of 99.75%. Women who unaware of this knowlegde (0.3%) have pregnancy under the age of 20.

Most of Indonesian women married at the age 20-35 years with percentage of 59.05%. Most of Indonesian women have their first child at the age 20-35 years with a percentage of 73.36%.

From the results above, active counseling and interpersonal communication from midwifery is required for all maried couple, so that unexpected circumstances and adverse events in teenage pregnancy can be anticipated as early as possible.

Counseling and interpersonal communication for couple below 20 years is required to prevent teenage pregnancy and risk related to it can be anticipated as early as possible.

Evaluation of Mass Drug Administration (A Cross Sectional Study in Sanggu Village, South Barito, Central Kalimantan, Indonesia)

Vipi Nurpila[1], Lintang Dian Saraswati[2], Martini Martini[3], Praba Ginandjar[4]

[1]Jaraga Sasameh Hospital, Buntok, South Barito, Central Kalimantan, [2]Epidemiology and Tropical Diseases, Faculty of Public Health, [3]Master Program of Epidemiology, School of Postgraduate Studies, [4]Department Epidemiology and Tropical Diseases, Faculty of Public Health, Diponegoro University, Semarang, Indonesia

Abstract

Barito Selatan was one of the endemic areas of filariasis with Mf rate of 1.34% in 2004. MDA filariasis has been carried out in 2005-2013 gradually. Transmission assessment survey in 2014 obtained Mf rate of 1.7% with most cases in the village Sanggu. As a result, South Barito must add MDA Filariasis for 2 years. MDA filariasis 2015 was done. The purpose of this study was to evaluate the filariasis mass treatment, indicated with Mf rate and type of microfilariae,in the village Sanggu South Barito regency in Central Kalimantan. This research was a descriptive with *cross sectional* design. The sample was part of filariasis MDA target in 2015 aged> 2 years in the village of Sanggu. The sampling technique using *a simple random sampling*. The minimum sample size as many as 102 people. The inclusion criteriawere willing to become subject and age <15 years accompanied by a parent. We excluded subjects who moved from Sanggu village,pregnant, and children aged <5 years of marasmus.The results showed that the rate Mf Sanggu Village at 2.9% with type *B. malayi* microfilariae. Characteristics of subjectswere average age of 36.24 years, 52.9% were female, 25.5% were students, 35.3% had finished high school, 67.1% had poor knowledge, 55.9% were taking the medication from MDA program and 59.8% did not received support from implementer elimination (TPE). Suggested to do follow up study for variables that may be associated with filariasis mass treatment such as the degree of endemicity, gender, education, knowledge, practice taking medication, the support of implementer elimination, selective treatment of old patients and monitoring the implementation of filariasis mass treatment.

Keywords: *Evaluation, filariasis, mass drug administration.*

Introduction

Filariasis is a tropical disease caused by infection of filarial worm *Wuchereria bancrofti*, *Brugia malayi* and *B. timori* which are transmitted through mosquito bites.[1,2] Filariasis rarely causes death, but it may cause permanent disability.[3] The data from WHO in 2016 show that there are 1.103 million populations at risk of filariasis in 73 countries and 632 million (57%) of countries in Southeast Asia, including Indonesia, as the endemic countries.[4] Based on the data from the Directorate General of Disease Control and Environmental Health, Ministry of Health of the Republic of Indonesia, the number of filariasis clinical cases from 2000 to 2014 have increased from 6,233 cases to 14,932 cases, with more than 102 million people (43%) of Indonesian's population at risk of filariasis.[5,6]

South Barito is an endemic district in Central Kalimantan. Finger blood surveys were first conducted in 2004 with MF rate of 1.34%.[7] According to the policy from the Ministry of Health of the Republic of Indonesia, if an area has Mf rate of > 1%, it belongs to the category of filariasis endemic area. To eliminate the filariasis, Mass Drug Administration (MDA) for Filariasis is conducted. There are two mass treatment

Corresponding Author:
Lintang Dian Saraswati

strategies that are carried out doing MDA once a year for 5 consecutive years in endemic areas and clinical management for chronic filariasis patients. [8]In South Barito regency, MDA for Filariasis was implemented from 2005-2013 gradually. Mass treatment was not done simultaneously due to limited budget. However, until 2014 Mf rate of 1.7% was still obtained with the type of microfilaria *B. malayi*.[9] Consequently, South Barito should implement MDA for Filariasis again for 2 consecutive years. The sixth round of MDA for filariasis were conducted simultaneously in all sub-districts in South Barito in October 2015.

Research in Papua New Guinea showed that there was a decrease of Mf rate after mass treatment was conducted.[10]. Research in Egypt showed similar result in the decrease of Mf rate which ranged between 0.2%-2.7% after mass treatment was conducted.[11]

In the implementation of mass treatment, the Health Office is assisted by the Elimination Executors (TPE) of Filariasis due to the wide area of treatment target.[6] Each elimination executor is responsible for 20-30 families. The elimination executor is in charge of distributing drugs, administering medical cards, reporting side effects and assisting in counseling.[12]

Based on the explanation above, the research on Evaluation of Mass Treatment Admission for Filariasis in Sanggu village South Barito regency, Central Kalimantan is conducted.

Method

This research is descriptive research using cross sectional design by observing the independent variables and dependent variable. The independent variables in this study are age, sex, occupation, education, knowledge, practice of medicine intake, Elimination Executor's support, endemicity level and microfilaria species. While the dependent variable is evaluation of mass treatment admission for filariasis.

The research was conducted in Sanggu village, South Barito regency, Central Kalimantan on April 4 to April 29, 2016. The population of the research is all the target of filariasis mass treatment in 2015 aged > 2 years in Sanggu village. While the study sample is part of the entire target of filariasis mass treatment in 2015 aged > 2 years in Sanggu village. The inclusion criteria consist of willingness to be respondent and aged <15 years accompanied by parents while the exclusion criteria consist of moved out respondents, pregnant and children aged <5 years with marasmus. The sample was taken using simple random sampling technique. The sample size is determined through the calculation using the proportion estimation formula of 102 respondents.

The research uses primary data taken by conducting direct interviews to the respondents' house with structured questionnaires and finger blood examination which then continued by conducting in-depth interviews. The study uses univariate analysis which aims to get the idea of frequency distribution result on each variable.

Results and Discussions

Finger blood test from 102 respondents in Sanggu village resulted in 3 positive blood preparations containing microfilariae. It resulted in Mf rate in Sanggu village to be 2.9% with *Brugia malayi* microfilaria type and infection from another microfilaria type is found to be none.

The previous study conducted in Ghana, found that the microfilaria rate was 4.6%. [13]. While in study conducted by Upadhayula et al in Karimnagar district, India found the mf rate range from 0,0%-10,5%, and in Chittoor district ranged from 0,0%-7,0%.[14]

Table.1 Characteristic of the respondents based on sex, education and jobs (n=102)

No.	Characteristics (n=102)	f	%
1.	Sex		
	• Male	48	47.1
	• Female	54	52.9
2.	Educations		
	• Do not attend school	2	2
	• Kindergarten	2	2
	• Elementary School	17	16.7
	• Do not graduate Elementary School	6	5.9
	• Elementary School graduates	19	18.6
	• Junior High School graduate	11	10.8
	• Senior High School graduates	36	35.3
	• College graduates	5	4.9
	• University graduates	4	3.9
3.	**Jobs**		
	• Unemployed	4	3.9
	• Housewives	18	17.6
	• Students	26	25.5
	• Farmers	15	14.7
	• Rubber Tappers	7	6.9
	• Wood Collectors	2	2.0
	• Merchants	3	2.9
	• Private Employees	10	9.8
	• Civil Servants/Armies/Polices	11	10.8
	• Others	6	5.9

From the table 1 we know the average respondent aged 36.24 years old with the youngest aged 5 years old and the oldest aged 90 years old. Table 1. shows that more than half of the respondents are female (52.9%). A quarter of the respondents are students (25.5%) and one third of the respondents are high school graduates (35.3%).While study in Tanzania reported the median age of the respondents was 16.6 years, and more than half of them were female (51,0%).[15]. Another study in Kuwait also reported that respondents aged 29,2 range between 14-61 years old, more than half of them were male (57,4%), working as migrant workers.[16]. The result of this study revealed that more than thirty of the respondents have poor knowledge about filariasis (32.9%). The previous study Ghana, Malaysia and Indonesia also reported that the knowledge of the community toward filariasis still poor. [17–19]. Most respondents are wrong about the arguments of filariasis cannot be healed (78.4%), what causes it (95,1%), each patients drink 2 kinds of medicines (85,3%), the drug is meant only for filariasis patient 64.7%), medicines are taken by all aged > 15 years (67.6%), 2 year-old patients may take the medicine (85.3%) and side effects arise as a result of the death of microfilariae (75.5%). This results were in line with the study conducted by Amaechi et al who found that most of the respondents (82,1%) had not heard about filariasis, and several of the said filariasis caused by charms (77,9%), nearly a quarter of them don't know what the symptom of filariasis (24,2).[20]. Another study also reported that most of the community don't know the cause of filaraisis and the disease transmission.[21]

Table 2. The knowledge level of filariasis (n=82)

Knowledge	f	%
Good	55	67.1
Poor	27	32.9

Table 3 revealed that more than half of the respondents do not take medication (55.9%) during mass drug administration for filariasis in 2015. For the previous years, from 2010-2014, there were no respondents who took filariasis drugs. We know that the compliance of the respondents in taking medication were still low in this study. The previous study also reported the compliance of the community still low in India.[12,22] In contrary with the study conducted by Elaziz et al in Egypt who found the compliance of the respondents in Giza village was 85,7%, and in the Delta village was (84,8%).[23].

The results found that most of the reasons the respondents do not take the medication are due to the fear of side effects (45.6%) and the parents do not give the children a chance to take filariasis medication (35.1%). (Table 5) The previous study conducted by Hussain et al also foun that 77,0% of the non-compliance of MDA because fear the side effect.[12]

Table 3. The medication practices (n=102)

Medication practice	f	%
Do not take drugs	57	55.9
Take drugs	45	44.1

Table 4. The knowledge of filariasis prevention (n=57)

Reason of not taking drugs	f	%
Scared of side effects	26	45.6
Do not have filariaris	1	1.8
Parents do not give the children a chance to take filariasis drug	20	35.1
Do not receive filariasis drug	2	3.5
Lazy	7	12.3
Too old	1	1.8

Table 5. Distribution of Respondents Based on Examination Executors' Support (n=82)

Examination Executors' Support	f	%
Supporting	33	40.2
Not Supporting	49	59.8

More than half of the respondents do not get support from Elimination Executors (59.8%). The role of Elimination Executors were not optimal, they do not inform anyone about who should take the medication (59.8%), the benefit of mass drug administration (54.9%), the side effects (68.3%), do not monitor drug intake directly (86.6 %), and do not ask for possible treatment reactions (92.7%). The study conducted by Ginandjar et al in Pekalongan District reported that obtained socialization about MDA and obtain information from elimination officer was associated with the knowledge level of the community about MDA. Knowledge was predisposing factor for the MDA compliance, so the adequate information about MDA may increase the compliance of the community in taking filariasis medication during MDA.[19] The study conducted by Babu et al reported the reason why most of the respondents do not take the medication because they fear the side effect of the drugs. And results of qualitative

study participants said that the elimination officer just gave the drugs without giving any further information.[24]. The role elimination officers have an important role to play in the community's compliance with the MDA in terms of providing additional information such as informing the public of the side effects of drugs and what they should do if that happens. So that will reduce people's fear of the side effects of drugs, and perhaps it would increase the community compliance of taking filariasis medication during MDA.

Conclusions

The rate of microfilaria in Sanggu village after the 6th round of mass drug administration for filariasis has been done in 2016 is 2.9%. It means that mass drug administration for filariasis in Sanggu village has not reached WHO target. Factors that may be associated with the drug administration for filariasis are the level of endemicity, sex, education, knowledge, medication practice, Examination Executors' support and long-term selective treatment and monitoring of the implementation of mass drug administration for filariasis.

Conflict of Interest: The author reports no conflicts of interest in this work.

Acknowledgements: The authors thank the study participants, District Health Office of Barito Selatan with all their Primary Health Centre and Sanggu Village for their cooperation in facilitating the study.

Ethical Clearence: Ethical clearance was obtained from Ethic Commission of Health Research, Faculty of Public Health UNDIP (67/EC/FKM/2016). All subjects signed informed consent to join the study.

The Effectiveness of Gymnastics of the Elderly to Decrease the Blood Pressure of the Elderly in the Elderly Health Care Werda Tama (PLWT) Wayut, Jiwan, Madiun

Karina Nur Ramadhanintyas[1,2], Hari Basuki Notobroto[3], Rachmah Indawati[3]

[1]Student Master of Public Health at Airlangga University Surabaya, [2]STIKES Bhakti Husada Mulia Madiun, East Java, [3]Departement of Biostatistics, Faculty of Public Health, Airlangga University Surabaya, Indonesia

Abstract

Introduction: one of the indicators of success in development is the increasing life expectancy age. Some studies of the elderly are actively moving and exercising more is healthy and has a lower risk for chronic diseases. Elderly exercise be one way for the elderly to move the body so that blood pressure is always controlled.

Objective: to know the effect of gymnastics on blood pressure in elderly in the Elderly health care Werda Tama (PLWT) Wayut, Jiwan, Madiun.

Method: this research is Quasi Experiment with design one group pretest-posttest. The sample in this study, 21 people were taken by random.

Results: The test Results of the Paired T Test to compare blood pressure before and after treatment (gymnastics seniors) obtained a value of 0,018 means that elderly exercise is effective for lowering blood pressure elderly.

Conclusion: Elderly exercise can lower blood pressure. For further research using a sample of more with research method case control.

Keyword: Elderly, gymnastics, one group pretest-posttest.

Introduction

One of the indicators of success in development is the increasing life expectancy age. Burean of the census USA issued a report the demographic data of the population international, that Indonesia is no year 1990-2025 will have a rise in the number of elderly by 414%[1]. Elderly bring the consequences of the rising variety of cardiovascular diseases. A disease that is often experienced by the elderly is blood pressure[2].

Handling health problems regarding blood pressure can be classified into the handling of nonpharmacologic and pharmacologic. Administration of antihypertensive drugs in a long period of time will cause side effects. Because the onset of side effects such handling of non farmakologis highly recommended way of weight loss restrictions on tobacco and alcohol, physical exercise and relaxation[3].

Physical exercise for seniors one of which is the gymnastics of the elderly which is the handling of non-pharmacological recommended. [4], in his research if the elderly exercise done regularly can prevent loss of functional diakbatkan olehpenakit cardiovascular. Other benefits of elderly exercise that lower blood pressure, lose weight and strengthen the muscles of the heart[5].

This research can provide benefits in the field of nursing to improve and maintain the health of the cardiovascular in the elderly with use handling of non-pharmacological that does not harm the environment health.

Method

This type of research is quantitative using the method of experimental design with one group pretest-posttest. The population of research are the elderly in the Elderly health care Werda of All the Village Wayut Kecamatan Jiwan, Madiun Regency. The sample in this study as many as 21 people.

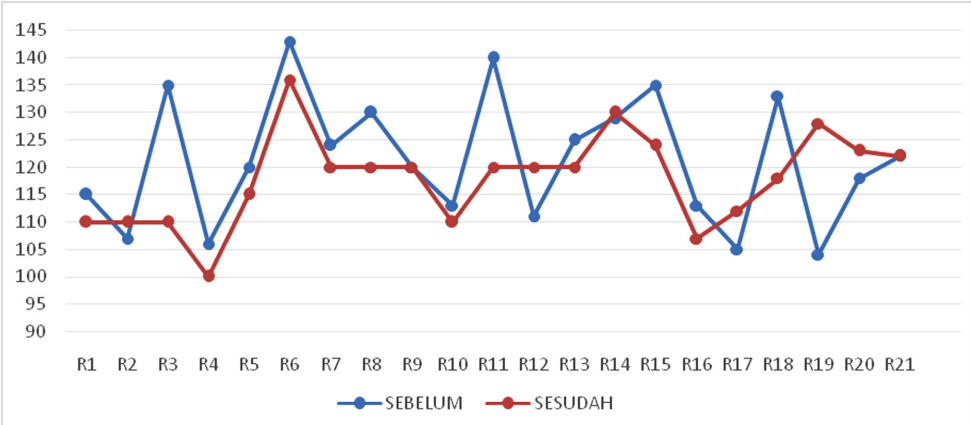
Elderly every morning at 09.00 PM for 7 days taken blood pressure data, then given treatment gymnastics for 15 minutes and wait 30 minutes then (09.45 WIB) rechecked blood pressure after treatment gymnastics.

Results

Elderly health care Werda Tama (PLWT) one of the elderly health care under the auspices of the health center Klagenserut Jiwan Madiun. PLWT is the integrated service post for the elderly in the Village Wayut, which is driven by the community (cadres).

Table 1: Characteristics of study respondents in PLWT Wayut, Jiwan, Madiun February 2019

No	Characteristic	Frequency	Percentage
1	Age		
	60-64	13	61,9
	65-69	7	33,3
	70-75+	1	4,8
Total		**21**	**100**
2	Gender		
	Men	3	14,3
	Women	18	85,7
Total		**21**	**100**
3	Body Mass Index		
	Less (<18,5)	3	14,3
	Normal (18,5-25)	12	57,1
	Excess (>25)	6	28,6
Total		**21**	**100**



Normality test Shapiro-wilk with α=0,05. Distribution of Data is normal if p-value >α and the data is not normally distributed if p-value <α. The results of the normality distribution of data is normal that data blood pressure pre-test value p-value 0,503 and blood pressure post-test value p-value 0,651.

Table 2 Analysis of the Blood Pressure Systole before and after a given treatment elderly exercise on the respondents in the PLWT Wayut Jiwan, Madiun Februari 2019.

Variable		Mean	Min-Max	*p-value*	α
Pre-test	Sistole	121,33 mmHg	104-143 mmHg	0,018	5%
Post-test	Sistole	117,85 mmHg	100-136 mmHg		

Table 2 above shows the results of paired t test with p–value 0,018 these results suggest treatment elderly exercise is effective for lowering blood pressure systole respondents. As illustrated in the following chart :

Picture 1 the results of the blood pressure systole of the elderly before and after the gymnastics of the elderly on the respondents in the PLWT Wayut Jiwan, Madiun February 2019

Discussion

The results of the analysis in table 2 shows that the average blood pressure systole of the respondents before treatment (pre-test) 121,33 mmHg. To get blood pressure stable handling that is done to the respondents in the tudy this is the gymnastics of the elderly[3]. And the results of

the average blood pressure systole of respondents after treatment (post-test) 117,85 mmHg.

This study consisted of 18 female respondents and 3 male respondents and it turns out that gender did not influence the treatment given to the response of the body, in accordance with research [6] in Australia which states that gender affects the risk of incidence of hypertension but not with response to treatment in lowering blood pressure.

This study describes elderly exercise can lower blood pressure, koesterol,weight and maximize oxygen intake, muscle mass, total body potassium er fat-free soft tissue, and body fat [7]. And also the results of the research [8]in Korea which provide aerobic exercise there are elderly women, that aerobic axercise does not give the changes in left ventricular function but showed a positive influence on the body, namely the absorption of oxygen and fat to the maximum. [9]Prove excercise affect parasypatic cardiac control by means of the affect insulin sensitivity and glucose metabolism secondary, so that can reduce arterial stiffness and arterioskerosis that will facilitate blood flow and lower blood pressure.

CONCLUSION

Elderly exercise is effective in lowering the blood pressure with the difference in blood pressure systole before and after a given treatment (p-value 0,018) with α=0,05. Changes in blood pressure systole what happens is the average before treatment elderly exercise 121,33 mmHg decreased to 117,85 mmHg.

Other researchers are advised to develop gymnastics for the elderly and other method to lower blood pressure which is optimal.

Determinant Factors Affecting the Nutritional Status of Children in Regional Health Center of Gresik

Abdulmuhith[1], Mohamad Yusakanshori[2], Setiya Purbasari[3]

[1]Nursing Science Department, University of Nahdlatul Ulama Surabaya (UNUSA), Indonesia, [2]University of Nahdlatul Ulama Surabaya (UNUSA), Indonesia, [3]Institute of Health Science Surya Mitra Husada Kediri

Abstract

Preschool children are at risk developing PEM as they are not breastfed and the food consumed may not fuilfill the nutrients need for their progressive growth. Nutritional status of preschool children is indirectly associated to the socioeconomic and hygiene status and directly associated to the level of consumptions and infections. The aims of this research is to analyze the associations between socioeconomic factors, hygiene, level of consumptions, and infections with the nutritional status of preschool children in Gresik District. The result of statistical analysis using the Multiple Linear Regression Test showed that maternal education, knowledge, environmental hygienity and protein energy intake have a significant influence on nutritional status of children,while maternal parenting, URI incident and diarrhea and family income variables have no significant influence on nutritional status. Early detection through intensification monitoring of toddler growth at posyandu, followed by determination of nutritional status by village midwife or other health worker. It is a striving for a dynamic food and environment where monitoring of critical indicators of resources, availability and access to food and nutrition at all levels of society required.

Keywords: *Nutritional status, maternal education, knowledge, hygienity, protein energy,children aged 24-60 months.*

Background

Underweight or poor nutrition in infancy and children, especially at the age of less than 5 years can lead to disruption of physical growth and child intelligence.[1] Growth of brain cells takes place very quickly and will stop or reach the perfect stage at the age of 4-5 years.[2] Rapid brain development can only be achieved if the child has good nutritional status.[3] Growth monitoring of infant development is very important to know the existence of early infant growth disorder, by way of weight measurement as the best way to assess the nutritional status of children every month so that child growth will be monitored.How to assess nutritional status can be done with anthropometric, clinical, biochemical, and biophysical measurements. Anthropometric measurements can be performed with several measurements: weight measurement, height, upper arm circumference, and so on. One indicator of health in children under five years old (toddlers) can be seen from the nutritional status. Nutritional status of children can be measured by age, weight (BW), height (BH). Monitoring the nutritional status of children under five can be seen from three indicators of anthropometry, namely: weight by age (BW/A), body height by age (BH/A) and weight by body (BW/BH). Based on the indicator of BW/BH, nutritional status is divided into 4 namely malnutrition, underweight, good nutrition, and fat.Based on the results of Basic Health Research in 2013, it is known that the percentage of underweighted BW/A status by province in Indonesia is 33 percent higher, the prevalence of malnutrition in infants (BW/BH) by province in Indonesia is 18,7 percent in 2013. Meanwhile,the percentage of underweight and underweight nutrition (BW/A) according to regencies and municipalities in East Java Province in 2013 was 4.9% and nutritional status less 14.2%.[4]

Based on the data of PSG data from the Health Office of Gresik Regency in 2016, it shows that percentage of nutritional status under fives index BC/U in 2014 until 2015 for under-five children with malnutrition decreased significantly from 5.43% to 0.7% but in year 2016 increased slightly to 0.98%, while under-fives

with underweight nutrition continued to increase from year to year, ie in 2014 by 0.26% (203 under-fives), by 2015 soaring. equal to 4, 9% (3907 under-fives), and in 2016 increased to 5.93% (4547 children under five). Malnutrition events need to be detected early on through intensification of infant growth monitoring at posyandu, followed by determination of nutritional status by village midwives or other health workers. Malnutrition data in East Java is based on 2 categories ie by indicator comparing BW/A and second category is compare BW/BH.

Research Methodology: This research is a quantitative research using analytical survey with cross sectional design or design. Cross-sectional survey is a study to study the correlation dynamics between risk factors and effects by approach, observation or point time approach meaning that each subject is observed only once and the measurement is done on the character or variable status subject at the time of examination. The population of this study is all mothers who have children under five in the working area of Puskesmas Kabupaten Gresik. Respondent in this research is mother toddler, while sample unit is toddler age 24-60 month amount 1315 balita. The minimum sample size in this study was 90 mothers and children aged 24-60 months, taken by proportional random sampling. Respondents were mothers of the sample. The statistical test used is Multiple Linear Regression. The independent variables in this research are education, mother's knowledge, environmental higines level, protein energy intake, family income, mother care pattern, and incidence of URI and diarrhea with nutritional status of children. Dependent variable in this study is nutritional status of children aged 24-60 months.

Research Results: Table 1 shows that of 90 respondents most of the mothers have high school education background and normal nutritional status of children (64.4%). Result of data analysis using t test got t count equal to 2,526 and p = 0.013, so p <0.05. This means that there is significant influence between mother education with nutritional status. The level of maternal education determine their attitudes and actions in dealing with various problems and has an important role in the health and growth of the child. This can be demonstrated by the fact that children from mothers with higher educational backgrounds will have a better chance to live and grow better and more readily accept broader insight into nutrition.[5,6]

Table 1. Cross-tabulation of maternal education and nutritional status of children

		Nutritional status				Total (person) Percentage (%)
		Bad	Insufficient	Normal	Fat	
Education	SD	3	0	0	0	3
		3.3%	0.0%	0.0%	0.0%	3.3%
	SMP	0	8	4	0	12
		0.0%	8.9%	4.4%	0.0%	13.3%
	SMA	0	1	58	10	69
		0.0%	1.1%	64.4%	11.1%	76.7%
	PT	0	1	3	2	6
		0.0%	1.1%	3.3%	2.2%	6.7%
Total		3	10	65	12	90
		3.3%	11.1%	72.2%	13.3%	100.0%

Table 2 shows that of 90 respondents most mothers have high income is>Rp. 1,200,000 and her children have normal nutritional status (67.8%). The result of data analysis using t test got t count equal to 0.561 and p = 0.567, so p> 0.05. This means that there is no significant influence between family income with nutritional status of children.Some studies highlighted the relations of family income and nutritional status.[7,8]Thus the incidence of nutritional disorders is not only found in families who earn less but also in high-income families. This situation indicates that ignorance of the benefits of food for the health of the body causes the poor nutritional quality of family food, especially toddlers.

Table 2. Cross-tabulation of income family and nutritional status

			Nutritional status				Total
			Bad	Insufficient	Normal	Fat	
Family income	Low (<IDR 1.200.000)	Count	136.928	0.000	4	2	11
		% of Total	1.1%	4.4%	4.4%	2.2%	12.2%
	High (>IDR 1.200.000)	Count	2	6	61	10	79
		% of Total	2.2%	6.7%	67.8%	11.1%	87.8%
Total		Count	3	10	65	12	90
		% of Total	3.3%	11.1%	72.2%	13.3%	100.0%

t_{count}= 0.561, p =0.567

Table 3 shows that of 90 respondents most mothers have enough knowledge and normal nutritional status (60%). The result of data analysis using t test obtained t count equal to 5,729 and p = 0.000, so p <0.05. This means that there is significant influence between mother's knowledge about nutrition with nutritional status of children. Nutrition knowledge of parents is one of the factors that affect child nutrition.[9] Mother's knowledge determines the behavior of food consumption, one of them through nutrition education so that will improve the habit of food consumption.[10] Lack of knowledge about nutrition or the ability to apply in everyday life is an important cause of nutritional disorders.

Table 3. Cross-tabulation of mother's knowledge about nutrition with nutritional status.

			Nutritional status				Total
			Bad	Insufficient	Normal	Over	
Knowledge	Less	Count	0	4	0	0	4
		% of Total	0.0%	4.4%	0.0%	0.0%	4.4%
	Enough	Count	2	5	54	0	61
		% of Total	2.2%	5.6%	60.0%	0.0%	67.8%
	Good	Count	1	1	11	12	25
		% of Total	1.1%	1.1%	12.2%	13.3%	27.8%
Total		Count	3	10	65	12	90
		% of Total	3.3%	11.1%	72.2%	13.3%	100.0%

t_{count}= 5.729, p=0.000

Table 4 shows that of 90 respondents almost half of the mother's parenting pattern is enough and normal nutritional status (42.2%). The result of data analysis using t test got t count equal to 0.553 and p = 0.582, so p> 0.05. This means that there is no significant influence between mother care pattern with nutritional status of children. Patterns of parenting also contribute to the nutritional status of children, one of the patterns of care related to the nutritional status of children is the pattern of feeding.[11] In addition to eating patterns, mother's health patterns also affect the health status of children and will ultimately affect the child's nutritional status indirectly.

Table 4. Cross tabulation of mother's parenting with nutritional status

			Nutritional status				Total
			Bad	Insufficient	Normal	Fat	
Mother's parenting	Less	Count	0	2	19	2	23
		% of Total	0.0%	2.2%	21.1%	2.2%	25.6%
	Enough	Count	1	5	38	2	46
		% of Total	1.1%	5.6%	42.2%	2.2%	51.1%
	Good	Count	2	3	8	8	21
		% of Total	2.2%	3.3%	8.9%	8.9%	23.3%
Total		Count	3	10	65	12	90
		% of Total	3.3%	11.1%	72.2%	13.3%	100.0%

t_{count}= 0.553, p=0.582

Table 5 shows that of 90 respondents most of the good environmental hygienitas and toddlers normal nutritional status (67.8%). Result of data analysis using t test got t count equal to 3,753 and p = 0.000, so p <0.05. This reveal a significant influence between hygienitas environment with nutritional status of children.Some studies found the link between environmental hygiene and nutritional conditions.[12,13] Health status can be improved by maintaining health and physical and social environment. From an epidemiological point of view the nutritional problems are strongly influenced by the host, the agency, the environment. The imbalance between these three factors, such as the occurrence of nutrient insufficiency. Poor environmental sanitation will make children more susceptible to infectious diseases that may ultimately affect nutritional status.

Table 5. Cross-linking of environmental hygienity with nutritional status

			Nutritional status				Total
			Bad	Insufficient	Normal	Fat	
Hygienity level	Less	Count	3	0	0	0	3
		% of Total	3.3%	0.0%	0.0%	0.0%	3.3%
	Enough	Count	0	8	4	2	14
		% of Total	0.0%	8.9%	4.4%	2.2%	15.6%
	Good	Count	0	2	61	10	73
		% of Total	0.0%	2.2%	67.8%	11.1%	81.1%
Total		Count	3	10	65	12	90
		% of Total	3.3%	11.1%	72.2%	13.3%	100.0%

t_{count}= 3.753, p=0.000

Table 6 shows that of 90 respondents most of the incidence of URI and diarrhea is absent and children under normal nutritional status (72.2%). Result of data analysis using t test got t count equal to-1,313 and p = 0,193, so p> 0.05. Thus, there is no significant influence between incidence of URI and diarrhea with nutritional status of children. Malnutrition due to dietary intake can be affected by childhood illness, such as URI and diarrhea. This will be important enough to get serious attention in childhood because it can enter a variety of disorders of growth and development of nutritional status. Similarly, diarrhea can cause nutritional disorders due to reduced food intake.[14]Less nutritional status leads to decreased body resistance and stronger viral pathogens, resulting in a balance of disorders and infection.

Table 6. Cross tabulation of incidence of URI and diarrhea with nutritional status

			Nutritional status				Total
			Bad	Insufficient	Normal	Fat	
URI and diarrhea	Exist	Count	1	2	0	5	8
		% of Total	1.1%	2.2%	0.0%	5.6%	8.9%
	No	Count	2	8	65	7	82
		% of Total	2.2%	8.9%	72.2%	7.8%	91.1%
Total		Count	3	10	65	12	90
		% of Total	3.3%	11.1%	72.2%	13.3%	100.0%

t_{count}=-1.313, p=0.193

Lastly, the testing results of the effect of energy and protein consumption levels on nutritional statusshow that out of 90 respondents, most of the level of energy and protein consumption is normal and toddlers normal nutritional status (52.2%). The result of data analysis using t test got t count equal to 4,751 and p = 0.000, so p <0.05, mean H0 rejected and H1 accepted so there is significant influence between nutrient intake with nutritional status of children aged 24-60 months. Nutrition is a substance or chemical element contained in the food needed for metabolism in the body normally. Nutrition needed by the body consists of carbohydrates, fats, proteins, vitamins, minerals and water. In an effort to achieve adequate consumption, the two most important factors that can affect the daily consumption of nutrients of availability of food and nutritional knowledge.[15]A person will be able to provide adequate consumption when they are able to provide nutritional food.

Conclusion

The findings reveal that there is a significant influence between maternal education variables on nutritional status of children aged 24-60 months in 3 Puskesmas Kab. Gresik. The variables of knowledge, environmental hygienity and protein energy intake have a significant influence on nutritional status of children. Moreover, there is no significant influencesof parenting, URI incident and diarrhea and family income variable on nutritional status of children.Of the factors above, the most dominant influence the nutritional status of children aged 24-60 months is the knowledge and protein energy intake. This encourages the community, especially the nanny, or the mother of the child 2-5 years to increase knowledge about child nutrition, and for healthcare workers to routinely hold program both in mother and children related to child nutrition.

Determinant of the Puskesmas Utilization in Madura Island

Agung Dwi Laksono[1,2], Ratna Dwi Wulandari[3]

[1]Indonesian Agency for Health Research and Development of the Ministry of Health. Jl. Percetakan Negara 29, Jakarta, [2]Doctoral Program, Faculty of Public Health, Universitas Airlangga, Surabaya, [3]Department of Health Policy and Administration, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia

Abstract

Madurese communities often have a low public health status. These could be seen from the health development achievements four regencieson the island. This research was intended to analyze the determinant ofthe Puskesmas utilization in Madura Island. The Data derived from the 2013 Riskesdas. The analysis usingbinary logistic regression to examine the determinant of the Puskesmas utilization. The results of the study showed the Madurese in Bangkalan likelihood 2,120 times more utilize the Puskesmas than in Sumenep (OR 2.120; 95% CI 1.448–3.105). Madurese in Pamekasan 1.410 times more likely to utilize the Puskesmas than in Sumenep (OR 1.410; 95% CI 1.025–1.940). Age affects the Puskesmas utilization, while rurality did not show a significant influence. Those who pass the primary school were likelihood 0.225 times to utilize of Puskesmas than the graduates of the college (OR 0.225; 95% CI 0.054–0.946). The Madurese in quintile 4 seen has no difference from those in quintile 5. While the Madurese who insured likelihood 0.650 times to utilize the Puskesmas than who not insured (OR 0.650; 95% CI 0.517–0.818). The Madurese that has a shorter time to the Puskesmas likelihood 0.616 times more utilize than that have a long time (OR 0.616; 95% CI 0.479–0.791). The research concluded that from 9 factors related to the Puskesmas utilization in Madura Island, there are 7 factors that are determinants, namely the regency, age, education, work status, socioeconomic, insurance, and travel time.

Keywords: *Utilization determinant, healthcare, health services, Madura, Riskesdas.*

Background

Madura is one of the islands which is in the working area of the province of East Java, Indonesia. Madura Island very special because it is dominated by the community in one tribe, Madura[1]. Health development in Madura has its own notes. This is because often the health development in four regencies in Madura Island (Bangkalan Sampang, Pamekasan and Sumenep) left behind than others regency in East Java Province. The Indonesian Public Health Development Index (PHDI), an index rating, is processed based on the data of 2007 Indonesian Basic Health Research (Riskesdas). PHDI put 4 regencies in Madura Island in the bottom five ranking from 38 regencies in East Java Province[2]. Indonesian PHDI released back in the year 2014. This time the index rating is done based on the results of 2013 Riskesdas. The result 3 regencies remain in the bottom five ranking, and 1 regency (Sampang) successfully slightly rose to the position of the bottom ten ranking[3].

Community Health Center in Indonesia called Puskesmas is a technical executive unit regency health office which is responsible for holding the health development in a regency's working area. The existence of a Puskesmas in the community is vital because the Puskesmas is a primary health service as the spearhead health services[4,5]. The Puskesmas in its implementation serve outpatient and emergency, but also inpatient for some specific regions, especially that far from the hospital[6].

The Puskesmas utilization as the spearhead in Madura was considered very important. Because the Puskesmas is the first entrance for the community to get health services[7]. The determinants of Puskesmas utilization must be really understood by the policymakers in Madura to policy decisions made can really give impact to the health status of the Madurese communities[8]. Based on the background then this article was written to analyze the determinant of the Puskesmas utilization in Madura Island.

Method

The source of the data used in the analysis of this study was the 2013 Riskesdas. The Puskesmas utilization was a community visit to Puskesmas, both outpatients and inpatient. Outpatient was a community visit that done the last month, and inpatient was a community visit that done the last year. There were eleven factors analyzed in relation to the Puskesmas utilization. The eleven factors were a regency, rurality, age, gender, marital status, education, work status, socioeconomic, insurance, time traveled, and transportation cost to the Puskesmas.

The analysis unit in this research was the inhabitants of Madura Island 15 years old and above. At the age was assumed respondents have been able to take his own decision to do utilize the Puskesmas or not. Samples size were analyzed some 7.135 respondents.

The Chi-Square used to test dichotomous variables and T-tests for a continuous variable. This test was used to assess whether there were differences in the utilization of the Puskesmas. The estimation used binary logistic regression tests to analyze the factors that influence (determinant) on the Puskesmas utilization.

Findings: Table 1 is a statistical representation of the characteristics of the community respondents Madura Island which becomes the object of analysis in this research. Table 1 shows that there is a significant difference between Madurese people who utilize the Puskesmas based on the Regency. The average of Madurese that utilized of the Puskesmas a little older than that does not utilized. Table 1 also shows that the Madurese that utilizes the Puskesmas more women than men. However, based on the statistics test shown that gender and marital status were not different in statistics.

Table 1: Descriptive Statistics

Characteristic	The Puskesmas Utilization		All	P
	Utilized	Not Utilized		
Regency				0.000*
● Bangkalan	40 (11.6%)	1,658 (24.4%)	1,698 (23.8%)	
● Sampang	110 (31,9%)	1,617 (23.8%)	1,727 (24,2%)	
● Pamekasan	68 (19.7%)	1,657 (24.4%)	1,725 (24,2%)	
● Sumenep (Ref.)	127 (36.8%)	1,858 (27.4%)	1,985 (27.8%)	
Age (mean)	345 (45.49)	6,790 (42.95)	7,135 (43.08)	0.006*
The Area				0.002*
● Urban	90 (26.1%)	2,317 (34,1%)	2,407 (33.7%)	
● Rural (Ref.)	255 (73.9%)	4,473 (65.9%)	4,728 (66.3%)	
Gender				0.151
● Male	140 (40.6%)	3,023 (44.5%)	3,163 (44.3%)	
● Female (Ref.)	205 (59.4%)	3,767 (55.5%)	3,972 (55.7%)	
Marital Status				0.717
● Single	46 (13.3%)	1,097 (16.2%)	1,143 (16,0%)	
● Married	256 (74.2%)	4,854 (71.5%)	5,110 (71.6%)	
● Live together without married	0 (0.0%)	6 (0.1%)	6 (0.1%)	
● Divorce	5 (1.4%)	117 (1.7%)	122 (1.7%)	
● Separate	1 (0.3%)	10 (0.1%)	11 (0.2%)	
● Dead divorce (Ref.)	37 (10.7%)	706 (10.4%)	743 (10.4%)	
Education				0.000*
● Under primary school	186 (53.9%)	3,081 (45.4%)	3,267 (45.8%)	

Characteristic	The Puskesmas Utilization		All	P
	Utilized	Not Utilized		
● Primary school	95 (27.5%)	1,843 (27.1%)	1,938 (27.2%)	
● Junior high school	37 (10.7%)	775 (11.4%)	812 (11.4%)	
● Senior high school	25 (7.2%)	797 (11.7%)	822 (11.5%)	
● College (Ref.)	2 (0.6%)	294 (4.3%)	296 (4.1%)	
Work Status				0.030*
● No worked	127 (36.8%)	1,987 (29.3%)	2,114 (29.6%)	
● Worked	199 (57.7%)	4,389 (64.6%)	4,588 (64.4%)	
● Looking for work	2 (0.6%)	43 (0.6%)	45 (0.6%)	
● Schooling (Ref.)	17 (4.9%)	371 (5.5%)	388 (5.4%)	
Socioeconomic Status				0.000*
● Quintile 1	136 (39.4%)	2.109 (31,1%)	2,245 (31.5%)	
● Quintile 2	112 (32.5%)	1,950 (28,7%)	2,062 (28.9%)	
● Quintile 3	59 (17.1%)	1,169 (17.2%)	1,228 (17.2%)	
● Quintile 4	23 (6.7%)	2,284 (13.8%)	960 (13.5%)	
● Quintile 5 (of Ref.)	15 (4.3%)	625 (9.2%)	640 (9.0%)	
Insurance				0.000*
● Insured	175 (50.7%)	2,554 (37.6%)	2,729 (38.2%)	
● No insured (Ref.)	170 (49.3%)	4,236 (62.4%)	4,406 (61.8%)	
The travel time				0.000*
● ≤ 15 minutes	199 (57.7%)	3,171 (46.7%)	3,370 (47.2%)	
● > 15 minutes (of Ref.)	146 (42.3%)	3,619 (53.3%)	3,765 (52.8%)	
Transportation cost				0.000*
● ≤ IDR 10,000	305 (88.4%)	5,475 (80.6%)	5,780 (81.0%)	
● >IDR 10,000 (of Ref.)	40 (11.6%)	1,315 (19.4%)	1,355 (19.0%)	

Note: Chi-Square used for a dichotomous variable, and T-test for a continuous variable; *significant at 95% levels.

Table 1 shows that there is a difference between the Puskesmas utilization in Madura Island based on education level. Seen them that make use of the services is dominated by which has education status under the primary school. This results in line with differences in the utilization based on socioeconomic level. Madurese people who utilize Puskesmas was dominated by who was in the quintile 1 (very poor). Based on the work status of those who have the work dominate the Puskesmas utilization.

Three other variables also have a significant difference in the Puskesmasutilization. Among the insured and not, among that takes time quickly (≤ 15 minutes) and takes a long time, and among the cheaper transportation cost (≤ IDR 10,000) and the more expensive transportation costs.

Table 2: Logistic Binary Regression of the Puskesmas Utilization in Madura Island

Predictor	The Puskesmas Utilization			
	Sig.	OR	The lower bound	The upper bound
Regency: Bangkalan	0.000*	2.120	1.448	3.105
Regency: Sampang	0.629	0.933	0.705	1.235
Regency: Pamekasan	0.035	1.410	1.025	1.940
Age	0.009*	0.990	0.982	0.997
Area: Urban	0.119	1.248	0.945	1.649
Education: Under primary school	0.065	0.258	0.061	1.086
Education: Primary school	0.042*	0.225	0.054	0.946
Education: Junior high school	0.048*	0.229	0.053	0.984

Predictor	The Puskesmas Utilization			
	Sig.	OR	The lower bound	The upper bound
Education: senior high school	0.084	0.277	0.064	1.191
Work status: No worked	0.574	0.851	0.484	1.495
Work status: Worked	0.347	1.305	0.749	2.274
Work status: looking for work	0.929	0.933	0.204	4.274
Socioeconomic: Quintile 1	0.002*	0.391	0.215	0.712
Socioeconomic: Quintile 2	0.003*	0.405	0.224	0.732
Socioeconomic: Quintile 3	0.025*	0.501	0.274	0.917
Socioeconomic: Quintile 4	0.880	0.949	0.485	1.857
Insurance: Insured	0.000*	0.650	0.517	0.818
The travel time: ≤ 15 minutes	0.000*	0.616	0.479	0.791
Transportation cost: ≤ IDR 10,000	0.057	0.693	0.475	1.010

Note: Category reference is "No utilized"; OR Confidence Interval 95%; *Significant at 95% levels.

Table 2 displays the results of the binary logistic regression tests to illustrate the factors that affect the Puskesmas utilization in Madura Island. Selected category reference was "No utilized". Table 2 shows that the Madurese living in Bangkalan likelihood 2.120 times more utilize the Puskesmas than the Madurese in Sumenep (OR 2.120; 95% CI 1.448–3.105). The Madurese living in Pamekasan likelihood 1.410 times more utilize the Puskesmas than those living in Sumenep (OR 1.410; 95% CI 1.025–1.940). While there is no significant difference between Madurese living in Sampang and Sumenep in Puskesmas utilization.

Table 2 shows that the age effect significantly against the Puskesmas utilization. While rurality did not show a significant impact. Based on education level, partially influencing against the Puskesmas utilization. The Madurese are graduated primary school likelihood 0,225 times utilize the Puskesmas than the college graduates (OR 0.225; 95% CI 0.054–0.946). The graduates of junior high schools' likelihood 0,229 times than those which college graduates in the Puskesmas utilization. Based on the work status, there is not a significant impact on the Puskesmas utilization.

There is a partially influence the Puskesmas utilization based on socioeconomic level. The Madurese in quintile 4 seen has no difference from those in quintile 5. While those who have insurance was likelihood 0.650 times utilize the Puskesmas more than those who have no insurance (OR 0.650; 95% CI 0.517–0.818). Different from the results of other studies that reveal the positive impact of insurance in relation to the straight path towards the utilization of health services[9,10,11,12,13], Madurese people who utilized the Puskesmas dominant who do not have insurance. This asserts that the tariff services of Puskesmas in Indonesia are classified as cheap. The possibility of these conditions creates Madurese loyal to utilize the Puskesmas[14,15,16]. This makes the role of the replacement of the risk through insurance mechanisms less so necessary in the Puskesmas utilization.

Based on time traveled, Madurese that have shorter time likelihood 0.616 times more utilize than those who have time traveled longer (OR 0.616; 95% CI 0.479–0.791). The results of this study strengthen the results of other research that shows the relationship between the travel time with the health services utilization[17,18,19,20].

Based on the table 2 can be known that there are 7 factors that proved statistically significant as a determinant of Puskesmas utilization in 4 regencies in Madura Island. Examining the determinants are seen that the societies of the Madurese are most many utilize the Puskesmas was that those in marginal groups. This condition can be seen from their domination of the low educated and poor (quintile 1 and quintile 2), and do not have insurance to have the possibility of higher utilize the Puskesmas services. This description in accordance with some research results on the image of the previous Puskesmas utilization[21,22,23,24]. Based on the results of this can be stated that the Puskesmas in Madura Island was the main choice when marginal communities who need the health services.

The choice of society marginal Madura against the Puskesmas very reasonable. The Puskesmas is the nearest health service facilities and has the cost of the services cheap and even free. Access to Puskesmas that is physically close is a guarantee of cheaper transportation costs[25,26]. A rational choice for the marginal group.

Conclusion

Based on the research results it can be concluded there are 9 factors that are related to the Puskesmas utilization in Madura Island. From 9 factors, 7 selected

factors that are statistically significant. The seven factors are a regency, age, education, work status, socioeconomic, insurance, and time traveled to the Puskesmas.

Ethic and Consent: The 2013 Riskesdas survey had an ethical clearance that was approved by the national ethical committee in the NIHRD (ethic number: 01.1206.207). Informed consent was used during data collection, which considered aspects of the data collection procedure, voluntary, and confidentiality.

A Comparative Study in Healthy Psychological Burning among Football Referees and Football Referees of First Class Halls in Southern Zone

Ahmed Sa'ad Abdul Razak[1], Ali Hussein Ali[1], Anmar Atshan Khargan[1], Asmaa Sattar Khudhair[1]

[1]*THI-QAR University, College of Physical Education and Sports Sciences*

Abstract

Term of (Burnout) is being repeated in last years within sources of sports psychology which means (Burning) and it is a case of psychological & physical exhausting which may infects the athletic due to accumulating of emption and entertainment and as a source for worry and fear to fail instead of desire to success, win and rising, Process of refereeing in football is a difficult mission the referee bears heavy loads and many troubles but he became delighted to practice it because the foundation of his practice of it is a pure hobby so he always seeks to a success in it through continuous work despite physical, technical and social obligations, The research aimed to know about differences in the phenomenon of psychological burning among football referees and football referees of first class halls in southern zone.

The researchers assumed that there are differences with moral guidance in the phenomenon of psychological burning among football referees and football referees of first class halls in southern zone.

The researchers had mentioned to the theoretical studies that contained of multiple researches related to the topic of the research. The researchers used the describing method by principle of comparative studies due to is suitable for the problem of the research, The research sample was contained from (28) referees divided onto (14) football referees and (14) referees of first class halls after implementing measure of psychological burning on a sample of research the researchers did to find differences between the two groups by using the law of (T) for the independent samples, After that theses results has been previewed and analysis and discussed so the researchers reached to conclusions the most important of the is that there are no any moral differences between the groups of football referees and football referees of first class halls in southern zone.

As for the most important recommendations that there is a necessity to insert referees whether football referees and football referees of first-class halls in southern zone. And would be supervised by psychological consultant for sake to instruct them about the psychological burning phenomenon and causing reasons so to insure their acknowledgment of this phenomenon in future.

Keywords: *Psychological Burning, society, Referees.*

Introduction

Preface and importance of the research: Psychology is to be considered of important sciences that needs study and big deepening due to is has big biological effecting on individuals, So it is a science which is so needful in last years especially in the sport field due to it has active effecting whether in training or competing some gave it priority in classification because it effects on the physiological sides of different body organs that do an active role in performance so it has been repeated in last years the term of (Burnout) within the terms of sport psychology which means (burning) where it is the status of physical and psychological exhausting that may infects the athletic due to accumulating of loads of ambition and entertainment and a source for worry and fear instead of desire in superiority, win and highness.

Refereeing process is to be considered a difficult mission the referee bears heavy loads and many troubles but he feels delighted to practice it because the basis of practicing is a pure hobby so he seeks always to

success through continuous work despite it has physical, technical and social obligations and this the top of the evolution and success to reach top levels and big degrees.

So the occupation of referee is most occupations that being subjected to psychological stresses and these stresses by its turn causes psychological burning and the psychological burning leads to creating negative situations against others which would leads to a case of restless and self conflict and down fall of personal relations where it effects on the personality in all ad this effect would be more clear in the psychological and physical health and performance in work which will causes that the referee will not be able to do his role in complete that participate in his feeling to be disable and gloominess with exhausting effort leads to a case of exhausting and psychological exhausting the thing that will enforce him to performs with low than its required from him.

The football game and football for halls are most popular games in the world and the role of the referee would be considered very important in managing the wheel of the match and to lead it to the safe lands and this requires high physical and psychological effort where the nature of psychological stresses that are being faced by the referee whether they where from the audience or press or media means, competing teams or referee committee that he works with them gives and big importance to be studied, Due to its role in rising the level of referee occupation and developing it and to rise it to the required level which will make practice of this occupation clear of problems and to get rid of its negatives that which will maintain giving his value and respected status for the sport referee in the society[1].

Through what has been mentioned and in view of available scientific resources about this important psychological phenomenon so the importance of the current research shows clearly in dealing with one of the sport jobs that impacts on sport field and joins with others in showing level of matches by shining & honoring vision for any sports activity being practiced, from here the importance of the research come out to know the phenomenon of psychological burning of football referees and football referees of fist class halls in order to know the referees of any of these two games are more subjecting to the psychological burning other than others. For sake to reduce the severity of psychological burning in them through knowing the reasons that causes that caused their burning.

Problem of the study: Few of people knows the size of big work that has been assigned on the shoulders of the referee whether before or after or during the match so he works under big stresses despite multi global and Arabic studies that took the phenomenon of psychological burning in the sport field but most of them (according to the acknowledgment limits of the two researchers) has not mentioned to the psychological burning of the sport referee especially foot bal referees and football referees of halls which may play an important role in leading the match and give it big beauty, through observation and private meeting for some of the referees and following by the researchers of the periodic and referees the problem of the research appeared that there are a number of referees does not continues in work due to being subjected for some psychological stresses or they may continue in their work with no acceptance about this work and then falling of their level of achievements, These stresses that are causing psychological burning varies by the difference of the game and its requirements which has pushed us to try to explore about these differences in the phenomenon of psychological burning of them.

Aims of the research: Identification on differences in the phenomenon of psychological burning among football referees and football referees of first class halls in southern zone.

Supposition of the research: There are differences with moral guidance in the phenomenon of psychological burning among football referees and football referees of first class halls in southern zone.

Scope of the research:

1. 5.1 Human field:-football referees and football referees of first class halls in southern zone–republic of Iraq
1. 5.2. Time field 15/5/2018-1/2/2019
1. 5.3. Location field, Stadiums and halls of football in southern zone

2. Method of research and its field procedures:

2.1. Research method the two researchers used the describing method by principle of comparing due to its suitable for the research problem.

2.2. Society of the research and its sample:

The society of the research has been formed from football referees and football referees of first class halls in southern zone (Basra–THI-QAR–Maisaan, Mothanna

governorates) and those who had been really recorded in the union of the football federation who are (39) referees of football and (28) referees for halls football, but the sample of the research has been chosen by random method where (28) referees had been chosen with reality of (14) referees for football and (14) referees for first class halls and the table (1) represents some of the information about society and sample of the research.

Table (1): Indicates number of society and research sample

Number Province	Number of football referees		Number of referees of halls	
	Total number	Sample	Total number	Sample
Basra	11	4	9	3
THI-QAR	15	6	6	5
Maisaan	7	2	6	3
Muthanna	6	2	7	3
Total	39	14	28	14

Research Method

2-3-1 Psychological burning measurement of the sport referee: The measurement has been designed by[3] to measure the feeling of the sport referee in burning under title of burning in refereeing and it is a measurement being abstracted from list of (Masilas) of burning and has been translated to Arabic[4], The measurement includes (15) phrases the referee answers on the item of the measurement according to seven substitutes (never implemented on me, implements on me very little, implements on me little,implements of me middle, implements on me with large size, implements on me with very large size, totally implements on me) the degrees from (1–7) is being given respectively except items (11.7.5) where their degrees is to be counted reversely. As much the total referee degree comes close from (105) it means he reached the degree of burning appendix (1)

2-3-2 Scientific specifications of the measurement

2-3-2-1 Credibility of the measurement: The two researchers had depended on measurement outward credibility and that a group of specialists to evaluate the validity of the measurement to measure the mark that it has been made for it, so the researchers did showed the measurement on a group of specialists appendix (2) in the field of sport psychology and football to go over the items of the measurement and to indicate how far is the validity and after collecting the forms from the specialists those forms has been emptied by the two researchers where the ratio of the agreement (100%)

2-3-2-2-measurement stability: The tool would be considered stable if it gives same results if measures the phenomenon for several times where the method of measurement stability through retesting is most used method in finding stability factors and most common and for sake to get of measurement stability the researchers has divided the measurement on a sample consisted of (8) referees from those who do periodic first class football teams and football for the halls and not from oral test sample then the same test repeated after two weeks from the first test on same sample after collecting the data they had been treated statistically by using the factors of simple connecting and the value of (R) 0.91 and this proofs that there is high connection and then excitant of stable factor of the measurement .

2-4 Statistical means: The following statistical treatments had been used:-

1. Accountant media
2. standard deviation
3. difference factors
4. simple connection factors
5. T Test for independent samples

3-preview results analysis & discussing them:

3-1preview and analysis the results of psychological burning measurement: 3-1-1 among football referees and football referees of halls

Table (2) Shows the differences in psychological burning among football referees and football referees of first class halls in southern zone

Treatments Changes	Football Referees		Football Referees of halls		Value of T		Statistical guidance
	S	+/-A	S	+/-A	Accounted	Table	
Psychological burning	45.21	11.15	49.66	7.41	1.199	2.06	Non moral

Value of (T) table at degree freedom (26) and the level of guidance (0.05) is (2.06)

Table (2) indicates the accountant middle and standard deviations and value of (T) accounted in the measurement of psychological burning of football referees and football referees of halls in the southern zone, results showed that then accountant middle of the group of football referees where (45.21) with standard deviation (11.15) but the accountant middle of the group of referees of halls where (49.66) with standard deviation (7.41) but the value of (T) accounted where (1.199) which is less than (T) table value of (2.06) with freedom degree (26) and below level guidance of (0.05) and this proofs that there are no any moral differences among football referees and football referees of halls in the psychological burning.

Discussion

It is clear from the table (4) that there are no any moral differences in the results of the measurement of psychological burning among football referees and football referees of halls in the southern zone the researchers justifies that it belongs to the good preparation and programmed training by the referees whether football referees or football referees of halls to reach by their selves to high level of physical fullness that enables them to good performance along the time of match as well as big desire by referees for this job and their love to it also the personal experience of those referees and their understanding of the items of the international law in managing the match and how to deal with the players in good manner as well as the exchanged cooperation between the referee and his associates in leading the match has caused not excitant of phenomenon of psychological burning for them … and this is what has been mentioned by [5] that the control on the burning requires from the athletics that they are aware of resisting against the burning where it is possible that they will analysis with constructive form and conveys their feelings to the others and by that they are reducing the burning . defined steps that leads to reduce the burning, The athletic or the referee can learn principles of psychological stress and get benefits by close examination, relaxing and others also knowing stresses is the side that enable the athletic to reduce traces of burning also that the best technique for the athletic is to identify on the problem and bearing it as much as he can then reducing it and then removing it.

Recommendations and Conclusions

Conclusions and recommendations

Conclusions

No existent of moral differences between the two research groups of referees of football and football referees of halls of first class in southern zone.

Recommendations: Basing on the results of the research the two researchers recommends by the following:

1. Participating referees whether football referees or football referees of halls in courses related to psychological sides and under supervision of psychological specialist for sake to let them know about the phenomenon of psychological burning and causes so that to ensure their acknowledgment of the phenomenon in future.
2. Raising the level of the physical fitness of the referees to stop phenomenon of physical psychological exhausting which impacts on his performance during the matches.
3. Providing financial and moral support for the referees who suffers from psychological burning symptoms.
4. Making researches and implementing similar studies treats the phenomenon of psychological burning or any other psychological variable.

The Relationship between Nutrient Intake and Blood Glucose Levels of Male High School Students in Madiun City

Alma Dwi Kartika[1], Sugiarto[2], Endang Sutisna Sulaeman[2]

[1]Student, [2]Lecturer in Master of Nutrition Science Program, Sebelas Maret University, Surakarta, Indonesia

Abstract

Introduction: Macro nutrients consisting of carbohydrates, proteins, fats and micronutrients are instrumental in the incidence of obesity and diabetes. Micro nutrient substances that play a role in this situation include vitamin A, vitamin C, vitamin D, and zinc which are important elements for synthesis, storage and secretion of insulin.

Aim: The aim of the study was to analyze the relationship between nutrient intake and blood glucose levels in male high school students.

Method: The study used a cross sectional design. A total of 103 male high school students with overweight (BMI ≥ 25) and underweight condition (BMI<18) were recruited as the respondents. Data collection on nutrient intake was carried out by conducting interviews three times using food models. The amount of food intake was calculated using the Nutri Survey SEAMEO-TROPMED RCCN Indonesia University application. Blood glucose levels were determined by measuring fasting blood glucose levels. Statistical analysis was performed with Pearson correlation test on normally distributed data and with Spearman rank test on abnormally distributed data.

Findings: The findings showed the relationship of energy intake (r = 0.344, p = 0.000), protein (r = 0.202, p = 0.041), fats (r = 0.297, p = 0.002), carbohydrates (r = 0.292, p = 0.048), vitamin A (r = -0.097, p = 0.331), vitamin C (r = -0.140, p = 0.158), vitamin D (r = 0.287, p = 0.046), vitamin E (r = 0.015, p = 0.880), zinc (r = -0.003, p = 0.976) with blood glucose levels. The average blood glucose level was 94.45 ± 18.09 g / dl, energy intake 1984.38 ± 289.32 Cal, protein 74.69 ± 14.42 gr, fat 82.03 ± 19.17 gr, carbohydrates 238.49 ± 44.47 gr, vitamin A 671.76 ± 785.65 ug, vitamin C 21.64 ± 34.18 mg, vitamin D 1.66 ± 2.13 ug, vitamin E 4.96 ± 1, 89 mg, zinc 7.34 ± 1.73 mg.

Conclusions: In conclusion, the findings highlight that there is a significant relationship between energy intake, protein, fats, carbohydrates, and vitamin D with blood glucose levels in male high school students. While vitamin A, vitamin C, and zinc have no significant relationship.

Keywords: *Nutrient intake, blood glucose levels.*

Introduction

Adolescence is a period of physical and social change, and a period of development that affect choices in maintaining health and eating behavior. Behavior in food selection during adolescence is very important because the behavior patterns obtained during adolescence tend to last until adulthood(1).

Problems in nutrition are not only the problem of malnutrition but also the problem of over nutrition. At present, nutrition problems with high prevalence are overweight and obesity. Obesity is a world nutrition problem which the impact is starting to shift from adult to childhood(2).

Obesity has a risk for type 2 diabetes[3]. Overweight can occur due to an imbalance between energy consumption and needs. Excess energy consumption is stored in subcutaneous tissue and intestinal tissue [4].

Macro nutrients consisting of carbohydrates, proteins and fats play a role in the incidence of obesity and diabetes. Excessive consumption can affect glucose metabolism by changing cell membrane function, enzyme activity, insulin releases and gene expression [5].

Moreover, micronutrients are also significant in the incidence of diabetes. Zinc is one of the micronutrients that is beneficial in the synthesis, storage and secretion of insulin. Zinc is also useful for the synthesis, storage and secretion of insulin. The function of zinc in the body metabolism is based on the enzymatic affinity of the enzyme or metalloenzyme complex [6].

Other micronutrients that engage in the incidence of diabetes are vitamins A, C, D and E. Lack of vitamins A, C and E can cause obesity. Vitamins A, C and E have been shown to reduce or inhibit the formation of leptin in both humans and animals so that it can increase appetite [7] ([8]. Children and adolescents who are obese have lower concentrations of vitamins A, C and E than those who have normal weight [9]. Consuming vitamins C and E for three months can reduce hypertension and blood glucose by increasing superoxide levels of dismutase and glutathione [10].

Another vitamin that involved in overweight and insulin resistance is vitamin D. Vitamin D is essential in increasing the activation of transcription from insulin receptor genes and in increasing the total number of insulin receptors without changing its affinity. 1,25 (OH) 2D increases insulin sensitivity by activating the delta receptor active peroxisome prolifator that regulates fatty acid metabolism in skeletal muscle and adipose tissue[5].

Method

This research was an observational analytic study with a cross-sectional design. This study was conducted at public high school 5 and 6, Madiun City. The data was taken from March to May 2019.

The respondents were a total of 130 male high school students who were overweight (BMI ≥ 25) and underweight (BMI <18). The variables in this study were the independent variables and the dependent variable. The independent variable was the nutrient intake (carbohydrates, protein, fats, vitamin A, vitamin C, vitamin D, vitamin E and zinc). The dependent variable was blood glucose level.

The data was taken by conducting three-time structured interviews using food recall tables. Blood glucose level was measured by using fasting blood glucose. Nutrient intake data was calculated by using the 2007 SEAMEO-TROPMED RCCN Nutri Survey Indonesia University application program.

Statistical analysis was performed with Pearson correlation test on normally distributed data and with Spearman rank test on abnormally distributed data. This study was stated ethically feasible by the Health Research Ethics Committee in Faculty of Medicine, Sebelas Maret University with number series 441/ UN27.06/KEPK/2019 date 20 March 2019.

Findings:

Table 1: Respondents Distribution Based on Blood Glucose Levels and Nutrient Intake

No	Variable	Mean	Median	SD
1	Blood glucose level (g/dl)	94,45	92	19,09
2	Energy (Cal)	1984.37	2021.9	289.32
3	Protein (g)	74.69	72.5	14.42
4	Fats (g)	82.03	82.5	19.17
5	Carbohydrates (g)	238.49	239.8	44.47
6	Vitamin A (ug)	671.76	493.3	785.65
7	Vitamin C (mg)	21.64	15.3	34.18
8	Vitamin D (ug)	1.66	0.8	2.13
9	Vitamin E (mg)	4.96	4.7	1.89
10	Zinc (mg)	7.34	7	1.73

Table 1 showed that the average of blood glucose level was equal to 94.45 ± 18.09 g / dl, energy intake = 1984.38 ± 289.32 Cal, protein = 74.69 ± 14.42 g, fats = 82.03 ± 19, 17 g, carbohydrates = 238.49 ± 44.47 g, vitamin A = 671.76 ± 785.65 ug, vitamin C = 21.64 ± 34.18 mg, vitamin D = 1.66 ± 2.13 ug, vitamin E = 4, 96 ± 1.89 mg, zinc = 7.34 ± 1.73 mg.

Table 2: Pearson Test of the Relationship between Energy, Protein, Fats, Carbohydrates and Vitamin E with Blood Glucose Levels in Male High School Students

No	Variable	Pearson Correlation	Sig. 2-tailled
1	Energy	0,344	0,000
2	Protein	0,202	0,041
3	Fats	0,297	0,002
4	Carbohydrates	0,292	0,048
5	Vitamin E	0,015	0,880

Table 2 showed if energy had the most significant relationship with blood glucose levels with r = 0.344 and p = 0,000.

Table 3: Spearman Test of the Relationship between Vitamin A, Vitamin C, Vitamin D and Zinc with Blood Glucose Levels in Male High School Students

No	Variable	Correlation Coefficient	Sig. 2-tailled
1	Vitamin A	-0,097	0,331
2	Vitamin C	-0,140	0,158
3	Vitamin D	0,287	0,046
4	Zinc	-0,003	0,976

Based on the results above, there was a significant relationship between blood glucose levels and the energy intake in male high school students (r = 0.344, p = 0,000). Blood glucose levels are associated with the intake of energy-dense food, especially food with high fats and carbohydrates. Blood glucose levels, obesity, and insulin resistance are influenced by high-energy food [11].

There was a significant relationship between blood glucose levels and protein intake (r =-0.202 p = 0.041). Animal protein and plant protein intake are associated with the risk of type 2 diabetes [12]. A high-protein diet can reduce overweight and obesity so that diabetes can be prevented [13]. Low protein diet can change the positive energy balance through the adaptation of thermogenesis, whereas high protein diets are useful for preventing that condition [14].

There was a noticeable relationship between blood glucose levels and fats intake (r = 0.297, p = 0.002). Consumption of fatty acids is associated with several diseases. These effects influence glucose metabolism by changing cell membrane function, enzyme activity, insulin signaling, and gene expression. The imbalance of omega-6 or omega-3 fat ratio strongly supports the existence of pro-inflammation which gives results in the incidence of atherosclerosis, obesity and diabetes. Consumption of MUFA (Monounsaturated Fatty Acids) is also associated with impaired glucose tolerance and fasting serum insulin. High intake of n-3 PUFA (Polyunsaturated Fatty Acids) can increase blood glucose levels and decrease insulin sensitivity, especially in obese persons [15].

There was a noticeable relationship between blood glucose levels and carbohydrates intake (r = 0.292, p = 0.048). Carbohydrates are the biggest source of energy. Carbohydrates needs to maintain health are about 55%-75%, most of which are complex carbohydrates and 10% are simple carbohydrates. These compositions can reduce the risk of type 2 diabetes [16].

There was no significant relationship between blood glucose levels and vitamin E (r = 0.015, p = 0.880). In this study, the respondents' vitamin E intake had an average of 4.96 mg. That average is still below the recommendation number which is 15 mg. Vitamin E is a cofactor in enzymatic and antioxidant reactions. Vitamin E acts as a peroxyl scavenger, it can prevent lipid membrane oxidation which has a relationship with diabetes mellitus [17].

There was no noticeable relationship between blood glucose levels and vitamin A (r =-0.097, p = 0.33). Vitamin A deficiency can cause an accumulation of fats in body tissues. But in this study, the average intake of vitamin A was 671.76 ug so it was still below the recommendation number, 1100 ug. Vitamin A coordinates lipid metabolism through the retinaldehyde dehydrogenase 1 enzyme [7]. High or moderate intake of vitamin A and high fruit intake are associated with metabolic syndrome problems. Health strategies must focus on increasing consumption of vitamin A to prevent metabolic syndrome [18].

There was no significant relationship between blood glucose levels and vitamin C (r =-0.140, p = 0.158). This study showed the average vitamin C intake was 21.64 mg so it was still below the recommendation number which is 100 mg. That is different with previous study which showed that there was a relationship between vitamin C intake and the incidence of diabetes [19]. Vitamin C as an antioxidants can reduce insulin resistance, oxidative stress, hypertension, blood glucose and increase superoxide dismutase and glutathione [10]. In this study, there was no relationship of vitamin C with blood glucose levels due to low fruit and vegetable intake.

There was a particular relationship between blood glucose levels with vitamin D (p = 0.046, r = 0.287). There are several ways in which vitamin D can affect insulin sensitivity. One of them are through 1.25 (OH) 2D which enters responsive insulin cells and interacts with VDR as a consequence, it can activate VDR retinoic acid X receptors and then binds to vitamin D in human insulin receptors. The process can increase the activation of transcription from insulin receptor genes and increase the total number of insulin receptors without changing its affinity. Moreover, 1.25 (OH) 2D increases insulin sensitivity by activating the delta receptor active peroxisome proliferator which is a transcription that regulates the metabolism of fatty acids in skeletal muscle and adipose tissue [20]. Vitamin D

indirectly affects insulin resistance through the renin-angiotensin aldosterone system (RAAS). Vitamin D deficiency is associated with increased fat infiltration in skeletal muscle and gives impact on decreasing insulin action [21].

There was no significant relationship between blood glucose levels and zinc intake (r =-0.003, p = 0.976). In this study, the average intake of zinc was 7.34 mg so it was still below the recommendation number which is 10 mg. Zinc is a micronutrient that plays a role in metabolic processes, regulation of endocrine hormones, immune responses, as well as human growth and development. Low zinc intake is associated with decreased insulin sensitivity and impaired glucose use in the body, whereas higher zinc intake can provide protection against type 2 diabetes mellitus [22]. Zinc also plays a role in insulin synthesis and action. Thus, low zinc levels will cause a decrease in insulin sensitivity, impaired glucose utilization and type 2 diabetes mellitus [23].

Conclusions

In conclusion, there is a significant relationship between energy, protein, fats and vitamin D intake with blood glucose levels in male high school students. However, there is no significant relationship between vitamin A, vitamin C, vitamin E and zinc intake with blood glucose levels in male high school students. Therefore to reduce the risk of diabetes mellitus in male high school students, energy intake should be limited yet fruit and vegetable consumption must be increased in order to fulfill vitamin intake.

Conflict of Interest: There is no conflict of interest in this study.

Source of Funding: Funding in this study as a whole is accounted on the researcher independently. There are no other funding sources.

Parents Determination Factors Influencing Incomplete Basic Immunization for Infantsin Sorong City, West Papua Province

Alva Cherry Mustamu[1], Serly A. Markus[2]

[1]Health Polytechnic of Health Ministry, [2]Sorong City Health Service, Sorong, Indonesia

Abstract

Background: The implementation of complete Indonesian basic immunization has decreased in the period of 2012-2015. West Papua is one of the provinces with the lowest immunization coverage, which is 57.1% and the city of Sorong is only 21.9%.

Objective: to investigate the determinant factors of parents in complete basic immunization of infants months in Sorong City, West Papua Province

Method : This study was cross-sectional in design. The subjects consisted of apurposive samplingof 134 parents of children aged 1-5 years old,have incomplete basic immunization from immunization records and who visit 10 health center in Sorong City. Data were collected from parents using questionaires and immunization records. Logistic regression were used for data analysis.

Results: Simultaneously, mother's age, education level, occupational status, number of children, experience of having children, distance to the place of immunization, knowledge, family support, immunization officers and attitudes did not affect the incompleteness basic immunization (f count 1.768).Only the number of children (t = 0.017) and immunization staff support (t = 0.044) which affected the incomplete immunization. sequentially, number of children (β = 0.003), immunization support staff (β = 0.004), distance to immunization site (β = 0.035) and attitudes (β = 0.027) which most contribute to incomplete immunization.

Conclusion: Number of children, immunization officers support, distance to immunization site and attitudes which contribute to incomplete immunization.

Keywords: *Vaccine, parental attitude, infants.*

Introduction

Reduction of serious infections which are indicators of global public health success can be done by immunization. However, the implementation still found many obstacles which until now have not been found a solution because the scope of its implementation has not been comprehensive to all recipient subjects. The World Health Organization in 2017 estimates that around 19.4 million infants, children and toddlers throughout the world have not received complete basic immunization. About 60% of them live in low and middle income countries such as Asia, Africa and Ukraine including Indonesia[1].

According to the Indonesian Ministry of Health's Center for Data and Information, the implementation of complete basic immunization for the 2012-2015 period did not reach the target and even decreased by 75% of the 80% target of the National Medium Term Development Plan. West Papua is the province with the lowest immunization coverage (57.1%) and Sorong City only 21.9[2].

The priority of immunization programs in each country varies, including Indonesia. Indonesia requires 3 doses of DPT-HB-Hib, 1 dose of Hepatitis B, BCG,

Corresponding Author:
Alva Cherry Mustamu
Health Polytechnic of Health Ministry, Sorong, Indonesia, BasukiRahmat St, 11 Km, Sorong, Indonesia
e-mail: alvamustamu@gmail.com

measles and 4 doses of polio[2]. Indonesia managed to carry out basic immunizations in all city districts such as measles and BCG which almost 95%. But it did not occur in Hepatitis B, DPT, Polio and Tetanus immunizations in Papua and West Papua which were only under 80% [2].

Although immunization is the biggest success in the health sector, there are still various obstacles to implementation[3]. These problems include lack of access to health facilities due to poverty and ignorance and controversial ethics such as regulation, development, religion and beliefs, research and testing, informed consent and access gaps.

These obstacles cause 2-3 million infant deaths in Indonesia each year[4].Even though the implementation of immunization in Indonesia is protected by law and the government is very active in carrying out it, but still encounters obstacles when implemented. Therefore, looking for causes for planning solutions must be done immediately.

This epidemiological study can help provide advice on selecting vaccines to be included in public health programs, identify target pathogens and disease-causing transmission pathways, disease burden, design disease control, determine appropriate strategies, monitor performance indicators, eradicate, monitor strategies, measure progress and the impact of the vaccination strategy.

Method

Study design: This was a correlational research with cross sectional design to analyze the factorinfluencing incomplete basic immunization for infants in Sorong City, West Papua Province.

Setting: This study was conducted in 10 health centers in the city of Sorong is Malawei, Remu, Klasaman, Cape cassowary, doom, Malanu, Sorong West, East Sorong, Malaisimsa, Sorong City from October to November 2018.

Sample: The subjects consisted of a purposive sampling of 134 parents of children aged 1-5 years old, have incomplete basic immunization from immunization records and who visit 10 health center in Sorong Cityand willing to be respondents.

Instrument: A questionnaire was used to measure the demographic of the participants consisting mother's age, education level, occupational status, number of children, experience of having children, distance to the place of immunization, knowledge, family support, immunization officers and attitudes. Instrument for measuring complete basic immunization for infants was immunizationrecord in health centre. immunization record is record of infants condition that showed history of immunization contains 3 doses of DPT-HB-Hib, 1 dose of Hepatitis B, BCG, measles and 4 doses of polio. Validity and reliability by Winarni.

Data analysis: Univarate analysis was used to describe the findings. Bivariate and multivariate logistic regression analyses were conducted to analyze the associations that existed among constructs and identify the factors that most influence the incompleteness of basic immunization status for infants.

Results

There was a 100% response rate, of which, the large majority of them 128 (95.5%) were in the less 35 years age group. A total of 127 (94.8%) the study participants have high education. Half of the study participants were unemployed 75 (54.03%). Total 78 (58,2%) the study participants have had only had children. Most of them have less than 2 children in their home 128 (95.5%). Most participants have male children 80 (59,7%). Most of them havehigh level of knowledge about immunization92 (68.7%) and are supported by families 75 (56%) but were not supported by immunization officers to immunize their children 69 (51.5%) even though access to the immunization site is very close 100 (74.6%). Therefore, respondents have a negative attitude towards immunization 100 (74.6%) (Table 1)

Table 1: Socio-demographics and economic Characteristics of participants for the behavioral determinants survey, 2018, Sorong

The factors that most influence the incompleteness of basic immunization status for infants in Sorong City during 2018 are presented in table 2. In the multivariate analysis, simultaneously mother's age, education level, occupational status, number of children, experience of having children, distance to the place of immunization, knowledge, family support, immunization officers and attitudes did not affect the incompleteness basic immunization (f count 1.768). Only the number of children (t = 0.017) and immunization staff support (t = 0.044) which affected the incomplete immunization. sequentially, number of children (β = 0.003), immunization support staff (β = 0.004), distance to immunization site (β = 0.035) and attitudes (β = 0.027) which contribute to incomplete immunization.

Table 2: Multivariable logistic regression analysis of factors involved in the incomplete immunization.

Variabel	F	t	Beta	p-value
Mother's Age (Years)	1.768	1.458	0.127	0.147
Education levels		1.028	0.090	0.306
Occupational status		1.337	0.114	0.184

Immunization officers support		0.044	0.004	0.965
Attitudes		0.364	0.035	0.717

Discussion

According to the Indonesian Ministry of Health's Center for Data and Information, the implementation of complete basic immunization for the 2012-2015 period did not reach the target and even decreased by 75% of the 80% target of the National Medium Term Development Plan. West Papua is the province with the lowest immunization coverage (57.1%) and Sorong City only 21.9%[2]. The main reason for vaccine uptake among HCWs, as supported by other studies, is that vaccination protects family members, friends and patients from being infected[5,6,7].

We found that,the variable that greatly influences the incompleteness immunization status of infants is number of children, immunization support staff, distance to immunization site and attitudes which most contribute to incomplete immunization.

Doubts and anti-immunization movements are always present in every immunization exercise[8,9]. besides religious and lifestyle reasons[10,11,12] Concerns that too many infants are immunized simultaneously[13,14]. concerns from parents who oppose or only some who accept immunization become one of the concerns about the safety and consequences of vaccines long-term unknowns to date[15,16,17,18].. because it is related to vaccine safety perhaps because parents are concerned by parents about their child's development.

Many parents worry about vaccine safety because the controversy regarding the use of mercury in vaccines has been around since 1999. But after that, the American Academy of Pediatrics and US Public Health Services recommended that children's immunization vaccines be made without preservatives[3]. In addition, it was strengthened by immunization officers providing counseling to parents about vaccine safety.

Research shows that rarely accessing health services may make parents vulnerable to conflicting information from neighbors in their environment or media (online) [19,20]. Searching for immunizations on the Internet, especially through search engines and on social media, can cause confusion and hesitation among parents. Another explanation that might underlie parents who refuse vaccination is insufficient knowledge, and distrust of immunization officers. More research is needed to find out what information parents need and want to make decisions about vaccinating children.

Planning behavior theory is one theory that has been successfully applied to improve immunization implementation decisions because it includes the process of consideration by decision makers; information processing available by thinking of the consequences of decisions and weighing pros and cons[21,22,23]. Vaccination decisions are included in health decisions that require consideration by parents. Deliberations between husband and wife can increase positive attitudes in the implementation of immunization. More research is needed on the reasons for consideration of parents who receive vaccinations because this will result in a more stable attitude towards child immunization.

Availability and access to immunization services tend to be worse in suburbs or sub-areas that are less densely populated or mountainous areas, where people are rarely West Papua. Although perceptions of the distance between parents and others in accessing immunization facilities in shingles are not clear, this problem seems to be related to immunization status. This finding was also seen in other studies. For example, a study in Bangladesh found that women who reported having the nearest health facility (<1 km) were more likely to fully immunize their children[24].

Another study, in India, found a positive relationship between the existence of a health center within 2 km of the village. urban slums and immunization status of children[26]. Further studies are needed to understand the perceptions of parents in the city of Sorong about the distance to immunization and other health services.

Seasonal migration in homes anchored to and from urban shocks is quite common and affects immunization coverage. Families sailing to become fishermen for better economic opportunities directly affect the use of health services and immunization. the problem encountered was that they lost time to immunize, children were left by caregivers, or parents forgot immunization records.

An integrated tracking and reporting system must be implemented so that the baby gets complete basic immunization from sites other than the designated site. This system can track these children for the next vaccination. This study has important implications in the development of policies and programs for the implementation of complete basic immunization in infants. Vaccination coverage can be increased in remote areas by increasing access and reducing travel time to health facilities. hospitals and health centers that assist in the delivery process can have integrated data with health facilities in the patient's domicile. so, health workers can carry out immunizations to the patient's home.

Additional immunization activities can also contribute to increasing measles immunization coverage in infancy and reducing inequality. If necessary, outreach programs and additional immunization activities should be considered to increase coverage in remote areas. In addition, a new vaccine strategy is needed for the most difficult to reach children in West Papua and other parts of West Papua

Conclusion

Affordability to immunization facilities and support from immunization officers greatly influences the attitudes of parents in carrying out immunizations. motivation in carrying out immunization is very dependent on the right information and the comfort of the subjects receiving immunization services. in addition, integrated information between health facilities from the birth process to the age of 12 months is very helpful in meeting the targets of complete basic immunization.

Ethical consideration: This research had been approved by the Committee ethics of the Health Polytechnic of health ministry Sorong, with number: DM.03.05/6/101/2018. Before the conduct of the field work, the researchers sought permission from each administrator at all levels. Each study participant was

asked to participate in the study after explaining the aim of the study and after assuring confidentiality of personal information using code numbers instead of names.

Effect of Zirconium Oxide and Yttrium oxide Nanoparticles on Plant Germination of Cucumis Sativus

Alyaa Muhsin Yousif[1], Sundus Hameed Ahmed[1], Rasha Saad Nuaman[1], Isam Hussain T. Al-Karkhi[2]

[1]Mustansiriyah University/ College of Science/ Biology Department, [2]Former Associate Professor, University of Baghdad, Iraq

Abstract

Nanoparticals of earth metal oxides were widely used and applied in agriculture, precisely in germination. In this study Yttrium oxide and Zirconium oxide were used in the germination of *Cucumis* seeds. The seeds were immersed in sterile water or metal oxide nanoparticles (NPs) suspensions for 2 hrs, fourteen treatments were done, then every ten seeds were transferred into a Petri dish with a filter paper on the each Petri dish. The germination was conducted in dark at 25 °C for 5 days. After that, the germination rate, the root length and shoot length were measured and it was found that Zirconium + Gibbriline gave the best parameters in comparison with the other treatment. The mechanism of metal oxide NP phytotoxicity is related to the NP species, test plants, concentration, chemical composition, surface modification and particle size of the nanoparticles itself.

Keywords: *Cucumis sativus, germination, Yttrium oxide, Zirconium oxide.*

Introduction

The effect of Manufactured Nanomaterials MNMs on diverse plants types can differ significantly, and there are reports of both positive and negative effects. Among positive effects, it can speed up the germination and growth was promoted by a mixture of nano-sized materials oxides due to its ability silicon to absorb water and fertilizer, and stimulated the antioxidant system [1-3].

Yttrium oxide (Y_2O_3), and Zirconium oxide (ZrO_2) are important oxides along with rare earth compounds, it has been actively studied in the recent years, and were considered as the most promising elements for commercial products, cosmetics, medicine, as well as agriculture. In addition to that, it is widely used as a host material for various rare earth dopant and is of interest for potential applications in biological imaging as well as photodynamic therapy[4,5]. Nanoparticles of ZrO_2 uses in the manufacture of dentures and cosmetic fillings. Therefore, it is necessary to produce new antibiotics without side effects such as particles of ZrO_2 nanoparticles that can inhibit a wide range of microorganisms [6.7].

Cucumber fruit is composed generally of water; more than 96% as well as other constituents such as vitamins, minerals, amino acids, phytosterols, phenolic acids, fatty acids, taces of essential oil, pectins, vitamin C, and other useful compounds which enable it for a wide pharmaceutical applications [8].

In this study the researchers used manufactured Nanomaterials (MMNs) tto enhance the germination of cucumber seeds and minimize the toxic effect of soil on the seeds to ensure a smooth and healthy growth.

Material and Method

Chemiclas: Nanoparticle (Zirconium and Yttrium) bught form the local market, Naphthol Acetic Acid (NAA), Indol acetic acid (IAA) and Gibberellin.

Seed Germination: For germination, the seeds *Cucumis* were surface sterilized by soaking in 70% ethanol for 2 min. Then the seeds were rinsed with sterile water several times to remove any remaining ethanol.

Subsequently, the seeds were immersed in sterile water or metal oxide NPs suspensions for 2 hrs. This had been done for fourteen treatments with different solution component every time, as shown in table (1). After that, every ten seeds were transferred into a Petri dish (100 mm, for 15 mm) with a filter paper on each Petri dish. Finally, the Petri dishes were covered and sealed with tape. The germination was conducted in dark at 25 °C. After 5 days, the germination rate was evaluated via measuring the root length and shoot length [9].

Figure 1: Germination of Cucumis seeds on Petri dishes

3	Yttrium 300 µg
4	Zirconium 100 µg
5	Zirconium 300 µg
6	Gibbrilne 300 µg
7	IAA
8	NAA
9	(6+2)
10	(7+2)
11	(8+2)
12	(6+4)
13	(7+4)
14	(8+4)

IAA = Indol Acetic Acid (Plant Hormone), NAA = NaphthaleneAcetic Acid

Data Analysis: Each treatment was conducted with three replicates and all of the experiment groups were conducted in triplicates, the dates were showed as mean p< 0.05) SD (standard deviation). Difference analysis was conducted with ANOVA (analysis of variance, LSD). Statistical significance was based on probabilities of p< 0.05).

Result and Discussion

The germination rate was calculated based on the equation listed below. The results of an experiment compared the effect of plant hormones and nanomaterials on germination and growth of seeds.

$$Germination\ Percent\ (GP\%) = \frac{GN}{SN}\ X\ 100$$

Where: GN is the total number of germinated seed;SN is the total number of seeds tested.

The results of an experiment compared the effect of plant hormones and nanomaterials on germination and growth of seeds.Significantly Yttrium 100µg and Zirconium and Gibberellin had the highest seed Germination 100% followed by Zirconium 100µg, Ytterium+ Gibberellin and Ytterium+Indol Acetic Acid 93.3% in compare with acetic acid in compare with other treatment.Seed Vigor Index : SVI=Germination% (GP)× (root length + shoot length) Vigor index I= Germination % × Seedling length (cm).We found that significantly Ytterium +Gibbrillen and Zirconium +Gibbrilline gave the highest vigor Index 5280 & 5133 followed by the other treatments. The result of Vigor index II, calculate by equation = Germination % × Seedling weight (g)

We found that Zirconium with Indol Acetic Acid significantly gave the highest value 177.4 in compare with all treatments. While in column E, the result showed non-significant differences between all treatments. In column F (Number of root), also the results indicate no significant differences.Ytterbium +Gibbriline and Indol Acetic Acid significantly gave the highest value 34.3, 34.1, while ytterbium +Naphthalene acetic acid significantly gave the lowest value 5.8.as shown in column G. Significantly Zirconium +Indol Acetic Acid had the highest length of shoot in compare with other treatment. Zirconium and Gibbriline gave the highest value in wet weight and dry weightin compare with the other treatment, columns I and J in table 2.

From experimental results and the collected data, it was found that Zirconium +Gibbriline gave the best parameters in compare with the other treatment. The mechanism of metal oxide NP phytotoxicity could be related to the NP species, test plants, concentration, chemical composition, surface modification andparticle size [10].The addition of different material on seed treatment in comparison with control, the initial growth stages showed a positive effect on *Cucumis* seed plants. There were increases of over 100% in seedling height

with all the evaluated concentrations of material under study. These findings are in full agreement with those reported by Xing and his coworkers[8] who observed that treatment participate in the formation of adventitious roots, cell differentiation, and root morphogenesis. Increases in root length from the effect of these elements have also been observed in other species. Table indicates the comparison between different treatments while figure 2 shows different germination treatment (root + shoot).

Mapping National Health Insurance Health Services Based on Preference and Community Needs in South Sulawesi

Amir Mahmud Hafsa[1,2], Alimin Maidin[3], Sukri Palutturi[4], Stang[5]

[1]Doctoral Student Program, Faculty of Public Health, [2]Dentistry Department, Faculty of Dentistry, [3]Hospital Management Department, Faculty of Public Health, [4]Health Administration and Policy Department, Faculty of Public Health, [5]Biostatistics, Population and Family Planning Department, Faculty of Public Health, Universitas Hasanuddin, Makassar, Indonesia

Abstract

The increase in the population of South Sulawesi is in line with the increasing needs of the population related to national health referral guarantee information. The problem is the unavailability of a clear geographical picture and complete information about the state and distribution of public health services. The research aims to map national health insurance health services based on the tastes and needs of the people in South Sulawesi. This research uses a qualitative approach. Data were analyzed using content analysis based on method triangulation, source triangulation, and data triangulation. The results of the study found that the mapping of health services in South Sulawesi has not run as expected so that increasing access and at the same time can be an accelerated step to achieve equity in the health referral system performance. The achievement of equity in health services and access to health services must be determined by the preference and actual needs of health services rather than merely the ability to pay or geographical location.

Keywords: *Mapping, National Health Insurance, Health Service, Preference, Needs.*

Introduction

The quality of health services, including National Health Insurance participants, is still an issue that has not been resolved until today [1-5].The Health Social Security Provider has not met the equity principle in accordance with the National Social Security System Act. The mandate of the Act is the mapping of health service areas adjusted to the referral area[6]. Health development in the 2015-2019 period is a Healthy Indonesia Program that is implemented with 3 main pillars, namely the healthy paradigm, strengthening health services, and the National Health Insurance. The strengthening of health services is carried out with strategies to improve access to health services, optimize the referral system and improve the quality of health services, using a continuum of care approach and health risk-based interventions[7]. The health care referral system in Indonesia is still a problem. This problem is a consequence of Indonesia's geographical condition as an archipelago and topographic conditions that can be very extreme between regions[8].

With the increase in the population of South Sulawesi, the population needs related to the national health referral guarantee information on public health services will also increase[9]. This is because people are increasingly aware and believe that health is a major asset in everyday life. But it is unfortunate, until now the type of health service information available is only limited to non-spatial data and is limited. The unavailability of a clear geographical picture and complete information about the state and distribution of public health services in South Sulawesi is a major problem in the service referral system. The mapping of public health services is expected to be able to provide solutions to the problems faced by making it easy for anyone to access health service information.

Based on this information, a mapping of the level of accessibility of health services in South Sulawesi is

Corresponding Author:
Sukri Palutturi
Health Administration and Policy Department, Faculty of Public Health, Universitas Hasanuddin, Makassar, Indonesia
e-mail: sukritanatoa72@gmail.com

needed. This mapping is important to be carried out as an equal distribution effort that has been carried out, as well as determining development priorities for improving the accessibility of health services in South Sulawesi.

Materials and Method

This study uses a qualitative method[10-12]. Data were analyzed using content analysis based on method triangulation, source triangulation, and data triangulation. This research was conducted at Daya Hospital and Waihidin Hospital, South Sulawesi Province.

Results and Discussion

a. Mapping Health Service based on the Community Preference

The public preference in the health service system must be based on the needs of the health service. The meaning is that the community is given the opportunity to choose health facilities, choose the doctor to be referred to either referred or own initiative in conducting health services. The preference is still based on the need for indication and diagnosis of the disease they are suffering from as well as the type of BPJS membership class.If something is forcing to move up or down grade due to lack of facilities and infrastructure when they want to do treatment for the disease. This is for people in the border area between two regions both in one region and another region, even different provinces so that they are still given the opportunity to choose the closest health facility to provide health services and can still be served as a BPJS participant.

For example, patients ask to go to Bantaeng because it is near the Jeneponto border, it must go to BPJS Bantaeng asking for access to services. Likewise, the people of Bangkala Sub-District, Jeneponto Regency and Takalar Regency Hospital and all inter-regional boundaries in South Sulawesi need to be mapped. Wing-wing solution in this case is that the government must immediately adopt a short-term policy between two neighboring regions, namely conducting an MOU on access to health services together, as complained by informants R17, R1 and four other informants as follows:

In general, all patients can be referred according to the wishes of patients, but BPJS rules do not allow that, especially outpatients. Their references must be tiered unless they approach the BPJS (R17).

Many patients in Barru Regency Hospital asked to be referred to Parepare Hospital because the principle is faster, more precise and more quality, even though for orderly, they have to go to Daya Makassar Hospital far enough (R1 59 years),

The community is very difficult to regulate in relation to these references. Therefore, as a doctor, we must have a lot of patience in dealing with patients with such diverse problems. The results showed that many health workers confirmed that the referral system was problematic. Many references are given to the community based on the request of the patient or the patient's family.

In general, patients are referred at their own request, so the doctor gives a lot of policy with the doctor's reasoning and analysis that the referral place can carry out an extension of the mandate, (R16).

Why is the regionalization not running, actually it is still running but many people ask to be referred to a particular hospital / doctor, they should go to Labuang Baji Hospital but ask to Hajj Hospital or UIT Hospital (R19)

b. Mapping Health Service based on the Community Needs

BPJS Health is a legal entity formed to organize a national health insurance program. There are still issues that need to be addressed. These problems are related to systems, procedures, human resources (medical personnel), as well as infrastructure and the application of the principle of responsiveness to the needs of the community in order to improve the quality of public services in the health sector. Health services do not meet good public service standards, community access to benefit services is very limited, people cannot yet get services in all health facilities[13].

Developing a public sector service model of customer loyalty in consumer theory by incorporating customer perceptions of equity and customer brand values and preferences into an integrated loyalty analysis, illustrating the extent of customer loyalty. There are seven factors which influence service quality, equity and value, customer satisfaction, customer loyalty, expected switching costs and clinical recommendations[14]. The general model is implemented for JKN customers in a comprehensive and retired service. This analysis found that although perceived quality does not directly affect

customer satisfaction, it is done indirectly through customer equity and perceived value. The study also found that customer loyalty in the past was not directly related to customer satisfaction or current service recommendations and that brand preference was an intervening factor between customer satisfaction and returning customer intentions. The main factors affecting brand preference are perceived value with customer satisfaction and switching costs that are expected to have less effect[15].

Regionalization is still expected to run based on community interests. Some informants' views, for example:

Regionalization continues but the community wants it to be of interest to a particular hospital/doctor (R19).

The regulation has been running, for example, from Type C Hospital to Wahidin Hospital immediately rejected, but from the Puskesmas to Type B Hospital it has not been strict, for example from the Puskesmas to Daya Hospital here (R11)

Community interest in treatment is low so that if there is a health facility close by, they choose it rather than being far away (R7)

In my opinion (doctor) BPJS is strange, there are patients from Jeneponto being referred, seeking treatment to Takalar or to Bantaeng, complete documents but cannot be served as BPJS patients (R18)

Patients can ask to be referred to certain health facilities with a reasonable reason but in terms of rules they cannot ask for their own referral goals, there is already a frame work (R16).

Regionalization contradicts regional autonomy because regionalization limits the rights of citizens to obtain health services according to the desired standard.

Conclusion

Health services in South Sulawesi did not go as expected. Increasing access and at the same time can be an accelerated step to achieve equity (fairness) in the performance of the health referral system. The achievement of equitable health service equity has a number of dimensions. Access to health services must be determined by actual preference and needs for health services rather than merely the ability to pay or geographic location.

Dental Caries Experience and Salivary Total Protein among 5 Years Passive Smokers in Tikrit City, Iraq

Ammar Yaser Mohammed[1], Nibal Mohammed Hoobi[1]

[1]*Department of Pedodontic and Preventive Dentistry, College of Dentistry,University of Baghdad, Iraq*

Abstract

Passive smoking is perhaps one of the most important toxic exposures in childhood. The evidence for a causal association between smoking and premature tooth loss is rapidly growing .Dental caries occurs predominantly in younger children, and various factors may influence development of dental caries including passive smoking. This study was designed to assess dental caries experience and salivary total protein among 5 years old passive smokers in Tikrit city. This study included 60 kindergarten children (32 boys, 28 girls) aged 5 years old,Passive smokers group included thirty children was compared with control group consist of thirty children matching in number, age and gender,but they were not passive smokers. Caries-experience was diagnosed and recorded according to criteria of decayed, missing and filling Surface index (dmfs index for primary teeth) described by WHO 2013. Stimulated salivary samples were collected for the estimation of total protein concentration. All data were analyzed using statistical package for social science (SPSS) version 21.The percentage of dental caries occurrence was found higher in study group than control group. Concerning dental caries experience represented by dmfs, results showed that mean values of dmfs and its component (ds,ms and fs) were higher among passive smoker group. Regarding mean values of dmfs and ds, the difference was statistically highly significant (P>0.01), while it was not significant for ms and fs (P< 0.05).The data of study also revealed that salivary total protein concentration was higher among control group with statistically non-significant difference. In addition there was a negative correlation of dmfs with salivary total protein among control group, while it was positive for study group. It can be concluded that higher caries experience and lower salivary total protein concentration among passive smoker group compared to control group was found in the current study indicating influential harmful effect of passive smoking on oral health including caries experience and salivary composition.

Keywords: *Dental Caries, Salivary Total Protein, Passive Smokers.*

Introduction

Tobacco smoking is a global major problem of public health. The continued popularity of tobacco smoking appears to defy rational explanation. Smokers mostly acknowledge the harm they are doing to themselves and many report that they do not enjoy it, yet they continue to smoke [(1)] .The reason is that nicotine from cigarettes generates strong urges to smoke that undermine and overwhelm concerns about the negative consequences of smoking, and the resolve not to smoke in those trying to stop [(2)] .

Passive smoking can negatively influence the health of non-smokers of all ages [(3)]. Passive smoking (environmental tobacco smoke), on the one hand, is the result of spontaneous cigarette burning, and on the other hand, is the result of side stream of cigarette as well as the smoke exhaled by active smokers." Unwilling to smoke" also means passive smoking because the individuals who inhales it often has no choice to matter [(4,5)] .

Study at (2015) recorded that a similar increase in the risk of certain diseases for passive smoking and active smoking[(6)]. An important report introduced by World Health Organization (WHO) has indicated that passive smoking, especially among young children, may cause serious health hazards[(7)]. The most frequent oral problems are dental caries and periodontal disease. They can start early and progress to tooth loss unless they are treated[(8)] . It has been observed that caries experience was higher in passive smokers than non-smokers[(9,10)].

All human saliva usually contains approximately l mg / dl of total proteins, which are secreted from parotids, sublingual and some small glands. These polypeptides play an important role as a biomarker for the survey of the status of human disease[11].

The identification of salivary proteins as biomarkers for dental caries would allow a subject to be classified as a caries susceptible individual when a salivary biomarker was present. Based on this, the individual could take part in an oral health program in order to control diet and hygienic habits to prevent dental caries development[12] A non-significant difference was recorded between smokers and non-smokers groups regarding salivary total protein concentration[13] a study conducted among healthy students found that higher levels but statistically non-significant differences of total protein in the caries active group compared to caries-free groups[14], in controversy with a study in Iraq among pre-school children that found that total protein levels increase in caries-free children compared to caries active with statistically non-significant difference [15] .

As far as,there is no available Iraqi study about effect of passive smoking on dental caries experience and salivary total protein among kindergarten children and because passive smokers represent a large percent in our population, for all of the above reasons this study was designed to investigate about the harmful effect of passive smoking on oral health of children and give awareness about its danger.

Materials and Method

The study group included 60 kindergarten children (32 boys, 28 girls) aged 5 years old, Passive smokers group include thirty children was compared with control group consist of thirty children matching in number, age and gender,but they were not passive smokers, the criteria of passive smoker selection was: [9,16,17]

1. One of the parents of the children is smoker.
2. The number of cigarettes smoked per day are at least 20.
3. The smoking is indoors (inside the house(.
4. The exposure of subject to environmental smoking was at least for 5 years

Caries-experience was diagnosed and recorded according to decayed, missing and filling Surface index (dmfs index for primary teeth) .described by WHO 2013. Stimulated salivary samples were collected for the estimation of total protein concentration chemical analyses. The samples were immediately stored at-20C for biochemical analysis determination[18]. Then centrifuging have been done at 3000 rpm for 10 min, and the clear supernatant saliva was collected by micropipette into tubes and biochemical analysis determination of total protein have been done. All data were analyzed using statistical package for social science (SPSS) version 21.

Result

The sample of this study include 60 kindergarten children (32 boys and 28 girls) aged 5 years old. Distribution of children according to gender is shown in table (1).

The sample was divided equally into passive smokers group and control group. For both groups the percentage of males was (53.33 %) higher than females (46.66 %).

The occurrence of dental caries is illustrated in table (2). Dental caries was found to be 100 % of passive smokers group, while it was 86.67 % for control group.

Caries experience in primary dentition represented by (dmfs) and its component (ds,ms,fs) has been shown in Table (3) .The mean values of (dmfs) and (ds) in study group were higher than among control group, statistically these difference were highly significant($p<0.01$) . The mean values of (ms) and (fs) among study group were higher than among control group, statistically these difference were not significant .

The salivary total proteinconcentration (TP) among study and control groups has been shown in Table (4). Mean value of total protein was higher among control group than study group with statistically not significant difference ($p>0.05$).

Correlation coefficient between caries experience dmfs and salivary total protein has been illustrated in the Table (5) . The caries experience represented by dmfs was weak and positive correlated with total protein among study group, but weak and negative correlated among control group, however both correlated were not significant ($p>0.05$).

Table (1): Distribution of the sample as study and control groups by genders

Discussion

Dental caries is the most prevalent infectious chronic disease affecting all age in both genders and both races [19] . In the present study, the index used for recording dental caries was dmfs, which is the most sensitive index used because it is measure caries in the term of surfaces rather than teeth .However because radiographic examination was not applied, so there may be underestimation of dental caries record as interproximal caries may need X ray for better diagnosis.

Data of present study revealed that study group had 100% dental caries, while control group had 86.67 % dental caries .

Result of the present study revealed the caries experience was higher among study group compared to control group . The same result reported by others studies concerning tobacco in cigarette [20,21].This result may be attributed to lower pH and lower buffering capacity among smoker group [22]. Another reason, may be due to lower salivary flow rate among smokers [23] .

Nicotine content of cigarette enhances the proliferation of cariogenic bacteria such as mutans streptococcus in the smoking mother oral cavity that transport these cariogenic bacteria to their infants. Additionally, nicotine reduces vitamin C level, which is associated with S. mutans proliferation and results in subsequently increased caries risk [24].They have been suggested that parents who smoke might have children with poorer oral health and health behaviors with high S. mutans counts that can be transmitted to their children [25(.In present study passive smoking is positively associated with dental caries and this result is in agreement with other studies [10,26], however it disagree with some studies which revealed that there is no association between passive smoking and dental caries [9,20,27].The mean value of decay component od dmfs was higher among passive smokers children with statistically highly significant difference, this will lead to increasing in need for dental treatment.

The differences in the result among different studies may be attributed to differences in, characteristicthe life style of population, smoking habits and the design of the study used.The data of the present study revealed that the total protein concentration among control group was higher than passive smokers group, the same result reported by [9,28], while it disagree with Avşar (2009) [29]. This finding may explain the anticaries protective role of total protein. Salivary proteins adsorbs on the tooth surfaces and may decrease risk of dental caries[30]**.** Finding of present study showed that therewas no significant difference in total protein concentration between study and control groups and thisresult agree with Rezaei and Sariri[31].Salivary total protein have both detrimental and protective properties. Salivary proteins function may depend on the molecule's location or site of action. Some proteins such as antimicrobial and pH modulating proteins play a protective role in the oral cavity, while adhesions and agglutinins play a detrimental role by increasing the colonization of microorganisms[32].

Conclusions

Higher experience among passive smokers group compared to control group was found in current study, with no significant between dental caries experience and total protein concentration among study group.

KAOMBO: Preservation of Coastal Environment Based on Local Wisdom in Siompu Island, South Buton Regency

Andi Tenri[1], Andi Asrina[2], Vivianti Nafii[3], La Ode Abdul Munafi[1], Sukri Palutturi[4]

[1]Lecturer, Dayanu Ikhsanuddin University Baubau, [2]Lecturer, Faculty of Public Health, Muslim University of Indonesia Makassar, [3]Postgraduate, Dayanu Ikhsanuddin University Baubau, [4]Professor, Faculty of Public Health Hasanuddin University, Makassar, Indonesia

Abstract

Kaombo is a knowledge system of the Buton community which is believed to create harmonization of relations between humans and their environment. Kaombo as a social institution functions as an instrumentfor environmental management and preservation while preventing the adverse effects of environmental ecosystem damage. This study describes Kaombo in environmental management, the dynamics of community symbolic interpretation of Kaombo, and Kaombo's conservation efforts in managing the coastal environment on Siompu Island. This study shows that Kaombo as a form of harmonization of community relations with its environment is manifested in the system of values, ideas, and knowledge of the people of Buton. Kaombo forms a code of conduct that binds every society to act wisely and wisely to protect the ecosystem of the environment. Although Kaombo is interpreted differently by the community, both as a system of values, norms and symbolism that contains mystical elements, kaombo is still understood as a system of knowledge that can guide behavior in living and interacting with the environment. On Siompu Island, the community maintains and preserves kaombo through strengthening traditional institutions in the form of traditional party rituals and thanksgiving.

Introduction

The Buton area is a region that has a strong tradition in terms of trust in human relations, nature and the environment, as well as in terms of medicine[1,2]. Kaombo is one of the local wisdom in the Buton Islands region of Southeast Sulawesi Province[3]. Kaombo is instrument because it contains normative elements. The normative value of the Kaombo contained in the Seven Butonese Dignity Act, outlines the legal provisions of community behavior in relation to efforts to manage and preserve the biological environment ecosystem. By the people of Buton, the Kaombo is a set of values that are binding and compelling and are believed to contain magical elements whose purpose is to prevent humans from irresponsible actions[4].

As a manifestation of a group of ideas and knowledge of the Buton community, Kaombo is believed to be able to create a harmonious relationship between humans and the environment physically. The achievement of the Kaombo role is essentially a preventive effort in preventing possible adverse effects from damage to the environmental ecosystem. Therefore, the existence of Kaombo is quite potential as an instrument in efforts to manage and preserve the environment[5].Forest protection is even included in efforts to create a healthy environment and city[6-9].

Siompu Island is one of a group of islands in Buton Islands. Siompu Island consists of two sub-districts and there are eighteen villages, which are included in the administrative area of South Buton Regency. The daily life of the people of Siompu Island is closely related to the customs and religion of Islam. The rules that apply in Siompu indigenous people are the rules regarding

Kaombo. The Kaombo is determined by a customary institution through a meeting headed by Parabella in Baruga[10]. Parabella in its history is a leader and symbol of the continuity of adat in a traditional region under the Buton Sultanate.

Kaombo is a prohibited area to take something in an area to be used both in land and sea areas, the rules about managing marine resources in Buton are known as marinekaombo. One of them is regulating the time of closing the area and the opening and retrieval of marine resources. Basically the Kaombo system works by providing a time limit for the community (fishermen) in carrying out certain resource exploitation activities.

This study aims to describe the existence of Kaombo as a local wisdom that applies to the people of Siompu Island in an effort to preserve the coastal environment and the efforts made to maintain it.

Materials and Method

The study was conducted from October 2018 to January 2019 which is located on Siompu Island, South Buton Regency. The method used is qualitative [11]. The research subjects were residents living in the coastal area of Siompu Island. The main informants were determined through purposive and snowball techniques with the aim of digging information on Kaombo local wisdom related to the activities of local fishermen. To support the main information, key information was also determined from local government officials, community leaders, religious leaders, educator figures and the fishing community in general.

A qualitative approach is intended to explore various information about Kaombo as a local wisdom of the Buton people on Siompu Island. Primary data comes from key informants and secondary data sourced from various documentation studies. Data were analyzed descriptively through four stages: data collection, data reduction, data display, and drawing or verifying conclusions[12].

Results and Discussion

Kaombo and Customary Institutions on Siompu Island: Siompu District is one of the coastal areas in South Buton Regency, Southeast Sulawesi Province. Marine Kaombo (nambo) is a local wisdom in the management of traditional natural / marine resources that is still valid until now in Siompu. The management of natural resources practiced by people in the area is by regulating the area of exploitation of natural resources and the types of resources. In the management of marine resources, community members cannot freely exploit marine resources in all regions and all types of marine resources that exist. But there are certain regions and certain resources that can be exploited, or in other words there is a prohibition on exploiting certain marine resources or certain regions at certain times.

The customary communal area in Siompu is divided into 5 institutions. These traditional institutions include the Biwinapada Customary Institution, the Kaimbulawa Customary Institution, the Lontoi Customary Institution, the Molona Customary Institution, and the Lalole Customary Institution. The five customary institutions each have customary territories in the sea or have a marine Kaombo (nambo). Of the five customary institutions there are eight Kaombo, both marine Kaombo (nambo) and kaombo terrestrial (pangholo) and five of them are Marine Protected Areas (DPL).

Kaombo, which is a DPL area, in addition to being supervised by all members in the customary institutions linked, also receives close supervision by DPL officers. Kaombo which is included in the DPL area has never been opened for its marine products. In the Kaombo region that is included in the DPL area, we can be sure to be safe from illegal activities both from an indigenous perspective and from state law. Because there is a DPL device that has a special duty to protect the Kaombo area. This device gets a salary from the state so that Kaombo's security is maintained. While Kaombo is purely custom supervised by all members of the customary institution concerned.

Dynamics of Kaombo and its Utilization: The implementation of marine Kaombo (closure of the sea area) is determined through deliberation. Deliberations are held to discuss the boundaries of the regions to be combated, marine resources that are prohibited from being exploited, the deadline for the application of Kaombo (starting from the prohibition / closure of the territory and opening) and sanctions against violators.

In addition to announcements to residents, there were also signs of closing waters boundaries that were closed, carried out by wati (members of the religious council / sara in charge of general regulations), and moji (member of the religious council in charge of religious regulations). The boundary mark can be in the form

of a pillar that is given mushrooms which are fixed on the seafront. At the time of the installation of boundary markers, spells or batata were read out which essentially contained statements of sanctions that would be imposed on violators of the traditonal rules.

At the time of deliberation, both when the Kaombo will be implemented (sea area closure or prohibition of extracting resources) and bongkanokaombo (opening of the Kaombo), community leaders in traditional institutions (Parabella, Wati, Pangara and others) use Buton traditional clothing according to their respective positions-one.

Marine Kaombo usually lasts for 6 months to a year. Actually, the length of the application of the Kaombo also depends on the community's need to hold a traditional party. At the time the sea was closed, first when the sea area was also combined, community members should not enter the sea at all, let alone take their resources. However, after a change in regulation, the community may enter a region that is being combated, but may only capture certain resources such as fish but may not take resources such as lola, sea cucumber and japing-japing. The opening of the sea area to be utilized by the community is called bongkaanokaombo. Similar to Kaombo, the implementation of Bongkaanokaombo was also begun with community leaders' meetings led by Parabella.

If there are residents of Siompu community who violate the Kaombo, then the sanction will be felt by the residents. Trusted by the Siompu community, residents who commit violations will feel the sanctions given by nature. For example by entering the Kaombo region and taking prohibited resources, the person will get sick or even die. In addition, the imposition of sanctions that have been set out in the same time will be imposed on residents who violate the rules. If there are people who violate the Kaombo rules that have been delivered by Parabella at a traditional party in Baruga (traditional house), sanctions are imposed.

Perspective of Symbolic Interactionism on the Kaombo: Aside from being a set of concepts and ideas, Kaombo is also a symbolic communication in the continuation of the process of social interaction. How not, kaombo is also imaged in a particular container or the installation of boundary signs of waters which are closed in the form of a pillar that is given mushrooms which are planted on the seafront, which is carried out by Wati (a member of the religious council in charge of general regulations), and Moji (member of the religious council in charge of religious regulations).

Based on the description above, it is not surprising that the increasingly heteregon general public in Buton knows Kaombo more as something that has magical power / mystical power even though in essence it also functions as a set of concepts, ideas and knowledge about the management and preservation of land, sea, forest and environment, as stated in the Buton Sultanate State Law. Therefore, the image of Kaombo as something that is truly magical or sacred is nothing more than a transformation of Kaombo to a more micro-scale, so it forms as a set of symbols from a vast and open sea area for anyone to become a marine area which is prohibited and even sacred.

Kaombo as one of the important elements of the cultural values of the Buton community is functionally binding on every member of the community to carry out their roles and functions in accordance with the rules and values of culture (Buton locality) in realizing harmonious human life with the environment, especially to nature. The Kaombo region and its contents should not be used in any way without the legality of the Buton Sultanate Government for its exploration activities, moreover exploiting the potential of its natural resources as is the case in various regions in Indonesia.

Kaombo is a limited sea area unit, under the supervision of the value system by the Buton Sultanate at that time, and since the integration of the Buton Sultanate into the lap of the Unitary Republic of Indonesia, the responsibility for governance and supervision of Kaombo was carried out entirely by the Local Government (Regent / Mayor) and related government agencies. In this biological conservation effort, Kaombo is not only a protected area of marine territory, but also the highest value system that is understood by the Government of the Buton Sultanate and its people in managing, and using the sea in an effective, sustainable manner and does not cause destruction to the environment.

Mangunjaya, Heriyanto, and Gholami (2007) in his book on forest conservation efforts entitled "Planting Before Doomsday: Islam, Ecology and the Movement of the Environment" explained that: "The Kaombo is a reflective effort of the Buton community towards their respect for nature. and the resources in it. In other words, Kaombo is a reflection of the system of ideas, concepts,

ideas and views of the Buton community towards efforts to conserve nature.

Apart from the magical/mystical elements contained in the "Kaombo", the Marine Kaombo (nambo) is actually from the term of conservation marine area or Marine Protected Area (DPL) and sea by the Government of the Buton Sultanate culturally is a norm that wants to regulate and direct morality (ethics) of society in a more human direction that comes from conscience, as well as the realization of normative values that bind the collectivity of social behavior of the community. In line with the description, Herimanto and Winarno (2010)[13] put forward meaningful theoretical relations, that moral is related to the value of good and bad human actions. Moral actions are human actions that are carried out consciously, willingly, and knowingly and those actions are related to moral values.

Efforts to Maintain the Kaombo: The ritual implementation in the form of traditional parties and thanksgiving rituals is the best means of strengthening traditional institutions on Siompu Island. The ritual involves all elements of society in the area of customary institutions. They participate according to their respective social positions. Community members will participate as providers of energy or support in the form of rice or other ingredients needed by a ritual. Likewise, community leaders or stakeholders of government institutions will have a role in the ritual.

In traditional rituals, a declaration will be issued regarding the life of the community. Parabella through yaro will convey views and norms relating to their lives. Parabella will convey matters relating to the natural environment in the form of weather in the year that will run until the moral behavior of the community. This natural environment influences the results of fishing by the fishermen and the results of farming; while behavior concerning the norms of society must be done and that must be avoided. Because the presence or absence of violations of the norm will bring goodness and ugliness to live in a society in general in the indigenous region. This view will be heard and obeyed by the community.

The implementation of traditional rituals greatly influenced the existence of Kaombo in Siompu. Rituals in the form of traditional parties and thanksgiving rituals are the most important elements in maintaining the continuity of traditional institutions and their norms. Because ritual is a concrete form that a custom still takes place in the traditional institution concerned. When traditional parties are still ongoing, the structure of the adat institution is still in existence and is still ongoing. Because customary institutions that hold traditional parties and in traditional parties have announcements regarding the structure of traditional institutions.

Conclusion

Kaombo as a form of harmonization of Buton society with the environment is manifested in the system of values, ideas and ideas of the Butonese community. The Kaombo is intended as a form of behavior that is binding on every Buton community to always be wise and wise in protecting the environmental ecosystem. The achievement of the role of the Kaombo in its essence is a preventive effort in preventing possible adverse effects that can be caused from damage to the environmental ecosystem. Even though Kaombo can be interpreted differently by the community, whether it is a system of values and norms of local culture or materialism symbolism of material and special meanings containing elements of mysticism, kaombo is still understood as a group of ideas, knowledge, and advancement of local human mindset in guarding behavior life of its citizens in relation to the existence and existence of physical interactions with the environment.

Abstract

According to Law No. 1 1974, article 7, paragraph (1) "Marriage is allowed only when the man has reached the age of 19 (nineteen) years and the woman has reached the age of 16 (sixteen) years". A marriage of under-age marriage is said to be the case when the age of one or both families are under the age specified. Banjar district ranks the second highest cases of early marriage in South Kalimantan in 2017. Figures for the early marriage Banjar district from 2016 as many as 15 cases and an increase in 2017 as many as 74 cases, 67 cases of which are in Sub-Aluh Aluh. This study aims to explain the risk factors associated with the incidence of early marriage in the wetlands. This study is a quantitative research, with case control design with a ratio of 1: 2 and using purposive sampling technique. The number of respondents in this research were 105 people consisting of 35 respondents 70 cases and the control group respondents. Based on the research results attitudinal variables and the environment girls associated with the incidence of early marriage (p value = 0.001 and p value = 0.001), while the variables of education and culture (p value = 1.000 and p value = 0.011), not associated with the incidence of early marriage. The conclusion of this research is no relationship between environmental attitudes and girls with the incidence of early marriage, whereas no correlation between education and culture with the incidence of early marriage.

Keywords: *The incidence of early marriage, attitude, environment.*

Introduction

Early marriage is inner and outer bond between men and women who are young. Early marriage is a marriage on girls under the age of 16 years should not yet ready to perform marriages [1].This is contrary to Law No. 1 1974, article 7, paragraph (1) which states that "marriage is allowed only when the man has reached the age of 19 (nineteen) years and the woman has reached the age of 16 (sixteen) years". A marriage of under-age marriage is said to be the case when the age of one or both families are under the age specified [2,3].

Indonesia is among countries with a high percentage of young age marriage in the world (rank 37). This position is the second highest in ASEAN after Cambodia. Based Health Research (Riskesdas) in 2013, South Kalimantan Province was ranked second after West Java in the case of early marriage at the youngest age between 10-14 years. Based on data from the BKKBN, the number of teenagers in South Kalimantan families are 2483 people with a number of early marriages reached 18% of the total number of adolescents aged 14-16 years[4,5].

Data Based Population and Family Planning Agency (BKKBN) in 2012 about early marriage, shows the percentage of early marriages in the province of South Kalimantan at 4.84% exceeds the national average by 40 early marriages per 1,000 population. Whereas in 2014 the percentage of early marriages in South Kalimantan rose to 5.85%[6].

According to the Ministry of Religious Affairs, South Kalimantan 3 cases of early marriage with the highest ranking in South Kalimantan in 2017 respectively Hulu Sungai Tengah Regency as many as 101 cases, as many as 74 cases of Banjar Regency and Tanah Laut as many as 32 cases. The Ministry of Religious Affairs According to the Banjar district early marriage figures for Banjar of 2016 as many as 15 cases and an increase

in 2017 as many as 74 cases. Figures early marriage in Banjar district in 2017 was 74 cases, consisting of the District Aluh-Aluh with the highest number of as many as 67 cases[7,8].

The high incidence of early marriage will lead to a high risk of the incidence of pregnancy at a young age. Among them are miscarriage, premature delivery, low birth weight (LBW), congenital abnormalities, easy to infection, anemia in pregnancy, pregnancy poisoning and death [9,10]. Pregnancy at a very young age correlated with maternal mortality and morbidity. Girls aged 10-14 years 5 times the risk of dying during pregnancy or childbirth compared to 20-24 years age group. This risk is increased 2-fold in the age group 15-19 years[11]. Based on the background mentioned above, the research on "The relationship between education,

Materials and Method

This study is a quantitative research, this study used a case control study design with a ratio of 1: 2 and using purposive sampling technique. The number of respondents in this research were 105 people consisting of 35 respondents 70 cases and the control group respondents.

The research instrument is a checklist sheet, the sheet. The bivariate analysis using chi square test. The variables in this study are education, attitudes, culture and the environment and the dependent variable was the incidence of early marriage.

Results and Discussion

A. Univariate Analysis

Table 1. Frequency Distribution

Variables	Respondents	
	N	%
Education		
Low education (primary and junior)	104	99.0
Higher education (SLTA)	1	1.0
Attitude		
Support	38	36.2
Does not support	67	63.8
Culture		
Support	34	34.4
Does not support	71	67.6
Environment		
Support	39	37.1
Does not support	66	62.9

Table 1 shows that the frequency distribution of education levels reveals that a number of teenage girls who berpindidikan larger lower than girls who are highly educated (99.0% versus (1.0%). On the attitude of the frequency distribution shows that the number of teenage girls that does not support early marriage is greater than the girls who support early marriage (63.8 versus 36.2%). In the culture of the frequency distribution shows that the number of teenage girls who do not support early marriage is greater than the girls who support early marriage (67.6 versus 34.4%).In the neighborhood frequency distribution indicate that the number of teenage girls who are in an environment that does not support early marriage which is greater than the number of girls who are in an environment that supports early marriage (62.9% versus 37.1%).

Support	33	94.3	6	8.6	39	100	0,001	176
Does not support	2	5.7	64	91.4	66	100		

Discussion

Based on table 2, the results showed that the attitude and environment variables girls is associated with the incidence of early marriage, while education and culture are not associated with the incidence of early marriage.

Based on the results of the chi square test showed that there is no relationship between education girls with the incidence of early marriage with a p-value = 1.000. This is caused by the age range of married respondents in this study is from <16 years, so it only consists of two categories of educational level. The results are consistent with research conducted by Priyanti (2013) which shows the p-value = 0.195, which indicates there is no correlation between education girls with the incidence of early marriage. These results indicate that the higher education does not determine a person to perform early marriage [12].

Based on the results of the chi square test showed that there is a relationship between the attitude of girls with the incidence of early marriage with a p-value = 0.001. This is because the girls are still in a culture that supports early marriage, early marriage so that he believes it is a natural thing for him and their willingness to channel the emotional needs through marriage considering they view marriage is better than dating.

This is in line with research conducted by Kartika (2013) which shows the perception of girls about early marriage will affect early marriages by 30.8% and is based on research Rafidah (2009) which stated that the respondents who have a perception of a less risky marriage 4.6 times more likely to marry at age <20 years compared to respondents who have a perception of a good marriage[13,14].

Based on the results of the chi square test showed that there was no relationship between culture and girls with the incidence of early marriage with a p-value = 0.011. At respondents who did not favor early marriage, but still get married early, there is an important role by parent respondents. Parents marry off their children is dominated by a strong belief of religion to avoid their children from fornication. According Dahro (2009), parents who still hold on to the old culture is to match and marry off their children at an early age because parents fear that their children are considered a spinster. This is in line with the results of in-depth interviews conducted by Haryono (2008) which states that according to the religion of parents are obliged to marry his daughter was of age (puberty) not committing fornication[15,16].

This is in line with research Pandaleke (2017), which shows the value of p = value p = 0.272> 0.05), then H0 is accepted or not there is a relationship between culture with early marriage. The results of this study are also consistent with research Rahma (2014), which examined the factors that influence the incidence of early marriage among women with results of bivariate analysis showed there was no correlation (p-value = 0.321) between the culture of early marriage[10].

Based on the results of the chi square test showed that there is a relationship between the environment and girls with the incidence of early marriage with a p-value = 0.001 it is because parents have a greater role than environment.

Conclusions

Based on the research results, conclusions obtained as follows:

a. Girls education was not associated with early marriage in Sub-Aluh Aluh Banjar district (p-value = 0.48).

b. The attitude of girls associated with early marriage in Sub-Aluh Aluh Banjar district

(p-value = 0.001 and OR = 113.7).

c. Culture girls are not associated with early marriage in Sub-Aluh Aluh Banjar district

(p-value = 0.011).

d. Environment girls associated with early marriage in Sub-Aluh Aluh Banjar district

(p-value = 0.001 and OR = 176).

Suggestion:

1. Given this research are expected for people, especially parents to be wise in making a decision to marry her after knowing the impact of early marriage
2. For adolesscent girl, it is better before deciding to get married, they must first consider the maturity of age in marriage

Ethical Clearance: The study was approved and received ethical clearance from the Research Ethics Committee of Public Health, Faculty of Medicine, University of Mangkurat, Indonesia. In this study we followed the guidelines of the Committee on Public Health Public Health Committee on Research Ethics, Faculty of Medicine, University of Mangkurat, Indonesia for permission etchical and informed consent. informed consent, including the study title, objectives, participants correctly, confidentiality and signature.

Analysis of Factors Related to Mother Behavior on the Utilization of Integrated Service Post (POSYANDU) in Kotabaru District

Raudatul Jannah[1], Husaini[2], Meitria Syahadatina Noor[2], Roselina Panghiyangani[2], Lenie Marlinae[2]

[1]College Student of Public Health, [2] Departement of Public Health, Medical Faculty, Lambung Mangkurat University, Indonesia

Abstract

The main strategy to reduce the prevalence of nutritional problems is through improving monitoring the children growth in Posyandu. The percentage of children under five years old was weighed in the last 6 months of 2016 in South Kalimantan Province was 68.7% and the district with the lowest coverage was Kotabaru District (43.60%). The Local Area Monitoring Report (PWS) nutritional development program in 2016, showed that D/S coverage at Dirgahayu Health Center based on the toddler age group were 44.79%, 24.57% and 19.72% and if the percentage compared with the district, provincial and national targets, it is still very low (less than 80%). This study aims to analyze the factors related to mother behavior in the utilization of posyandu in Kotabaru district. This research is a quantitative study with case control research design and in a study consisting of 95 cases and 95 controls with simple random sampling technique. There is a correlation between knowledge (p=0,0001), level of education (p=0,0001), community leaders support (p=0,005), and health worker support (p=0,005) with posyandu utilization behavior while dominant factors related to Posyandu utilization behavior is knowledge (p=0.0001).

Keywords: *Behavior, Utilization, Posyandu, Mother, Toddler.*

Introduction

One of the targets of the 2015-2019 National Medium Term Development Plan (RPJMN) is the decrease in the prevalence of malnutrition problems in children under five years old.[1] Posyandu is a form of Community Resource Health Efforts (UKBM) that are managed and organized from, by, for and with the community in the implementation of health development.[2]

Community visits to posyandu in Indonesia are still relatively low. Based on data from the Basic Health Research (Riskesdas) in 2010 62.5% of households did not utilize posyandu because they stated didn't need it.[3] Riskesdas (2013) data showed the frequency of weighing of children under five years old during the span of 6 months of observation in South Kalimantan Province is 29.5%. [4] Community participation in growth monitoring in posyandu (D/S) in South Kalimantan at 2016 was 68.7%. Of the 13 districts/cities, as many as 12 districts/cities did not reach the target (80%) with districts with the lowest coverage were Kotabaru District (43.60%).[5,6]

Based on the Local Area Monitoring Report (PWS) of Kotabaru District Health Office in 2016, out of 28 community health centers in Kotabaru the lowest percentage of family use posyandu (bringing toddlers to posyandu aged 0-11 months, 12-23 months and 24-59 month) in the Dirgahayu Community Health Center. Dirgahayu Community Health Center was ranked as the 4th (fourth) lowest percentage the three age groups of toddler which was 44.79%, 24.57% and 19.72%. When compared with the district, provincial and national targets, it is still very low (less than 80%).

Dirgahayu Community Health Center is one of the Posyandu that has 3,212 mothers who have children with the highest level of education is elementary school as many as 1,179 people (36.7%) .[7] Dirgahayu community health center is supported by 59 community leaders and 11 religious leaders and is not separated from the assistance of cadres, both health cadres as many as 934 people and cadres of Family Empowerment and Welfare (PKK) as many as 546 people. The Dirgahayu Health Center in 2016 had 13 midwives and 2 nutritional

workers. With the support of resources in the working area, Dirgahayu Community Health Center should be able to support in increasing maternal interest in utilizing Posyandu.

Community use of health services, especially posyandu, is influenced by many factors. The results of Sakbaniyah's research (2013) showed the factors that cause low interest of mothers to bring their babies to the posyandu are education, distance, cadre, knowledge, attitude, family, health workers, support of community leaders, and husband's support. In addition, it was also motivated by the support of cadres, religious leaders and stakeholders.[9] Based on the background above, the authors aimed to do research about factors related to maternal behavior in the use of posyandu in Kotabaru District.

Materials and Method

This research is an analytic observational study with case control design. The location that became the place of research was one of community health center in Kotabaru District, that is Dirgahayu Health Center which was held in March-September 2018.

The population in the study were mothers who had toddlers in the work area of the Dirgahayu Community Health Center as many as 3,212 people. Case samples were 95 mothers of toddlers who did not routinely carry their children every month to the Posyandu, while 95 control samples were mothers of toddlers who came regularly carry their children every month to the Posyandu. The sampling technique is simple random sampling.

The independent variables include knowledge level, level of education, support of community leaders, cadre support, PKK support, house distance, and support of health workers. while the dependent variable is mother's behavior in utilization of Posyandu. Research instruments are questionnaires that have been tested for validity and reliability. The analysis was carried out in univariate, bivariate (chi square, with 95% confidence interval (α=0,05) and multivariate with multiple logistic regression test.

Result And Discussion

1. Univariate Analysis

Source: Primary Data 2018

Based on table 1 it is known that mothers knowledge about posyandu mostly in the good category (80.5%). The mother's education level is mostly on elementary or junior high school (53.6%). Most community leaders did not support community to make use of posyandu (57.4%) because respondents felt that there was no consultation activity to plan activities related to posyandu and they did not provide motivation and suggestions to routinely bring the children to posyandu.

Based on table 1 it is known that most of the cadre support in good category (60.5%). Most of PKK support is still lacking (57.4%). Based on the findings in the field it was found that PKK support was felt to be lacking due to the mother feeling the PKK was not motivated to be independent in the use of posyandu, not mobilizing resources to support posyandu activities, not routinely coming to the posyandu and not helping the posyandu activities.

Most of the health workers' support is in the good category (86.8%). The results of the study show that most of the distance from the posyandu to mother's house in the category <10 minutes if taken by foot. The results showed that there were 95 respondents (50%) mothers who routinely used Posyandu and 95 respondents (50%) who did not routinely used Posyandu.

*significant

Based on table 2 it is known that there is a significant correlation between the level of knowledge with posyandu utilization behavior in mothers who have children under five years old (p=0.0001) with an OR is 7.18 which means that mothers who have less knowledge have 7,18 times more likely not routinely take their children to the posyandu. This is in line with research conducted by Hutami and Ardianto (2014) which states that there is a relationship between the level of knowledge of mothers and toddler visits at posyandu. The knowledge of mothers is the basics for the realization of the importance activities in Posyandu.[10] Changes in knowledge are not always be the cause of behavior changes, but knowledge closely related to the initial determination for someone to behave.[11]

Based on statistical tests, it was found that there was correlation between level of education and posyandu utilization behavior (p=0.0001) with OR 2.827 which means mothers who have low education 2.827 more likely not routinely bring their children to posyandu. According to Hidayat (2005) with good education, mothers can obtained basic knowledge about posyandu activities.[12] This is in line with research conducted by Halimah N (2012) which states that there is a significant relationship between the level of mothers education and the level of attendance of children under five years old at posyandu. Good education will support mothers to be able to receive all information from outside and will have an impact on changes in health behavior so that awareness to visit the posyandu.[13]

Statistical test results showed that there was correlation community leader support and posyandu utilization behavior (p=0.005) with an OR value= 2.168, which means that mothers who lack support from community 2,168 more likely to behave badly in utilizing posyandu services. This is in line with the research of Yuryanti (2010) which states that the active role of health workers and community leaders is needed to increase participation in Posyandu implementation because community leaders are the drivers of the community to be present and play an active role in the utilization of posyandu.[14]

Statistical test results showed that there was no relationship between cadre support (p=0,103) and PKK support (p=0,660) with posyandu utilization behavior (p=0.103). Factors that caused there was no correlation between cadre support and PKK support with posyandu utilization were inadequate PKK support in this study. This is in line with the research by Hasanah (2011) which states that there is no relationship between PKK support and the behavior of mothers of toddlers in considering their children to the posyandu. The study stated that mothers visits to posyandu were more influenced by the activeness of mothers.[15]

There was a relationship between health workers support with posyandu utilization behavior (p=0.005) with OR= 3.708, which means that mothers who do not get the support of health workers 3,708 more like have less posyandu utilization behavior. The results of this study are in line with the research conducted by Putri (2015) which states that there is a relationship between health workers supports and mother visits to posyandu.[16] Based on research conducted by Reihana et al. (2014), there was a relationship between the presence of health workers and mother participation in weighing their children to the Posyandu. Every program with the target community, especially the posyandu program, will not succeed if the community does not understand the importance of posyandu. Therefore, there is a need for participation and support from health.[17]

Based on the results of statistical tests, it was found that there was no correlation between posyandu distance and posyandu utilization behavior (p=0.745). This is because the number of mothers who have close house distance (<10 minutes) from posyandu have more bad behavior in the utilization of health services (73.7%). Another factor is because some of the respondents' education level is still low. The results of this study are in line with research conducted by Fitriah et al (2013) which states that there is no relationship between distance of residence and mother visits to posyandu, this is because if knowledge, education, support from community leaders, cadres, and health workers are well, even though the distance is quite far, a mother will still come to the posyandu because they are aware of the importance of coming to the posyandu for toddler health and growth.[18]

3. Multivariate Analysis

Multivariate analysis was performed using multiple logistic regression tests using the backward method. Variables that include to multivariate model candidates are independent variables with bivariate results with p-value <0.25. For independent variables whose bivariate results showed p-value> 0.25 but are important in substance, these variables can be included in the multivariate model. The variables included in the multivariate model can be seen in the table below:

Tabel 3: Variable Selection

No	Variabel	P-value
1	Level of Knowledge	0,0001*
2	Level of Educatiom	0,0001*
3	Community Leader Support	0,005*
4	Cadre Support	0,103*
5	PKK Support	0,660**
6	Health Worker Support	0,005*
7	Posyandu Distance	0,745**

Explanation: p-value = Correlation Value, * = Continue to Statistic Analysis, ** = Discontinue to Statistic Analysis

Tabel 4: Last Results of Multivariate Analysis

No	Variable	Sig.	Exp (B)
1	Level of Knowledge	0,0001	5,625
2	Level of Education	0,004	2,609
3	Community Leader Support	0,018	2,197
4	Health Worker Support	0,025	3,347

The results of the multivariate analysis showed the knowledge variable was the most dominant variable related to posyandu utilization behavior by mothers who had children with p-value=0.0001 and Odd Ratio=5.625, which means that mothers with less knowledge 5,635 more likely to not routinely take their children to the posyandu. Notoatmodjo (2003) stated that knowledge or cognitive is a very important domain in shaping one's actions. Insufficient knowledge makes mothers not aware of the importance of the benefits of bringing toddlers to the posyandu so that mothers lack awareness and positive attitudes to participate in activities at the posyandu. If knowledge comes from personal experience, the mother who follows the posyandu repeatedly, even regularly, will certainly know the benefits of posyandu.[19]

Conclusions

There was a relationship between knowledge, education, community leaders support, and health workers support with posyandu utilization behavior, while the cadres support, PKK support, and posyandu distance doesnt have a significant relationship with posyandu utilization behavior. It is expected that the Health Service and Community Health Centers to conduct health promotion activities for mothers who have children under five years old to increase the knowledge of mothers about the importance of bring children to posyandu, and for the local government needs to strengthen the performance of PKK and posyandu cadres in Kotabaru District to support improved mothers behavior in the utilization of posyandu.

Ethical Clearance: This study approved and received ethical clearance from the Committee of Public Health Research Ethics of Medical Faculty, Lambung Mangkurat University, Indonesia. In this study we followed the guidelines from the Committee of Public Health Committee of Public Health Research Ethics of Medical Faculty, Lambung Mangkurat University, Indonesia for etchical clearance and informed consent. The informed consent included the research tittle, purpose, participants's right, confidentiality and signature.

A Comparative Study of Early Response Rate between Patient Given Standard Chemotherapy with Patient Given Combination Targeted Therapy in Non-Hodgkin Lymphoma Patients

Ardan Miraz[1], Andi Fachruddin Benyamin[2], Tutik Harjianti[2], Rahmawati Minhajat[2], Syakib Bakri[1], Hasyim Kasim[1], Harun Iskandar[1]

[1]Internal Medicine Department, Faculty of Medicine, Hasanuddin University, Makassar, South Sulawesi, Indonesia, [2] Medical Hematology and Oncology Division of Internal Medicine Department, Faculty of Medicine, Hasanuddin University, Makassar, South Sulawesi, Indonesia

Abstract

Background: Treatment for non-Hodgin Lymphoma (NHL) with cyclophosphamide, doxorubicin, vincristine, and prednisone (CHOP) has been standard chemotherapy regimens for treatment of patients with diffuse large B cell lymphoma and follicular lymphoma. Rituximab, a chimeric monoclonal antibody against the CD20 B-cell antigen. Rituximab in combination with CHOP (RCHOP) increases better response rate without any significant increase in toxicity. The standard definition of treatment responseis based on changes in lesion dimensions with time. We conducted a comparative study to compare early response rate between CHOP andCHOP in NHL patients.

Method: This study was using cohort prospective analysis and conducted at Wahidin Sudirohusodo Hospital from September 2018 until June 2019. The response rate was measured with the longest diameter of tumor and compared after 2 observational cycle periods of chemotherapy. Analysis to compare responserate was carried out using Independent T-test analysis.

Results: Seventy patients enroll this study consisting of 38 subjects in CHOP group and 32 subjects in RCHOP group. Analysis to compare early responserate between CHOP and RCHOP was significant with p-value 0.001 (46.6% vs 67.0%;).

Conclusions: Early response rate in patient given combination targeted therapy have better response rate than patient given standard regiment chemotherapy.

Keywords: *Early ResponseRate, RCHOP, CHOP, non-Hodgkin Lymphoma.*

Background

Malignant lymphoma is divided into 2 large groups of neoplasms namely Hodgin Lymphoma (HL) which characterized by presence of reed sternberg cells and non-Hodgin Lymphoma (NHL) which characterized by a collection of abnormal lymphocytes.[1,2] Non-Hodgin's lymphoma represent 80-90% of all malignant lymphoma.[3,4,5]. The most frequent type of NHL isdiffuse large B cell lymphoma (DLBCL), accounts for approximately 40% of lymphoma new cases.[6, 7] In Indonesia, NHL along with Hodgkin disease and leukemia ranks as the sixth most frequent diseases.[3, 8]

The management of NHL depends on several things including histophatological type, stage, differentiation, progression, age and patient's general condition.[3,9]

Combination chemotherapy of cyclophospamide, doxorubicin, vincristin, prednison (CHOP) has emerged as the standard therapy for agrresive type of NHL for more than two decades.[7] Randomized studies had shown that CHOP is a chemotherapy that has same effectiveness with other regimens but has minimal toxicity.[7] Rituximab, a monoclonal antibody that binds specifically to CD20 antigen, which is expressed on the B lymphocytes surfaces.[7] Rituximab is given to NHL patients with positive CD20.[10] Various multicenter studies showed that rituximab combination with CHOP (RCHOP) increased survival rate and completed remission in first-line chemotherapy of DLBCL patients compared to CHOP alone.[6,11]

The first widely-used standard response categories for malignant lymphoma in the CT imaging erawere usingthe Cotswolds criteria.[12] Moreover, the most commonly used nowadays is NHL International Workshop Response criteria.[13] These standard definitions of treatment response are based on changes in lesion dimensions with time.[14] CT assessment of lymphoma after one or two cycles of chemotherapy may show some tumor shrinkage but the response was usually incomplete at that stage, especially tumors in larger size.[13,14] The studies on responserate comparing RCHOP with CHOP in NHL patientsand factors that influenced the responseratewere limited. Based on these findings, it is tempting to conduct the study especially in Makassar, Indonesia.

Method

This study used a prospective cohort design for patients with NHL who underwent chemotheraphy at Wahidin Sudirohusodo Hospital in Makassar from September 2018 to June 2019. Research subjects is population that meets research inclusion criteria. Patients were eligible if they wereabove eightteen years of age and histopathological examination showed non-Hodgin Lymphoma.All subjects provided written informed consent. Subjects were excluded if they wereusing other chemotherapy regimens besides CHOP and RCHOP or had obtaining radiotherapy during observation period.Subjects were drop out if have not completed 2 chemotherapy cyclesduring observation period.

We divided the subjects into 2 groups. The CHOP group weresubjects who received cyclophospamide, doxorubicin, vincristin, prednisoneand andthe RCHOP group were subjects who received rituximab addition to CHOP with a positive CD 20. Age was divided into groups by age <60 years and ≥60 years. Performance status was grouped into ECOG 0, I, II, III, IV. Subjects were grouped into without or with presenceof B symptoms if there was weight loss, excessive sweating and fever without other causes. Serum LDH was grouped into less than upper limit normal (ULN) (<220 U/L) and greater than ULNor equal to ULN (LDH ≥ 220 U/L). Ann Arbor stage consisting of stages I, II, III, IV. Subjects were grouped bulky disease (maximal tumordiametergreater than 7 cmor greater than one-third of internal transverse diameter of posterior-anteriorchest radiograph) or without bulky disease. Prognostic risk based on IPI Score is grouped into ; low risk: score 0-1, moderate risk: score 2, moderate-high risk: score 3 and high risk: score 4-5.

Earlyresponse rate was assessed based on changes in size of tumor before and after 2 chemotherapy cycles. If tumors more than one, we used the Sum of Longest Diameters (SLD) comparison. Tumors that can be assessed on body surface were assessed using a caliper while tumors located in internal organs of the body and involving extra nodules are assessed with radiology (chest X-ray or CT Scan).

Findings: Descriptive data analysis was performed on 70 subjects, CHOP group were 38 subjects (54.3%) and RCHOP group were 32 subjects (45.7%). This study consisted of male (61.4%) and female (38.4%). The age range of subjects was between 19-79 years with an average 50 ± 14 years, based on age was divided into <60 years (74.3%) and ≥60 years (25.7%). Serum LDH were grouped into less than ULN (24.3%) and greater than ULN or equal to ULN (75.7%).Immunohistochemical examination in this study subjects were 46 subjects with positive CD 20 (65.7%) and with negative CD 20 were 24 subjects (34.3%). B symptomspresenced in 32 subjects (45.7%) and absensed in 38 subjects (54.3%). Based on Ann Arbor stage, stage 1 (45.7%), stage 2 (17.1%), stage 3 (22.9%) and stage 4 (14.3%). Bulky disease presentedin study were 16 subjects (22.9%) and absense of bulky disease were 54 subjects (77.1%). Performance status with ECOG 1 (68.9%) and ECOG 2 (31.4%). Prognosisrisk which had low risk (50%), moderate risk (31.1%), and moderate risk (12.9%). (Table 1).

Table 1. Basic Characteristics

Variable	Characteristic	n	%
Chemotherapy	CHOP	38	54.3
	RCHOP	32	45.7
Gender	Male	43	61.4
	Female	27	38.6
Age	<60 years old	52	74.3
	≥60 years old	18	25.7
Serum LDH	Less than ULN	17	24.3
	Greater than ULN or equal to ULN	53	75.7
CD20	Positive	46	65.7
	Negative	24	34.3
B Symptoms	Presense	32	45.7
	Absense	38	54.3
Ann Arbor Stage	1	32	45.7
	2	12	17.1
	3	16	22.9
	4	10	14.3
Bulky Disease	Yes	16	22.9
	Not	54	77.1
Performance Status (ECOG)	1	48	68.6
	2	22	31.4
Prognosis Risk (IPI score)	Low	35	50.0
	Intermediate	26	37.1
	High-Intemediate	9	12.9

Histopathological features of anatomic pathology examination showed that Diffuse Large B Cell Lymphoma was the highest percentage with 26 subjects (37.1%), non-specific Hodgkin Lymphoma with 25 subjects (35.7%), Small Lymphocytic Lymphoma with15 subjects (21.4%), Follicular Lymphoma with 2 subjects (2.9%), Malignant Lymphoma Intermediate Cell with 1 subject (1.4%), and MALT Lymphoma with1 subject respectively (1.4%). (Table 2)

Table 2. Histopathological Features

Histopathological features	n	%
Diffuse Large B Cell Lymphoma	26	37.1
non-specific Hodgkin's lymphoma	25	35.7
Small Lymphocytic Lymphoma	15	21.4
Follicular Lymphoma	2	2,9
Malignant lymphoma Intermediate Cell	1	1,4
MALT Lymphoma	1	1,4
Total	**70**	**100.0**

The RCHOP group showed a better earlyresponse rate based on tumor size shrinkage percentage compared to CHOP group(67.0% vs 46.6%) significantly with p value 0.001. (Table 3).

Table 3. Comparison ofearlyresponserate of standard chemotherapy therapy with combination targeted therapy

Chemotherapy	n	Mean of early response	Standard devation	p-value
CHOP	38	46.6	26.2	0.001
RCHOP	32	67.0	21.8	

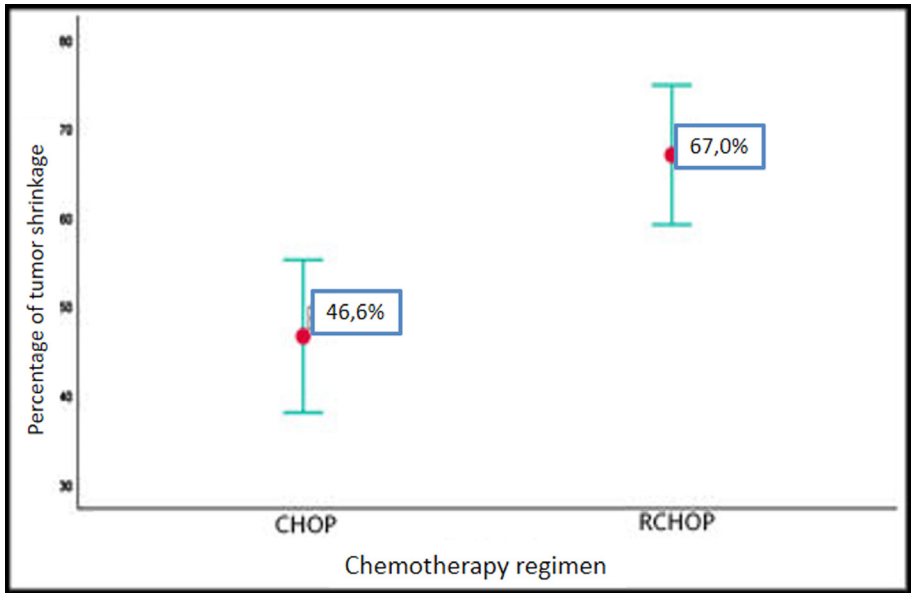

Figure 1. The comparison of early response rate between CHOP and RCHOP

Discussion

In this study, numbers of male subjects more than female subjects with a ratio of 1.6: 1, this is in line with the Intragumtornchai et al study, in 4056 patients with ratio of men than women 1.3: 1 and according to WHO data, in the United States ratio of male to female patients was 1.5: 1.[15,16] The age range of subjects in this study was 19-79 years with an average 50 ± 14 years. This is in accordance with subjects in study by Itragumtornchai et al with range of 16-99 years with an average age of 56 years.[15] Based on histopathological features in this study found that the highest prevalence was DLBCL, this is consistent with the data from WHO that among the malignancies of NHL, DLBCL was the highest prevalence of subtype.[17] Most aggressive lymphoma is DLBCL and its prevalence continue to increase by 3-4% every year.[18] We found that more patients had LDH serum greater than ULN. These result in accordance with study of Kasir et al that found all of the subjects hadLDH serumgreater than ULN.[19] LDH serum is prognostic factor and can be monitored to assess response rate.[20] Analysis in B limphocytes showed thatmost NHL have a positive CD20, but some of previous studied found that to 1-2% patients had negative CD20.[21] Based on B symptom, in this study 54.3% of subjects showed anabsense of B symptoms, according to previous NHL study that B symptoms were more common in aggressive lymphoma (41%) than in indolent lymphoma (19%).[22]

The RCHOP group showed better early response rate when compared to CHOP group (67.0% vs 46.6%; p=0.001). This study results were in line with studies by Delgado et al found that combination Rituximab with CHOP improvedcomplete response (CR) and delayed disease progression in folicular lymphoma patients.[23] In the same study, in DLBCL group the combination Rituximab showed no significant difference in long-term outcome.[23] Coifier et al study, found that patients who received 8 RCHOP chemotherapy cyclesgroup showed better CR number than CHOP group (76% vs 63%, P <0.05).[6] In addition to Nishimori et al study in Japan,patients who received 3-4 cycle of standard chemotheraphy regimen showed a greater CR difference in RCHOP group compared CHOP group (77.7% vs 69.4%, p<0.01).[7] Rituximab has an important role in calcium channels for B cell survival.[24] Complement-dependent cytotoxicity and human FC receptors are activated which trigger cellular antibody toxicity of cellular when rituximab which binds to CD20 receptor.[24] Rituximab mediates immune system and induces apoptosis.[24]

Conclusion

Early responserate in patients given combination targeted therapies showed better responserate than patients given standard regiments of Chemotherapy.

Conflict of Interest: No Potential conflict of interest relevant to be declared.

Source of Funding: This study was conducted with self funding, no external funding sources for this study

Ethical Clearance: The study has been permitted and acknowledged by Hasanuddin University Ethic Medical Committee. Before each interview, each participant was given written information on the study. Each participant was also informed that his or her participant was voluntary. Before each interview, we emphasized the importance of maintaining confidentiality in relation to patient cases. All participants provided written consent to participate in this study.

Relationship between Exposure of Cement Dust Emission on Blood Level of Chromium and Nickel as Acarcinogenic Factor of Retinoblastoma

Ardizal Rahman

Ophthalmology department M. Djamil General Hospital Padang, Medical Faculty of Andalas University, Perintis Kemerdekaan Street No. 94 Jati, Padang, West Sumatra-Indonesia

Abstract

Background: Retinoblastoma is the most commonprimary intraocular malignant tumor in children with genetic etiology. Cement dust is genotoxic and can cause changes in the genetic structure of somatic and germ cells. Cement dust contains metal compounds that are harmful to human health such as chromium and nickel that can enter the human body. Chromium is mutagenic while nickel is a toxic and carcinogenic metal.

Method: This study is analytic cross sectional study in three population groups that are exposed and not exposed to PT. Semen Padang and the group of fathers of children with retinoblastoma. The total sample size is 304 people. Each sample is grouped by sex, occupation, and chromium and nickel levels in the blood.

Results: There were no significant differences in chromium levels of the male and female sample groups (p value 0,598) and no significant differences in the nickel level of the male and female sample groups exposed to cement dust (p value 0.401) . There were no significant differences in chromium levels of the male and female sample groups (p value 0.753) and no significant differences were found in the nickel level of the male and female sample groups not exposed to cement dust, (p value 0.234).

Conclusions: This study showed no statistically significant association between chromium and nickel levels in the blood as carcinogenic substances in retinoblastoma patients to exposure to dust mortar and its

Conclusions: This study showed no statistically significant association between chromium and nickel levels in the blood as carcinogenic substances in retinoblastoma patients to exposure to cement dust and its effects as carcinogenic substances in retinoblastoma disease.

Keywords: *Retinoblastoma, cement dust, chromium, nickel.*

Introduction

Retinoblastoma is the most frequent primary intraocular malignant tumor in children. Genetically, this tumor develops due to a long-arm mutation of the chromosome at the locus 13q14. Mutations in both Rb1 gene alleles are a prerequisite for this tumor to develop. These tumors can be hereditary or sporadic derived, and may be unilateral (70-75% of cases), or bilaterally (25-30% of cases). There is no predilection of sex and race with age that is often subjected to an average age of 18 months and 90% of patients diagnosed before the age of 5 years.[1,2,3,4]

The occupation of the father before and after the conception of the child requires an investigation to explore the etiological factors in both forms of retinoblstoma. From some studies of parental work and cancer in children, the work of the father in the form

of television or radio repairmen related specifically to retinoblastoma. Another significant finding is the association of preconceptional work on work relating to metals and nonhereditic retinoblastoma. The biological explanations are caused by the carcinogenes of 2 metal compounds namely nickel and chromium. Cement dust contains metal compounds that are harmful to human health such as chromium and nickel that can enter the human body through respiratory system due to polluted air as well as digestive system due to drinking water pollution from the precipitated metal compound. In this study we wanted to know the relationship between levels of chromium and nickel in blood to exposure to cement dust emissions and their effects as carcinogenic substances in retinoblastoma disease. [5,6,7,8]

Method

This study has obtained ethical clearance from the ethical committee of Faculty of Medicine Andalas University. The design of this study is analytic cross sectional study in three population groups that are exposed and not exposed to PT. Semen Padang and the group of fathersof children with retinoblastoma. This study was conducted at Eye Health Clinic of Dr.M.Djamil Padang and also around Semen Padang with distance from location based on radius ≤ 10 km (exposed location) and ≥ 30 km (unexposed location). The location taken is an area corresponding to the wind direction for the city of Padang which averages toward the west, northwest, and southwest. The study was conducted from June 2015 to September 2016. For each group exposed and not exposed to cement plant dust emissions 189 samples were obtained for groups of people living in the vicinity of semen padang and 102 samples for unexposed groups while the number of samples for groups of people old people with retinoblastoma that is 13 people. The total sample size is 304 people. Each sample is grouped by age, sex, occupation, cromium and nickel levels in the blood.

Inclusion criteria are the parents of patients who have been diagnosed with retinoblastoma by a doctor at the Eye Health clinic of Dr. M. Djamil and has agreed in writing to participate in the study. For the exposed group of residents who live around the cement plant and have been living for at least 2 years and are willing and agree to participate in the study and undertake to meet the rules of the inspection conducted. The exclusion criteria in this study were the elderly people with retinoblastoma who had died or moved the address of the residence. Residents who disagree and do not undertake are included in the study.

The study was conducted on the inhabitants of cement factory and residents outside the cement factory and the fathers whose children suffered from retinoblastoma. The three sample groups were informed consent, then interviewed with questionnaires, slit lamp examination, fundoscopic examination, and blood sampling for examination of chromium and nickel levels in blood serum using spectrophotometer method. A group of low grade chromium and nickel and groups with high grade chromium and nickel were obtained.

Results

The data were collected at the Ophthalmology Department of Dr. M. Djamil Hospital Padang and people living around Semen Padang area with distance from the location of ≤ 10 km (exposed location) and ≥ 30 km (unexposed location). The location taken is an area corresponding to the wind direction for the city of Padang with averages toward the west, northwest, and southwest. The total sample size is 304 people (table 1). Each sample is grouped by sex, occupation, chromium and nickel levels in the blood. Table 1 shows the mean ratio of chromium and nickel levels in the blood of fathers of children withretinoblastoma, people exposed and not exposed to cement dust.

Table 1: Comparison of chromium and nickel level in all three groups of samples

Sample	Amount	Chromium(mg/dl)	P value	Nickel (mg/dl)	P value
The father ofretinoblastoma	13	4,282	0,741	28,730	0,459
Exposed	189	3,957		23,732	
Not exposed	102	3,857		23,888	

Based on Table 1, there was no significant difference between mean chromium levels in fathers of children with retinoblastoma, people exposed and not exposed to cement dust (p 0.741). In addition, nickel level in the group offathers of children withretinoblastoma, people exposed and not exposed to cement dust also did not

differ significantly (p 0.459). In general, however, mean chromium and nickel levels in the blood of fathers of children with retinoblastoma were higher than those exposed and not exposed to cement dust. By sex, the relationship between blood level of chromium and nickel in the exposed group and not exposed group to cement semen dust is shown in Table 2.

Table 2. Chromium and nickel level based on sex in the exposed group and not exposed to cement dust

Gender	Amount	Chromium (mg/dl)	Standard Deviation	P value	Nikel (mg/dl)	Standard Deviation	P value
Exposed							
Man	47	11,587	6,4312	0,598	100,81	14400,67	0,224
Women	142	10,940	7,5416		93,08	48,905	
Not Exposed							
Man	33	50,17	2,9569	0,753	46,45	20,8411	0,234
Women	69	52,14	3,6482		53,91	24,6599	

In table 2, the number of male samples in the are exposed to cement dust were 47 people and the number of female samples were 142 people, whereas in the environment not exposed to cement dust we obtained 33 men and 69 women. Based on statistical results, there was no significant difference in mean chromium level (p value 0,598) and nickel (p value 0.224) in the men and women exposed to cement dust. In addition, chromium and nickel levels in the male and female samples in areas not exposed to cement dust also showed no significant difference (p value 0.753 and 0.234). However, chromium and nickel levels were higher in men than women in areas exposed to cement dust, whereas in areas not exposed to cement dust the chromium and nickel levels were found to be higher in the female sample group. Chromium and nickel level by type of occupation of the three sample groups are shown in Table 3.

Table 3. Chromium and nickel blood level based on type of occupation.

Type of Work	Amount	Chromium (mg/dl)	Standard Deviation	P value	Nikel (mg/dl)	Standard Deviation	P Value
Fathers of children with retinoblasroma							
Indoor	9	6,06	4,7010	0,459	7,11	37,8832	0,309
Outdoor	3	7,83	3,0184		4,67	1,2061	
Exposed							
Indoor	158	11,052	7,0851	0,741	87,275	7,9440	0,224
Outdoor	31	8,812	5,5438		100,822	7,0725	
Not exposed							
Indoor	85	50,188	2,7888	0,058	48,675	2,1437	0,052
outdoor	17	73,935	5,9574		72,9	2,9998	

In table 3, most types of occupations of retinoblastoma patient's father were outdoor workers. While exposed and not exposed to cement dust samples were mostly in door worker. Based on statistical results, there was no significant difference in mean chromium (p value 0.459) and nickel level (p value 0.309) in father of children with retinoblastoma who worked indoor or outdoor. In the group exposed to cement dust, there was no significant difference in mean chromium and nickel level for both indoor and outdoor worker groups (p value 0.741 and 0.224). Likewise in the groups not exposed to cement dust, there was no significant difference in mean chromium and nickel level for both indoor and outdoor worker groups (p value 0.058 and 0.052).

Discussion

The chemical composition of cement dust shows a toxic constituent and requires the evaluation of occupational populations exposed to the genotoxic effect in order to assess the mutagenic potential of cement dust. Semen doses are genotoxic and can cause changes in the genetic structure of somatic and germ cells of exposed

workers. Toxic substances entering the human body cause disruption to the normal condition and behavior of chromosomes which ultimately lead to a change in the arrangement of hereditary materials that cause chromosomal aberration and gene mutations in somatic and germ cells. The chromosomal aberration illustrates the presence of damage to DNA. [11,12,13]

In this study we obtained 189 samples for groups of people living in the vicinity of semen padang and 102 samples for unexposed groups while the number of samples for fathers of children with retinoblastoma was 13. Of the 189 samples for the group living around the cement padang, there were 47 men and 142 women, while from 102 samples for unexposed groups there were 33 men and 69 women. Epidemiologically, exposure to the elderly before the conception of the child can affect the development of inherited sporadic retinoblastoma.

Chromium is a hard, shiny, gray metal that has a high melting point. Chromium is also odorless, tasteless and altered. The trivalent chromium compound is a stable form and is therefore found in the extracted material and most often in the remaining kilns of kilns and cement. The hexavalent chromium compounds are strong and unstable oxidizers and have high solubility in water. The hexavalent chromium compounds are more toxic than trivalent chromium. Respiratory tract is the main target organ of hexavalent chromium compound, in acute (short-term) and chronic (long-term) inhalation exposure.

Study by the International Agency for Study on Cancer in animal experiments supports the assumption that the most potent chromium compounds are carcinogenic compounds of hexavalent chromium, especially calcium chromate. The exact mechanisms of carcinogenicity of hexavalent chromium compounds have not been fully understood. It is thought that hexavalent chromium compounds govern the majority of cytotoxic and genotoxic effects by causing oxidative stress, forming stable DNA-chromium adducts, DNA-DNA crosslinks, and solving single-stranded and double-stranded DNA. DNA damage triggered by hexavalent chromium compounds may affect the replication, transcription, and translation of DNA in altered gene expression. Changes in gene expression mediated by DNA damage are considered as the key mechanisms underlying the genotoxic and carcinogenic activity of hexavalent chromium compounds. [14,15,16,17]

Nickel is a nonessential metal widely used in the production of coins, jewelry, batteries, medical equipment, carbon particles as well as in coating and welding processes. Nickel particles are the most dangerous in humans, especially in the lungs where the crystalline nickel becomes settled in the mucosa before it is phagocytosed by epithelial cells and macrophages. When inside the cell, the nickel compound is gradually destroyed and releases reactive nickel ions. The phagocytic properties of nickel intake mean significant amounts of nickel can accumulate over time, harm the lung tissue and often cause latent effects in individuals exposed to nickel for many years before. [14,18]

In this study, we found nosignificant difference between mean chromium levels in fathers of children withretinoblastoma, people exposed and not exposed to cement dust (p 0.741). In addition, nickel level in the group of fathers of children withretinoblastoma, people exposed and not exposed to cement dust also did not differ significantly (p 0.459). In general, however, mean chromium and nickel levels in the blood of fathers of children with retinoblastoma were higher than those exposed and not exposed to cement dust.

There was no significant difference in mean chromium level (p value 0,598) and nickel (p value 0.224) in the men and women exposed to cement dust. In addition, chromium and nickel levels in the male and female samples in areas not exposed to cement dust also showed no significant difference (p value 0.753 and 0.234). However, chromium and nickel levels were higher in men than women in areas exposed to cement dust, whereas in areas not exposed to cement dust the chromium and nickel levels were found to be higher in the female sample group.

From some studies of parental occupation and cancer in children, the work of the father in the form of television or radio repairmen related specifically to retinoblastoma. Bunin et al in his study, observed five significant associations between occupation and retinoblastoma. In the form of inherited diseases, more cases than controls have fathers working in welder groups and machine interpreters and grandparents of the mother's side working as farmers. Another significant finding is the linkage of preconceptional work to work relating to metals and nonhereditic. [4,5,8]

In this study, most fathers of children suffering from retinoblastoma were outdoor workers. While

exposed and not exposed to cement dust samples were mostly worker indoor. However, we found no significant difference in blood level of chromiumand nickel in father of children with retinoblastoma who worked indoor or outdoor. Likewise, in the groups exposed and not exposed to cement dust, the blood level of chromium and nickel in both indoor and outdoor workers were also not statistically different.

Conclusion

This study showed no statistically significant relationship between chromium and nickel levels in fathers of children with retinoblastoma, exposed group, and unexposed group to cement dust emissions and their effects as carcinogenic substances in retinoblastoma disease. There is no association between increased levels of chromium and nickel in blood to exposure to cement dust, thus further studyon toxic metals and other pollutants suspected to be associated with the pathogenesis of retinoblastoma is needed.

[1]Faculty of Veterinary Medicine, Universitas Airlangga, Kampus C Universitas Airlangga, 60115, Surabaya, Indonesia

Abstract

The aim of this study was to examine the effect of feeding using complete feed added with various formula toward the level of milk's palmitic and palmitoleic acids in Holstein-Friesian cross cow. In this study, we used ten female Holstein-Friesian cross cows between four and seven years with two to six lactation periods. The substances were control feed P0 and complete feed with different formula P1, P2, P3, P4. The study was completely randomized design with five treatments and two replications. The data were analyzed using analysis of variance and the differences means between of the treatments were tested by Duncan's multiple range tests. The software that was used to analyze the data was windows Statistical Program of Social Science 22 (SPSS 22). Interestingly, the result of the study showed that P3 complete feed containing the lowest crude fiber among the treatments could increase the levels of palmitic and palmitoleic acids in the milk of cow. In conclusion, fed dairy cows using complete feed with a different formula affect the levels of palmitic and palmitoleic acids in cow's milk significantly.

Keywords: *Palmitic acid, palmitoleic acid, complete feed, milk, Holstein-Friesian.*

Introduction

The livestock revolution is primarily driven by demand. Poor people everywhere are eating more animal products as their incomes rise above poverty level and as they become urbanized. By 2020, the share of developing countries in total world meat consumption will expand from 52% currently to 63%. By 2020, developing countries will consume 107 million metric tons (mmt) more meat and 177 mmt more milk than they did in 1996/1998, dwarfing developed-country increases of 19 mmt for meat and 32 mmt for milk[1]. Milk is a considerable resource of products whose composition varies[2]. Fat serves as an efficient source of energy for the body directly and potentially, when stored in adipose tissue[1]. Fatty acid is a constituent part of the lipid. Fatty acid play a number of key roles in metabolism [3].

A variety of fatty acids exists in the diet of humans, in the bloodstream of humans, and in cells and tissues of humans. Fatty acids are energy sources and membrane constituents. They have biological activities that act to influence cell and tissue metabolism, function, and responsiveness to hormonal and other signals. The biological activities may be grouped as regulation of membrane structure and function; regulation of intracellular signaling pathways, transcription factor activity, and gene expression; and regulation of the production of bioactive lipid mediators[4].

Palmitic and palmitoleic acids are two of the various fatty acids in the cow's milk. Palmitic acid itself has a high substance in milk fat in the appeal of other fatty acids as a shaper of milk fat. Palmitoleic acid has a low substance than palmitic acid, however palmitoleic acid also play a role as a forming of milk fat. According to Sulistyowati[5], palmitic acid contained in human and cow fat milk is 22.6%. A comparison between the effects of foods containing lauric, myristic, and palmitic acids, that palmitic acid can lower serum cholesterol level. Besides the replacement of foods that contain lauric-myristic to palmitic-oleic in human have beneficial effect on thromboxane index (one transmitter protein that play a role in blood clotting process and includes class arachidonic acid) to prostacyclin in plasma. While palmitoleic acid has its own function, according to Mozaffarian *et al*.[6], circulating trans-palmitoleic acid is associated with lower insulin resistance, presence of atherogenic dyslipidemia, and diabetes incidence.

The fat content in cow's milk in Indonesia is still not qualified in the standard of SNI 01-3141-1998 in the amount of 3%. Based on research in Bogor, the fat content of cow's milk from farmers is only about 2.5%[7], even lower results obtained in Riau province in which the results of a study states that the fat content in cow's milk is only 1.6%, in the range of 1.21-2.05%[8].

Quantity and quality of milk in farm where located in the tropical area are influenced by the nutrient substance of feed. Poor feed quality causes nutrients from a feed material that is absorbed in the digestive tract for milk production is decreasing. This condition affects the quantity and quality of milk produced[9]. One of the efforts to improve the quality of milk is improving the quality of feed[10]. The aim of the present study was to examine the portion of contribution of the dairy cows digestive system in absorbing nutrients for the formation of palmitic and palmitoleic acids in milk.

Materials and Method

This study used completely randomized design (CRD), which consists of five kinds of treatments and two replications using the different replications. This study was conducted at Teaching Farm (owned by Faculty of Veterinary Medicine, Universitas Airlangga), Gresik, Indonesia. Experimental animals used in this study were 10 dairy cows. Dairy cows used in this study were female productive cross dairy cows of Holstein-Friesian, at 4 to 7 years old, and were in second to the sixth month lactation with an average production of 10 liters/head/day.

The study was conducted by providing a complete feed with a variety of formulas to experimental animals. Experimental animals were randomly assigned using a simple random system. In this study, each treatment has two replications. P0 was a control treatment using forage and soy pulp, whereas P1, P2, P3, and P4 itself were a complete feed consisting of concentrates and forages that have been measured in different compositions for each treatment.

This study used several phases, including: the adaptation phase of feed, feed treatment phase, sampling phase, the phase of milk fatty acid analysis, feed fatty acid analysis, and data analysis phase. During the adaptation phase, P0 conventional feed, complete feed P1, P2, P3, and P4 were fed for a week. Adaptation of the feed was intended to have the experimental animals to consume the feed in accordance with the provisions of regular and stable feed.

Feed treatment phase was to provide a complete feed for each animal according to type of treatment. P0 as a control treatment used a forage and soy food pulp, while the P1, P2, P3, and P4 used a complete feed with a different composition for each treatment. Control feed given to the animal was 15 kg of forage and 10 kg of soy pulp per day, whereas the complete feed was given to each animal in the morning for 7.5 kg and 7.5 kg in the afternoon, so the feed given was 15 kg/head/day in each treatment group. This stage was conducted for a week.

The research lasted two weeks, with details of a week for the process of adaptation, and a week for treatment. Samples of feed derived from complete feed formed. In this phase, the milk was taken twice a day, in the morning and afternoon, for a liter each time. After that, the sample milk was coded and grouped according to the treatment and then stored at 15 °C, so that the composition of milk was not changed or damaged. At the end of this study, all samples of milk from the Teaching Farm, Gresik, Indonesia collected at the Faculty of Veterinary Medicine, Universitas Airlangga, Surabaya, Indonesia has been stored at 15°C. Milk was thawed, homogenized and labeled according to the treatment. All the samples were analysis of palmitic and palmitoleic acids with feed and milk as samples. Fatty acid analysis performed by the method of HPLC (High Performance Liquid Chromatography).

The data were analyzed by the method of ANOVA (one-way analysis) with Statistical Program for Social Science 22 (SPSS 22) and for average differences between treatments were tested with a range of Duncan's multiple range test, with standard real for $\alpha = 0.05$.

Results

The results of palmitic and palmitoleic acids analysis in feed were as follow (Table 1). In accordance with the data below (Table 1) P4 and P3 complete feeds contain high level of palmitic acid, while the high level of palmitoleic acid among the treatment found in P1, P2, P3, P4 complete feeds. The lowest level of palmitoleic acid found in P0 control feed.

The results in regard to using P0 as a control feed and P1, P2, P3, as well as P4 as complete feed for dairy cows toward the level of palmitic and palmitoleic acids were as follow (Table 2). Feeding dairy cow with complete feed brought significant effect ($p<0.05$) toward the level of palmitic and palmitoleic acids contained in milk.

The result showed that there was significant difference ($p<0.05$) in the palmitic and palmitoleic acids levels in the dairy cow's milk due to different treatments. The level of palmitic acid among different treatments was on the different level; that was 35.76% (P0), 17.07% (P1), 6.31% (P2), 43.48% (P3), and 12.61% (P4). Likewise, the level of palmitoleic acid among different treatments in this study was on the different level; that was 1.76% (P0), 0.59% (P1), 0.34% (P2), 2.57% (P3), and 0.76% (P4).

The high level of palmitic acid in milk found in P3 treatment (43.48%), in this group the cow consuming P3 complete feed which contain the lowest crude fiber (22.00%), highest protein (21.35%), and high level of palmitic acid (56.92%) in the feed composition among the treatment. The level of palmitic acid in the milk of cow in P0 and P1 treatments did not differ from P3 treatment, but P0 and P1 treatments also did not differ from P2 and P4 treatments. So, the cow consuming complete feed P3 could increase the level of palmitic acid in cow milk with the highest mean 43.48%. The high level of palmitoleic acid in milk was found in P3 treatment (2.57%). The level of palmitoleic acid in the milk of cow in P0, P1, P4 treatments did not differ from P3 treatment, but P0, P1, P4 treatments also did not differ from P2 treatment.

Table 1: Analysis of the Level of Palmitic and Palmitoleic Acids in Feed

Feed Treatment	Palmitic acid (%)	Palmitoleic acid (%)
P0	3.315	0
P1	18.611	13.792
P2	25.593	6.635
P3	56.922	8.682
P4	69.569	8.778

Table 2: Analysis of the Level of Palmitic and Palmitoleic Acids in Milk

Feed Treatment	Palmitic acid (%)	Palmitoleic acid (%)
P0	$35.76^{ab} \pm 23.55$	$1.76^{ab} \pm 1.09$
P1	$17.07^{ab} \pm 4.63$	$0.59^{ab} \pm 0.62$
P2	$6.31^{b} \pm 2.95$	$0.34^{b} \pm 0.41$
P3	$43.48^{a} \pm 36,69$	$2.57^{a} \pm 2.49$
P4	$12.61^{b} \pm 6.83$	$0.76^{ab} \pm 0.75$

Different superscript on same column showed a significantly different average level of palmitic acid and palmitoleic acid in milk ($p<0.05$).

Discussion

The study result showed that complete feed gave significant effect toward the palmitic and palmitoleic acids level in the milk of cow. Some factors could influence the level of palimitic and palmitoleic acids in milk of cow. According to Allison [11], the ruminant ability to consume feed could be influenced by many factors: (1) cow factor, for example, body weight, physiology condition, genetic, production level and the cow health. (2) feed factor, for example, nutrient composition, anti-nutrient substance, feed forming. (3) and environmental factor, for example temperature, humidity, air, rainfall, farm condition, and feed storage.

The high level of palmitic and palmitoleic acids found in P3 treatment is caused by the content of crude fiber in feed on the lowest level (22.00%) among treatments. According to Hatmaya[12], there was negative correlation betwen the crude fiber digestibility and organic matter digestibility. The high level of crude fiber in the feed was limiting factor for the digestion length time so it would affect the rate of digestion and decrease feed intake. Increased consumption of feed for cattle equaled by increasing the quality and digestibility of feed given, while digestibility of feed depends on the fiber content that could not be used by cow.

Fat content in feed for ruminant, usually was low because ruminant animals a partly of their feed derived from plant which contain fat around 1-4%, so the level of fat that is high in ruminant feed would cause an increase in the sensitivity of rumen fermentation[13]. According to Ressang and Nasution (1992)[14], the fat content consumed would affect acidity level in rumen that could cause: (1) plant cell wall decomposition in rumen be slow, consequently feed that had high crude fiber like grass and the other forage could not be digested and left behind in rumen so feed number consumed will decrease; (2) utilization of the other feed substances contained in forage cells would be inhibited because the cell wall could not be digested; (3) nutrients will be more widely used to increase body weight than for their milk production.

Milk fat is formed from about 12.5% glycerol and 85.5% fatty acids, it had a density 0.93. Milk fatty acids derived from microbiological activity in the rumen or from synthetic process in secretory cells. Fatty acids are composed by the hydrocarbon chains and carboxyl groups[15]. According to Ressang and Nasution[14], fatty acids are formed from medium to long-chain fatty acids

that joined with the glycerol compound. In the rumen, crude fat is separated into organic acids and fatty acids. After that fatty acid is converted into free fatty acid that would be absorbed in the small intestine.

Organic acid and glycerol would be converted into acetic, propionic and butyrate acids in the rumen. Acetic acid is the main ingredient for the formation of milk fat. Acetic and propionic acids entering the liver through the the rumen wall, as well as butyric acid that would be converted into hydroxy butyrate before penetrate the wall of the rumen. The next process in the liver is to distribute acetic acid and beta hydroxy butyrate to around the body through the circulatory system. Propionic acid entering the liver would be broken down into glucose. On the other hand, acetic acid entering the mammary gland would be used as precursor of milk fat formation. According to Rosalin[15], absorption of short chain fatty acids (e.g. acetic acid, propionic, or butyric acids) in the intestine and glucose in small amounts could influence milk fat synthesis. If the production of propionic acid or unsaturated fatty acids increases, the reduction of milk fat secretion would be occurred. Increased in absorption of acetate or butyrate improve *de novo* synthesis and secretion of several C4-C16 fatty acids, so that increased absorption of propionate or glucose decrease the secretion of several major long-chain fatty acids. According to Romziah *et al.*[16], the other factor that could influence the quality of milk is rumen microorganisms. Rumen microorganisms could change feed substance to saturated condition so that saturated fatty acid level in fat circulation is high.

The level of palmitic and palmitoleic acids in milk among treatment gave significant effect. P3 complete feed could increase the level of palmitic and also palmitoleic acids in the milk of cow. P3 complete feed could become an alternative feed to fulfil the cow's nutrition need, since it is more economic and efficient feed for farmer in village. Not only fulfil the cow nutrition need but also the cow could produce high quality of milk.

Conclusion

In conclusion, feeding using complete feed with a different formula affect the level of palmitic and palmitoleic acids in cow's milk significantly.

Conflict of Interest: The authors declare that they have no conflict of interest.

Caesar Labor without Medical Indication Problem: The Midwives Challenge of Midwifery Care

Lasiyati Yuswo Yani[1], Tria Wahyuningrum[1], Asef Wildan Munfadlila[1]

[1]School of Health BinaSehat PPNI Mojokerto East Java Indonesia

Abstract

Quality midwives are neededto reduce maternal and infant mortality. Not only medical skills but also interpersonal and soft skills that are culturally and indigenous responsiveness essential in midwifery services, especially in childbirth assistance. A competent midwife will make a woman comfortable so that she entrusts her health and baby to the midwife, especially in childbirth assistance. This review aims to find facts about the delivery care needed by the community. The literature review was used to explore more information from several studies. This literature study is sourced from a systematic search of the computerizeddatabase (CINAHL, ProQuest, PubMed, EBSCOhost, Google Scholar) as well as research journals and literature studies.

Keywords: *Caesar section, No medical indication problem, Midwife.*

Introduction

Childbirth is a natural process that will naturally take place when labor arrives. The mother will feel the symptoms of childbirth, and through the birth process, the baby will be born alone through the birth canal[(1)]. This natural labor can be difficult and requires the help of tools or even surgery due to power problems, passenger, passage, pass way(4P)[(2)]. In addition to the 4P, the psychological condition of the mother also influences the union process[(3)].

Natural childbirth has its advantages compared to delivery with the help of tools and surgery. Childbirth goes naturally, without the preparation of various types of equipment, without anesthesia, without an operating room, besides the recovery process after childbirth is faster than labor by cesarean section[(4)]. But nowadays, cesarean section is often the primary choice for labor when a mother is going to give birth.

Cesarean delivery must be done when there are indications of complications in power, passenger, passage and pass way (4P)[(3)]. Caesar section of delivering baby has a high risk, not only for the mother but also for the fetus they contain[(5)]. Nevertheless, in reality, the incidence of cesarean section continues to increase in many countries including Indonesia. But currently, there are not a few mothers who want labor by surgery (cesarean section on request) even though there is no indication. Some of them are afraid of going through the natural process of childbirth, worrying about delivery, so they feel that the labor process is an excruciating process and cannot be done alone. Wanting their baby to be born on a certain date is also the reason for cesarean delivery [(6)].

WHO survey results in 2004-2008 on three continents namely Latin America, Africa,and Asia found the lowest incidence of cesarean section in Angola, which was 2.3% and the highest in China was 46.2%. Labor with cesarean section in Asia also increased sharply. The results of the study in Thailand showed an increase in the rate of cesarean section delivery from 15.2% in 1990 to 22.4% in 1996. While in China, the rate of cesarean section delivery reached 36.3% in 2011 from 19.2% in the year 2003[(7)].

In Indonesia, the rate of Caesarean section delivery in major cities has increased. Based on the 2013 Health research basic program, the highest Caesarean section delivery rate occurred in Jakarta at 19.9% and the lowest SC delivery in Southeast Sulawesi was 3.3% of the total incidence of SC in Indonesia at 9.8%. In general, the pattern of delivery through cesarean section according to the characteristics shows the highest proportion in the top ownership index quartile (18.9%), living in urban areas (13.8%), employment as employees (20.9%) and education D1-D3 / PT (25.1%).

Midwives as female friends throughout the life cycle of women from preconception to menopause. Midwives have an important role in pursuing natural and safe delivery assistance. Midwives will accompany women from before pregnancy, up to 9 months of pregnancy, seek and help with safe delivery, postpartum booting, support to the baby, until the mother does family planning[8].

The midwife helps not a few mothers who are worried about giving birth. Families with middle and upper socioeconomic status prefer to give birth in hospitals, families with lower socioeconomic status are still seeking help from shaman even though the State has aided deliver labor by health workers.

A good midwife character is needed to build public trust in midwives as health workers at the primary service level[9]. Continuity of care is fundamental in the midwifery practice model to provide holistic care, build sustainable partnerships to provide support and foster mutual trust between midwives and clients[10]. Thus clients from all walks of life will entrust their reproductive health to Midwives, especially in childbirth assistance. It will reduce Cesarean section event events without indication.

Material and Method

The literature review was used to explore more information from several studies. This literature study originated from a systematic search of the computerizeddatabase (CINAHL, Pro Quest, Pub Med, EBSCO host, Google Scholar) in the form of research journals as well as literature studies.

Finding and Discussion

This review literature found various problems related to the selection of cesarean section community in Indonesia. Four topics related to the challenges of midwives in normal delivery care in the community, including 1. Reasons for choosing a cesarean section; 2. Place of delivery; 3. Childbirth Helper; 4. The character of Midwife as Childbirth Helper.

Reasons for choosing cesarean section delivery: There are four highest reasons for choosing CESAREAN SECTION delivery, among others: 1. There are complications of labor; 2. Higher levels of maternal and family education; 3. Middle and upper economic status; 4. Mother gave birth for the first time[11–13]. There was an increase in demand for cesarean section delivery without indications of complications of 21, 24 times in 2015[13,14]. Childbirth cesarean delivery is not always caused by indications,but from obstetric socio-demographic and medico factors must be considered[15]. Previous experience of giving birth to Cesarean section also determined the choice of delivery with CESAREAN SECTION (16,17)

Place of delivery: Maternity aid places that are the choice of mothers in childbirth include public hospitals[18]. Private hospitals are also an option for birth[19].

Childbirth Helper: The increasing demand for delivery of cesarean section without medical indications is not only influenced by the socioeconomic status of society, but also by the condition of Education. Both of these things are related to the level of community trust in midwives as birth attendants in primary care. Communities with middle and upper socioeconomic status feel calmer if their delivery is done in a hospital with a doctor or an origin specialist as a delivery helper. Communities with higher levels of education tend to have deliveries to doctors who are considered to have better knowledge and skills in childbirth assistance than midwives.

Midwives as primary service providers in the community, should not only be an option for middle-class people. Midwives should be able to improve their quality so that they can be chosen by all levels of society, both upper and lower layers. In childbirth assistance, this is expected to reduce cesarean section delivery without medical indications that should be born spontaneously without surgery[20].

The character of midwives as birth attendants: The midwife's character performance shows the quality of midwives in providing midwifery services during the service. Characteristics are taught not only in appearance, but also in clinical skills, and no less important are soft skills and interpersonal skills by the needs of the community who are culturally responsive and supported by evidently based on current research[21].

The quality of these ideal midwives in developing countries is hard to find causing barriers to the provision of quality midwifery services. It can be caused by three things, social; economy; and professionalism [22].Social factors can be interpreted as a lack of social welfare. The economic factor in question is the low salary that is not

proportional to the burden and responsibility of the job. While professionalism can be interpreted as registration, legislation, state accreditation that protects midwifery services by applicable laws.

The quality of delivery services is not only determined by the mid wife itself, but also must receive facilities and infrastructure support from service providers[23]. Availability of vehicles, affordability, completeness of service facilities is a part that supports service providers in addition to medical skills for midwives, soft skills and interpersonal skills.

Conclusion

The character of midwives as childbirth assistants in primary care should prioritize not only performance and medical skills but also more critical interpersonal skills that are culturally and indigenous responsiveness. The character is related to the trust and comfort of the community; it is hoped that with this character the midwife will get a separate place in all levels of society in the care of the midwife. Thus, cesarean delivery without medical indications is expected to decrease.

Medical Students' Syndrome–A Myth or Reality?: A Cross Sectional Study among Medical Students of Jouf University, Saudi Arabia

Ashokkumar Thirunavukkarasu[1], Umar Farooq Dar[1], Farooq Ahmed Wani[2], Assaf Al Sirhani[3], Ahmad Naseer Alsamarh[3], Turki Derzi Alshammery[3], Abdullah Alghotaight[3]

[1]Assistant Professor of Community Medicine, [2]Assistant Professor of Pathology, [3]Medical Student, College of Medicine, Jouf University

Abstract

Background: Prevalence of stress, anxiety and depression among medical students are high all over the world. It has been attributed by huge amount of psychological stress due to the constant work required, frequent examinations. Medical student syndrome (MSS) is a condition commonly reported among medical students, that they repeatedly develop anxiety and symptoms of ill health of diseases of what they are studying.

Objectives: To assess the prevalence and risk factors of medical students' syndrome among Jouf university medical students.

Materials and Method: An analytical cross sectional study done among the medical students of Jouf University in Saudi Arabia by using standard and validated student health questionnaire. Statistical Package for Social Sciences (SPSS) software version 20 was used to enter and analyze data. Descriptive statistics were presented as number and percentage. Chi square test was used to identify the risk factors and p value less than 0.05 is considered as statistically significant.

Results: Medical students' syndrome found among 58 (16.11%) students of the 360 participants and was statistically significant ($p<.05$) among the students with less than 22 years of age, who studied basic sciences and smokers (daily and rarely).

Conclusion: Health education programs in medical schools should be implemented to improve their mental health status. This has to be implemented from the first year of their Hence, they can work effectively for the health of the people in the community.

Keywords: *Medical student syndrome, Help seeking, Hypochondriasis, Anxiety and Stress.*

Introduction

Medical students' syndrome (MSS) is a condition commonly reported among medical students, that they repeatedly develop anxiety and symptoms of ill health of diseases of what they are studying[1,2]. This phenomenon is reportedly common among medical students than non medical students[3]. In fact, it has been even included in the medical psychology courses of several medical colleges[3].

Prevalence of stress, anxiety and depression among medical students are high all over the world[4-7]. It has been attributed by huge amount of psychological stress due to the constant work required, frequent examinations[8,9]. Studying in medical school is a stressful process in which students may undergo mental and physical health consequences[10]. This psychological anxiety and stress

leads to detection of hypochondria symptoms, a main element of medical students' syndrome. This is usually manifested by augmented physical sensations and appearance of hypochondria symptoms[9].

As a part of medical school curriculum, students undergo extensive clinical training and obtain new clinical knowledge. The anxiety and stress and newly obtained clinical knowledge makes students to diagnose themselves with a disease with even simple body dysfunction[1].

"Medical Student Syndrome" is consisting of two elements as cognitive and distress. Firstly, cognitive element includes the thoughts of a student that he has the disease being studied and the secondly, a distress element that includes development of anxiety due to cognitive element. The cognitive element is present among all students and it progresses from the beginning of their medical education to till graduation. In contrast to cognitive element, distress element is common among initial period of medical school and is insignificant among senior students because with the year progress students acquire more knowledge and development of maturity among students (6-8). The clinical examination on students on several occasions may not reveal conditions that fully responsible for the person's worrying about the disease or symptoms, that makes it is a diagnosis of exclusion. Unfortunately, the fears frequently persist among medical students despite medical reassurance, affecting their concentration during their training[9].

Numerous attempts[4,7,9,11] have been made in the past by several authors on the assessment of depression, anxiety and stress among medical students in the world as well as in the Kingdom of Saudi Arabia. Despite high prevalence of stress, anxiety and depression among the medical students in the Kingdom of Saudi Arabia, there are very few studies on assessment of prevalence of medical students' and its risk factors.

It is essential to improve the mental health status of medical students as they are tomorrow's backbone of health care system. Assessment of prevalence medical student syndrome and its risk factors will help to identify mental health of medical students and will help us to improve their mental health so that they can be involved effectively in health care delivery. Hence, this study is planned.

Objectives: To assess the prevalence of medical student syndrome among the medical students' of Jouf university and to identify the factors influencing for the development medical students' syndrome among them.

Materials and Method

It is an analytical cross sectional study designs done among the medical students of college of medicine, Jouf University. All the students of college medicine were requested to participate in this study. This study was done between November 2018 to March 2019.

The data was collected through the "student health questionnaire" (Adopted from Waterman LZ et al, 2014)[3]. It is a standard and validated questionnaire. Our data collection profroma had two parts. First part enquire about socio–demographic details of the of the students (age, gender, year of education, resident status etc). The second part was aimed to assess 'Hypochondriacal and Help-Seeking Behaviour (HHSB) " of the students through student health questionnaire as HHSB is the core component of medical students' syndrome. Our study data were entered and analyzed by using the Statistical Package for Social Sciences (SPSS) software version 20. Descriptive statistics were presented as number and percentage. Chi square test was used to identify the risk factors and p value less than 0.05 is considered as statistically significant.

Results

Table 1: Socio-demographic details (n = 360)

Variable	No (%)
Age (years)	
Less than 22	201 (55.83)
22 and above	159 (44.17)
Gender	
Male	220 (61.11)
Female	140 (38.89)
Year of education	
1st year	88 (24.44)
2nd year	77 (21.39)
3rd year	71 (19.72)
4th Year	65 (18.06)
5th Year	59 (16.39)
Smoking status	
Daily	39 (10.83)
Rarely	25 (6.94)
Non smoker	296 (82.22)
Residence status	
Hostler	58 (16.11)
Living with family	302 (83.89)
Marital status	
Married	35 (9.72)
Unmarried	325 (90.28)

Table 1 shows, among the 360 participants studied, majority of the participants were males (61.11%), living with their families (83.89%) and unmarried (90.28%)

Table 2: Prevalence of MSS (n= 58)

Variable	No (%)
Age (years)	
Less than 22	41 (20.39)
22 and above	17 (10.69)
Gender	
Male	37 (16.82)
Female	21 (15)
Year of education	
1st year	17 (19.32)
2nd year	15 (19.48)
3rd year	14 (19.71)
4th Year	7 (10.77)
5th Year	5 (8.47)
Smoking status	
Daily	10 (25.64)
Rarely	6(24)
Non smoker	42 (14.19)
Residence status	
Hostler	14 (24.14)
Living with family	44 (14.57)
Marital status	
Married	5 (14.29)
Unmarried	53 (16.31)

Our study found 58 (16.11%) students were affected with medical students' syndrome. Table 2 presents the variation of prevalence in each category. The prevalence is high among male gender, age group less than 22 years, daily smokers, hostlers and unmarried participants.

Table 3: Factors influencing MSS (n = 58)

Variable	No (%)	P value
Age (years)		
Less than 22	41 (20.39)	0.013
22 and above	17 (10.69)	
Gender		
Male	37 (16.82)	0.647
Female	21 (15)	
Year of education		
Basic sciences	46 (18.64)	0.016
Clinical sciences	12 (11.29)	
Smoking status		
Smokers (daily and rarely)	16 (17.98)	0.032
Non smoker	42 (14.19)	
Residence status		
Hostler	14 (24.14)	.069
Living with family	44 (14.57)	
Marital status		
Married	5 (14.29)	0.757
Unmarried	53 (16.31)	

Chi square test was done to find the statistical difference between each variables. Variables with more than two categories are clubbed to make two categories. In year of education category, up to year 3 was considered as basic sciences and year 4 and 5 was considered as clinical sciences.

Medical students' syndrome was statistically significant ($p<.05$) among the students with less than 22 years of age, who studied basic sciences and smokers (daily and rarely).

Discussion

Medical students' syndrome is widely known phenomenon and common among medical students[12,13]. Hypochondriasis, a core component of medical students' syndrome cause stress and anxiety; students may hesitate to seek help and care under several circumstances. This will not be good for the profession, as medical doctors are already known to be shy or unwilling to show themselves as patients[14,15].

The present study found 16.11% of medical students are affected with MSS. This study finding is similar to several studies[4,6] done in the Kingdom of Saudi Arabia with the slight variation in prevalence. But in contrast to our findings, some studies[13,15] found very high prevalence of hypchondrial symptoms among medical students. This is most likely due to study settings in which study is done, as these studies are done in either Asian or European settings. Also, cultural factors might have played a role as female participants are less in our study in comparing to the other studies as females may not describe their symptoms completely.

Our study found the MSS prevalence is statistically significant among basic sciences and age group less than 22 years of age. This almost similar to studies done by Saggab (2013) and Sara S et al (2018). In their study they found initial years of medical school hypochondrial symptoms are very high. This is most probably explained as initial years students are not completely aware about symptoms and clinical correlations and as they enter

clinical sciences program they may correlate well with these hypochondrial symptoms, which is a core symptom of MSS.

The present study identified MSS is statistically high among the smokers than the non smokers. This findings also similar to previous studies done in different settings all over the world[2,4,6,13&15] This can be explained by the relationship between smoking and stress, anxiety as published in previous studies.[3,5,7&10]

Conclusion

There is high prevalence of hypochondrial symptoms among the medical students. These symptoms may lead to further anxiety and stress among them. Hence, health education programs in medical schools should be implemented to improve their mental health status. This has to be implemented from the first year. Hence, they can work effectively for the health of the people in the community. Further, unnecessary overload in course to be avoided by decreasing number of lectures as continuous lecture may not be help in retention of information delivered[16]. Finally smoking cessations program to be encouraged regularly as it is one of the major risk factor for medical students' syndrome

Conflict of Interest: None

Source of Funding: Self

Acknowledgments: The authors would like to thank the H.E Dean of college of medicine, Dr. Abdulrahman Hamdan Almaeen for his help in facilitating data collection from medical students of Jouf university.

Ethical Approval: This study proposal was approved by the Local Committee for Bioethics (LCBE) of Jouf University (Approval number: 13-22-2/40)

Abstract

Background: The relationship between extraesophageal reflux and chronic rhinosinusitis remains a controversial feature in the literature. Recently some research has been done to prove this relationship and it found that there was relationship between gastroesophageal reflux disease with the occurrence of chronic rhinosinusitis. This research aimed to determine and analyze the presence and levels of pepsin and pH in nasal secretions due to extraesophageal reflux amongpatients with chronic rhinosinusitis concerning to complaints of laryngopharyngeal Reflux.

Method: The research was an analytical research with cross-sectional design. The research involved 27 patients with chronic rhinosinusitis, who were divided into two groups. Group 1 consisting of 8 patients with chronic rhinosinusitis accompanied with complaints of laryngopharyngeal reflux, and group 2 consisting of 19 patients with chronic rhinosinusitis without complaints of laryngopharyngeal reflux. The laryngopharyngeal reflux was determined from the questionnaires value of *Reflux Symptom Index*>13 and *Reflux Finding Score* determined by a flexible nasolaryngoendos copy examination with score >7. The level of pepsin and pH of both groups of patients were examined from the nasal secretion. The examination of pepsin using ELISA method and pH level measurement was using by pHmetri.

Result: Characteristic of respondence, 82.0% of respondence were their ages over 25 years old and 59.3% of them were females. 29.6% of chronic rhinosinusitis patients were accompanied by pharyngeal larynx reflux. Pepsin was found in all nasal secretions of chronic rhinosinusitis patients. Pepsin level of nasal secretions among Chronic Rhinosinusitis patients was 19.00 to 75.80 pg/ml with median 52.20 pg/ml. The pH level of nasal secretions among chronic rhinosinusitis patients were ranged from 6.00 to 6.80 with median of 6,39. Analysis by Mann-Whitney U-test revealed a significant change difference ($p<0,05$) between the two group. The level of pepsin was higher in the group chronic rhinosinusitis patients than complaints of laryngopharyngeal Reflux patients. The pH levels not statistically significant difference ($p> 0.05$) although it was found that the degree of acidity was higher (pH <6.5) in chronic rhinosinusitis patients than complaints of laryngopharyngeal reflux.

Conclusion: Extraesophageal reflux may be one of the factors that can cause chronic rhinosinusitis or aggravate chronic rhinosinusitis caused by infection or allergies. The presence of pepsin with high acidity (pH <6.5) can cause irritation of thelarynx mucosa, pharynx and sinonasal.So, the assessment of RSI, RFS, and pepsin and antirefluks therapy (PPI) is recommended to people with chronic rhinosinusitis who do not respond well or recurrent with standard chronic rhinosinusitis treatment.

Introduction

Chronic rhinosinusitis (CRS) according to EPOS (European Position Paper on Rhinosinusitis and Nasal Polyposis) criteria is nasal and paranasal sinuses inflammation lasting more than 12 weeks.Its symptoms are nasal congestion/obstruction/congestion or colds

anterior/posterior nasal secretions, with or without facial pain/suppression on the face, with or without interruption of inhalation.Nasoendoscopic also shown polyps or mucopurulent secretions from the meatus medius and mucosal obstruction/mucosa in the Meatus Medius.A picture of computer tomography shown mucosal changes in the osteomata andor sinus complexes.[1]Chronic rhinosinusitis has a high prevalence in the community. three hospitals In Makassar reported 45% of all cases were chronic rhinosinusitis handled by Sub Division Rhinology of ENT departmentin the period 2003-2007.[2]

The relationship between chronic rhinosinusitis and extraesophageal reflux is still a controversial issue in the literature.Chronic rhinosinusitis and gastroesophageal reflux are two common conditions that occur together more often than expected.[3]Therefore, it has been suggested that gastroesophageal reflux disease may have an etiological role in the occurrence of chronic rhinosinusitis. There is a relative prevalence of reflux with controlled CRS. There is still little controlled research with a large number of patients to confirm this hypothesis.[4]

Gastroesophagealreflux (GER) is a backflow of gastric contents into the esophagus. The esophagus and laryngopharynx are separated by the upper esophageal sphincter (SEA) which is the last barrier to prevent reflux from entering the laryngopharynx. Reflux increase SEA tone leads to esophageal distention resulting in relaxation of SEA leading to exposure to esophageal fluid called extraesophageal reflux (EER). It can reach the larynx, pharynx, nasal cavity and middle ear.Cause of laryngitis and pharyngitis in the form of laryngopharyngeal reflux (LPR), and may cause chronic rhinosinusitis. Gastric fluid may contain pepsin, stomach acid (HCl), mucin and renin.

Pepsin plays many major roles in the development of reflux-related disorders. Pepsin is considered an important etiologic factor of reflux disease in aerodigestive channels and biomarkers for reflux, whose level and acidity may be related to the severity of the damage.[5,6] The research was obtained 29 of 33 patients with reflux suffering cause of chronic rhinosinusitis. The results of pepsin fluorometric examination correlated with 24hour dual probe monitoring results for laryngopharyngeal reflux diagnosis with 100% sensitivity and 92.5% specificity. It can be asserted that there is a relationship between CSR and LPR.Detection of pepsin in nasal fluids can be performed as a non-invasive and feasible method for LPR skrining.[7]another research reported that radiologic and endoscopic values of rhinosinusitis patients were worse in patients who also suffered from laryngopharyngeal reflux.[8]

LPR assessment based of RSI and RFS score[9,10]

Method

Research Site: This research was conducted in the outpatient unit of ENT department Dr. Wahidin Sudirohusodo Hospital Makassar starting from October-December 2017. Processing of research result was at laboratory of Education Hospital of Hasanuddin University Makassar.

Design: The design of this study was an analytical research with cross-sectional design. The independent variable in this study was extraesophageal reflux, while the dependent variable was pepsin and pH.

Samples: The sampling technique was performed randomly. In this study patients that positive (27) with chronic rhinosinusitis were divided into two groups. Group 1 consisting of 8 patients with chronic rhinosinusitis accompanied with complaints of laryngopharyngeal reflux, and group 2 consisting of 19 patients with chronic rhinosinusitis without complaints of laryngopharyngeal reflux. The laryngopharyngeal reflux was determined from the questionnaires value of *Reflux Symptom Index*>13 and *Reflux Finding Score* determined by a flexible nasolaryloendoscopy Examination with score >7. The level of pepsin and pH of both groups of patients were examined from the nasal secretion.

Exclusion Criteria: Patients who are contraindicated performed a flexible nasolaringoendoskopi examination, patients who received on treatment of PPI therapy, anti-histamine 2, antacids in the past 4 weeks.

Statistical Analysis: Data were analyzed using Statistical Package for Social Sciences (SPSS) software (version 23.0 for Windows; SPSS Inc, Chicago, IL).

Results

Table 1: Characteristics of Population Research

Characteristics		n	%
Age	16-24 y.o	5	18 %
	25-55 y.o	22	82 %
Gender	Male	11	40,7 %
	Female	16	59,3 %
LPR	Yes	8	29,6 %
	No	19	70,4 %

From Characteristics of the study population were shown in Table 1. The results showed of the subject demography of the research is all of chronic rhinosinusitis patients 82.0% were over 25 years old and more in females than males (59.3% vs 40.7%) and from 27 chronic rhinosinusitis patients were also accompanied by Laryngopharyngeal Reflux /LPR (29.6%).

Table 2. Levels of Pepsin and pH in nasal secretions of chronic rhinosinusitis (CRS)

Variabel	PEPSIN		Pepsin Level (pg/ml)		pH Level	
	Yes	No	Min/Max	Median	Min/Max	Median
CRS (n=27)	27	-	19,0 / 75,8	52,20	6,00/6,80	6,395
Total	**100%**	**0%**				

From table 2 it can be seen that pepsin was found in all nasal secretions of chronic rhinosinusitis patients which pepsin level of nasal secretions in Chronic Rhinosinusitis ranged from 19.00 to 75.80 pg/ml with median 52.20 pg/ml and the pH level of nasal secretions of chronic rhinosinusitis patients ranged from 6.00 to 6.80 with median of 6,395.

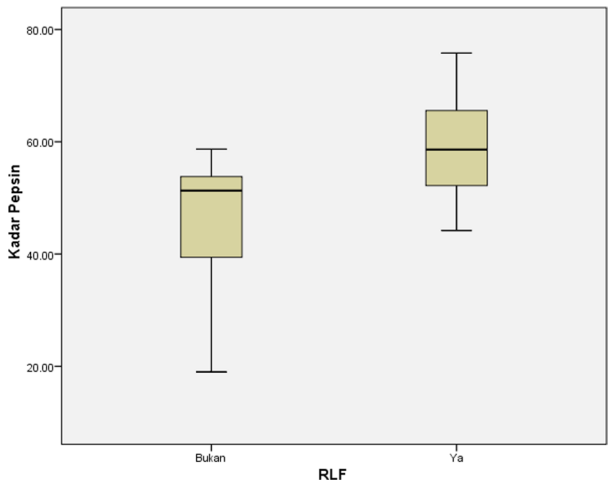

Table 3: Pepsin levels and pH nasal secretions of chronic rhinosinusitis patients based on presence complaints of laryngopharyngeal reflux (LPR)

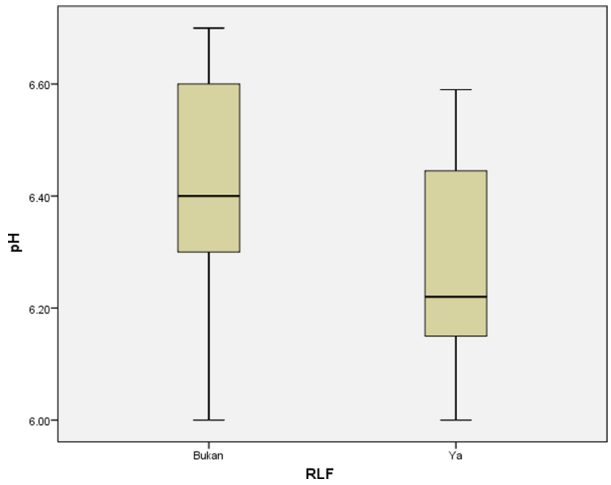
Variabel	Yes LPR (n=19)		No LPR (n=8)		Total (n=27)		p*
	Median	Min/Max	Median	Min/Max	Median	Min/Max	
Pepsin (pg/ml)	58,60	44,2/ 75,8	51,30	19,0/ 58,5	52,20	19,0 / 75,8	0,035
pH	6,22	6,00/6,35	6,450	6,00/6,70	6,395	6,00/6,80	0,095



*Mann-Whitney U test

The results of the Mann-Whitney U test shown significantly different pepsin nasal secretions ($p < 0.05$) between chronic rhinosinusitis patients with LPR complaints and chronic rhinosinusitis without LPR complaints.The pepsin content of chronic rhinosinusitis patients with LPR complaints was higher than which

has no LPR complaint (median 58.60 vs 51.30 pg/ml). The pH level in nasal secretions of patients with chronic rhinosinusitis with LPR was lower than chronic Rhinosinusitis without LPR (6.22 vs 6.45) but not statistically significant (p> 0.05)

Graph 1: Box Plot of Pepsin levels nasal secretions in both groups

Graph 2: Box Plot of pH level nasal secretions in both groups

Graph 1 can be seen the average pepsin levels of nasal secretions of people with chronic rhinosinusitis accompanied by LPR complaints higher than patients with chronic rhinosinusitis without complaints LPR. Graph 2 shown the average pH level of nasal secretions among patients with chronic rhinosinusitis accompanied by LPR complaints is lower (acid) than patients with chronic rhinosinusitis without complaints LPR.

Discussion

Pepsin was found in all sample's nasal secretions with varying levels. 8 of respondents also gave LPR complaints assessed based on RSI and RFS scores, although there was pepsin in all nasal secretions. 19 respondents did not give LPR complaints. 21 of respondence gave a RSI score >13 where this led to LPR only 8 samples also provided an RFS score supporting LPR with score > 7. This could be due to improved RSI and RFS scores.Some respondence say had previous LPR complaints that were felt to have diminished in recent months, 11 of 19 respondents suffering from CRS without LPR complaints have changed their eating habits even without taking drugs. More regular eating patterns have also been undertaken i.e eating often with a small portion and large portions of food may increase the pressure and reflux of the stomach.

Diet and behavior were very influential in the occurrence of reflux. In people who often eat chocolate for long periods of time it can be a risk factor for reflux where it is known that chocolate contains methylxanthine, which has been shown to reduce the pressure of Lower esophageal sphincter by causing smooth muscle relaxation. However, the presence of pepsin in nasal secretions is clearly a sign that there has been a reflux of gastric fluid that reaches the sinonasal region because pepsin in the body only in the production of the stomach.

The results of this study obtained pH level nasal secretion chronic rhinosinusitis patients are an average of 6.39. The pH level of nasal secretions of chronic rhinosinusitis accompanied by LPR complaints is lower than chronic rhinosinusitis without LPR complaints Although statistically these two groups do not give significant difference. Its shown that pepsin can respond in an acidic atmosphere. Pepsin is active at pH 2-6.5 and inactive at pH> 6.5 and remains stable at pH 8 and pH variation affects the motility and morphology of cilia in the respiratory mucosa.[5]Sinonasal mucosa is not designed to withstand damage caused by pepsin and acids.

The pepsin presence and the acidic atmosphere of nasal secretions causes active pepsin and pathologic of the paranasal sinus mucosa. Its causes of an inflammatory reaction in the sinonasalmucus ostium and eventually creates a favorable condition for the development of a rhinosinusitis. A rhinosinusitis becomes the ideal condition for the development of colonization bacteria.[11] It has been proved by numerous studies that extraesophageal reflux can cause laryngitis and pharyngitis in the form of laryngopharyngeal Reflux.

So, it can also lead to chronic rhinosinusitis. The nasal mucosal, larynx and pharyngeal layers are not the same as the esophageal mucosa where the esophagus has a layer better mucosal and cilia as barrier to the effects of pepsin and stomach acid than the pharyngeal, larynx and Sinonasal.

Therefore chronic rhinosinusitis accompanied by LPR complaints in this study is undetermined as a cause of irritant factors caused by pepsin and acids.A higher level of pepsin and a lower acid level can activate pepsin (pH <6.5) and it was found in patients with chronic rhinosinusitis with LPR complaint than without LPR complaint.Although pepsin examination is not done on the secretions in the larynx and pharynx, but the presence of pepsin in the nasal cavity must pass through the larynx and pharynx first. Thus, gastroesophageal reflux may be a risk factor for chronic rhinosinusitis.

High levels of pepsin and acidic conditions over time cause irritation of the sinonasal mucosa which is a risk factor for chronic rhinosinusitis.Others factors of chronic rhinosinusitis are infection (bacteria, virus, fungi), allergies and others. Other study reported that pepsin was detected in sinus fluid in 4 of 6 chronic rhinosinusitis patients with an invitro examination and they concluded that pepsin can cause damage to mitochondria in nose epithelial cells.[12]The CRSs caused by infection or allergies have been treated with standard treatment management for CRS. One of which needs to be suspected is the presence of mucosal inflammation due to the direct irritant effects of pepsin and high acid derived from extra esophageal reflux.

Therefore, CRS patients who have been given standard treatment but still have not responded well or often recurrent, pepsin examination of nasal secretions and antireflux therapy (PPI) is recommended, especially if the CRS sufferers also have symptoms or signs of RLF obtained from the score RSI >13 and RFS >7. This is consistent with previous study regarding the provision of PPI therapy shows at least some improvement in CRS symptoms, some experiencing complete or near-complete resolution of symptoms. Improvement of sinus symptoms is associated with improved LPR symptoms.[13] This suggests that antireflux therapy may play a role in the treatment of CRS disease. It suggests that management of CRS, especially those with RLF symptoms should consider the LPR therapy.This treatmentreduces or change the administration of drugs for CRS.

Conclusions

Excessesophageal reflux is one of the risk factors of chronic rhinosinusitis, with evidence that the discovery of pepsin and acidic atmosphere (ph<6.5) in nasal secretions of chronic rhinosinusitis patients, Higher levels of pepsin and acidity are found in nasal secretions of CRS patients accompanied by LPR complaints. In the management of chronic rhinosinusitis, screening of RSI scores should be screened. It is better if the determination of the score of RFS or pepsin examination on nasal secretions in adequate facilities and infrastructure, and anti-reflux therapy (PPI) additional should be considered.

Parental Knowledge on the Perpetrators and the Impacts of Child Sexual Abuse towards Parental Protection Efforts to Prevent Children from Being the Victims of Sexual Abuse

Elok Permatasari[1], Kuntoro[2], Shrimarti R. Devy[2], Wiwin Hendriani[3]

[1]Student in Doctoral Program of Public Health, Public Health Faculty, [2]Public Health Faculty, [3]Psychology Faculty, University of Airlangga Surabaya, East Java Province, Indonesia

Abstract

Cases of sexual harassment and sexual abuse are believed to occur since children interact with other people or strangers who are not known before. In fact, the perpetrators of sexual abuse are the closest people who actually are in the environment around the children(1) Sexual abuse has a very large impact on early childhood, such as sexual trauma, stigmatization, rejection (neglect), and helplessness(2). Cases of early child sexual abuse in Jember are caused by the low role of parents in providing protection to children. Thus, new parents find out about cases of sexual abuse experienced by children after the case is repeatedly experienced by children. This research aimed to analyze parental understanding of the perpetrators and the effects of sexual abuse on the role of parents in providing protection from the risk of child sexual abuse. It was carried out in Jemberby involving 170 parents as the research respondents. The results of the study showed that parental understanding of perpetrators of sexual abuse has significant effects on parental protection efforts that are applied in daily care. Comprehensive knowledge of perpetrators of sexual abuse, both from internal and external families, will increase the sensitivity of parents to prevent and protect against the risk of sexual abuse in early childhood.

Keywords: *Parental knowledge, child sexual abuse, sexual abuse impacts.*

Background

Early childhood becomes a category that is vulnerable to sexual abuse. The victims of child sexual abuse reached more than 73% compared to victims of adult age. The Indonesian Child Protection Commission (KPAI) stated that Indonesia was in the status of "Emergency of Sexual Abuse in Children" because the trend of cases of sexual abuse against children continued to increase. Also, there is a trend of sexual abusein East Java Province that is not much different from the picture of cases of sexual abuse at the national level. There were reports of sexual abuse in children in 2014 of 27 cases increasing to 263 cases in 2015. Jember is a district that has a high level of sexual abuse in East Java and continues to increase from year to year. In 2014 there were 127 reports of cases of sexual abuse in children, and in mid-2015 cases of sexual abuse against children reached 111 cases.

Most opinions believe that the safety of early childhood is more threatened by strangers, than people who are known to children. At home and at school, parents and teachers emphasize to children that they cannot talk to strangers or receive candy or toys from them. However, the reality is that children are sexually abused by someone they know and trust, including parents, siblings, teachers, child care operators, pastors, or trainers. Sexual offenders come from all walks of life, all races, and all socioeconomic levels. Furthermore, adults are not the only perpetrators of abuse. Teenagers and teenagers, including brothers and sisters, are also able to become perpetrators of sexual abuse in early childhood(3).

Faller shows another model, in which several factors that cause sexual abuse - such as perpetrators feel sexually aroused by children and the tendency to act on the basis of sexual desire - are prerequisites for sexual harassment. Contributing factors can come from the family system, culture, and life situation, personality, or previous experience of perpetrators of sexual abuse(3).

Sexual abuse in children has long-term sequelae including early onset of sexual activity at risk of sexually transmitted infections (STIs) and pelvic inflammatory disease[3]. Finkelhor divides the impact of child sexual abuse into four main categories: sexual trauma, stigmatization, rejection (neglect), and helplessness[4]. This impact can extend until adulthood and the victims have worse physical health including obesity and somatization. They have mental health problems including drugs and alcohol abuse, intentional self-harm, post-traumatic stress disorder (PTSD), depression and problems in interacting with others[5].

Parents are the first child educators and perhaps the most influential for their children, and important parenting assignments are preparing children to be sexually healthy, not only as adults but from the start[6]. The role of parents as protectors and child educators, in this case related to the prevention of sexual abuse in early childhood[7]. A study shows that children suspected of experiencing sexual abuse are in a problem of parenting. The care situation encountered is: uncertainty about the occurrence of abuse or abuse; protection dilemma; changes in parent-child relationships; changes in personal support networks; dependence on professional competence and severe emotional tension[8]. This research aimed to analyze parental understanding of perpetrators and the impact of sexual abuse on safeguards undertaken to prevent children from being victims of sexual abuse.

Material and Method

This research aimed to find outthe causality among several sub variables of research through hypothesis testing.

This research analyzed parental understanding of perpetrators and the impact of sexual abuse on safeguards undertaken to prevent children from being victims of sexual abuse.

The subjects are parents of children aged 3-6 years who live in urban areas in Jember. The samples were 170 pairs of parents (170 fathers and 170 mothers) taken by simple random sampling from 10 kindergartens in the urban area of Jember.

Linear regression analysis was carried out to analyze the influence of parental understanding of the perpetrators and the effects of sexual abuse on protection measures taken to prevent sexual abuse in early childhood.

Findings

Respondents' Characteristics: Most of the maternal respondents in the study were aged 26-35 years (66%). The education level of most mothers is high school graduation (38.2%), and most mothers work as housewives (45.9%).

While the respondents' father, most aged 31-35 years (34.1%). Similar to maternal respondents, most fathers have senior high school graduates (42.4%) with employment as self-employed or private sector employees (75.3%).

Most of these parents have 5-year-olds (40%) with male sex (51.8%).

Knowledge on the Perpetrators of Sexual Abuse: Most parents have a high level of knowledge (49.41%) about perpetrators of sexual abuse in children. Most parents with high knowledge about perpetrators of sexual abuse are parents who have children aged 5 years (58.82%) and female (57.32%).

Parent's knowledge of perpetrators of sexual abuse includes: (1) Perpetrators from internal families and (2) Perpetrators from external families (External family). Most parents have low knowledge about sexual abuse perpetrators who come from the family's internal environment (mean = 15.5). Most of the parents as respondents felt that the perpetrators of sexual abuse came from the family's external environment not from the family's internal environment.

Table 1: Frequency Distribution of the Perpetrators of Early child sexual abuse (n=170)

Parental Knowledge on Sexual Abuse Perpetrators	Mean	Med.	Modus	Std.Dev	Min	Max	Sum
Internal Family	15.53	16.0	18.00	4.25	6.00	24.00	2639.50
External Family	18.39	19.0	18.00	3.76	6.00	24.00	3125.50

Knowledge on the Impacts of Sexual Abuse: Most parents as research respondents have a low level of knowledge (94.71%) about the impact that can be experienced by children who are victims of sexual abuse. Most parents who have a low level of knowledge have children aged 5 years (91.18%) and male (95.45%).

Assessment of the knowledge of the impacts of sexual abuse on early childhood consists of: (1) physical impact, (2) psychological impact and (3) social impact). Most parents as respondents have high knowledge about the impact of victims of psychological sexual abuse (mean = 6.15), while knowledge that tends to be less on physical impact (mean = 3.08) resulting from sexual abuse in early childhood.

Table 2: Frequency Distribution of the Impacts of Early child sexual abuse (n=170)

Parental Knowledge on Sexual Abuse Impacts	Mean	Med.	Modus	Std.Dev	Min	Max	Sum
Physical Impacts	3.08	3.0	3.00	0.45	1.67	4.00	523.17
Psychological Impacts	6.15	6.0	6.00	0.92	3.50	8.00	1046.00
Social Impacts	3.20	3.2	3.00	0.46	1.17	4.00	544.32

Prevention from the Risk of Sexual Abuse: Most parents make self-protection efforts to children against sexual abuse in children in good category (75.88%). Most parents have taken protective measures to prevent their children from becoming victims of sexual abuse optimally. most parents feel more able to provide protection in the home than providing protection to early childhood outside the home. This is indicated by the mean score of child protection in the home (mean = 10.89) greater than the protection of children outside the home (mean = 8.21). The obstacle faced by most parents in providing protection outside the home is the obstacle of parents' activities, one of which works. Therefore, most parents feel less optimal in providing protection outside the home.

Table 3. Frequency Distribution of the Aspects on Parental Prevention Indicators in Parental Control Skill Variables of Early childhood

	Mean	Med.	Modus	Std.Dev	Min	Max	Sum
Protection inside the home	10.89	11	12.00	1.15	7.00	12.00	1851.0
Protection outside the home	8.21	8	8.00	1.41	4.00	12.00	1395.5

Effects of Parental Knowledge with Parental Protection Efforts: Based on the results of the cross tabulation it is known that most parents who have a high understanding have high protection efforts against children from the risk of sexual abuse (51.9%). As with the understanding of the impact of sexual abuse, most parents who have an understanding of the effects of low sexual abuse still have high protection efforts against the risk of sexual abuse in early childhood (93.8%).

Statistical analysis using linear regression test was carried out to analyze the influence of parental understanding of the perpetrators and the impact of sexual abuse on children on the protection efforts of parents. The results show that there is a significant influence between parents 'understanding of who is the perpetrator of sexual abuse in children against the parents' protection efforts (sig = 0.032). There is no significant influence on the variable of parents' understanding of the impact of sexual abuse (sig = 0.309).

Table 4. Cross tabulation of parental knowledge on the perpetrators and the impacts of sexual abuse with parental protection efforts

Parental Protection		Low		Medium		High		Amount	%
		f	%	f	%	f	%		
Knowledge on Perpetrators	Low	0	0	8	19.5	7	5.4	15	100.0
	Medium	0	0	16	39.0	55	4.6	71	100.0
	High	0	0	17	41.5	67	51.9	84	100.0
	Total	0	0	41	100.0	129	100.0	170	100.0
Knowledge on Impacts	Low	0	0	40	97.6	121	93.8	161	100.0
	Medium	0	0	1	2.4	8	6.2	9	100.0
	High	0	0	0	0	0	0	0	0
	Total	0	0	41	100.0	129	100.0	170	100.0

Discussion

Regardless of the form of early child sexual abuse, once sexual abuse occurs, the child will feel trapped and continue to keep his secret or decide to reveal it to other parents or other trusted adults. If the disclosure is untrusted or causes a lot of pressure to be handled by the child, the child can withdraw the disclosure [(3)].

Mothers (female parents) often believe that most perpetrators of sexual abuse are men, not women[(9)]. In addition, the occurrence of sexual abuse in early childhood is still considered because children have sexual attraction in the eyes of adults, making them vulnerable to becoming victims of sexual abuse. In fact, sexual attraction in children, although common, is not the only motivating factor that influences the behavior of perpetrators of sexual abuse in children. The perpetrator chooses to act sexually with a child as a means to satisfy his needs. The principal motivation of the offender is the desire for personal affirmation, seeking power and control over others, or a mixture of more than one factor[(10)]. The results show that the more parents understand who at risk as a perpetratorof sexual abuse, the greater the efforts made by parents to protect children from the risk of sexual abuse.

On the other hand, most respondents better understand the impact of psychological sexual abuse compared to the physical and social impacts experienced by victims of sexual abuse in the future. The experience of sexual abuse in boys by perpetrators who are also male (homosexual) will contribute greatly to the formation of similar behavior in children who are victims, namely to become homosexual[(11)]. The impacts of sexual abuse is important, not only on the mental aspects but also to be observed about the future impact on children as victims in terms of sexual behavior and children's social life [(12)].

Parents basically have a large role and contribution in improving control of their children primarily as an effort to protect against sexual abuse in children. One study explained that parents try to modify children's behavior in situations they perceive as risky (for example, after learning that his sister-in-law is photographing his daughter under a table and in bed, instructing his daughter to be careful in the way she sits in a dress). Parents must understand well that they have the power to intervene in alleged sexual harassment. Can use direct and indirect verbal and nonverbal communication by increasing the protection of temporary children in the presence of potential perpetrators and reducing social contact with people who fear parents will or have crossed sexual boundaries with their children[(13)].

Conclusion

Some efforts to protect early childhood from the risks of sexual abuse around them need to be applied by parents in daily care practices. Parents, as the primary environment of children, have an important role in preventing sexual abuse and protecting children from being the victims of sexual abuse. Implementing comprehensive understanding of sexual abuse, especially about one(s) who can be at risk of becoming a perpetrator of sexual abuse, is an important factor to increase the initiation of efforts to protect early childhoodfrom the risk of sexual abuse.

Estimation of Osteocalcin and Insulin in Men with Type 2 Diabetes in Misan Province Iraq

Eman Ali Hussein Al-Saidy[1], Zainab Abdul Jabbar Ridha Al-Ali[1]

[1]Department of Biology, College of Science, University of Misan, Maysan, Iraq

Abstract

The present study aimed to evaluation of osteocalcin and insulin in the serum of men with T2D Mat Misan province during the period from December of 2018 to May of 2019. The study include of 110 men (66 type 2 diabetic and 44 health men) with average aged 35-49 years,the sample of study divided by age into three groups, the first (35-39) years, second (40-44) years and third (45-49), also divided by the body mass index to four groups,the normal weight (18.5-24.9),overweight (25-29.9), obesity class l (30-34.9) and obesity class ll (35- 39.9) groups. The result showed the following; According to age, the mean value of FBG, HbA1 cincrease significantly in diabetic subjects when compared with the control. The mean values of insulin of T2DM significantly increase in the first group of age. OC increase significantly in second and third group in compare with control. According to BMI mean value of FBG, HbA1c increase significantly in diabetic subjects when compared with the control. The mean value of insulin in T2DM according to BMI was increase significantly in each of obesity class l and overweight groups compare control groups**.** OC value of T2DM significantly increases in the group obesity class ll and overweight.

Keywords: *Osteocalcin, Insulin, T2DM, Men, Misan.*

Introduction

Diabetes is a metabolic disorder with an growing prevalence worldwide, the number of influenced people may reach to 300 million in 2025[1], of whom 85% will have Type 2 diabetes mellitus (T2DM)[2]. D.M. is a clinical syndrome characterized by hyperglycemia due to absolute or relative deficiency of insulin producing from pancreatic β- cell[3].

One more complication has been associated with DM, an augmented risk of fragility fractures which seems to be rather independent of bone mineral density (BMD) [4,5]. T2DM patients have, normal BMD,implicating abnormalities in bone material strength and/or bone micro architecture[6].In general,the processes involved in the decreased bone formation in T2DM include a decrease in bone quality, alterations of the mesenchymal cell differentiation and bone microcirculation, as well as changes in osteoblasts and osteoclasts[7]. Bone can secret hormone named osteocalcin (OC)[8], OC is the most abundant noncollagenous protein in bone matrix[9]. It is a product of differentiated osteoblasts, made of 46 to 50 amino acids related to species[10].

In humans, it is a 49 amino acid with three glutamic acid residues which stimulates proliferation of pancreatic cells, insulin secretion, and insulin sensitivity[11,12]. OC receptor is expressed in different tissues including the liver, skeletal muscle, brain, testis, bone,and pancreatic β-Cells.Insulin signaling in osteoblasts enhances OC action, which, in turn, favors insulin secretion[13,14]. T2DM has been associated with poor bone quality by several mechanisms include, insulin resistance and hyperglycemia on the bone and bone marrow microenvironment, advanced glycation end products of bone matrix proteins[15,16,17].

Materials and Method

Study Population: This study was carried out at the AL-sadder Teaching Hospital and center for Endocrinology and diabetes specialist in Misan province as showed in (Figure,1) and BMI was estimated according to formula: BMI =W/H2 kg/m^2[18].

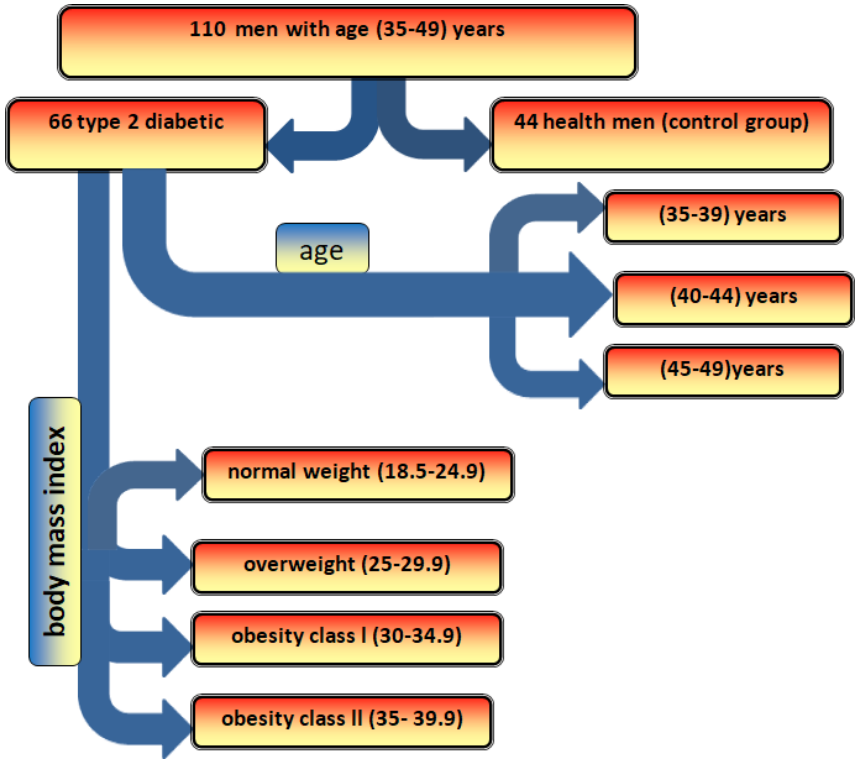

Figure (1): Study Population

Blood sampling and Preparation of serumfor Measurement HbA1c, FBG, Osteocalcin and Insulin: Venous blood (6 ml) pull draw from all fasting study population at (8-10 A.M). Blood sample was divided into two portions:2.5 ml was transferred into EDTA tube for HbA1c determination by Bio-Rad Variant Hemoglobin A1C program according to[19], and (3.5 ml) for serum preparation according to[20], to measure Fasting blood glucose (FBG) according to (Accu-Chek, Roch diagnostic GmbH, Mannheim,Germany)[21], and evaluation of OC by kit supply from Shanghai company (China) according to[22], while insulin determined by kit supply from Demediteccompany (Germany) according to[23].

Statistical Analysis: The data was analyzed statistically to determine the significance of the different parameters by student's t-test and one way ANOVA, the values present as means ± SE[24].

Result

Biochemical analysis (According to age)

Fasting Blood Glucose (F.B.G.) and HbA1c level: The results of F.B.G and HbA1c values for the study populations as showed in Table (1) the results elucidated no significant differences in F.B.G and HbA1c values among patients of T2DM in first, second and third groups.

Table (1): The values of F.B.G and HbA1c in control and patient with T2DM (According to age)

Groups	Parameter	Control	Patient	P-value
Group First (35-39)year	FBG (mg/dl)	94.67±2.37	210.61±14.96*	0.00
	HbA1c %	5.09±0.08	9.27±0.47*	0.00
Second group (40-44)year	FBG (mg/dl)	93.05±2.42	207.09±15.44*	0.00
	HbA1c%	5.35±0.05	9.55±0.45*	0.00
Third group(45-49)year	FBG (mg/dl)	93.90±3.31	205.03±15.29*	0.00
	HbA1c%	5.39±0.04	9.45±0.54*	0.00

*Significant between control and patient at the ($p<0.05$), Values represent mean±S.E.

Osteocalcin (OC) and Insulin level: The results for OC showed that the level among patients with T2DM increased significantly (P<0.05)in second group comparison with first group, while there are no significant difference between second and third groups. Also there are no significant difference between third and first groups of T2DM (Table,2).

The results showed no significant difference of insulin levels in patients of second and third groups comparison to the control of second groups and third groups. There are no significant difference in insulin level among patients of T2DM in first, second and third groups.

Table (2): The values of OC and insulin in control and patient with T2DM (According to age)

Groups	Parameter	Control	Patient	P-value
First group (35-39) year	OC ng/ml	1.08±0.15	1.03±0.21 [b]	0.84
	INμIU/mL	10.90±1.03	22.45±4.40*	0.01
Second group (40-44) year	OC ng/ml	0.97±0.22	2.01±0.31*[a]	0.01
	INμIU/mL	15.38±1.79	18.98±2.74	0.28
Third group (45-49) year	OC ng/ml	0.55±0.18	1.83±0.31*[ab]	0.01
	INμIU/mL	15.79±3.40	19.23±2.90	0.26
LSD of OC= 0.98				

*Significant at the (p<0.05), Values represent mean± S.E.

Different letters refer to significant differences while similar letters refer to non- significant differences among patient groups.

According to body mass index

Fasting Blood Glucose level: The results of F.B.G and HbA1c values for the study populations as showed in Table 3 the results elucidated F.B.G No significant difference in F.B.G and HbA1c values among patients of T2DM in different BMI.

Table (3): The values of F.B.G and HbA1c in control and patient with T2DM (According to BMI)

Groups	Parameter	Control	Patient	P-value
Normal weight (18.5-24.9)	FBG (mg/dI)	103.48±3.31	205.40±26.34*	0.04
	HbA1c %	5.32±0.03	9.05±0.71*	0.01

Discussion

According to age: The present study showed the FBG, HbA1C and insulin level in patient of T2DM which increased significantly (P<0.05),the patient with T2DM has high serum glucose, either due to the insulin that is produced by body does not enough, or because body cell do not respond to the insulin that is produced[25,26].The increasing in the level of FBG was in agreement with many researchers[27,28];which define diabetes is a group of metabolic diseases characterized by high level serum glucose. Hyperglycemia is the main characteristic of DM and its increase may associated with the increase of glucagonlevel that characterized by hepatic glucose production,the main factor that partake in fasting and postprandialhyperglycemia[29].

In this study the OC level which increased significantly (P<0.05) in patient with T2DM in both second and third age groups compare to the control groups.This result agreement with[30] that reported OC increase with age,while disagreement with[31] that reported OC levels are drop in diabetic than in healthy subjects.The result show no significant different between patient and control in first age group,also showed OC level of patient in second and third group increase significantly compare with patient of first group,this result may be because balance in bone formation and absorption in this stage of age.

In current study the insulin level in patient of first group increase significantly compare with control, this may be because insulin level increase in patient with T2DM due to insulin resistance,agreement with[32]that mention patients with T2DM have hyperinsulinemia,due to weakened cellular sensitivity to insulin, and hyperglycemia, due to insulin resistance.The insulin in most people of diabetic patients who are unable to use its glucose for energy and because of a problem with the cell body's insulin receptors and to problems with the chemical that makeup insulin itself; and this condition is called insulin resistance[33,34].

According to BMI: The result of the present study showed that the diabetic patients had significantly high concentration of FBG and HbA1C (P<0.05) than control group agreement with that reported by[35]that diabeticpatients FBG level ≥ 126 mg/dl. Increasing ofHbA1c levels in our study indicates poor control of FBGlevels or poor glycemic index agreement with[36]. Blood glucose is controlled by two main processes: insulin secretion by β-cells in response to a nutrient challenge and insulin action on major target organs, i.e., skeletal muscle, liver and adipose tissue, T2DM is often associated with obesity and results from insufficient insulin production and/or secretion and IR[37].

In this study OC level increased significantly in overweight, and obesity class II, this result agreement with[38]may be because insulin has an anabolic effect on osteoblasts [39]., may be suggest insulin resistance cause decrease in bone formation, increase bone absorption and increase OC released in to blood.Our result disagreement

with [40]. which reported that serum OC concentration in metabolic syndrome patients was significantly decreased than in control group. On the other hand, the OC level was significantly and negatively correlated with weight, BMI and fat mass[31].

The current study showed increase insulin level significantly (P<0.05) in patient with T2DM which suffer from obesity,Obesity may result in hyperinsulinism and insulin resistance, with a close relationship between the increased amassing of visceral fat and the degree of insulin resistance as well as hyperinsulinism this result agreement with study by[41].

Cubbon, *et al.*,[42] reported that T2DM is most commonly associated with obesity in middle-aged individuals, it is because of defects in insulin receptors on the plasma membrane of cells in target tissues, or an abnormal binding of insulin to receptors.

In the present study there was significant increased serum insulin in T2DM obese group in comparison to control group; this is in agreement with[40] which reported that subjects with metabolic syndrome had significantly higher serum insulin. Also, Goran, *et al*.[43] reported that occurrence of obesity was higher in adolescence leading to development of insulin resistance and the duration of obesity was independent risk factor for the development of T2DM. Furthermore,[44] reported that obesity main causes of develop insulin resistance in individuals having higher levels of insulin, obesity associated insulin resistance was the major risk factor for development of multiple diseases including cardiovascular diseases and T2DM. Finally, Margoni,*et al*[45] suggested that insulin sensitivity in obese has an important role in the advance of pathogenesis of obesity related insulin resistance.

Conclusion

This study revealed no relationship between OC level and T2DM and BMI

Evaluation of Prolactin, Total Testosterone and Anti Mullarian Hormones in Women with Hypothyroidism at Misan City Iraq

Eman Kamil Aati[1], Zainab Abdul Jabbar Ridha[1]

[1]*Department of Biology, college of science, University of Misan, Maysan, Iraq*

Abstract

Hypothyroidism is a common endocrine disorder,resulting from insufficient production of thyroid hormones. It is affect metabolism of sex steroids and ovarian function in women. This study included 88 women atage (20-35) years. 5 to 7 ml of blood was drawn and serum obtained. Thyroid and reproductive hormones tests performed to all women. The results showed: the values of TSH increased significantly (P<0.05) in the C (hypothyroidism women) and D (hypothyroidism and infertility women) groups, while T3 and T4 results show decreased significantly (P<0.05) in the C (hypothyroidism women) and D (hypothyroidism and infertility women) groups. The values of AMH and TT decreased significantly (P<0.05) in the C (hypothyroidism women) and D (hypothyroidism and infertility women) groups, while the values of PRL did not differences significantly among all groups. The present study demonstrates low level of AMH and TT in hypothyroidism women, while PRL show normal levels in all groups.

Keywords: *Hypothyroidism,prolactin, testosterone, AMH, women.*

Introduction

The thyroid is one of the largest endocrine glands found in the body[1]. Thyroid hormones (THs) are released by thyroid gland follicular cells whose true structure is Thyroxine (T4) and Triiodothyronine (T3) [2]. Disorders of the thyroid are usually acquired and can occur at any time in life. Thyroid autoimmunity is the most prevalent cause of disorder in the reproductive age of females[3,4]. Thyroid disorders increase with age, following exposure to radiation, and females are ten times more probable than males. The most prevalent endocrine defects in both Saudi Arabia and Middle East are thyroid disorders[5,6&7]. According to the American Association of Clinical Endocrinologists about 4.78% of the United State population have undiagnosed thyroid dysfunction and according to the American Thyroid Association, one in eight women will develop thyroid problems during her life time[8]. Hypothyroidism is connected with a wide range of reproductive illnesses ranging from abnormal sexual growth to infertility through menstrual irregularities, modified ovarian function, menstrual irregularities, subfertility[9,10]. In women have a greater incidence of anovulatory cycles leading to infertility and have a greater rate of fetal loss in the first trimester of pregnancy occurs[11,12].

The interior pituitary gland secrets hormones play roles in physiological mechanisms, including metabolism, growth, development and reproduction[13]. Gonadotropin-releasing hormone (GnRH) regulates the release of FSH from anterior pituitary. FSH causes follicle maturation and aromatase androgen-converting enzyme synthesis. LH and FSH foster ovulation and boost ovarian sex hormone secretion of estradiol and progesterone. The receptors of thyroid hormones are found in human oocytes, cumulus and granulose cells,some of hormones are impacted by hypothyroidism, such as prolactin, LH, and FSH[14,15].

Method

This study was conducting on 88 women in reproductive age (20-35) years who reviewed Al-Sadder Teaching Hospital and the Diabetes and Endocrine Center in Misan city, from the period December 2018 to June 2019. Women divided in to four groups as the following: group A (Control group), group B(Infertility women), group C (Women with hypothyroidism) and group D (Women with hypothyroidism and infertility).

Blood sample: 5 to 7 ml of blood was obtained by syringe at 8-10 a.m. Blood sample was poured in a plane container and then centrifuged. Serum was kept

as – 20 °C till used for the thyroid hormones,PRL, TT and AMHmeasure.

Measurement of hormones: Measurements weredone by the Chemiluminescent Automates Immunoassay System (Cobas e 411,Roche diagnostic, Germany). While; AMH hormone measured by used the ELISA system, according to the[16,17,18,19&20].

Statistical analysis: The data obtained during the current study were analyzed statistically to determine the significance of the different parameters by ANOVA. The comparisons between means were made using least significant differences, the data are presented as mean ± S.D.

Results

As shown in Table (1),the value of TSH in the D group increased significantly (P<0.05) in comparison with A,B and C groupsrespectively. C group differ significantly in comparison with A and B groups. No differences significantly between A and B groups. The values of T3 and T4increased significantly (P<0.05) in the A group in comparison with C and D groups. But A group did not differ significantly in comparison with B group. No significant differences between C and D groups.

The values of PRL don't differ significantly (P<0.05) in the A, B, C and D groups (Figure 1).The values of TT in the B group increased significantly (P<0.05) in comparison with A, C and D groups. No differences significantly among A,C, and D groups (Figure 2).The values of AMH in the A group increased significantly (P<0.05) in comparison with C and D groups. A group did not differ significantly in comparison with Bgroup, No differences significantly between C and D groups (Figure 3).

Discussion

This study agreement with[21]which found T3 and T4 levels are significantly decreased and TSH levels were significantly increased in clinical hypothyroid females compared to controls. These Biochemical decreases in T4 and T3 lead to hyper-secretion of TSH from pituitary gland and amplified rises of its concentrations in serum[22]. TSH concentration highly significant increased in primary hypothyroidism group as compared to the control group[23], another study carry out by[24] which found higher significant rise in TSH levels in the infertility women group compared to the control group. TSH level was found higher in infertile women than fertile[25]. Generally, serum TSH measurement in infertile females is used for hypothyroidism detection[26].

Hypothyroidism was diagnosed on the basis of history,physical examination findings and thyroid function tests showing high levels of TSH and low T3

and T4[27]. Women with elevated TSH concentrations above 2.5 mIU/L had more menstrual disturbances and an ovulatory cycles, reduced oocyte fertilization and pregnancy rates, increased risk of in-vitro fertilization failure and greater recurrent miscarriage rates[28,29]. TSH was found to be rises in 4% and overt hypothyroidism was identified in 3.3%, ovulatory dysfunction was dominant compared to other cases of infertilityaccording to study by[30].

The prevalence of hypothyroidism differ, in the infertile females, was revealed to range from 0.7% to 43%, this broad prevalence range was attribute to the variations in TSH measurement sensitivity[28,31,32,33]. 0.9% of infertile women had overt hypothyroidism but none had subclinical hypothyroidism according to study by[34].

The results of hormones in current study agree with the study done by[35] which found decreased significantly in the levels of testosterone and progesterone in hypothyroidism females, and agreement with the study done by[36] that found hypothyroidism is associated with decreases levels of Testosterone,but the current study did not agreement with study by[37] that found 40.7% of infertile women with hypothyroidism exhibiting hyperprolactinemia. About 66% of testosterone is bound to SHBG and 33% is bound to albumin, leaving only 1-2% of testosterone unbound, this unbound can enters target tissues[38]. Hypothyroid women demonstrate a reduced androgen metabolite proportion of 5 α/β and an increase in the excretion of 2-oxygenated estrogens[39].

The result observed by[40] which found PRL elevation in 36% of patients with overt hypothyroidism and 22% with subclinical hypothyroidism, PRL level decreased to normal after thyroid functions were normalized by L-thyroxine treatment and E2 levels increased significantly,treatment also reverses menstrual abnormalities and increases spontaneous fertility[41].

Other study showed increase in PRL levels in hypothyroidism women, these increase may be due to TRH stimulation, as lactotropic which resemble thyrotropic cells, express membrane receptors to releasing hormone. In addition, the increase in PRL may be due to an increase in pituitary vasoactive intestinal peptide, which acting as a paracrine or autocrine to affects PRL secretion regulator according to study by[42].

Current study agreementwith study done by[43] which found the concentration of AMH was inversely correlated with concentration of TSH in women at reproductive age suffering from infertility. The study done by[44] which investigated the association ofAMH values and ovarian reserve in women with autoimmune thyroid disease, which demonstrated low serum AMH concentration in women with AITD, but don't reach to significant level,women with hypothyroidismare at increased risk for development ofovarian insufficiency.In infertile patients with elevated serum TSH concentrations also revealed high prevalence clinical information of decreased ovarian reserve [43,45].TSH concentrations were an important predictor of IVF failure, as TSH concentrations were considerably greater among females who manufactured non-fertilized oocytes[46]. The TSH in patients with hypothyroidism could directly suppress the growth of follicles. Also, depleted thyroid hormones secretion may have an additional adverse effect on follicle recruitment[47].

Conclusion: The present study demonstrates low level of AMH and TT in hypothyroidism women, while PRL show normal levels in all groups.

Synthesis, Antioxidant, Antimicrobial and Docking Study of Novel 2-Pyrazoline Derivatives Bearing Imine Moiety

Ban Hasan Taresh[1], Ahmed Mutanabbi Abdula[1], Mustafa Taha Mohammed[1]

[1]Mustansiriyah University, Department of Chemistry, Baghdad, Iraq

Abstract

In our attempt to exploring new class of antimicrobial and antioxidant agents, novel pyrazoline derivatives (3-11) were synthesized and characterized by some spectroscopic method such as FTIR[1] HNMR and GCMass. The antimicrobial study of the synthesized compounds against various bacterial species. Escherichia coli klebsiella sp (gram negative), Staphylococcus epidermidis, Staphylococcus aureus (gram positive) and one fungi (candida albicans). The scavenging properties of all the synthesized derivatives were evaluated against DPPH radical by using *TLC* autographic assay and the scavenging activity was determined by using spectroscopic method.

Keywords: *Chalcone, Pyrazoline, Schiff bases, antimicrobial, antioxidant, docking study.*

Introduction

Pyrazoline and its derivatives were member of nitrogen containing heterocycles [1] in their structure, two nitrogen atoms were present in five-membered ring. This nucleus contains a C=N double bond[2] Pyrazoline derivatives have been found in natural products in the form of vitamins, alkaloids and pigments[3]. In the last decade, great attention has been paid on the pyrazoline derivatives due to their unique molecular structure with simplicity of preparation and wide application in pharmaceutical field. They have shown interesting pharmacological activities such as anticancer[4] anti-inflammatory [5,] antimicrobial[6] antioxidant [7] and antidepressant[8].Therefore, our attempts to find novel antimicrobial and antioxidant agents focus on the pyrazoline derivatives. Pyrazoline derivatives (3-11) were in vitro screened against various bacterial species. Escherichia coli klebsiella sp (gram negative), Staphylococcus epidermidis, Staphylococcus aureus (gram positive) and one fungi (candida albicans). and found to exhibit mild to potent activity. Docking study of the most active discovered hit **6** was achieved to evaluate the binding affinity tawred the active site of glucosamine-6-phosphate synthase, the specific enzyme for the antimicrobial agents.

Methodology

Material: All chemicals and materials were used without purification**.** Melting points were determined on electrothermal capillary apparatus and are uncorrected. UV light, FTIR-8400S measurements were recorded on a Shimadzu GCMS-QP2010 Ultra apparatus. ^{1}HNMR spectra were gained with a Bruker spectrophotometer model ultra-shield at 300 MHz in DMSO-d6 solution with the TMS an internal standard.

Synthesis

Synthesis of (E)-1-(4-aminophenyl)-3-(thiophen-2-yl) prop-2-en-1-one (1): This compound was synthesized according to the method qualified in the published work[9]. To a solution of 4-aminoacetophenone (1 mmol) in ethanol absolute (10 mL), sodium hydroxide (40%, 1mL) was added and the mixture was shaking for (30) minutes. Then the aromatic aldehyde (1 mmol), was added and the reaction mixture was shaking overnight. The mixture was allowed to remained at room temperature. The product was dried and recrystallized from ethanol.

Yellow powder, yield 92%, m.p 110-111˚C; IR ($\bar{\upsilon}$cm^{-1}): 3317, 3219 (NH_2), 3101(aromaticC-H), 1633 (C=O), 1600 (CH=CH), 1577 (aromatic C=C). ^{1}H-NMR (300MHz, DMSO-d_6) δ (ppm): 6.10 (s, 2H,NH_2)**,** 6.61 (d, 2H, *Ar-H*, j=8.56 Hz), 7.15-7.86 (m, 7H, 5*Ar-H*, -*CH=CH*). Mass (EI) m/e: 229 M^+ For $C_{13}H_{11}NOS$,Rf = 0.42 (5:5), Hexane:Ethyl acetate.

Synthesis of 4-(5-(thiophen-2-yl)-4,5-dihydro-1H-pyrazol-3-yl) aniline (2): This compound was prepared depending to the modified method in reported reference[10]. Chalcone compound (1) (1 mmol) in ethanol (10 ml) and excess of hydrazine hydrate 80% (1 ml) was refluxed for 6 hrs. The precipitate product was recrystallized from ethanol.white powder, yield 80%, m.p 120-122°C, IR (cm^{-1}): 3327, 3286 (NH_2), 3205 (NH-pyrazoline), 3107 (aromaticC-H), 2933(aliphatic C-H),1622 (C=N), 1600 (C=C). ^{1}HNMR (300MHz, DMSO-d_6) δ (ppm): 3.00 (dd,1H, CH_a-pyrazoline, j= 11, 4 Hz), 3.30 (m, 1H,CH_b-pyrazoline), 4.94-5.01 (t,1H, CH_x-pyrazoline, *j = 11 Hz*), 6.45-7.40 (m,9H, 5 Ar-H, NH_2). Mass (EI) m/e: 243 M^+ for $C_{13}H_{13}N_3S$, R.*f* = 0.42 (7:3, Hexane: Ethyl acetate).

Synthesis of Schiff bases (3-11): These compounds were synthesized depending to a modified method described in the reported reference[11]. Substituted aldehyde (1 mmol) was dissolved in methanol with few drops of glacial acetic acid and then was added (1 mmol) of pyrazoline derivatives. The blend was refluxed for (10 h) and the reaction process was observed by *TLC* using ethyl acetate: hexane system (1:1 and 3:7). The precipitate was filtered and washed with methanol dried, dried and recrystallized from ethanol.

1-(4-chlorophenyl)-N-(4-(5-(thiophen-2-yl)-4,5-dihydro-1H-pyrazol-3-yl)phenyl)methanimine(3)

yellow powder, yield 50 %, m.p80-82◦C; IR (cm^{-1}): 3375(NH-pyrazoline), 3070 (C-H aromatic),3000(aliphatic C-H),2885 (HC=N), 1620 (C=N), 1595 (C=N pyrazoline), 1512 (C=C aromatic). ^{1}HNMR (300MHz, DMSO-*d6*) δ (ppm): 2.70-2.90 (m, 1H, *CH_a*pyrazoline), 3.40-3.50 (m, 1H, *CH_b-pyrazoline),* 5.30-5.40 (m, 1H, *CH_x-pyrazoline),* 7.00-8.00 (m,11H, 11 ArH*)*, 8.70 (s, 1H, *CH=N*).

1-(4-nitrophenyl)-N-(4-(5-(thiophen-2-yl)-4,5-dihydro-1H-pyrazol-3-yl)phenyl)methanimine(4): Yellow powder, yield 60 %, m.p118-120◦C; IR (cm^{-1}): 3383 (NH-pyrazoline)**,** 3010 (C-H aromatic),2974(aliphatic *C*-H), 2899 (HC=N), 1620 (C=N), 1597 (C=Npyrazoline), 1516 -1342 (NO_2).[1] HNMR (300MHz, DMSO-*d6*) δ (ppm): 2.60-2.70 (m, 1H, *CH_a*pyrazoline), 3.55-4.10 (m, 1H, *CH_b-pyrazoline),* 5.20-5.40 (m, 1H, *CH_x-pyrazoline),* 6.50-8.40 (m,11H, 11 ArH*),* 8.80 (s, 1H, *CH=N*). Mass (EI) m/e: 376 M^+ for $C_{20}H_{16}N_4O_2S$: R.*f* = 0.65 (3:7, Hexane: Ethyl acetate).

1-(thiophen-2-yl)-N-(4-(5-(thiophen-2-yl)-4,5-dihydro-1H-pyrazol-3-yl)phenyl) methanimine(5): Orange powder, yield 55%, m.p 125-127°C; IR (cm^{-1}): 3300 (NH- pyrazoline), 3100 (C-H aromatic),2974(aliphatic C-H), 2899 (HC=N), 1612 (C=N), 1589 (C=Npyrazoline).[1] HNMR (300MHz, DMSO-*d6*) δ (ppm): 3.20-3.40 (m, 1H, *CH_a*pyrazoline), 3.20-3.40 (m, 1H, *CH_b-pyrazoline),* 5.05-5.15 (m, 1H, *CH_x-pyrazoline),* 7.00-8.10 (m,10H, 10 ArH*),* 8.90 (s, 1H, *CH=N*), R.*f* = 0.50 (3:7, Hexane: Ethyl acetate).

1-(1H-pyrrol-2-yl)-N-(4-(5-(thiophen-2-yl)-4,5-dihydro-1H-pyrazol-3-yl)phenyl)methanimine(6): red powder, yield 55 %, m.p130-131°C; IR (cm^{-1}): 3362 (NH-pyrazoline), 3113 (C-H aromatic),2964(aliphatic *C-H*),2885 (HC=N), 1618 (C=N), 1589 (C=N pyrazoline).[1] HNMR (300MHz, DMSO-*d6*) δ (ppm): 3.00-3.20 (m, 1H, *CH_a*pyrazoline), 3.20-3.40 (m, 1H, *CH_b-pyrazoline),* 5.05-5.15 (m, 1H, *CH_x-pyrazoline),* 6.50-8.10 (m, 10H, 10 ArH*),* 8.50 (s, 1H, *CH=N*).11.00 (NH-pyrrole) R.*f* = 0.50 (3:7, Hexane: Ethyl acetate).

1-phenyl-N-(4-(5-(thiophen-2-yl)-4,5-dihydro-1H-pyrazol-3-yl)phenyl) methanimine (7): Brown powder, yield 55 %, m.p130-131◦C; IR (cm^{-1}): 3352 (NH- pyrazoline), 3103 (C-H aromatic), 2972 (aliphatic C-H),2889 (HC=N), 1624 (C=N), 1593 (C=N pyrazoline).[1] HNMR (300MHz, DMSO-*d6*) δ (ppm): 2.60-2.75 (m, 1H, *CH_a*pyrazoline), 3.20-3.40 (m, 1H, *CH_b-pyrazoline),* 5.10-5.25 (m, 1H, *CH_x-pyrazoline),* 6.50-8.40 (m,11H, 11 ArH*),* 8.60 (s, 1H, *CH=N*). N,N-dimethyl-4-(((4-(5-(thiophen-2-yl)-4,5-dihydro-1H-pyrazol-3-yl)phenyl)imino)methyl) aniline(8): Red powder, yield 55%, m.p150-131°C; IR (cm^{-1}): 3338 (NH-pyrazoline), 3066 (C-H aromatic), 2895 (aliphatic C-H), 2850 (HC=N), 1653 (C=N), 1581 (C=Npyrazoline).[1] HNMR (300MHz, DMSO-*d6*) δ (ppm): 2.70-2.80 (m, 1H, *CH_a*pyrazoline), 3.00 (s, 6H,$N(CH_3)_2$, 3.20-3.40 (m, 1H, *CH_b-pyrazoline),* 5.25-5.45 (m, 1H, *CH_x-pyrazoline),* 6.50-7.90 (m, 11H, 11 ArH*),* 8.50 (s, 1H,*CH=N*):R.*f*=0.60 (3:7,Hexane:Ethyl acetate).

1-(4-methoxyphenyl)-N-(4-(5-(thiophen-2-yl)-4,5-dihydro-1H-pyrazol-3-yl)phenyl) methanimine(9): Brown powder, yield 55 %, m.p150-151◦C; IR (cm^{-1}) : 3360 (NH- pyrazoline), 3107 (C-H aromatic), 2999 (aliphatic C-H),2895 (HC=N), 1620 (C=N), 1593 (C=N ***pyrazoline***).[1] HNMR (300MHz, DMSO-*d6*) δ (ppm): 2.60-2.70 (m, 1H, *CH_a*pyrazoline), 3.20-3.90 (m, 4H, 1 *OCH_3*, *CH_b-pyrazoline),* 5.30-5.40

(m, 1H, *CH_x-pyrazoline),* 7.00-8.00 (m,11H, 11 ArH*),* 8.60 (s, 1H, *CH=N*), R.*f* = 0.60 (3:7, Hexane: Ethyl acetate).

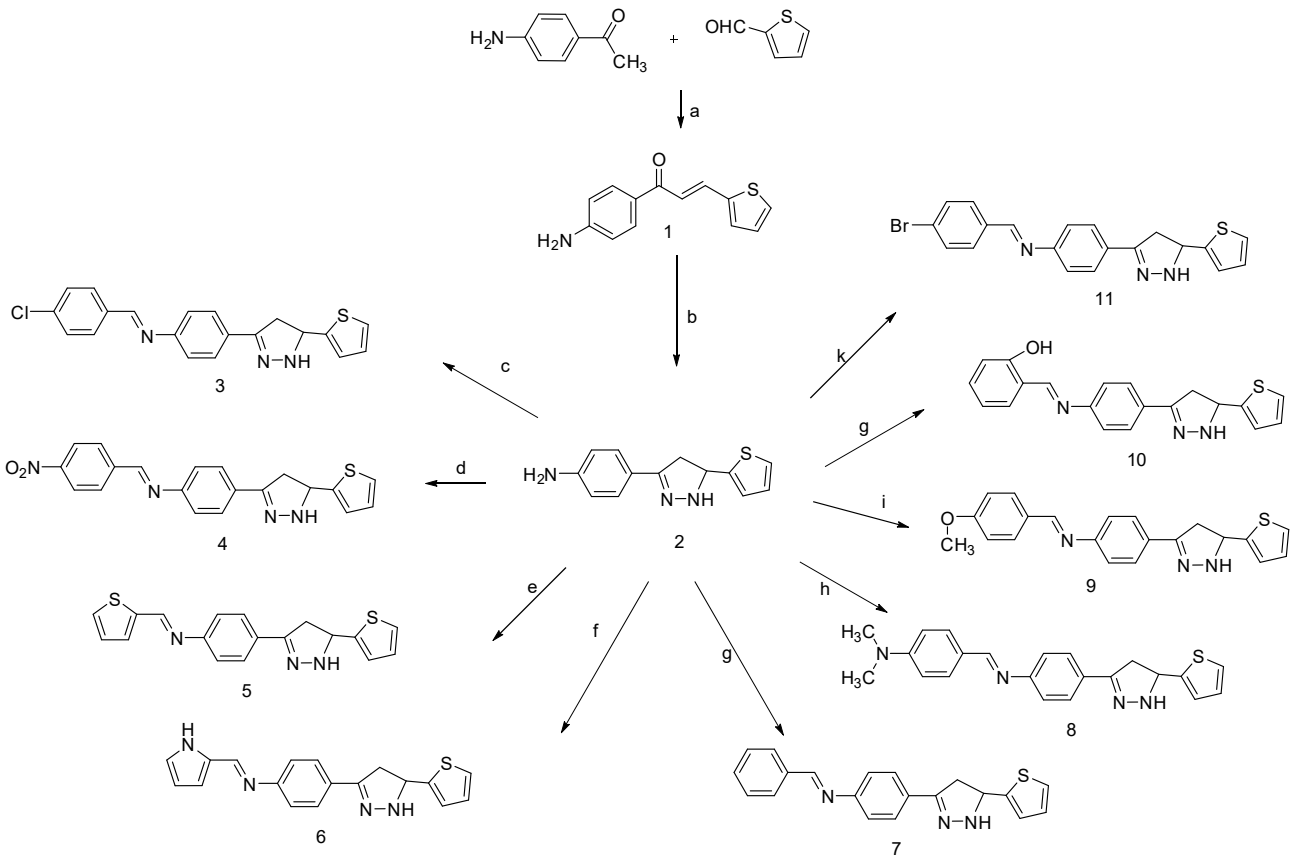
2-(((4-(5-(thiophen-2-yl)-4,5-dihydro-1H-pyrazol-3-yl)phenyl)imino)methyl)phenol(10): Orange powder, yield 60 %, m.p95-97◦C; IR (cm^{-1}): 3398 (NH-pyrazoline), 3107 (C-H aromatic),2987(aliphatic C-H), 2895 (HC=N), 1616 (C=N), 1595 (C=N pyrazoline).[1] HNMR (300MHz, DMSO-*d6*) δ (ppm): 2.75-3.00 (m, 1H, *CH_a*pyrazoline), 4.5-4.70 (m, 1H, *CH_b*pyrazoline) 5.10-5.40 (m, 1H, *CH_x-pyrazoline),* 6.50-9.10 (m, 13H, 11 Ar-H, NH pyrazoline, CH=N), 12.00 (s, 1H, OH). R.*f* = 0.5 (3:7, Hexane: Ethyl acetate).

1-(4-bromophenyl)-N-(4-(5-(thiophen-2-yl)-4,5-dihydro-1H-pyrazol-3-yl)phenyl)methanimine(11): Brown powder, yield 60 %, m.p111-112◦C; IR (cm^{-1}): 3336 (NH-pyrazoline), 3064 (C-H aromatic), 2987 (aliphatic C-H), 2881 (HC=N), 1624 (C=N), 1585 (C=N pyrazoline).[1] HNMR (300MHz, DMSO-*d6*) δ (ppm): 2.75-2.90 (m, 1H, *CH_a*pyrazoline), 3.60-3.90 (m, 1H, *CH_b-pyrazoline),* 5.10-5.20 (m, 1H, *CH_x-pyrazoline),* 7.00-8.00 (m,11H, 11 ArH*)*, 8.40 (s, 1H, *CH=N*). Mass (EI) m/e: 410 M^+ for $C_{20}H_{16}N_3SBr$: R.*f* = 0.60 (3:7, Hexane: Ethyl acetate).

Determination of scavenging activity:

Qualitative method using Thin layer chromatography: Few milligrams of synthnthesized compounds (1-11) dissolved in methanol were added to the TLC plate by small capillary. Then after drying TLC plates were sprayed with methanolic solution of 0.2 % DPPH, the plates were examined 30 minute after spraying. Potent derivatives appears as blue or yellow spots against a purple background[12].

Quantitative determination using spectroscopic method: (1.0 mL) of the synthesized compounds (1-11) atconcentration (5,25,50,100,200) µg/ml were added to 0.5 mL DPPH solution (2mL of 0.013g/L DPPH) in methanol. The reduction of DPPH was measured at 517 nm versus a blank assay at 30 min. The percentage of residual radical in medium is calculated as the absorbance of the sample split by that of DPPH control at the same time multiplied by 100. The capability to scavenge the DPPH radical was calculated using the following equation: DPPH scavenging effect (%) = (A0 – A1/A0)×100, where A0 is the absorbance of the control reaction and A1 is the absorbance in the presence of the samples or standards. The results of DPPH scavenging effect (%) were plotted against scavenger concentration to calculate IC50.[13]



Antimicrobial studiy using well diffution method:

Well diffusion method: Agar well diffusion method for bactericidal susceptibility was carried out according to standard method to assess the presence of antibacterial activity for compounds using *Escherichia coli, klebsiellasp, Staphylococcus epidermidis* and*, Staphylococcus aureus*. The studied compounds were dissolved in 5% DMSO to prepare solution with 1 mg\ ml concentration,. The medium was sterilized at 120°C in autoclave. Then the medium was transported into sterilized Petri plates and kept at 37°C for solidification. The bacterial strains were diffused on the Petri plates using loop. On each plate, a single well of 4mm diameter was made using a gel pierce. From each compound (5µl) was added into the wells. The plates were incubated at 37°Cfor 24 hrs. The experiments were accomplished in triplicates and the zone of inhibition was measured[14]. The Dimethyl sulfoxide was used as control.

Docking study: Auto Dock 4.2 package software was selected to explore the binding of compound **6**into the active site of GlcN-6-P synthase as described by the reported reference[15-16]. The pdb file format (PDB code 1 MOQ) of receptor was obtained from the Protein Data Bank (RCSB) and applied as a rigid molecule. All the water molecules were eliminated then the hydrogen atoms were added to the amino acid residues. Chem Draw ultra 7.0 tool was used to constructed the mol file of the docked compound, while the open Babel 2.3.1 software was used to build the pdb file. In order to achieve the docking study, grid dimensions of 30.5, 17.5 and -2.2, were applied. On the other hand, Lamarckian Genetic algorithm was employed with 10 runs, 150 population size, 2,500,000 maximum number of energy evaluations and 27,000 maximum number of generations.

Results and Discussion

Organic Synthesis: Chalcone derivative (1) and the pyrazoline compound (2) were prepared and characterized as described by previous work[9]. Schiff bases (3-11) were obtained from the reaction of 2-pyrazoline derivative (2) with different aromatic aldehydes in ethanoic solution, using glacial acetic acid as a catalyst (Scheme 1).

Scheme (1) : Schematic representation for the synthesized derivatives: (a) NaOH, EtOH, (b) Hydrazine hydrate, EtOH, (c) p-chlorobenzaldehyde, AcOH (d) p-nitrobenzaldehyde, AcOH (e) 2-thiophenecarboxaldehyde, AcOH (f) pyrrole-2-carboxaldehyde, AcOH (g) benzaldehyde, AcOH (h) N, N-dimethylaminobenzaldehyde, AcOH (i) p-methoxybenzaldehyde, AcOH (j) o-salicyaldehyde, AcOH (k) p-bromobenzaldehyde, AcOH

The synthesized derivatives were characterized by spectral analysis. The FT- *IR* spectra of compounds (3-11) showed absorption bands at 2850-2899 cm^{-1} and 1612-1653 cm^{-1} regions due to the stretching vibrations of the *CH=N* and *C=N*, respectively. The disappearance of the NH_2 stretching frequencies strongly enhances the elucidation of synthesized compounds. The *HNMR* spectra of the synthesized compounds (3-11) showed singlet at the 8.40-8.90 ppm regions due to *CH=N* protons with the absent of the singlet signal at 6.18 related to NH_2 group in compound **2**. Mass analysis for the synthesized derivatives strongly confirming the structure elucidation.

Antioxidant scavenging activity: Thin layerautographic assay (***TLC***) were used to evaluate the scavenging properties of all the synthesized derivatives **S_2(1), $1S_2$(2), $2S_2$(3), $4S_2$(4), $3S_2$(5), $6S_2$(6), $10S_2$(7), $8S_2$(8), $12S_2$(9), $11S_2$(10), $5S_2$(11)**against DPPH radical. The synthesized compounds dissolved in methanol were distributed on *TLC* plate using spotting capillary. After drying and spraying the DPPH solution, the most active compounds **S_2(1), $1S_2$(2), $2S_2$(3), $4S_2$(4), $3S_2$(5), $6S_2$(6), $10S_2$(7), $8S_2$(8), $12S_2$(9), $11S_2$(10), $5S_2$(11)**appeared as yellow or blue spots with purple background. The scavenging activity of the lead derivatives **S_2(1), $1S_2$(2), $2S_2$(3), $4S_2$(4), $3S_2$(5), $6S_2$(6), $10S_2$(7), $8S_2$(8), $12S_2$(9), $11S_2$(10), $5S_2$(11)**was determined using spectroscopic method as described in the experimental section. The IC_{50} was calculated from the plotting of DPPH scavenging activity against different concentrations of each tested compound (5, 25, 50, 100 and 200 µg/ml) as shown in Figure **1** and depicted in **Table 1**.

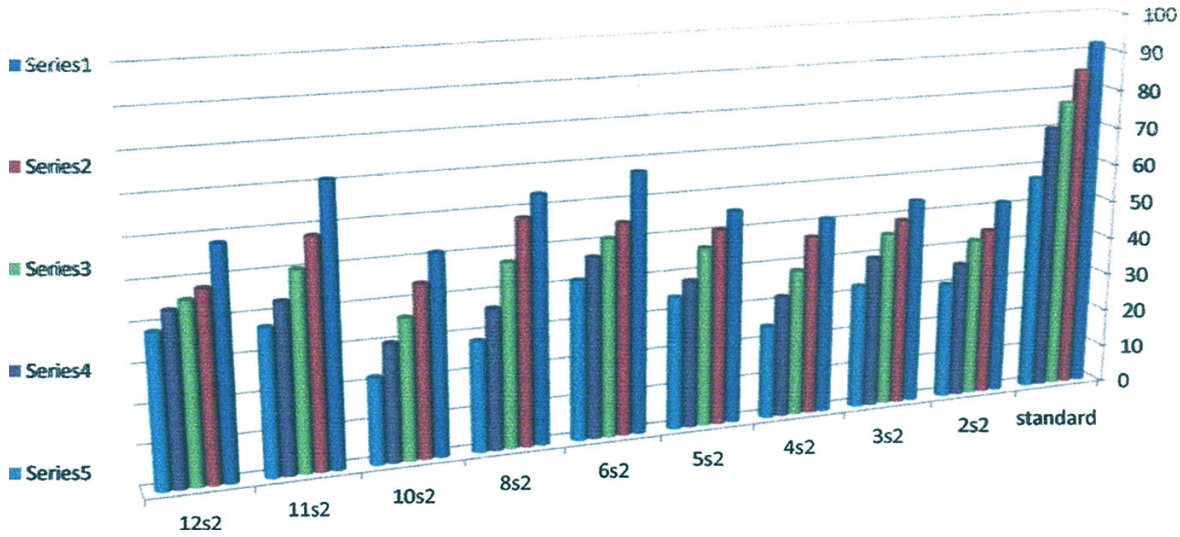


Figure 1: Comparison of DPPH scavenging assay of potent compounds S_2(1), $1S_2$(2), $2S_2$(3), $4S_2$(4), $3S_2$(5), $6S_2$(6), $10S_2$(7), $8S_2$(8), $12S_2$(9), $11S_2$(10), $5S_2$(11)against Gallic acid

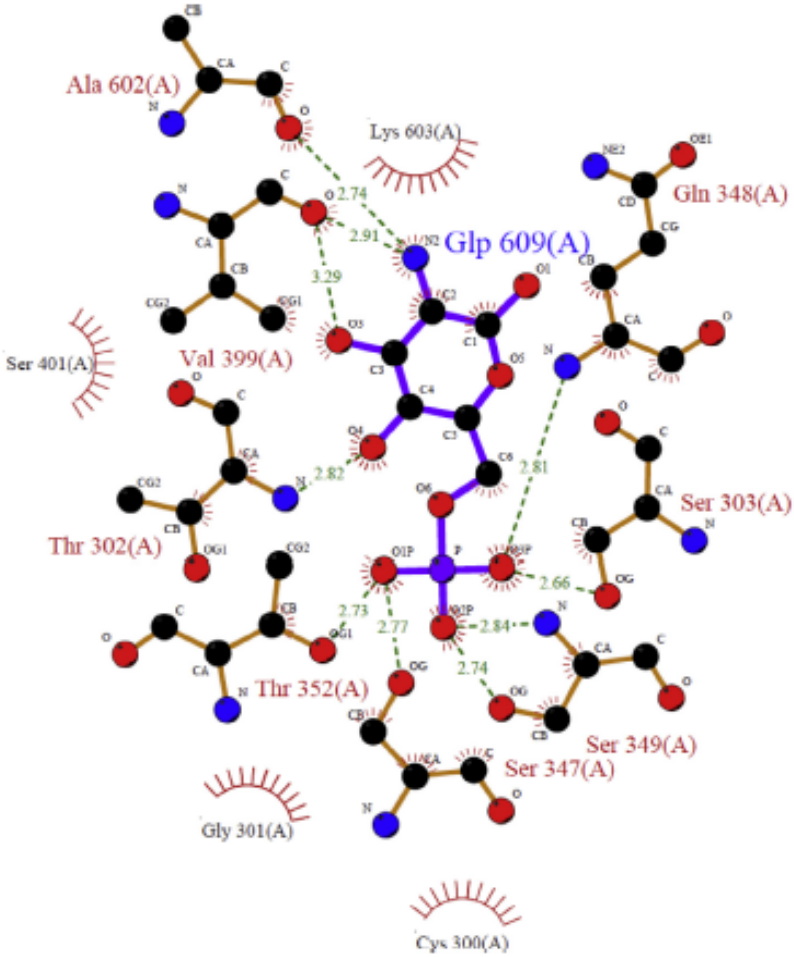
Docking study: The docking approach of the potent active 2-pyrazoline derivative 6 into the binding pocket of glucosamine-6-phosphate synthase, the potential target forantifungal & antibacterial agents was achieved. The grid box was constructed to include all the binding residues of enzyme (Cys 300, Gly 301, Thr 302, Ser 303, Ser 347, Gln 348, Ser 349, Thr 352, Val 399, Ser 401, Ala 602 and Lys 603) as indicated by the X-ray study (**Figure 2**)[17].



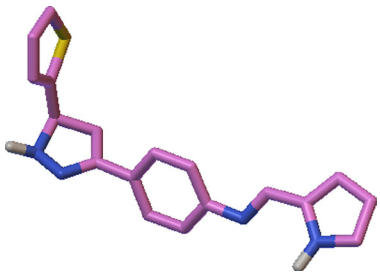


Figure 2: Ligplot of GlcN-6-P showing the binding of glucosamine-6-phosphate in an active site of enzyme

The docking parameters for the ten generated conformers by the Autodock 4.2 are illustrated in **Table 3**. The binding energy of the best generated conformer is -7.56 Kcal mol^{-1} with -8.75 Kcal mol^{-1} intermolecular energy. The calculated inhibition constant (Ki) was 2.88 µM as determined by the docking approach. The best conformer bonds the enzyme pocket with two hydrogen bonding, the first one with ALA602 while the second with the LIG residue as shown in **Figure 3**.

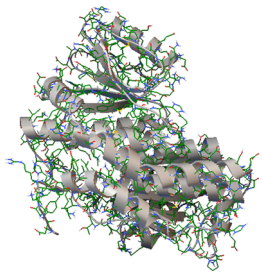

Table 3: Docking parameters of 2-pyrazoline derivative 6

Structure of compound 6

3D structure of GlcN-6-P

Best generated conformer inside the binding site of GlcN-6-P

Figure 3: The docking of the best generated conformer of compound 6 inside the binding pocket of L-Glutamine: D-fructose-6-phosphate amidotransferase (GlcN-6-P)

The docking results of generated conformers within the binding pocket strongly related to the antibacterial activities and enhancing the discovered hit (compound 6) as promising antimicrobial agents at lower concentration.

Conclusion

The present research summarized the synthesis of novel 3,5-disubstituted-4,5-dihydro-1 *H*-pyrazoles derivatives containing imine moiety. The antioxidant activity for all the derivatives were determined by using DPPH radical. The discovered hits which exhibited promising antioxidant results were screened against various bacterial species and Candida Albicans to explore the antimicrobial activity of the novel derivatives. On the other hand, docking approach using Autodock 4.2 was achieved to illustrate the binding state of the potent hit inside the glucosamine-6-phosphate synthase.

Abstract

The effectiveness of the use of Autologous platelet concentrates was studied to improve the regenerative processes of trophic ulcers. The study involved 41 patients of the surgical department of "Simferopol Central Clinical Hospital" with trophic ulcers (TU) of the lower extremities of various sizes and shapes from 4 to 26 cm^2. In addition to the complex treatment of trophic ulcers, patients of the 1st group received topical treatment with stimulants of the regenerative process - Autologous Platelet Concentrates (APC), followed by repeated applications if necessary. According to standard approaches, 20 patients with TU were treated (group 2). The use of APC therapy in the complex treatment of TU was clinically effective. The applied method in the 1st group helped to accelerate the processes of wound repair, reduce the healing time of trophic ulcers and statistically significant decrease in the area of the wound defect compared with patients of the 2nd group were found. The use of APC therapy in the treatment of TU is clinically effective. The applied method contributed to the acceleration of wound recovery processes.

Keywords: *Trophic ulcer, Autologous platelet concentrate, Surgery.*

Introduction

Wound healing is one of the oldest surgical problems, which has still not lost its relevance [2]. When treating wounds, surgeons often deal with soft tissue defects, which are characterized by signs of chronic inflammation, high bacterial contamination, and the predominance of degenerative processes over regenerative ones [1]. Such conditions include wounds, non healing for a long time, fistulas, bedsores [3]. Despite the wide range of drugs and various method for treating skin wounds, trophic ulcers (TU) remain a significant problem [4].

The use of autologous platelet concentrates (APC) is a specialized local therapy for the treatment of TU [8]. APC is a part of the blood obtained from the patient's autologous blood (Fig. 1&2), which initiate wound healing by releasing local growth factors released during degranulation of α-granules. The α-granules contain secretory proteins: platelet growth factor (PDGF), AA-, BB and AB-isomers, transforming growth factor p (TGF-p), platelet factor 4 (PF4), interleukin-1 (IL-1), platelet angiogenesis factor (PDAF), vascular endothelial factor (VEGF), epidermal growth factor (EGF), platelet endothelial growth factor (PDEGF), epithelial cell growth factor (ECGF), insulin-like growth factor (IGF), osteocalcin (Oc), osteonectin (O), fibrinogen (Fg), vitronectin (Vn), fibronectin (Fn), thrombospondin-1 (TSP-1) [6]. All of them contribute to the involvement of undifferentiated cells in the newly formed matrix and the launch of cell division. APC also inhibits the release of cytokines and limits the inflammation process, thereby improving healing [5,7].

Published experimental and clinical data[9] indicate a positive effect of APC on the stimulation of tissue angiogenesis and wound healing (Fig. 5), which in turn suggests that the use of APC in patients with TU is effective and promising [10].

Purpose of the study: Improving the regenerative processes of TU through the use of APC therapy in the complex of therapeutic measures.

Materials and Method

Since 2014 to 2019 on the basis of the surgical department of "Simferopol Central Clinical Hospital" a comprehensive examination and treatment was carried out according to the proposed methodology of 21 patients with TU (group 1). In addition to the complex treatment of TU, patients of this group received topical treatment with stimulants of the regenerative process - APC, followed by repeated applications if necessary. And 2nd group contains 20 patients who were treated with standard approaches of TU.

Patients of the 1st group had a wound process that was heterogeneous in etiology. Therefore, in the 1st group, two subgroups were distinguished: 1A - 10 (45.4%) patients with trophic ulcers and chronic arterial insufficiency (CAI); 1B - 11 (54.6%) patients with trophic ulcers and chronic venous insufficiency (CVI).

To analyze the results obtained, similarly with the 2nd group, two subgroups 2A were identified - 10 (50%) patients with trophic ulcers and CAI; 2 B - 10 (50%) patients with trophic ulcers and CVI.

Both groups are comparable in age, gender, severity of general condition, the nature of the concomitant pathology. The duration of the wound process in patients of the 1st group correlated with the duration of the wound process in patients of the 2nd group and ranged from 5 weeks up to 4 months. All patients of the studied groups at the prehospital stage were consulted by an angiosurgeon, received outpatient treatment from the surgeon at the place of medical care, and in case of a long term wound history - treatment was carried out in a general surgical hospital. All patients with trophic ulcers and CVI were treated with elastic compression, phlebotonics, and systemic phleboprotectors were prescribed. Treatment of patients with subgroups 1A and 2A with diabetes included functional relief, correction of hyperglycemia, as well as existing neuro and angiopathic disorders in accordance with existing recommendations.

All patients of both groups underwent local treatment of TU with the standard method, including surgical treatment of the purulent foci, in which dead tissue was removed (Fig. 4), and if possible, the existing scab and fibrin layers, which often covered granulation tissue, were radically removed. Subsequently, various antiseptics were used locally to clean the wound surface, including chlorhexidine solutions, 3% of hydrogen peroxide solution, 10% of povidone-iodine solution, they irrigated the wound surface during surgery or daily dressings. Then an aseptic gauze dressing was applied with a 0.5% solution of dioxidine or ointment agents on a water-soluble basis (levosin, levomekol). All patients were prescribed antibiotic therapy from the 1st day of hospitalization in accordance with generally accepted schemes.

Patients of the 1st group used APC in the form of daily applications, which was obtained by centrifugation of autologous blood [5]. The resulting Autologous platelet concentrates in the form of an application were applied to the wound defect (Fig. 3) and covered with a dry cloth and a hydrophilic film coating for 24 hours.

To study and objectify the healing processes of TU in patients of both groups, the area of wound defects was determined using the LesionMeter program from OS Android. To measure the surface area of TU using this program, a limb segment with a wound defect was photographed, where the scaling standard was placed in the form of a standard plastic card, after that the wound defect was circled around the perimeter with the cursor and automatically received its area in cm^2. The result obtained was recorded in the program archive.

The area of the initial wound defect was determined upon admission to the hospital before treatment and during the treatment period to determine the dynamics of wound healing on days 4, 8, 12, 16, and 20, as well as at the end of treatment.

Depending on the size of the wound defect, TUs were divided into small ones - up to 9 cm^2 in area, medium - 10 - 18 cm^2, large - 19 - 26 cm^2. The structure of patients of both groups depending on the area of the wound defect was compared (Table 1). The distribution of patients of both groups over the area of TB was uniform.

Table 1. The structure of the studied groups of patients depending on the area of the wound defect

Area of wound defect	Groups							
	1st Group				2nd Group			
	subgroups				subgroups			
	1A		1B		2A		2B	
	No. of patients	%	No. of patients	%	No. of patients	%	No. of patients	%
Less than 9 cm^2	3	30.0	4	36.4	3	30.0	4	40.0
10-18 cm^2	4	40.0	4	36.4	3	30.0	3	30.0
19 - 26 cm^2	3	30.0	3	27.2	4	40.0	3	30.0
Total	**10**	**100.0**	**11**	**100.0**	**10**	**100.0**	**10**	**100.0**

Results

Before starting treatment in all subgroups of the 1st and 2nd groups, the average values of the area of the wound defect were compared (Table 2).

In subgroup 1A and subgroup 2A, the area of the wound defect average were (15.5 ± 1.2) and (15.7 ± 1.1) cm^2 respectively, which did not have a statistically significant difference (p> 0.05). In subgroup 1B, the area of the trophic ulcer averaged was (15.9 ± 1.4) cm^2, and in subgroup 2B - (15.8 ± 1.7) cm^2, which also did not have a statistically significant difference (p> 0.05).

Table 2. The area of the wound defect in patients of the 1st and 2nd groups before starting of treatment (x ± t)

Area of wound defect	Groups			
	1st Group		2nd Group	
	subgroups		subgroups	
	1A	1B	2A	2B
Less than 9 cm^2	7.2 ± 0.6	6.8 ± 0.8	6.9 ± 0.7	7.1 ± 0.8
10-18 cm^2	16.8 ± 0.9	17.1 ± 0.8	16.3 ± 0.6	15.9 ± 0.9
19 - 26 cm^2	22.5 ± 1.1	23.9 ± 1.4	24.1 ± 1.9	24.8 ± 1.7

The overall dynamics of reduction in the area of the wound defect (Table 3) in patients with TU and CAI of subgroup 1A did not have statistically significant difference in the first 8 days of treatment compared with patients of subgroup 2A (p> 0.05). However, after the 12th day of complex treatment, patients of subgroup 1A showed a clear statistically significant difference (p <0.05) in the healing rate of TU compared with subgroup 2A, and this significant of difference continued until the end of treatment.

Table 3. The dynamics of healing of TU in patients of the 1st and 2nd groups (x ± t).

20th	7.5 ± 3.4 *	13.5 ± 3.9	15.8 ± 3.8	15.9 ± 4.2
24th	4.2 ± 3.5 *	12.7 ± 3.7	15.2 ± 3.4	15.3 ± 3.9

Note. * Statistically significant differences compared with the corresponding subgroups of the 2nd group.

Patients of subgroup 1B with trophic ulcers and CVI also showed a more rapid decrease in the area of the wound defect compared to patients of subgroup 2B, however, no statistically significant differences were observed during the entire period of inpatient treatment ($p > 0.05$).

The main criterion for evaluating the results of treatment was the degree of reduction in the area of the wound defect: “a” - complete wound healing; “b” - reduction of the area of the wound by 70% and more than its original area; “c” - reduction of the area of the wound by 50 - 69%; “d” - reduction of the area of the wound by 30 - 49%; “e” - the absence of signs of regeneration or a decrease in trophic ulcers by less than 30%.

Criteria “a” and “b” were considered as a good result of treatment, satisfactory - criterion “c”, unsatisfactory - criteria “d” and “e”.

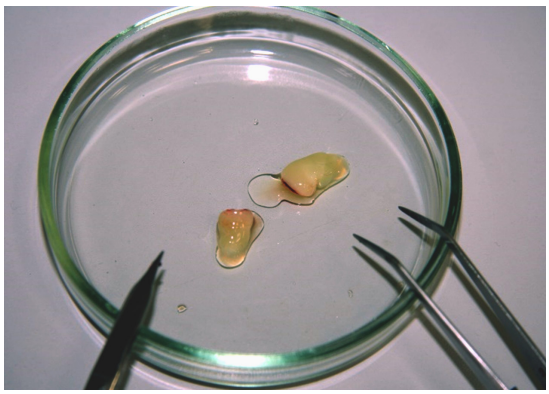

Fig. 2. Concentrates of autologous platelets from autologous blood in a Petri dish.

Fig. 3. Patient H. - application of autogenous platelet concentrates on the surface of the trophic ulcer.

Fig. 4. Patient H. - trophic ulcers of the right foot before treatment.

Fig. 5. Patient H. - healing of trophic ulcers of the right foot for 25 days.

Discussion

Table 4 shows subgroup 1A of 1st group, a good treatment result was obtained in 9 (90.0%) patients, in subgroup 2A - only in 5 (50.0%) patients. A decrease in the area of a wound defect by 50 - 69.0% in subgroup 1A was observed only in 1 (10.0%) patients, in a subgroup 2A - in 30 (30.0%), a decrease in the area of a wound defect by 49% or less in a subgroup 2A was only in 2 (20.0%) patients. A good treatment result was observed in 4 (36.4%) patients of subgroup 1B and in 3 (30.0%) patients of subgroup 2B; unsatisfactory results were found in 3 (27.3%) and 4 (40.0%) patients, respectively.

Table 4. Evaluation of the effectiveness of treatment of patients of the studied groups.

Criteria for evaluation	Groups							
	1st Group				2nd Group			
	subgroups				subgroups			
	1A		1B		2A		2B	
	No. of patients	%	No. of patients	%	No. of patients	%	No. of patients	%
«a»	6	60.0	2	18.2	2	20.0	1	10.0
«в»	3	30.0	2	18.2	3	30.0	2	20.0
«c»	1	10.0	4	36.3	3	30.0	3	30.0
«d»	-	-	3	27.3	1	10.0	3	30.0
«e»	-	-	-	-	1	10.0	1	10.0

Conclusion

A study of the planimetric indicators of the healing of TU in patients of the 1st group, to whom conventional therapeutic measures were supplemented with topical application of APC, showed that the area of wound defects in subgroup 1A was statistically significantly reduced on the 8th and 12th days respectively, compared with subgroup 2A. However, in patients of subgroup 1B, such a significant difference with subgroup 2B in the processes of repair of TU was not established.

As a result of evaluating the effectiveness of treatment, the best indicators were also obtained in patients of subgroup 1A: complete healing of the wound or reduction of its area by 70% or more was found in 60.0% of patients. In the 2nd group, complete or significant healing of TU was achieved only in 20% of patients of subgroup 2A. In turn, in patients with TU and CVI, the treatment efficiency remained low and amounted to 36.4% in subgroup 1B and 30.0% in subgroup 2B.

The use of APC therapy in the complex treatment of TU is clinically effective. The applied method contributed to the acceleration of wound repair processes, a decrease in the healing time of TU, and a statistically significant decrease in the area of the wound defect.

Conflict of Interest: None declared.

Anemia in Children Due to Airborne Lead Exposure of Used Lead-Acid Battery Recycling Area in Jabodetabek, Indonesia

Basuki Rachmat[1], Haryoto Kusnoputranto[1], and Inswiasri[2]

[1]Department of Environmental Health, Faculty of Public Health, University of Indonesia, Depok 16424,
[2]National Institute of Health Research and Development, Ministry of Health of Republic of Indonesia, Jakarta, Indonesia

Abstract

This study aims to determine the relationship between the concentration of airborne lead exposure to anemia in children aged 7 to 13 living near the informal used lead-acid battery recycling area in Jabodetabek. A cross-sectional study was conducted at four locations in Jabodetabek (Tangerang, Bogor, Bekasi and Depok), in which there were informal battery recycling. The study population was children aged 7 to 13 living in the area of informal used lead-acid battery recycling units. The number of children who were willing to participate was 418 children. The respondents were interviewed by using structured questionnaires. Environmental samples measured the airborne lead concentration using High Volume Air Sampler (HVAS) and analyzed using atomic absorption spectrometry (AAS). To identify anemia, blood Hb measurements were taken using HemoCue® Hb 201+ System. The Logistic Regression risk factor model was used to determine the correlation of airborne lead with anemia in children. The results showed an average concentration of airborne lead (n = 52) was 2.96 μg/m^3. The average blood Hb level of children (n = 418) was 11.89 g/dL, with prevalence of anemia of 51.2%. High airborne lead concentration is strongly associated with an increased anemia incidence in children (OR: 3.96; 95% CI: 1.83-8.56) after behavioral factors of calcium intake was controlled (OR: 0.68; 95% CI: 0.46-1.01). This study reveals the correlation between airborne lead exposures and anemia as well as underlines the needs to strengthen the policies, supervision, and development of strategies to reduce airborne lead exposure.

Keywords: *Airborne Lead; Anemia; Battery Recycling; Environment.*

Introduction

Lead is used in many industrial products such as batteries, ammunition, metal products, instruments to shield X-ray radiation and others. [1,2]. The high level of lead pollutants in Guiyu China comes from the burning of used lead-acid batteries and electronic waste containing lead. This affects the high level of lead in blood in children, workers, and breast milk[3]. The high level of airborne lead is associated with the high level of lead in human blood[4].

Lead toxicity affects almost every organ system in the body [5,6]. From a research in Dakar, Senegal on November 2007 to March 2008, there were 18 children who died of progressive (chronic) central nervous system disease which could not be explained in a community involved in a battery recycling in the suburbs[7]. Intoxication of high levels of lead exposure also causes death in children. Children are more vulnerable to lead exposure since they are still in growth stage [8,9].

Airborne lead interacting with population enters human body through oral and inhalation routes [10,11]. Lead in blood will change the hematological system by inhibiting the activity of several enzymes involved in heme biosynthesis that function as red blood cell formation, then disruption of the hematopoietic system will cause a decrease in hemoglobin levels in the body, shorten the life of erythrocytes, and will cause anemia[11,12].

In Indonesia, it is estimated that more than 200 smelters of used lead-acid battery, around 71 smelters are in Jabodetabek [9,13]. Health impacts of illegal smelting of used lead-acid battery for children including difficulties in achieving high grades in school and having stunting or other problems of physical development [13]. Anemia is one of the symptoms caused by the toxic effect of high levels of lead in the blood [14,15]. Until now, the correlation between airborne lead exposure and anemia in children aged 7 to 13 in the area of informal used lead-acid battery recycling in Jabodetabek Indonesia, is still unknown. The purpose of this study is to analyze the relationship between airborne lead exposure concentration and anemia in children aged 7 to 13 years old in the area of informal used lead-acid battery recycling in Jabodetabek, Indonesia.

Method

In 2014, the Joint Committee for Leaded Gasoline Phase-Out (KPBB) conducted a mapping of the location of used lead-acid batteries recycling units in Jakarta and its surroundings [16]. Based on the results of the study, the research location was selected with inclusion criteria: there are locations of used lead-acid battery recycling in residential areas, there is population of children aged 6-13, the children are in good health or have recovered from illness at least 7 days before blood sampling is performed, female children are not menstruating. Thus, the areas that fulfill the inclusion criteria were; Tangerang Regency (Pasar Kemis Village and West Kedaung Village), Bekasi Regency (Satriajaya Village), Depok City (Pancoran Mas Village and Beji Village), and Bogor Regency (Cinangka Village). This study used a cross-sectional data set from a specific research on used lead-acid battery recycling in 2014 to examine the correlation between airborne lead concentration and anemia incidence.

The sample was calculated using Lemeshow formula to test the hypothesis, resulting in the minimum number of samples of 238 children. While from the data collection results of Specific Research on Used Lead-Acid Battery Recycling in 2014, it was found 418 children. Therefore, the number of samples needed in this study was sufficient to meet the minimum requirements. During the data collection, the sample was determined using population list of children aged 7-13 years old in the integrated health service post (Posyandu cadre), and then a random sampling was conducted. The number of samples in each region was determined proportionally, with the inclusion criteria of living <700 m from used lead-acid battery recycling units. So, the sample distribution according to regency/city were Tangerang Regency of 95 respondents, Bekasi Regency of 110 respondents, Depok City 109 of respondents, and Bogor Regency of 104 respondents. Lead sampling in ambient air had a ratio of 1: 10, meaning that 1 sample of air measurement could represent 10 respondents. The total air measurements amounted to 52 locations, with 20 locations in Tangerang Regency, 7 locations in Bekasi Regency, 15 locations in Depok City, and 10 locations in Bogor Regency.

The types of data collected included: 1). Pb levels in the air, measured by collecting airborne lead particles (aerosol) in the filter using High Volume Air Sampler (HVAS), then dissolving each lead in the filter and analyzing sample solutions with Atomic Absorption Spectrometry (AAS) [17]; 2). Anemia was determined by measuring blood Hb with HemoCue® Hb 201+ System, by taking a blood sample of 50 µl from the fingertips (peripheral blood) using microcuvettes and the diagnosis of anemia could be seen from blood Hb less than 12 g/dl [18,19]; 3). Height (BH) was measured using anthropometry; 4) Body weight (BW) was measured using standardized weight scales; 5) Data on individual characteristics, behavior, and education of parents were obtained using a structured questionnaire through an in-depth interview with each respondent. The analysis used descriptive statistics, chi-squared test, and Multivariate Logistic Risk Factor Regression.

Results

Respondent aged 7 to 10 years was 272 respondents (65.1%), Almost all of the respondents had the behavior of washing hands before eating amounted to 336 respondents (87.6%). Most of the respondents' parents had a low educational background (equivalent to junior high or ≤ 9 years) amounted to 303 respondents (72.5%). Respondents exposed to airborne lead ≥ 2 µg/m^3 were 41 respondents (9.8%) and those with anemia were 214 respondents (51.2%).

Table 1. Category Distribution of Child Characteristics, Hb levels, and lead exposure in informal used lead-acid batteries recycling areas (n = 418)

Variable	Total	Percentage
Age		
7 – 10 Years old (Children)	272	65.1
11 – 13 Years old (Teenager)	146	34.9
Nutritional status		
Obesity (≥ 25.0 Kg/m^2)	30	7.2
Non-obese (< 25.0 Kg/m^2)	388	92.8
Sex		
Female	230	55.0
Male	188	45.0
Washing Hands Before Eating		
No	52	12.4
Yes	366	87.6
High Calcium Food Consumption		
No	226	54.1
Yes	192	45.9
Parents' Education		
≤ 9 years old	303	72.5
> 9 years old	115	27.5
Airborne lead		
Not Eligible (≥ 2 µg/m^3)	41	9.8
Eligible (<2 µg/m^3)	377	90.2
Anemia Incidence		
Anemia (Hb <12 g/dL)	214	51.2
No anemia (Hb≥12 g/dL)	204	48.8

Measurement of airborne lead was performed on sunny days. The tool was installed at 1.25 m height from ground level or as high as upper respiratory tract in children. The farthest distance of air measurement location from the used lead-acid batteries recycling was 750 m. From the analysis results, it was found that the average lead level in ambient air in the residential area near the used lead-acid batteries recycling was 2.9 µg/m^3. This value has exceeded the standard value determined by Government Regulation Republic of Indonesia number 41 of 1999 of 2 µg/m^3. According to WHO, anemia in children aged 7-13 years old is known when there is a decrease in blood Hb levels from normal of 12 g/dL. In Table 5.11, the average Hb level of children is 11.89 g/dL, showing that the average respondent is affected by mild anemia or normal. However, there are respondents with very low blood Hb values of 7.7 g/dL, it is assumed that these respondents had acute anemia.

Table 2. Distribution of Airborne Lead Exposure Concentration (n = 52) and Hemoglobin Levels in Blood (n = 418) in the informal recycling areas of used lead-acid battery

Variable	Mean	Median	SD	Minimum-Maximum	95% CI	Quality standards
Airborne lead (µg/m^3)	2.96	0,273	13.23	0.01 -78.05	0.725 – 6.64	2.0
Blood Hb (g/dL)	11.89	11.9	1.36	7.70 – 16.10	11.7 – 12.03	12

In Table 3, the analysis results show that there is a statistically significant correlation between airborne Pb and anemia (p = 0.001). Children who live in areas with high lead exposure concentrations (≥ 2 µg/m3) in ambient air are 3.8 times (95% CI: 1.77-8.20) to suffer from anemia than children living in areas with low lead exposure concentrations (<2 µg/m^3) in ambient air.

Table 3. Analysis Results of Correlation between Airborne Lead Exposure and Other Variables to Anemia in Children Aged 7-13

Variable	Anemia n (%)	P Value	OR	95% CI
Airborne Lead				
≥ 2 µg/m^3	32(78)	0.001	3.81	1.77-8.20
2 µg/m^3	182(48.3)			
Age				
7 – 10 Years old	107 (54.3)	0.269	1.26	0.86-1.86
11 – 13 Years old	107(48.4)			

Variable	Anemia n (%)	P Value	OR	95% CI
Sex				
Female	116 (50.4)	0.806	0.93	0.63-1.37
Male	98 (52.1)			
Nutritional Status				
Obesity	18 (60)	0.417	1.46	0.68-3.13
Non-Obese	196 (50.5)			
Parents' Education				
Low (≤ 9 years)	165 (54.5)	0.04	1.61	1.04-2.48
High (> 9 years)	49 (42.6)			
Hand washing behavior				
Not	22 (42.3)	0.222	0.66	0.37-1.19
Yes	192 (52.5)			
Calcium Behavior				
Not	107 (47.3)	0.107	0.7	0.48-1.05
Yes	107 (55.7)			

From the final modeling above, it can be explained that children living in areas with high lead exposure concentrations (≥ 2 μg/m^3) in ambient air are 3.96 times more likely to develop anemia than children who live in areas with low lead exposure concentrations (<2 μg/m^3) in ambient air after being controlled with the variable of high calcium food consumption.

Table 4. Final Modeling Results of Multivariate Logistic Regression Analysis between Independent Variables and the Anemia in Children Aged 7-13 Years old

Variable	P value	OR	95% CI
Airborne Pb	0.0001	3.963	1.83-8.56
Calcium Consumption	0.057	0.683	0.46-1.01
Constant	0.008	0.120	

Discussion

The analysis results show there is a significant correlation between airborne Pb with anemia statistically. The significant correlation between airborne Pb levels with anemia in children aged 7-13 years old in the area of used lead-acid batteries recycling has answered the research hypothesis. This finding is consistent with the findings of other studies, which revealed that there was a correlation between airborne Pb exposure and anemia [20,21].

The average lead concentration in ambient air in a residential area where there is a used battery recycling activity is 2.9 μg/m^3. This value exceeds the standard value set by Government Regulation Republic of Indonesia No. 41/1999, which is equal to 2 μg/m^3, even though this threshold value is still above the quality standards set by the EPA of 0.15 μg/m^3 [14,22]. If children are exposed to lead for a long period of time, the most dangerous effect for children is a decrease in intelligence and nervous system disorders. Anemia is not one of the dangerous diseases, but if there is a prolonged exposure with a dose exceeding the quality standard, it may cause chronic anemia leading to death [22,23]. Another impact caused by the condition of anemic people will certainly reduce work productivity in the region [24].

Air pollution in the used lead-acid battery recycling has been proven by the high levels of airborne lead. Lead pollution from used lead-acid battery recycling into the surrounding environment occurs at each stage of the process, starting from sorting, evaporation, and combustion. Generally, air pollution in the environment around the informal recycling areas of used lead-acid battery is sourced from the combustion of lead plates producing dust particles containing lead. The dust particles from combustion that is carried by the wind will fall directly onto the residential areas. This happens because the process of informal used lead-acid batteries recycling does not use chimney with filters. Therefore, the local Environment Agency should audit the used lead-acid battery smelting process as well as conduct an airborne lead monitoring around the surrounding area of the recycling operation. Meanwhile, the Community Health Center and the local Health Office should monitor the blood lead level of the local community.

Conclusions

High airborne lead concentrations are strongly associated with an increase of anemia in children (OR: 3,96; 95% CI: 1,83-8,56) after controlled by calcium consumption behavior factor (OR: 0,68; 95% CI: 0,46-1,01). This study shows the correlation between airborne lead exposure and anemia as well as highlights the needs to strengthen policies, supervision, and development of strategies to reduce lead exposure. The local Environment Agency should audit the process of used lead-acid batteries smelting industry as well as conduct airborne lead monitoring in the surrounding area of the recycling operation.

Prototyping Personal Health Records for Type 2 Diabetes Mellitus Prevention

Berly Nisa Srimayarti[1], Kemal N. Siregar[2]

[1]Master Study Program of Health Informatics, [2]Department of Biostatistics and Population Studies, Faculty of Public Health, Universitas Indonesia

Abstract

Background: Diabetes mellitus is one of the four most prioritized non-communicable diseases (NCD) in the world. The global diabetes prevalence increases every year, with type 2 diabetes as the highest contributor. Based on Indonesian Basic Health Research, the type 2 diabetes prevalence for the age group >15 years was 5.7% in 2007, increased to 6.9% in 2013, and reached 8.5% in 2018. Around 70% of people with type 2 diabetes are often unaware of their illness, and 25% of them only realize their condition once they experience complications of diabetes. The purpose of this study is to design a prototype personal health record (PHR), which could help prevent and control the risk factors of type 2 diabetes mellitus.

Method: The method followed the systems development life cycle (SDLC), using the rapid application development (RAD) approach with prototyping techniques.

Results: This prototype provides information regarding diabetes, a main menu for users, medical history data collection, scoring of risk factors for type 2 diabetes mellitus, and health recommendations in the form of text and videos.

Conclusions: This Android-based PHR could be developed further as tool for the prevention of and control of risk factors for type 2 diabetes mellitus. This tool aims to give a dependable prediction of type 2 diabetes mellitus occurrence in the community. This user-friendly application, with its simple design and interface, could encourage users to improve their behavior toward a healthier lifestyle.

Keywords: *Type 2 diabetes mellitus; prevention; personal health record; healthy behaviors.*

Background

The global prevalence of diabetes is increasing, particularly cases of type 2 diabetes. Many people with type 2 diabetes remain unaware of their illness for a long time because symptoms may take years to appear[1]. Around 2/3 of diabetics do not realize that they have diabetes, and various factors may delay their access to health services, so complications often occur[2]. Diabetes is the main cause of blindness, kidney failure, cardiovascular disease, and lower limb amputations. Diabetes is dangerous for mothers during pregnancy: If a diabetic mother's glucose levels are not well controlled this can have an impact on both mother and baby[3]. One solution for the prevention and control of diabetes risk could involve utilizing technological advances—specifically, the use of a Personal Health Record (PHR), which is an Android-based application that is managed individually.

Based on data from the International Diabetes Federation (IDF), the number of diabetes cases world wide is increasing; there were 381.8 million cases in 2013, 415 million in 2015, and 425 million in 2017 (of diabetics in the age range of 20 to 79 years). It is estimated that by 2045 the number of diabetes cases will increase to 629 million people globally. About 80% of diabetics are in low- and middle-income countries[3].

Cases of diabetes are also increasing in Indonesia. Based on Indonesian Basic Health Research, the

Corresponding Author:

e-mail: nazarudin.kemal51@gmail.com

national prevalence of people with type 2 diabetes >15 years old, increased from 5.7% in 2007 to 6.9% in 2013 and reached 8.5% in 2018. Furthermore, diabetes is a disease that is not fully diagnosed: Around 70% of people with type 2 diabetes are unaware of their illness, and 25% of them only realize their condition once they experience complications from diabetes[4]. If this situation is not immediately managed, it ispredicted that by 2045 Indonesia will be among the top 10 countries with diabetic cases(the others are India, China, the United States, Mexico, Brazil, Egypt, Indonesia, Pakistan, Bangladesh, and Turkey)[3].

An increase in prevalence will also increase the health financing burden. Based on data from the Center for Health Financing and Assurance in Indonesia, the cost of type 2 diabetes in outpatient data up to June 2014 amounted to 485 million from 1,415 cases handled, and the 70,584 cases of hospitalization cost 313 billion IDR[4].

Personal Health Record (PHR) is one of the tools of m Health, which is a user-centered health information system[5]. PHR is an internet-based individual health record; with it, a patient can access and coordinate their lifetime health information with their health service providers[6,7]. This suggests there is an opportunity to design a Personal Health Record prototype to prevent and control risk factors for type 2 diabetes. The application could help a person control their health, and the health recommendations made by the app would motivate changes in health behavior of the users.

Because of advancements in technology, prevention of disease and control of personal health can be done individually through an application on cellular phones. Based on the Central Bureau of Statistics, in Indonesia data cellular telephone users reached 59.59% in 2017. This growth was followed by internet access in as many as 57.33% of households[8]. This advancement in technology and information is accepted by people of various ages and socio-economic status, and represents an opportunity for self-management in the prevention and control of type 2 diabetes mellitus, by facilitating self-monitoring habits[9].

Method

The prototype design used for the PHR was the systems development life cycle (SDLC). SDLC is a method describing the route that directs developers from problems to solutions. The particular SDLC method used was rapid application development (RAD) with prototyping techniques. RAD was selected as it has a short and fast system development cycle a technique that fit within the time constraints of the study[10].

Identification of system requirements was done through data collection by in-depth interviews, observations, and systematic studies at the Health Office and Beji Public Health Center, Depok City, in February–May 2019. Five informants were used in this study: one member of the non-communicable disease (NCD) prevention program in Depok City Health Office, one diabetes mellitus (DM) program holder at Beji Public Health Center, and three general practitioners at Beji Public Health Center. The design of the prototype in this study was carried out to meet level 4 of the Technology Readiness Level scale (TRL). Tests were carried out to validate components against application prototypes that had been built on a laboratory scale.

Results

The research was carried out by (1) needs analysis and (2) feasibility analysis, to assess whether this application can be built and will provide benefits. Next, (3) RAD was used to make Android-based applications, and (4) Diagram of using PHR steps.

1. **Needs Analysis:** Needs analysis is done through in-depth interviews and observations in the field. This analysis revealed several obstacles that have prevented diabetes prevention programs from running optimally. The existing problems identified were the following:
    1. Cases of diabetes continue to increase, and the costs of diabetes and its complications are high.
    2. Existing applications related to prevention and control of risk factors for type 2 diabetes mellitus (NCD surveillance) have not been able to detect whether an individual has been screened individually before.
    3. There is a lack of public interest in visiting the Integrated Development Post NCD (Posbindu) program.
    4. There is no individual-based application for the prevention and control of type 2 diabetes mellitus risk factors.
    5. Increasing awareness and changing public health behavior are needed to carry out preventive activities.
2. **Feasibility Analysis:** The TELOS criteria (technics, economics, law, operations, schedule) were used to determine whether this application is feasible[11].

1. Technical Feasibility: The development of a system is based on the reasons why the system must be built and its expected value[10]. If the desired application is user friendly, easy to access, and inexpensive, then technically the proposed system requirements can be declared feasible. The proposed PHR application can be developed and implemented using Android.
2. Economic Feasibility: The main consideration in terms of economics is to calculate the profits and loss from designing the application. Based on the results of a World Economic Forum publication in April 2015[12], the potential loss due to NCDs in Indonesia in the 2012–2030 period is predicted to reach US$ 4.47 trillion, or 5.1 times Indonesia's 2012 gross domestic product (GDP). This shows that there is a high expenditure in cases of NCDs, one of which is diabetes mellitus. Furthermore, the appearance of NCDs in the 2030 Sustainable Development Goals suggest that NCDs should be made a national priority[12].
3. Legal Feasibility: The Minister of Health Regulation of the Republic of Indonesia has shown that e-healthcare applications area solution to support the care and handling of health services by utilizing technological advances. PHRs can be developed in Indonesia as a solution to healthcare issues[13].
4. Operational Feasibility: An assessment of operational feasibility is conducted by looking at how the application operates. This application processes automatically, so after inputting data according to the existing variables, users will receive health recommendations[14].
5. Schedule Feasibility: Data were collected until the prototype was made in February to May 2019.

3. **Rapid Application Development: Making Android-Based Applications:** Figure 1 outlines the process of making an Android-based application using the RAD method and the Android studio tool.

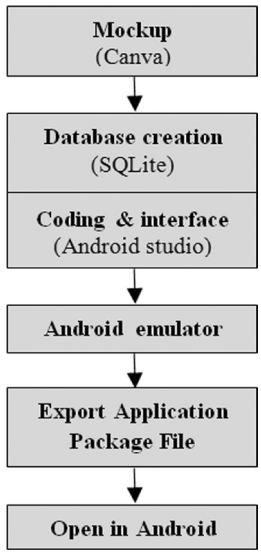

Figure 1. Steps for making Android-based applications

4. Diagram of Using PHR Steps

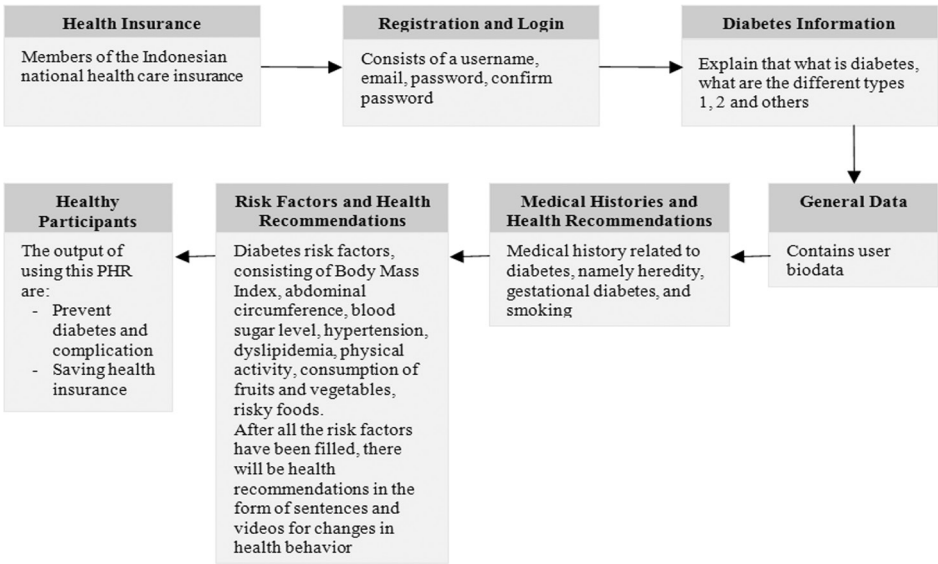

Figure 2. Steps of using PHR Android-based application.

Discussion

1. **Application Design Implementation:** Based on the guidelines, the prevention and control of type 2 diabetes mellitus is a promotive and preventive program from a public health center. The program is conducted in the Posbindus in the villages. However, only a few people visited their local Posbindu[15].

The type 2 diabetes mellitus (DM2) PHR application is an application designed to make it easier for health service providers, cadres, and the public to prevent and control risk factors for type 2 diabetes mellitus. The general data available in this application are similar to the general data provided by the NCD surveillance by the Ministry of Health. But this application is designed specifically for diabetes mellitus. PHR can be a form of primary care development[16].

This study produced an application prototype which can later be developed and integrated with the applications in public health centers. This application can be used anywhere and anytime and it could help public health center in collecting data. Thus, prevention and control of risk factors for type 2 diabetes mellitus can be managed, and data collection can also be implemented properly.

2. **Advantages and Development to the Next Level:** This application has several advantages. First, it can be used as a tool for type 2 diabetes mellitus prevention and the control of associated risk factors. Second, the application is easily accessible because it is based on Android. Third, it will educate people about managing risk factors for diabetes, via its diabetes mellitus information menu. Fourth, it will help motivate changes in health behavior, because it includes a menu of information on diabetes, general data, medical histories, risk factors and health recommendations. Fifth, users can learn more about the potential risks of type 2 diabetes mellitus.

Despite these advantages, this Android application requires improvement to reach the next level of implementation in accordance with the TRL. First, this application can only be used on Android-based smart phones. Second, it requires internet use, so it depends on users having an internet connection. Third, it cannot yet be integrated with applications in public health centers. Fourth, it cannot store data continuously.

3. **Technology Readiness Level (TRL):** The prototype follows the level 4TRL standards (see Table 1).

Table 1. Technology Readiness Level (TRL)[4]

Level 4 TRL Standards	Prototype Level
1. Separate laboratory tests of components have been carried out	Design and coding are carried outand databases are created and tested in Android emulator, after which they are extracted as files in the form of anApplication Package (APK).Trials are carried out on Android, with a minimum specification of 2 GB RAM, 1080 x 1920: 420dpi resolution, and API 15: Android 4.0.3 (Ice Cream Sandwich).
2. System requirements for applications according to the user are known	Analysis and identification of needs have been carried out through in-depth interviews, observations, and document studies at the Depok City Health Office and BejiPublic Health Center.
3. The results of laboratory experiments on components indicate that it can operate	The trials carried out indicate that the application can operate in Android.
4. The main functions of technology in the relevant environment have been experimented with	A menu has been created in the Personal Health Record (PHR) application, resulting in a resume and health recommendations for changes in health behavior.
5. Laboratory-scale technology prototypes have been made	The application is designed at a laboratory scale based on risk factor guidelines for type 2 diabetes mellitus and general data (identical to the data in non-communicable disease surveillance).
6. Component integration research has begun	Component integration starts from the needs analysis in the field; then components are designed in the Android application.
7. The key process has been identified and reviewed in the laboratory	The application includes a menu with the available DM2 information, general data, medical history data, and risk factor data. After data input is carried out, a resume and health recommendations will be provided.
8. Integration of technology systems and laboratory-scale design has been completed[17].	The design was tested on members of the Faculty of Public Health in Universitas Indonesia, using Android, the Java programming language, and the SQLite database[18].

Conclusions

Based on the results obtained during the design of the Personal Health Record prototype to prevent and control the risk factors for type 2 diabetes mellitus, the following conclusions are drawn:

1. PHRcan be a usefulAndroid-based tool for developing a complete health record for the prevention and control of risk factors for type 2 diabetes mellitus.
2. The feasibility study conducted allows this application to provide valuable benefits and shows it can be developed to the next levelof technological readiness.
3. Users can discover their potential risk for type 2 diabetes mellitus.
4. The application can provide health information and recommendations to encourage behavioral change in users.

Ethical Considerations: This study was approved by the Ethical Committee of the Faculty of Public Health, Universitas Indonesia (No.43/UN2.F10/PPM.00.02/2019).

Conflict of Interest: The authors declare that there are no conflicts of interest.

Acknowledgements: The authors are very grateful to the Depok Health Office and Beji Public Health Center, which provided research facilities.

Abstract

Non-syndromic cleft lip and palate is a common face malformation of all ethnic in population and one of factors caused it was nutritional deficiency. Micronutrient deficiency which mostly occurred in developing countries were Zinc (Zn) and folate acid deficiency. The deficiency of Zn serum in pregnant women was suspected in increasing the complication risk during pregnancy and the deformity risk of non-syndromic cleft lip and cleft palate. This study aimed to analyze the correlation between mother's zinc level and their babies which suffered with non-syndromic cleft lip and palate, also to determine the median of zinc level among mothers and babies between group of cleft lip, cleft palate, and cleft lip & palate. This was observational and analytical study with cross-sectional design. The participants were 35 babies with Non-syndromic cleft lip and palate and their mother attended the unit of perinatology, Dr. Hasan Sadikin Hospital, Bandung and network hospitals during September 2016-June 2017. The study used consecutive sampling to measured zinc level with ICP-AES (Inductively Coupled Plasma-Atomic Emission Spectrometer) method. The result showed the mean of zinc level among mothers was higher than the babies. The test showed significant correlation ($p=0.04$ or $p<0.05$) with the correlation coefficient $r=0.35$ with term of moderate correlation. There was no difference in median of zinc level among mothers and babies between group of cleft lip, cleft palate, and cleft lip & palate. It concluded that there was moderate correlation between zinc level between mothers and babies with non-syndromic cleft lip and palate.

Keywords: *Baby, non-syndromic cleft lip and palate, zinc level, mother, deficiency.*

Introduction

Non-syndromic cleft lip and palate defined as a common face malformation occurred in the community and ethnic group. The cases reported were about 65% from all anomalies on the head and neck[1–3]. Approximately 70% of orofacial clefts were isolated and non-syndromic deformity; classified into two groups which were cleft lip with or without cleft palate and cleft palate only[4–12]. This might be occurred in unilateral or bilateral involved tissue on lips, alveolus bone, nasal base, and cartilage bone both part and complete[8,12]. The Prevalence of cleft lip and palate are varied depending on race and ethnic, geographical location, and social-economy[1,3,13]. Prevalence from several races were high in Asian and American-Indian with ratio of 1 per 500

Corresponding Author:

births followed by European with 1 per 1000 births, and Caucasian & African that had lowest prevalence rate of 1 per 2500 births. The prevalence of cleft lip and palate in Indonesia has remained unknown. Kembaren[14] reported that the people with cleft lip and palate in Indonesia increased with average of 7,500 persons per year.

One of the factors influenced to the prevalence of cleft lip and palate was nutritional deficiency. Since the beginning of twentieth century, many studies found that malnutrition related to cleft lip and palate. The nutritional intake of the low social-economy and low educated mother correlated with the increased prevalence of cleft lip and palate[15,16]. The women in modern era could obtain lots of food but their malnutrition status particularly because of zincdeficiency[16]. High substance of dietary zinc and iron commonly found in food source such as oyster, beef, turkey, chicken, cereal, and processed beans[17]. The severe stage of Zn deficiency among mothers could be the risk factor of cleft lip and palate[12]. This study aimed to analyze the correlation of Zinc level between mothers and babies with the occurrence of non-syndromic cleft lip and palate.

Method

This study was analytical and observational research with cross-sectional design. The research was conducted at Dr. Hasan Sadikin Hospital and network hospitals in Bandung such as Ujung Berung Hospital, Cibabat Hospital, Mother and Children Hospital, and Indonesian Cleft Center during September 2016 until June 2017. The participants were 35 babies with cleft lip and palate, and mothers who attended the hospital mentioned above. The sample technique used consecutive sampling that eligible with the inclusion and exclusion criteria, and limited time.

The method to assess Zinc level was ICP-AES (Inductively Coupled Plasma – Atomic Emission Spectrometer). Statistical analysis used spearman test to analyze the correlation Zinc level between the mothers and their babies, and chi-square Kruskal-Wallis test to analyze the difference Zinc level in mothers and babies among phenotype types of cleft lip, cleft palate, and cleft lip & palate.

Results

Table 1 depicted the characteristic of participants in this study. Most of mothers were 25 – 29 years old (34%) and the other were distributed into 6 age groups. The characteristic of babies was divided into sex and type of cleft lip and palate. Most of babies were female (60%) and suffered unilateral cleft lip and palate (66%).

Table 1. The Characteristic of Participants (n=35)

No	Participant	Characteristic	Frequency	
			n	%
1.	Mothers	Age group (years old)		
		15 – 19	3	8.57
		20 – 24	4	11.43
		25 – 29	12	34
		30 – 34	10	28
		35 – 40	4	11.43
		≥40	2	5.71
2.	Babies	Sex		
		Female	14	40
		Male	21	60
		Deformity type		
		Cleft lip	5	14
		Unilateral Cleft Lip & Palate	23	66
		Bilateral Cleft Lip & Palate	2	6
		Cleft Palate	5	14

Table 2. The Correlation Spearman Test of Zinc Level between Mothers and Babies with Non-Syndromic Cleft Lip & Palate

Variable	Mothers				Babies				p	R
	N	Mean	SD	Median	N	Mean	SD	Median		
Zinc level	35	5.05	3.30	4.75	35	3.39	2.14	2.99	0.04	0.35

Table 2 showed there was a correlation of zinc level between mothers and babies with non-syndromic cleft lip and palate ($p < \alpha$=?). The correlation coefficient that showed by r between both variables was moderate. The mean and median of Zinc level in mothers were higher than the babies.

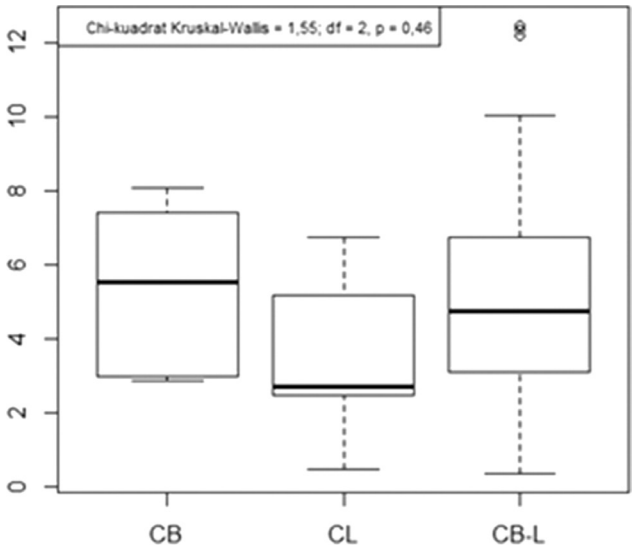

Figure 1. Zinc Level in Babies with Phenotype of Cleft Lip, Cleft Palate, and Cleft Lip & Palate

The median of Zinc level in babies with phenotype of cleft lip & palate was the lowest (2.93 µg/dL) from other phenotypes of cleft palate (3.53 µg/dL) and cleft lip (2.99 µg/dL). The figure 1 depicted the result of Chi-Square Kruskal-Wallis that there was no difference (p=0.99) Zinc level in babies among phenotype types.

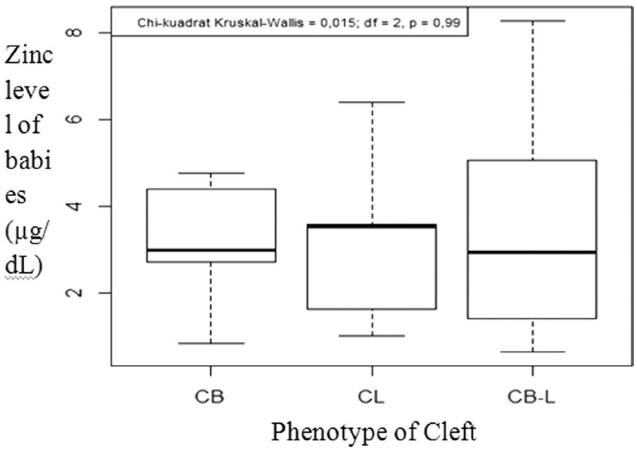

Figure 2. Zinc Level of Mothers who had Babies with Cleft Lip, Cleft Palate, or Cleft Lip & Palate

The median of zinc levels of mothers with cleft lip baby was the highest (5.54 µg/dL) among other phenotype of cleft palate (2.68 µg/dL) and cleft lip & palate (4.75 µg/dL). There was no difference in mothers with baby suffered cleft lip, cleft palate, and cleft lip & palate based on result of Chi-square Kruskal-Wallis (p=0,46). Most of the babies with cleft palate (75%) were under the median of zinc level, otherwise the majority babies with cleft lip was above the median value.

Discussion

Heredity and environment factor such as mother's nutritional status was known to be an influence variable in etiology towards orofacial cleft including cleft lip, cleft palate, and cleft lip & palate[18,19]. The sex ratio in babies suffered cleft lip & palate according a prior research was 3:2 for male and female[12]. Some studies indicated that nutritional deficiency from folate, cholesterol, multivitamin, and micronutrients like Zinc of the mothers might increase the risk of orofacial cleft in babies[18-20]. Otherwise, food fortification by adding the folate for pregnant women was proven in some studies to reduce the risk of orofacial cleft in babies[18,21]. However, the function of Zinc level as the risk factor of orofacial cleft in babies has been controversy. Study by Munger et al.[20] in 2005 showed Zinc deficiency in Philippine mothers had been associated in increasing the risk of orofacial cleft in babies, but the result could not be replicated in the Utah population, US.

The pregnant women according the literature should need Zinc with amount 11.5-11.75 mg/dL to meet the normative requirement during pregnancy. As stated by Caulfield et al., about 82% pregnant women in the world had less intake of Zinc[22]. However, the study did not apply for the developed countries because the pregnant women had higher weight and Zinc intake than the women in the developing countries[23].

Deficiency of zinc serum in pregnant women was suspected to be a factor that might increase the complication risk during pregnancy and risk of congenital deformity of lip and palate. The research conducted in East Nusa Tenggara showed average of 71% of pregnant women suffered deficiency of Zn serum (<7µg/dl). Another study conducted in Central Java stated the prevalence of deficiency of Zn serum was about 70%-90%[24]. The data and reports of epidemiology, and experimental research showed severe Zn deficiency might cause deformity fetus[23,25], and cleft lip and palate, malformation of brain and eyes, various heart abnormal, lungs and urogenital system[25].

Zn is an important element for enzyme function and growth hormone during pregnancy, so it played important role in growth. For the example, during pregnancy, placental alkaline phosphates required Zn to induct DNA synthesis and cell proliferation[26]. The lowest Zn in plasma correlated with complication of pregnancy like hypertension, postpartum bleeding, spontaneous abortion, and congenital malformation[27].

It was important for pregnant women to haveadequate nutritional intake before and during pregnancy to achieve its optimum. However, many reproductive women in sub-Sahara Africa particularly who lived in the poor village experienced deficiency because they had less intake of essential nutrition. Severe nutritional deficiency could lead the risk factor for both mother and her baby. As deficiency of iron and zinc frequently happened, about 56% of sub-Sahara African women were estimated with anemia and about 80% of sub-Sahara African women were risked of Zinc deficiency because inadequate food intake. Nutritional deficiency in women was related to bad pregnant result including low birth weight, young maternal age, and prematurity[28].

The status of maternal nutrition was influenced the nutritional element in placenta and fetus. The fetus during pregnancy was depended on nutritional transport to placenta. The nutrition was carried via special transporter located at placenta and basal microvillus membrane. The result from animal experiment showed a low micronutrient intake in mothers caused high signal from the fetus to regulate expression and activity of microscopic transporter in placenta. When the nutritional intake was adequate for the mother, the expression and transporter activity was lower than the inadequate intake. Thus, the response of nutritional placenta transporter to status of maternal nutrition was a key to assess the growth of fetus nutritionduring pregnancy[29].

Nutritional factor had an important role for growth and embryo differentiation including Zinc. As eloquently stated by the past research that low zinc level in mothers might increase risk of orofacial cleft, it was not clear whether low zinc level factor in mothers and babies could be associated with all of orofacial cleft phenotypes or only one of phenotypes considering Zinc was needed in palatogenesis process during the beginning of embryogenesis.

According to this study, zinc level which was under the median mostly occurred to babies with cleft palate. The trend of low zinc level was more associated with cleft palate phenotype than other two orofacial cleft phenotypes. This study coincided with the reference that mentioned Zinc was needed in palatogenesis process during the beginning of embryo growth. Zinc deficiency might interrupt the process of palate fusion; suspectedto be the cause of cleft lip in babies.

Conclusion

There was correlation of Zinc level between mothers and their babies suffered non-syndromic cleft lip and palate. The correlation coefficient was categorized in moderate correlation. In addition, there was no difference of median in zinc level of mothers and babies among phenotype types of cleft lip, cleft palate, and cleft lip & palate.

Abstract

Objective: This study aims analyze the effect of psychoeducation-modification (MP) intervention on the improvement of spiritual response, perception stigma, anxiety level, and cortisol levels among lepers.

Method and Materials: This study was a mixed method design. The first stage used qualitative method to develop a psychoeducation-modification module and the second stage was a quantitative method with quasi-experiment using pre-test post-test with control group design. The population was patients who received MDT (Multi Drugs Therapy) treatment, with a total sample of 35 respondents. Statistical tests used the T test, ANOVA test, and pathway analysis. Interventions for psychoeducation-modification were provided in 5 sessions and each session 60-90 minutes

Results: There were significant differences in mean scores of spiritual response, perception stigma and anxiety levels scores between intervention group and control group (p-value <0.05) and there was no difference in mean scores of cortisol levels intervention group and control group (p-value> 0.05). The psychoeducation modification effect was more targeted at improving emotional and spiritual intelligence which had an impact on the improvement of spiritual response, Perception Stigma, anxiety level and stability in cortisol levels decrease.

Conclusion: Psychoeducation-modification was effective in improving spiritual response, perception stigma, anxiety level, and cortisol levels among lepers compared to intervention using psychoeducation only. It is recommended to integrate psychoeducation modification intervention into the leprosy prevention service program as a holistic service that includes spiritual bio-psycho-social aspects.

Keywords: *Intelligence, spiritual response, Perception Stigma, anxiety level, cortisol levels.*

Introduction

The psychological effects of leprosy stigma are changes in emotions such as fear, anxiety, depression, loss of self-esteem, withdrawal, despair, and stress[(1),(2)] Studies among blacks in South Africa reported that one third of them thought of suicide when they were diagnosed with leprosy[(3)]. In Indonesia the discovery of a new case of NCDR (New Case Detection Rate) leprosy still continue, it is static and tends to increase in prevalence[(4)]. In 2011-2013 there were 14 provinces including West Java in the category of high leprosy burden.[(5)]Based on the health profile of the Cirebon District Health Office, it was found NCDR in 2017 of 10.2% per 100,000 population and in 2018 of 10.15% per 100,000 population[(6)]. A study in Bangladesh among 189 lepers found 50% perception stigma. A study among

77 lepers showed that 90.9% experienced anxiety and 58.4% lost self-esteem[7].

Anxiety due to stigma can cause distress. Stress activates two systems in the body, the first system is the autonomic nervous system and the second system is the hypothalamus pituitary axis and the adrenal gland. Activation of the hypothalamus will trigger the anterior pituitary gland to secrete adrenocorticotropic hormone (ACTH). The ACTH hormone will stimulate the adrenal cortex to secrete cortisol[8]. Psychological problems affect physical, emotional, intellectual, social and spiritual conditions[9]. The awareness of the patient that he has leprosy will make him able to cope with the disease well. The ability to accept illness is based on intelligence, spiritual, emotional, intellectual, and adversity of the patient.

Some programs that have been carried out and developed by the Government have not been optimal, including there are no efforts to reduce the problem of stigma and even the spiritual aspects of lepers so that patients are more distressed, the patients' condition worsen, which causes their quality of life to decline[10]. The cause of leprosy stigma is an error in the perception of the cause of leprosy. Misperception of the cause and all conditions due to leprosy is a cognitive process error. Then the intervention can be done through psychoeducation[11]. Various studies proved that one's level of faith was closely related to immunity. For example some verses in a religion (Islam) can be practiced as a prayer for those who are suffering from stress, anxiety, depression or other physical illness[12].

There was a previous study related to stigma, namely group counseling (psychoeducation therapy) but there was no session to improve emotional aspects in the topic of the intervention given. There had been no efforts on the spiritual impact due to the stigma of leprosy. This study aims to prove and explain the effect of psychoeducation modification intervention on the improvement of spiritual response, Perception Stigma, anxiety level, and cortisol levels among lepers.

Method and Materials

Study Design: This study was a combined study which used mixed method, wherein the first stage used qualitative method to develop a psychoeducation modification module and the second stage was a quantitative method with quasi-experiment using pre-test post-test with control group design.[13] The study population was patients who received MDT. The total sample in 3 groups was 35 lepers. The sampling technique used cluster sampling and simple random sampling techniques.[14]This study was conducted in Cirebon District. Statistical tests used One-way ANOVA, Kruskal-Wallis test and PLS (Partial Least Square) path analysis.

Description of Treatment Model: The treatment group consisted of three groups, the first treatment-group was psychoeducation modification (MP) that was given psychoeducation modification intervention and standard therapy for leprosy prevention program namely Multi Drugs Therapy (MDT), the second treatment group was psychoeducation (P) that was give psychoeducation intervention and MDT, and the control group (control group) K) was only given standard therapy of MDT. Psychoeducation modification intervention was provided in 5 sessions and consisted of 3 intervention topics namely knowledge management, anxiety management and prayer. Each psychoeducation modification intervention session lasted for 60-90 minutes

Results

The mean age of the study subjects in group MP was 31.42 years, in group P was 33.91 years and in group K was 45.50 years. The mean duration of treatment in group MP was 6.08 months, in group P was 6.91 months, and in group K was 10.25 months.

* Anova test, ** Post Hoc Test

Psychoeducation modification reduce anxiety level score among lepers (p-value of<0.05). Psychoeducation modification reduce in the mean score of cortisol (p-value of > 0.05). The path in the study showed that psychoeducation modification effect was more targeted at improving emotional and spiritual intelligence which had an impact on the spiritual response improvement, Perception Stigma, anxiety level and stability in cortisol levels decrease.

Discussion

Psychoeducation modification increase the spiritual response score among lepers. Positive emotional reactions could improve a person's immune system[15]. Previous study stated that participation in spiritual therapy programs could improve spiritual condition, quality of life, including physical, emotional, and social functions among breast cancer sufferers[16] through counseling with a spiritual approach among pregnant women[17]. Prayer during illness produced physical benefits such as reducing blood pressure, psychological benefits such as decreased depression, anxiety, and spiritual benefits. Patients stated that prayer could give them comfort and had a positive effect on the recovery of their pain[18].

Psychoeducation modification decreased the perceived stigma score among leprosy patients.

Psychoeducation is a therapy to provide information to sufferers who experience distress and can improve skills and coping due to health problems[19]. To change attitudes, it is very important that a patient is consistently exposed to new information that can be integrated into his view. Psychoeducation provides a cognitive framework that help accept their illness and improve adherence, reduce psychological which in turn provided hope about opportunities for a productive life[20]. Previous studies stated that psychoeducation significantly reduced the Perception Stigma and provided greater coping after treatment among patients with chronic mental illness[20]. The concepts developed from previous studies are related to the Perception Stigma by involving a spiritual approach[21],[22]. People with skin disorders often experienced stigma and even discrimination, the countermeasures by spiritual method had brought healing to the stigma they felt[23].

This study proved that psychoeducation modification could reduce the anxiety level score among lepers. Psychotherapy could influence psychobiological responses to stress including cognitive assessment and coping style[24]. Regarding physiological aspect, relaxation can reduce anxiety through the mechanism of increasing parasympathetic nerves by inhibiting the work of sympathetic nerves. The relaxation response caused by the parasympathetic nerve works by stimulating the adrenal medulla to decrease epinephrine, norepinephrine, cortisol release and increase nitric oxide. This situation will cause changes in the body's responses such as a decrease in pulse rate, blood pressure, oxygen consumption, metabolism, and a person will feel comfortable[25].

These results are consistent with previous studies, which stated that psychoeducation interventions could reduce anxiety and depression in heart disease[26]. Education could reduce anxiety, depression, and stress among pulmonary TB patients[27]. Spiritual interventions could reduce anxiety levels among preoperative patients. [28]Post-prayer evaluation showed decreased anxiety and depression, and a greater spiritual state compared to baseline size among patients with depression and anxiety[29]. Prayer therapy was effective with a significant difference in anxiety levels between the intervention group and the control group among cancer patients[30].

This study proved that psychoeducation modification could reduce cortisol levels among leprosy patients. When the body meets with stressors, the body will activate the nerve and hormone responses to carry out defense measures in order to cope with emergencies. General adaptation syndrome is controlled by the hypothalamus. The hypothalamus will directly respond by activating the sympathetic nervous system. It also releases CRH to stimulate ACTH and cortisol secretion. Sympathetic stimulation will cause epinephrine secretion, both of which have secretion effects on insulin and glucagon by the pancreas. A balanced body system affects the hormonal balance in a physiological state. When the remembrance focus phrase is combined with the relaxation response it can inhibit the work of the sympathetic nervous system which regulates the speed of the heart rate, pulse, respiration and metabolism[31]. Previous study showed an effect on the decrease in cortisol hormone production among HIV/AIDS sufferers, but overall there was no significant difference between the treatment and control groups[32],[33].

Emotional intelligence is very necessary to cause patience which will further show the important role of spiritual intelligence. The path showed that psychoeducation modification effect was more targeted at improving emotional and spiritual intelligence which had an impact on the improvement of spiritual response, perception stigma, anxiety level and stability in cortisol levels decrease.. The mechanism of the relationship between emotional and spiritual states on the cortisol levels can be performed through human cognitive proces which may cause changes in cortisol levels as a marker of emotional and spiritual situations[34),(35].

Conclusion

It can be concluded that psychoeducation modification was effective in improving spiritual response, Perception Stigma, anxiety level, and cortisol levels among lepers. The path showed that psychoeducation modification effect was more targeted at improving emotional and spiritual intelligence which had an impact on the improvement of spiritual response, perception stigma, anxiety level and stability in cortisol levels decrease. It is recommended to integrate psychoeducation modification intervention into the leprosy prevention service program as a holistic service that includes spiritual biopsychosocial aspects. It is necessary to improve emotional and spiritual intelligence so that it can improve the immunity of lepers which in turn have an impact on the healing process of the illness.

EEBE-HOTS: Developing Environmental Enrichment Book Eco-label Based on Higher Order Thinking Skills for 21st Century Learning

Diana Vivanti Sigit[1,2], Mieke Miarsyah[1], Ilmi Zajuli Ichsan[1]

[1]Master Program of Biology Education, [2]Program Study of Biology Education, Faculty of Mathematics and Natural Science, Universitas Negeri Jakarta, Indonesia

Abstract

Environmental learning about eco-label in schools has not been done too much. The purpose of this study was to develop an Environmental Enrichment Book Eco-label based on HOTS (EEBE-HOTS). The research method used is research and development by Borg and Gall model (2003). The research was conduct in April-June 2019 at the State University of Jakarta (Jakarta State University). The results of the study showed that EEBE-HOTS is very valid and suitable for used in learning with average score percentage from learning material expert (92.65%), learning media expert (89.71%), user 1 (98.53%), user 2 (89.71%), user 3 (88.24%), and user 4 (94.12%). EEBE-HOTS is an innovation in 21st-century learning because it is very contextual with current environmental problems. Besides that, EEBE-HOTS can be applied online. The conclusion is that EEBE-HOTS products can be used in learning.

Keywords: *Eco-label, enrichment book, environment, HOTS.*

Introduction

Environmental problems are a problem that must be solved. One of the environmental problems that we are facing is using environmentally friendly products. Environmentally friendly products have several characteristics, for example, made from environmentally friendly materials, environmentally processes, and product packaging also adheres to environmentally friendly principles. The problem is that most people do not understands the production process of a product. This is one of the reasons of an eco-label problem study[1–3].

Eco-label is a label contained in a product that indicates product is environmentally friendly or not. A product that has an eco-label means that the production process has gone through stages that are environmentally friendly[4,5]. The next problem is that many people do not understand the various types of eco-labels. Especially for students at the secondary school level, Junior High School and Senior High School, they are a group of consumers who must know eco-labels. The problem that arises is that there has not been much learning about eco-labels in schools. Teachers in school usually convey information about the general environment and do not follow the current issues including eco-labels [6–8].

Students need Higher Order Thinking Skills (HOTS) in solving environmental problems specially related to the eco-labels. Student need to analyze, evaluate the product according to the eco-label or not. They should also be able to create innovations about environmentally friendly products, for example making eco-friendly shopping bags[5,9,10].

This problem can be overcome by developing a book specifically discussing eco-label topicsthrough HOTS. Based on research in the world that has been carried out relating to eco-labels is about people's perceptions of eco-labels[1,11,12]. Studies are still lack in developing about eco-labels books and are still thinking about implementation in schools. Also, in other studies related to HOTS, many studies only discussed the HOTS profile of students[13–16]. Not many have done eco-label

e-mail: dianav@unj.ac.id

development related to HOTS. Based on this, the novelty of this research is a development topic on Eco-label and HOTS-based topics. The purpose of this research was to develop Environmental Enrichment Book Eco-label based on HOTS (EEBE-HOTS).

Method

This research was conducted in April-June 2019. This study used research and development method by following the steps of Borg and Gall. There are 6 steps from development research, namely (1) Conduct analysis of various references/needs assessment (2) Conduct development planning (3) Develop Products (4) Conduct limited trials (5) Revise products (6) Conduct trials with larger scale [17].As for this study only carried out only until the third stage until product development.

In the first stage, a needs analysis was carried out, referring to previous research that found that the enrichment eco-label was a product that was rarely developed before at the school and university level[6]. In the second stage, EEBE-HOTS product development planning was carried out at the State University of Jakarta (Universitas Negeri Jakarta), Indonesia. Then the third step is to develop EEBE-HOTS products.

Products developed are in the form of electronic books (e-books) with the contents of the book (1) definition of eco-label (2) type of eco-label (3) how to assess a product based on eco-labels (4) student activity sheets. The HOTS aspect used is analyze, evaluate, and create [18]. The HOTS aspect is inserted in the contents of the book and activity sheet. Then after development, material and media validation tests were carried out. The experts appointed as material and media experts are lectures on the Biology education program, and four Biology teachers as users. The validation criteria used refer to Ratumanan & Laurens [19]. Also, the data is also presented as a percentage. The percentage category refers to the category validation, according to Akbar[20]. More details can be seen in tables 1 and 2.

Table 1. Category validation based on score interval

Score Interval	Category
$3.25 < x \leq 4.00$	Very Valid
$2.50 \leq x \leq 3.25$	Valid
$1.75 < x < 2.50$	Less Valid
$1.00 < x < 1.75$	Not Valid

Source: Ratumanan& Laurens[19]

Table 2. Validation categories based on percentage scores

Percentage Score	Category	Note
81 % - 100%	Very Valid	Can be used without repair
61 % - 80%	Valid	Can be used with a little improvement
41 % - 60%	Less Valid	Can be used with many improvements
21 % - 40%	Invalid	Cannot be used
0% - 20%	Invalid	Cannot be used

Source: Akbar[20]

Findings And Discussion

The results of development products are made in full color and use Indonesian language. In the cover section, there is a book title, author's name, and also an illustration of eco-label. While in the contents of the book there is an explanation of eco-labels and various types of eco-labels such as the Forest Stewardship Council (FSC) logo, the Program for Endorsement of Forest Certification (PEFC), the Marine Stewardship Council (MSC), etc. More details can be seen in Figure 1

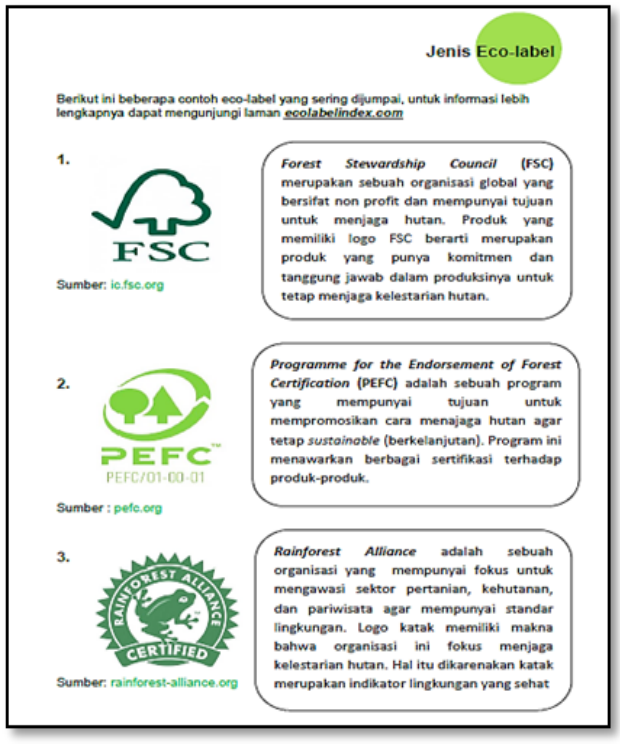

Figure 1. Cover and content of EEBE-HOTS

Then another part besides the explanation about eco-labels also explained about how to evaluate an eco-label based product. Finally, students were asked to work on an activity sheet containing tasks based on Higher Order Thinking Skills (HOTS). For example, in the first worksheet, students are asked to make an analysis and evaluate a product. Of course, the products requested to be analyzed everyday products that they often use such as soap, shampoo, paper, cooking oil etc. Then on the second worksheet, students are asked to design a product that meets eco-label based criteria.

Validation results are presented in the form of tables from expert learning materials, Learning media experts, and users. The overall results showed that EEBE-HOTS has a very valid category, so EEBE-HOTS is suitable for use in learning in schools for Junior High School and Senior High School levels. More details can be seen in tables 3,4,5 and 6.

Table 3. Results of Learning Material and Media expert validation

No	Indicator	Average	Percentage
Learning Material Expert			
1	Material Accuracy	4.00	100.0
2	Depth of Material	3.50	87.50
3	Language Clarity	3.75	93.75
4	Use of sentences, words and punctuation	3.50	87.50
Learning Media Expert			
1	Suitability of images and colors	3.60	90.00
2	Compatibility of letter and writing formats	3.75	93.75
3	Language clarity	3.50	87.50
4	Use of sentences, words and punctuation	3.50	87.50

Table 4. Results of user validation for each indicator

No	Indicator	User 1	User 2	User 3	User 4	Average
1	Suitability of images and colors	4.00	3.40	3.60	3.60	3.65
2	Conformity of Material with syllabus	4.00	3.50	3.50	3.75	3.68
3	Language clarity	3.75	3.75	3.75	4.00	3.81
4	Use of sentences, words and punctuation	4.00	3.75	3.25	3.75	3.68

Table 5. The results of the all validators with category

Validators	Average Score	percentage	Category
Learning Material Expert	3.70	92.65	Very Valid
Learning Media Expert	3.58	89.71	Very Valid
User 1	3.94	98.53	Very Valid
User 2	3.59	89.71	Very Valid
User 3	3.53	88.24	Very Valid
User 4	3.76	94.12	Very Valid

Based on table 3, it can be seen that the score given by learning material expert was greater than that of the learning media expert. This makes EEBE-HOTS able to present accurate information because it comes from valid information[21–24]. In the table, the highest 6 points are found in the indicators of letter format and writing conformity. This is because the EEBE-HOTS is presented with standard information. Based on user validation, this book is also according to the syllabus and basic competencies in the school, so that it can be used in the classroom[25,26].

After obtaining the results of validation, the next discussion is about the function of EEBE-HOTS. EEBE-HOTS is an enrichment book which has the function of deepening the material for students. Based on its function, this EEBE-HOTS does have a function to deepen students' knowledge about eco-labels. This is necessary because in school, learning does not discuss in detail about eco-labels [5,21]. Even though in daily life, students are very concerned with eco-labels.

Students who do not understand the eco-label will easily buy the items they need without considering the quality of the product and do not care about environmentally friendly aspects. This underlying the EEBE-HOTS book developed has a section specifically discussing "how to assess an eco-label based item". This makes students know what steps are needed to choose an eco-label based item. This component becomes important in an enrichment book because this will make students' knowledge deeper and wider [23,27].

In the menu "how to assess an eco-label based item" this is also by one aspect of HOTS, namely evaluate. Students are taught how to assess the quality of an item based on eco-label aspects. The other HOTS aspects of the EEBE-HOTS book can be found in the "student activity sheets part 1" menu section. In this menu, the students further after learning how to assess an item, students are now asked to assess and analyze the various products around them in terms of eco-labels. This activity is very suitable with HOTS, where students are trained to analyze and evaluate. The benefit that can be obtained by students with this activity is to become accustomed to buying an eco-label based item[4,28,29].

The create aspect which is the highest level in HOTS is in the "student activity sheets part 2" menu. Students are asked to design a product using the eco-label principle. This activity can take place, for example, by making handicrafts from used materials. Students can make a bag from unused cloth. This activity in addition to relating to HOTS also relates to students' skills in working together and practicing student creativity [30–33]. The last discussion is EEBE-HOTS as an innovation in 21st-century learning. As innovation in environmental learning in schools, the development of EEBE-HOTS is considered appropriate because it is based on more contextual or current environmental issues [34–36]

Conclusion

Based on the results of the study, it can be concluded that EEBE-HOTS has a very valid and appropriate category of learning. EEBE-HOTS content that contains HOTS aspects is located on the "how to assess an eco-label based item" menu and the "student activity sheets"menu. EEBE-HOTS is a learning media innovation and teaching material in 21st-century environmental learning.

The Association of Triglycerides Glucose Index with Diabetic Retinopathy in Patients with Type 2 Diabetes Mellitus

Ekhlas Khalid Hameed[1], Zina Hassan Abdul-Qahar[2], Tahrir Etihad Kadium[3]

[1]MBChB, Al-Kindy, [2]MBChB, [3]PhD, Al-Kindy College of Medicine, University of Baghdad, Iraq

Abstract

Aim: The aim of this study is to evaluate the association of the Triglycerides glucose index, (TyG index), a marker of insulin resistance, with diabetic retinopathy in patients with type 2 diabetes mellitus.

Method: This is a cross sectional study, carried out during the period from April 2016 to November 2017. 416 patients with type 2 diabetes mellitus were enrolled in this study (194 male and 222 female). Fasting blood sample was obtained to measure the blood glucose, glycated hemoglobin, and lipid profile. Patients were referred to ophthalmological assessment for the diagnosis of diabetic retinopathy. Body mass index and waist circumference were measured by standardized procedure. TyG index was calculated according to a published formula. Statistical analysis was performed by using SPSS

Results: Seventy patients had diabetic retinopathy (28 male and 42 female).TyG index was higher in patients with diabetic retinopathy, the prevalence of diabetic retinopathy increased across TyG index quartiles (p=0.000). The correlation between TyG index and the presence of retinopathy was significant (r = 0.247, P=0.000) after adjusting for the confounders. Area under the curve showed that TyG index has a good discriminating power to predict the presence of diabetic retinopathy.

Conclusion: TyG index could be used as an indicator of the presence of diabetic retinopathy. It shows a good association with diabetic retinopathy

Keywords: *Triglycerides glucose index; diabetic retinopathy; type 2 diabetes mellitus; insulin resistance.*

Introduction

Diabetic retinopathy (DR) is the leading cause of vision impairment and blindness globally [1, 2]. DR prevalence in patients with diabetes is about one-third and expected to increase in the coming years [3].

Many well known risk factors are involved in the pathogenesis of retinopathy as hyperglycemia hypertention, dyslipidemia and diabetic duration [4]. Hyperglycemia remains the key risk factor [3,] however, in the UK Prospective Diabetes Study (UKPDS), a 10 year follow up of participants was newly diagnosed with type 2 diabetes,it has been found that even with intensive glycemic control the overall micro-vascular complications rate are reduced only by 25% [5]. So, this leads us to the hypothesis that there are other risk factors that are involved in the pathogenesis of DR.

A few studies have investigated the relation between insulin resistance and the development of DR, Insulin resistance is a feature of type 2 diabetes mellitus, diabetic cardiovascular and renal complications [6, 7]. Therefore it is hypothesized that insulin resistance may play a role in the development of DR.

The gold standard method for assessing insulin resistance is the hyperinsulinemic-euglycemic clamp. However, the need for an accessible, reliable marker has proposed the use of Triglycerides glucose index (TyG) as a novel marker for insulin resistance with a high specificity and sensitivity[8,9]. Previous researches

have demonstrated the role of TyG as a predicator of metabolically obese normal weight subjects, non alcoholic fatty liver and metabolic syndrome [9].

The aim of this study is to determine the association of TyG index, as a non invasive, simple, inexpensive marker of insulin resistance, with the presence of DR in patients with type 2 diabetes mellitus

Subjects and Method

Study design: This is a cross sectional study conducted during the period from April 2016 to November 2017 in Diabetic centers in Baghdad. The data **were** collected from both patients visiting the diabetic centers,in addition some cases **were** collected from the saved records and files which **were** retrospectively viewed and collected to get complete information of each diabetic patient.

The records of 500 T2DM subjects aged (18-70 years) were initially assessed for eligibility. Among these, 34 patients were excluded due to missing data or certain diseases or medication as insulin therapy that affect the tested parameters. Patients with type 2 diabetes mellitus meeting any of the following exclusion criteria were not included in this study eg., less than 18 years old, gestational diabetes, previous ocular surgery or contact lens wear; eye trauma; ocular inflammatory diseases;corneal and conjunctival diseases; glaucoma; vascular or degenerative retinal. Finally, 416 type 2 diabetic subjects (154 men and 129 women) were enrolled

The participants provided written informed consent for use of their health screening data in this research. The study was approved by the ethical and scientific committee in AL-Kindly College of Medicine-University of Baghdad. The study was carried out in accordance with the Helsinki Declaration of 1975.

Biochemical measurement: After 12h fasting, venous blood samples were collected from all the participants. Serum was collected in EDTA tube, centrifuged at 5000 rpm for 15min. The clear supernatant was then separated and analyzed.

Fasting glucose (FPG), triglycerides (TG), total cholesterol (TC), and high density lipoprotein (HDL-C) were measured by using chemistry auto analyzer (Roche Modular P-800, Germany).

The level of LDL cholesterol was determined using the Friedewald formula:

HbA1c was measured by high performance liquid chromatography (HPLC supplied by Variant company, USA)

Definitions: According to the American Diabetes Association (ADA) criteria; diabetes was defined as levels of fasting glucose ≥ 126 mg/dL or HbA1c ≥ 6.5% and/or the current use of antihyperglycemic drugs[10].

LDL-C (mg/dL)=TC (mg/dL)-HDL-C (mg/dL)-TG (mg/dL)/5[11].

TyG index was calculated according to the formula [12,13]:

TyG index = ln (fasting TG [mg/dL]/fasting glucose [mg/dL]/2)

Ophthalmological assessment: As part of routine follow up for patients with diabetes, they underwent opthalamoscopic assessment. Standard equipments and techniques were used for clinical examination; and the retinal assessment was done using a direct/indirect ophthalmoscope or 90D lens on slit lamp. The presence of macular edema and the grading of the retinopathy were kept outside the scope of this study,any type of DR was included.

Anthropometric measurements: The body weight, height and waist circumference (WC) were measured according to a standardized protocol. Measurements were done while the participants wore light clothes with bare feet. WC **was** measured midway between the costal margin and the iliac crest at the end of expiration. Weight and height **were** measured to the nearest 0.1 kg and 0.1 cm respectively. The BMI had been calculated as the weight in (kg) divided by the height in (m) squared.

Statistical analysis: Statistical software SPSS version 23.0 software (Chicago, IL, USA) was used for statistical analysis. A value of $p < 0.05$ was considered statistically significant.

Participants were grouped into patients with and without diabetic retinopathy. and their baseline characteristics were compared using the Independent samples t-test (2-tailed) and the results were expressed as mean ± standard deviation or standard error of mean as appropriate. The TyG index **was** calculated as quartiles and the measured parameters were compared

by (ANOVA) test as appropriate. the Chi square tests was used to compare the categorical variables with percentages.

Correlation test was used to assess correlations between the TyG index and DR adjusted for other factors. Receiver Operating Characteristic (ROC) curve was used to compare the strength of TYG indices in discriminating the presence of diabetic retinopathy depending on the area under the curve (AUC) with the 95% confidence interval (CI) was calculated.

Result

Four hundred sixteen patients with type 2 diabetes **were** enrolled in this study (194 male and 222 female). 70 patients had diabetic retinopathy (28 male and 42 female). The baseline parameters of the patients with and without diabetic retinopathy are illustrated in table 1. TyG index was higher in patients with diabetic retinopathy, in addition, most of the tested parameters were higher in the DR group but,only diabetes duration, patients age, SBP and LDL-C reach a statistically significant higher level in the DR group.

Table 2 shows the characteristics of the patients according to the TyG index quartiles,the metabolic profile and the anthropometric measures worsen with the increase in the TyG index.

The correlation between TyG index and the presence of retinopathy was significant (r = 0.247 P=0.000) after controlling (age, duration of diabetes, FBG, HbA1C, SBP,DBP, TC, TG,HDL,WC and BMI) as shown in table 3

In table 4 we assess the potential power of TyG index to predict the presence of DR **which** illustrated a good discriminating power

Table 1: Characteristics of patients with type 2 diabetes mellitus by the presence or absence of retinopathy

	Patients without Diabetic retinopathy	Patients with Diabetic retinopathy	P value
Number	346	70	
Gender (male:female)	166:180	28:42	0.194
Age (years)	54.56±9.31	58.98 ±7.63	0.001**

Test result	Area under the curve	Asymptomatic 95% confidence interval		P value
		Lower bound	Upper bound	
TyG	0.704	0.613	0.795	0.000

P value less than 0.05 is statistically significant.

Discussion

The TyG index has been proposed as a surrogate marker of IR [14]. Hence in the present study, we have explored the association of TyG index with DR. we found that TyG index was significantly associated with the presence of DR. TyG index was higher in patients who had diabetic retinopathy. In addition, the number of patients with DR increases across the TyG quartiles. The area under the curve showed that TyG index had a good discriminating power to identify the presence of DR.

Currently, the studies that link TyG Index and DR are scarce. Our results agree with a study done by Parvanova et al[15] which reported the association of retinopathy with insulin resistance using a hyperinsulinemic-euglycemic clamp in 115 patients with type 2 diabetes mellitus. He found that insulin resistance was the only considered biomarker to maintain a significant association with the severity of retinopathy. However, the use of hyperinsulinemic-euglycemic clamp to assess insulin resistance is impractical as it is expensive, invasive and not available in every clinical setting.In contrast, the TyG Index is practical,available and inexpensive. TyG index only requires the measurement of glucose and triglycerides level, hence, both are routinely measured in patients with diabetes to assess the metabolic profile, In addition, using TyG index may better interpret their joint effect in Diabetic retinopathy risk prediction. Our results confirm and broaden previous studies [16-18], including the report by Maneschi *et al*.[19] illustrating that patients with Diabetic retinopathy tended to be more insulin resistant than those without retinopathy.

How insulin resistance enhances the development of diabetic retinopathy remains a subject of debate. Many proposed mechanisms are involved. First of all, abnormal fibrinolysis caused by excessive activity of plasminogen activator inhibitor-1 with the inhibition of the antiatherogenic action of insulin may lead to the occlusion of retinal capillaries resulting in ischemia-

induced neovascularization[20]. The other proposed mechanism is the ischemic damage **which** can be further increased by insulin resistance due to a lower ability of insulin to induce vasodilatation through defective endothelial nitric oxide production or excessive inactivation[21].

There were several limitations in the present study. Firstly, the cross sectional design of the study, Secondly,the sample size might not be large enough, third, the measurements of TG and glucose had unavoidable intra-individual biological variation, Hence, larger sample and long-term studies are needed to confirm our findings

In conclusion, the TyG index represents a useful and accessible tool, more severe insulin resistance is associated with DR in patients type 2 diabetes mellitus. Early screening for insulin resistance by a simple measure as the TyG index can spot high risk patients who may benefit most from preventive and curative measures so that interventions that improve insulin resistance may also decrease the risk of diabetic retinopathy.

Abstract

According to Law No. 1 1974, article 7, paragraph (1) "Marriage is allowed only when the man has reached the age of 19 (nineteen) years and the woman has reached the age of 16 (sixteen) years". A marriage of under-age marriage is said to be the case when the age of one or both families are under the age specified. Banjar district ranks the second highest cases of early marriage in South Kalimantan in 2017. Figures for the early marriage Banjar district from 2016 as many as 15 cases and an increase in 2017 as many as 74 cases, 67 cases of which are in Sub-Aluh Aluh. This study aims to explain the risk factors associated with the incidence of early marriage in the wetlands. This study is a quantitative research, with case control design with a ratio of 1: 2 and using purposive sampling technique. The number of respondents in this research were 105 people consisting of 35 respondents 70 cases and the control group respondents. Based on the research results attitudinal variables and the environment girls associated with the incidence of early marriage (p value = 0.001 and p value = 0.001), while the variables of education and culture (p value = 1.000 and p value = 0.011), not associated with the incidence of early marriage. The conclusion of this research is no relationship between environmental attitudes and girls with the incidence of early marriage, whereas no correlation between education and culture with the incidence of early marriage.

Keywords: *The incidence of early marriage, attitude, environment.*

Introduction

Early marriage is inner and outer bond between men and women who are young. Early marriage is a marriage on girls under the age of 16 years should not yet ready to perform marriages [1]. This is contrary to Law No. 1 1974, article 7, paragraph (1) which states that "marriage is allowed only when the man has reached the age of 19 (nineteen) years and the woman has reached the age of 16 (sixteen) years". A marriage of under-age marriage is said to be the case when the age of one or both families are under the age specified [2,3].

Indonesia is among countries with a high percentage of young age marriage in the world (rank 37). This position is the second highest in ASEAN after Cambodia. Based Health Research (Riskesdas) in 2013, South Kalimantan Province was ranked second after West Java in the case of early marriage at the youngest age between 10-14 years. Based on data from the BKKBN, the number of teenagers in South Kalimantan families are 2483 people with a number of early marriages reached 18% of the total number of adolescents aged 14-16 years[4,5].

Data Based Population and Family Planning Agency (BKKBN) in 2012 about early marriage, shows the percentage of early marriages in the province of South Kalimantan at 4.84% exceeds the national average by 40 early marriages per 1,000 population. Whereas in 2014 the percentage of early marriages in South Kalimantan rose to 5.85%[6].

According to the Ministry of Religious Affairs, South Kalimantan 3 cases of early marriage with the highest ranking in South Kalimantan in 2017 respectively Hulu Sungai Tengah Regency as many as 101 cases, as many as 74 cases of Banjar Regency and Tanah Laut as many as 32 cases. The Ministry of Religious Affairs According to the Banjar district early marriage figures for Banjar of 2016 as many as 15 cases and an increase in 2017 as many as 74 cases. Figures early marriage in Banjar district in 2017 was 74 cases, consisting of the

District Aluh-Aluh with the highest number of as many as 67 cases[7,8].

The high incidence of early marriage will lead to a high risk of the incidence of pregnancy at a young age. Among them are miscarriage, premature delivery, low birth weight (LBW), congenital abnormalities, easy to infection, anemia in pregnancy, pregnancy poisoning and death [9,10]. Pregnancy at a very young age correlated with maternal mortality and morbidity. Girls aged 10-14 years 5 times the risk of dying during pregnancy or childbirth compared to 20-24 years age group. This risk is increased 2-fold in the age group 15-19 years[11]. Based on the background mentioned above, the research on "The relationship between education,

Materials and Method

This study is a quantitative research, this study used a case control study design with a ratio of 1: 2 and using purposive sampling technique. The number of respondents in this research were 105 people consisting of 35 respondents 70 cases and the control group respondents.

The research instrument is a checklist sheet, the sheet. The bivariate analysis using chi square test. The variables in this study are education, attitudes, culture and the environment and the dependent variable was the incidence of early marriage.

Results and Discussion

A. Univariate Analysis

Table 1: Frequency Distribution

Variables	Respondents	
	N	%
Education		
Low education (primary and junior)	104	99.0
Higher education (SLTA)	1	1.0
Attitude		
Support	38	36.2
Does not support	67	63.8
Culture		
Support	34	34.4
Does not support	71	67.6
Environment		
Support	39	37.1
Does not support	66	62.9

Table 1 shows that the frequency distribution of education levels reveals that a number of teenage girls who berpindidikan larger lower than girls who are highly educated (99.0% versus (1.0%). On the attitude of the frequency distribution shows that the number of teenage girls that does not support early marriage is greater than the girls who support early marriage (63.8 versus 36.2%). In the culture of the frequency distribution shows that the number of teenage girls who do not support early marriage is greater than the girls who support early marriage (67.6 versus 34.4%).In the neighborhood frequency distribution indicate that the number of teenage girls who are in an environment that does not support early marriage which is greater than the number of girls who are in an environment that supports early marriage (62.9% versus 37.1%).

B. Analysis Bivariat

Table 2. Analysis of Risk Factors Related to Early Marriage Event In Area Wetland

Variables	Genesis Early Marriage				Total		p-value	OR
	Early married		Not Married Early					
	n	%	n	%	N	%		
Education

Support	8	22.9	26	37.1	34	100	0,011	-
Does not support	27	77.1	44	62.9	71	100		
Environment								
Support	33	94.3	6	8.6	39	100	0,001	176
Does not support	2	5.7	64	91.4	66	100		

Discussion

Based on table 2, the results showed that the attitude and environment variables girls is associated with the incidence of early marriage, while education and culture are not associated with the incidence of early marriage.

Based on the results of the chi square test showed that there is no relationship between education girls with the incidence of early marriage with a p-value = 1.000. This is caused by the age range of married respondents in this study is from <16 years, so it only consists of two categories of educational level. The results are consistent with research conducted by Priyanti (2013) which shows the p-value = 0.195, which indicates there is no correlation between education girls with the incidence of early marriage. These results indicate that the higher education does not determine a person to perform early marriage [12].

Based on the results of the chi square test showed that there is a relationship between the attitude of girls with the incidence of early marriage with a p-value = 0.001. This is because the girls are still in a culture that supports early marriage, early marriage so that he believes it is a natural thing for him and their willingness to channel the emotional needs through marriage considering they view marriage is better than dating.

This is in line with research conducted by Kartika (2013) which shows the perception of girls about early marriage will affect early marriages by 30.8% and is based on research Rafidah (2009) which stated that the respondents who have a perception of a less risky marriage 4.6 times more likely to marry at age <20 years compared to respondents who have a perception of a good marriage[13,14].

Based on the results of the chi square test showed that there was no relationship between culture and girls with the incidence of early marriage with a p-value = 0.011. At respondents who did not favor early marriage, but still get married early, there is an important role by parent respondents. Parents marry off their children is dominated by a strong belief of religion to avoid their children from fornication. According Dahro (2009), parents who still hold on to the old culture is to match and marry off their children at an early age because parents fear that their children are considered a spinster. This is in line with the results of in-depth interviews conducted by Haryono (2008) which states that according to the religion of parents are obliged to marry his daughter was of age (puberty) not committing fornication[15,16].

This is in line with research Pandaleke (2017), which shows the value of p = value p = 0.272> 0.05), then H0 is accepted or not there is a relationship between culture with early marriage. The results of this study are also consistent with research Rahma (2014), which examined the factors that influence the incidence of early marriage among women with results of bivariate analysis showed there was no correlation (p-value = 0.321) between the culture of early marriage[10].

Based on the results of the chi square test showed that there is a relationship between the environment and girls with the incidence of early marriage with a p-value = 0.001 it is because parents have a greater role than environment.

Conclusions

Based on the research results, conclusions obtained as follows:

a. Girls education was not associated with early marriage in Sub-Aluh Aluh Banjar district (p-value = 0.48).

b. The attitude of girls associated with early marriage in Sub-Aluh Aluh Banjar district (p-value = 0.001 and OR = 113.7).

c. Culture girls are not associated with early marriage in Sub-Aluh Aluh Banjar district (p-value = 0.011).

d. Environment girls associated with early marriage in Sub-Aluh Aluh Banjar district (p-value = 0.001 and OR = 176).

Suggestion:

1. Given this research are expected for people, especially parents to be wise in making a decision to marry her after knowing the impact of early marriage
2. For adolesscent girl, it is better before deciding to get married, they must first consider the maturity of age in marriage

Ethical Clearance: The study was approved and received ethical clearance from the Research Ethics Committee of Public Health, Faculty of Medicine, University of Mangkurat, Indonesia. In this study we followed the guidelines of the Committee on Public Health Public Health Committee on Research Ethics, Faculty of Medicine, University of Mangkurat, Indonesia for permission etchical and informed consent. informed consent, including the study title, objectives, participants correctly, confidentiality and signature.

Abstract

This study were conducted to analyze the homology and the relation of nucleotidesencoding partial genomic sequence of Fusion (F) protein Newcastle Disease Virus (NDV) isolated from swanusing phylogenetic tree. Samples were collected from cloacal swabs of seventy one waterfowls. Consisting of twenty four Domestic swan, thirty three Muscovy ducks, and fourteen Domestic ducks form waterfowl in East Java Province, and also positive LaSota isolate (ATCC). Samples were isolated in embryonated chicken eggs(ECEs) with specific pathogen free (SPF)and identified by HA test and confirmed as NDV by HI test. Positive samples were performed by RT-PCR using a forward and reverse primer with a target of 699 bp.The nucleotide sequences from field isolates were compared with the gene of vaccine viruses isolates encoded F protein NDV that used in Indonesia and vaccine viruses encoded F protein NDV that spread across the globe obtained at GenBank data and had very close phylogenetic relation with those vaccine viruses LaSota.Analysis of homology and phylogenetic from isolates in this study relate to isolate of vaccine viruses.

Keywords: *Newcastle disease virus, F protein, Homology, Phylogenetic Tree, RT-PCR.*

Introduction

Newcastle disease virus (NDV) is avian paramyxovirus (APMV) type 1 belong to genus *Avulavirus* in the family *Paramyxoviridae*. NDV has a single-stranded, negative sense RNA genome of 15.186 to 15.198 nt in length.[1] It has six genes that encode for a nucleoprotein (N), a phosphoprotein (P), a matrix protein (M), a fusion protein (F), an attachment protein called hemagglutinin-neuraminidase (HN), and a large polymerase protein (L).[2] Theoretically, F protein requires cooperation with HN protein to perform a membrane fusion during the fusion process so that the virus may penetrate a host cell's surface. [3,4]This virus has the ability to infect almost all bird species, both wild and domesticated birds.[5] Outbreaks of Newcastle disease (ND) occuring in Indonesia are usually caused by Asian-type velogenic strains which means including acute, highly lethal, and highly pathogenic virus. Cross protection that accurs between the *Newcastledisease* virus (NDV) can counter the challenges of other NDV, the underlying nature of vaccine production is the low virulence (lentogenic and mesogenic) ND strains.[6] Wild bird, especially waterfowl can be reservoirs of lentogenic strain, so they can be developed for vaccine production.[7]

Newcastle Disease Virus (NDV) cases in Indonesia could occur despite intensive vaccination programs on farms.[8] Vaccination failures due to genetic changes of viruses is being put into consideration when using an existing vaccines commercial and encouraging the preparation of the newer vaccines.[9,10]Conducting research and developing the ND vaccine by utilizing local isolates is one of the strategies undertaken to develop the ND vaccine in Indonesia according to Bahri *et al*.[11] Thus, it is necessary to study the viruses isolated waterfowl to better understand the molecular characterization to control the NDV and ND Vaccines formulated with closer phylogenetically with field viruses can provide a better control by reducing transmission of ND virus from infected poultry.[12]

Materials and Method

Sample collection and virus isolation: Seventy one samples were collected from water fowls consisting of twenty four Domestic swan, thirty three Muscovy ducks, and fourteen Domestic ducks from waterfowl in East Java Province. Cloacal swab were placed in 1,m ml centifuge tubes containing 1,0 ml of transport medium phosphate buffer saline pH 7.0-7.4 with antibiotics (penicillin, 1000 U/mL); streptomycin (2 mg/mL) and fungison (1000 U/mL). All samples were inoculated in 9-to-11-day-old specific pathogen free embryonated chicken eggs (SPF-ECE) and incubated for 4-7 days with the temperature of 37°C.[7]

Haemagglutination (HA) and Haemagglutination inhibition (HI) test: HA and HI were used for virus identification follows standart procedure.[7] The 0,5% washed chicken RBC was used for spot HA testing individual alantoic fluid from the dead embryos prior to harvesting. Four HAU were used in HI test using reference anti-NDV (PUSVETMA, INDO).

Viral RNA extraction: RNAs of the viruses were extracted from allantoic fluids using Trizol LS reagen (Invitrogen, Carlsbad, CA) following the manufacture's instructions. Sample suspension was used for extraction, and RNA product store at -20°C.

Reverse Transcription Polymerase Chain Reaction (RT-PCR) and gene sequensing: RT-PCR was used for detection of partial F-gene of NDV using following primers Forward: (5'-GAC CGC TGA CCA CGA GGT TA-3', nucleotide position 4306-4326) and Reverse: (5'-AGT CGG AGG ATG TTG GCA GC-3',nucleotide position 4981-5005) oligonucleotide primer sets were used for amplification of 699 bp. Reverse transcription and PCR amplification followed QIAamp one step RT-PCR procedure (QIAGEN). A 25 µL total reaction mix was prepared using 12.5 µL 2x RT Mix component, 1 µL primary forward, 1 µL reverse primer, 1 µL superscript III, 8.5 µL NFW and 1 µL RNA. Conditions for amplification RT-PCR of complate F genes was follow 95°C lid on setting, 94°C predenaturation for 10 minutes; 94°C denaturationfor 1 minute; 57°C annealing for 1 minute; extention 72°C, for 10 minutes; and keep it at 4°C.RT-PCR products were analyzed by 1.5% agarose gel electrophoresis and visualized by ultraviolet transillumination.The target band was purified using the QuickClean DNA Gel Extraction Kit (QIAGEN) and purified products were sequenced using an automatic Applied Biosystem 3130xl Genetic Analyzer (HITACHI).

Molecular analysis: For homology analysis, the nucleotide sequences from field isolates were compared with the gene of vaccine viruses isolates encoded F protein NDV that used in Indonesia and vaccine viruses encoded F protein NDV that spread across the world obtained at GenBank data. The obtained sequence was edited using BioEdit Software Version 8 to create consensus sequence. Other isolate samples from GenBank were input into BioEdit for alignment using the ClustalW menu. The homology analysis of the F genes was performed using BLAST program of NCBI online on the Global Align tool (Needleman-Wunsch) which comprises two different sequences for the determination of similarity relationships.Phylogenetic trees were drawn using the maximum likelihood method found in MEGA6 software. [13]

Results and Discussion

Virus Isolation and Identification: All samples were inoculated in specific-pathogen-free (chicken embryos) allantoic fluid aged 9-10 days for 5 days and were observed every 24 hours. Cloacal swabs had been done because NDV known to be transmitted through digestive and respiratory systems.[7] Foursamples showing positive results of HA, ND/SW1/2018, ND/SW2/2018,ND/SW3/2018 and ND/SW4/2018. Samples with positive HA were confirmed by HI (haemagglutinin inhibition) using ND antiserum obtained from PUSVETMA. Growth of NDV in allantoic fluid is known by HA test to see the ability of haemagglutination of erythrocytes in viral envelope capable of agglutating erythrocytes of chickens. [14]. HI test is based on

principle that the hemagglutin on the viral envelope can agglutinate the chicken erythtocytes and this can be inhibited by specific antibodies. Agglutination inhibition occurs perfectly against 4 HA Unit antigen. Haemagglutinin of NDV can bind specifically to sialic acid on sensitive cell surface receptors and facilitate the infection process. This delicate receptor is also owned by red blood cells (erythrocytes) of chickens. [15]

RT-PCR: Samples ND/SW1/2018, ND/SW2/2018, ND/SW3/2018, ND/SW4/2018, and LaSota positive isolate continued to RT-PCR. RT-PCR has been established to identify of NDV.[16,17,18] The electrophoresis results showed good results with proven detection of DNA fragments in the sample with length of 699bp.

Homology analysis: Homology analysis carried out in this study used sixteen isolates comparison consisting of circulating virus vaccine and *Newcastle disease virus* (NDV) isolates in Indonesia. Vaccine virus isolates used were strains F, LaSota, V4, B1, Beaudatte C and Komarov and Newcastle disease virus (NDV) isolates were circulating is isolates with F protein sequence found in GenBank. Isolates ND/SW1/2018, ND/SW2/2018, ND/SW3/2018 in this research have the highest homology with LaSota vaccine about 97-98% and isolate ND/SW4/2018 have highest homology with LaSota vaccine about 94%.Homology analysis conducted on this studi using 17 comparative isolates consisting vaccine viruses and NDV isolates circulating in Indonesia (Table-2). Homology analysis revealed that the isolates in this research had high homology with some vaccine isolates.

Phylogenetic Tree: Phylogenetic analysis showed that samples from Lumajang and Kenjeran were placed in class II. We found that samples had a close genetic relationship with vaccine virus as LaSota, V4, B1, Beaudette C strains were used as in Indonesia Phylogeny tree were shown in Figure-1. Phylogenetic analysis revealed that the isolates in this study were closely related to isolatesfrom LaSota vaccine. However, Dirmitry *et al*[19] have reported vaccines that were phylogenetically close to outbreak-causing NDVs to provide better protection against ND. This indicates that the possibility of lentogenic and mesogenic virus vacine circulating in the Surabaya and Lumajang areas, and possibly due to virus shedding from release or contamination of viruses from vaccinated chicken on farms to sorrounding environment. Although the live vaccives could effectively protect against clinical signs and mortality caused by virulent isolates, they can be shed from vaccinated domestic poultry into the environment. [20] Therefore our results revealed that the samples and vaccine virus in Indonesia present a close phylogenetic relationship.

Table 1: HA and HI test result

Sample	MDT	Identification test	
		HA	HI
ND/SW1/2018	96 h	2^8	2^6
ND/SW2/2018	96 h	2^9	2^6
ND/SW3/2018	96 h	2^7	2^6
ND/SW4/2018	120 h	2^8	2^6

Table 2: Area from observed samples, previously-recorded isolates from Indonesia in GenBank, and vaccine viruses

Conclusion

Therefore, it can be concluded that the isolates in this research had high homology and closely related with some vaccine isolates.

Conflict of Interest: The authors declare that they have no competing interests.

Source of Funding: The authors would like to thank the Ministry of Research, Technology and Higher Education of the Republic of Indonesia through Master Degree to Doctorate for Superior Scholarship Program (PMDSU), grant number 2146/D3/PG/2017.

Ethical Approval: The research does not need ethical approval. However, samples were collected as per standart collection method without any harm and stress to the animals.

Early Detection of Risk Factors and Severity of Airway Obstruction Through Measurement of Critical Values of FVC and FEV_1 on Bus Terminalofficers

Sudiro Sudiro[1], Martono Martono[1], Nursalam Nursalam[2], Ferry Efendi[2]

[1]Nursing Department Health Polytechnic of Surakarta, Indonesia, JL. Letjend Sutoyo, Surakarta,
[2]Faculty of Nursing, Universitas Airlangga, Surabaya, Indonesia

Abstract

Purpose: The purpose of this study was to explain the extent to which critical values of FVC and FEV1 were able to predict risk factors for severity of airway obstruction in bus terminal Officers in Solo Raya Indonesia.

Method: This study used a descriptive survey design with a cross-sectional approach. The sample of this study was the bus terminal Officers in Solo Raya Indonesia who work in the field of traffic, vehicle inspection, and parking. The sample consisted of 139 random respondents. The severity of airway obstruction was measured through critical values of FVC and FEV1 using Spirometry. The research data analysis technique used the Logistic Regression Test with a significance level of 95%.

Result: The results of this study showed that the prevalence of sex for the majority of men was 64.7%, the age group 43-50 years was 30.9%, the years of service of 21-30 years was 38.8%, and the severity of obstruction of the airway was mostly in the light category of 52.5 %. The measurement model for critical values of FVC and FEV1 was able to predict the significant severity of obstruction of airway by 80.7% and the traffic officers were at higher risk of obstructing airway significantly by 3.88 times compared to those working in parking, or vehicle inspection as indicated by $\rho = 0.008 < 0.05$; at least, the traffic officers had 1,420 to 10,637 times higher to get airway obstruction.

Conclusion: Officers who serve in the field of traffic work have a tendency to be exposed to exhaust emissions of motorized vehicles on the highway, so there is a risk of an increase in the severity of road obstruction compared to those in other occupations. For this reason, the need for early detection through routine inspection and increasing the capacity of traffic Officers and road transport in an effort to prevent the severity of airway obstruction through the movement of work safety discipline using masks. This is important because of the risk of exposure to exhaust gas emission air pollution on the highway.

Keywords: *Severity, respiratory tract obstruction, FVC, FEV_1, Officer.*

Introduction

The growth of the automotive industry, ease of loans, and increased public purchasing power has increased the number of motorized vehicles. This triggers air pollution which can reduce air quality which can endanger human health. World Health Organization (2017) reports globally that in 2015 there were more than 3.17 million people in the world died by exposure to indoor and outdoor air pollution, as well as dust and smoke. Jeems (2015) explains that the level of air pollution in Indonesia is currently ranked the 8th most deadly, with an average mortality rate of 50,000 people per year. This is lower than China, with an average of 1.3 million people dying every year.

From the perspective of nursing, the impact of air pollution can cause disruption to the airway, both obstruction, and electricity. Chronic Obstructive

Pulmonary Disease (COPD) is a term often used in groups of lung diseases that last a long time and are characterized by increased resistance to air flow. The disease currently has become a serious health problem in Indonesia, along with increasing life expectancy and the increased exposure to risk factors, such as smokers, and air pollution. Global Obstruction Lung Disease/GOLD (2015) explains that there are around 3 million people dying of COPD in 2005, it means 5% of all deaths globally. In 2002 COPD was the fifth leading cause of death in the world and is estimated to be the third leading cause of death worldwide in 2030[1].

Basic Health Research (2013) explained that in 2007 the mortality rate from COPD was ranked 6th out of 10 causes of death in Indonesia and the average prevalence of COPD was 3.7%. The survey results in five provincial hospitals in Indonesia (West Java, Central Java, East Java, Lampung and South Sumatra) in 2004 showed COPD ranked first in the number of patients at 35%, followed by bronchial asthma by 33%, lung cancer by 30% and the other 2%[2].

The purpose of this study is to explain the extent to which critical values of FVC and FEV1 are able to predict risk factors for airway obstruction severity in bus terminal Officers in Solo Raya Indonesia.

Research Method

Research design: This study uses a descriptive survey design with a cross-sectional approach. The severity of obstruction of the airway in this study was assessed based on the results of measurements of critical values of FVC and FEV1 using Spirometry. The data analysis technique of this study uses the Logistic Regression Test with a significant level of 95%.

Sampleand Setting: The sample in this study was randomly selected from bus terminal officers who worked in the field of vehicle inspection, traffic, and parking in the area of Solo Raya, Indonesia. The FVC and FEV1 critical values of all bus terminal officers were examined using Spirometry. Inclusion criteria were officers who still work in the bus terminal who work in vehicle inspection, traffic, and parking, and do not have a smoking history.

Research instrument: The research data was collected through FVC and FEV1 measurements using calibrated spirometry.

Results

Demographic Characteristic: Of the 155 FVC and FEV_1 study subjects measured using Spirometry, 139 respondents (89.7%) met the sample criteria and 16 respondents (10.3%) did not meet the sample criteria. Based on the characteristics of 139 respondents, the picture is as follows:

Table 1. Demographic Characteristic (n=139)

Characteristic	n	%
Sex		
a. Men	90	64.7
b. Women	49	35.3
Age		
a. 19-26 years	24	17.3
b. 27-34 years	30	21.6
c. 35-42 years	29	20.9
d. 43-50 years	43	30.9
e. 51-58 years	13	9.4
Education		
a. Elementary school	3	2.2
b. Junior high school	10	7.2
c. Senior high school	79	58.8
d. Bachelor	47	33.8
Years of service		
a. <10 years	36	25.9
b. 10-20 years	49	35.3
c. 20-30 years	54	38.8
Field of work		
a. Traffic	71	51.1
b. Parking	32	23.0
c. Vehicle inspection	36	25.9
Airway Obstruction		
a. Airway obstruction negative	44	31.7
b. Airway obstruction positive	95	68.3
NasalSeverity		
a. Normal	43	30.9
b. Mild	73	52.5
c. Moderate	23	16.5
d. Severe	0	0

Based on table 1, out of 139 subjects conducted the study found that 64.7% men and 35.3% women, 30.9% were 43-50 years old, 58.8% were high school graduates, years of service were 20-30 years (38.8%), and 51.1% of respondents work in the traffic sector.

Based on the results of the Chi-Square Test shown in table 2, it can be explained that the characteristics of age, years of service, and fields of work have a significant correlation with the level of obstruction of the airway. While sex and education do not show a correlation with the level of obstruction of airway.

Table 2. Correlation between the severity of airway obstruction and sex, years of service, fields of work, and education (n=139).

Variable	Chi-Square	Sig.
Sex * Obstruction level	0.612	0.736
Age*Obstruction level	15.615	0.048
Years of service* Obstruction level	10.119	0.038
Fields of work*Obstruction level	111.490	0.000
Education*Obstruction level	2.770	0.837

This study used three-times Spirometry to measure the critical values of FVC and FEV1. Table 3 showed that 90 respondents (68.3%) experienced airway obstruction and 44 (31.7%) of the remaining respondents did not experience airway obstruction. For the airway obstruction level, 52.5% of respondents experienced mild airway obstruction, a moderate level of 16.5%, and a normal level of 30.9%.

Obstruction Severity Prediction: The results of the logistic regression statistics showed that the predictive value of the logistic regression model was shown in overall percentage which is equal to 80.7%, the Exp (B) value is 3.88, $\rho = 0.008$. It means that the measurement model for the critical value of FVC and FEV1 was able to correctly predict the severity of airway obstruction by 80.7%. While the odds ratio value shown in the Exp (B) value is 3.88, which means that the traffic officers have an airway obstruction risk of 3.88 times higher than those who work in vehicle inspection and parking.

Table 4. Logistic Regression Statistics Test Results

Logistic Regression Test	Results	ρ	CI Exp (B) 95%	
			Lower	Upper
Exp (B) Predicted	3.88 80.7%	0.008	1.420	10.637

Discussion

The results of this study indicated that out of 139 respondents in the bus terminal were male (64.7%) with the prevalence of age groups between 43-50 years. Men are more adaptable and more quickly to make decisions in solving problems at the bus terminal. These characteristics are consistent with a retrospective study conducted by Sun et al. (2015) which explained that patients in Korea who were examined using spirometry and diagnosed with Chronic obstructive pulmonary disease (COPD) were mostly men (404 samples) and the rest were women[3]. In addition, the literature review conducted by Rycroft, Heyes, Lanza, & Becker (2012) explains that out of 2838 articles, more men experience airway obstruction than women[4].

The results of this study differed from the cross-sectional study conducted by Schneider et al. (2009) which explains that 57.7% of the 219 subjects affected by this disease were women[5]. However, the characteristics of the sex ratio must be considered because even though men are more likely to be exposed to airway obstruction, this does not mean that men are more likely to be affected by the disease; differences in sex ratios in the population or sample studied affect the results of a study.

The prevalence of most age groups in this study was 43-50 years (64.7%). This research was carried out in the bus terminal management environment in Solo Raya Indonesia so that the age group was more productive, but the work did not determine and became a factor that influenced lung function.This is consistent with the research conducted by Mokoagow, Uyainah, Subardi, Rumende, & Amin (2014) which explains that the percentage of age <60 years is more than other groups[6]. The age group characteristic in this study was differed the retrospective study conducted by Damiputraet al. (2016), which explained that the age category of 56-65 years was higher than other age groups.

Most of the years of service characteristic in this study were 20-30 years (38.8%). Furthermore, the characteristics of years of service in this study have a correlation with airway obstruction. Years of service are risk factors that are directly related to the length of exposure to automotive air pollution in bus terminals which increases the risk of respiratory disorders. The results of this study are consistent with the research conducted by Guo et al. (2018) which explained that long-term exposure to air pollution (particulate matter) is associated with a decrease in lung function[7]. Long-term exposure to air pollution (particulate matter) is also associated with an increased risk of COPD events.

This showed that the traffic officers in the bus terminal have a risk of having airway obstruction 3.88 times higher than those in other fields. This means that traffic officers have a higher risk to be exposed to automotive emissions. Thus, people who live or do their activities around the highway are more often exposed to pollutants whose levels depend on the conditions of each road. This is in accordance with research conducted by Dement et al. (2015) on construction workers that explained that construction workers were solid predictors of the risk of COPD[8]. The results of this study were also in accordance with the research conducted by Rice et al., (2015) which explained that those who live less than 100 m from the highway experienced a decrease in FEV1 value of 5.0 ml/year[3].

Conclusion

Officers who serve in the field of traffic work have a tendency to be exposed to exhaust emissions of motorized vehicles on the highway, so there is a risk of an

increase in the severity of road obstruction compared to those in other occupations. For this reason, the need for early detection through routine inspection and increasing the capacity of traffic managers and road transport in an effort to prevent the severity of airway obstruction through the movement of work safety discipline using masks. This is important because of the risk of exposure to exhaust gas emission air pollution on the highway.

Preceptorship Method Development Based on Experiential Learning to Improve Preceptor Clinic Competency

Fitri Chandra[1], Nursalam[1], Slamet Riyadi Yuwono[2]

[1]Faculty of Nursing, Airlangga University, Surabaya, [2]Politics of Health, Ministry of Health of the Republic of Indonesia, Surabaya, Indonesia

Abstract

Introduction: Preceptorship is an intense partner of people who are more skilled or experienced with fewer skills or experience, with goals agreed upon by people who have less experience to add and develop specific competencies, with increasing numbers of new nurses in the Lavalette hospital then increasing also the problems that exist in the Lavalette hospital. The most common problem experienced by preceptors is the schedule of guidance with new nurses is not the same as the preceptor schedule when serving, preceptors undergo expert level education and most of the reasons are due to lack of information on preceptorship training, unbalanced preceptor ratios with new nurses, so that preceptors do not know the task in detail. The purpose of this study was to develop a preceptorship method based on experiential learning to improve the competence of preceptor clinics.

Method: This type of research a Research and Development research (R & D). The sampling method used was purposive sampling with 112 people divided into two groups (control group and treatment group). The intervention of the control group was applied every day for 4 meetings, and the treatment group was applied 4 times.

Result and Analysis: The independent t-test results in the control group were $p < 0.05$ in the experiential learning variable.

Discusion and Conclusions: In this study is the development of the preceptorship method based on experiential learning simultaneously will affect the increase in the competence of preceptor clinics.

Keywords: *Preceptor, Preceptorship, Experiential Learning, Clinical Competence.*

Introduction

Preceptorship is an intense partner of people who are more skilled or experienced with fewer skills or experience, with goals agreed upon by people who have less experience to add and develop specific competencies[1]. Preceptorship is a teaching method commonly used in many professions, including the nursing profession[2]. Experiential learning-based learning theory suggests that learning becomes more effective if based on experience[3]

Corresponding Author:
Nursalam

Preceptorship activities involve someone who is wiser, more experienced in conveying their knowledge to someone who is less experienced. A preceptors become models/role models in preceptorship activities while simultaneously providing expert advice to the preceptee. This is a relationship that is given free of charge and in which there is a push, guidance, support, and advice neutrally to help preceptors in organizational development and personal development.

The form of preceptorship is in the form of advice that relates to practice in the workplace including role models in one-to-one groups and organizations. [4]said that increasing nurse retention was described as an advantage of the preceptorship program.

Preceptors are role models of nurses who are

good and worthy of being exemplified because of their attitudes, behavior, professional abilities above average. Preceptors are clinical abilities, professional skills, critical thinking and professional behavior[2]

One of the efforts to optimize the preceptorship program is to organize and streamline guidance to new nurses, namely the preceptorship program based on experiential learning.

This study aims to provide an overview of the implementation of preceptors based on experiential learning in hospitals.

Method

This type of research a Research and Development research (R & D)

Design: The design of this study uses a descriptive design.

Respondents: The sample in this study was a preceptor with a total of 112 people in the November period 2018 to April 2019. The sampling technique used was purposive sampling technique using inclusion and exclusion criteria.

Data collection: Research and Development research (R & D) shapes knowledge based on specific events and takes the form of practical contexts. The research sampling technique uses the Purposive Sampling technique. The inclusion and exclusion criteria in this study are as follows:

Inclusion criteria: Nurses who work in the regional hospital PTPN XI in East Java, Nurses who have worked for at least 5 years, Nurses who are permanent employees, Minimum education in D3 Nursing. Exclusion criteria: Nurses who are on maternity leave, Nurses who are training, Nurses who are licensed or study assignments, Has played a role in testing the reliability of the instrument

Instrument: The instrument of this research uses a questionnaire sheet.

Analysis: Descriptive analysis was carried out through frequency distribution based on the categories of each variable and descriptive category with a column row analysis approach. Data analysis for the results of Focus Group Discussion (FGD) was obtained from audiovisual recordings and field notes during the discussion. The results of the Focus Group Discussion (FGD) will be copied and analyzed according to the results found. The researcher will also increase the persistence of observation by repeating audiovisual recordings to analyze the context.

Results

The study was conducted from February 28 to April 28, 2019, at the Lavalette hospital. During the data collection, 112 preceptors were obtained with the following results:

1. Orientation Ability: Activity capabilities in this preceptorship program not yet referring at Standard Hospital Accreditation (SNARS)
2. Learning in class: The preceptor is not yet capable do effective communication in giving care
3. Professional Transition Session: Not able to provide an experience of ability: Other in nursing care, it has not been able to provide its experience in nursing attitudes and ethics
4. Learning Exchange Clinic: The preceptor has not been able to carry out the transfer at work
5. Evaluation: Not yet able to provide an evaluation in nursing care
6. Clinic guidance: Not yet able to do guidance with a different work schedule

Discussion

The preceptorship is measured using the module preceptorship based on the[5]. The standards for implementing preceptors consist of preceptorship management, learning method, preceptorship method, and evaluation. Timing, meeting schedule, competency list, and evaluation results are part of standard preceptorship management, learning method, preceptorship method, and evaluation. However, the management strategy, learning method, preceptorship method, and evaluation of time, in particular, are not following the standard Preceptorship Guide to Professional Education Students[5]. This includes the absence of a preceptorship program based on experiential learning, the absence of implementation time, the absence of a meeting schedule, the absence of a list of competencies, and the absence of evaluation results since its enactment in April 2018.

At the location of the study, researchers found that the independence of precepts was very lacking in implementing programs in hospitals. This is due

to a lack of involvement of preceptors in conducting guidance processes with precepts. Preceptee views that those who are more entitled and competent to carry out hospital programs are preceptors. Whereas preceptors are also lacking in involving themselves during the hospital. Preceptee is only involved in daily activities in the hospital because of routines, without knowing the standards in the hospital.

Experiential learning is a process of change that uses the experience as a medium of learning or learning[3]. [6]showed the success of 78% of students using experiential learning method. Experiential learning styles intend to accommodate individual tendencies in how to receive and process information in learning. The experiential learning style is an indicator of stable learning about how students are taught to see, interact and demonstrate learning outcomes. The experiential learning model is developed based on Kolb's theory, which emphasizes the central role of experience in the learning process[6]. Based on perceptive epistemology, experiential learning is a model of learning with constructivism learning theory, which directs students to build learning from their learning experiences[6]. In the preceptorship, the preceptor conducts clinical guidance to pay attention to aspects of orientation, classroom learning, professional transition sessions, exchange of clinical learning, evaluation, and clinical guidance. The implementation of each aspect of the assessment is followed by four stages in experiential learning. The stages in experiential learning consist of concrete experience, reflective observation, abstract conceptualization, and active experimentation.

The first stage of the Concrete Experience is to involve nurses in real activities during preceptorship. At this stage, the preceptor only performs the task. The task in question is an act of clinical competence. The head of the room observes the actions taken by the preceptor, adjusted to the standard set. The second stage is Reflective Observation. At this stage, the preceptor evaluates actions that are not by the standard, then exemplifies the precepts in real action that should be done according to the standard. Preceptor provides an opportunity for supervised precepts to pay attention to examples of technical competency actions carried out by preceptors and reflect them with actions that have been carried out previously. The next step is the abstract conceptualization. This stage is the thinking phase meaning that the preceptor can understand and explain what is obtained from the results of observation and reflection. The preceptor allows the precepts to convey the concept obtained from the observations. The last step is Active Experimentation which is to provide preceptor motivation to carry out clinical competence actions in daily activities.

Conclusions

The Development of preceptors based on experiential learning includes: there are times of training and development, implementation schedules, knowledge of competency lists, and evaluation results so module preceptorship based on experiential learning is needed to improve the competency of preceptor clinics developed to improve service quality in nursing.

Abstract

Obstetric complications are among the deadliest plagues that devour most developing countries. Due to the substantial obstetrical issues seen in developing countries, research analysis demonstrates that countries such as Nigeria, India, and Bangladesh have seen the death of more than a third of pregnant women. India serves as the most vulnerable country in terms of maternal health due to its large population and for the fact that it is a developing country. This paper outlines a health education, using a mnemonic "VIBGYOR" and using a research review mapping to support and illustrate the various interventions to address the maternal and childbirth issue.

Keywords: *VIBGYOR, Risk Factor, Obstetric Complication, Health Education, High Risk, Millennium Development Goals, Sustainable Development goals.*

Introduction

Millions of women and girls perish annually due to obstetric and childbirth issues. Even though a handful of women have a high risk of enduring maternal problems in developed countries, a large number of women are at high risk of developing maternal complications in developing countries. Tragedies associated with women mortality over obstetric complications traumatize not only their lives, but also their children, their families, and the entire community.[1,2].

In 2010, developing countries recorded that approximately 15% of pregnant women, developed obstetrical complications. The United Nation's report of 2010 unveiled that Nigeria and India saw the death of more than a third of pregnant women[1]. More than 15 research articles were utilized to develop a literature review on maternal health issues between 2001 and 2010. The review focused on three countries; India, Nepal, and Bangladesh. The results revealed that about 12% to 75% of pregnant women report difficulties in at least one of their pregnancies.[2] Sustainable Development Goals which came after the end of MDGs demands the end of newborn deaths by 2020 where all countries aim at decreasing the neonatal deaths to less than 12 in every 1000 live births.[3]

Even though the Indian government has launched several health care programs that consistently functions to deliver safe mother-hood process, they fail to ensure that they satisfy the needs of citizens[4]. Some of those healthcare programs include; Safe Motherhood program, National Rural Health Mission, National Population Policy, Child and Health Programme, and Child Survival program. India experienced a high maternal mortality rate, leading to only 570 live births per every 100,000 in the 90s. The phenomenon has since decreased by about 4.9% recording 63,000 maternal deaths in 2012 due to their undying efforts to attain the MDG of reducing MMR by 75%. The most recent trends in MMR, India accounts for 15% of mortality rate.[5]

Root Cause Analysis of Pregnancy-related complication.

Biological Risk Factors: Women enduring teenage

Lecturers, MCH Dept., CON, Sultan Qaboos University, Muscat
e-mail: frincy.s@squ.edu.om

pregnancy or elderly primigravida serve as the most adversely affected group. A significant number of the group suffers from risks such as malnutrition, Null parity, and stillbirth history, which in turn leads to obstetric complications as well as maternal deaths. The difficulties usually vary between those who regularly visit the clinic during pregnancy, as well as those booked and unbooked.[6]

Table 1. Childbirth/Obstetric Complications as well as their prevalence levels

Complications During Pregnancy	Prevalence Level
Hypertensive Disorder	6-8%
Premature Pre-term Membrane Rupture	3%
Placenta Previa	0.64%
Restriction of Intra Uterine Growth	7%
Oligohydramnios	4.45%
Anemia	14% (1st World nations), 51% (3rd World nations), and 65%- 75% complication rates in India.

Social Economic Risk Factors: According to South Asian Research findings, obstetric complications are associated with low socio-economic status, illiteracy, poverty, as well as inadequate knowledge on risks and mitigation measures of illnesses in both postpartum and pregnancy periods[7]. Other studies on District Household and Facility Survey (DLHS-2) conducted in Odisha[8], have since contradicted the above findings, pinpointing that urban lifestyle, younger age, and enhanced educations are the critical reasons for high morbidity rates associated with pregnancy. The Empowered Action Group EAG in Indiaconducted a research study in economically challenged regions andfound that more than 50% of women either report pregnancy and or post-pregnancy complications. [9]

Psychosocial Factors: Psychosocial factors may impact complications during pregnancy. According to a field research finding by Shegufta et al. in Bangladesh, more than 43% of women endured difficulties due to social psychological factors within their vicinity. The study compared obstetric complication to couples' pregnancy wantedness. It was evident that 20.1% of the women had pregnancy and childbirth complications and 36.7% nearly missed the difficulties if the couples wanted the pregnancy, as 61.9% received complication if couples never planned to have the pregnancy.[10]

Sociocultural Risk Factors: The third world nations have geographical regions which are divided into rural, urban, and semi-urban. In this case, the most adversely affected by the administration of Emergency Obstetric Care naturally becomes the population within the rural setup, especially those living within hilly terrains. Particular traditional values and rituals which some groups tend to abide by, yet lacks scientific backgrounds can easily affect maternal health. Some of the traditions include; preventing pregnant women from consuming a large sum of food, which is believed to enhance the size of the fetus, resulting in difficulties in giving birth.[11]Certain regions such as Jharkhand, women often take locally brewed alcohol, which acts as pain relievers. Such communities also prefer traditional untrained midwives during delivery.[12]

Crucial period to act: Determent of the obstetric problems is a key requirement.

Sustainable Development Goals

A slow transition was made from the MDGs to Sustainable Development Goals was developed to gain and carry on the momentum of the previous MDGs.[13,14] In order for India to attain Sustainable Development Goals as at 2030, India needs to prioritize Goal's development agenda. Even though SDG has made tremendous progress in decreasing the child and maternal mortality, the country is still among the world countries registering pregnancy complications and deaths. The phenomenon is despite the halving of child and maternal mortality rates from 1990 to 2015. This report suggests 57% of the death occur during neonatal time. The countdown report states that the MMR in India was 180 per 1000 live births as at 2013. The SDGs targets to reduce the MMR to less than 2 per every 1000 live births as at 2030.[15]

The government has scheduled all relevant mitigations through launching essential countrywide programs concerned with maternal well-being to ascertain secure motherhood and consequently ensure that active health institutions attain the objective group. This resolution are crucial tasks vested on all citizens who require to commit themselves to advance and achieve the MDG-5 missions currently through the SDGs.[16] The most pressing issues towards achieving quality maternal care through the sustainable developmental goals are outlined in an article as the need for prioritizing maternity services, universal coverage by promoting gender equality, strengthening the available health

systems, accelerate progress through evidence based practices.[17]

Methodology: Inflicting knowledge toward the available obstetric issues the threatening symptoms will prompt access to effective obstetric care as well as aid in efficient innervations to decrease maternal death mortality and morbidity.[18] This paper is concerned on a few essential factors that are critical to improving the well-being of overall population by echoing on the importance of initial diagnosis of high-risk situations coupled with consistent antenatal care.[19] Thus the primary elements are articulated on the mnemonic "VIBGYOR" to develop the course of gestation an attractive event by using a research review mapping approach with studies supporting each element of the mnemonic.

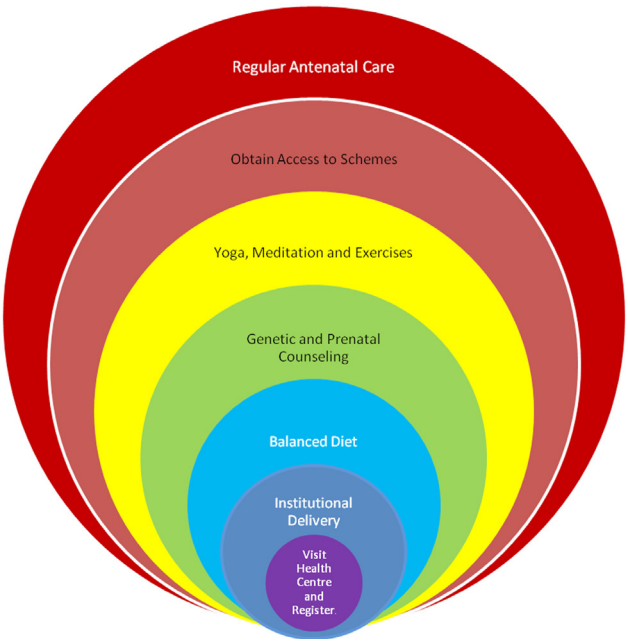

Figure 1. Representation of "VIBGYOR"– MNEMONIC essential for teaching women on hedging obstetric complications

Research Literature Review on the Viable Mitigations Strategies.

Visit and Record at the nearest medical institution immediately gestation is confirmed: Gestation is a natural situation which is often indicated as normal not until complications accrues. Health professions recommend that once an expectant is diagnosed with complications, it is essential to make early registration and a consistent visit to the primary health institution concerned with initial detection and referral of adverse patients. Initial registration alongside diagnosis is promoting eradication of maternal morbidity and mortality burden.[20]

Institutional parturition aimed at deterring complications: A study conducted in India shows substantial data evidence to prove that accessing health institutions for parturition is averagely 5km. The long-distance of hospitals is the primary reason resulting in high home deliveries. Despite Indian's government 2010 objective of attaining 80% rural deliveries conducted in health facilities being achievable, the result unfolded negatively. Moreover, the same study unraveled no acceleration in the diagnosis of health complications.[21]

Achieving Millennium Development Goal 5 required improvement of attendance's skills towards delivering a quality service to expectant women to reduce child mortality which is still a mandatory concern while continuing the achievement of the SDG.[22] Besides the scheduled delivery improved in the hospital, it is essential for expectant women to deliver in vicinities fully furnished with life-saving equipment alongside good hygiene to eradicate bacterial and viral infections.[23]

Balanced Diet is mandatory particularly calcium and Iron-rich foods: A study unravels that the malnourished women are vulnerable to contracting parturition complications, not excluding premature birth.[24] According to the WHO's medical report, almost 55 percent of expectant mothers in developing countries suffer from Anemia that primarily results from an inappropriate diet regimen[25]. Insufficient Iron concentration is attributing to 1/10 of maternal mortality, especially in developing nations. The factors predisposing women towards contracting Anemia includes nutritional related elements such as deficient folic acid, iron, and Vitamin B12. Besides the nutritional concerns, other health factors such as excessive blood loss during parturition and metabolic malfunction also contribute immensely to anemic condition. In a study Atrashin Bangladesh, social factors such as the nutritional stereotype that restrict expectant women from accessing nutritional diet contributes to parturition complications in sub-Saharan Countries.[26]

Generic alongside Prenatal Counselling aids to the diagnosis of hereditary infections: The CDC organization, from its headquarters in New York, the *Preconception Care Work* strategy recommends the necessity of prenatal therapeutic session for new couples before working out pregnancy issues helps deter parturition complications.[27] The Center for Disease control also initiated a Preconception Counselling policies in 2006 that recommended an improvement of

attitude, behaviors, and knowledge of couple concerned preconception well-being.[28]

Yoga and Meditation promote a healthy as well as stress-free gestation: Yoga has a positive effect on hedging obstetric complications. The randomized controlled test conducted on 78 vulnerable expectant women sorted into Yoga alongside Control groups. The group which accessed Yoga were exposed to at least hourly sessions three times in a week on the third trimester, a fewer PIH, IUGR, Preeclampsia, and PIH manifested. Another controlled study conducted among 59 individuals unraveled an improvement in fetus placenta circulation and intrauterine growth. Performing Yoga in expectant thus proved to curb stress[21], anxiety, depression, and low back pain in expectant women. Therefore, expectant women ought to follow prescribed yoga instructions depending on their body features.[29]

Obtain the correct knowledge about the programs initiated for maternity services and the threatening symptoms during gestation from healthcare practitioners: The antenatal insights and therapeutic sessions ought to consider essential topics especially threatening symptoms of gestation complication. The gestation education to expectant women aims at delivering adequate information through straightforward antenatal programs. The risky symptoms include elements such as headache, blurred vision, vaginal bleeding, abdominal pain, reduced fatal movement, and inflamed pyrexia.[30] Several authors emphasize the necessity of dispensing expectant women with appropriate information essential for the gestation period.[2,31,32]

Routine Antenatal Care is mandatory for early detection of High Risk Pregnancy: A minimum of three visits is recommended as mandatory for a pregnant woman. Research studies conducted to observe the impact of Janani Suraksha Yojana, a cash transfer scheme reported the increase in antenatal visits and consultations and improved rates of hospital delivery among at risk pregnant women.[33]

Conclusion

The healthcare policymakers and the industry is in a unique position to get involved in taking the neglected health aspects to the most vulnerable group–pregnant women. Creativity in delivering health education is essential to capture the attention of the target group influencing their health seeking behaviors and practices.[34] The paper has outlined health education which illustrate several resolutions to curb maternal mortality.

Effect of Chemomechanical Caries Removal with Papacarie Gel on Bond Strength of Composite Resin Restoration

Gamal A.M.[1], Khattab N.M.[2]

[1]Assistant Lecturer of Pediatric and Community Dentistry, [2]Professor and Head of Pediatric and Community Dentistry, Faculty of Dentistry, Minia University, Egypt

Abstract

Aim: The aim of the current study was to evaluate the effect of chemomechanical caries removal with papacarie gel on bond strength of composite resin restoration.

Method: Caries in twenty extracted primary molars with large carious cavities was removed using papacarie gel. Samples were divided into two basic groups (10/each). Group (1) was treated with Adper™ Scotchbond™ SE Self-Etch Adhesive and group (2) was treated with iBond® Total Etch. Both groups were restored with Harvard Restore Composite. Teeth were sectioned vertically with diamond disc, then embedded in self-cure acrylic resin and polished. Teeth were immersed in sodium hypochlorite, followed by hydrochloric acid then rinsed and dehydrated with alcohol. Specimens were dried, mounted on aluminum stab and scanned with electron microscope to evaluate the resin tags qualitatively and quantitatively.

Results: in self-etch group micro-tags were longer, dense and with numerous lateral branches than the total etch group with no significant difference.

Conclusion: Self-etch adhesive system showed longer, dense and numerous lateral branches of resin tags than the total etch after usage of papacarie gel as caries removal.

Keywords: *(Papacarie gel), (Chemomechanical caries removal), (Bond strength), (Self etch), (Total etch).*

Introduction

Chemomechanical caries removal (CMCR) is a noninvasive technique eliminating infected dentine via a chemical agent. This process not only removes infected tissues, it also preserves healthy dental structure, avoiding pulp irritation and patient discomfort. This method of caries removal based on dissolution of infected tissues instead of drilling, this method uses a chemical agent assisted by an atraumatic mechanical force to remove soft carious structure **(Jain et al., 2015)**[1].

This method of caries removal is characterized by the use of a material that acts on the pre-degraded collagen of the lesion, promotes its softening, doesn't affect the adjacent healthy tissues, and avoids pain stimuli (chemical action), then the softened carious tissue is removed with gentle excavation, which makes this technique an effective alternative method to treat carious lesions since it allies no traumatic characteristics with bactericide and bacteriostatic action **(Maragakis et al., 2001)**[2].

A research project in Brazil in 2003 led to the development of a new formula to universalize the use of chemomechanical method for caries removal commercially known as Papacarie®. Papacarie® is basically comprised of papain, chloramines, toluidine blue, salts, thickening vehicle, which together are responsible for the bactericide, bacteriostatic and anti-inflammatory characteristics **(Bussadori et al., 2005)**[3].

Papain acts only in infected tissue because infected tissue lack a plasmatic anti protease called Anti-trypsin. Antitrypsin is present only in sound tissue and it inhibits protein digestion. The absence of anti-trypsin in infected tissue allows papain to break the partially degraded collagen molecules, contributing to the degradation and elimination of the fibrin "mantle" formed by carious process **(Piva et al., 2008)**[4].

Papacarie causes cleavage of the polypeptide chains and hydrolyses the crosslinks of collagen fibrils. After the degradation, oxygen is freed, and this explains the appearance of bubbles on the surface and blearing of the gel during the clinical procedure. These signs demonstrated that the removal process has been started **(Bittencourt et al., 2010)**[5].

Therefore the current study was conducted to evaluate the effect of chemomechanical caries removal with papacarie gel on bond strength of composite resin.

Materials and Method

1. **Collection of samples:** Twenty extracted human permanent molars, with large and visible carious cavities involving the occlusal surface and extending into dentine, were used as samples in the study. All the teeth were cleaned, disinfected and stored in distilled water until use **(Dominiciet al., 2001)**[6]**.**

2. **Caries removing procedures:**

- The Papacarie™ gel (1) was applied to the caries lesion for 30 to 40 seconds, and then softened carious tissue was removed with the blunt end of an excavator.
- The gel was reapplied, if necessary, until the complete removal of the carious tissue was achieved.
- The texture of the remaining dentine was inspected with the use of an exploratory probe to determine successful removal of all caries.

3. **Grouping the samples:**

Selected molars were divided randomly into two main groups:

- **Group1:** Consisted of 10 samples treated with Adper™ Scotchbond™ SE Self-Etch Adhesive (2) and Harvard Restore Composite (3).
- **Group 2:** Consisted of 10 samples prepared for evaluating the bonding characteristics using iBond®(4) Total Etch and Harvard Restore Composite.

(1) Papacarie gel: Gabrie Garcia Ceballos. Mexico.

(2) Adper™ Scotchbond™ SE Self-Etch Adhesive: 3M ESPE. USA.

(3) Harvard Restore Composite: Harvard Dental International GmbH. Germany

(4) iBond®: Kulzer GmbH. Germany

4. **Bonding and restoration:** Each type of etching system was applied according to manufacture instructions. Then Harvard Restore Composite was applied in increments of 2 mm. layers and polymerized for 40 seconds till the whole cavity was restored.

5. **Preparation of samples for scanning:**

- Teeth were sectioned vertically through the resin fillings and dentin with the help of a diamond disc under running water to expose the resin-dentine interface.
- Teeth were embedded in self-cure acrylic resin and polished with 600, 1000, 2000 grit polishing paper and soflex finishing and polishing system. Then they were immersed in 4 % sodium hypochlorite for 20 minutes, followed by 20 % hydrochloric acid for 30 seconds.
- Specimens of both groups were rinsed with distilled water and sequentially dehydrated in 60%, 70%, 80%, 90% alcohol for 20 minutes each and in 100% alcohol for 1 hour.
- Surface morphology and dentin resin interface were dried, mounted on aluminum stubs, placed in a vacuum chamber, sputter coated with gold and observed under a scanning electron microscope.

They were then embedded in self-cure acrylic resin and pol-ished with 600, 1000, 2000 grit polishing paper and Sof lex nishing and polishing systems

They were then embedded in self-cure acrylic resin (figure 9) and polished with 600, 1000, 2000 grit polishing paper and Soflex finishing and polishing systems. Then they were immersed in 4% sodium hypochlorite for 20 mins, followed by 20% hydrochloric acid for 30 sec. The specimens of both groups were rinsed with distilled water and sequentially dehydrated in 60%,70%, 80%, 90% alcohol for 20 minutes each and in 100% alcohol for 1 hour. Surface morphology and dentine-resin interface were dried, mounted on aluminum stubs, placed in a vacuum chamber, sputter coated with gold and observed under a scanning electron microscope.

- A series of photomicrographs were taken at a magnification of 2000x and 5000x for viewing the surface morphology and 1000x for viewing the resin-dentine interface.
- Resin tags were evaluated qualitatively and quantitatively.

- ❖ Qualitative evaluation was carried out by measuring the length of the resin tags according to the scale given on the photographs.
- ❖ Quantitative evaluation of the tags, a four- step (0-3) scale method was used for evaluation of resin-dentine interfaces **[Ferrari et al., 2002]**[7] as follows:
  - Score 0 – no resin tag formation.
  - Score 1- few and short resin tags.
  - Score 2- when long resin tags were visible.
  - Score 3- dense resin tags with numerous lateral branches.

6. **Statistical analysis:** All data were collected, tabulated and statistical analyzed using (SPSS) software version 15 to identify the difference between resin tags formed at the resin-dentine interface using Adper™ Scotchbond™ SE Self-Etch Adhesive and iBond® Total Etch after use of papacarie gel. The significance level was set at $p< 0.05$.

Results

The results revealed that 20% of samples in group (I), showed few and short resin tags with length ≈ 15-20 µm (score 1), 60% of them had long resin tags (score 2) reach to length 80 µm, and the remaining 20% showed dense resin tags with numerous lateral branches (score 3). While in group (2) the percentages were 20%, 70% and 10% for scores 1, 2, 3 respectively (figure 1-6). However no statistical significant differences were detected between groups ($P > 0.05$).

(Table 1) Comparison between the studied groups regarding Resin tags

Resin tags scores	Group 1 N %	Group 2 N %	p^2
Score 1: Few and short resin tags	2(20%)	2(20%)	0.8
Score 2: When long resin tags were Visible	6(60%)	7(70%)	
Score 3: Dense resin tags with numerous lateral branches	2(20%)	1(10%)	

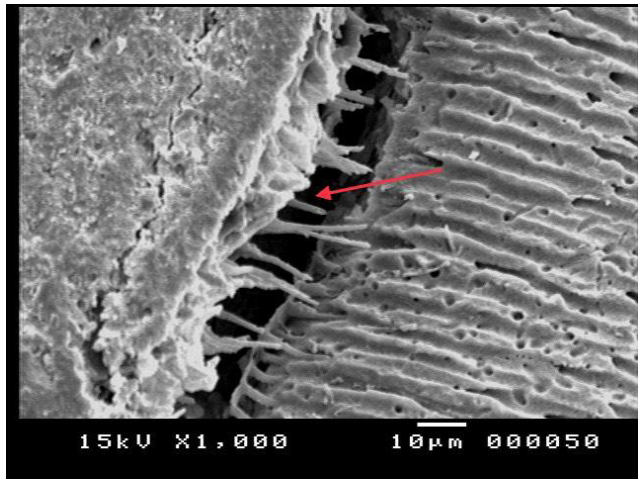

Figure (1): Photomicrograph of scanning electron microscopy (SEM) for samples treated with self – etch (group 1), showed few and short resin tags.

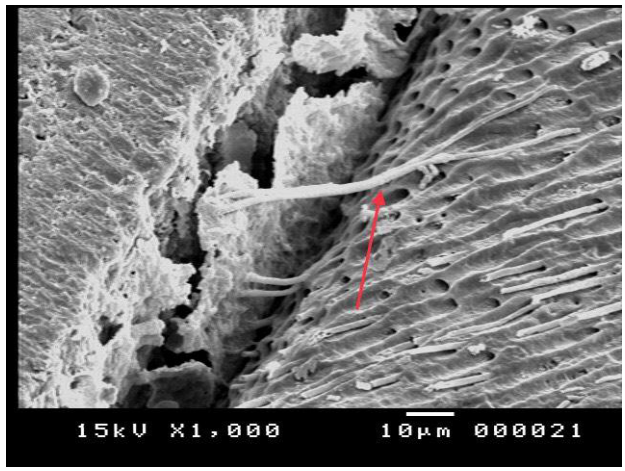

Figure (2): Photomicrograph of scanning electron microscopy (SEM) for samples treated with self – etch, showed long resin tags with lateral branches.

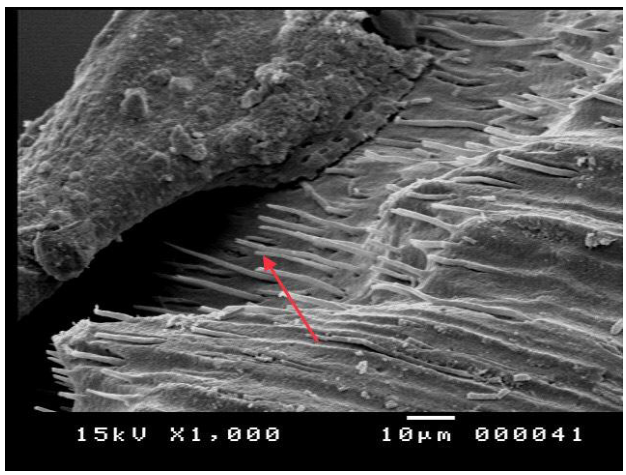

Figure (3): Photomicrograph of scanning electron microscopy (SEM) for samples treated with self – etch, showed dense resin tags.

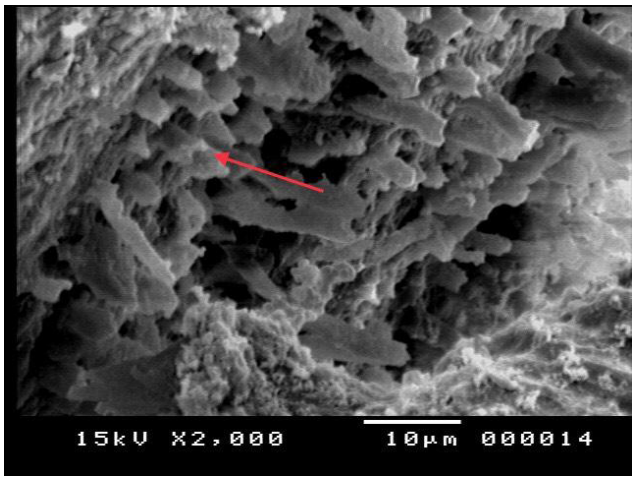

Figure (4): Photomicrograph of scanning electron microscopy (SEM) for samples treated with total-etch (group 2), showed few and short resin tags.

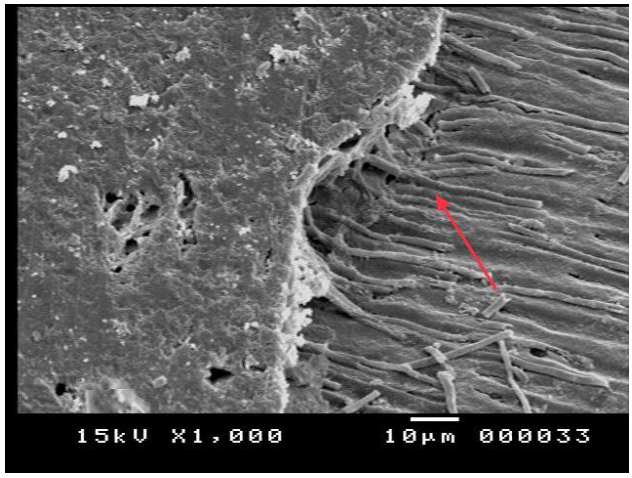

Figure (5): Photomicrograph of scanning electron microscopy (SEM) for samples treated with total-etch, showed long resin tags.

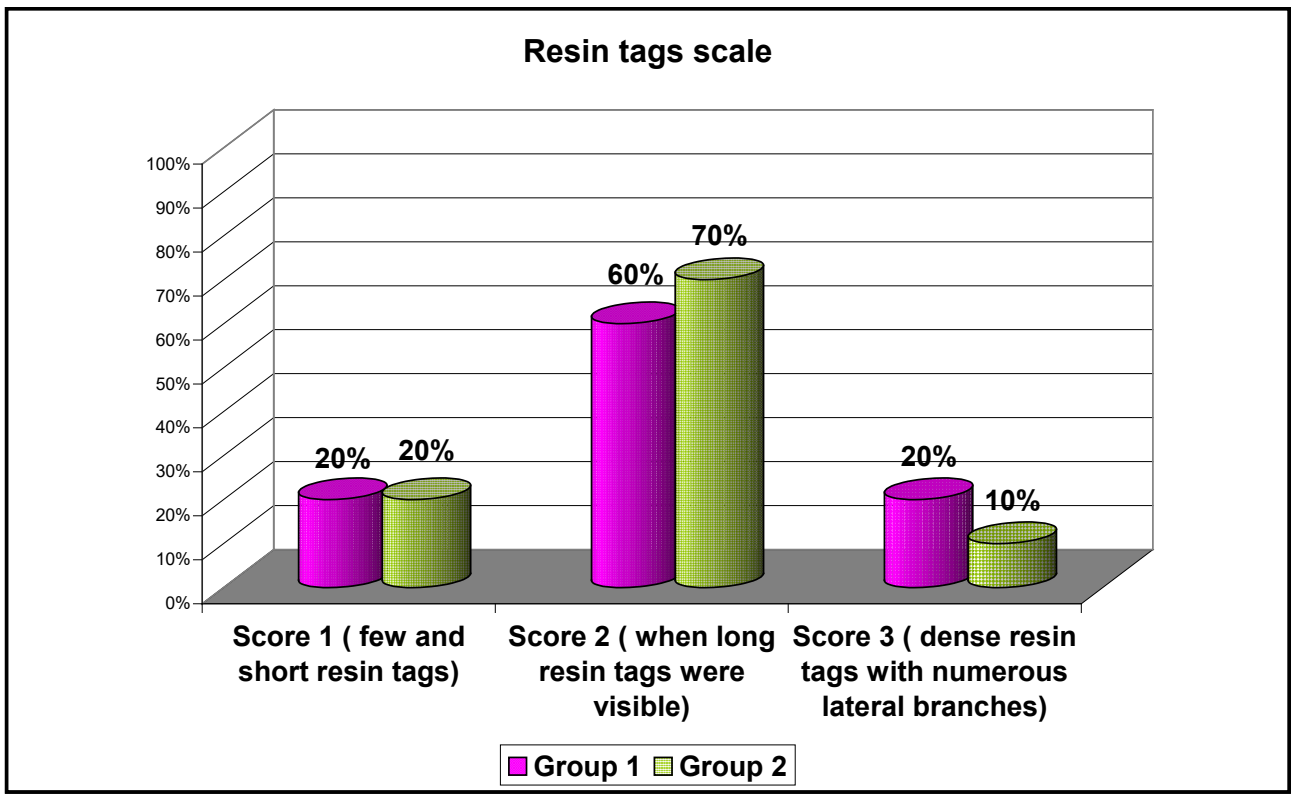

Figure (6): Comparison between the studied groups regarding Resin tags.

Discussion

Caries removal by minimally invasive method followed by achieving perfect coronal seal is the most needed procedures in pediatric dentistry. Mechanical method for caries removal like air rotor and carbide bur remove carious dentin aggressively and large amount of affected dentin is also removed. All latest inventions support minimal removal of caries to prevent any harm to underlying young pulp. One of recent method of minimally invasive caries removal is chemomechanical caries removal.

Papacarie is a formula of chemomechanical caries removal, allows the maximum preservation of healthy dental structures, with antibacterial and anti-inflammatory effects. The advantage of Papacarie is its easy application which does not need special instruments **(Sulianti et al., 2019)**[8].

This study evaluated the influence of a papain based gel (Papacarié) as a chemo-mechanical caries removal agent on the bond strength of micro hybrid photopolymerised composite after bonding with two different adhesive techniques, are self-adhesive and total etch adhesive techniques. These materials are selected for the investigation since they are the most commonly used ones in restorative Pediatric Dentistry.

Resin tags were evaluated qualitatively by measuring the length of the resin tags and quantitatively by determining the density and length of resin tags, these evaluations were done using electron microscope (SEM). **(Atwan and Sullivan)**[9]. SEM was employed in this study because it is simple, inexpensive and does not need sophisticated equipment.

Bond strength and sealing between tooth structure and composite restoration could be affected by three main factors. The first is the composite polymerization shrinkage that induces stress at the bonding interface. Second factor is the substrate, a biological tissue, which makes adhesion difficult. Third factor is chemical composition of adhesive itself **(Guéders et. al., 2006)**[10].

According to these factors that affect the bond strength, the current study evaluated the effect of papacarie gel on bond strength of one type of composite which was universal hybrid photopolymerized composite (Harvard Restore Composite) but the adhesive system was changed, which were Adper Scotchbond SE Self-Etch Adhesive in one group and iBond Total Etch in the second group.

Based on the results of the present study, the bond strength of self-etch adhesive system is better than etch and rinse adhesive system but with no significant difference between two groups after use of a papain based chemomechanical method for caries removal. these findings goes in accordance with the study conducted by **(Anjali, 2017)**[11] who compared the extent of microleakage between tooth and restoration interface in class V composite resin restorations after using Total Etch (Adper single bond) in first group and using Self Etch (Adper ™ SE Plus, Adper ™ Easy One) in second group, results showed that one step self-etch agents had less microleakage than total etches.

In Self Etch adhesives the acidic characteristics of the active monomers are responsible for dissolving the smear layer and demineralizing the underlying dentin. This demineralization is self-limiting because the acidity of the monomers is gradually buffered by the mineral content of the dentin. This implies that the resultant morphological aspect of the bonded interface is largely dependent on the characteristics of the dentin to which the adhesive is being applied and on the aggressiveness of the acidic monomers (**Carvalho et. al., 2012)**[12]**.**

Strong self-etch systems dissolve the smear layer completely similar to etch and rinse while ultra mild leaves the tubules intact with smear plug. the partial demineralization resulting from mild and and ultra mild Self Etch systems has reported to be an advantage because of the possibility of chemical interaction between some functional monomers (such as MDP and 4-META)and the remaining hydroxyapatite crystals along the collagen fibrils. It has been claimed that this chemical bonding resulting in the improved bond durability reported for these systems **(Carvalho et al. 2012)**.

On the other hand **(Ceballos 2003)**[13] observed that an etch and rinse adhesive system exhibit higher bond strength to caries affected dentin than the self-etch system, he suggested that the caries affected dentin contains dentin tubules that are filled with acid resistant minerals than can be solubilized with the application of phosphoric acid on the dentin, therapy contributing to better resin retention.

Conclusion

It was concluded that the self-etching adhesive system achieves better bonding for composite resin restoration than of total etching adhesives to caries-affected dentin after caries removal with papacarie gel.

Ethical Clearance: No need for ethical committee because research was on extracted teeth.

Establishing Nursing Diagnoses Profile for Patients with Multiple Sclerosis: Maslow's Model Application

Hadeer Salah Eldin Abd Elsamea[1], Hanan Ahmed Al Sebaee[2], Heba Ahmed Mohammed[3]

[1]Clinical instructor, Medical Surgical Nursing, [2]Professor, Medical Surgical Nursing, [3]Assistant Professor, Medical Surgical Nursing, Faculty of Nursing, Cairo University, Egypt

Abstract

Multiple Sclerosis (MS) is a chronic inflammatory and autoimmune disease, estimates about 2.5 million people around the world had MS. Furthermore, scanty studies were carried out to document nursing diagnoses among Egyptian patients suffering from MS. The aim of the current study was to establish the actual nursing diagnoses profile for patients with MS applying Maslow's model as assessed by (I) personal information and medical background tool, (II) physical examination tool based on Maslow's model, and (III) Multiple Sclerosis Nursing Diagnoses Profile (MSNDP) that developed by the investigators. Non experimental design was utilized in this study. A convenient sample of 100 adult male and female patients with MS was involved. The current study findings revealed that 29 actual nursing diagnoses for patients with MS based on Maslow's hierarchy were established. The most common actual nursing diagnoses were imbalanced nutrition, activity intolerance and anxiety. Therefore, it is recommended to replicate the study using large sample from different geographical areas in Egypt to obtain more generalized data.

Keywords: *Multiple sclerosis, Nursing diagnosis, Maslow's hierarchy.*

Introduction

Multiple sclerosis (MS) is an autoimmune disease, a chronic inflammatory, demyelinating and neurodegenerative disorder through inflammatory process of unknown etiology and complex factors[1-2] such as immunologic, genetic, viral and environmental factors that may affect on the disease's progression, so it causes neurological disability by decreasing nerve conduction[3,4]. It is estimated that about 2.5 million people around the world had MS[5]. The last annual statistics for inpatient with MS among Egyptian attending El Kasr Al Ainy MS research unit at Cairo University in the last three years 2016, 2017 and 2018 was 1439, 1957 and 1402 respectively[6].

There's no cure for MS to date although early pharmacological treatments can delay the progression of the disease[7]. Management of multiple sclerosis requires integration of multiple disciplines of health professionals who should have the basic knowledge and skills necessary to provide optimal care for the dynamic demands of the patient and the family. The nurse is a key member of health care team because the nurse is more contacted with patient and family. Nursing intervention is individualized for each patient through continuous assessment for patient progression. Appropriate care focuses on safety, prevention of complications, assistance with physical therapy and emotional support during diagnostic and therapy stages[8].

Applying care through nursing process provide nurses with an organized frame of reference regarding patients' problems and skills. The nurse gather all relevant information depend on the clinical situation, patient status, time available and purpose of data collection[9]. Accurate assessment information is essential for the provision of high quality nursing care [10-11]. All humans are born with instinctive needs, these needs grouped into five categories which arranged from physical survival to develop a person's fullest potential according to Maslow's hierarchy of human needs. People are motivated to achieve lower level needs; once

Clinical instructor, Medical Surgical Nursing
e-mail: hadeer.eldin1991@gmail.com
Mobile Phone: 01149054098

that level is fulfilled the next level up motivates people, and so on[12].

Based on literature review, the investigators found wide variety of nursing diagnoses related to patients with MS as fatigue, self-care deficit, self-esteem disturbance, sleep disturbance, social isolation and potential for ineffective family coping as reported by[3]. Ineffective activity planning and ineffective airway clearance were reported by[9]. Costa et al., [13] found that the most frequent nursing diagnoses in patients with MS were: impaired physical mobility and activity intolerance; while the least frequent was a risk of disuse syndrome. Furthermore, scanty research studies were carried out to document nursing diagnoses among Egyptian patients suffering from MS based on Maslow's model; therefore, the aim of this study is to establish nursing diagnoses profile for patients with multiple sclerosis using Maslow's model as a frame.

Significance of the study: Nursing diagnoses profile will help nurses, researches, patients and their family in determining properly patients' needs and make appropriate decision in caring and consequently improving quality of care. Nurses can monitor patient condition through identifying defining characteristics and contributing factors, so they can prevent or reduce complications which faced patients during disease process. They will provide scientific evidence for nurses to give proper instructions for patients or/and family members to cope with expected problems.

Nursing diagnoses profile will increase patient satisfaction by knowing health problems and how to cope with it; consequently patient hospital stay or readmission will be reduced and psychological status of patient and family will be maintained and enhanced. Moreover, it will decrease the level of stress for patient's family through enhancing patient's outcome. It will guide researchers to explore about proper management in caring of patients with MS to improve their quality of life.

Method

Aim of the Study: This study aimed to establish actual nursing diagnoses profile for patients with multiple sclerosis applying Maslow's model.

Research question: To fulfill the aim of the study, the following research question was postulated:

What is actual nursing diagnosis profile of patient with multiple sclerosis: Maslow's model application?

Research Design: Non experimental, descriptive - explorative design was utilized in the current study

Sample: A convenient sample of 100 adult male and female patients with a confirmed diagnosis of MS and able to communicate constituted the study sample through a consecutive six months duration at multiple sclerosis research unit (KAMSU) affiliated to Cairo University.

Data Collection Tools:

Data was collected using three developed tools:

(I) Personal information and medical background tool; which included demographic and medical background.

(II) Physical examination tool based on Maslow's model; it designed according to the levels of Maslow's hierarchy of needs. Every level gathered through physical examination and patient's verbalization.

(III) Multiple Sclerosis Nursing Diagnoses Profile (MSNDP): This tool included defining characteristics and contributing factors of nursing diagnoses.

Validity & Reliability: Tools were validated by a panel of five experts in the field of Medical-Surgical Nursing and modifications were carried out. Reliability was tested using Cronbach's alpha with value of 0.98.

Procedure: Relevant data was collected after individualized interview with patients, it took one - two hours to fill the tools and record patients' responses.

Statistical analysis: Descriptive statistics were utilized to analyze collected data by using SPSS version 20.

Results

Section I: Demographic characteristics and background: More than three quarters of the study sample were female; age ranged from 30 - 40 years for more than one quarter with a mean of 32.27 ± 8.02; around two thirds were married and more than two thirds were unemployed.

Figure (1) shows that 78% of studied sample was diagnosed with relapsing remitting MS

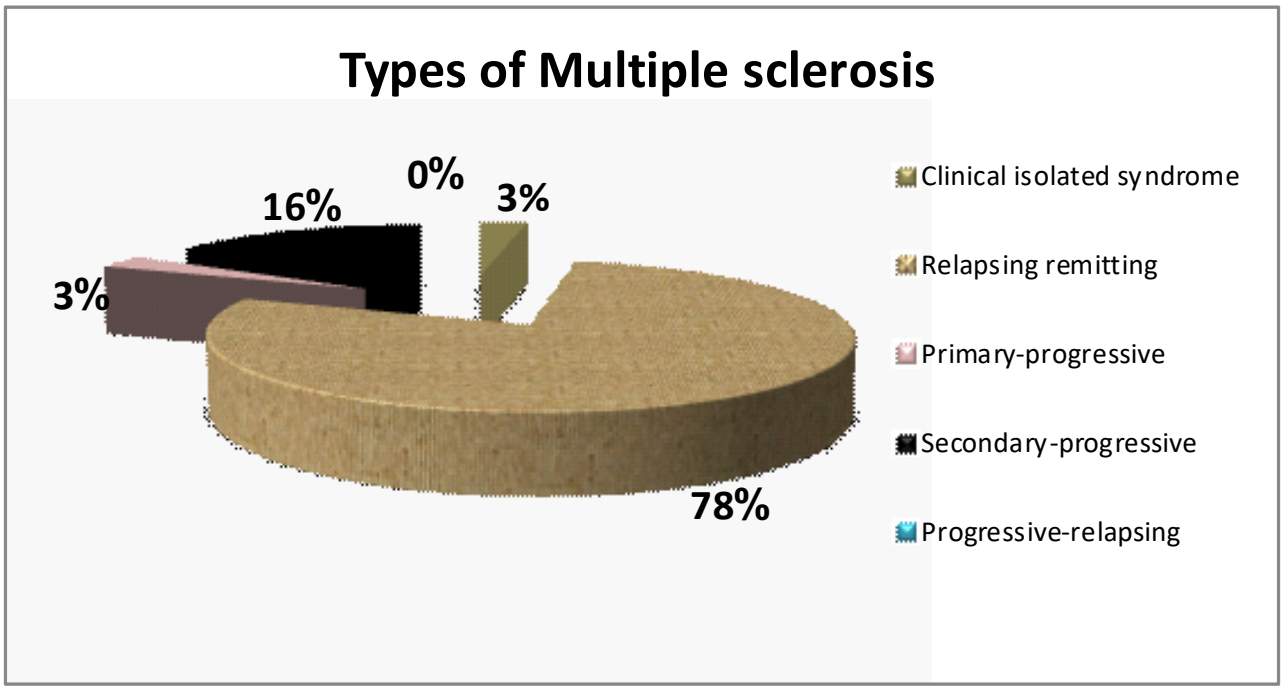

Figure (1): Percentage distribution of sample according to types of MS (N=100).

Section II: Actual nursing diagnoses profile for patients had Multiple Sclerosis according to Maslow's hierarchy.

Table 1: Percentage distribution of actual nursing diagnoses profile according to physiological needs of Maslow's hierarchy (N=100).

Levels of needs	Actual nursing diagnoses	Defining characteristics	Contributing factor/s	%
Physiological needs	Imbalanced nutrition: less than body requirements	Recent change of body weight	Alternation in GIT function (nausea-vomiting-anorexia)	85
	Decreased cardiac output	Edema	Alteration in tissue perfusion	83
	Ineffective peripheral tissue perfusion	Edema	Limitation of vascular functioning	83
	Impaired skin integrity	Edema	Ineffective peripheral tissue perfusion	83
	Alteration in comfort	Increase severity of pain	Alteration in motor &sensory functions	64
	Disturbed sleep pattern	Feeling unrested	Alteration in comfort	64
	Impaired urinary elimination	Incontinence	Loss of motor & sensory function	54
	Sexual dysfunction	Alteration (activity/ satisfaction/desire)	Psychological problems	39
	Impaired bowel elimination	Change in bowel pattern	Alteration in nutrition oral habit	32
	Disturbed in health management of disease	Express doesn't continuous in management	Long time administration	24
	Ineffective breathing pattern	Tachypnea	Using accessory muscles	19

Table (1) clarifies that the highest percentage of actual nursing diagnoses was imbalanced nutrition 85%; while the ineffective breathing pattern constituted 19%.

Table 2: Percentage distribution of actual nursing diagnoses profile according to safety and security needs; love and belonging of Maslow's hierarchy (N=100).

Levels of needs	Actual nursing diagnoses	Defining characteristics	Contributing factor/s	%
Safety and security needs	Activity intolerance	Fatigue	Generalized weakness	84
	Disturbed Sensory Perception	Alteration in vision	Alteration in motor &sensory	79
	Impaired physical mobility	Slowed movement	Loss or limitation in motor & sensory	79
	Self-care deficit	Toileting: partial dependent	Alteration in physical ability	79
	Deficient Knowledge	Statement of misconception	Unfamiliarity with the disease and management	42
	Impaired memory	Forgetfulness	Alteration in neurological function	32
		Inability to recall events or rain new information		
Love and belonging needs	Anxiety	Express about anxiety	Management of disease	86
	Chronic sorrow/Grieving	Psychological distress	Change of role performance	80
	Self –neglect	Change of body image	Alteration in physical ability	79
	Interrupted family processes	Assigned tasks change	Inability to fulfill expected roles	78
	Social isolation	Desire to be alone	Change communication	70
	Powerlessness	Alienation	Illness-related regimen	69
	Spiritual distress	Impaired spiritual activity	Alteration of physical ability	24

Table (2) illustrates the highest percentage of actual nursing diagnoses according to safety and security needs was activity intolerance 84%; while the lowest percentage was impaired memory 32% and regarding to love and belonging needs the highest percentage was anxiety 86%; while the lowest percentage was spiritual distress 24%.

Table 3: Percentage distribution of actual nursing diagnoses profile according to self-esteem and self-actualization needs of Maslow's hierarchy (N=100).

Levels of needs	Actual nursing diagnoses	Defining characteristics	Contributing factor/s	%
Self-esteem needs	Low self-esteem	Rosenberg scale (low score)	Ineffective coping with loss	70
	Ineffective coping	Reporting coping disability	Change in physical & Psychological	70
Self-actualization needs	Deficit diversional activity engagement	Reduced participation in recreational	Disease process	52
	Decisional conflict	Delay in decision-making	Insufficient support system	42
	Ineffective activity planning	Inability to prepare for a set of action (un ambition)	Alteration of psychological status	41

Table (3) clarifies that the highest percentage of actual nursing diagnoses regarding to self-esteem needs were low self-esteem and ineffective coping 70% and regarding to self-actualization needs the highest percentage was deficit diversional activity engagement 52% and the lowest percentage was ineffective activity planning 41%.

Discussion

Actual nursing diagnoses profile regarding physiological needs of Maslow's hierarchy: Imbalanced nutrition was documented by more than two thirds of patients. It might be due to alternation in GIT functions (nausea, vomiting, loss of appetite) and side effect of medications that lead to loss or change of body

weight. This result was contradicted with study done by Huizen[4] who found that 10% of patients with MS had nausea and vomiting.

Ineffective breathing pattern and use accessory muscles were observed for less than one quarter of sample because of chest muscles weakness. On the same line, a study done by Health line[1] and a study done by Ackley, Ladwing, Makic[9] reported the same findings.

Actual nursing diagnoses profile regarding safety and security; love and belonging needs of Maslow's hierarchy: Activity intolerance expressed by fatigue was reported by more than three quarters of sample as MS affects the muscles' functions that result in improper physical mobility, disturbance in sleep, incontinence of bladder function, pain, psychological distress, and self-care deficit. This result agreed with Huizen[4] who reported fatigue from 80% of patients. However, this result contradicted with Costa et al[13] where less than half of sample reported fatigue.

Impaired memory was reported by more than one quarter of sample. It might be a result of disease process on the cognitive status and neurological functions. This finding partially agreed with Pittsburgh Institute[14] which reported that approximately half of patient with MS had cognitive dysfunction. It was congruent with Huizen[4] and Costa et al[13] in symptoms of cognitive change (remembering recent information, organize and solve problem or recall events).

Anxiety was found in the majority of the sample. It might be related to the nature of the disease and its distressing sequences as a chronic inflammatory and neurodegenerative disorder. This finding was partially supported by Pittsburgh Institute[14] who reported that 35% of patients with MS had anxiety and by Costa et al[13] who reported that less than half of sample had anxiety.

Spiritual distress was expressed by approximately one quarter of sample. It might be related to improper physical mobility and psychological distress. Rest of sample had healthy spiritual status especially after getting diseased with MS that it might be related to the culture beliefs to attach with spiritual activities in confronting any disaster. The result of the current study was in the same line with Niyazmand, Abbasszadeh, Borhani & Sefidkar[15] who found spiritual health and hope could have positive improvement of psychological status in patient with MS.

Actual nursing diagnoses profile for patients with MS regarding self-esteem and self-actualization needs of Maslow's hierarchy: Low self-esteem was found in around two thirds of sample. It might be resulted from reported coping disability, increased incidence of female gender, unemployment status or related to type of MS. This result consistent with study done by American Association of Neurosurgical Nurses[16] and Zitnik, Mills, Tennant and Young[17] who reported that low self-esteem in MS related to fatigue, level of disability and employment status. The result partially agreed with N Ifantopoulou et al[18] who reported that perceived stress had significant effect on low self-esteem and depression was around fifty percentages. This result contradicted with Costa et al[13] who reported that more than one third of sample had low self-esteem.

Deficit diversional activity engagement was reported by more than half of sample. It might be related to the effect of disease on physical mobility, psychological disturbance, insufficient encouragement of family members, ineffective coping with disease or delay in decision making and formulating planning for activity. The same finding was reported by studies done by Huizen[4] and Costa et al [13].

Ineffective activity planning was found in more than one third of sample. It might be related to the effect of disease on body systems, un acceptance of MS as chronic uncured disease and awareness of patient about the progressive nature of the disease that lead to development of chronic sorrow, change of role performance and feeling of powerlessness. The findings were supported by Huizen[4] who reported that MS had an improper effect on physical and psychological status of patients that result in un ambition to perform any activity.

Conclusion and implications: Finally, the most common actual nursing diagnoses for MS patients were anxiety, imbalanced nutrition, activity intolerance, decreased cardiac output, ineffective peripheral tissue perfusion and impaired skin integrity. This result will guide nurses about nursing diagnoses which might face MS patients and their family members, so direct them regarding accurate instructions to cope with problems; consequently decrease level of stress for patients or/and family members, hence, enhance patient's outcomes. Nurses can improve quality of care through formulating appropriate comprehensive nursing care plan for patient's needs based on Maslow's hierarchy of needs.

The study recommended the following:

- Replication of the study on a larger probability sample selected from different geographical areas in Egypt to obtain more generalized results.
- Organize workshop for students, nurses, patients and family members to increase awareness about problems for patients had multiple sclerosis.

Ethical Clearance: A research approval was obtained from the Research and Ethical committee at Faculty of Nursing - Cairo University and official permission was obtained from the administrators at study setting. Written informed consent was obtained from each patient.

Conflict of Interest: The authors declare that there is no conflict of interest.

Source of Funding: Self-funding.

Abstract

Identifying socioeconomic factors affecting immunization status may provide the insight to facilitate the development of effective strategies and policies to reduce the number of incomplete immunizations among children, therefore decreasing child mortality and morbidity. This study, conducted from October to November 2018, aimed to identify socioeconomic factors influencing immunization status in under-five children in Tanah Tinggi, Johar Baru, Central Jakarta. A total of 237 subjects were recruited to participate in this study. The prevalence of complete immunization status was 84.8%. Most cases of incomplete immunization were found among children aged 12–23 months. Significant socioeconomic determinants for complete immunization status were age group, families of one to two children (odds ratio [OR]= 2.85; 95% confidence interval[CI]: 1.29 to 6.33), and highly educated mothers (OR = 2.72; 95% CI: 1.24 to 5.96). Multidisciplinary approach to intervene these risk factors could be effective for decreasing the number of incomplete immunizations.

Keywords: *Children; determinants; immunization; slum; socioeconomic; urban.*

Introduction

Children are an important asset for the future of a country. Since 1978, the World Health Organization (WHO)/UNICEF Expanded Program on Immunization has successfully decreased child mortality rates for vaccine-preventable diseases in both developed and developing countries but apparently has not decreased the number of unvaccinated children[1,2]. In 2013, more than six million children five years of age and above died during the neonatal period due to infectious diseases, such as pneumonia, diarrhea, malaria, meningitis, and measles[3]; some of which can be prevented by vaccination. During the same year, 21.8 million children one year of age and above had not been fully immunized with diphtheria, tetanus, pertussis, and measles vaccines[2]. Meanwhile, recent data from Indonesia in 2018 showed the rate of children with complete, incomplete, and without primary immunization was 57.9%, 32.9%, and 9.2%, respectively[4].

Socioeconomic status plays an important role in determining both life and health standards. It also has an impact on social security in terms of accessibility, affordability, acceptability, and utility of health facilities. Evidence has shown that children with a well-educated parent, high family income, or those living in an urban area have more complete immunization status[5] which showed that immunization practice favored children with relatively higher socioeconomic status[6]. Identifying socioeconomic factors which may influence immunization status may provide much-needed insight to develop effective strategies and policies to reduce the number of incomplete immunizations among children.

Given this background, our study aimed to determine the socioeconomic factors influencing immunization

status in under-five children in Tanah Tinggi, Johar Baru, Central Jakarta.

Material and Method

This was a cross-sectional study in which a questionnaire was applied and filled by health workers while they were conducting community service in Tanah Tinggi, Johar Baru District, Central Jakarta from October to November 2018. This is a densely populated slum in urban area. Children aged 0–60 months were included in this study by stratified random sampling. We examined 294 children, of which 56 were dropped out because of incomplete data and one was excluded (aged 61 months old). Participants' parent or caregiver signed a written informed consent form prior to study participation.

The interview with the mother or caregiver was done individually using a questionnaire. Independent variables in this study were: age, sex, birth order, total number of children in the family, primary caregiver, mother's education, working mother, and family income. Age grouping was done according to the immunization schedule: 0–11 months (primary immunization); 12–23 months (secondary immunization); and 24–60 months (catch-up immunization). Birth order was categorized into 1–2 (first and second child) and more than two (third child or more). The total number of children in the family was classified one to two and more than two. The primary caregiver was classified into mother and other than the mother. The mother's education was categorized as less educated (below senior high school) and highly educated (senior high school and above). The mother's occupation was classified as working and not working. Classification of family income was made according to regional minimum wages in DKI Jakarta province in 2018 for low (below 3,600,000 IDR) and high income (3,600,000 IDR and above). The dependent variable was the immunization status. Complete immunization included full primary immunization provided by the national program until nine months of age (hepatitis B, BCG, polio, DTP-HB-Hib, measles/MR) and booster (DTP-HB-Hib, measles/MR) immunization according to age[7]. Incomplete immunization referred to children who missed one or more immunization doses or who had never been vaccinated.

Statistical analysis was done using Statistical Package for Social Sciences version 20.0. Bivariate analysis for proportional differences was done using Chi-square and Fisher test as appropriate. Variables with p value<.25 were included in multivariate logistic regression analysis and considered significant if p value<.05.

Findings: This study included 237 subjects aged 0–60 months old. Most subjects were male (54.4%) and aged between 24 and 60 months (60.8%). The prevalence of low and highly educated mothers in our study population was comparable (43.9% vs. 56.1%). Most mothers did not work (86.5%) and acted as primary caregivers (85.2%). About two thirds of the subjects came from low-income families.

The prevalence of complete immunization status in under-five children in Tanah Tinggi was 84.8% (201/237 subjects). Table 1 provides an analysis of the socioeconomic factors affecting immunization status. We found a significant difference between complete and incomplete immunization status for the following variables: age group, birth order, total number of children, and mother's education. Three variables were found to have significant association with immunization status in the final model (Table 2): age 24–60 months, 1–2 children in a family, and highly educated mother.

Discussion

The prevalence of complete immunization in under-five children in this study was 84.8%; higher than that reported in a basic health research study conducted in 2018 (57.9% in children aged 12–23 months old)[4] and similar to the WHO and UNICEF's Global Immunization Vision and Strategy target (80%)[8]. Results from a study in a densely populated area, such as ours, may describe a socioeconomic condition that can be extrapolated to the general population in Indonesia as well as other developing countries.

We found no significant differences between sexes in immunization status, which is similar to previous studies[9,10]. This finding denoted no discrimination toward Indonesian children of any sex. In contrast, other studies showed more complete immunization status in male children[1,11,12]. Women in low-income countries are more dependent on men socially, economically, and culturally. This resulted in disadvantages for women, one of which was a lack of preventive health care such as vaccinations[5,12]. Previous study reported higher prevalence of unimmunized females than males; however, immune response after vaccination was better in females. Adverse events following immunization such as fever, pain, and inflammation were more serious in females, leading to more vaccination refusals.[13]

Most incomplete immunization cases were found among children aged 12–23 months (44.4%), while the least cases were found among children aged 0–11 months (19.4%). According to previous study, child's increasing age was negatively associated with complete immunization coverage of five traditional vaccines (DTP/DTaP, IPV/OPV, Hib, MMR, and HBV). Except for hepatitis B, coverage for age-appropriate immunization of those vaccines was satisfactory at the age of 12 months but gradually decreased thereafter at the ages of 24 and 60 months[14]. This finding was supported by a study conducted in Gambia[15], which reported high vaccination coverage in the first year of life. Lower booster coverage was probably because parents were less likely to bring the children back for later doses of vaccines as they gave more attention to younger siblings as well as limited knowledge and unawareness about booster doses[16].

Similar to previous studies[1,11], our study showed a significant difference between birth order and immunization status. This is probably a result of the differences in parenting method in terms of birth order as parents give more attention to their first or second child. This was supported by our finding in which families with one or two children were two times more likely to have complete immunization status compared to those with more than two children. Parents in a larger family are unable to focus on one child only and have other priorities over the timely immunizations[17]. Families with ≥3 children aged under 18 were more likely to have incomplete immunization status because parents tend to forget or miss the immunization schedule and have difficulty in remembering or coordinating the immunization schedule among the children[17–19].

A higher level of maternal education was related to the child's health and had an impact on the understanding of the benefits of immunization[5,6,12,17,20]. Mothers with higher education tend to know more about the importance of immunization and have modern thinking and confidence in making the best decision for family health and toward receiving health information. Furthermore, preventive health services were more acceptable among highly educated people[17].

The mother's occupation was not associated with immunization status. In contrast, previous study by Ueda et al.[20] showed a strong association between working mothers and incomplete immunization status mainly because working mothers did not have spare time to take the children for immunization. Moreover, missing a day of work would result in decreased pay. The difference in the findings are probably attributable to the cultural differences between the Japanese and Indonesian populations. Working mothers in Indonesia may still strive to get her children immunized by taking them to health care facilities during the weekend or even asking for permission during weekdays. Another caregiver may also bring the children for immunization as more relatives live nearby.

Previous studies have showed that an increase in family income may increase the complete immunization status[17,18,21,22]. Reportedly, incomplete immunization status in a low-income family is because they spend more time at work rather than getting immunizations and have lower awareness for health-seeking behavior[18]. However, we found no significant difference between family income and immunization status. This finding could be explained by the presence of free government vaccination programs which are routinely applied by community-based health services, such as *Pos Pelayanan Terpadu (Posyandu)* and Primary Healthcare Center. Community-based health services are more acceptable in low socioeconomic population as the travel time to health facilities is shorter, the transportation costs are lower,[10] and the immunizations are free of charge. Unavailability of health services nearby may cause vaccination hesitancy which is not explored in this study because there was a primary health center 15 minutes away on foot from the subjects' residences.

The main limitation of our study was a possible risk of recall bias. Several subjects who forgot to bring or lost their maternal and child health handbook gave information about immunization status based solely on recall. To avoid such bias, we suggest further research to include a check of all subjects' immunization statuses from the medical records or maternal and child health handbooks.

Table 1. Bivariate analysis for determinant socioeconomic factors of immunization status

Socioeconomic factors	Description	Immunization status		OR (95% CI)	p value
		Complete (n=201)	Incomplete (n=36)		
Sex					
	Male	107	22	0.72 (0.35–1.50)	.382
	Female	94	14

Total number of children (1–2)	1.048	2.85 (1.29–6.33)	.010*
Mother's education (≥ senior high school)	0.999	2.72 (1.24–5.96)	.013*
Constant	-0.171	0.84	.758

*p value < .05

Conclusion

In conclusion, identifying contributing socioeconomic factors of complete immunization status will provide a much-needed insight to implement effective immunization programs. The prevalence of complete immunization status in our study was 84.8%. Most cases of incomplete immunization were found among children aged 12–23 months, a period during which these children are supposed to receive booster doses. Birth order (>2) and total number of children in the family (>2) contributed significantly to incomplete immunization status. Family planning would probably indirectly increase the immunization status if done

properly. The mother's education was one of the main contributing factors for complete immunization status. Therefore, parents should encourage their children, especially daughters, to complete the 12-year compulsory education.

Additional Information: There is no conflict of interest related to this research: This work was supported by the Department of Child Health Faculty of Medicine Universitas Indonesia Post-graduate Pediatrics Training Program Community Development Fund [383/L/PPDS IKA/VIII/2018].

This study has obtained ethical approval from the Ethics Committee of the Faculty of Medicine Universitas Indonesia (0921/UN2.F1/ETIK/2018).

Effects of Serum Ferritin and White Blood Cell on Overweight and Obesity in South Korean Adults

Hea Shoon Lee

Department of Nursing, Hannam University, Daejeon 34430, Republic of Korea

Abstract

The purpose of this study was to determine the difference between WBC and ferrit in according to obesity level in Korean adults. This study was performed the 5,281 subjects older than 19 years. Data were analyzed using descriptive statistics, ANOVA, χ^2-test, Scheffe's test, Pearson correlation coefficient and logistic regression analysis. The ferrit in showed higher in the obesity, overweight than the normal weight. The WBC was highest in obesity, followed by overweight, and the lowest in the normal weight. Second, BMI was positively correlated with ferrit in and WBC. Third, The ferritin was greater than normal weight in overweight 1.01 times and obesity 1.03 times. WBC was greater than normal weight in overweight 1.07 times and obesity 1.19 times. Obesity and overweight were associated with ferritin and WBC. Thus, intervention for ferritin and WBC should be included in the obesity management and prevention program for Korean adult.

Keywords: *Adult, Body mass index, Ferritins, White Blood Cells.*

Introduction

Obesity is a global health problem,600 million adults are obese in 2014.[1] Raised BMI is a major risk factor for non-communicable diseases, which were the leading cause of death.[2] The obesity was classified as a "disease" in 2013 by the American Medical Association.[3] Obesity is risk factors for ischemic heart disease, diabetes, metabolic syndrome et al.[4] In addition, the increase in the occurrence of iron deficiency (ID) and iron deficiency anemia (IDA), obesity also increases the social and economic burden.[5] Obesity people persisted in subclinical inflammation, leading to ID, malignancy, and so forth.[6-8]

Serum ferritin is used as a marker of iron deficiency.[9] Serum ferritin levels are present in abnormal conditions because they are acute phase reactants, serum ferritin levels are high in obesity, which are generalized inflammatory conditions.[10] For this reason, the use of serum ferritin as a marker of ID or IDA in obese is controversial.[11] The inflammation caused by the increase of the adiposity will be suggested as a link between iron status and obesity.[12] Among the many metabolic activities of obesity, high BMI is associated with incompatibility of iron parameters.[13,14]. Obesity of chronic inflammation showed low iron status.[15] Physical activity may be another factor associated with body iron reduction in obesity.[16]

The WBC is needed to protect against invading organisms and the immune system.[17,18] There is strong evidence for a link between obesity and increased WBC count.[19,20] Obesity is also associated with increased leptin levels.[21] WBC has a positive correlation with percentage body fat and leptin concentrations.[22]

The relationship between serum ferritin and WBC has been extensively studied as a subject of foreign obesity,[15,16,19-22], but there are few studies of obesity in Korea. In particular, studies investigating the difference in serum ferritin and WBC in overweight and obese are rare.

In this study, we suggested a fundamental data of adult obesity prevention and management program by identifying the relationship between BMI, serum ferritin and WBC.

Materials and Method

Research Design: This study is a descriptive survey study which attends a secondary analysis of the

Fifth Korea National Health and Nutrition Examination Survey's raw data to check the differences of serum ferritin and WBC depends on Korean adults' obesity degree.

Samples and setting: Subject of this study is adult(over 19 years) and data is based on 'The Fifth Korea National Health and Nutrition Examination Survey (KNHANES V-3), 2015' which Ministry of Health and Welfare and Korea Centers for Disease control and prevention conducted.

According to classification standard of BMI groups were divided in normal weight 2303 subject, overweight 1282 subject and obesity 1696 subject. The final 5281 subjects were analyzed as the data of this study.

Measuring method: BMI: The representative method to measure obesity is BMI, and the way to change BMI into clinical obesity category has slight difference following weight distribution of west and east.[23,24] Based on this, the BMI categories are normal weight (BMI<23 kg/m²), overweigh (23≤BMI<25 kg/m²) and obesity (BMI≥25 kg/m²).[25]

Blood measurement: The serum ferritin measurements, immunoradiometric as say was used for inspection method, IRMA-mat Ferritin (Dia Sorin/ U.S.A) for reagent. It is analyzed, with 1470 WIZARD gamma-Counter (Perkin Elmer/Finland). WBC measurements was performed with, laserflow cytometry as inspection method, Detergent, Cellclean (Sysmex/ Japan) for reagent. Ii is analyzed, with XE-2100D (Sysmex/Japan).

Data analysis: The difference of serum ferritin, WBC depends on subject's obesity degree was analyzed by ANOVA, χ^2-test, Scheffe's test. The relation between subject's BMI, serum ferritin, WBC was analyzed by Pearson correlation coefficient. The factors influencing overweight and obesity were analyzed by logistic regression (SPSS 24.0).

Findings

General characteristics of subject: The average BMI is 23.76, specifically, normal weight was 43.6%, overweigh was 24.3%, and obesity was 32.1%. The mean serum ferritin was 81.88 and WBC was 5.87 (Table 1).

Table 1. General characteristics of subject (N=5.281)

Variables	Category	Mean±SD N(%)	Acquired score range
Age (years)		50.80±16.39	19~88
Gender	Male	2219(42.0)	
	Female	3062(58.0)	
Education level	Under elementary school	1314(24.9)	
	Middle School	565(10.7)	
	High school	1787(33.9)	
	Above college	1607(30.5)	
Weight change over the past year	No change (within 0-3Kg)	3568(67.6)	
	Weight loss	747(14.1)	
	Weight gain	966(18.3)	
BMI		**23.76±3.40**	**14.42~53.54**
	Normal weight(BMI<23)	2303(43.6)	
	Overweigh(23≤BMI<25)	1282(24.3)	
	Obese(BMI≥25)	1696(32.1)	
Serum ferritin		**81.88±24.23**	**12.00~450.40**
WBC		**5.87±1.65**	**2.00~24.00**

Differences in serum ferritin, WBC according to subject's BMI: The age of subjects was higher in overweight and obese than in normal group (F=58.953, p<0.001). According to obesity, there was a difference in gender (χ^2 = 55.937, p<0.001),education level (χ^2 = 111.371, p<0.001) and weight change over the past year (χ^2 = 150.469, p<0.001).According to obesity, there was a difference in BMI (F = 7012.793, p<0.001), serum ferritin (F=59.122, p<0.001) and WBC (F=57.490, p<0.001) (Table 2).

Table 2. Differences in serum ferritin, WBC according to subject's BMI (N=5,281)

Variables	Category	Normal weigh G[1] N=2303 Mean±SD N(%)	Overweigh G[2] N=1282 Mean±SD N(%)	Obesity G[3] N=1696 Mean±SD N(%)	F/χ^2 (p value)

WBC		5.63±1.65	5.89±1.54	6.19±1.67	57.490(<0.001) 3>2>1

Correlation between subject's BMI, Serum ferritin and WBC: The subject's BMI was positively correlated with serum ferritin (r=0.152, p<0.001) and WBC (r=0.157, p<0.001) (Table 3).

Table 3. Correlation between subject's BMI, Serum ferritin and WBC (N=5,281)

Variables	BMI	Serum ferritin	WBC
	r (p value)		
BMI	1		
Serum ferritin	0.152(<0.001)	1	
WBC	0.157(<0.001)	0.120(<0.001)	1

Factors Affecting Overweight and Obesity: As the age goes up, the overweight 1.02 time sand obesity 1.01 times increased. In gender, female were higher overweight 1.38 times and obesity 1.22 times than male. At the educational level, overweight was lower in the middle school 0.71 times and high school 0.74 times compared to the under elementary school. On the other hand, above college 1.40 times increased. Obesity was lower in the middle school 0.58 times and high school 0.75 times compared to the under elementary school. At the weight change over the past year, overweight was reduced in weight loss 0.73 times compared to no change, and overweight was increased in weight gain 2.29 times compared to no change. Obesity was increased in weight gain 3.58 times compared to no change.

The overweight (as compared to those being of normal weight) had 1.01 times greater odds of serum ferritin. In addition, obesity(as compared to those being of normal weight had 1.03 times greater odds of serum ferritin. The overweight group had 1.07 times greater odds of WBC, In addition, obesity group had 1.19 times greater odds of WBC (p<0.001) (Table 4).

Table 4. Factors Affecting Overweight and Obesity (N=5,281)

Variable	Category	Normal weight vs Overweight		Normal weight vs Obesity

Discussion

In this study, overweight and obesity showed more female than male. This is more common for female and obesity is considered a serious health threat.[26] In this study, BMI and serum ferritin were positive correlation, and serum ferritin was the highest in obesity and the lowest in normal weight. In addition, serum ferritin was greater than normal weight in overweight 1.01 times and obesity 1.03 times. The study second, third and fourth quartiles of serum ferritin levels were 1.08 times, 1.14 times, and 1.24 times as compared with the first quartile, There was also a consistent association with severe obesity (BMI ≥ 30 kg/m²),[27] Our data showed similar conclusion with above study.

Serum ferritin is a marker of inflammation in overweight and obese subjects, and There was a high BMI is to have a high level of serum ferritin, which can be caused because of the dominant inflammatory conditions, in the presence of an increased adipose tissue.[8]

Increased body fat tissue appears to be associated with an increased risk of iron deficiency that can be masked by elevated serum ferritin levels.[28] Serum ferritin is a prime indicator for estimating iron status.[29] Ferritin expression is stimulated by a number of factors, including cytokines released during inflammation and liver disease, Inflammation in turn leads to liver synthesis of acute phase proteins.[30]

ID is found in obesepeople and low iron levels in overweight and obese patients are most likely due to inflammatory mechanisms.[31] IDA occurs most often due to malnutrition. Obesity, on the other hand, is often caused by excessive nutrition. Therefore, the coexistence of IDA and obesity in the same person indicates malnutrition and hypernutrition. Among the factors responsible for mutual co-existence, such as diluted hypoferremia, lack of dietary iron intake, increased iron demand, and/or iron absorption disorder, hepcidin has recently been identified as a major cause of obesity ID or IDA.[32]

Chronic inflammation caused by excessive fat tissue, rather than diet, provides an explanation for obesity's ID/IDA, but the presence of acute and chronic infections should also be considered and inflammatory diseases should be considered.[33] As a result, higher ferritin levels secondary to asymptomatic inflammation of overweight and obese people can conceal iron deficiency because they are acute-phase responders,[32] supporting the results of this study.

In this study, BMI and WBC were positive correlation. The WBC was not only the highest in obesity but also the lowest in normal weight. In addition, WBC was greater than normal weight in overweight 1.07 times and obesity 1.19 times. The study found a positive correlation between BMI and WBC in the obese group, The number of WBC in overweight and obesity was 1.06 times and 1.11 times, respectively.[34] A previous study

showed some factors that cause continuous increase in WBC in obese patients.[35] Obesity was the only identified cause in patients with leukopenia. Obesity has also been demonstrated to be associated with low-grade subclinical and smoldering inflammation,[36] supporting the results of this study.

In this study, it is meaningful to confirm the difference between serum ferritin and WBC according to BMI of South Korean adult. The results of this study are intended to provide basic data for prevention and management of obesity in adult.

Conclusions

In this research, BMI of Korean adults was significantly correlated with serum ferritin and WBC. Serum ferritin and WBC were the highest in the obese, followed by the overweight and the normal weight. Serum ferritin and WBC were found to affect overweight and obesity. In conclusion, adult obesity prevention and management programs should include serum ferritin and WBC intervention.

Abstract

Ficus species are rich sources of compounds that treat various diseases with limited reports examining those cultivated in Egypt. We compared the antibacterial, antifungal, anti-leishmanial, anti-malarial and anti-trypanosomal activities of the total methanolic extracts of seven Egyptian *Ficus* species leaves andone bark of *F.bengalensis*. The extracts were tested against two fungal strains;namely *Candida albicans* (*C.albicans*), and *Aspergillus niger* (*A.niger*), and against four bacterial species, namely *Staphylococcus aureus* (*S.aureus*), *Bacillus subtilus* (*B.subtilus*), *Klebsiella pneumoniae* (*K.pneumoniae*), and *Escherichia coli*(*E. coli*) using disc diffusion method. Also, the extracts were tested for their anti-leishmanial, anti-malarial and anti-trypanosomal activities. All the extracts of *Ficus* showed moderate to high antibacterial activity against Gram positive and Gram-negative bacteria. *F.retusa* showed the highest activity against *E.coli* (inhibition zone=24mm), followed by *F.elastica and F.cycomorous* (inhibition zone=22mm). The highest inhibition zones against *K. pneumoniae*were for *F.platyphylla* and *F.retusa* (inhibition zone=24 and 22mm, respectively). All the extractsshowed no antifungal activity against *A.niger*. Also, no anti-leishmanial, oranti-malarial or anti-trypanosomal activities against the microorganismstested. In conclusion, methanolic extracts of different *Ficus* species had promising antibacterial activity and could be used as a cure for some bacterial diseases.

Keywords: *Antimicrobials; Anti-leishmanial; Anti-malarial; anti-trypanosomal; Ficus.*

Introduction

Natural products are considered renewable natural resourcesof diverse bioactive compounds[(1)].The use of natural remedies in medicineis usually to find novel antimicrobial drugs from natural sources to avoid microbial resistance[(2)].

Leishmaniasis is a major public health problem in Africa, Asia and Latin America[(3)] while malaria is a global health problem. Concomitantly, human African trypanosomiasis (HAT) is caused by trypanosoma[(4)]. Tillnow, there is no drug of plant origin for treatment of trypanosomiasis, although, some plants exhibited considerable anti-trypanosomal activity[(5)].

Family Moraceae (Mulberry) is one of the largest among angiosperms, comprising 73 genera and 1100 worldwide species. Several members of the genus *Ficus*;a member of Moraceae Family;are used traditionally in a wide variety of ethnomedical remedies. *Ficus* sp. were reported as a rich source of compounds, which have multidimensional curative properties[(6)]. However,

there are limited reports examining the activities of *Ficus* species cultivated in Egypt. Accordingly, seven *Ficus* species cultivated in Egypt were selected for this study to investigate their antifungal, antibacterial, anti-leishmanial, anti-malarial and anti-trypanosomal activities aiming to discover new antimicrobial agents from natural sources.

Materials and Method

Plant materials: Fresh leaves of seven *Ficus species (F.bengalensis, F.platyphylla, F.hawaii, F.elastica, F.sycomorus, F.infectoria, and F.retusa)* and the bark of *F.bengalensis,* were collected from the Experimental Station of Ornamental Plants, Faculty of Agriculture, Minia University and were kindly identified and authenticated by Prof. Dr. Mahmoud Abd El-Hady, Professor of Horticulture, Faculty of Agriculture, Minia University, Egypt. All the plants were kept and dried in shade. The dried leaves and bark were pulverized into powdered form and weighed to give 250g of each.

Preparation of crude extracts: The air-dried powders of the leaves and bark of *Ficus* species were separately extracted by maceration with 90% methanol at room temperature (3×1L) till exhaustion. Each methanolic extract was concentrated by a vacuum rotary evaporator and left to dry as described[7]. Each crude dry extract (0.5g) was used to explore the antimicrobial activities and the rest was preserved at 4°C in air-tight bottles until used.

Antimicrobial assay strains: *In-vitro* antimicrobial screening was carried out using cultures of two fungal strains namely *Candida albicans* (*C.albicans;* ATCC10231), and *Aspergillus niger* (*A.niger*; ATCC16404), as well as four bacteria species namely, Gram positive bacteria, *Staphylococcus aureus* (*S.aureus*; ATCC29213), and *Bacillus subtilus* (*B.subtilus*; ATCC6051), Gram negative bacteria, *Klebsiella pneumoniae* (*K.pneumonia*; ATCC700603), and *Escherichia coli* (*E.coli*; ATCC25922).

Antileishmanial assay: The *in-vitro* anti-leishmanial activity was carried out on the total methanolic extractsof *Ficus* species, on cultures of *Leishmania donovani promastigotes, L.donovani Amastigote,* and *L.donovani Amastigote/*on *THP* human monocytic cell lineas described previously[8].

Antimalarial assay: *In-vitro* screeningof antimalarial activity was performed against Chloroquine-sensitive strain (D2, Sierra Leone) of *P.falciparum*by measuring plasmodial lactate dehydrogenase activity (LDH) as described[9].

Antitrypanosomal assay: Anti-trypanosomal activity was tested against *Trypanosoma brucei brucei* strain TC221 (10^4 trypanosomes per ml) as described[10].

Antimicrobial activity testing:: Antimicrobial activity was determined using the agar disc diffusion method as described[2]. The tested organisms were sub-cultured on Trypticase soya agar medium (Oxoid Laboratories, UK) and Sabouraud dextrose agar (Oxoid Laboratories, UK) for bacteria andfungi, respectively. Chloramphenicol (30µg) and Sulphamethoxazole/ Trimethoprim (23.75/1.25µg; SEDICO, Egypt)were used as positive control antibacterial agents and dimethylsulfoxide (DMSO) was used as a negative control to evaluate the potency of the tested extracts under the same conditions. Also, fluconazole (Pfizer, Egypt) was used as a positive control antifungal agent. The dried methanolic extracts were dissolved in DMSO with a stock concentration of 1mg/ml. The tests were performedin triplicate cultures and average zone of inhibition was calculated. Inhibition zones <10mm were considered as no/weak activity, 10-20mm were considered as moderate activity, while >20mm was considered as high activity.

Antileishmanial activity testing: The *in-vitro* anti-leishmanial activity was carried out on the total methanolic extractsof *Ficus* species on cultures of *Leishmania donovani* promastigotes*, L.donovani* Amastigote*, L.donovani* Amastigote on *THP* cell lineas described[8]. Pentamidine and Amphotericin B were used as standard anti-leishmanial agents. IC_{50} values for each extract were computed from the growth inhibition curve.

Antimalarial activity testing:: The total methanolic extracts were *in-vitro* screened for their antimalarial activity against a chloroquine-sensitive strain(D2, Sierra Leone) of *P.falciparum*by measuring plasmodial LDH activity as described [9]. Chloroquine was included as a positive control. DMSO (0.25%) was used as a negative control vehicle.

Antitrypanosomal activity testing: Anti-trypanosomal activity was tested following a publishedprotocol[10]. *Trypanosoma brucei brucei* strain TC221 (10^4 trypanosomes/ml) was cultivated in Complete Baltz medium(Sigma-Aldrich, Germany).

For controls, 1% DMSO as well as, parasites without any test extracts or fractions was used simultaneously in each plate to secure absence of activity of 1% DMSO The IC_{50} values of the tested extracts were quantified by linear interpolation of three independent measurements.

Findings:

Antifungal activity: *In-vitro* examination of antifungal activity of the seven *Ficus* species was performed against two fungal strains (*C.albicans,*and *A.niger*) as described in the Materials and Methodsection and the results are shown in Table 1. The datashowedthat the most effective extract against *C.albicans* was *F.infectoria* (inhibition zone=15mm), followed by *F.elastica and F.cycamorous* (inhibition zone=14mm each) and finally *F.hawaii* and *F.bengalensis* leaves (inhibition zone=12, 11 mm, respectively). All these results are considered as moderate activity. Leaf extracts of *F.retusa, F.platyphylla, F.bengalensis* bark showed no activity against *C.albicans.*As shown in Table1, all extracts showed weak or no activity against *A.niger*. Fluconazole; the positive antifungal control; had inhibition zones of 38 and 26mm against *C.albicans*and *A.niger*, respectively.

Antibacterial activity of the totalFicus extracts: Data in Table 1 showed that *F.elastica* had the highest activity against ***S.aureus*** when compared with other extracts (inhibition zone=19mm), followed by *F.platyphylla*and *F.bengalensis* bark (inhibition zone=18 mm), then *F.retusa*and *F.hawaii* (inhibition zone=14, and 13mm, respectively).The obtained results indicated their higher potency compared to that of Sulphamethoxazole/Trimethoprim (13mm) but were still considered of moderate activity. However, the data revealed that all the extracts showed lower activity compared to that of chloramphenicol(inhibition zone=25mm). *F.cycomorous*and *F.bengalensis*leaf showed inhibition zonesof 11 mm (moderate activity) while *F.infectoria* did not show any activity against *S.aureus.*

*F.elastic, F.bengalensis*leaves, *F.platyphylla, F.retusa, F.bengalensis*bark and *F.hawaii*showed moderate activity against ***B.subtilus*** with inhibition zones of 17, 15, 12, 12, 11, and 11mm, respectively. *F.cycomorous* and *F.infectoria* showed weak/ noantibacterial activityagainst Gram-positive bacteria (Table1).

F.retusa showed strong activity against ***K.pneumoniae*** (inhibition zone=22mm)while *F.platyphylla* hadthe same activity as that of chloramphenicol (inhibition zone=24mm) and is comparable to that of Sulphamethoxazole/Trimethoprim (23mm). *F.cycamorous*and *F.bengalensis*bark showed moderate activity (inhibition zone=18mm each), followed by *F.elastica* and *F.hawaii* (inhibition zone=17, and 16mm, respectively). Both *F. bengalensis* and *F.infectoria* leaf extracts showed moderate activity with inhibition zones equal 12, and 10mm, respectively (Table1).

F.retusa was highly active against ***E. coli*** (inhibition zone=24mm), which is like that of chloramphenicol and double the activity of Sulphamethoxazole/Trimethoprim (inhibition zone=12mm). Also, *F.cycamorous* and *F.elastica* exhibited strong activity (inhibition zone=22mm). Although the antimicrobial activity of *F.platyphylla, F.bengalensis* leaf and *F.bengalensis* bark (inhibition zone=20, 18 and 14mm, respectively) are of moderate activity, they were higher than that of Sulphamethoxazole/Trimethoprim.*F.infectoria* and *F.hawaii* showed inhibition zones equal to 12, and 11mm, respectively (Table1).

Antileishmanial activity: The *in-vitro* anti-leishmanial activity were initially tested in a primary phase assay at 20µg/ml in duplicates. All the extracts showed no activity against *Leishmania donovani* promastigotes*, L.donovani* Amastigote*, L.donovani* Amastigote on *THP* human monocytic cell line at concentrations upto20µg/ml while pentamidine showed IC_{50} of 2.4µg/ml (Table2).

Antimalarial activity: As shown in the Table 3, the extract of *F.elastica* showed weak antimalarial activity (17%), followed by *F.infectoria* (14%). The rest of extracts didn't show any antimalarial activity, higher doses may be needed for noticeableeffects.

Antitrypanosomal activity: The *in-vitro* anti-trypanosomal activity was carried out against *Trypanosoma brucei* and THP1 cell line and the $\mathbf{IC_{50}}$ and $\mathbf{IC_{90}}$ were determined in comparison with the positive control (Alpha-diflouromethylornithine) which showed $\mathbf{IC_{50}}$ and $\mathbf{IC_{90}}$ of 6.35 and 12.4µg/ml, respectively. As shown in Table 4, all the extracts didn'tshow any effect against *Trypanosoma brucei brucei* strain TC221 at concentrationsup to 20µg/ml.

Discussion

In thisstudy, all the extracts showed high to moderate antibacterial activity except *F.infectoria.* They showed moderate activity against *C.albicans*andno antifungal activity against *A.niger.* The antibacterial activity of *F.bengalensis* leaf and bark against *B.subtilus*, *E.coli* and *S.aureus* were previously reported[11] but with smaller inhibition zones than ours. By contrast, the reported inhibition zone of *F.retusa*[11] was identical to ours (14mm). Others[12], reported that *F.bengalesis* and *F.elastica* didn't give any action against *E.coli,* while*F. infectoria* gave an inhibition zone of 1 mm at 5mg/ml concentrations.

The inhibition zone of *F.cycomorous* against *S.aureus*was higher than that (7.8mm) reported by others[13]. Leaf extracts of *F.platyphylla* and *F.cycomorous* showed inhibition zones of 17.5 and 21.3mm, respectively against *S.aureus*at concentration of 100mg/ml. These data are relatively higher than ours but we used only 1mg/ml of the extracts[14]. The results of *F.retusa* against *E.coli*and *S.aureus* were higher than those reported byothers[15].One study[16], reported inhibition zones of *F.elastica* against *E.coli*, *K.pneumoniae* and *S.aureus*, which were relatively lower than ours for *E.coli* and *K.pneumoniae*, and no activity against *S.aureus*. Ethanolic extract of *F.platyphylla* leaves showed no activity against *B.subtilus* and *S.aureus*, and the inhibition zone was 10.6mm against *E.coli*[17], which is much lower than ours.

One study[18], reported that hydroalcholic extract of leaves and twigs of *F.bengalensis* cultivated in Iran showed anti-leishmanial activity against *L.major*at concentration of 5-500µg/ml.*F.platyphylla* bark showed antitrypanosomal activity at 25µg/ml and exhibited no activity against *L.donovani*at 100µg/ml[19]. Also, the stem bark of *F.sycomorus* ceased *T.brucei brucei* motility *in-vitro* with IC_{50} of 4mg/ml[20]. In addition, the wood of aerial roots of *F.elastica* reported anti-trypanosomal effect with IC_{50} value 0.9µg/mL and antimalarial activity with IC_{50} of 9.5µg/ml[21]. Egyptian *Ficus* species tested did not have any antileismanial, antimalarial or antitrypanosomal activity. In conclusion, methanolic extracts of different Egyptian *Ficus* species could be considered promising antimicrobial agents that could be used for curing some human bacterial diseases.

Life Skill Improvement of the Hydrokura Method on the Community at Astambul Subdistrict of Banjar District

Husaini[1], Laily Khairiyati[1], Rudi Fakhriadi[1], Lenie Marlinae[1], Fauzie Rahman[1], Dian Rosadi[1], Idham Azhari[1]

[1]Public Health Study Program, Faculty of Medicine, Lambung Mangkurat University, Banjarmasin, Indonesia

Abstract

In 2020 the volume of waste in Indonesia will increase fivefold. Approximately 91.83% of the people in the Astambul village was still throwing garbage in the river. Also, the organic waste produced by fruit trees reaches 500 kg/day even though almost all household did not have garbage disposal outside the house, which is 74 households (87.06%). Wrong littering behavior is due to the lack of management specifically that handle the garbage problem in Astambul and Kelampayan Ilir Village. This study aims to create a sustainable integrated management program for the community, namely the hydrokura method which is the development of organic compost as a local potential by utilizing waste to be effective and developing the life skills of the Astambul's people by performing organic compost as fertilizer for hydoponic plants such as vegetables and fruit. The results that have been achieved are already carried out counselling in the Astambul village with the theme of making organic compost and manufacture of bio-activator and activities of composting with takakura and planting hydroponic techniques from simple composting activity results. The output of this activity is increased knowledge by 78% and self-management commitment and formation of cadre organizational structures to increase life skills of the hydrokura method.

Keywords*: Life Skill, hydroponics, takakura.*

Introduction

Health is one of the most important elements of the quality of life in national development.[1] According to Blum theory, one of the factors that affect a person's health is the environment and health services.[2] The Ministry of Environment data in 2010 stated that the average volume of waste in Indonesia reached 200 thousand tons per day. If the waste problem is not immediately addressed, by 2020 the volume of waste in Indonesia will increase five-fold. It means 1 million tons of garbage in a day.[3] Therefore, the management of waste is needed.

Law Number 18 of 2008 concerning Waste Management has regulated the way of managing household waste. The management method in question is to apply the 3R principles, namely reduce, reuse, and recycle.[4] The purpose of this management is to be able to be reused so that it can reduce the pile of garbage and obtain economic value from waste.[5] One program that utilizes the economic value of waste is by using the hydrokura method.

Based on priority issues from the results of Field Learning students of the Public Health Study Program of Lambung Mangkurat University, it was found that around 91.83% of the people in Astambul Subdistrict were still throwing garbage in the river. This arbitrary trash behavior is due to the absence of specific management that handles garbage problems in Astambul Kota Village. In addition, according to the head of Astambul Kota Village, it is estimated that organic waste produced by the fruit market reaches 500 kg/day.

According to Tien Aminatun research, the amount of organic waste produced per household per day averaged

2.67 kg.[6.] Meanwhile, 1 kg of organic waste can produce 0.6 kg of compost.[7] Thus, it is known that in a day a household can produce around 1.6 kg of compost and produce around 48 kg in 1 month. If 1 kg of compost is sold at Rp. 2,500/kg, then organic waste is produced home stairs per month worth 120,000 IDR, whereas village got income around 22,500 IDR/month of organic waste derived from the fruit market.

Potency value economical that is potency non-acceptance could be ruled out in effort create sustainability of management programs integrated garbage in a community.[8] Based on the dedication activities carried out in 2016, there is potential economy on garbage, which is increasing income and fulfilment community needs both economic value, knowledge and skill value, and improving health value.[9] The value of health and economy is obtained from the reduction of the amount of generation as much as 38 kg/day resulting from 2 kg/day from 19 cadres with economic value to those that have been obtained for 950,000 IDR with the sale of 1 package 30,000 IDR - 50,000 IDR. Therefore, a program is needed to develop organic compost as a local potential by utilizing waste to be effective and developing the life skills of the people of Astambul by performing organic compost as fertilizer for hydoponic plants such as vegetables and fruits.

The hydrokura method is expected that the people of Astambul village can get these benefits. Hydrokura method is one of the strategies in reducing the volume of waste by combining hydroponic method for farming and takakura method for composting. This method intends to empower the community so that the community can manage household waste, not throw garbage into the river, reduce the volume of waste in the environment, and increase public income. Judging from the successful implementation of community service that has been implemented previously regarding waste management self-management, there is an increase in community knowledge of 64.29% regarding waste management.

Waste management that is not handled wisely will cause environmental problems and pollution. The problem of the people in Astambul Subdistrict, especially in the Astambul City and Kelampayan Ilir Villages that are the focus of activities is the garbage problem that is still not well managed. If household waste is managed properly, household waste will produce an economic value that can increase public income.

These problems relate to practical waste management science that has not received optimal guidance and supervision for rural communities and is developed and empowered optimally so that the problems that have existed so far will become economic potential. Based on community diagnosis and question and answer with village officials it is known that the amount of generation produced is 2 kg/day from 346 households with the amount of waste generation as much as 692 kg/day. The reduction of the amount of waste that has been done is as much as 38 kg/day resulting from 2 kg/day from 19 cadres with an economic value of which has been obtained for 950,000 IDR with the sale of 1 package of 30,000 IDR - 50,000 IDR.

Therefore, a program is needed to develop organic compost as a local potential by utilizing waste to be effective and developing the life skills of Astambul's people by doing organic compost as fertilizer for hydroponic plants such as vegetables and fruits. The community wants a solid waste management program with the hydrokura method. Judging from the success of the implementation of community service that had been carried out previously regarding self-management of waste management, there was an increase in community knowledge of 64.29% regarding waste management.

Materials and Method

The program implementation in Astambul Kota Village and Kelampayan Ilir Village cannot be separated from the participation of the community. In the implementation of this program, the community acts as the implementer of the program that has been implemented. Aside from being the executor, the community also acts as the main target in the use of the program results that have been carried out. In general, the method of implementing this community service program is as follows:

Preparation: The strategy used in this program is the Advocacy, Atmosphere Development and Community Movement. First, advocacy is carried out with the health agencies and the local village government. In this case is Public Health Center whose working area is located in Astambul Kota Village and Kelampayan Ilir Village. Advocacy is then carried out to the heads of the Astambul Kota Village and Kelampayan Ilir Village to support this program so that it can run according to goals, objectives and plans. Community development is carried out with the local community with support from

community leaders and public health center to encourage the community to carry out waste management.

Implementation: Before conducting counselling and establishing a waste management post, cadres from the village community were formed as parties who would assist and supervise the running of the program.

Evaluation: Assessment of the success of this program is seen from the ability of the community to make hydroponic plants and composting, ability to process, designing, selling organic compost and hydroponic crop yields as well as the community income coming from the method.

Findings and Discussion

The results that have been achieved are already carried out counselling in the Astambul and Kelampaian Ilir Village on August 27, 2018, with extension activities hydrokura waste management method (hydroponics and takakura) consisting of organic and composting activities making bio-activators and making hydroponics and compost by takakura method. Counselling and establishment of waste management posts. Choosing cadres are managing hydrokura. The cadre of the Hydrokura post manager is from the local community in Istanbul Kota Village and Kelampayan Ilir Village. Cadres are chosen together with the local community and village officials. The chosen cadres are expected to have more time to manage hydrokura, have good communication skills with the local community, and have a commitment to carry out the tasks for the sustainability of the hydrokura program.

Based on this commitment a cadre organizational structure was made so that community empowerment activities could be implemented properly in self-management regarding the organic waste management of the hydrokura method. People in Astambul and Kelampaian Ilir Village very enthusiastic outreach activities and provision of material. This is evidenced by the fact that there is an increase in knowledge and skills related to waste processing by 78%.

Following is documentation of community partnership program activities in Astambul Kota Village:

Figure 1. Counselling and Provision of Pre-Post Test

Figure 2. Head of Astambul Kota Village and cadres

Figure 3. Composting Training with the Banjar Regency Environmental Agency

Program Sustainability: The activity of counselling and the provision of skills will still be carried out even though the activities have been completed so that the continuity of the activity program by involving the community, students and lecturers of public health study programs is upright. Monitoring through selected cadres is expected to have more time to manage hydrokura, have good communication skills with the local community, and have a commitment to carry out tasks for the sustainability of the hydrokura program. Conducting hydroponics and compost with takakura method in order to get economic additions to the community and continue to teach teaching activities, selling organic compost and hydroponic crops.

Conclusion

Counselling was conducted at the Astambul Kota Village namely counselling of organic composting and manufacture of bio-activator and activities of composting with takakura and hydroponic planting techniques from simple composting activity results. The people of Astambul Kota Village were very enthusiastic about participating in counselling and material giving activities. This is evidenced by the results of self-management commitment and the formation of cadre organizational structures to improve the life of the hydrokura method skill. In addition, there was an increase in knowledge of 78%.

Ethical Clearance: Before conducting the data retrieval, the researchers conducted a decent test of ethics conducted at the Faculty of Medicine, Lambung Mangkurat University to determine that this study has met the feasibility. Information on an ethical test that the study is eligible to continue. The feasibility of the research was conducted to protect the human rights and security of research subjects.

Source Funding: This study was done by self-funding from the authors.

Conflict of Interest: The authors declare that they have no conflict interests.

Support and Self Efficacy of Tuberculosis Lung Clients: Literature Review

Ikbal Fradianto[1,2], Astuti Yuni Nursasi[3]

[1]Faculty of Nursing, University of Indonesia, [2]Indonesia Endowment Fund For Education, [3]Faculty of Nursing, University of Indonesia

Abstract

Self-efficacy and support are important to improve health status patient TB and MDR TB. The purpose of this study is to find out research articles explaining self-efficacy and support for pulmonary TB clients, so that it can be an intervention suggestion that can be used effectively with an existing proof. The strategy is comprehensive strategy. In the efficacy all the research conducted explains that the impact of self-efficacy is very positive on the patient in carrying out the treatment and treatment process. Support of TB clients this can be grouped into several categories: social support, family support, socioeconomic support, facility support, financial support, health system support, using media.

Keywords: *Tuberculosis, Lung, Support, self-efficacy, client.*

Background

Tuberculosis (TB) is an infectious disease that occurs primarily in the pulmonary parenchyma. TB spreads directly and is caused by mycobacterium tuberculosis[(2)]. Pulmonary TB sufferers are productive ages (15-50 years) ranging from 75%, which can lead to a loss of average work time of 3-4 months and income from clients with pulmonary TB is reduced annually to 20-30% [(19)].

WHO explains that TB by 2015 has 10.4 million people infected with TB and 1.8 million died from TB disease including those with HIV AIDS of 0.4 million. In cases of death due to tuberculosis there are almost 95% of countries in the middle economic level down. Indonesia has second rank among the highest TB countries in the world[(23)].

Confidence about self-efficacy will provide the basis for one's motivation, well-being and achievement. Self-efficacy will determine how a person feels, thinks, motivates himself or behaves[(1)]. One of the things that can affect self-efficacy is social persuasive that can be support. While the definition of support is the provision of encouragement, motivation, or spirit and advice to others who are in a situation to determine the decision[(5)].

Most self-efficacy is needed in chronic diseases and requires treatment over a long period of time. Self-efficacy can be established one of them through support. According to research conducted that relationship between one of them is social support that can affect the self-efficacy. Pulmonary TB is one of the diseases that require treatment in the long term so that although different from chronic illness but the treatment that is lived has a time span that is not different, that is takes a short time[(11)].

The purpose of this study is to find out research articles explaining self-efficacy and support for pulmonary TB clients, so that it can be an intervention suggestion that can be used effectively with existing evidence. A literature review describing support and self-efficacy in pulmonary tuberculosis clients still does not exist. Certainly this literature review will be very meaningful and can be developed appropriate nursing interventions to be given to clients of pulmonary TB

Method

The strategy is comprehensive strategy, looking for research articles in the online and offline database. The data has been obtained presented in the form of

Corresponding Author:
Astuti Yuni Nursasi
Faculty of Nursing, University of Indonesia
e-mail: ayunin@ui.ac.id

description for each article's content that obtained. This search is done by using keywords based on what you want found that is self-efficacy and support on the tuberculosis. On the online search used keywords, self-efficacy, tuberculosis, support. In the search done with the punctuation "AND" between the two of "self-efficacy and tuberculosis" and "support and tuberculosis"

Results

Based on the results of the search engine data base journal then got the total articles from the six journals conducted search then obtained amounted to 14 articles, where for self-efficacy tuberculosis amounted to 5 articles and to support tuberculosis amounted to 9 articles. In the efficacy cell all the research conducted explains that the impact of self-efficacy is very positive on the patient in carrying out the treatment and treatment process. In 5 researches that can be classified as impacts in self efficacy that is to help improve TB treatment process, the meaning of life is enhanced by self-efficacy in TB clients, and factors that can form self-efficacy in TB clients.

In a study was explained that the TB clients studied were between the TB treatment relationships that were being run with the self-efficacy of pulmonary tuberculosis patients during the course of the ongoing treatment[15].

Self-efficacy is also not fully able to directly affect the treatment and care of TB clients. This can be maximized by the conclusion of self-efficacy with other aspects of consideration such as in research articles which explains that self-efficacy done with social support can increase the meaning of life of TB clients, in this study explained that so high self-efficacy and social support then the higher meaningfulness of life. This research was conducted by using correlation study, in taking samples conducted purposive sampling with 53 respondents involved, with criteria of advanced patients with the minimum age of 15 years to 54 years with the education level taken at least elementary school[17].

Self-efficacy that can be shown good results also to restore the health of clients with TB then the factor that can realize self-efficacy is in each client self must be known, in research conducted by Handuto et al explained that 79.5% of respondents who have Good self-efficacy is not determined by age. But the factors that determine the self-efficacy of this is the level of education owned by respondents, habits of smoking behaviour in everyday life and low income also be a determinant. Research conducted by using descriptive with total sampling that the number of respondents is as much as 39 respondents[9]. Another similar study conducted by Mason et al using a correlation study using as many as 75 respondents who diagnosed TB with unexplained sampling obtained the results of factors that determine the formation of self-efficacy in TB clients is a good education or literacy that is owned by Tb clients are very influential[13].

In support of TB clients this can be grouped into several categories: social support, family support, socioeconomic support, facility support, financial support, health system support, using media. Various kinds of support gained from various research results are various results obtained and overall have a good and positive impact although there is some support is still minimal function. Social support is one of the supports that can assist in the process of treatment and care that is lived by patients with TB, the results research that using sampling with total sampling of 220 respondents with a cross-sectional study, explaining that MDR patients TB Found to have very low social support, social support sourced from the family and from the influencing environment in running the TB treatment process that lasts long enough. Patients with social or isolated activity restrictions show a lack of support from the surrounding environment, MDR TB patients need more social support in the process of performing their TB treatment again[4]. Social support as a supporter in TB treatment is also explained in other research that explained social support combined with self-efficacy of TB clients can improve meaningful life of TB clients. This study was using purposive sampling to 53 respondents with correlation study[17].

Family support is a support needed by TB patients. This family support is described in a study conducted that explains less harmonious family support also contributes to the MDR of TB in patients, family support that part of social support has a role important to be improved when MDR TB patients will start treatment again[4]. Other research is described that health behaviour can regulate and prevent the occurrence of TB, whereas in health behaviour is the most important factor that plays a role in family support, where the result is that the higher the family support the better the health behaviour Will be done by TB patients. Research with this study description with sampling by purposive sampling with number of respondents counted 126 respondents[3].

Socioeconomic support is one aspect of support that can be given to patients with TB, according to Wingfield et al with a study control study involving 312 participating households with 135 intervention groups and 147 control groups taken non-blind randomization The result is that socioeconomics can rapidly increase the spread of TB and is said to be a good TB prevention. Support through this socioeconomic cause a decrease in the incidence of TB since the year 2004 to 2015 [22].

Facility support with the implementation of a policy project in support of health facilities in controlling TB by 2016 that obtained results of 7 out of 8 built facilities indicates that the reduction in TB transmission rates occurred over a period of 10 months. The facilities built are TB assessment and control facilities, development and planning facilities, TB training and control facilities, and field visit facilities[20]. Research using 5 FGDs and 47 in-depth interviews with TB and MDR TB samples and healthcare providers, the results obtained that patients with TB require enormous costs because of their long treatment, support in the form of cost subsidies by freeing up medical and treatment costs and medical insurance is a much-needed support [8].

Support of health system according to the study by using semi-structured interviews, observing the system from 5 countries in Europe got health system is very helpful in overcoming MDR in some countries, this can be shown from several things done starting from Rapid diagnosis of MDR TB clients, convinced financial systems can be accessed overall care and treatment performed for clients with MDR TB, a patient-centered approach with the power of inter-sector collaboration aimed at emotional and social needs of the patient, motivation and dedication of the worker who provides Health services with sufficient command and which means supporting the patient and maintaining the sustainability of the management that has been running[21].

Media support is a viable support for TB patients that studies involving 5 facilities of health care providers in Mozambiq. SMS automatically as health promotions and reminders sent to patients with RCT techniques, with Total counts being 141 patients and 40 health-care workers interviewed. The results of this study are both patients and workers explained by the SMS system provided is very useful and reliable. Positive impact points are reducing the number of failures in drug taking and scheduling health service meetings. Patients are confident in the system[16].

Most feel the system improves communication between healthcare providers and patients, and this can lead to education or counselling and motivation. Patients with this system are very easy to ask and health care providers can also easily answer them. But with this system there are some disadvantages that sometimes when patients complain or tell the story then the workers forget to take a documentation patient in status patient. The use of other media is to use the application by using a sophisticated smartphone, which is currently a smartphone that is very close to every person, but based on research that using 3 applications for purchase for online, Used are applications that focus on TB and use English, Spanish and Portuguese. 11 functions are reviewed such as information, structure, history or recording. The results show that of 1332 applications identified was relevant, with 24 existing inclusion criteria. All applications can be downloaded for free but there are 7 that require login and password and are developed specifically for specific clinics, specific areas, or research needs. The identified application is found to be minimal in function; the primary target focuses only on primary care workers in TB health services. The focus of TB information is only general, guides and news or data sets of notifications based on recent data or tracking. Some applications are developed for TB patients and are not developed to support TB patients in improving and managing their self-care such as reminders of monitor side effects or improving interaction with health care providers, limited this application focusing on patient care[10].

Discussion

Self-efficacy in patients with TB and MDR TB then self-efficacy is a much needed thing to be established for every TB patient. Self-efficacy is one of the parts that can keep patients in long treatment and for patients who will repeat TB treatment is something that must be formed. Self-efficacy can make TB and MDR TB patients survive to continue to fight against the disease and undergo the treatment process. If we look at the research that has been done then self-efficacy has a supporting factor in this formation that is one of them is the level of education enough. If seen with the case of TB in Indonesia are mostly middle to low class with minimal education then this is a new challenge for health providers in Indonesia to try to establish self-efficacy TB patients in Indonesia because need a special approach in improving self-efficacy for the community with TB who have low education.

Various supports that can be done in help to treatment process and prevention and transmission. Support certainly will help to overcome this TB problem, but what needs to be attention is one of the support provided from media facilities that can be accessed by the community through smartphones, even today in Indonesia smartphones can be obtained at an affordable price, based on existing research applications information provider And others related to tuberculosis provide very minimal benefits, ranging from very general information so it will be not easily digested directly by ordinary people, in particular the website provided intend to provide support to TB patients but can lead to erroneous information when not controlled, So the need for confirmation of what is obtained by the community.

Conclusion

Self-efficacy is one of the things that are needed for TB patients and MDR TB, so it is necessary to know the factors that can support the establishment of self-efficacy, the factor obtained in the form of TB patient education background becomes an important consideration in the formation of self-efficacy. Support for TB is also variously considered effective as a bodyguard for the treatment and prevention and dissemination of TB in the form of social support, family, socio-economic, health systems, financial and media.

Comparison of Child Development between Aterm and Premature Birth at Age 2-3 Years Old in Kabupaten Probolinggo, Indonesia

Innas Tiara Ardhiani[1], Ahmad Suryawan[2], Martono Tri Utomo[3]

[1]Department of Reproductive Health Science, Faculty of Medicine, Airlangga University, [2]Department of Child Health, Faculty of Medicine, Airlangga University and General Hospital Dr. Soetomo, [3]Department of Child Health, Faculty of Medicine, Airlangga University and General Hospital Dr. Soetomo

Abstract

Cases of preterm birth are still a problem in developing countries. WHO data in 2013 shows the rate of preterm birth in Indonesia at 2010 was 15.5% of total births. The prevalence of preterm birth in Kabupaten Probolinggo tends to increase from 2011 to 2013. Premature births are at risk of developing language delays, motor balance and coordination. This study aims to analyze developmental differences in children with a history of premature birth and term. The data used was primary data through filling questionnaires and interviews to subjects. This study was observational analytic with retrospective cohort design. The population was all 2-3 years old children at Kabupaten Probolinggo. Sampling was using a simple sampling formula and obtained 100 children into 2 groups. First group was 50 children who aterm at birth. Second group was 50 children who premature at birth. The result showed that there were there is significant differentat child development between aterm and premature born childen ($p<0.05$). The relativerisk (RR) analysis showed that the value is significant enough. Children development was influenced by type of born (RR=1.647x).

Keywords: *Children development, premature birth, development disorder.*

Introduction

Premature birth is defined by the estimated gestational age as a measure of maturity. Three subgroups were distinguished by the World Health Organization (WHO): premature pregnancy (<37 weeks), very premature (<32 weeks), and very premature (<28 weeks)[1].

More than 60% of premature births occur in Africa and South Asia, but preterm birth is truly a global problem. In low-income countries, on average, 12% of babies are born too early compared to 9% in high-income countries[2].

WHO data shows in 2013 there are 15.5 per 100 live births or as many as 675.700 people were born prematurely[3]. In the Probolinggo Public Health Office report in 2015 there were 992 babies (5.36%) who suffered from premature birth and Low Birth Weight (LBW), this number increased from 2014 which totaled 956 infants[4].

Progress of neonatology in recent decades has significantly reduced mortality and morbidity of high-risk infants[5]. However, premature babies have a higher risk ofdecreasing levels of physical growth, delays in language development, motor balance, coordination and developmental deficits when compared to children born with childbirth[6].

Increasing and decreasing GM (gray matter) and WM (white matter) volumes have been described in young adults with very pre-term (VPT)/very low birt weight (VLBW), especially in the internal capsule, insula, prefrontal cortex, medial gyrus/parahippocampalgyrus and putamen[7]. This volume growth is mainly due to the growth of new neurons and synapses[8].

e-mail: inezt12@hotmail.com

Significant 'wiring' occurs during the first years of a child's life and this effectively programs child development. At three, a child has around 1000 trillion brain connections or synapses, which in later development are selectively pruned.It is the experiences and relationships that infants and young children have that continuously develop their brains and build the neural circuits that will be the foundation for later development[9]. A child's experience plays a large role in determining which surplus connections are gradually eliminated during childhood and adolescence, a process sometimes called pruning[8].

In the neonatal period, the development of premature infants shows that they are distinctively different compared to infants in relation to autonomic responses, motor responses, behavioral conditions, attention/ interaction and self-regulation systems[5].Among the problems found in the neonatal period, brain damage, especially periventricular hemorrhage, is prominent, namely abnormalities that most commonly affect the central nervous system(CNS) of premature infants[10]. They may also experience respiratory complications such as chronic lung disease, which can jeopardize the functioning of the CNS, increase the occurrence of neurological sequelae and, as a result, learning difficulties during school[11].

Cheong et al. noted that the percentage of children with microcephaly increased from 2 years of age, which indicates a failure of postpartum brain growth[12]. A recent study also found that children with small heads consistently during the first 2 years of life were seven times more likely to experience neurocognitive disorders[13].

Child development is a dynamic process whereby children develop from dependence on caregivers in all areas that function during growth, towards growing independence in childhood (primary school age), adolescence and adulthood. Skills appear in a number of related domains: motor, cognitive, communication and social-emotional sensory[14].

In the neonatal period, the development of premature infants shows that they differ significantly compared to infants in relation to autonomic responses, motor responses, behavioral, attention/interaction and self-regulation systems[15]. This is influenced by a variety of biological and environmental factors, some of which protect and enhance their development while others compromise the results of their development[14].

Whereas the first years of life, especially the period from the fetus in the womb to a 2-year-old child are a very important period of child growth and development. This period is a golden opportunity as well as a period that is vulnerable to negative influences. Childhood is an important phase in growth and development because the experience during childhood can affect the outcome of one's life[14,15].

However, it has never been compared directly whether there is a significant difference between children born with a history of premature and aterm born at the age of golden age of growth (2-3 years old).

Materials and Method

This study was observational analytic with retrospective cohort design. The population was all 2-3 years old children at Kabupaten Probolinggo.

Sampling was using a simple sampling formula and obtained 100 children then divided into 2 groups. First group was 50 children who aterm at birth. Second group was 50 children who premature at birth. Inclusion criteria of this study were : The child age was ≥ 2 and <4 years old at April 2018, healthy, past gestational age 37-40 weeks and <37 weeks (for premature group).

This study used primary data through doing children development test from Indonesia Ministry of Health (KPSP) to subjects. The test tool and equipment were provided by researcher. Examiners are certified by Kabupaten Probolinggo Public Health Office.

The The independent variables were child at 2-3 years old age with aterm and premature born. The dependent variable was child developmental, wich is normal or there are developmental disorder. SPSS Statistics 22.0 was used for data analysis. Bivariate analysis were compared using cross-tabulations and Chi-Square Test with $p = 0.05$.

Findings

Table 1: Bivariate analysis between type of birth and child development

Variable	Aterm		Premature		Total		p value (Sig)	RR	95% CI
	n	%	n	%	N	%			
Child Development									
Normal	33	33	22	22	55	55	0,027	1,647	1,042-2,603
Possibility of Disorder	19	19	26	26	45	45			

*Significantly different using Chi-Square Test (p > 0.05)

Based on the **Table 1** above, it can be seen that the results of chi-square statistical tests indicate that the results of the calculation of p value is 0.027, which means the value (p< 0.05). This means that there is significant difference in the development of premature or aterm born children.

The RR results indicate that children born prematurely have a chance of 1.647x to be affected by growth disorders. RR value is, because the value of RR where the sample is taken is 1,042-2,603 (RR>1) which means the risk of developing developmental disorders inchildren born with premature is 1,042 to 2,603 times.

Discussion

On the KPSP test (Pre Development Screening Questionnaire) which is a series of tests from SDIDTK (Early Stimulation, Detection and Intervention of Child Development) can be found aspects of development, gross motor movement, fine motor, speech and language, and socialization and independence.

During the development test, there are several development points that the KPSP test results indicate failure. As many as 70% of premature children showed that they still did not fulfill 2 aspects, namely the aspects of speech and language, as well as aspects of socialization and independence.

Premature birth coincides with a higher level of problem with language function compared to children born at term[16]. In a meta-analysis by van Noort-van der Speket al. revealed that premature children received significantly lower scores compared to children born at a simple age, as well as in complex language function tests, during childhood, even without major disabilities and independent of SES (socio-economic status)[17].

Premature born or low birth weight children show lower performance in functional capacity and independence compared to children without these characteristics, but environmental and socioeconomic conditions appear to have a significant effect on the results found[18,19].

What happens before birth and within a few years of life plays an important role in health and social outcomes. While genetic factors play a role in shaping child development, evidence shows that the environment has a major influence during childhood[14].Australian Early Development Census said that key features of early brain development can be fostered by relationships with caregivers, and can be supported by optimal community environments for families and children. Brain development is also vulnerable to toxic stress (depending on length and number of stressors for the child)[9].Therefore children with a history of premature birth need special guidance and stimulation from parents and those around them during the development period so that they can experience optimal childhood.

Ministry of Health suggests that growth and development in the early stages determine the next development. The developmental stage of a child follows regular and sequential patterns. These stages cannot occur upside down, for example the child is first able to make a circle before being able to draw a box, the child is able to stand before walking and so on[15].

According to the Ministry of Health about the stages of development and stimulation aged 24-36 months, in the speech and language column, the child should be able to: talk well using 2 words. Can appoint 1 or more parts of his body when asked. See images and can correctly call the names of 2 or more objects. Help pick up their own toys or help lift plates if requested[15].

But what the researchers found in the field, children had difficulty communicating, still could not construct the word correctly and had not been able to speak by

forming 2 words well according to age level. While the other points, most of them have been able to carry out activities according to their age.

Toddler growth and development will be optimal if the environment provides positive support or vice versa[20]. Environmental factors are factors that determine whether or not an innate potential is made up of a bio-psycho-social environment[21]. We suggest that children who are still unable to communicate can be stimulated by development, for example: read storybooks before going to sleep, encourage children to want to tell stories and talk more, use good language and not slur when talking to children.

Socio-emotional functioning involves the ability to learn to successfully interact and communicate within a social context and to efficiently deal with emotions, deficits in multisensory processing may affect speech perception, subsequently resulting in difficulties in communication and social interactions[22,23].While in the socialization and independence column, the Ministry of Health also stated that children should be able to eat their own rice without spilling and removing their own clothes[15]. In the field, we have found that children cannot eat on their own, if the child can eat alone, their food tends to spill out of its place.

Most children also still cannot take off their own clothes, but some children can just take off their pants. We recommend that children be given more stimulation to stimulate socialization and independence aspect, for example: teach children to dress themselves without help, give children the opportunity to choose the clothes they will wear. Encourage children to clean their bodies when dirty and then wipe them with as little help as possibleand do light housework.

Conclusion

The development of 2-3 years old children is very important because it is the gold age for the growth and development period, especially children with a history of premature birth who have a risk of developmental disorders. Parents should give more attention in providing appropriate developmental stimulation according to the child's age.

OCOP "One Caregiver One Pregnancy" Intervention to Increase Knowledge, Attitude and Family Facing Practices in Pregnancy Care

Ita Rahmawati[1], Anies[1], Sakundarno Adi[1], Cahyono Hadi[1]

[1]Doctoral Program in Public Health, Faculty of Public Health, Diponegoro University, Semarang, Central Java, Indonesia

Abstract

Objective: The objective of this study was to analyze the effect of OCOP "One Caregiver One Pregnancy" intervention on knowledge, attitudes, and practice of family accompaniment to pregnant women in pregnancy care.

Method: Quasi-experimental research with a non-equivalent control group design was conducted in Jepara Regency. The sample was 128 pregnant women in the first trimester pregnant, 8-12 weeks of gestational age, who met the inclusion criteria. Data were analyzed by the Mann-Whitney Test, and calculated using adjusted odds ratio (ORs) with 95% confidence interval (CI).

Results: The results showed that, after one month of OCOP intervention, there were significant differences in knowledge, attitudes, and practices of family accompaniment in pregnant women in pregnancy care between intervention group and control group ($p < 0.005$). In addition, an increase took place in the mean value of knowledge by 5.81, family attitudes of 9.27, and practice of family assistance for pregnant women in pregnancy care by 14.18.

Conclusion: OCOP intervention increases family knowledge and positive attitudes towards pregnancy care, thereby increases practice of family accompaniment to pregnant women in pregnancy care.

Keywords: *Caregiver, Pregnancy, Knowledge, Attitude, Practice.*

Introduction

One effort to reduce maternal and infant mortality is to improve the health status of pregnant women because 10-15% of pregnancies are accompanied by complications.[1,2] Pregnancy care is one of the interventions and strategies of regional, international and various government organizations to improve maternal health.[3] Behavior during pregnancy that can give a bad risk to pregnant women include keeping their daily activities the same as before pregnancy which includes strenuous activities.[4]

Morbidity and mortality of pregnant women can be prevented by increasing the ability of families to recognize danger signs of pregnancy and try to seek health help.[5] Family empowerment means how the family enables itself by facilitating others to improve the health status of the family by increasing the ability of the family to conduct family health care.[6] Therefore, the family has an important role in assisting pregnant women in seeking health services so that the status of pregnant women who receive moral support from family members has contributed to the increased use of maternal health services.[7,8]

One of the strategies for maternal and child health including pregnancy care is family empowerment.[9] The role of parents influences the behavior of pregnant women,[10] because decision making and utilization of health services are still very dependent on the family.[11,12]

Sources of advice during pregnancy are sourced from in-laws (62.96%), and parents (53.70%),[13] family social support and family advice of pregnant women (parents, in-laws, grandmothers, etc.) related to pregnancy care.[14,15] However, family practice in assisting with pregnancy care was found to be still low, 65% of families had not provided information about pregnancy care, 57% of families had not informed about the hygiene of pregnant women, 73% of families had not accompanied pregnant women to do light exercise, 52% of families had not prepared food which is nutritious for pregnant women and 52% of families do not remind consumption of Fe tablets.[16]

Various studies on pregnancy care have shown that self-care behavior during pregnancy is not appropriate so that family accompaniment is needed in pregnancy care. Therefore, research is needed to analyze the effect of OCOP "One Caregiver One Pregnancy" interventions on the behavior of pregnant women in pregnancy care.

Material and Method

The quasi-experiment with a non-equivalent control group design was used to analyze treatment group (group 1) and non-treatment group/control (group2).[19] This study was conducted in Jepara Regency from August to September 2019 to pilot the OCOP "One Caregiver One Pregnancy" intervention on family knowledge, family attitudes, and family assistance practices for pregnant women in pregnancy care. The sample was 128 pregnant women in the first trimester pregnant, 8-12 weeks of gestational age, who met the inclusion criteria.

Family inclusion criteria are extended family type, biological mother or parents-in-law who live in the same house as pregnant women, biological mothers or in-laws who are willing to accompany pregnant women during pregnancy, biological mothers or in-laws who are able to read and write, biological mothers or in-laws able communicate well, biological mothers or in-laws aged 36 years - 50 years, and biological mothers or in-laws who are willing to be respondents. Exclusion criteria are family members who are experiencing pain who must be hospitalized and unable to perform normal activities.

The subjects of group 1 treated with OCOP intervention took a pre-test, being treated with OCOP intervention for 1 month, then took a post-test. The result of the pre-test was compared to the post-test to determine changes in family knowledge, family attitudes, and family assistance practices in pregnant women in pregnancy care before and after getting OCOP intervention. Meanwhile, the control subjects (group 2), which were not treated with the OCOP intervention took a pre-test and after one month they took a post-test. The result of the pre-test was compared to that of post-test. Further, the result of group 1 was compared to that of group 2.

All data were analyzed with SPSS software version 21.0 package. Continuous variables were compared using Mann-Whitney test and presented as mean. Adjusted odds ratio (ORs) with 95% confidence interval (CI) was calculated. A p-value < 0.05 was considered statistically significant.

Findings

Table 1. Differences between intervention groups and control groups related to family knowledge about pregnancy care

Mean Rank of Knowledge Score	Intervention Group (n = 64)	Control Group (n = 64)	Difference (Δ)	ρ value*
Before OCOP Intervention	76.29	70.71	-0.808	0.419
After OCOP intervention (1 month)	104.73	74.27	-8.976	0.000

*Mann-Whitney Test

Based on table 1. above it can be seen that significant difference in family knowledge after being given an OCOP intervention for 1 month between the intervention group and the control group (p> 0.05). This proves that OCOP intervention for one month can increase family knowledge about pregnancy care.

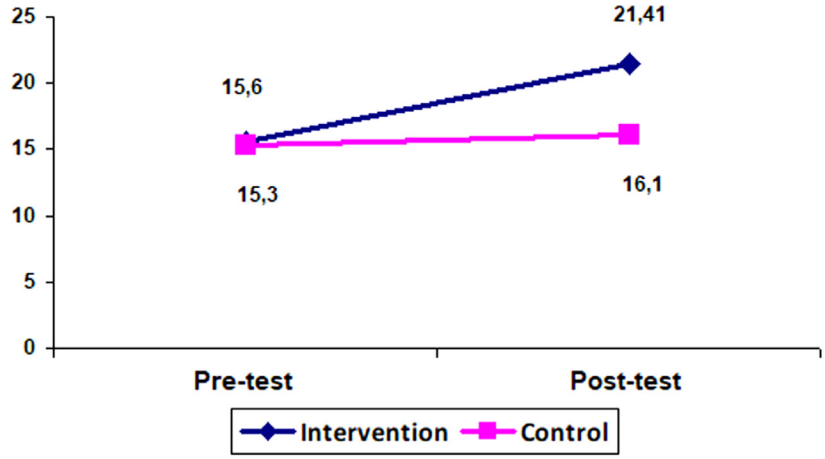

Figure 1. Change in the mean (average) of family knowledge about pregnancy care

The results of the study in Figure 1 above show that the average (mean value) of knowledge after getting the OCOP intervention for 1 month in the intervention group is higher than the control group.

The results of this study are following the results of various studies on pregnancy care obtained results most of the respondents have low knowledge about the signs of danger of pregnancy.[17–19] Efforts to realize the independence of the family in maintaining maternal and child health, one of the efforts of the health program is to improve family knowledge and skills.[20]

Table 2. Differences in scores of family attitudes towards pregnancy care in the intervention and control groups.

Mean Rank Attitude Score	Intervention Group (n = 64)	Control Group (n = 64)	Difference (Δ)	ρ *value**
Before OCOP Intervention	74,73	72,27	-0,358	0,720
After OCOP intervention (1 month)	110,00	37,00	-10,533	0,000

*Mann-Whitney Test

Based on table 2. above it can be seen that significant differences in family attitudes after being given an OCOP intervention for 1 month between the intervention group and the control group ($p > 0.05$). This proves that OCOP interventions for one month can improve family attitudes towards pregnancy care.

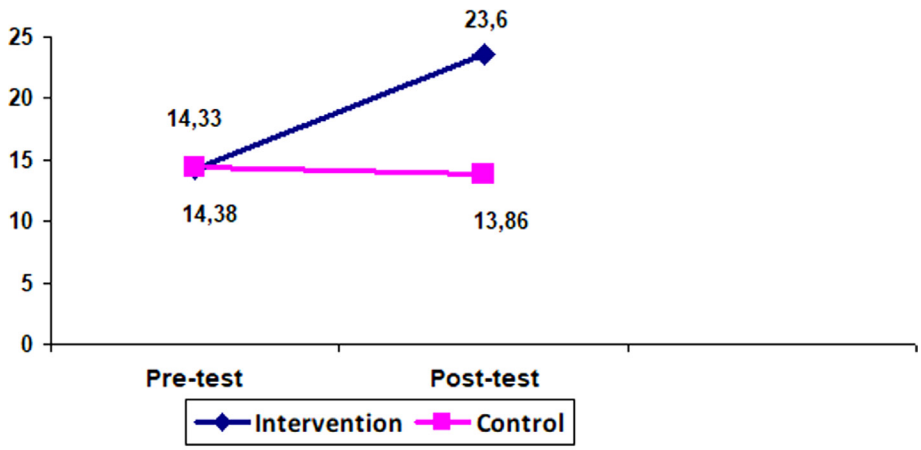

Figure 2. Changes in mean (average) family attitudes towards pregnancy care

The results of the study in Figure 2. The above shows that the average (mean value) of family attitudes in the intervention group is higher than the control group after the OCOP intervention for 1 month. In fact, in the control group after 1 month there was a decrease in the mean value of family attitudes towards pregnancy care by 0.52.

The results of this study are not following previous studies where the level of awareness and knowledge of the mother-in-law is still low so they only receive pregnancy information and do not care about the danger signs of pregnancy.[21]

Table 3. Differences in scores of family accompaniment practices in pregnant women in pregnancy care in the intervention and control groups.

Mean Rank Score practice of family accompaniment	Intervention Group (n = 64)	Control Group (n = 64)	Difference (Δ)	ρ *value**
Before OCOP Intervention	72,39	74,61	-0,319	0,750
After OCOP intervention (1 month)	110,00	37,00	-10,458	0,000

*Uji Mann-Whitney Test

Based on table 3. above it can be seen that significant differences in the practice of family assistance for pregnant women in pregnancy care after being given an OCOP intervention for 1 month between the intervention group and the control group (p> 0.05). This proves that OCOP intervention for one month can improve the practice of family assistance to pregnant women in pregnancy care.

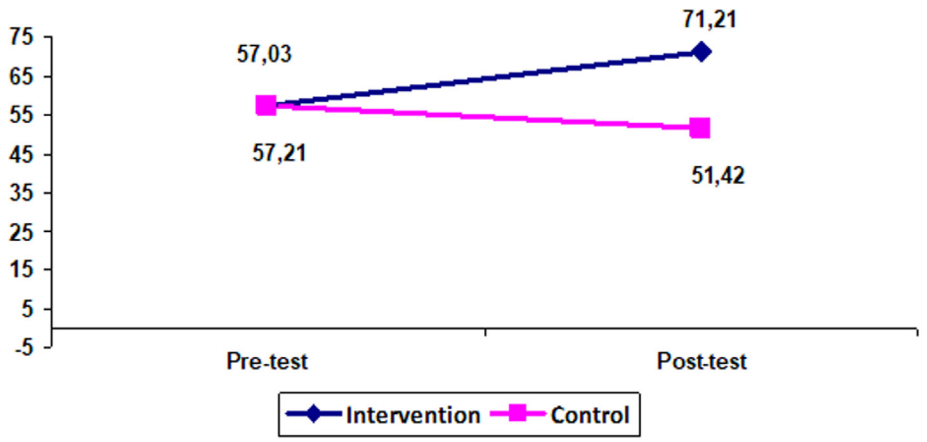

Figure 3. Changes in the mean (average) practice of family assistance to pregnant women in pregnancy care

Based on Figure 3. above shows that the average (mean value) of family assistance practices in pregnant women in pregnancy care after getting the OCOP intervention for 1 month in the intervention group was higher than the control group. However, the control group after 1 month there was a decrease in the mean value of family assistance practices for pregnant women in pregnancy care by 5.79.

The practice of family assistance in providing pregnancy care affected the health status of the pregnant women. A family being able to carry out health tasks will also be able to solve health problems.[22] Pregnant women treated in a family-centered model will experience greater satisfaction with their baby's birth experience. Pregnant women will participate in the decision making process that will increase their confidence. They will validate their learning with real-life experiences. Health care providers who work in a family-centered model will also experience greater satisfaction.[23]

The results of this study are in line with studies

that show that patients who together with families get family empowerment interventions have higher self-efficacy than the control group. In family empowerment in pregnancy care, pregnant women get interventions to improve communication and interaction between pregnant women and families through the practice of family assistance in pregnancy care in the form of simulation activities between pregnant women and families, so pregnant women will get very strong support to increase self-confidence so that pregnant women feel confident in their ability to perform pregnancy care.[24]

Supporting research results show that pregnant women are in dire need of support from family and husband during their pregnancy period. Likewise with the results of research that pregnant women need help and support from both their families and from health practitioners when they undergo their first pregnancy.[25] Other research that supports is Martin, et al. (2007) social support affects prenatal care visits and decreases in the amount of cigarette consumption by pregnant women during their pregnancy.[26]

Conclusion

The research results show that the OCOP "One Caregiver One Pregnancy" intervention increased family knowledge and positive attitudes towards pregnancy care, thereby increasing the practice of family accompaniment to pregnant women in pregnancy care. The OCOP intervention provided is a family empowerment activity through simulations between pregnant women and families related to family assistance to pregnant women in pregnancy care using the "One Caregiver, One Pregnancy" method. It is hoped that the OCOP intervention can be widely used in the community to improve the practice of family assistance to pregnant women in pregnancy care so that pregnancy care can be carried out by pregnant women appropriately.

Conflict of Interest: None declared.

Abstract

Background: The burden of tuberculosis (TB) is exacerbated by anti-TB drug resistant especially multidrug-resistant TB (MDR-TB). There has been an increasing trend of Multidrug-resistant TB in Indonesia. However, there is lack of epidemiological study on risk factors of MDR-TB in Indonesia.

Objective: This study aimed to determine the influence of TB treatments as risk factors on MDR-TB in Central Java Indonesia while controlling other covariates.

Method: A case-control study was conducted between August 2017 and February 2018. The study subjects were selected using inclusion criteria. Cases were 81 MDR-TB patients in intensive phase that lived in Central Java and recorded in the Moewardi Hospital, a referral hospital. The controls were 228 patients who received first-line anti-TB treatment without drug resistance. A structured questionnaire interview was used to collect the data. Multiple logistic regression analysis was used to identify the association.

Results: The proportion of gender among the 81 cases and 228 controls were 64.2% vs. 43.0% for males, and 35.8% vs. 57.0% for females. TB treatment that were significantly associated with MDR-TB were: length of TB treatment > 6 months (aOR =14.1; 95% CI: 6.68-29.86), continued TB treatment (aOR =11.695% 95%CI: 5.36-25.48). Other significant covariates were had no formal education or primary education (aOR = 2.89; 95% CI: 1.38-6.02) and low monthly income (aOR =2.86; 95%CI: 1.18-6.92)

Conclusions: Long duration, discontinuity of TB treatment, and low socioeconomic status increase the risk of MDR-TB.

Keywords: *Multidrug resistant tuberculosis, MDR-TB, risk factors, Central Java, Indonesia.*

Introduction

Tuberculosis (TB) remained one of the top 10 causes of death worldwide[1]. 93.4% (5.7 million) or 6.1 million TB patients were newly diagnosis cases, and only 6.5% of them were previously having TB treatment[2]. Anti-TB drug resistant exacerbated burden in a country. Globally, around 3.5% (95% CI:2.2-4.7%) of all newly TB diagnosed patients and 20.5% (95% CI: 13.6-27.5%) of previously treated had MDR-TB[2]. In addition, it is a growing global health problem[3].

MDR-TB is defined as resistance to two most powerful TB drugs, isoniazid and rifampicin, with or without resistance to other first-line drugs (FLD)[5, 6].

Corresponding Author:
Wongsa Loahasiriwong
Faculty of Public Health, Khon Kaen University, Thailand-40002
e-mail: drwongsa@gmail.com

Two main pathways of developing active drug-resistant TB were primary and acquired (secondary) drug resistance [7].

Resistance to anti-TB drugs is an important challenge in global TB control due to going to be mutant wild-type *Mycobacterium.* Previous studies reported that factors associated with drug resistant were poor case management, overcrowding, delayed diagnosis, inadequate treatment, and poor institutional infection control [9].

Indonesia was the second highest of TB cases in the world after India [1]. Indonesia ranked 8th of 27 countries with the highest MDR-TB in the world between 2009 and 2014 [10]. A survey from Indonesia in 2006 reported that 1.9% MDR-TB was from new cases, whereas 17.1% was from previous TB treatment [11]. Central Java province is one of the highest population among provinces.

The rate of MDR TB in Central Java Province was 2% in people who had never received anti-TB treatment before, while 16% in people who had previously received anti-TB treatment [12]. The case notification rate (CNR) of new positive tuberculosis smears in 2017 was 60.91 per 100,000 populations and CNR for all TB cases in Central Java 2017 was 132.9 per 100,000 populations. The success rate was 82.36%, which means that there was still 18% failed treatment [13].

Material and Method

We conducted a population-based case-control study to estimate TB treatment as a risk factor of MDR TB while controlling for other covariates.

Inclusion criteria for cases: Indonesian citizens, aged ≥18 years old, diagnosed as MDR-TB that were confirmed with molecular test (GeneXpert) and culture examination, in the intensive phase of MDR-TB treatment, registered in the MDR unit at Dr. Moewardi Hospital (a referral hospital) in Surakarta, Indonesia.

Inclusion criteria for control: Indonesian citizens, aged ≥18 years old, a TB patient without resistance to rifampicin and isoniazid, were in the intensive phase of TB treatment and registered in 28 community health care units (PUSKESMAS) of Sukoharjo, Wonogiri, Boyolali, and Kudus districts, and Surakata city. Patients who did not speak or understand Bahasa, who were severely sick, or were not able to respond to the interview, were excluded from the study.

Sample size calculation: A total of 81 MDR-TB cases and 228 controls who met the inclusion criteria were included in the study. Data were collected by a face-to-face interview. The questionnaire was developed and validated by 5 specialists in MDR-TB and TB. A reliability test was conducted involving 30 cases and controls. The Cronbach alpha coefficient was > 0.80. This study was conducted from August 2017-February 2018.

Statistical analysis: A bivariate analysis was performed using simple logistic regression to determine the associations of TB treatment, socioeconomic status, and health status with MDR-TB, with standard statistics including crude Odds Ratio (OR), 95% confidence interval (95% CI), and p-value.

Multivariable logistic regression[15,16] was used to determine the effect of risk factors on MDR-TB, while controlling for the effects of confounder. Independent variables for the multivariable analysis were selected according to two criteria: firstly, variables in the crude analysis which were found to have a p-value of less than 0.25, and secondly, variables showed from a literature review to have an association with MDR-TB. The method of backward stepwise elimination was used as the model fitting strategy. A likelihood ratio test was performed to assess the goodness-of-fit of the final model. All analyses were performed using Stata version 10.0[17]. Adjusted Odds Ratios (aOR) and 95% CI indicated the magnitude of association of the risk factors.

Findings:

Table 1: Bivariate analysis of factors associated with MDR TB

Factors	MDR-TB				cOR (95% CI)	p
	Cases (Number=81)		Control (Number=228)

Previous study stated that inappropriate treatment was associated with MDR-TB (OR=24.2; 95% CI=6.9-85.1; p<0.001)[23]. In addition, defaulter of TB treatment might be a risk factor of MDR-TB (OR=2.9; 95%CI=0.22-37.4; p>0.05)[24]. The duration of MDR-TB treatment was 19-24 months with an initial stage of an oral drug administration and injection for at least six months or 4 months after conversion of culture. Then the next stage was oral medication without injection[21]. Prolonged treatment with low-to-severe side effects may lead to comorbidity.

Another study reported that comorbidities had statistically significant association with MDR-TB (OR=2.0; 95% CI=1.24-3.50; p=0.005). Comorbidities were associated with poor health outcomes, more complex clinical management, and increased health care costs[25]. Some comorbid diseases including diabetes, cardiovascular, other respiratory diseases, and cancer were indicated as risk factors of primary MDR-TB (aOR= 57.1; 95% CI=8.6–424.2) due to their chronic disease nature that can damage or suppress immunity[8].

Table 5 Multiple logistic regression of factors affecting MDR-TB while controlling for confounding factors

TB patients with drug resistance can transmit the disease to others with directly drug-resistant bacteria [20]. TB treatments in Indonesia were as follows: Intensive treatment stage for two months, and advanced stage for four months treatment duration. There was then a re-treatment stage due to relapse, failure of previous first-line anti-TB treatment, and re-treated patients after dropping out of treatment (lost to follow up) [21]. However, there are challenges associated with management of the second line drugs arise from less effectiveness, more side effects, higher toxicity, and higher cost [22].

Previous study reported that continuity of TB treatment was found significantly associated with MDR-TB (aOR =11.6; 95%CI= 5.36-25.48; p<0.001), which means that the odd to get MDR-TB for recurrent TB treatment were 11.6 times higher than the continue treatment. Previous treatment of tuberculosis has been identified as a key covariate for MDR-TB, and the association becomes stronger in the previous TB treatment groups of 6-11 months and over 12 months [26]. Likewise, another study in Pakistan reported that previous TB treatments were associated with MDR-TB (aOR= 5.88; 95%CI= 4.32-7.99; p<0.001) [27]. The patients with prior TB treatment were more likely to get MDR-TB (aOR= 4.2; 95%CI= 1.1, 15.4) and (aOR=21; 95%CI=17.8–28) [28, 29]. TB drug resistant occurred when TB did not respond to the standard six-month treatment with first-line anti-TB drugs [30], including resistance to at least rifampicin and isoniazid. Consistent with other studies, a study in South Africa indicated that previous TB treatment was a strong risk factor for MDR-TB [32], as well as in Ethiopia (OR=2.9; 95%CI= 0.22-37.4; p>0.05) [24].

Educational attainment and income were found as significant covariates of MDR-TB. Low educational attainment might limited the patient knowledge on TB severity, TB treatment and susceptible of treatment resistance. A previous study on risk factor for default TB drug stated that completed high school is a protective factor of TB resistance (HR=0.59; 95%CI=0.35-0.97; p=0.04) [33]. Similar study also indicated that the higher education level, the lower probability of getting MDR-TB [34]. Inadequate knowledge and misperceptions related to TB/MDR-TB for patients as well as health personnel could hinder the TB control programs[35]. Low level of knowledge was statistically significant association with MDR-TB (OR=1.93; 95%CI=1.61-

3.23; p =0.011). Sir John Crofton-conveyed that the burden was not only for patients himself but also for others due to infect other people with his drug-resistant organism [30]. The previous study in Henan China found that the odds of MDR-TB for having poor knowledge was OR=2.87 (95%CI=2.46–3.88; p<0.001) [36].

The severely underweight patients had two-fold odds of persistent smear positive [37]. Patients treated with the second-line drug in Estonia, Philippines, Russia, and Peru with BMI <18.5 kg/m^2 (under nutrition) had a higher risk of death, failure, and default of MDR-TB (RR=2.71; 95%CI 1.91-3.95) [38]. A previous study stated that low income was a risk factor of MDR-TB (aOR=1.1; 95%CI=0.34-0.47) [24]. A study indicated that the odd of MDR-TB for those with BMI <18.5 kg/m^2 was 1.17 times the odds of those with BMI ≥ 18.5 kg/m^2 [39]. In addition, low body weight had a longer time to initiate culture conversion among MDR-TB patients [37]. Although the 6 months long TB treatment and the 24 months long MDR-TB treatment are provided free of charge, patients have to bear other costs such as travel cost to the primary health center to get medication once a week. The patients with low income were more likely to miss the follow up for taking the drug regularly because there was no transportation and insufficient funds. Another study reported that annual low income was associated with primary MDR-TB (OR=6.33; 95%CI=1.87-21.40; p=0.003) [8].

Conclusions

The risk factors of MDR-TB were the length of TB treatment, continuity of TB treatment, educational attainment, and monthly income. TB drug treatment irregularity is closely related to TB resistance since TB medication requires adherence and continuity according to the prescribed schedule.

Abstract

Type 2 diabetes is now a major problem worldwide, including in rural as well as urban Thailand. One measure for control is increasing physical exercise. In the elderly traditional style dancing is an attractive option. The quasi experimental research was conducted to assess the influence of a 16 weeks program focusing on Thai local (Champasri) dance in experimental of 27 Thai females aged 60-69 by integrate stretching, warm up, exercise and cool down 50 min by using DVD which conducted by researchers, and limited to 29 female elderly in the control group. Outcome variables were fasting glucose and BMI values. significant decrease $p<0.001$ and hemoglobinA1c no significant at the end of the program.. In addition, physical fitness parameters like chair stand test, arm curl, chair sit & reach, back scratch, 8 Ft up & go and 6 min walk testwere also improvedsignificant $p<0.001$ Conclusion, North East Thai local(Chapasri) dance trainingcan be recommended for diabetes control in elderly women.

Keywords: *The effectiveness, North East Thailand local dance, high risk to type 2 diabetes mellitus, 60-69 year old women.*

Introduction

Diabetes is the complexity of chronic diseases that require continued medical treatment with various risk reduction strategies. Adoption of a healthy lifestyle may delay progression from the precursor high risk to type 2 diabetes mellitus. Mahasarakham province, Northeast Thailand has become a new patient increasing steadily from 2014–2017, rising from 2.31-2.88%.[1] Northeast Thai local dance in Mahasarakham province is called "Champasri dance", is for recreation among adolescent and important festivals as well as no test for exercise science. This research concerns to improve Champasri dance by integrating stretching muscle training, warm up, exercise, cool down and extent to 50 minutes. It can promote physical fitness and reduction of the risk in diabetes Mellitus type 2 in women aged 60-69.

This study aims tocompare physical fitness andto assess a percent of hemoglobin A1c (HbA1c) and fasting blood sugar(FBS) changing before and after training

Method

Study Design and Sampling: The research design was quasi-experimental. Its intervention was "Champasri dance training" for women volunteer aged 60-69. The sample size calculation was compared the average between two groups[2]. Each groups has 35 female volunteers and must pass the inclusion criteria as follows. FBS from the fingertip in the previous year at 100-125 mg/dl, body mass index (BMI) 18.50-24.99 or more than 80 centimeters waist circumference have had. The researcher helped volunteers from the community leaders to clarify, persuade, and sign the consent form.

Correspondent Author:
Chuloporn Sota

e-mail: chusot@kku.ac.th

Data Collection and Training: There are data collection (April-June 2018)and dancing places (Nadun Sub district–Municipal for experimental group and Khanthararat Sub-district, Kantharawichai district for control group). Intervention procedures for Champasri dancing were DVD conduction and demonstration. The training had started from week 1-16, 3 days a week, 50 minutes, 16 weeks totally, 04.10-05.00 pm., on Wednesday, Tuesday, and Friday. The clarification, consent, and record form were improved quality of three experts. Volunteers received supports for all facilities and transportation fees for dance trainings and tests.

Data Analysis: Data analysis was carried out using SPSS ver.26. The differences within groups used a pair t-test and wilcoxon signed-rank tests and between groups used an independent t-test and mannwhitney u tests. Analysis of covariance: ANCOVA has used to test the variables.

Results

1. Seven female volunteers have 7 days training with using of polar heart rate test compared to American Heart Association Guidelines. They had moderated intensity level at HR 50-60%.
2. There were 27 participants in the experimental group have the average ages 66.15 (SD = 1.936) and 29 participants in the control group were 65.00 (SD = 2.673).13 female volunteers have to leave the criteria.
3. The changes comparison of physical fitness before and after training.
   - 3.1 The experimental group had statistically significant ($p<0.001$). The control group, the mean values of chair sit & reach, back scratch: left,back scratch: right,8 Ft up & go and 6 min walk had p-value <0.001.
   - 3.2 The physical fitness test between groups after experiment had statistically significant ($p<0.001$). The experimental group, mean values higher or better than the control group as shown in Table 1-2.

Table 1: The comparison of the changes of physical fitness before and after training between groups by using the Independent t-test.

4. The blood sugar comparison and effects after fasting before and after training.

   4.1 The change in HbA1c and FBS within groups, HbA1c and FBS has statistically significant ($p<0.05$). The mean after experiment in the control group was higher than the experimental group.

   4.2 The change in HbA1c between groups. After training, had no statistically significant ($p>0.05$) but the experimental group's mean (SD) had a lower value than the control groups. The change test of FBS, after the experiment between groups has statistically significant ($p<0.05$) as shown in Table 3-4.

Table 3: The comparison of the changes of fasting blood sugar after training groups by using the Independent t-test

Dependent Variable	Before				After			
	Exper G. M(SD), (n=27)	Control G. M(SD), (n=29)	t	p-value	Exper G. M(SD), (n=27)	Control G. M(SD), (n=29)	t	p-value
FBS	106.518(10.860)	107.103(9.969)	-0.210	-0.834	94.444(11.981)	107.620(11.216)	-4.251	0.000

Table 4: The comparison of the changes of hemoglobin A1c after training groups by using the ANCOVA-test

Hemoglobin A1c	Expe.G. M(SD), (n=27)	Control G. M(SD), (n=29)	SS	df	MS	F	P-value
%HbA1c	5.400(0.378)	5.306(0.409)	0.072	1	0.072	0.631	0.430

Changes in exercise techniques and food consumption at home before and after the experiment are not significantly ($p>0.05$). The study believes that the experimental and control area have similar living style.

Discussion and Conclusion

Comparing and analyzing the results between groups appeared the dance cannot change the results of cardiovascular health and cardio-respiratory rate clearly as same as to the previous study[3,17,20,28]. Butit has the effect of changing muscle strength and gait ability. The results can add the benefits beyond the previous study that changes on BMI, balance, and flexibility.

Discussion

After the dance training, Chair stand test, arm curl, chair sit & reach, back scratch, 8 Ft up & go and 6 min walk in the experimental group changes better than the control group. Results of fitness test of dance trainings: Greek Traditional[4], Thai traditional[5,19], Waltz[6], Ballroom[7], Rumba swing[7], Samba[7] and Bolero[7], Creative[8], Argentinetango[9,15,27,30], Aerobic[10,17,18,31,33], Turkish[11], Caribbean[12], Salsa[13], Tango and Waltz/ Foxtrot Dance[14], Exercise Dance for Senior (EXDASE) [16], Greek dance[20,32], Agilando Dance[21], Dance Therapy (Healthy-Steps) [22], and Dance Therapy (Lebed method)[23] are line dances[35] that have a moderate intense level like the Korean dance, aerobic, and resistance exercises[,29] lower than Greek Dance[28], beneficial for obese older women or high risks of cardiovascular diseases. BMI in the experimental group has normal means close to the BMI assessment from Bollywood Dance training[36] and Bhangra Dance[24]. In 16 weeks was appropriate to change BMI values. The Creative[8], Greek[20], Korean, and Aerobic dance, and resistance exercise[25,29], Ballroom dance meetings, toning exercise[26], low-impact aerobic dance[34], had statistically significant within groups better after experiment. It associates with lower exercise tolerance as measuring by peak oxygen consumption[39]. BMI values associate with higher exercise tolerance after training. The experimental group's mean has a lower value or risk than the control group. The result of a chemistry test from the

Bollywood dance training[36], Bhangra dance training[24], percent of HbA1c result from Korean dance, aerobic and resistance exercises training[25], had statistically significant difference within group as same as the result of this study. FBS after the experiment differed statistically significantly in the experimental group has a lower mean or risk of diabetes. The control group has a slight to increase of the mean and consistent with the study of FBS in aerobic exercise[37]. In results of Tai Chi training, FBS has decreased within 6,000

minutes of exercise[38]. It can be determined the study used the aerobic exercise period by the dance for only 2,400 minutes that can affect FBS reduction. It may cause from Thai dance style is a continuous slow dance focuses on relationship between movement and music. It was more complex than Tai Chi[19]. If the frequency increasing, long duration, continuity, and moderate exercise nearby the real intensity level and consistent with the lifestyle and funny exercise. The effect of changing in% Hb A1c will be clearer.

Conclusion

Northeast Thailand local dance Training is resulting in a healthy body from the evaluation of physical fitness test. The shape has a greater proportion from results of BMI, succeeded in controlling the level of FBS, and has a tendency of decreasing% Hb A1c.

Recommendation for research applying: The older women needed to have their writing skills, to improve and pay more attention to memorize their routines, to reduce the risk of having dementia.

Recommendation for further research: The participants can have a sustainable healthy diet by themselves and have the rights to choose food and their families go along with the local culture and activities. It will help sustain healthy.

Conflict of Interest Statement: No conflict of interest to declare.

Source of Funding: The Research and Training Center for Enhancing Quality of Life of Working Age People.

Health Education in Increasing Prevention Behavior of Dengue Hemorrhagic Fever in Families at Gubeng Village, Surabaya, Indonesia

Nur Hasanah[1], Indriatie[1]

[1]*Lecturer of the Department of Nursing, Health Polytechnic of the Ministry of Health (Poltekkes Kemenkes), Surabaya, Indonesia*

Abstract

Dengue Hemorrhagic Fever (DHF) is the fastest spread of mosquito-borne viral disease in the world–an annual health problem in Indonesia. Efforts to prevent and eradicate DHF are focused on efforts to control infectious vectors through the Mosquito Nest Eradication movement known as 3M Plus, but community participation in preventing DHF is still low due to a lack of understanding in its importance, so that the health education is needed to improve understanding and awareness of DHF. This study aims to analyze the effect of health education on the increasing prevention behavior of DHF. This research is a type of comparative analytic research using non-equivalent control group with a quasi-experimental design. The sample of this study–72 families–are the people who lived in RT 03 RW 03 Gubeng, Surabaya, which was taken using a cluster sampling technique. Data were analyzed using the Wilcoxon sign rank test and Wilcoxon Mann-Whitney test with a significance level of 0.05. The results showed that there was a significant increase in family behavior in the prevention of DHF between before and after health education was carried out in the treatment group. Also, there were significant differences in family behavior in the prevention of DHF between the treatment and control groups after health education. Considering that health education has a significant influence in improving family behavior in the prevention of dengue, it is advisable to health workers in the Puskesmas to conduct health education about DHF and its prevention regularly and continuously to reduce the incidence of DHF.

Keywords: *Health education, behavior, prevention, Dengue Hemorrhagic Fever.*

Introduction

Dengue Hemorrhagic Fever (DHF) is the fastest spread of mosquito-borne viral disease in the world. In the past 50 years, the incidence of dengue has increased 30-fold with extensive geographical expansion[1]. Dengue fever is also still a health problem in Indonesia every year, especially during the rainy season. Data taken from the Directorate of Vector and Zoonoses Infectious Diseases Control of the Ministry of Health of Indonesia said that during January 2016[2] there were 3,298 cases of dengue fever with 50 deaths or Case Fatality Rate (CFR) of 1.5%. In 9 Regencies and 2 Cities from 7 Provinces which are KLB areas, there were 492 cases, 25 of which died or CFR of 5%. In Surabaya, which is an endemic area of dengue fever, we need to watch out for the possibility of a case surge. The Surabaya City Health Office found 60 cases of dengue fever in January 2016. This number increased compared to the same month in 2015 totaling 48 cases.

Vaccines to prevent and drugs to effectively eradicate dengue virus are not yet available. Therefore, prevention and eradication of dengue fever focused on efforts to control the infectious vectors through the Mosquito Nest Eradication. However, in reality, community participation in the prevention of dengue fever is still lacking. Therefore, the behavior of eradicating mosquito nests needs to be continually grown, especially in many countries that have been proven to reduce dengue fever

cases. Outbreaks of dengue fever in Indonesia related to a variety of risk factors, including the limited public understanding of the importance of eradicating mosquito nests[2]. To increase knowledge, understanding, and awareness of the community can be pursued through health education.

Method

This research is a type of comparative analytic research that compares the prevention behavior of DHF of the community who get the health education and who was not. The research design used was a quasi-experimental non-equivalent control group. The study population is a family who lives in the area of RW 03 Gubeng Surabaya, Indonesia. The sample of this study was the family who lived in the area by using cluster sampling. The sample divided into two groups, namely the treatment group (36 families who get health education) and the control group (36 families who did not get health education). Data collected by filling out a questionnaire and analyzed using the Wilcoxon sign rank test and the Wilcoxon Mann-Whitney test with a significance level of 0.05.

Results

The results of this study include family demographic data as well as specific data on the prevention behavior of DHF; before and after health education. Demographic data shows that all (100%) of respondents are women. One-third (33.33%) of the treatment group and half (52.78%) of the control group were middle-aged. Nearly half (41.66%) of the respondents in the treatment group and the majority (61.11%) in the control group had a high school education, and a small proportion (16.67%) had college. Most (55.56%) of the respondents in the treatment group and 52.78% of the respondents in the control group worked as private employees, entrepreneurs, and civil servants. Majority of the treatment group (80.56%) and control group (83.33%) did not have a history of dengue fever–the complete data presented in Table 1.

Table 1. Distribution of family demographic characteristics

Demographic Data	Treatment Group F (%)	Control Group F (%)
Gender:		
Male	0 (0)	0 (0)
Female	36 (100)	36 (100)
Age:		
Young (21-40 y.o)	15 (41.67)	10 (27.78)
Middle-aged (41-59)	12 (33.33)	19 (52.78)
Elderly (≥ 60 y.o)	9 (25.00)	7 (19.44)
Education:		
Elementary School	10 (27.78)	5 (13.89)
Junior High School	10 (27.78)	3 (8.33)
Senior High School	15 (41.66)	22 (61.1)
College	1 (2.78)	6 (16.67)
Occupation:		
Not working	16 (44.44)	16 (44.44)
Civil Servant	0 (0)	4 (11.11)
Private employe	7 (19.44)	5 (13.89)
Entrepreneur	13 (36.12)	11 (30.56)
History of DHF:		
There is	7 (19.44)	6 (16.67)
None	29 (80.56)	30 (83.33)

The results of this study indicate that the behavior of DHF prevention when prior to health education in the treatment group was obtained almost entirely (80.56%) in the sufficient category and only a small proportion (19.44%) behaved well, whereas in the control group obtained most (63.89%) behaved adequately and almost half (36.11%) behaved well (Table 2). Based on Table 2, it can be concluded that the behavior of DHF prevention, before health education, is better in the control group than the treatment group.

Table 2. Distribution of family behavior of DHF prevention before health education

Behavior of DHF Prevention	Treatment Group F (%)	Control Group F (%)
Good	7 (19.44)	13 (36.11)
Enough	29 (80.56)	23 (63.89)
Total	**36 (100)**	**36 (100)**

Table 3 indicates that the behavior of DHF prevention after health education in the treatment group found most (58.33%) in the sufficient category and almost half (41.67%) in the good category. The same condition was also found in the control group, where most (63.89%) families behaved adequately, and almost half (36.11%) behaved well in the prevention of DHF.

Table 3. Distribution of family behavior of DHF prevention after health education

Behavior of DHF Prevention	Treatment Group F (%)	Control Group F (%)
Good	15 (41.67)	13 (36.11)
Enough	21 (58.33)	23 (63.89)
Total	36 (100)	36 (100)

After being given health education to the treatment group, their behavior in preventing DHF showed improvement (Table 2 and Table 3), where before being given health education, it was seen that families who behaved well at 19.44% then after being given health education the number increased to 41.67%.

Descriptive statistics on the score of DHF prevention behavior in the treatment group also showed an increase after being given health education, both in the mean value and median value, as listed in Table 4.

Table 4. Differences in DHF prevention behavior between before and after health education in the treatment group

Behavior of DHF Prevention	Descriptive Statistics	
	Before HE	After HE
Mean	70.03	74.28
Median	69.50	73.50
St. deviation	7.15	5.81

p = 0,000

Based on the results of hypothesis testing using the Wilcoxon signed ranks test, it obtained a p-value of 0.000, which means that DHF prevention behavior in the treatment group after getting health education was higher or better than before getting health education.

Descriptive statistics about the difference in scores of DHF prevention behavior between before and after health education showed that the treatment group had a higher difference than the control group, as listed in Table 5.

Table 5. Differences in DHF prevention behavior between treatment and control groups after health education conducted

Behavior of DHF Prevention	Descriptive statistics	
	Treatment Group	Control Group
Mean of the difference in score	4.31	0.33
Median of the difference in score	4.00	0.00
Std deviation of the difference in score	4.88	1.24

p = 0.000

The results of hypothesis testing using the Wilcoxon-Mann Whitney test showed that the behavior of DHF prevention after health education in the treatment group was higher or better than the control group, with a p-value of 0.000.

Discussion

Before health education was carried out in the treatment group, almost all (80.56%) of DHF prevention behavior in families were in the sufficient category and only a small percentage (19.44%) behaved well, whereas in the control group, most of them (63.89%) behave adequately and almost half (36.11%) behave well. DHF prevention behavior in the community influenced by knowledge from various media. The level of education strongly influences the ability of the community to understand information. In the control group, high school and tertiary education levels are more than the treatment group, so the ability to receive information is easier so that it produces better behavior than people with low levels of education. This research is in line with the results of a study that junior high school education has a preventive behavior of low dengue hemorrhagic fever before health education[3] and it in accordance with a theory which states that education influences the learning process, the higher one's education the easier it is for the person to receive information[4]. The more information about health that comes in, the more knowledge gained about health. Communities with low education need empowerment through health education to increase their knowledge. With his awareness and knowledge, the ability of the community to behave well in the prevention of dengue arises.

Prevention of DHF behavior before health counseling can also be attributed to family experience in treating DHF patients, which in the treatment and control groups is almost the same, both have experience

having treated family members who suffer from dengue. Thus people who have experienced dengue hemorrhagic fever will participate more in preventing DHF by doing 3M Plus. Notoatmodjo said that behavior is the result of experience and the process of interaction with the environment, which manifests in the form of knowledge, attitudes, and practices so that a balanced state between the driving force and the holding strength achieved[5]. This statement is supported by a study which states that experience as a source of knowledge is a way to obtain the truth of knowledge by repeating the knowledge gained in solving problems in the past[4]. So that experience is what gives us lessons about how to avoid dengue.

After health education for the treatment group, most of them (58.33%) behaved adequately, and almost half (41.67%) were in a good category. The same condition was also found in the control group, where most families behaved adequately, and almost half behaved well in the prevention of DHF. The results of this study indicate that health education about the prevention of DHF has a positive effect on improving community behavior in preventing DHF. Following the opinion of Azwar[6] quoted by Maulana[7] in the general conception of health, health education defined as health education activities carried out by disseminating messages and instilling confidence. Thus, the community not only is aware, knows, and understands, but also wants and can make health-related recommendations. Fitriani[8] added that health education is a dynamic process of behavior change, not a process of transferring material or messages from someone to another person and not a set of procedures.

In this study health education changed family behavior to better prevent dengue hemorrhagic fever by doing 3M Plus, where it is following Mubarak[9] statement that counseling for health education, in general, is to change unhealthy behavior, to be healthy. Families after receiving health education change unhealthy behaviors into healthy behaviors because they already have the awareness that in the preventive behavior of dengue hemorrhagic fever through 3M Plus is beneficial for themselves, their families and surrounding communities. Surya[10], as cited in Maulana[7], that counseling is a relief effort given to counseling (students) so that they gain self-concept and self-confidence, to be utilized by him in improving his behavior in the future. With the concept of self-confidence, the family can improve its behavior in the prevention of dengue hemorrhagic fever. This statement reinforced by WHO[11], as cited in Mubarak[9], that the goal of health education is to change the behavior of people or society from unhealthy behavior to healthy behavior.

The results of this study indicate that there is a significant increase in DHF prevention behavior in the treatment group between before and after health education. In other words, health education has proven effective in improving family knowledge about prevention of dengue. According to Notoatmodjo[5], if there are an innovation or development programs in the community, then what often happens is that some people are swift to accept the innovation or change that is changing their behavior, and some people are prolonged to accept the innovation or change because each person has a willingness to change or readiness to change that is different. Every person in a society has a different willingness to change, even though the conditions are the same. Notoatmodjo[5] also states that health education can influence and or invite others, both individuals, groups, and communities to carry out healthy behavior. Operationally is an activity to provide knowledge, attitudes, and practices of the community in maintaining and improving their health.

The basic principle of health education is the learning process. In this process, there is a reciprocal influence of various factors, including the subject of learning, teaching, learning method and techniques, learning aids, and the material or material learned. In this study health education was carried out in groups with a total target of 36 participants housed in the Post RT room, the material was delivered using the lecture and question and answer method with the media of powerpoint slides and leaflets equipped with images relevant to the material. The participants seemed enthusiastic and focused their attention on the material discussed. Classical or group counseling also enables interaction and sharing of information and experiences between participants, thus increasing their broader horizons. This condition is following Notoatmodjo[5] states that for large groups where more than 15 counseling participants, good method include lectures. Factors that influence an educational process in addition to input are method, materials or messages, educators, or officers who do and assistive devices or educational aids. In order to achieve an optimal result, these factors must work in harmony.

DHF prevention behavior after health education in the treatment group is higher or better than the control group. According to Azwar[6], changes in one's behavior influenced by knowledge, experience, and certain

environmental situations. Therefore, families can change to behave better after getting a lot of information and knowledge while attending counseling. In conducting health counseling, the instructor must be able to convince information about the family. After hearing and seeing the educational slide shows and pictures on the leaflets, awareness of the family will arise so that their behavior will change for the better. Good behavior that occurs in the family is possible to arise because the family has gained good knowledge about dengue fever so that it will affect behavior changes from before it is not good to be good. After the family gets good knowledge about dengue fever, they can see things related to dengue fever prevention so that their behavior changes to pay more attention to their health.

Conclusions

There is a significant increase in the behavior of dengue prevention between before and after health education is carried out in the families of the treatment group.After conducting health education, behavioral prevention of DHF in the treatment group was higher or significantly better than the control group.Given that health education has a significant influence in improving family behavior in the prevention of dengue, it is advisable to health workers in the health center to conduct health education about DHF and its prevention regularly and continuously in order to reduce the incidence of DHF.

Abstract

Martapura River has the greatest potential for fish farming compared to other regencies in South Kalimantan. With the condition of the region and the results of the cultivation, this area should have the potential as a fishery source that plays a role in the supply of animal protein such as fish that can be used by the community to improve community nutrition, such as osteopenia in girls. Osteoporosis/osteopenia is more common in women about 80% of men 20%. The study design used Pre and Post test One Group Design. The research subjects were all teenage girls in Islamic boarding schools in the Martapura River area, Banjar Regency. Sampling was done by measuring the nutritional status of female teenagers using the WHO anthropometry 2007 reference standard with the following criteria: female teenagers said to be overweight with z scores > + 1 SD, Obesity with z scores> +2 SD, normal with z scores-2 SD to +1 SD, Thin (Thinness) with z scores-3 SD to-2 SD, and Very thin (Severe Thinness) with z score <-3 SD. Research instruments are mikrotoice and stepping scales. Measuring the degree of bone density using a quantitative ultrasound bone densitometry. Protein and calcium intake using 24-hour food recall form. Eduche Method (Healthy Education Card) with CTL (Contextual Teaching Learning) approach to TGT (Team Games Tournament) settings. The results showed osteopenia respondents were 65 people (79.3%), the most dominant factors related were low protein intake (p value = 0.001. Eduche Method (Education Card Healthy) with CTL (Contextual Teaching Learning) TGT settings (Team Games Tournament) effectively increase respondents' knowledge about osteopenia (p value 0.0001).

Keywords: *Teenage girls, eduche, osteopenia, CTL, TGT.*

Introduction

The degree of bone density is to describe the state of the bone after a period of perfect development. Signs of early low degrees of bone density are osteopenia, while further osteoporosis. Osteoporosis is bone loss, especially in the spine, upper arms and pelvic bones. Symptoms of osteoporosis are difficult to detect, most are only realized when there is swelling of the spine, fractures or broken bones, pinched nerves. One of the causes of osteoporosis is the lack of daily calcium intake and protein. Women are more at risk due to less bone mass they have and faster bone loss compared to men and women experience faster loss than men due to menstruation, pregnancy, breastfeeding and menopause[1,2]. The results of Rahayu and Putri's research in 2016 in the Banjar Regency region have found that there were still quite a number of respondents who had protein and calcium intake in the unfavorable category, namely 37.8% and 42.2% [3,4]. This result is supported by the results of the Rahayu and Yulidasari 2015 research that most of the adolescents with low protein intake are due to their low level of nutritional knowledge which is 53.7% [5]. Potentials that can prevent osteoporosis can be in the form of biological wealth such as fish cultivation which provides a source of nutrients that are beneficial

to the body including helping in the formation of bone mass[6].

The method can be in the form of EDUCHE Method (Education Card Healthy) is a method that will be implemented by the counseling guidance teacher in collaboration with researchers as a form of improvement efforts in overcoming osteopenia in young women by giving counseling for teenage girls and providing nutritional knowledge of girls through an approach to CTL (Contextual Teaching Learning) approach to setting TGT (Team Games Tournament). Teenage girls will be given a health education card (Education Card Healthy) at the end of each month as a form of learning evaluation. This approach is one of the cooperative learning models that is easy to implement, involving the activities of all female adolescents with osteopenia whose learning activities with games designed in cooperative learning model of Teams Games Tournament (TGT) enable female teenagers to learn to relax more than foster responsibility, honesty, cooperation, healthy competition and learning involvement absorb knowledge provided using participatory methodologies and participatory learning and action processes, so as to increase knowledge about osteopenia.

Materials and Method

This research is an action research (Operational research). The study design used Pre and Post test One Group Design. The subject of the study were all teenage girls in Darul Islamic boarding schools in the area of the Martapura riverbank, Banjar Regency, while the determination of the sample was chosen 1 (one) school which had the largest number of female adolescents with osteopenia who were screened. Then samples will be taken with the following inclusion criteria: (1) female adolescents with osteopenia based on measurements of the degree of bone density using a quantitative ultrasound bone densitometry; (2) The female teenagers are family members who live as residents on the banks of the Martapura river. (3) When researching girls are not fasting. (4) When research girls are not experiencing pain which results in reduced appetite.

In this study the following research instruments were used: 1) quantitative ultrasound bone densitometry for degree of bone density, 2) scales for measuring body weight, 3) microtoice for measuring height, 4) 2x24 hour form recall for measuring protein and calcium intake, 5) Question sheet to identify knowledge before and after nutritional education through the CTL approach to TGT settings during the education process, 6) Evaluation sheet for EDUCHE activities (Education Card Healthy) to find out the progress of educational material that has been given at the end of the month with components: height changes/body length according to age (BMI); protein and calcium intake, 7) Fill in the characteristics of respondents and family. The independent variable (independent variable) in this study is the Effectiveness of EDUCHE Method (Education Card Healthy) with the CTL (Contextual Teaching Learning) approach of TGT (Team Games Tournament) settings, while the dependent variable (dependent variable) is the Osteopenia Occurrence in Girls. Meanwhile, the variables measured were the degree of bone density, BMI, protein and calcium intake and the level of nutritional knowledge of girls.

Primary data collected includes: (1) family characteristics using a structured questionnaire; (2) IMT data was determined using the BMI indicator according to age with the WHO 2007 standard using microtoice instruments and stepping scales with the category of Overweight (> Overweight) if> 1 SD, Obesity if> + 2 SD, Normal if-2 SD up to +1 SD, Thinness if-3 SD to-2 SD, and Very thin (Severe Thinness) if <-3 SD; (3) knowledge of adolescent nutrition was collected through evaluation forms on the CTL approach of the TGT setting (4) data on protein and calcium intake were obtained using a 24-hour recall form. Protein intake consists of 3 categories according to the recommended nutritional adequacy rate which is less if <80%, normal if 80-100% and more if> 100%. While the category of calcium intake is divided into 3 categories, namely if <800, normal if 800-1000 and more if> 1000 (5) osteopenia data obtained by measuring the degree of bone density using quantitative ultrasound bone densitometry using conversion according to Meilnikow, 2005. As for Bone density category consists of 3 categories: Normal if>-1 SD, Osteopenia if-1 SD to-2.5 SD, and Osteoporosis if <-2.5 SD (6) data on changes in protein, calcium and BMI intake are known from the method EDUCHE. Data for family characteristics were made in the form of percentages, data on EDUCHE method activities in the form of narrative, and BMI, protein and calcium intake. To find out the relationship between independent and dependent variables, che square test was used and to find out the most dominant factors associated using multiple logistic regression analysis.

Result

Univariate Analysis: Table 1 shows the distribution of variables according to categories that are likely related to the incidence of osteopenia in respondents.

Table 1: Frequency distribution of respondent and family characteristics

Osteopenia category	Frequency (person)	Percentage (%)
a. Osteopenia	65	79,3
b. Normal	17	20,7
IMT category		
a. Abnormal	51	62,2
b. Normal	31	37,8
Father's Education Level Category		
a. Not finised-SMP	62	74,6
b. SMA-PT	20	24,4
Mother's Education Level Category		
a. Not finished-SMP	61	74,4

b. ≥UMK	20	24,4
Number of Family Members		
a. >5 person	54	65,9
b. < 5 person	28	34,1
Adequacy of protein intake		
a. Defisit	62	75,6
b. Enough	20	24,4
Adequacy of calsium intake		
a. Defisit	52	63,4
b. Enough	30	35,6
Tingkat pengetahuan		
a. Kurang	20	24,4
b. Good	62	75,6

Table 1 shows that most of the respondents experienced osteopenia which is 65 people (79.3%). Several other potential variables have a relationship with osteopenia incidence in respondents, namely BMI, father's education level, mother's education level, family income, number of family members, protein intake and calcium intake. Table 1 shows that adolescents who have a BMI category are not more normal than adolescents with normal BMI, namely 51 people (62.2%), father and mother who do not complete the primary to junior secondary education level, amounting to 61 each. people (74.6%) and 62 people (74.4%). With the level of education of parents who fall into the low category, the income earned by the elderly/family becomes insufficient to meet the consumption needs of family food. The results of this study indicate that most of the family income is still below the UMK (Minimum Wage for Employees) that is equal to 60 people (75.6%). This UMK refers to the UMK of Banjar Regency in the amount of Rp.2,248,000. In addition, the factors that also contribute to the incidence of osteopenia are the number of family members.

The results of this study found that most respondents had a relatively large number of family members (> 5 people), namely 54 people (65.9%). The possibility with this relatively large number of family members will affect the family distribution of food. The results of this study showed that protein and calcium intake were mostly in the less categories of 62 people (75.6%) and 52 people (63.4%) and found that there were still adolescents who had less knowledge about osteopenia, risk factors, and the impact in the future for girls is 20 people (24.4%). The magnitude of the frequency distribution between each of these variables has not been able to show a relationship between the variables of the characteristics of respondents and family with the incidence of osteopenia in the respondents, so it needs a bivariate analysis so that the relationship between these two variables is known to be meaningful, in detail can be seen in Table 2.

Bivariate Analysis

Table 2. The relationship between the characteristics of respondents and families with osteopenia status in adolescents

Variables	p value*	Information
1. IMT	0,0001	Significan
2. Father's Education Level	0,110	Not Significan
3. Mother's Education Level	0,032	Significan
4. Family income level	0,24	Not Significan
5. Number of Family Members	0,644	Not Significan
6. Adequacy of protein intake	0,0001	Significan
7. Adequacy of calsium intake	0,001	Significan

**p value* (<0,05)

Table 2 shows that some variables show an association with osteopenia status in respondents. These variables are BMI (Body Mass Index) with p value = 0.0001, mother's education level with p = 0.032, adequacy of protein intake with p value = 0.0001 and adequacy of calcium intake with p value = 0.001. This analysis uses the Che Square test with a 95% confidence level. How many of these variables are still unknown is the factor most associated with osteopenia status in respondents. Therefore, in order to know the most dominant variables associated with osteopenia, further analysis is needed, namely multivatiate analysis using logistic regression. Can be seen in detail in Table 3.

Multivariate Analysis

Table 3. The most dominant factors related to osteopenia status in respondents

No	Variables	B	SE	Wald	Sig	Exp (B)
1	IMT	2,272	885	6,586	0,010	9,696
2	Father's Education Level	-168	1,466	1,164	0,281	0,206
3	Mother's Education Level	-1,582	1,716	0,010	0,922	0,845
4	Family income level	-2,256	1,717	1,727	0,189	9,549
5	Adequacy of protein intake	2,257	0,747	11,708	0,001	12,981

Table 3 shows that the variable protein adequacy is the most dominant risk factor for osteopenia in adolescent girls in Darussalam Martapura Islamic Boarding School with p = 0.001 (<0.05), with Exp (B) = 12.981 which means that girls with less protein intake Nutritional adequacy rates that are recommended to have a risk of 12,981 times greater osteopenia than adolescents with adequate protein intake.

Difference Test Analysis

Table 4. Different test of effectiveness of Educe CTL approach to TGT setting in changing the level of knowledge of respondents by using the Wilcoxon Signed Ranks Test

	pengetahuan_akhir-pengetahuan_awal
Z	-5.284[b]
Asymp. Sig. (2-tailed)	.0001

a. Test Statistics[a], b. Wilcoxon Signed Ranks Test, c. Based on negative ranks.

Table 4 shows the results of the Wilcoxon Signed Ranks Test on changes in the level of knowledge of respondents related to osteopenia with the results that there were differences before and after giving education using the Eduche method (Education Card Healthy) with the CTL (Contextual Teaching Learning) approach to setting TGT (Team Games Tournament) on respnden knowledge about osteopenia, risk factors, and their impact on future girls. This result means that the Eduche (Education Card Healthy) method with the CTL (Contextual Teaching Learning) approach to TGT (Team Games Tournament) settings effectively increases respondents' knowledge of osteopenia (p value = 0,0001).

In addition to intake, Jiga BMI acts as a cause of osteopenia in adolescents. The results of Permatasari's research (2011) have found that adolescents who have abnormal BMI (nutritional status) have a risk of 3.958 times greater osteopenia than adolescents who have a normal BMI. Similarly, the results of research conducted by Nafilah (2014) found that there was a relationship between body mass index and bone density in female adolescents (p = 0,000). This means that the higher the adolescent who has less nutritional status (BMI), the higher the rate of osteopenia in adolescent girls[9]. So, during childhood and adolescence, new bones are formed faster than old bones (which are removed), so the bones become larger, heavy and dense[10].

Conclusions

Most respondents still experienced osteopenia by 65 people (79.3%) out of 82 total respondents. The most dominant risk factor in the incidence of osteopenia in respondents in Darussalam Martapura Pesantren, with p = 0.001 (<0.05) and Exp (B) = 12.981 which means that girls with protein intake are less than the nutritional adequacy rate recommended (AKG) at risk 12,981 times greater osteopenia than adolescent girls with adequate protein intake. There is a difference in the level of knowledge before and after giving education with the Eduche method. The Eduche Method (Healthy Education Card) with the CTL (Contextual Teaching Learning) approach effectively adjusts respondents' knowledge about osteopenia.

Ethical Clearance: This study has received ethical approval from the Medical Faculty Research Ethics Committee of Lambung Mangkurat University, Banjarmasin, Indonesia. In this study we followed the

guidelines of the Ethics Committee on Public Health Research including completing the title of the study, informed consent, research objectives, the right of respondents to the confidentiality of data obtained and also completed with the signature of the researcher and respondent chairman.

Source of Funding: This research was funded by the Faculty of Medicine of the University of Lambung Mangkurat, Banjarmasin, Indonesia through a competitive grant of the Faculty of Primary Basic Research scheme.

Conflict of Interest: The authors in this study did not experience conflicts of interest with anywhere and with anyone.

Analysis of Fish Derived Protein Intake Adequacy and Cultural Factors and its Correlation with the Occurrence of Stunting among Children Under Two Years Old in Martapura Riverbanks, Banjar District Area

Atikah Rahayu[1], Fahrini Yulidasari[1], Andini Octaviana Putri[1], Nur Laily[1]

[1]Departement of Public Health, Medical Faculty, Lambung Mangkurat University

Abstract

Banjar is an area of higher fish farming production compared to other districts in South Kalimantan. Taking the condition of the area and the fish farming production into account, Banjar is an area of significant potential to become the source of fish as supplies of animal protein to be utilized by people to improve their nutritional status and overcome the protein energy malnutrition problems. Correlations have been demonstrated between food consumption and nutritional status. The implication of chronic malnutrition for children under two years old is called stunting. To conduct an in-depth analysis on the cultural factors and fish-origin protein intake adequacy with the occurrence of stunting. This three month cross-sectional study recruited 36 children aged 6-24 months as samples. The study was conducted for three months in 2015 in Sungai Pinang, Banjar District. The children's nutritional status was determined according to the 2005 edition of WHO anthropometry reference standard with categories as follows: 1) stunting (very short, z score <-3.0 SD); 2) short (≥-3 SD sd <-2 SD); 3) no stunting (normal status, ≥ 2 SD). Protein intake adequacy was determined by the standards of Nutrition Adequacy Score for children For Age 0-3 Year on WNPG 2004. Data were analyzed using chi square test with 95% confidence interval. This study demonstrated a correlation between the fish derived protein intake adequacy with the occurrence of stunting among children under two years old. Children of poor protein intake adequacy had 5.5 times greater risk of stunting. This significant number of stunting was partially caused by the culture of not establishing a habit of eating fish since early age and during pregnancy. The fish-origin protein intake adequacy and cultural factors played important roles on the occurrence of stunting among children under 6-24 months in Sungai Pinang, Bajar District.

Keywords: *Children under two years old, fish-origin protein intake adequacy, stunting, cultural factors.*

Introduction

The first two years of life is a period of heightened sensitivity toward environmental influences and this period was relatively brief and could not repeat, hence the recognition of this period as the golden period/the window of opportunity/the critical period. In addition, more than half death among infants and children under five years old is caused by inadequate nutrition during the first two years of life. Chronic nutritional deficiency might lead to stunting. Children who experience stunting have a higher possibility to develop to adults of low quality. Therefore, the issue of stunting is not negligible as it carries with it life-long consequences that might be hard to overcome.[1,2] Data from the Basic Health Research (Riset Kesehatan Dasar/Riskesdas) stated that the prevalence of stunting among children under two years old in Indonesia in 2007 was 36.8% and this prevalence seemed to be gradually increasing as demonstrated by the prevalence of 35.6% and 37.2% in 2010 and 2013, respectively. These prevalences of more than 30% has made stunting a significant public health burden. The 2007 Basic Health Research data of South Kalimantan Riskesdas stated that the prevalence of stunting among children under two years old was 35.3%. The 2013 data also demonstrated an increased prevalence to 45%. This further indicated the significance of stunting as a public health burden due to its high prevalence. [3,4,5]

The 2014 data from the local Health Office stated that Banjar is the district of highest contribution to cases of stunting in south Kalimantan. Among areas in Banjar, the highest number of case load was found in the Sungai Pinang Public Health Center's working coverage area (53.46%). This prevalence slightly increased than the 213 prevalence of 53.25%. The finding was intriguing as the working coverage area of Sungai Pinang Public Health Center included areas located in the riverbank that can be utilized for fish farming. As fish farming products might provide a significant source of protein, the areas shouldn't have had a public health problem of a high prevalence of stunting. [6,7]

Banjar district with its approximately 12595.9 tons of yearly production, is an area of highest fish farming production compared to other areas in South Kalimantan. The tremendous products mostly comes from the products of pond and fresh water fish cultivation, karamba, mina padi/sawah dan jaring apung. The conducive environment of Banjar district has allowed this various types of farming to develop. However, in concordance with the research conducted by Hartati, the number of riverbank inhabitants that consume fish is still really low despite the area's potential as a significant source of animal protein from fish farming products. The riverbank area should've been utilized by the community to manage with the low nutritional status, especially with stunting. [8,9]

Three categories of factors might lead to the occurrence of stunting: basic factors (e.g. economy, social, political factors), underlying factors (e.g. family and health service), and immediate factors (e.g. diet and health status). Family factors might also include genetics and parental level of educational attainment (that might significantly correlates with knowledge), social economy condition, and the number of children under two years old within the family. Dietary factors might include food intake of the children under two years old within the family.[10] As mentioned by Atmarita and Soekirman, lower socioeconomical status and level of educational attainment might affect their nutritional status. These risk factors might lead to the inability to buy and sort the food required for a balanced diet, hence the nutritional inadequacy. [1,2]

This research was conducted to better explore the cultural factors and fish-origin protein intake adequacy and its potential correlation with the occurrence of stunting among children under two years old in the riverbank of Martapura river in Banjar district. Specifically, this research aimed to conduct in-depth analysis of the factors that might prevent fish consumption within families with children who experience stunting, identify the types of fish consumed and its protein content, determine the adequacy fish derived protein intake, and its potential correlation with the occurrence of stunting.

Materials and Method

This research employed a mixed method with cross sectional design. The quantitative part of the research aimed at analyzing the adequacy of protein intake and other risk factors that might correlate with the occurrence of stunting, while the qualitative part was conducted to analyze the cultural factors that might prevent fish consumption among children under two years old in riverbanks within the working coverage of Sungai Pinang Public Health Center. Sample was taken during the nutritional status assessment conducted on children under two years old who met the predetermined inclusion criteria. The children's nutritional status was determined according to the 2005 edition of WHO anthropometry reference standard with categories as follows: 1) stunting (very short, z score <-3.0 SD); 2) short (≥-3 SD sd <-2 SD); 3) no stunting (normal status, ≥ 2 SD). Protein intake adequacy was determined by the standards of Nutrition Adequacy Score for children For Age 0-3 Year on WNPG 2004. [2]

The research subjects were mothers with children under two years old (age 6-24 months) within the working coverage area of Sungai Pinang Public Health Center, with a number of 36 subjects recruited [7]. The sample was obtained using the purposive sampling technique with a predetermined inclusion and exclusion criteria.[11] The inclusion criteria used were as follows: 1). Inhabitants of the riverbank within the working coverage area of Sungai Pinang Public Health Center, 2). Mothers with children under two years old (age 6-24 months), 3). The indexed children under two years old (age 6-24 months) were biological children, 4). When the family had more than one children under two years old (age 6-24 months), the one recruited was the youngest child, 5). Physically and mentally healthy, 6). Willing to participate as respondents as indicated by signing the informed consent form, 7). No congenital anomalies (physical disability) found in the children, 8). The indexed children did not suffer from conditions that might alter food absorption (TBC, hepatitis, shingles, worm infestation, diarrhea), 9). Subjects were available during the time of data collection.

Research instrument used in this research were as follows: 1). Anthropometry instruments for children age 6-24 months (a baby lenghtboard with the precision of 0.1 cm), 2). Informed consent form, 3). Food recall Form to collect the food intake data during three non consecutive twent-four-hour-period. This note was used determine the level of protein intake in the indexed children, 5). Basic demography form to note the subjects' and family identity. In addition, an interview manual was used to help gathering data about factors that might affect the fish derived protein consumption. Data collected were then analyzed using *chi square* statistical test with a 95% confidence interval to to determine the subjects' protein intake adequacy status and its possible correlation with the occurrence of stunting.

Result and Discussion

A. Univariate Analysis

Table 1. Distribution of Frequency

Variabel	N	%
Level of Protein Intake Adequacy		
Poor	25	69.4
Good	11	30.6
The state of stunting		
Stunting	15	41.7
No Stunting	21	58.3

B. Bivariate Analysis

Table 2. The correlation of fish derived protein intake adequacy and the occurrence of stunting among children under two years old

Level of protein intake adequacy	The state of stunting				Total		p value	OR (95% CI)
	Stunting		No stunting					
	n	%	n	%	n	%		
Poor	12	80.9	4	19.1	16	100	0.041	5,5 (1.277-23.693)
Good	3	19.1	17	80.9	20	100		

Table 2 showed that most children under two years old with poor fish derived protein intake adequacy experienced stunting (n=12; 80.9%). In contrast, a number of 17 (80.9%) children within the good protein intake adequacy never experienced stunting. A significant correlation was demonstrated between the fish-origin protein intake adequacy and the occurrence of stunting among children under two years old ($p<0.05$). The OR value of 5.5 indicated that children under two years old with poor fish derived protein intake adequacy had 5.5 higher risk of stunting than the children with good fish derived protein intake adequacy.

One of the indirect causes of stunting might be the socioeconomy state of the family that might correlate well with the level of the family income. When limited income prevents a good access for food, stunting would be highly more likely to occur. For countries undergoing nutritional transition like Indonesia, obesity might also emerge as a public health problem in addition to conditions related to the low nutritional adequacy such as stunting. While improved welfare might lead to improvements in food adequacy, the risk of consuming higher level of calories and saturated fat instead of protein should also be of concern due to its potential health risks in the far future.[12] This is because protein plays an important role in the growth and development of children, especially during the window of opportunity period. This might be well represented by the finding of this research. A number of 15 (41.7%) children under two years old in this research experienced stunting, and 80.9% of them were from the poor protein intake adequacy group. This was further supported by Hartati who has previously demonstrated the correlation of protein adequacy and the nutritional status of children under five years old. Protein is needed by human body as substrates for replacing damaged cells that would subsequently induce growth and development especially during infancy and under five years of age. [9]

A number of 3 (19.1%) subjects, however, still experienced stunting despite being in the good fish derived protein intake adequacy. This finding might present the bias potentially induced by the short research duration and the food recall period of three non consecutive days. These methodological aspects

might lead to the data being not entirely representative for the subjects' actual eating habit. The degree of fish availability might also affect the dietary pattern of the inhabitants from time to time. The cross sectional design of this research did not allow a further analysis on such changes and its possible correlation from the occurrence of stunting. It was also impossible to analyze internal factors such as genetics that might also play role in the occurrence of stunting. Further research should therefore be conducted with improvements on those factors.

Madanijah, *et al* (2006) further stated that the fish consumption among children in fishermen family was higher than non fishermen family as the dietary pattern would understandably be determined by the availability of the immediate food source. Some families might also prevent themselves from feeding their children with fish as preparing fish dish potentially requires some additional time to clean the fish bones and scales. Limited mothers' knowledge about the importance of fulfilling the nutritional status of children under two years old could also contribute to their tendency to not provide fish. Another misled belief that might lead to this reduced fish intake in children under two years old is the belief that the children have had their protein needs covered from the breast milk. Therefore, the fish should be provided to the mother instead. [13]

Conclusions

A significant correlation was demonstrated between the fish derived protein intake adequacy and the occurrence of stunting among children under two years old ($p<0.05$). The OR value of 5.5 indicated that children under two years old with poor fish derived protein intake adequacy had 5.5 times greater risk of experiencing stunting compared to children with good fish derived protein intake adequacy. The possible immediate approach to manage with this problem would be to provide nutritional education for mothers. This might include the education about the importance of maintaining a balanced diet, the process of preserving and preparing various fish derived food, and the role of fish derived protein in the growth and development of their children. When conducted during the window of opportunity period, this might allow the children who might be at risk to catch up on growth and development.

Ethical Clearance: This study approved and received ethical clearance from the Committee of Public Health Research Ethics of Medical Faculty, Lambung Mangkurat University, Indonesia. In this study we followed the guidelines from the Committee of Public Health Committee of Public Health Research Ethics of Medical Faculty, Lambung Mangkurat University, Indonesia for etchical clearance and informed consent. The informed consent included the research tittle, purpose, participants's right, confidentiality and signature.

Abstract

Background: Preeclampsia is one of the main causes of maternal and neonatal morbidity and mortality in developing countries. The infant mortality rate in Indonesia has decreased but is still quite high. The purpose of this study was to analyze the factors that contribute to the death of infants from mothers with preeclampsia.

Method: This research is a design retrospective cross-sectional study conducted in women with a history of preeclampsia are recorded in the data Dr. Soetomo hospital over a period of one year. Total respondents were 32 4. Demographic data on preeclamptic mothers (gestational age, age, parity and mode of delivery) and infant mortality data were collected which were then analyzed descriptively and chi-square test.

Results: The results showed a significant relationship between maternal age with preeclampsia (p = 0.005), age of maternal pregnancy with preeclampsia (p = 0.000) and mode of delivery of mothers with preeclampsia (p = 0.000) with the incidence of death in infants, and none a significant relationship between maternal parity status with preeclampsia (p = 0.043) with the incidence of death in infants.

Conclusion: factors that contribute to infant mortality from mothers with preeclampsia are age, gestational age, and mode of delivery.

Keywords: *Contributing factors; preeclampsia; neonatal death.*

Introduction

Sustainable Development Goals (SDGs) Program in Indonesia one of which is to reduce the neonatal mortality rate and child mortality rate. Events of infant or child death in Indonesia. The number of infant mortality cases dropped from 33,278 in 2015 to 32,007 in 2016, and in 2017 there were 10,294 cases. Similarly, the maternal mortality rate dropped from 4,999 in 2015 to 4912 in 2016 and in 2017 there were 1712 cases[1]. Despite the decline, the figure is still high.

Data from the World Health Organization, maternal mortality in the world amounted to 289,000 in 2013, maternal deaths occurred every day about 800 women died due to complications of pregnancy and childbirth. The main trial of maternal deaths in Indonesia are bleeding, preeclampsia and infection. Preeclampsia is a hypertensive condition k late pregnancy characterized by increased blood pressure and proteinuria[2]. In developing countries, preeclampsia is one of the main causes of maternal mortality ranging from 1.5-2.5 percent and infants range from 45-50 percent[3]. Based on these data, the percentage of infant deaths due to preeclampsia is greater than that of mothers. Infant mortality occurs due to several risk factors for preeclamptic mothers, such as preeclampsia in previous pregnancies, symptoms of chronic hypertension, pregnancies of more than 40 years, and others that have been carried out in advance[4].

The impact of preeclampsia other than on the mother also affects the baby. The condition of preeclampsia can interfere with blood flow to the placenta and fetus which can cause low birth weight babies, prematurity, asphyxia, respiratory distress syndrome, apnea[5]and infant mortality[6]. Babies who survive after birth from mothers with pre-eclampsia are also at risk of developing disorders due to disturbances while still a fetus.

Some factors that cause the handling of preeclampsia in pregnant women are lacking are lack of knowledge, lack of self-awareness and poor antenatal care[7]. Pre-

eclampsia conditions will increase the risk of mother and baby experiencing cardiovascular complications [8], maternal age> 30 years, parity, history of hypertension, and no antenatal care [9,10].

Research on preeclampsia that has been done more often looks at the risk factors of the mother and the effects on the fetus. But the contributing factors, especially in Indonesia, have not been found. The purpose of this study was to analyze the factors that contribute to infant mortality in women with preeclampsia.

Method

This research is a retrospective study conducted in the public hospital area of Dr. Soetomo Surabaya. The sample of this study is medical record data of preeclampsia patients in the period of January to December 2017 as many as 324 were taken by consecutive sampling.. Patient data is collected sequentially based on medical record numbers to avoid repetition of data and confusion when filling in data. Pre-eclampsia diagnosis is established by obstetricians. Pre-eclampsia diagnosis is blood pressure> 140/90 mmHg with proteinuri> +2. The independent variables of this study were age, gestational age, parity and mode of delivery. The dependent variable in this study was infant mortality defined as death in the first 28 days of life. Data were analyzed descriptively and chi-square test.

Results

Table of factors that contribute to infant mortality in women with pre-eclampsia

Variable (Mother)	Infant					P
	Life	%	Mortality	%	Total N (%)	
Age (Years)						
<20	14	4,3	0	0,0	14 (4)	0.005
20-35	180	55,6	31	9,6	211 (65)	
>35	72	22,2	27	8,3	99 (31)	
Age of Mother's Pregnancy (Weeks)						
<28	9	2,8	21	6,5	30 (9.3)	0.000
28-34	91	28,1	30	9,2	121 (37.3)	
>34	166	51,2	7	2,2	173 (53.4)	
Paritas						
Nulipara	96	29,6	20	6,2	116 (35.8)	0.463
Primipara	81	25,0	14	4,3	95 (29.3)	
Multipara	89	27,5	24	7,4	113 (34.9)	
How to Deliver						
Spontaneous Vaginal Discharge	47	14,5	13	4,0	60 (18.5)	0.000
Vaginal Induction	16	4,9	12	3,7	28 (8.6)	
Vagina with Instruments	9	2,8	4	1,2	13 (4)	
Perabdominam	193	59,6	26	8,0	219 (67.7)	
No Data	1	0,3	3	1,0	4 (1.2)	

Most respondents are aged 20-35 years (65%). Most of the respondents' gestational age was> 34 weeks (53.4%). Most of the respondents were nullipara (35.8%) and most of them had abdominal labor (67.7%).

Most respondents with pre-eclampsia with a baby who died were aged 20-35 years as many as 31 events (9.6%). Infant mortality from preeclampsia mothers was 30 events (9.2%) from pre-eclampsia mothers with 28-34 weeks gestational age. Infant mortality in pre-eclampsia mothers was 20 events (6.2%) occurred in pre-eclampsia mothers with nulliparous parity, and infant mortality occurred as many as 26 events (8%) occurred in pre-eclampsia mothers by means of gestational birth.

Statistical test results showed a significant relationship between maternal age with preeclampsia with the incidence of infant mortality (p = 0. 005), and

there was no significant relationship between the parity status of mothers with pre-eclampsia and mortality in infants (p = 0.463). The results of statistical tests also showed a significant relationship between the age of maternal pregnancy with preeclampsia (p = 0.000) and the method of delivery of mothers with preeclampsia (0.000) with the incidence of infant mortality.

Discussion

The age of mothers with preeclampsia has a significant relationship with the incidence of infant mortality. Infant mortality occurs in preeclamptic mothers in the age group of 20-35 years and age> 35 years.

The results of this study are in line with other studies which state that maternal age with young pre-eclampsia is associated with the risk of infant mortality[11,12]. Maternal age at risk of developing pre-eclampsia occurs in the age group <20 years and> 35 years.

In this study, besides that most of the respondents in this study were preeclamptic mothers aged 20-35 years. In preeclamptic mothers aged 20-35 years are included in the productive age where they are emotionally mature, especially in the face of pregnancy. In addition, the reproductive organs have also been mature and balanced[13]. Several other factors such as early treatment of the condition of preeclampsia and maternal conditions when treatment can affect maternal conditions.

Pregnancy age of mothers with preeclampsia has a significant relationship with the incidence of infant mortality. The infant mortality from mothers with preeclampsia most common in gestational age 28-34 weeks and <28 weeks.

The results of this study are in line with previous studies showing that the gestational age of mothers with preeclampsia is related to the morbidity and mortality of infants who born[14]. Other studies have shown that the high risk of infant mortality in preeclamptic mothers in the preterm period (gestational age less than 37 weeks)[15,16] and will be more severe at a gestational age of fewer than 24 weeks[17].

Babies born in the preterm period have a high risk of experiencing low birth weight babies, respiratory disorders such as asphyxia[18]that occur due to pulmonary growth disorders[6], intrauterine growth restriction (IUGR) and hematological disorders. Epidemiological research states that babies born to mothers with preeclampsia have a high risk of developing diabetes and cardiovascular disorders. The condition of preeclampsia can aggravate the baby's condition which is probably caused by impaired placental function due to preeclampsia or maternal system response to placental inability.

The method of delivery of mothers with pre-eclampsia has a significant relationship with the incidence of infant mortality. The majority of preeclamptic mothers in this study gave birth to a method of palpation. As well as the incidence of infant mortality from preeclamptic mothers occurred in the group of preeclamptic mothers who gave birth to a method of domination.

Previous studies have suggested that abdominal method of childbirth will increase the risk of respiratory distress in infants that can cause infant death[19,20]. In addition, the method of childbirth with abdominal can increase the risk of respiratory disorders in infants compared with childbirth with vaginal delivery. Previous studies have shown that abdominal delivery[21]cannot improve maternal and perinatal outcomes or reduce mortality and morbidity[22].

Most mothers with preeclampsia do the method of labor by abdominal. The reason for the majority of method of delivery per abdominal is because abdominal labor is the definitive treatment in patients with severe pre-eclampsia. The risk of childbirth in women who experience severe pre-eclampsia is very high because it can threaten the life of the mother and baby, so it is necessary to end the pregnancy by giving birth per abdominal. The condition of preeclampsia which has a negative impact on the baby as well as ways of abdominal delivery which increase the risk of disorders in infants can increase the risk of infant mortality from mothers with preeclampsia.

The parity status of mothers with preeclampsia does not have a significant relationship with the incidence of infant mortality. The total parity status of preeclamptic mothers in the study was almost the same in the nullipara, primiparous and multiparous groups.

Previous studies have shown that the status of nulliparous parity will increase the risk of the occurrence of preeclampsia[23] that would increase the risk of death in infants. Nulliparous pregnancies experience angiogenic imbalances so they are prone to pre-eclampsia compared to multiparous pregnancies[24]. The results of this study indicate that the incidence of infant mortality from

mothers with pre-eclampsia occurs in nulliparous parity status although there is no statistically significant relationship.

This study has several limitations because it is done retrospectively such as some data relating to maternal preeclampsia conditions such as income, increased maternal weight during pregnancy, or other diseases that can worsen the condition of preeclampsia.

The results of this study have implications for policies related to health interventions and treatment of women with preeclampsia, maternal complications,and complications in infants. This study has limitations, the severity of preeclampsia is still not differentiated and several other factors such as antenatal care visits, knowledge,and accompanying complications have not been measured. So it needs further study of these factors related to the incidence of infant mortality from mothers with preeclampsia.

Conclusion

Preeclampsia can threaten the mother and baby and can increase morbidity and mortality in infants. Factors that contribute to infant mortality from mothers with preeclampsia are maternal age, maternal gestational age,and maternal delivery method. The need for early antenatal care needs to be conveyed to pregnant women in order to screen crews for risk of preeclampsia and prevent worsening of the disease.

Recommendation: Preeclampsia is a preventable medical condition. Early pregnancy screening early and appropriate antenatal care can reduce the risk of morbidity and mortality in infants of mothers who experience pre-eclampsia. Increasing public awareness and health workers on the prevention of pre-eclampsia needs to be done through health education or including pre-eclampsia screening at standard examinations in pregnant women.

Ethical Clearance: This research has received ethical approval from the ethics committee of the general hospital health research area of Dr. Soetomo Surabaya number 0171/KEPK/IV/2018.

Conflict of Interest: None.

Mental Health Nurses and Community Leaders' Roles in Mental Health Enforcement: A Phenomenological Study

Nurul Arifah[1], Merryana Adriani[2], Hanik Endang N.[1]

[1]Faculty of Nursing, [2]Faculty of Public Health, Airlangga University, C Campus Mulyorejo, Surabaya, Indonesia

Abstract

The concept of mental health enforcement in the community makes mental health policies which are part of the national and regional health systems seek health implementation activities that are integrated in cross-sectoral programs and involve society participation. Mental health nurses and community leaders play main roles in implementing the mental health enforcement in society started from the family. The objective was to briefly describe the phenomenology study of mental health nurses and community leaders' roles in mental health enforcement in Surabaya urban society. This study used a qualitative research design with a phenomenological study approach. There were 7 representatives of authorized community leaders and health workers related to the mental health enforcement in the community which was taken by purposive technique. Data were taken using forum group discussion (FGD). Data were analyzed using the Colaizzi Analysis Method. The research findings obtained 7 themes and 12 sub-themes related to the roles of mental health nurses and community leaders in mental health enforcement. The mental health nurses and community leaders' roles in mental health enforcement are important in handling several cases of mental disorders within a family in the society.

Keywords: *Mental Health Nurse, Community Leader, Role, Enforcement, Phenomenology Study.*

Background

Community is a part of healing process for mental health illness. Mental illness recovery is drawn as a transformational process which ongoing to contribute to life.(1) In addition to somatic factors, psychological and socio-cultural factors also play a role as a source of mental disorders where from various predisposing factors to mental disorders, 60% of factors that determine a person's health status are social, cultural and environmental conditions(2). The society where the family lives influences the burden. The stressors, however, involve many types of care burdens, negative perceptions or stigma and lack of support from those in the surrounding environment (community)(3).

The prevalence of mental disorders in Indonesia is not much different from the prevalence in the world. The incidence of mental disorders in Indonesia based on data is 4.6/1000 people(4). This figure is equal to the median prevalence rate of mental disorders in the world. In East Java, people with mental disorders experienced a drastic increase in 2016. East Java Province showed the number of 2.2 people based on all East Java population of 38,005,413 lives, it could be concluded that 83.612 lives have mental disorders in East Java. In addition, national data on the incidence of severe mental illness (schizophrenia) in East Java was 1.4% and Surabaya accounted for 0.2%. While emotional mental disorders (such as anxiety, depression, etc.) by 35% and in Surabaya recorded 18.8%.

Mental health policies that are part of the national and regional health systems seek promotive and preventive integration across multiple cross-sectoral programs and involve community participation(5). One of the efforts that can be done to support the recovery of patientswith mental disorder according to the Decree of Health Minister no 220/Menkes/SK/III/2002 is to involve community participation in supporting the recovery of patients with mental disorders.(6) Mental health nurses and community leaders play main roles in implementing the mental health enforcement in society started from the family as a small part which builds community. The implementation of nursing care in the community is related to each other, because the services provided must be comprehensive, holistic and sustainable because the

needs of each individual are different from each other, the nurse must behave according to the individual's needs at that time[7]. The phenomenological study of how mental health nurses and community leaders' roles involve in mental health enforcement in the Surabaya urban city community becomes important primarily in concerning with each family's backgrounds integrated into planning, treatment, to participation in decision-making related to mental health care in society.

Method

A qualitative design with phenomenology study approach was used in this study. There were 7 informants which was taken by purposive technique. Inclusion criteria were the representatives of community leaders and health workers who are authorized in mental health enforcement in society. Data were taken using forum group discussion (FGD) in Keputih Public Health Centre in Surabaya as the first advanced implementation of mental health program in the city stated by the Surabaya City Health Office. Data were analyzed using the Colaizzi Analysis Method and validated using triangulation techniques.[8]

The questions asked in the forum group discussion were about the roles of mental health community nurse in implementing the mental health in general. Before the study, researcher firstly completed the permission procedures from Surabaya City Health Office to the head of Keputih Public Health Centre. The researcher conducted the forum group discussion with 7 representatives of mental health enforcement authorized persons in surrounding Keputih Public Health Centre's area consisted of 1 doctor, 2 nurses, 1 psychologist, 1 citizen association, and 2 cadres.

Findings: The results of forum group discussion found 7 themes and 12 sub-themes conveying about the roles of mental health nurses and community leaders in mental health enforcement included:

1. **Fostering collaboration with families in the form of family's approach and assistance:** Listen to and respect each family member. Respecting race, ethnicity, culture, and socio-economy, family background and experience according to patients and family preferences in planning and delivering health services.[9] In accordance to this, health workers implement a family mentoring system where community mental nurses (on duty in the field) become the supervisor of this activity. In handling cases of mental disorders in the community, nurses work with families because the family is the closest person to the sufferer. If there are obstacles, the officer then collaborates with community leaders to help the approach.

"..Citizen association must be able to be active in helping their citizens. At least the family, because with no management assistance, the family will find difficulty, how can he be accepted in the community.."(D1)

"So far, I have accompanied.." (R1)

"If it's about collaboration with family, it's just assistance..." (D2)

2. **Relying information about mental disorders through mental health education and socialization:** The value of care and care for family-centered patients and information sharing, respect, and collaboration with patients and families is also important for family care.[10] Mental health education is carried out as a form of information sharing by health workers (especially nurses who are directly involved in the field) to convey information related to mental disorders. Community leaders helped facilitate the extension activities to the community. Community leaders and other health workers (particularly nurse and cadres) who are authorized can also provide socialization according to their portion.

"We bridge to be able to provide health education to families.. . We connect with family and surrounding communities." (D1)

"Information about mental disorders, after the person concerned from the family came to the officer and to the health facilities… I have a little knowledge; I can convey it to him. And can increase knowledge for the handling of the patient."(A)

"..Routine health education at community events and sometimes the health office also goes down to socialize mental health problems."(D2)

3. **Improving family communication by providing understanding of the problem solving to families and society:** Providing understanding to families and communities regarding the problems that occur is a form of efforts to improve family communication with people with mental disorders and solutions to problem solving carried out in the community.

Constraints that are often faced are not only from the family but many problems that are also presented by the community. Therefore, the communication carried out is not only specific to the family but also to the surrounding community.

"*If there is outside interference so we invite, we connect with family. We convey the good aim. Maybe there is something that can be helped, assistance for healing, or subsequent follow-up. We help.* "(D1)

"*If it is a problem like that, we did it earlier... Outright, mentoring, then gave an explanation of mental health problems to his family. The real problem is not the average family in the community, but the neighbors. So we give an explanation. We also present the district to explain that it is not that easy to citizens..''* (R2)

All family nursing interventions occur in the context of nurse family relationships and are carried out primarily with therapeutic communication which teaches the principle of effective communication and teaches problem solving strategies.[11] The philosophy of nursing is known as the relationship between patient, care, and family centered.[12]

4. **Helping to use a service system with cross-sector coordination and collaboration:** In handling mental disorders in the community, mental health nurses cannot work alone even though they are directly responsible in the field. Cross-sector collaboration is always done to maximize performance so that problems faced by families and communities related to mental disorders can be resolved immediately. Cross-sectoral cooperation is carried out, which is related to the health office, urban village, sub-district, community leaders (community and cadres), to other health workers such as specialists and psychologists. All parties will coordinate so that cases of mental disorders in the community can be handled.

"...When it comes to referral and when it is outright to do it from a health worker, that is facilitated." (D2)

"...If this happens, then we will coordinate with several related parties." (D1)

*"Finally yesterday I took the initiative to come to public health centre and took action that I also reported to the district in outright, and brought to hospital..''(*R2)

"Then we finally report to the citizen association and the person in charge of social institution then finally take to it.." (E)

"..Because for the case of our society we cannot work alone, we should work with the sub-district administration.." (A)

Centralized patient and family care has been endorsed at the highest policy level in developed countries and has the privilege in the mission statement of most health care systems that have encouraged the creation of many patient and family care institutions that provide resources and collect data about their implementation.[5]

5. **Helping family members meet their own needs by communication and counseling (psycho-education):** Patients and families can become members of family counseling or other institutions in health care facilities.[9] The form of the way the community mental health nurse helps family members meet their needs is by doing counseling. The implementation of counseling can be done at the public health centre or Hospital. Counseling is done to the family to get the choice of the right actions to meet the problem of the needs of the patient, especially in terms of treatment and care. The mental health nurse involves the family to determine the needs.[13] The way carrying out this role is to do family psychoeducation. Community leaders also play a role in efforts to fulfill the needs of patients and families including cadres who strive to help families if there are family problems, so that families can be more open.

"..so far.. I always have communication when there is a development.. the family should give good communication to the patient.." (E)

"if family has problem, it is always welcome to consult with me.." (A)

"For the consultation there is now a mental health booth with psychologist. We concern more in the field.." (D2)

6. **Resolving specific issues about patients in the form of family empowerment:** In resolving a special issue about patients, community mental health nurses said they had tried to do family empowerment. This is certainly supported by a team of other health workers and community leaders. After the community leader assists in the approach

by giving advice to the family, health workers are then included in further management. But first, in empowering the family, it must be ensured that the family accepts the presence of assistance offered. If the family refuses, the decision will wait for follow-up from the family. Community mental health nurses continue to strive to give direction to things that families can do independently with family members who experience mental disorders.

"..we empower their families. If the nurses and doctors like that, focus on these patients, we don't have enough energy, so we empower the family. For health check-up, we also make it easier for patients, so families can focus on handling the independence of their patients."(De)

"If you face a family like that, the term is that they are still able to accompany the sick or not?.." (D)

"..I also said, please help (to the family to take care of the patient). Later when there is a need to be able to call us.. we are ready to assist all the problems.. "(Ri)

Family nurses have developed various models to implement with families. For example, the Calgary Family Assessment and Intervention Model[14] identifies relational family nursing interventions that guide nurses to explore how illness has affected their lives and their awareness of suffering the illness.

7. **Resolving specific issues about families with community empowerment (cadres):** Community mental health nurses also empower the community such as community leaders (community members and especially cadres) to help resolve specific issues about the family. Not only towards mental health cadres, other cadres are also directed to be able to help problems that exist in the community. With the empowerment of the community, health workers are assisted by the existence of reports and input on cases of mental disorders that exist in the family and community so that the relevant authorities can coordinate and follow up. On the contrary, the community also received attention from a team of health workers who were bridged by community leaders, especially cadres regarding the resolution of existing mental disorders cases.

*"Then there are mental health cadres too. So when there are activities, then we help.. "(*E)

*"... that is the active role of mental health cadres and then the administrators. Because this is a shared problem, and we must actively participate to be able to help.. . "(*A)

"In theory, we have mental health cadres, but we ask for help from all cadres." (D2)

"But we focus on the community through the Community Mental Health Management Team.. we collect cadres, across sectors, to talk about mental health, but we have not yet made the decree." (R1)

Demands to cover a broad group, not just an individual approach make the intervention must be able to be absorbed by certain communities in an appropriate, integrated, and continuous manner.[15] Therefore intervention in the Mental Health field is an integrated psychosocial program, which leads to group empowerment that is directly related to these social problems.

Conclusions

In handling several cases of mental disorders within a family in the society, mental health nurses and community leaders play important roles in implementing mental health enforcement. Community mental health sectors include all levels and actions of mental health enforcement have their own parts in advance. Empowering all potentials and resources in the society is also important to realize an independent society in maintaining mental health. The enforcement of mental health in urban society needs to be developed more widely and deeply that can be applied in order to improve the high quality of individuals' mental health in their life.

Abstract

Introduction: One indicator to assess hospital quality service is customer satisfaction. Customers satisfaction in health services are valuable assets in health business. The aim of this study was to analyze the influence of perceived value, perceived quality and perceived sacrifice to customer satisfaction at Inpatient Installation of Dr. Soetomo Hospital Surabaya, Indonesia.

Method: A cross-sectional observational analytical research with random sampling method. This study was conducted at the Inpatient Instalation Dr. Soetomo Hospital. The sample size of this study was 353 patients determined using Sample Size Determination in Health Studies application. The eligible patients were explained about the study objectives. Approval from patient regarding the participation in the study was obtained by written informed consents. The research instrument used consisted of a valid and reliable closed questionnaire. This questionnaire is used to measure perceived quality, perceived sacrifice, perceived value, and customer satisfaction variables through questionnaire-guided interview. All data was analyzed with $p<0.01$ were considered significant.

Results: The perceived quality has a positive significant influence in customer satisfaction ($p=0.0001$), the perceived sacrifice did not affect customer satisfaction ($p=0.691$); and the Perceived value have a positive significant influence on customer satisfaction ($p=0.000$) ($p<0.01$).

Conclusion: The Perceived Quality and Perceived Value have an influence and affect Customer Satisfaction significantly in Inpatient Installation of Dr. Soetomo Hospital Surabaya, Indonesia. Further study is needed and can be done to provide empirical evidence about other factors that affect customer satisfaction.

Keywords: *Perceived Quality, Perceived Value, Perceived Sacrifice, Customer Satisfaction, Service Quality.*

Introduction

Quality, fair and equitable health services are the basic rights of all patients. Indonesia Government must continue to improve health services. Hospital plays an important role in health service to improve patient health. The increasing number of hospitals that are accompanied by increased knowledge of service users (patient). It makes patients selectively choose health facilities. The health business competition surprisingly increased. The hospitals must to improve the quality of their health services.[1]

Service quality is defined as the comparison between expectations and reality obtained by customers.[2] The quality of health services should be improved by fulfill the demand, needs, and the customer desires to meet customer satisfaction. Customer satisfaction is customer's perception if the health service received is deemed appropriate or meets their expectations.[3] Customers satisfaction in health services are valuable assets in health business.[1]

Dr. Soetomo Surabaya is a tertiary general hospital in East Java Province since 1938 and the largest hospital in Eastern Indonesia. Dr. Soetomo Surabaya has a vision to be a trusted with high-quality health service by using the values of integrity, professionalism and innovation. Dr. Soetomo hospital should be ready to compete in health business competition. Dr Soetomo hospital must prepare many strategies to face the health business competition such as improve the health service quality. One indicator to assess hospital quality service is customer satisfaction. Customer satisfaction at Dr. Soetomo hospital Surabaya during 2012 to 2016 did not meet the standards set by the Quality Assurance Standard based on data from the 2016 Government Institution Performance Report of Dr. Soetomo hospital Surabaya. The other problems faced by Dr. RSUD Soetomo Surabaya was patient visit in 2016 decreased compared to the Inpatient Installation in 2015.

The aim of this study was to analyze the influence of perceived value, perceived quality and perceived sacrifice to customer satisfaction at Inpatient Installation of Dr. Soetomo Hospital Surabaya, Indonesia.

Material and Method

A cross-sectional observational analytical research was carried between October 2017 – December 2017 at the Inpatient Instalation Dr. Soetomo Hospital, Surabaya. The study protocol was approved by Ethics Committee of Dr. Soetomo Hospital (313/PANKE/IV/2017). Population of this study was all patients in Inpatient Instalation Dr. Soetomo Hospital, Surabaya. Determination sample size in accordance with the strata of Inpatient Installation using software or the Sample Size Determination in Health Studies application (Sample Size 2.0). Based on the calculation results obtained 353 patients for sample size. Prior to the study, the eligible patients were explained about the study objectives. Approval from patient regarding the participation in the study was obtained by written informed consents. The research instrument used consisted of a valid and reliable closed questionnaire. This questionnaire is used to measure perceived quality, perceived sacrifice, perceived value, and customer satisfaction variables through questionnaire-guided interview. All data was analyzed using Statistical Package of Social Sciences (SPSS) 17.0 for windows was used and p values <0.01 were considered significant.

Results

The hypothesis test results obtained from three hypotheses only one hypothesis rejected that can be seen in Table 1. It means that there is a variable that did not have a significant influence. The perceived quality has a positive significant influence in customer satisfaction. The variable perceived sacrifice did not affect customer satisfaction. Perceived value has a positive significant influence on customer satisfaction.

Table 1. The Influence of Perceived Quality, Sacrifice, and Value toward Customer Satisfaction Variable.

Variable	Original Sample	T-value	P Value
Perceived Quality to Customer Satisfaction	0.340	6.887	0.000*
Perceived Sacrifice to Customer Satisfaction	-0.018	-0.398	0.691
Perceived Value to Customer Satisfaction	0.317	6.381	0.000*

*Information: Significant at p<0.01

Discussion

There was significant influence of perceived quality and perceived value on customer satisfaction. Whereas for perceived sacrifice there is no positive and significant influence on customer satisfaction. Significant influence of perceived quality and perceived value on customer satisfaction can be interpreted as an increase or decrease in customer assessment of the quality and value of services provided by the Inpatient Installation of Dr. Soetomo Hospital Surabaya influences customer satisfaction with the service.

Perceived quality and customer satisfaction relationships are controversial issues in the marketing literature.[1] The results of this study indicate that the perceived quality has a significant effect on customer satisfaction at the Inpatient Installation of Dr. Soetomo Hospital. If the perceived quality is higher or better,

then customer satisfaction will increase for the services provided by the Inpatient Installation of Dr. Soetomo Hospital. The Influence of perceived quality with customer satisfaction due to both variables assess the performance of services that are directly felt by customers.

Customers feel that the service provided by the Inpatient Installation Dr. Soetomo hospital from the aspects of administrative services, doctor services, nurse services, pharmacy services and nutritional services have been good thus customers feel satisfied. These results are in accordance with the research conducted by Yang (2004) who found evidence that perceived quality variables have a positive and significant influence on customer satisfaction.[4] This statement is supported by the research of Cronin and Taylor (1994) which proves that customer satisfaction is determined by the perceived quality that has been given.[5] Fornell (1992) explained in his study that there was a perceived quality relationship with customer satisfaction.[6] Research conducted by Subagio and Saputra (2012) also shows that perceived quality affects customer satisfaction.[7] Many other studies have views that perceived quality is something that precedes or affects customer satisfaction.[2,5,8]

The test results show that the perceived sacrifice variable has a negative but not significant influence on customer satisfaction. It can be concluded that the sacrifice made by customers in the Inpatient Installation of RSUD Dr. Soetomo did not influence customer with the service. The results obtained in this study are not in line with the research conducted by Subagio and Saputra (2012) where the perceived sacrifice in the study had a significant influence on customer satisfaction.[7]

The non-influence of sacrifice on satisfaction can also be caused by customers in Dr. Soetomo Hospital mostly uses National Health Coverage or Badan Penyelenggara Jaminan Sosial (BPJS) as a source of medical expenses, so they receive any services provided by the hospital. The sacrifices that customers feel not significantly influence their satisfaction with the services they receive. In addition, the perceived sacrifice has no effect on customer satisfaction because of the type of product provided by Dr. Soetomo hospital is a health service where the most customers desperately needed health services. Customers assume that the sacrifice given is appropriate to be given, in contrast to companies engaged in other goods or services such as the research conducted by Subagio and Saputra (2012) at Garuda Indonesia Company.[7] Other studies by Krisno and Samuel (2013) also show the results of a significant influence between perceived sacrifice and customer satisfaction, but the study was conducted at Informa Pakuwon City Surabaya which is a sales company for non-health products like Dr. Soeetomo Hospital.[9]

The results show that perceived value has a significant influence on customer satisfaction. The influence of the perceived value is positive so it can be concluded that the higher the perceived value, the higher the customer satisfaction. Customer satisfaction is influenced by perceived value which is an overall evaluation of the benefits of a product or service received compared to the sacrifice made.[10] The values obtained from the perceived value, it can be concluded that the majority of customers feel the benefits of using services at the Inpatient Installation of Dr. Soetomo hospital Surabaya. The customers feel satisfied with the services provided. The results of these influences are in accordance with the research conducted by Subagio and Saputra (2012) where perceived value affects customer satisfaction.[7] Hallowell (1996) believes that perceived value is a consequence of customer satisfaction. Other studies that show the relationship between perceived value and customer satisfaction are research conducted by Krisno and Samuel (2013).[9,11] The positive influence between perceived value and customer loyalty is also shown by many studies of both products and services.[8,12,13]

Conclusion

The Perceived Quality and Perceived Value have an influence and affect Customer Satisfaction significantly in Inpatient Installation of Dr. Soetomo Hospital Surabaya, Indonesia. Further study is needed and can be done to provide empirical evidence about other factors that affect customer satisfaction.

Assessment of Health Knowledge on Pregnancy, After Delivery and Newborn Baby Danger Signs among Migrant Mothers in Tak Province at Thailand-Myanmar Border

Nyunt Naing Thein[1], Wongsa Laohasiriwong[2], Aung Kay Tu[3], Thin Thin Soe[3]

[1]Student, [2]Dean, [3]Research Associate, Faculty of Public Health, Khon Kaen University, Thailand

Abstract

Awareness of danger signs in pregnancy, after delivery and newborn baby among mothers lead to seek immediate health care and consequently reduce maternal and neonatal mortality. Thailand has accepted about 3 million blue-collar migrant workers from neighboring countries mainly from Myanmar. Understanding the level of knowledge of migrant mothers and its associated factors would be helpful for health agencies to implement suitable health promotion programs.

Myanmar migrant women who had been living in the five border districts of Tak province, Thailand and delivered in the health facilities in five districts during September 2017 to March 2018 were face to face mother interviewed after 12 weeks after delivery with structured questionnaires.

Among 723 migrant women, only 125 respondents (17.29%) could mention 8 or more danger signs and 218 participants (30.15%) knew only less than 4 danger signs out of total 16 danger signs. The level of health knowledge on danger signs were significantly associated with resident district (χ^2 = 17.52, P<0.001), mother education (χ^2 = 17.06, P=0.002), health insurance status (χ^2 = 9.52, P=0.009),household income (χ^2 = 26.92, P = <0.001), location of home in factory compounds or in villages (χ^2 = 18.94, P=0.001), watching TV regularly (χ^2 = 15.25, P<0.001).

The migrant mothers in this study showed low health knowledge on danger signs. The organizations working for migrant health in Thai-Myanmar border should focus the provision of pregnancy and newborn healthcare messages to the illiterate mothers with low family income without health insurance in living in agricultural farms and factory.

Keywords: *Knowledge on Danger Signs, Migrant women, Thailand-Myanmar Border.*

Introduction

Knowledge of danger signs in pregnancy complications and newborn are life saving health knowledge and health literacy to seek immediate health care to save lives to reduce maternal and newborn mortality. Most causes of maternal deaths were preventable and related to complications in pregnancy and childbirth [(1)]. There were evidences that knowledge of danger signs and access to Antenatal care are associated[(2)] and well documented findings of adequate ANC visits are cost-effective strategy to reduce maternal morbidity and mortality [(3)].Globally pregnancy or childbirth complications cause mother dead 830 every day (303,000 annually) in 2015 as estimated by WHO[(4)]. These situations were addressed under Millennium Development Goal 5A, reduced maternal dead 532,000 in 1990 to 303,000 in 2015. Under Sustainable Development Goal (SDG), result 3: continues commitment to reduce the global maternal mortality ratio to less than 70 per 100,000 live births and end preventable deaths of newborns and children under 5 years of age[(5)]. At 282 per 100,000 live births, Myanmar's maternal mortality ratio (MMR) is the second highest in ASEAN [(6)]. It was far higher than SDG target.

About seventy two percent of maternal death is attributed to direct causes of maternal mortality. Among those causes Hemorrhage, Hypertension, Sepsis,

Abortion, Embolism accounts 27%, 14%, 11%, 8% and 3% respectively[7]. These situations can be prevented by awareness of danger signs which could be well named by layman and identify by apparent well define signs and symptoms. Pregnant women have not enough knowledge and not understood danger signs and health related with childbearing and postpartum, would be poorly prepared to make decision on different choices and that will significantly jeopardize to their own well-being[8].

International Labor Organization reported that there are 3.25 million migrant workers in Thailand which compose 8.5% of workforce in country[9]. Most of these workers are blue collar labors and mostly working in low-skilled jobs settings; agriculture, construction, service industries like restaurants, petrol station, retail shops, domestic work, fishing, manufacturing, and other services. Studies in Thailand related with barriers of migrant health care accessibilities were illegal stay in Thailand, language barriers, lack of information hinder their accessibility and utilization of health services[10,11,12].

Mae Sot town in Thailand is one of the most famous border towns for many migrants who cross border from Myawaddy town of Myanmar to Mae Sot as entry point to Thailand. There are many unofficial crossing points along the border around Mae Sot and its surrounding districts. Many migrants especially undocumented migrants stay and work in Mae Sot and surrounding districts as easy to cross border and wait there to move into other big cities such as Bangkok and Chiang Mai etc. This situation creates nearly 50% of total Mae Sot population with 149,708 Thai citizen and estimate 30,000 are people from Myanmar. Other four Districts in Tak Province along border Tha Song Yang, Mae Ramat, Phop Phra and Umphang with total Thai population of 256,231 and 118,036 are from Myanmar. Post conflict affected areas of Kayin State in Myanmar are border areas of Tak province. However, there is lack of evidence-based information about Myanmar migrant mothers' level of knowledge on danger signs of pregnancy and new-born and factors associated in five border districts of Tak Province at the Thailand Myanmar Border where thousands of Myanmar migrants are working.

Material and Method

Study sites: The study was conducted in five districts hospitals of Tak Province which are bordering with Myanmar; Mae Sot, Tha Song Yang, Mae Ramat, Phop Phra, and Umphang District and one charity health facility Mae Tao Clinic. All six health facilities offered ANC for migrants with the same standard as citizens.

Study subjects: Between June to December 2017, total 723 participants in the study were gave birth in one of the six health facilities. Sample size from each study site was calculated proportionally according to the number of deliveries of migrant women in the previous year among the facilities.

Data collection: A structured questionnaire was used to collect data regarding migrant women's demographic and socio-economic status, previous pregnancy information, awareness about danger signs in pregnancy and health literacy concerning pregnancy and antenatal care. Face to face interviews were conducted for data collection by the trained interviewers at the health facilities. The timing and number of ANC attendances were verified with ANC record books. A pilot study was conducted in Mae Sot and Phop Pra areas to test the validity and reliability of the questionnaire.

Data analysis: The categorical data were described by using frequency and percentage. All analyses were performed using Stata version 13.0 (Stata Corp, College Station, TX). Descriptive analysis and chi square test has been done for association and p-value < 0.05 has been considered as significant. Knowledge of total 16 danger signs in pregnancy, postpartum and newborn to seek immediate health care to group as high level of knowledge (> 8 danger signs), moderate level of knowledge (4 to 7 danger signs) and poor level of knowledge (<4 danger signs).

Findings

Descriptive analysis: A total of 723 migrant women were selected in this cross-sectional study. Most of the mothers were in age under 25 years (43.6%) and 13.5% were illiterate. Majority lived in Mae Sot (74.6%) and majority (65.3%) lived independently in the communities whereas 16.2% and 18.5% lived in the in the vicinity of agricultural farms and factories where they were working, respectively. Nearly three quarters of the women (72.9%) were employed and 55.2% had no health insurance. A total of 529 women (73.2%) had sufficiently took antenatal care (i.e., they made at least four ANC visits).

Figure (1)shows knowledge items on pregnancy, after giving birth and newborn danger signs, 412 (57%) of mother mentioned spotting or bleeding per vagina

with highest score in the seven pregnancy danger signs. 461(64%) of mothers stated excessive bleeding in postpartum period with highest score among four danger signs. 366 (51%) of mothers mentioned fever as danger signs for newborn to seek immediate health care with health personals.

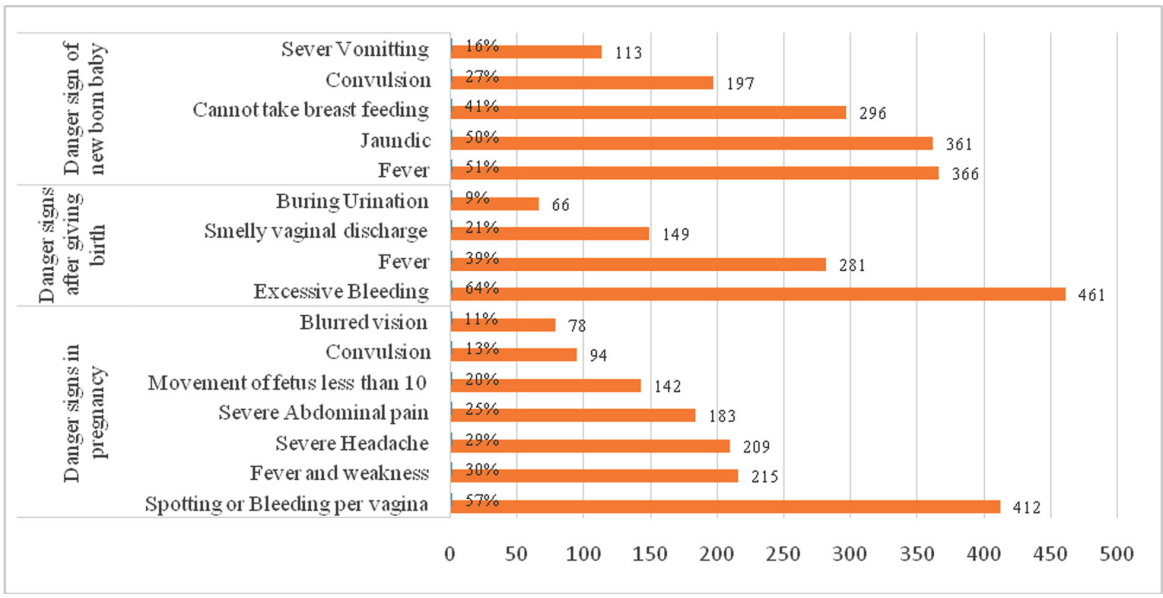

Figure (1). Health knowledge on pregnancy, after-delivery and newborn baby danger signs

Factors associated with level of knowledge of danger signs in Myanmar migrant mothers Knowledge levels of total 16 danger signs in pregnancy, post-partum and newborn to seek immediate health care were grouped as good e (> 8 danger signs), moderate(4 to 7 danger signs) and poor (<4 danger signs). Table (1) shows resident district, mothers' education, health insurance status, household income, location of home, watched TV were significantly Associated with level of health knowledge. Similar findings in Southern Ethiopia study mentioned that educational status of the respondents, monthly income were associated with mother knowledge of pregnancy danger signs[2]. Mother age, father age, fathers' education, legal stay permits, history of problems in the latest pregnancy were not associate with level of mother knowledge on danger signs in this study. However, Dessu S, et al found out that age of the respondent and history of previous pregnancy were found association with pregnancy danger signs[2].

Discussion

This study showed that the commonly mentioned danger sign in pregnancy was bleeding per vagina and it was same as other studies [2,14,15].Reduce fetal movement was answered only 142 (20%) in this study with similar with Kenyatta National Hospital (10.9%)[16], however in South Africa study,reduce fetal movement was mentioned higher (50%) [17].In Gambia study there was very low awareness of danger signs. The proportion of respondents answered signs of danger were anemia (29%), hypertension (24.6%), hemorrhage (14.8%) fever (12.9%) and puerperal sepsis (5%) [8]. The low level of health knowledge could be consequence to increase in medical expenses, morbidity and mortality and side effects of the diseases [18].The possibility of low health knowledge will be health education session is often verbal and health professional used professional medical languages and words, so most mothers can not perceive these words and these trainings are unusable [19].In Thailand there are strong primary health care networks in rural areas. These networks help migrant mothers who lived in rural areas able to learn more pregnancy related knowledge in not crowded rural health centers. Watching TV regularly and having health insurance also helped mothers to learn health education messages.

Conclusion

Understanding and awareness of dangers can save mother and newborn lives, if mothers are able to identify danger signs and seek immediate health care at the health facilities. More attention should be given to migrant communities in urban districts focusing on illiterate mothers without health insurance with lower family income. Pregnancy and newborn health care messages should be broadcasted in TV regularly.

A Prototype System for the Analysis of Sentiment Regarding Drug and Food Issues in Indonesia

Oke Dwiraswati[1], Kemal N. Siregar[2]

[1]Master Study Program of Health Informatics, [2]Department of Biostatistics and Population Studies, Faculty of Public Health, Universitas Indonesia, Building A, 2nd Floor Kampus UI Depok 16424, Indonesia

Abstract

Background: Drug and food policies or issues can give rise to various opinions in the community. In Indonesia, such perspectives can be quickly identified with the use of big data analytics software that can perform a sentiment analysis of Twitter content and complaints received by the country's ***National Agency of Drug and Food Control***. These tools are employed to examine positive or negative views regarding the aforementioned policies or issues. In consideration of these matters, this study was aimed at developing a prototype system for the analysis of sentiment regarding drug and food issues and integrating itwith Indonesia's information and complaints service network.

Method: To the above-mentioned ends, the research adopted a supervised machine learning classification method called a naive Bayes classifier (NBC), which was incorporated with evaluation parameters, namely, accuracy, precision, recall, and the F-measure. The systems development life cycle was used as a framework. The system was then tested using 10-fold cross-validation.

Results: The validation results showed that the highest accuracy exhibited by the system was 88%. It registered a precision of 81%, a recall of 100%, and an F-measure of 90% on 540 tweets that served as training data and 60 tweets that served as testing data. Sentiment analysis results are displayed on a dashboard.

Conclusion: An NBC exhibits reasonably good performance in the examination of sentiment toward drug and food issues in Indonesia. Sentiment data can serve as input that facilitates rapid response to these problems and subsequently clears the way for formulating appropriate education strategies for the community.

Keywords: *Drug and food; big data analytics; sentiment analysis; information and complaints service system; Twitter; naive Bayes classifier.*

Introduction

The Fourth Industrial Revolution is a period during which almost all people use digital innovations as their business vehicles. Its advent has driven online selling to emerge as one of the most effective avenues in which to address competition and current market movements, including the sale of drugs and food. This advantage, unfortunately, is also accompanied by increased cases of drug and food abuse, which directly affect the public,especially amid Industry 4.0. As reported by the World Health Organization, 50% of medicines sold online around the world are fake and that one out of 10 medical products in developing countries is substandard or counterfeit[1,2]. The Pangea Operation–an international initiative intended to combat the online trade of counterfeit and illegal drugs–found that websites through which illegal drugs and food are sold numbered 293, 214, and 370 in 2015, 2016, and 2017, respectively, and that 1,999, 1,312, and 4,796 items were sold in these sites over the same periods, respectively[3]. In the Indonesian context, the number of complaints received through the Consumer Complaints Service Unit of the country's National Agency of Drug and Food Control

(known as BPOM in the country) and Halo BPOM 1500533 Contact Center with regard to the circulation of drugs and food over the Internet increased from 303 in 2015 to 325 in 2016[4].

The persistence of the above-mentioned concerns is expected to increase public health problems. As an institution authorized to implement drug and food control in Indonesia, the BPOM has a drug and food control system with one component that is overseen by the community through the enhancement of knowledge, attitudes, and behaviors regarding ways to rationally choose and use products. To date, however, the BPOM has no integrated database that enables the fast, precise, and accurate review of data to support the effectiveness of communication, information, and education strategies. Compounding this deficiency is the lack of an efficacious system for the early detection of drug and food abuse. At present, the BPOM acquires such data from complaints and requests for information on drugs and food, which are coursed through a drug and food information and complaints service system.

In addition to accurate data management, a necessary approach is to involve the community in advancing effective communication, information, and education initiatives, one of which is the analysis of digital data derived from social media as a space where people express opinions on drug and food policies or issues. Social media sentiments should be analyzed using a system that can be integrated with existing networks. These requirements can be satisfied through big data technologies, which can perform sentiment analysis that allows for the identification of public responses to products[5]. Sentiment analysis is the process of extracting, processing, and understanding textual data automatically to identify the views reflected in an opinion sentence, whether such perspectives are positive, neutral, or negative[6].

Social media monitoring has presented many benefits in terms of overcoming public health problems by, among other outcomes, the detection of drug side effects[7]and the assessment of vaccination programs[8]. The same holds true for Twitter,features that render the micro blogging site one of the largest and most popular social media sites in the United States and the world. Twitter is a very valuable data source for researchers of public health informatics[9]. Despite the promising potential of sentiment analysis, however, its use in the health sector of Indonesia is rare. To address this gap, this study developed a prototype system for the analysis of sentiment regarding drug and food issues in Indonesia. The system, which was integrated into the country's drug and food information and complaints service network, examines Twitter data using a machine learning-based method referred to as a naive Bayes classifier (NBC). The NBC was incorporated with evaluation parameters, namely, accuracy, precision, recall, and the F-measure.

Method

The systems development life cycle was used as the framework in creating the sentiment analysis system, with the stages involved being identifying system requirements from a user perspective, designing and prototyping the system, and testing and evaluating it. A series of steps were then carried out to design the system application through the supervised machine learning techniques starting from problem identitication, data collection, preparation and manual labeling of input data, preprocessing, algorithm training, algorithm testing, and performance evaluation using 10-fold cross-validation.

The sentiment analysis system put forward in this work uses Python, which provides libraries for data preprocessing and NBC algorithms with Natural Language Toolkit tools as well as evaluates performance. The NBC is a classification method derived from Bayes' theorem by using probability and statistical approaches, such as the prediction of opportunities on the basis of previous experience[10]. After the system was created, it was integrated with the information and complaints service application (SIMPEL LPK) already being used at the BPOM. The Web-based prototype was developed using the PHP programming language and the My SQL database. The prototype development trials for the validation of system components were performed in a laboratory. The entire research was conducted at the Community Complaints Section of the Bureau of Public Relations and Management Support at the BPOM in Jakarta.

Results

1. Identification of System Requirements

On the basis of the in-depth interviews and document analysis implemented at the research site, the system-related needs that were identified areas follows:

a. Organizations need a system that can integrate the analysis of social media sentiments with

service provision for addressing drug-and food-relatedinformation and complaints.

b. Such sentiment analysis system is expected to provide easily readable and understandable information on real-world public opinionsregarding policydevelopment and matters associated with drugs and food.

c. The system is expected to be easy to use.

The system can be developed by taking into account aspects of policy, infrastructure, and resources.

2. Development of the Sentiment Analysis System

a. Problem Identification

This study pinpointed fivetopics related to drug andfood policy or issues:

- Online drug sales
- Electronic cigarettes
- Imported cosmeticuse
- Use of antibiotics
- 2D barcode application in drug and food control

b. Data Collection

Data were collected from 22 November 2018to9 March 2019, and two sources were used for this purpose:

- Data were collected from Twitter via the Web scraping of www.search.twitter.com and the use of key words that were determined using the Python Tweepy library.
- Data were extracted from the SIMPEL LPK application database.

c. Preparation and Manual Labeling of Input Data

The filtered Twitter and SIMPEL LPK data were merged, yielding a filtered data set comprising 600 tweets, which were randomly divided into 540 tweets serving as training data and 60 tweets used as testing data. The data were also labeled as two sentiment classes, namely, positive sentiments (e.g., statements that signify agreement, liking, happiness) and negative sentiments (e.g., statements reflecting disagreement, disliking, sadness,dissatisfaction). The amount of data were balanced between the classes.

d. Preprocessing

Preprocessing was conducted to eliminate inappropriate words, homogenize terms,and reduce the volume of words to be examined. The stages carried out are described below:

- Cleansing: Tweets were cleansed of unnecessary words or elements to reduce noise in the classification process.
- **Case folding:** All letters were converted into lowercase format.
- **Tokenization:** A set of characters in a text were broken down into units of words.
- **Normalization:** Words that are expressed in abbreviated form were changed into their full forms.
- Elimination of stop words: Stop words are terms that do not affect the classification process. A list of common stop words was obtained from Tala's[11] study and added to the training data.

e. Algorithm Training/Data Modeling

Training data were needed to build a probability model.

Table 1. Examples of Training Data

Tweets	Preprocessing	Account*	Label
Bangsa ini butuh antibiotic	bangsa butuh antibiotic	angganaxxxxx27	Positive
@FANBASEBOKEP jangan asal beli di toko online obat gitu banyak yg palsu	jangan beli toko online obat banyak palsu	Lazaruxxxxx	Negative

*Note: Twitter accounts wereanonymized.

f. Algorithm Testing

Data that were not used in the training process were employed in testing. When testing data are entered into the proposed system, it initiates the determination of features, their extraction, and their classification in accordance with the established probability model.

Table 2. Examples of Testing Data

Tweets	Preprocessing	Account*	Label	Prediction
LAGI JANGAN SEMBARANGAN MAKAN ANTIBIOTIK!!!!! https://t.co/FsY9BdU5xO	jangan sembarangan makan antibiotik	ma2taxxxx,,	Negative	Negative
@danirachmat Thanks mas Dan. Sedang menuju pulih nih. Emang kalo udah ketemu dokter sama antibiotik lgs cepet recovery nya	terimakasih pulih ketemu dokter antibiotik langsung cepat recovery	NonaXxxxx222	Positive	Positive

*Note: Twitter accounts wereanonymized.

g. Performance Evaluation

The performance of the classification model was evaluated by measuring its accuracy, precision, and recall. A confusion matrix (Table 3) shows various correct and incorrect predictions based on the classification design developed in this work[12].

Table 3. Confusion Matrix

		Predictedclass	
		Positive	Negative
Actual class	Positive	True positive (TP)	False negative (FN)
	Negative	False positive (FP)	True negative (TN)

h. 10-fold Cross-Validation

The classification was iterated 10 times on the data sets as a means of cross-validation to obtain the best predictive accuracy. In the cross-validation, the data employed were the 600 tweets, with a compositional training-to-testing ratio of 90:10.

Table 4. NBC Results

Iteration	TP	FN	FP	TN	Accuracy (%)	Precision (%)	Recall (%)	F-Measure (%)
1	24	6	5	25	82	83	80	81
2	23	7	6	24	78	79	77	78
3	18	12	3	27	75	86	60	71
4	11	19	1	29	67	92	37	52
5	23	7	6	24	78	79	77	78
6	24	6	12	18	70	67	80	73
7	30	0	7	23	88	81	100	90
8	25	5	5	25	83	83	83	83
9	25	5	3	27	87	89	83	86
10	26	4	6	24	83	81	87	84
Average					79	82	76	78

Sentiment Analysis Dashboard: The dashboard menu contains keyword search columns and the data source options Twitter, SIMPEL, and Twitter + SIMPEL, which extract data in realtime. The search results are then displayed in tabular and graphical forms (Figure 2).

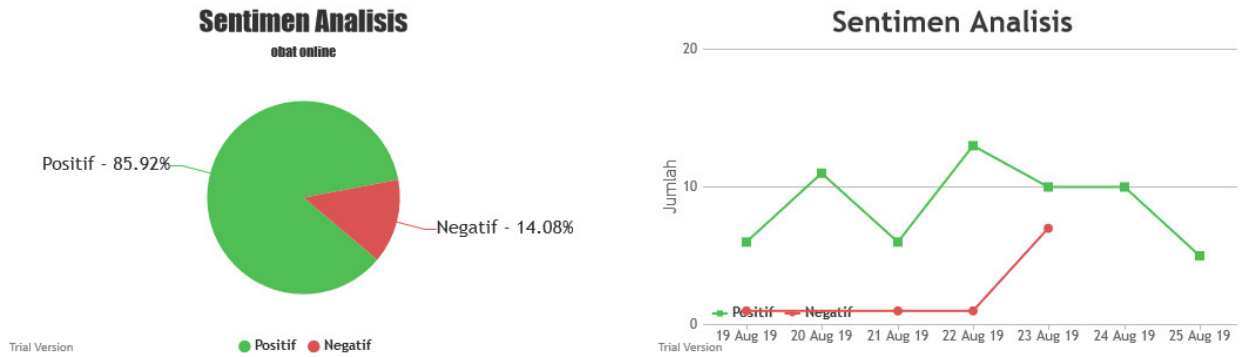

Figure 2. Graphical Forms on Sentiment Analysis Dashboard

Discussion

Social media-based data analysis is a qualitative examination of the behaviors of social media users with respect to their personal experience of an issue. Although the mining of Twitter messages cannot replace traditional survey method, the content of social media messages can be a useful, real-time, and publicly available source[13]. Social media sites also serve as forums in which to foster community awareness about health issues[13].The data derived from these platforms can be employed in the analysis of sentiment regarding drug and food policy or issues. The prototype sentiment analysis system developed in this research provides benefits to the BPOMas a decision support system for the real-time monitoring of drug-and food-related concerns, functioning as an early warning system that prompts immediate action in tracking issues in the field and as an additional source of input in the preparation of communication, information, and education strategies.

Application Performance: The prototype comes with a dashboard that displays real-time data analysis results. Table 4 shows that the system exhibited an accuracy of 88% (the highest) at the seventh testing iteration and an accuracy of 67% (the lowest) at the fourth testing iteration. After 10 iterations, the system achieved an average accuracy of 79%. In terms of precision, the highest level was 92%, achieved at the fourth iteration, whereas the lowest was 67%, realized at the sixth iteration. The average precision of the proposed system was 82%. The highest recall was 100%, registered at the seventh testing iteration, whereas the lowest was 37%, recorded at the fourth iteration. The average recall of the system was 76%. As regards the F-measure, the system put forward in this research exhibited the highest and lowest values of 90% and 52% at the seventh and fourth testing iterations, respectively. The average F-measure was 78%. These results indicate that the system implements satisfactory classification but that its machine learning performance still needs improvement. Such enhancement can be achieved with respect to four components, that is, increasing the quality of (1) data collection and reinforcing the performance of (2) algorithms, (3) tuning, and (4) ensembles[14].

Limitations: Certain constraints impeded the optimal functioning of the proposed prototype. These include the following:

1. The amount of training data was limited. Classification accuracy can be improved by increasing the volume of data used for training. The greater the amount of training data, the higher the accuracy of the system in recognizing testing data.
2. The accuracy of sentiment analysis depends on preprocessing. To ensure effective preprocessing, the following measures should be implemented:
    a. The stemming process should be strengthened to eliminate word affixes and thereby retain only basic terms. A sound stemming process can augment the accuracy of explorations into sentiments contained in text documents[15]. In this work, time constraints prevented the carrying out of stemming.
    b. A list of abbreviated words and stop words should be obtained.
3. The current system's features are insufficient as some of the required attributes have not been developed. These features include time filters and tag clouds.

Conclusions

1. The NBC exhibited reasonably good performance in the analysis of sentiment regarding drug and food issues in Indonesia. The average accuracy

of the system was 79%, and its average precision, recall, and F-measure were 82%, 76%, and 78%, respectively. At the seventh testing iteration, the system generated its highest accuracy, which was 88%, broken down into 81% precision, 100% recall, and 90% F-measure.

2. The built-indash board of the prototype system displays people's sentiments toward drug and food issues in realtime. Such information supports data and serves as input for rapid response to the aforementioned matters.

3. The system therefore functions as an early warning network that prompts immediate action in tracking issues in the field and as a source of input in the preparation of appropriate communication, information, and education strategies.

Ethical Considerations: This study was approved by the Ethical Committee of the Faculty of Public Health at Univers it as Indonesia (approval no.: 026/UN2.F10/PPM.00.02/2019).

Conflict of Interest: The authors declare no conflicts of interest.

Acknowledgments: The authors are very grateful to the Community Complaints Section of the Bureau of Public Relations and Management Support at the BPOM, which provided this research facility.

Funding Source: This study was sponsored by Universitas Indonesia through Hibah Publikasi Internasional Terindeks (Hibah PITTA B;no.: NKB-0595/UN2.R3.1/HKP.05.00/2019).

Reconstruction of Groin Defects Using the Extended Dissection Technique of the Gracilis Myocutaneous Flap

Omar Amr Khattab[1], Magdy Ibrahim El Sherbiny[1], Mohammed Ahmed Rifaat[1], Abdel Hamid Hussein Ezzat[1], Medhat Mohamed El Sebaii[2]

[1]MD, Surgical Oncology Department, [2]MD, Radiotherapy Department, National Cancer Institute, Cairo University, Egypt

Abstract

Background: Groin defect reconstruction is a problem which can present with devastating consequences. Such wounds are encountered after inguinal lymph node dissection (ILND), soft tissue sarcoma (STS) resection or radiation necrosis to the inguinal region. Gracilis myocutaneous (GMC) flap is an ideal option due to its easy accessibility and minimal donor site morbidity. Application of extended dissection technique makes the flap more reliable and improves its vascularity.

Method: This is a descriptive study with the purpose of determining the visibility of GMC flap in groin defects reconstruction at National Cancer Institute, Cairo University, Egypt.

Results: 15 patients underwent groin reconstruction using GMC flap. 10 patients had metastatic inguinal lymph nodes and 5 patients had groin STS. Skin island size ranged from 8 to 20 cm in length and from 6 to 10 cm in width. 10 cases were totally viable, 3 cases had partial skin loss and 2 cases had total skin loss. Only 1 case of donor site morbidity was reported.

Conclusion: GMC flap is a versatile flap that is harvested easily and with a minimal morbidity at the donor-site.

Keywords: *Defect, Flap, Gracilis, Groin, lymphadenectomy.*

Introduction

Groin wound management is a challenging problem which can present with dangerous consequences. Such wounds are commonly encountered after ILND, STS resection, radiation to the inguinal region and arterial revascularization[(1)]. Adequate coverage of these defects is extremely important to prevent the exposure of femoral vessels which may lead to life-threatening blow-outs and [(2)].

A variety of reconstructive options have been described for covering groin defects such as tensor fascia lata[(3)], rectus abdominis myocutaneous flap[(4)], rectus femoris [(5)], GMC flap [(6)] and anterolateral thigh (ALT) flap [(2)].

The gracilis muscle is used widely in reconstructive surgery, either as a pedicled flap or as a free microsurgical flap [(7)]. The gracilis muscle has the advantage of easily accessibility with minimum donor site morbidity. However, there are limitations when using a pedicled flap. Limited distal muscle bulk restricts its effective use for more extensive wounds. Short pedicle length limits the arc of rotation. These factors may be critical to successful reconstruction with the gracilis because the most distal portion is often the most crucial for wound closure [(8)].Application of the extended-dissection technique provides more direct access to the main pedicle, improves the arc of rotation and prevents torsion of the vascular pedicle. It also can deliver adequate muscle bulk to yield a successful reconstruction [(9)].

Aim of the work: To assess the versatility of GMC flap in reconstruction of groin with application of extended dissection technique.

Patients and Method: This descriptive, prospective study was conducted on patients suffered of groin soft tissue defects in National Cancer Institute, Cairo University, Egypt.

Inclusion Criteria: Groin defects which measure not more than 20 cm (length) X 10 cm (width) in maximum dimensions

Exclusion Criteria: Defects more than 20 cm (length) X 10 cm (width) in maximum dimensions and patients subjected to deep resections compromising branches of profunda femoris artery.

Procedure: The patient is placed in the supine position and the donor lower limb is abducted with slight flexion of the hip and knee joints. Then we mark the pubic tubercle superiorly and the medial tibial condyle inferiorly. The origin of adductor longus muscle is palpated and just beneath it, the gracilis muscle origin could be palpated and marked. A straight line is drawn between the point of the gracilis muscle origin and the medial tibial condyle. The skin paddle is designed over proximal two-thirds of this line (Fig. 1).

Figure (1): Skin paddle design over the gracilis muscle

Make the anterior incision then dissect through the subcutaneous fat in an oblique angle away from the flap to prevent undermining of the skin paddle.

It is easiest to begin dissection distal to the skin paddle by localization of the rounded gracilis tendon. The gracilis tendon should be circumferentially dissected and then placed under tension. At this stage, the skin paddle design must be reexamined to ensure that it has been correctly centered over the longitudinal axis of the gracilis muscle.

The gracilis tendon is transected and dissection proceeds in the avascular fascioareolar plane between the adductor longus and gracilis. Minor vascular pedicles of the gracilis, which may be 2-5 in number, are encountered and cauterized. The adductor longus is retracted anteriorly, and the dominant proximal pedicle of the gracilis is seen running between the adductor longus and brevis, entering the gracilis 8-11 cm distal to the pubic tubercle (Fig. 2).

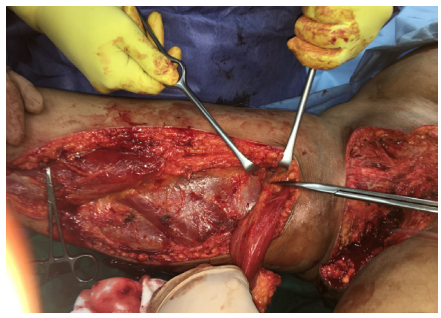

Figure (2): Isolation of the main vascular pedicle.

The main pedicle is the center of the arc of rotation of the flap, and further dissection of the muscle proximal to the major pedicle is continued. The muscle could be transected proximally above the main vascular pedicle if the arc of rotation in needed to be increased.

The adductor longus is dissected free from surrounding tissue and the gracilis flap is passed beneath it and brought out laterally to reach the recipient site. Then the flap is sutured to the surrounding skin over a suction drain. The last step is the donor site closure in anatomical layers over a suction drian.

The patient should stay supine in bed without movement of the affected limb for two days and elevated 30 degree above the body level to decrease edema and improve venous return.

Complete wound healing is expected after two weeks and full range of movement is anticipated 4 weeks postoperatively (Fig.3).

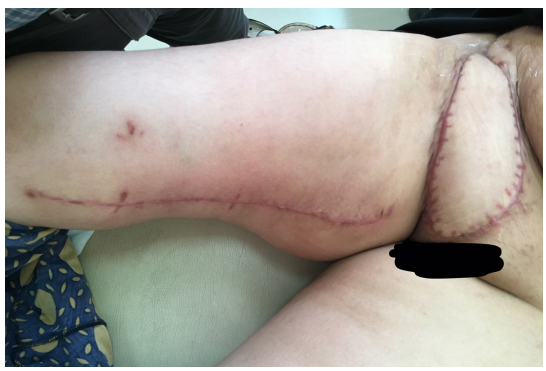

Figure (3): Complete healing 4 weeks postoperatively

Results: Fifteen patients with groin defects underwent reconstruction by GMC flap. There were 8 males (53%) and 7 females (47%) with mean age 57 years at the time of surgery (range 23-75 years).

10 patients had metastatic inguinal lymph nodes (66.5%). 5 patients had STS (33.5%). 10 patients underwent radical ILND and 5 patients underwent wide local excision of STS. The area of skin island ranged from 8 to 20 cm in length and from 6 to 10 cm in width with surface area up to 200 cm^2. Distance between pubic tubercle and main pedicle was ranged between 8 to 11 cm. The number of secondary pedicles ranged from 2 to 4 pedicles. All Donar sites were closed primarily. 10 cases were totally viable and complete healing occurred after three weeks. Partial skin necrosis occurred in 3 cases (20%). Only 2 cases (13%) had total skin loss due to venous congestion. All patients were able to adduct their affected lower limbs without limitation or pain after one month postoperatively.

Discussion:

Reconstruction of groin defects continued to pose a difficult task in surgical practice as coverage of such defects is an important issue to prevent the exposure of femoral vessels which may lead to life threatening blow-outs [10].

Flap closure of the groin has many advantages: The flap brings well-vascularized tissue from a distant area to the groin which enhances local immunity and wound healing. It covers the dead space in the femoral triangle and decreases seroma formation and postoperative radiotherapy can be safely given [11].

There are many options for reconstruction of the groin. They range from primary closure, grafting to flaps. Flaps include sartorius, gracilis, rectus abdominis, rectus femoris, tensor fascia lata muscle, anterolateral thigh flap and local skin flaps. Although, favorable results have been reported with these flaps, problems include donor-site morbidity, partial flap loss, and time-consuming procedures [12].

Tensor fascia lata is one of the most commonly used flaps for groin defects, but the donor site closure always requires a split skin graft and forms a big dog ear at the pivot point [3].

The rectus abdominis musculocutaneous flap has a reliable blood supply which is the inferior epigastric artery, a wide arc of rotation and the ipsilateral or contralateral muscle could be used [10]; however, the rectus abdominis is not a dispensable muscle, and the resulting donor-site morbidity is significant in the form of ventral hernia (19%) in addition to usage of prothetic mesh to close the donar site which lengths the operation time [13].

ALT flap is a perforator flap based can be used to cover a wide defect and can be raised as a very thin flap. However, there are few disadvantages; it is technically more demanding, the variability in position of perforators and the need for skin graft for donor site closure in some cases of large flaps [14].

The use of the rectus femoris muscle has been criticized for its potential for loss of full knee extension. Knee extension power following the use of the muscle has been reported to decrease by 24 to 28 percent on computerized dynamometer testing compared with a patient's contralateral limb [15].

The GMC flap is well known to reconstructive surgeons for its various uses as both a free and pedicled flap. It has a single major dominant pedicle in a constant location with a predictable blood supply from the profunda femoris, usually as a branch of the 'adductor artery' [16].

GMC flap also has the advantage of being mobilized easily and its speed of dissections in bloodless plane**.** Its superficial location on the medial aspect of the thigh makes it an ideal pedicled flap for coverage of groin and perineal defects. The gracilis muscle belly can help fill the defect but is small enough to avoid appearing bulky [17].

The gracilis muscle has one or more accessory pedicles ranging in number between 1-5. They originate from the superficial femoral artery or from the popliteal artery with a caliber of 2 mm [18]. In our series we found the number of secondary pedicles ranging from 2 to 4.

In this series, we found the distance between the pubic tubercle and the entry point of the primary pedicle into the gracilis muscle ranged from 8 to 11 cm. Harbans and et al reported that this distance measures 9.4 cm in males and 7.9 cm in females [19].

In our series, the length of the skin paddle ranged from 8 to 20 cm and the width ranged from 6 to 10 cm. In the series of Rasheedha and Sivakumar, the reported

the length ranged from 6 to 11 cm and the width ranged from 4 to 12 cm [17].

According to the literatures, the percentage of partial and major GMC flap necrosis varies between 6.8% and 38%.Copeland et al. reported 13% with the use of GMC flap for vaginal reconstruction [20]. Also, in Rasheedha and Sivakumar for perineal reconstruction, they reported 20% partial flap loss [17].

In our series, the percentage of partial and total flap loss were 20% and 13%, respectively. Venous congestion was the cause of flap failure.

In this series, the donar sites of all cases closed primarily after mobilization of the upper and lower skin flaps in subfascial plane and the resultant scarring can be easily concealed with clothing.

Complications of GMC flap are infrequent. Carr et al. reported a series of 104 GMC flaps in which 61 patients were adults and 43 children. According to their results, 15% of the patients reported a temporary reduction of leg strength with an average duration of 6 months. This was significantly shorter in children (3.4 months) than adults (10.8 months) [21].

Deutinger et al. reported a series of 42 patients. According to their findings, abduction strength of the ipsilateral hip joint was decreased by 11% when the gracilis was elevated, but the patients did not notice this decrease in strength [22].

We reported only one complication at the donar site in the form of partial wound dehiscence. In our study, we did not use dynamometric measurements of hip adduction strength, because the gracilis is not the only muscle responsible for hip adduction. Adduction primarily occurs via the gluteus medius as well as the gluteus minimus. But none of our patient complained of lower limb disability and all patients were able to mobilize early, with a full range of motion after maximally 4 weeks postoperatively and in our opinion the minimal donar site morbidity is considered the most important advantage of GMC flap in comparison to other flaps.

Like any other flaps, the GMC flap has few disadvantages. It causes some minimal contour deformity in the thigh. However, this was acceptable by all patients. Also, the application of extended dissection of the vascular pedicle is time consuming and requires meticulous dissection.

Conclusion

The GMC flap is a reliable reconstructive technique for immediate closure of a complex groin defects. GMC flap is a versatile flap that is easily harvested and with a low rate long-term morbidity at the donor-site. The extended dissection technique permits direct approach to and excellent observation of the proximal aspect of the dominant pedicle to the gracilis muscle.

Comparative Evaluation of Plaque Removal Efficacy of Plaque-Indicating Dye Dentifrice Vsnon-Dye Dentifrice in Enhancing Oral Hygiene among Orthodontic Patients. A Double Blind Randomized Clinical Trial

Priyanka Shenoy B.[1], P. Jayashri[2]

[1]Graduate Student, [2]Senior Lecturer, Department of Public Health Dentistry, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Background: Good oral hygiene is always a challenge for patients undergoing orthodontic treatment because food particles get readily trapped around the braces which makes it harder to remove plaque. Hence, keeping plaque under control is one of the most effective measure of maintaining healthy gingiva. Therefore, this can be achieved by the use of toothpaste containing plaque indicating dye which will demonstrate higher plaque removal efficacy than those using conventional disclosing tablets.

Methodology: A double blind randomised controlled trial was conducted among twenty orthodontic adults. The participants were randomly allocated into two groups. Group I-(experimental group) dye containing toothpastse, Group ll-(Negative control) tooth paste without dye. Oral hygiene instructions, brushing techniques and use of standardised tooth paste was explained to all the participants. The plaque and gingival index were recorded at baseline and 15th day of follow up. Wilcoxon signed Rank test is used to compare the mean differences before and after treatment within each group for plaque and gingival indices. Mannwhitney U test to estimate differences in the mean plaque and gingival indices between the groups.

Results: In the present study, a statistically significant reduction in the mean plaque Index and gingival index scores was observed in Group I when compared to Group II.

Conclusion: To conclude Plaque indicating dye containing toothpaste together with proper use and oral hygiene instructions, significantly increases plaque removal efficacy of the Orthodontic patients.

Introduction

Good oral hygiene maintenance is a challenging task among patients undergoing fixed appliance orthodontic treatment[1]. The brackets along with the other components present a favourable situation for rapid plaque accumulation and increased acid production leading to demineralization and incipient carious lesions[2,3].

Oral cleaning becomes more difficult with the presence of the orthodontic appliances and their components. Thus, the elimination of plaque is the main target to overcome the problems[4]. Orthodontic treatment alters the oral environment, increases plaque amount, changes the composition of the flora, and complicates the cleaning for the patient[5,6,7].

Dental plaque is known to be a major factor which contributes to gingivitis and other periodontal diseases,

and the effective daily control of plaque in orthodontic patients for optimal dental health is important[8].

It is known that because of the great possibility for the increased plaque accumulation orthodontic patients who are treated with fixed appliance, mainly generally belong to a potentially higher risk group. Orthodontic treatment may be hazardous for the subjects who have no motivation nor proper supervision or preventive programme. It is important for both patients and clinicians to prevent tooth decay, gingival as well as periodontal problems and tooth discoloration that could compromise the esthetic of smile and well being of the patients. The key for this is represented by dental plaque[9].

The importance of having a twice-daily, mechanical brushing routine as the basis for ensuring good oral health is well understood, but actually achieving effective plaque removal can still be a challenge for many individuals[10]. Beside of the use of fluoride containing toothpaste and brushing with conventional brushes, additional method could be suggested to improve oral hygiene[4]. In some cases the identification of plaque with the naked eye is difficult because it is similar to the teeth. In these cases, the accumulation of plaque and localization can be assessed by different method, thesimplest way being able to scrape the tooth surface with the use of a periodontal probe. Special disclosing tablets containing red or blue dye can be used which can disclose the plaque. One tablet is chewed thoroughly in the oral cavity, moving the mixture of saliva and dye over the teeth and gums for approximately 30 seconds. Then the mouth is rinsed with water and checking of the teeth is done to identify the stained plaque. The disadvantage of these disclosing tablets is the temporary discolouration on the lips,cheeks, mouth or tongue. Another method is using plaque fluorescence. A special fluorescent solution is swirled around the mouth and then rinsed with water gently. After that, the teeth and gums can be checked with an ultraviolet light. The plaque will show a brillant orange-yellow. This method does not leave stains on other tissues in the mouth but can cause a temporary discoloration on the tongue and the buccal mucosa. Matured and fresh plaque can be seen in different colors. More blue plaque coloration means improper oral hygiene [9]. Some dentifrices and rinses are formulated with antimicrobial agents to help with chemical plaque control. However, achieving effective plaque control can prove problematic for individuals, and the excessive regrowth of plaque can lead to oral health problems[11,12,13]. The home use of plaque disclosants has been recommended as a helpful adjunct to improve oral hygiene. Adding a visible dye to toothpaste to disclose remaining plaque after toothbrushing has the potential to enhance patients' awareness and encourage them to be more thorough when performing oral hygiene[14].

Lack of dental knowledge and poor oral hygiene have a negative impact on plaque removal efficacy and the ability to accurately evaluate oral status. Increasing education and instruction of techniques is one way to minimise the problem, but another valid option is to improve oral hygiene products to enhance plaque removal efficiency. This is especially important in populations of low socioeconomic status, and the elderly that traditionally have less access to regular professional oral care[15].The aim of this study was to compare the efficacy of plaque removal between a plaque-indicating dye dentifrice Vs non-dye dentifrice in enhancing oral hygiene among orthodontic patients as well as to explain the importance of maintaining proper oral hygiene.

Materials and Method

Study Design: It is a double-blinded, parallel group, randomized controlled clinical trial.

Study Population: Patients undergoing fixed orthodontic treatment at saveetha dental college and hospital, chennai were recruited.

Eligibility Criteria:

Inclusion criteria: Apparently Healthy patients without any known history of systemic illness above 18-25yrs of age and Patients withGood to Fair Plaque index score, mild to moderate gingivitis and those who brush their teeth twice daily were included.

Exclusion criteria: Patients with positive history of usage of anti microbial therapy and routine use of oral antiseptics in the previous 3 months and those with history of allergic and idiosyncratic reactions to product ingredients and presence of systemic diseases that could alter the production or composition of plaque

Sample Size Determination: Sample size was calculated based on study by Stevens K et al. (2016)[14] using a *priori* by G*Power 3.1.2 software. The minimum sample size of each group was calculated, following these input conditions: power of 0.95 and $P \leq 0.05$ and sample size arrived were 10 per group.

Randomization

Sequence Generation: Computer generated block randomization with a block size of five were used to generate the assignment schedule well in advance by a third person who was not related to the study. The investigator was blinded to the sequencing of the block and allocation of the groups.

Allocation Concealment: SNOSE (sequentially numbered, opaque, sealed envelopes) method was implemented for allocation concealment which conceals the sequence until interventions were assigned. Patients were assigned their study numbers as they sequentially entered the study. Based on the group assigned, respective treatment was carried out as described in the procedure.

Blinding: Although the investigator knows about the study design and products that were used in the study, investigator and patients were unaware about the treatment groups. Therefore the investigator and patients were blinded in the study. Both Group I and II dentifrices were transferred to a white opaque tubes to assist in keeping the subject blinded to the product's identity (Refer Figure 1).

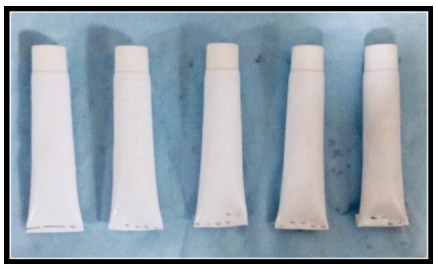

Figure 1: Blinding of the tested products

Figure 2: Study group

Study groups (Refer Figure 2**):** Group I-Plaque HD tooth paste, Group II-Colgate total advance health.

Study Procedure: Prior to the treatment, a careful medical and dental history was taken. Preoperative data for each patient was recorded in the predesigned proforma which includes age, gender and address. The study design was explained to the qualifying patients and informed consent was obtained from the voluntary patients who were willing to participate in the study.

Disclosing solution was generously applied to the surfaces of the teeth with the help of applicator brush. The study participants were instructed to rinse the mouth. Plaque index was recorded for the indexed teeth. The mean score of plaque and gingival index was recorded in the pre structured proforma. A standardized toothbrush and the toothpastes were allocated according to the group. Oral hygiene instructions with an emphasize on the appropriate brushing technique were given. The above mentioned steps were repeated at 15th day of follow up.

Figure 3: Plaque HD-plaque identifying tooth paste– (Targetol technology)

Data was entered in Microsoft excel spread sheet and analysed using SPSS software (version 17). **Wilcoxon signed Rank test** used to compare the mean differences before and after treatment within each group for Plaque and Gingival index score. **Mann whitney** U test to estimate differences in the mean Plaque and Gingival index score between the groups.

Results

Table1 shows Comparison of Mean Plaque and Gingival Index scores at Baseline, and 15th day time points of Group I and II. A statistically significant difference was observed in mean Plaque Index and Gingival Index score at Baseline and 15th day of follow up using Wilcoxon signed rank test. Table 2 depicts comparison of Mean Plaque and Gingival Index scores of Group I and II at Baseline and 15th day. There was no statistically significant difference was observed in mean

Mean Plaque and Gingival Index between the Groups using Mann-whitney U test.

Table 1: Comparison of Mean Plaque and Gingival Index scores at Baseline, and 15th day time points of Group I and II

Index	Groups	Time Points (Mean±SD)		Wilcoxon signed Rank test
		Baseline	15th day	P value
Mean Plaque Index	Group I	1.09±0.07	0.43±0.20	0.005**
	Group II	1.06±0.16	0.81±0.21	0.008**
Mean Gingival Index	Group I	0.51±0.14	0.18±0.07	0.05*
	Group II	0.54±0.15	0.35±0.13	0.07

Wilcoxon signed Rank test(P<0.05)

Table 2: Comparison of Mean Plaque and Gingival Index scores of Group I and II at Baseline and 15th day

Index	Time Points	Groups		Mann Whitney U test
		Group I	Group II	P value
Mean Plaque Index	Baseline	1.09±0.07	1.06±0.16	0.85
	15th day	0.43±0.20	0.81±0.21	0.002**
Mean Gingival Index	Baseline	0.51±0.14	0.54±0.15	0.79
	15th day	0.18±0.07	0.35±0.13	0.05*

Discussion

Oral cavity is an important part of the body and it plays a crucial role in chewing, swallowing, and in forming facial expression as well as maintaining nutritional status, system health and self esteem[16]. Oral hygiene has been risk indicator, risk factor and risk predictor and for various oral problems and other dental problems[17].

The purpose of oral hygiene is to prevent the formation of plaques, the sticky film of bacteria[18]. Oral hygiene measures should be implemented to remove plaque, soft bacterial deposits that adhere to the teeth and cause dental caries (decay or cavities) and periodontal (gums) diseases[19]. For preserving oral health and for preventing oral diseases oral self care such as toothbrushing is important[20]. Studies conducted by Nitin Chandrakantet al and Thanish Ahamed found that majority of the participants preferred Toothpaste to be the most commonest oral hygiene measure[21,22].

Orthodontic patients have a high susceptibility to the plaque accumulation on their teeth because of the various orthodontic appliances like bands, brackets, wires which impair plaque removal by physical method like normal tooth brush resulting in poor oral hygiene and gingival health. Orthodontic appliances present a challenge to the proper removal of plaque from tooth and gingival surfaces[23]. Numerous strategies and measures have been adapted to eliminate plaque and to reduce the bacterial colony counts to preserve the oral health for life time. One among them is toothbrushing. As tooth brushing is considered to be the most common oral hygiene method, dentifrices are the most ideal vehicle for plaque removal. Hence the present study was conducted to evaluate the plaque removal efficiency using novel dye containing dentifrice in enhancing oral hygiene among orthodontic patients as well as to explain the importance of maintaining proper oral hygiene.

The results of our present study were found to be similar when compared to the study done by Stevens K et al[24]. where Mechanical plaque removal by brushing with toothpaste containing plaque-indicating dye significantly reduced plaque compared to brushing with toothpaste without dye combined with proper use instructions. Thus this dentifrice may improve oral hygiene and reduce plaque-related damages to teeth and oral tissues. Toothpaste containing plaque-disclosing dye is more likely to work for patients rather using multiple products concurrently to achieve the same result. This reinforces improved hygiene habits by guiding the patients the areas they are deficient in removing plaque.

In a thesis done by Katharine Emilia Stevens, the greater overall reduction in plaque percentage of the experimental group(using plaque tooth paste containing a green disclosing dye) vs. the control group (using placebo toothpaste which does not contain the green disclosing dye and is white in colour) indicates that the presence of green dye in the test toothpaste helped the subjects identify areas of plaque accumulation than the subjects who brushed with placebo toothpaste[24].

In the present study, patients who were using plaque HD, after being given proper oral hygiene instructions demonstrated significantly better mechanical plaque removal because they were able to visualise the plaque at critical places and remove it because of the presence of dye in it. The long term use of such products promotes better oral hygiene habits. Therefore, this study concentrated on fixed orthodontic patients as they are at

a high risk for plaque related diseases. Hence, plaque HD gave better results when compared to control toothpaste.

Conclusion

To conclude, regular use of Plaque indicating dye containing toothpaste significantly increases plaque removal efficacy, thereby prevents plaque induced dental caries and periodontal diseases.

Prevalence of Disability in Uttar Pradesh: A District-wise Study

Ravi Prakash Jha[1], Krittika Bhattacharyya[2], Durgesh Shukla[1], Nisha Tiwari[1], Pawan Kumar Dubey[1]

[1]Research Scholar, Department of Community Medicine, Institute of Medical Sciences, Banaras Hindu University, Varanasi, Uttar Pradesh, [2]Research Scholar, National Institute of Biomedical Genomics, Kalyani, West Bengal

Abstract

Introduction: Information on disability is essential for the government to formulate policies, allocate adequate resources and implement appropriate programmes. The objective of this study was to measure the prevalence of disability and the estimation of distribution of disabilities by gender, advancing age, districts, geographical regions,work and marital status in the Uttar Pradesh.

Method: We analyzed the 2011 Census data of Uttar Pradesh. Age-adjusted disability rates and disability rates per 100 000 population were calculated.

Results: There were 4157514 individuals with disability in Uttar Pradesh in 2011 accounting for a disability rate of 2081 per 100 000 populations. The disability in hearing, seeing, and movement was most predominant with rates of 514, 382 and 339 per 100 000 respectively of the 71 districts, age-standardized disability rates in 20 districts were above the state average of 2081 per 100 000 population. In all kinds of disability there was mostly male predominance in both rural and urban areas across all agecategories.

Conclusion: About 2 in every 100 person in Uttar Pradesh (2080 per 100 000 persons) is either physically or mentally disabled. Disability rates reflect the overall health status of the population. Identification of the underlying causes and employing effective and focused preventive strategies will help to reduce the burden of disability and maximize the quality of life in Uttar Pradesh.

Keywords: *Disability, Age-standardized, Census, Uttar Pradesh.*

Introduction

Any restriction or lack of ability to perform an activity in a manner or within the range considered normal for the human beings, resulting from impairment is termed as disability. Impairment concerns the physical aspects of health; disability is the loss of functional capacity resulting from an impairment organ; handicap is a measure of the social and cultural consequences of an impairment or disability.[1]

Article 41 of the Indian Constitution states that the State shall within the limits of its economic capacity and development;make effective provisions for securing the right to work, education and public assistance in case of unemployment,old age, sickness and disablement. People with disabilities suffer undue hardships and they continue to bemarginalized, discriminated and abused. Moreover, people with disabilities suffer undue hardships and they continue to bemarginalized, discriminated and abused.[2] In December, 2016, the Indian Parliament passed a new law on the rights of persons with disabilities to facilitate greater access to public spaces, education, employment, and healthcare, and the integration and protection of rights, particularly of persons with mental illness or disability.[3]

It is essential that access to affordable healthcare and rehabilitation be offered to persons with disability. In India, the major sources of statistics on disability are the decadal Population Censuses and the regular large scale sample surveys on disability conducted by National Sample Survey Office (NSSO).[4]Although both

sources are used to provide representative estimates of the prevalence of various disabilities,but differ in terms of their coverage, the definition of disability they use, and the specific types of disability they track.[5] The 2011 census, which covers the entire population of India, provides reported information on disability as a medical condition (seven types of disability and one category for multiple disabilities).[6]

Census 2011 reported that, In India out of the 121 Cr population, 2.68 Cr persons are 'disabled' which is 2.21% of the total population. Among the disabled population, 56% (1.5 Cr) are males and 44% (1.18 Cr) are females. In the total population, the male and female populations are 51% and 49% respectively. Across the country, the highest number of disabled persons is from the State of Uttar Pradesh. Nearly 50% of the disabled persons belonged to one of the five States namely Uttar Pradesh (15.5%), Maharashtra (11.05%), Bihar (8.69%), Andhra Pradesh (8.45%), and West Bengal (7.52%). Moreover, The State of Uttar Pradesh is home for the highest number of disabled children (0-6 years).[7]

There is a need to quantify the burden of disability since this information is essential for the Government to formulate policies allocates adequate resources and implements appropriate intervention programmes for persons with disability.

The objective of this analysis was to measure the prevalence of disability and describe the types of disability in the Uttar Pradesh population based on the available dataon disabilities in the public domain under the Census 2011 database. We also estimated the distribution of disabilities by gender, advancing age, districts, geographical regions,work and marital status in the population.

Materials and Method

The Census in India is conducted once every 10 years following an extended de facto canvasser method.[8]The census questionnaire had three questions pertaining to disability which captured information on (i) presence of mental or physical disability (Yes 1, No 2); (ii) disability type (seeing 1, hearing 2, speech 3, movement 4, mental retardation 5, mental illness 6, any other 7, multiple 8); and (iii) the nature of disabilities (maximum of 3) in people in whom the response to the second question was 'multiple disability'.[6]

Data Analysis: Disability rates per 100 000 population were calculated. The 2011 data from C20 Table pertaining to Uttar Pradesh was used for the numerator which consisted of the number of disabled persons by type of disability, age, gender and type of residence (rural/urban).[9] The denominator was obtained from C-14 five-year age group data by residence and sex from Census 2011. This table provides information on the number of people in Uttar Pradesh as well as in districts in various age groups (5 yearly) starting from 0–4 years, up to 75–79 years and 85+ years. In addition, information on residence (rural/urban) and gender was used.[10] The following tables from Census 2011 were used to calculate disability rates related to literacy level, marital status, work status and social group: PCA-09, DDW-0900C-02-fer3-MDDS, DDW-C20-0900, DISAB03-0000, DDW-0000C-21, DDW-0000C-23, DISAB04SC-0000 and DISAB04ST-0000.[11]

Age-adjusted disability rates calculated by the direct standardization method were used for comparison and ranking of the districts with respect to each type of disability. The data were analyzed using Microsoft Excel windows 2016.

Results

There were 4157514 individuals with disability in Uttar Pradesh in 2011 accounting for a disability rate of 2081 per 100000 populations (2.08%; 2011 population of Uttar Pradesh: 199812341).

The disability in hearing, seeing, and movement was most predominant with rates of 514, 382 and 339 per 100,000 respectively. Disability rates in mental retardation, multiple disability, speech and mental illness were 91, 109, 133 and 38 respectively.

Disability in hearing, seeing and movement is 24.71%, 18.36% and 16.29% of the total disability burden. In addition, mental retardation, multiple disabilities, disability in speech and mental illness constituted 4.37%, 5.24%, 6.39% and 1.82% of the total disability, respectively. The remaining 22.78% of disability was due to other causes.

Disability rates in districts of Uttar Pradesh: of the 71 districts, age-standardized disability rates in 20 districts were above the state average of 2081 per 100 000 population. Moreover, disability rate ranged from 1447 to 3922 per 100 000 population (Fig.1). Kushinagar, Ghaziabad, Allahabad had the highest disability rates of 3922, 3102, 2992 per 100 000 population, respectively.

Jyotiba Phule Nagar, Balrampur districts had the lowest rates of 1247 and 1294 per 100 000 population, respectively.

Disability in seeing (1517 per 100 000) and hearing (1138 per 100 000) were both highest in Kushinagar district. Disability in movement and speech was highest in Auraiya (577 per 100 000) and Pratapgarh (242 per 100 000) respectively.

Disability rates by demographic variables: Disability rates increased as age advanced with the highest rate of4276 per 100 000 among people aged 60 years and above (Table 1). The disability rates were higher in males (2263 per 100000) and in urban areas (2227 per 100000) (Table 1).

The disability rate among the Scheduled Castes was higher (2279 per100 000) compared to the Scheduled Tribes and other social groups.

Higher disability rates were also observed among illiterates (2331 per 100 000), and in 'widowed, separated, divorced' taken together (4529 per 100 000) people. However, disabilities in working class (2198 per 100000) were higher than non-working class (2023 per 100000). (Table 1).

Work status	Working	65814715	1446393	2198
	Non-working	133997626	2711121	2023

Types of disability by age, gender and residence: Disability rates associated with seeing, hearing, speech and movement increased as the age advanced with rates of 1112, 947,163 and 878 per 100000 respectively, in the age group 60 years and above (Table 2). Mental retardation decreased with advancing age and was lowest with 70 per 100 000 in the age group 60 years and above. Mental illness was high in the age group 40–59 years with a disability rate of 54 per 100 000. Multiple disabilities were remarkably high in 60 and above age group (396 per 100000) in comparison to other age groups.

In all kinds of disability there was mostly male predominance in both rural and urban areas across all age categories (Fig. 2). In seeing, hearing, speech, mental retardation, and mental illness, and any other kind of disability the disability rate was higher in urban areas in comparison to rural areas in almost all age groups. In movement, there was more disability in rural areas than in urban areas in all age groups. In multiple kind of disability there was also rural dominance in all age group except 0-19 years.

Table 2: Differences in type of disability based on age groups in Uttar Pradesh, 2011

Type of disability	0-19 Years (n=94348646)		20-39 Years (n=57669381)		40-59 Years (n=30732348)		60 Years and above (n=15439904)	
	Total Disabled	Per 100,000	Total Disabled	Per 100,000	Total Disabled	Per 100,000	Total Disabled	Per 100,000

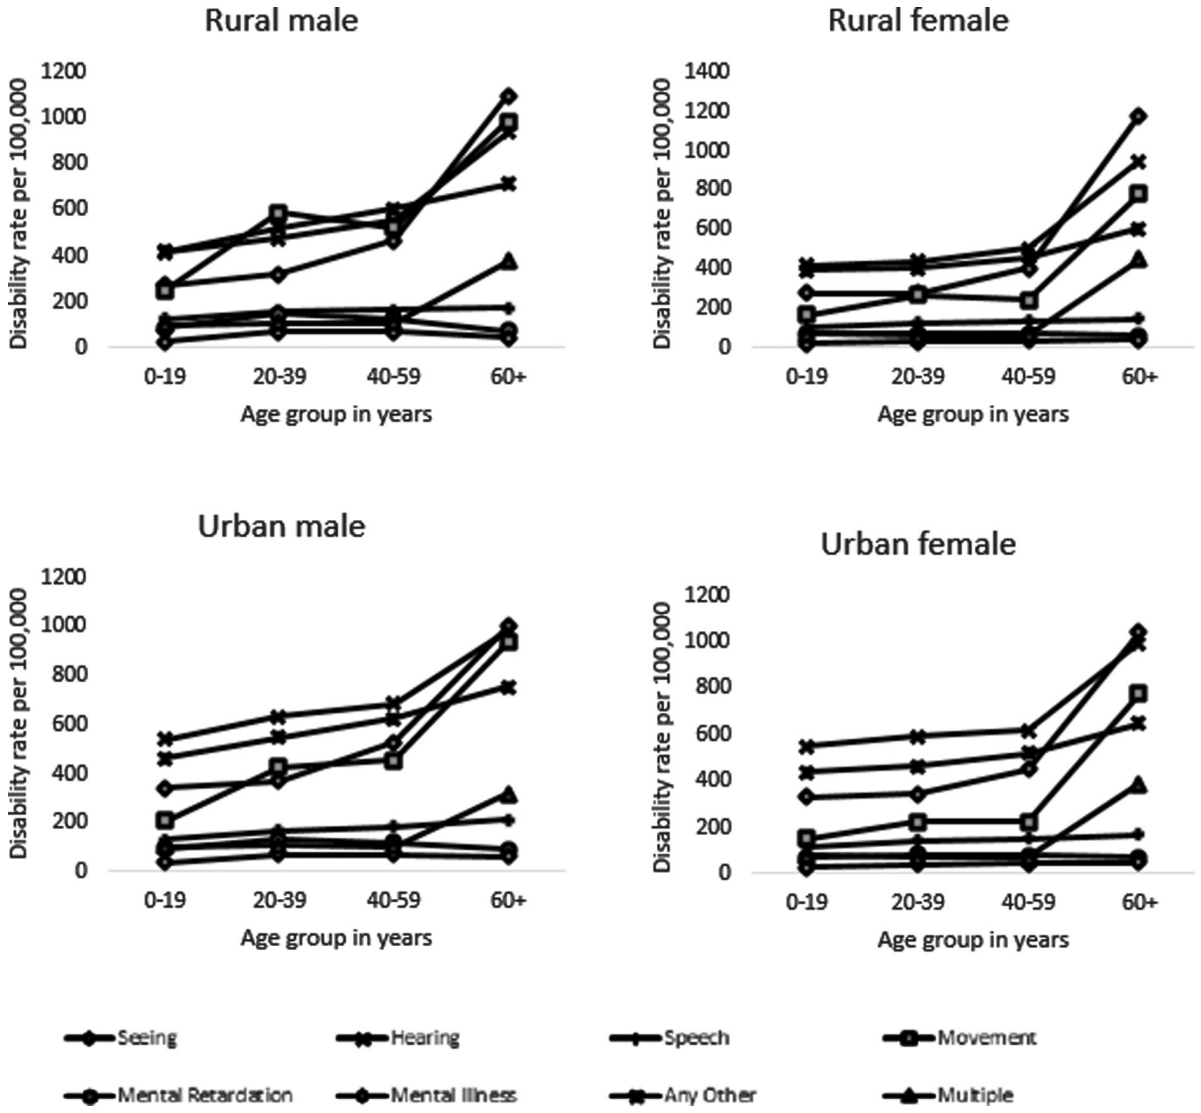

Figure 2: Disability rates by age, gender and location of residence (urban/rural) according to the type of disability in Uttar Pradesh, 2011.

Discussion and Conclusion

We observed that about 2 in every 100 person in Uttar Pradesh (2080 per 100 000 persons) is either physically or mentally disabled based on the data of Census 2011. This is similar to the analysis of 14 household surveys from 13 developing countries,which suggested that 1%–2% of the population have disabilities.[12] In the USA, overall 22.2% of adults reported any disability in 2013.[13] However, the prevalence rates for disability are not strictlycomparable owing to the differences in the definition used in different countries and different surveys.

According to census 2011, the states of Jammu and Kashmir, Sikkim and Odisha had 2.9% disabled in their population, which was more than UttarPradesh whereas some states like Assam, Meghalayaand Mizoram had lower disabled population (<1.5%).[14] The reason for suchdifferences could be because of differences in healthcare facilitiesand access to healthcare. However,this needs further exploration and research for varied disabilityrates across different states in India.

There ishigher disability rates in urbanareas compared to rural (2.22% v. 2.03%) in U.P. This is different from overall Indian scenario, which showed disability rates of (2.17% vs. 2.24%).[14] The geographical variation observed in our analysis needs to be explored further to generate evidence that would help in designing locally relevant interventions.

The observation of male predominance in disabilities with 2.3% to that of female 1.9% in this analysis is similar to that of higher disability rates in India among males which was 2.4% compared to that of females 2%.[14] This highlights the need to address the gender angle in the disability burden through appropriate strategies.

The disability in mental retardation and mental illness in Uttar Pradesh were 91 and 38 respectively. The reasons for mental retardation were serious illness or head injury during childhood, pregnancy and birth-related effects and hereditary disorders.[15] Understanding the causes of disability is important to plan appropriate preventive strategies and research is warranted in this area.

'Elderly' is defined as a person who is 60 years or more in age.[16] We observed the burden of disability to be high in the elderly in Uttar Pradesh. This would probably increase since the proportion of the elderly (>60 years) in India by 2026 is projected to be 12.17% of the overall population compared to 8.6% in 2011.[17] The absence of a strong safety net policy makes the disabled elderly vulnerable.

The observation of high burden of mental retardation, mental illness in the age group of 20-59 years and also the burden of movement, hearing related disability in these age groups (economically productive age group) in our analysis is a matter of concern.

Persons with disability could have been disadvantaged in getting educated, married and this might be reflecting high disability rates in those sections of the population observe din our analysis. Lower educational attainment among adults with disabilities has been reported from developing countries.[18] A study from the Organization for Economic Co-operation and Development (OECD) in 27 countries reported that persons with disability have significantly lower levels of education and working age persons with disabilities experience significant labour market disadvantage than working-age persons without disabilities.[19] The lives of disabled people are affected by poor health outcomes,lower educational achievements, less economic participation,high rates of poverty and increased dependency.[20] The Government of Uttar Pradesh is responsive to the needs of the disabled and offers many schemes and scholarships for rehabilitation of the disabled.[21]

Disability rates reflect the overall health status of the population.We have presented the estimates of disability prevalence, geographical and gender differentials in the disability rates in Uttar Pradesh. To understand the reasons to explain these, additional research studies will have to be planned out in regions and population groups with a higher burden of age-standardized disability. Identification of the underlying causes and employing effective and focused preventive strategies will help to reduce the burden of disability and maximize the quality of life in Uttar Pradesh in the years to come.

Lumbosacral MRI Findings in Chronic Lower Back Pain

Kermanj Ismail Bakr[1], Israa Mohammed Sadiq[2], Saman Anwer Nooruldeen[3]

[1]MBChB (Al-Mustansariy University), [2]MBChB (Tikrit University), DMRD (Baghdad University), FIBMS Radiology (Iraqi Board for Medical Specialization), Department of Surgery/Radiology, College of Medicine, University of Kirkuk, Kirkuk/Iraq, [3]Azadi Teaching Hospital, Kirkuk, Iraq

Abstract

Background: Low back pain (LBP) is one of the most common musculoskeletal disorders demanding hospital visits. Inter vertebral disc degeneration is a known cause of chronic low LBP back pain. The relation between changes in the lumbar spine and lower back pain is controversial.

Objectives: To assess LSS MRI findings in patients with CLBP, and to show the relation of disc degeneration with age and gender.

Material and Method: 218 adult patients with chronic lower back pain (pain more than 12 weeks) did Lumbosacral spine MRI, at Azadi Teaching Hospital/Kirkuk city, from March/2017 to April/2018, those with a positive history of spinal pathology other than osteoarthritis were excluded. The disc degenerative MRI changes at each lumbar disc were assessed and correlated according toage and gender.

Results: 146 of patients were male, and 72 of them were female, their age ranged from (16-73 years). Males and elderly patients were affected by disc degeneration more. 92.2% of patients had disc degeneration, followed by disc contour abnormality, facet joint arthrosis, high-intensity zone (HIZ), spinal canal stenosis, Modicchanges (MC), Schmorl's nodes (SN), and spondylolesthesis. L4-L5 disc was the most commonly involved level by disc degeneration, followed by L5-S1 disc, the least level was L1-L2.

Conclusions: Most patients with CLBP have DDD. Older males are the most susceptible people to develop DDD which affect most commonly L4-L5 disc level, other findings may associate with DDD are MC, SN, HIZ, facet joint arthrosis, spinal stenosis, and spondylolesthesis.

Keywords: *Chronic, lumbosacral, lower back pain, MRI.*

Introduction

Low back pain (LBP) is one of the most common musculoskeletal problems demanding hospital visits, and the main contributing cause of disability in adults. LBP occurs in most of the people during any period of life[1,2,3,4,5] Although several causes have been implicated in lowback pain, disc degeneration disease (DDD) is a known cause of this pain[6,7]. Chronic pain is defined as pain for more than 12 weeks.[8]

DDD of the lumbosacral spine (LSS) in adults can start in the third decade of life.[6]. There are several risk factors related to disc degeneration in the LSS, including age, increased physical loading, obesity, and genetic influences.[4,9,10]

Magnetic resonance imaging (MRI) is often requested and of choice in the management of patients with LBP as different abnormalities can be seen on spinal MRI[11,12,13] LSS MRI findings of DDD include decreased disc space, decreased signal intensity on T2W images which indicates disc dehydration. Disc degeneration on T2-weighted sagittal magnetic resonance images of the lumbar spine is appeared and graded as:

Grade (0): Normal No signal changes; Grade (1): the signal intensity of the nucleus pulposus is slightly decreased; Grade (2): seen as hypointense nucleus pulposus with preserved disc height; Grade (3): seen as hypointense nucleus pulposus with narrowing of disc space.[14]

Disc degeneration may be associated with disc bulging/herniation, and high-intensity zone(HIZ).[9,15] Herniated disk is defined as a "focal displacement of nucleus, cartilage, a piece of annulartissue or fragmented apophyseal bone beyond the space of the intervertebral disc.Disc displacement most commonly is classified into fivegrades (normal, disc bulge, protrusion, extrusion, and sequestration).[16,17] (HIZ) represents tear in the annulus fibrosus of the disc, seen as very bright signal intensity on T2 weighted images at the posterior part of the disc[18] Other findings which associated with DDD include Modic changes (MC), Schmorl's Nodes (SN), facetjoint degeneration, spondylolesthesis, and spinal stenosis.[19]

This study was done to assess LSS MRI findings in patients with CLBP, and to showthe relation of DDD with age and gender.

Patients and Method

Subjects: Inclusion criteria:Two hundred eighteen (218) adult patients with chronic lower back pain (more than 12 weeks) were sent to MRI department at Azadi teaching hospital/Kirkuk city/Iraq, as a part of the management of lower back pain, over the period fromMarch/2017 to April/2018. Their ages range from 16 to73 years.

Exclusion criteria: Those who had a history of spinal surgery or back trauma, known spinal pathology, malignant diseases,and athletes were excluded from the study.Clinical information was obtained from the documentation ofphysicians.

Imaging: All lumbosacral spine MRI examinations were done using the 1.5-T unit (Philips Acheiva,

Netherland (2010) with a dedicated lumber coil, imaging protocol was as follows:

1. T1-weighted sagittal Turbo spin echo (TSE) with 8 msec echo time (TE) and 500 msec repetition time(TR).
2. T2-weighted sagittal TSE with 100 msec TE and 4000 TR.
3. T2-weighted axial TSE with 120 msec TE and 4000 TR, and
4. Myelography with 1000 msec TE and 8000 TR.

The images were interpreted by two board-certified radiologists with 7 years experience, anydifference in opinion were settled by consensus.Each lumber level of 218 patients was assessed for disc degeneration scoring, disc bulging and herniation, HIZ,presence of MC, SN, facet joint degeneration, spondylolesthesis, and spinal stenosis.

Statistical analysis: It was a cross-sectional analytic study. The study population demographic criteria including age in years, weight in kilograms (kg), and height in centimeters (cm)were expressed as means(SD). Percentage of Disc degeneration at different lumber disc levels was assessed and related to gender and age, total degeneration score was estimated for each patient as average degeneration score of all lumbar disc levelsand related to age, using Chi-square test.*P*-value level of less than 0.05 was required for significance.Percentageof disc bulge/herniation, HIZ, MC, SN, sponylolisthese, facet joint arthropathy, and spinal stenosis were also estimated. SPSS software, version 17, was used for the statistical analyses.

Results: The demographic criteria of the study sample were as seen in table 1.

Table 1. The demographic criteria of the study sample

Category	Male ([a]N=146) Mean (SD)	Female (N=72) Mean (SD)	t-value	P value
Age (years)	43.5 (12.1)	42.5 (12.7)	0.5645	0.5730
Height (cm)	174.3 ± 6	161.3 ± 5.8	15.3747	0.0001
Weight (kg)	83.31 ± 14	74 ± 8	5.2332	0.0001

[a]Number.

There were 146 males and 72 females in the study sample; male to female ratio was 2:1, 141males (96.6%) and 60 (83.4%) of females had disc degenerative changes in their LSS MRI.

Males were significantly more affected than females by disc degeneration (*P*=0.0006).

Most of the patients had abnormal MRI findings 201 (92.2%), and only 17 (7.8%) had a normal MRI study. 32 patients were less than 35 years old, 140 patients were 36-55 years old, and 46 patients were more than55

years old. 68.8% of < 35 years old group,95% of 35-55 years old group, and All patients >55 years old group had disc degeneration change. The incidence of disc degeneration was significantlyincreased with advancing age (P<0.001)as seen in table 2.

Table 2. Relation of disc degeneration with age.

Age	Disc degeneration		Total
	Male	Female	
< 35	17	5	22
35-55	98	35	133
>55	26	20	46

The total number of the affected disc was 588 levels of a total of 218 patients. The mostcommonly affect level was L4-L5 in 32%, followed by L5-S1, L2-L3, L3-L4, and L1-L2 in

21.2%, 19.1%, 18%, and 9.2% respectively as seen in figure 1.

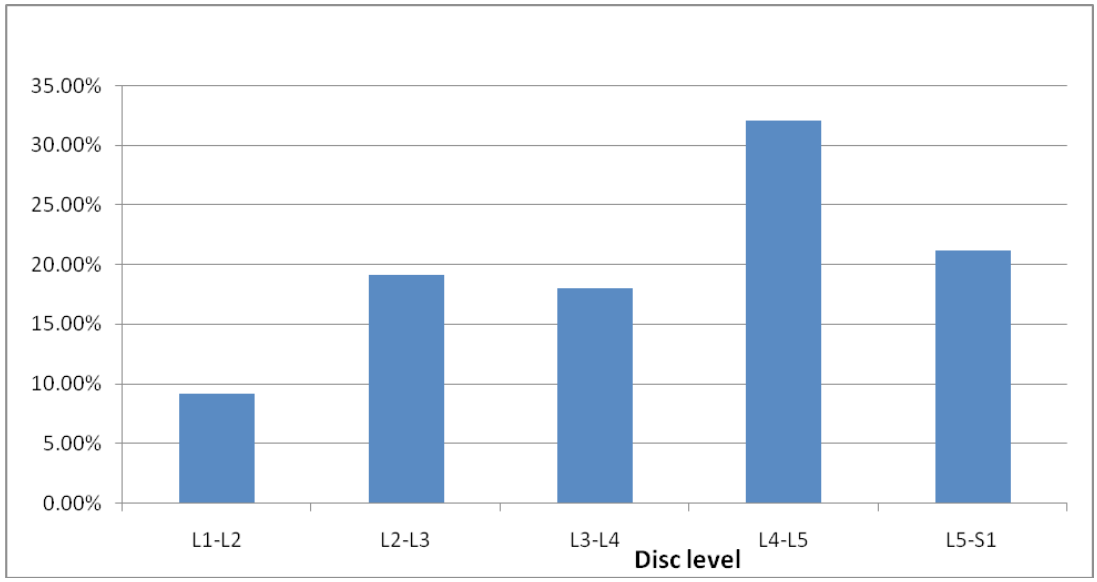

Figure 1: Distribution of disc degeneration according to disc level.

Disc degeneration was present at one level in 25%, and multilevel in 75%. The average disc degeneration score of each patient was score 0 in 7.8% (17 patients), score I in 30.1% (66 patients), score II in 37.2 (81 patients), and score III in 24.8% (54 patients) (Table 3).

Table 3-The relation between disc degeneration score and age.

Age (years)	Total degeneration score				Total
	0	I	II	III	
>35	10	18	4	0	32
36-55	7	40	61	32	140
55<	0	8	16	22	46
Total	**17**	**66**	**81**	**54**	**218**

Score 3 disc degeneration was not seen in <35 year's age group, and all patients who were <55years old group had degeneration with different scores, the score of degeneration was significantlyincreased with increasing age (*P*> 0.001).

Other LSS MRI findings were as the following: disc contourabnormality (70.7%), HIZ (27.8%), SN in (12.9%), MC (19.3%),spinal stenosis (20.4%), facet joint degeneration (45.2%), andspondylolisthesis (6.4%).

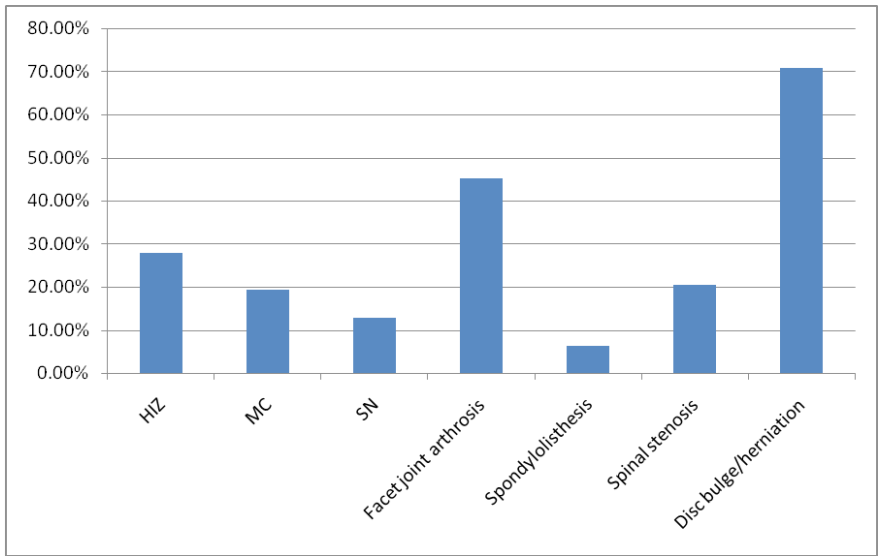

Figure 2: Percentage of MRI changes associated with disc degeneration.

Discussion

Degenerative changes were seen in the majority (92.2%) of patients with chronic lower back pain;most of these changes were observed at L4/L5 and L5/S1 levels and lowest rate of involvementwas noted at L1-L2 level. Similar outcomes had been perceived in most of the previous studies,due to the highest mechanical strain at these levels[20,21,22 and 23].

Multiple disc level involvement was common as compared to the single-disc involvement; which was also in line with past studies.[16, 24] In this study the incidence of disc degeneration significantly increased with age, due to agingprocesswhich involvesdecreased vascularization, and decreased delivery of nutrients and growth factors to the disc.[25] This result was similar to several studies.[20, 26] The fewer percentage of DDD that'sseen in younger age group also noticed in other studies like us, its exact etiology is not clearlyknown, but issues like genetic, autoimmune, and biochemical factors may play a role inthe pathogenesis of disc degeneration.[27]

Males were affected significantly more than females in our study which was comparable with other studies, [28, 29] as men engage in jobs associated with heavy workload compared with women.[30] Mechanical load that contributes to DDD might also have a role in the pathogenesis of disc contour abnormalities, HIZ, MC, and SN[31,23,33]

Conclusions

Most of patients with CLBP have DDD. Older males are the most susceptible people to develop DDD which affect most commonly L4-L5 disc level, other findings may associate with DDD including MC, SN, HIZ, facet joint arthrosis, spinal stenosis, and spondylolesthesis.

Spatial Association Patterns of Geographic Factors and Opisthorchis Viverrini Infection in the Northeast of Thailand

Kittipong Sornlorm[1], Wongsa Loahasiriwong[2]

[1]Doctor of Public Health Program, [2]Faculty of Public Health, KhonKaen University, Khon Kaen, Thailand

Abstract

Background: Thailand is the world highest prevalence's of Opisthorchis Viverrini (OV) infection. This study aimed to determine the spatial association of geographic factors with OV infection in the highest prevalence region, the Northeast (NE) of Thailand.

Method: This study was conducted using four geographic factors data sets of years 2016 and 2017. A Moran's *I* and Local Indicators of Spatial Association (LISA) were used to identify the spatial autocorrelation between geographic factors and OV infection within the region.

Results: Among the total of 189,231 participants in the NE, the regional prevalence of OV infection was 10.60%. The results indicated a spatial global autocorrelation of geographical factors with OV infections, those geographical factors included water sources including dams, reservoirs, weirs, canals and lagoons; proportion of rice field areas and number of dogs and cats per village, (Moran's *I* values of 0.28, 0.34, 0.11, 0.40 and 0.17, respectively). The LISA analysis identified significant positive spatial local autocorrelation of water resource: one of high-high cluster for the numbers of dams and reservoirs, three low-low clusters for the number of weirs and two of high-high clusters for the numbers of canals and lagoons. In addition, there were two high-high clusters and three low-low clusters of the proportion of rice field areas, and one low-low cluster of dogs and cats with OV infection.

Conclusion: There were spatial associations between physical geographic factors and OV infection in the NE of Thailand which should be taken into new policy recommendations for OV infection control. Especially, in the province with more rice fields, big water resources and had more dogs and cats.

Keywords: *Geographic factors, OV infection, Spatial association patterns, Northeast of Thailand.*

Introduction

Opisthorchis *viverrini* (OV) infection is a food-borne infection caused by a liver fluke[(1)] through consumptions of inappropriately cooked metacercariae, an infective stage of OV[(2-4)]. It was estimated that about 6 million Thai people were infected with OV, of which most of them lived in the Northeast of Thailand[(3)]. The concerned on OV infection is its strongly association with cholangiocarcinoma (CCA),with a high medical care cost worth up to[4] billion baht per year[(5)]. The most common reported causes of OV infection were eating raw or inappropriately cooked fishes[(4,6,7)], sanitation factors such as inappropriate waste disposal[(3,8)],and socio-demographic factors[(7, 9)]. Some previous studies indicated environment especially geographic factors as one of the important risk factors of OV infection includinglived near water reservoirs[(10)], irrigation areas[(11,12)]. Furthermore, dogs and cats were known as a major reservoir for spread of OV infection since OV is a common infection of the civet cat and other fish-eating mammals that spread the disease into the environment through defecation[(3,4,8)].

In Thailand, there have been intensive and continuous control activities on OV infection for more than 3 decades. Most of OV infection control measures were primarily focused on consumption behaviors and sanitation. However, the OV infection prevalence in the Northeast was still higher than 10 percent with the highest prevalence of 23.6-42.49 percent in 5 provinces[(13)] because of the provincial difference in term of health policy implementation and geographical influence OV infection.

Therefore, this study aims to determine the spatial association of geographic factors with OV infection in the Northeast of Thailand to provide comprehensive information for policy recommendations related to disease control and prevention of OV infection.

Materials and Method

Study design and Population: This cross-sectional study used 4 datasets for analysis including 1) a data set on OV infection status of 189,231 participants who registered with the OV-CCA screening project[3], 2) water sources distribution data from the Department of Water Resources[14],3) data on areas of rice field retrieved from the Office of Agricultural Economics[15],and 4) data on distribution of dogs and cats in the area from the Department of Livestock Development[16].The population in this study were people who lived in the Northeast of Thailand. The samples were those who registered in the OV-CCA screening project in years 2016 and 2017 that were screened for OV infection by one of three method including a fecal examination by Kato Katz thick smear, a Parasep stool kit or a Formalin ether concentration technique (FECT). All data sets were merged using postcode of district.

Factors of dependent and independent factors: The independent factors were geographic factors consisted of proportion rice plantation area, numbers of different types of water sources in a district, and numbers of dogs and cats per a village.The dependent variable was the prevalence of OV infection per province.

Statistical analysis: This study used the Quantum GIS program to describe the spatial distribution patterns geographic factors and OVinfection. The GeoDa program was used to analyze spatial autocorrelation by specifying 3 k-Nearest neighbor province that connecting as a criterion to identify grouping which using the weight matrix to analyze spatial correlation[17,18]. Bivariate Moran's *I* analysis was used to identify global autocorrelation within the region. The global autocorrelation statistics provide a single measure of spatial correlation for an attribute in a region as a whole[17,19]. The reports of the Moran scatter plot, consisted of a plot with the spatially lagged variable on the y-axis and the original variable on the x-axis[17,20]. Both variables were standardized and the graph was divided into four quadrants: high-high and low-low indicating positive spatial autocorrelation; and high-low and low-high indicating negative spatial autocorrelation. The slope of the linear fit to the scatter plot equals Moran's *I*[19,20]. The expected value of Moran's *I* is-1/(n-1), and the interpretation is similar to that of the product-moment correlation coefficient. Informally, +1 indicates strong positive spatial autocorrelation, 0 indicates random spatial ordering, and-1 indicates strong negative spatial autocorrelation[17,19].

Then, a LISA was used to determine the local spatial autocorrelation patterns of the variables[19,21]. This computes a measure of spatial association for each individual location. The maps depict the locations with significant Local Moran statistics (LISA significance maps) and classify those locations by type of association (LISA cluster maps)[17]. Which the reports that showed the High-High is an indication of spatial clusters when having a high frequency of geographic factor with a high frequency of OV infection in the identified province with three neighboring provinces. The Low-Low location is indication of spatial clusters when a low frequency of geographic factor with a low frequency of OV infection in the identified province with three neighboring provinces. In contrast, the High-Low and Low-High are indications of spatial outliers[17,21]. The statistical significance level was 0.05. The simulation used 999 permutations to evaluate the sensitivity of the results.

Results

Spatial distribution characteristics of factors: The overall prevalence of OV infection was 10.60%. The highest prevalence was in Srisaket province (18.21%). The quantile distribution in dictated the highest quantile of 13.30-18.20 percent in 5 provinces of Chaiyaphum, Mahasarakham, Kalasin, Surin, and Srisaket provinces (Table 1).The highest quantile distribution of number of dams and reservoirs was in Khonkaen, Nakhonratchasima, Buriram, Srisaket, and Ubonratchathani provinces. The highest quantile of number of weirs were also in Khonkaen,Nakhonratchasima, Mahasarakham, Surin, and Srisaket provinces. In term of number of canals and lagoons the highest quantile of number of canals and lagoons were found in Nongkhai, Nongbualamphu, Kalasin, Roi Ed, and Srisaket provinces. Concerning, the proportion of rice field areas, the highest quantile was in Mahasarakham, Roi Et, Yasothon, Surin, and Srisaket provinces. In addition, the highest quantile distribution of numbers of dogs and cats were found in Khonkaen, Nakhonratchasima, Buriram, Srisaket, and Ubonratchathani provinces.

Table 1: Province ranking on the prevalence of OV infections in the northeast of Thailand

No.	Province	Participants	Percent of OV infection
1.	Srisaket	9,170	18.2
2.	Kalasin	10,879	17.7
3.	Surin	6,562	16.6
4.	Chaiyaphum	7,633	14.1
5.	Mahasarakham	9,698	13.6
6.	Nakhonratchasima	7,189	13.2
7.	Nakhonphanom	17,878	11.3
8.	Roi Et	13,027	11.1
9.	Mukdahan	8,393	10.7
10.	Ubonratchathani	13,155	10.6
11.	Buriram	8,136	10.4
12.	Udonthani	7,945	9.86
13.	Buengkan	8,430	9.28
14.	Sakonnakhon	12,581	8.61
15.	Loei	6,729	8.2
16.	Yasothon	4,037	7.38
17.	Nongbualamphu	6,646	6.58
18.	Khonkaen	10,273	6.19
19.	Nongkhai	10,898	5.52
20.	Amnatcharoen	9,972	2.77
	Total	**189,231**	**10.60**

Factors associated with OV infection: The results of Moran's *I* indicated spatial autocorrelation with the distribution pattern of number of dams and reservoirs in the same direction as the OV infection distribution pattern (Moran's *I*: 0.28). LISA indicated areas with a concentration of dams and reservoirs and high prevalence OV infection with also the high values of surrounding 3 provinces (High-High) was in Surin province. The number of weirs had spatial autocorrelation with the same direction as the OV infection distribution pattern with the Moran's *I* of 0.34. LISA analysis showed cluster of a province with a low concentration of weirs and OV infection with also low values of surrounding 3 provinces(Low-Low). There were 3 low-low clusters found in Loei, Nongkhai, and Amnatcharoen provinces. In addition, there was a spatial autocorrelation of number of canals and lagoons and a distribution pattern in the same direction as OV infection with Moran's *I* of 0.11. The LISA analysis indicated 2 High-High clusters of high concentration of numbers of canals and lagoons and OV infections with also high values of the surrounding 3 provinces in Nakhonratchasima and Roi Et provinces. The proportion of rice field areas in a province had spatial autocorrelation with the OV infection (Moran's *I* of 0.40). Two High-High clusters of proportion of rice field areas and OV infection were in Surin and Sisaket provinces. Two low-low clusters of low proportion of rice field areas and low prevalence OV infection with also low values in 3 surrounding provinces were in Nongkhai and Loei provinces.In addition, there was a spatial autocorrelation of number of cats and dogs per village and OV infections (Moran's $I = 0.17$). There was a low-low cluster Yasothon province indicated the correlation of low concentration of dogs and cats in the province as well as low prevalence of OV infection in the province and the 3 surrounded provinces (Table 2).

Table 2. LISA and Moran's *I* scatter plot matrix of the geographic factors on OV infections in the Northeast of Thailand

Factors	Moran's I	LISA				p
		High-High	High-Low	Low-Low	Low-High	
1. Number of dams and reservoirs	0.2768	Surin*	Nakhonphanom* Mukdahan*			0.05*
2. Number of weirs	0.3398			Loei* Nongkhai* Amnatcharoen*	Buriram**	0.05* 0.01**
3. Number of canals and lagoons	0.1086	Nakhon-ratchasima* Roi Et*			Buriram*	0.05*
4. Proportionof rice field areas	0.3999	Surin** Srisaket*		Nongkhai* Loei* Nongbualamphu*	Ubon-ratchathani*	0.05* 0.01**
5. Dogs and cats	0.1705		Nakhonphanom* Mukdahan*	Yasothon*	Buriram*	0.05*

Discussions

Explaining the findings: The Northeast of Thailand is the biggest region of the country covers about one third of the country land area. There were 20 provinces in the region. The overall prevalence of OV infection in the Northeast of Thailand was 10.6%. The province with highest prevalence were Srisaket followed by Kalasin, Surin, Chaiyaphum, and Mahasarakham province (13.60-18.20 percent).The high prevalence of OV infection were in the provinces with more water resources. Similar pattern of high proportion of rice field areas and high prevalence of OV infection and high prevalence of OV infection was found in a province with had more dogs and cats per village as well. The Moran's *I* and LISA indicated the spatial association between geographic factors and OV infection. We found that there were 6 spatial correlation clusters of water resources and OV infections. Consideringone cluster involved a center province and others 3 surrounding provinces, 18 provinces had spatial pattern of correlation. However, some clusters shared were in the same province, therefore about 16 provinces were involved in the spatial pattern. Possible explanation on water resource were that with more water resources, people could access, catch or buy raw fishes for consumption for whole years. Similar results on association in access to fishes and OV infection was found in the area of Mekong River[22] more irrigation areas with high prevalence of OV infection[11,12] and higher OV infection prevalence in the areas near reservoirs[10]. Concerning the spatial correlation of proportion of rice filed area and OV infection, the possible explanation was that people could catch fishes from rice fields and they more likely consume raw or semi-cooked fish because the fish was still fresh which was consistent with the study of environmental factors affecting the OV infection in the Northeast of Thailand which reported a high prevalence of OV infection in the cultivated area[23] and lowland areas[24]. The positive clustering correlation between numbers of dogs and cats and OV infection in the Northeast of Thailand could be explained by that dogs and cats were more likely to eat raw fish and they also were more likely to defecate in water resources. It was also found in the study on liver fluke infection in Northeast Thailand[25] and the Epidemiology of OV infection[26]. However, some provinces such as Khonkaen, Ubonratchathani provinces had rather low prevalence of OV infection with no spatial autocorrelation with surrounding provinces. The possible explanation might be the impact of immense continuously OV infection control implementations in these public health education institutional provinces.

Conclusions

There was still high prevalence of OV infection in the Northeast region of Thailand.Geographic factors especially water resources,rice field areas, and concentration of cats and dogshad significant spatial autocorrelation withOV infection of most of the Northeastern provinces such as Srisaket, Surin, Nakhonratchasima, and Roi Et provinces. Health sectors and local administration should take into consideration of the geographical factors in their plans for additional surveillance in the high-risk areas as well put more effort on improving knowledge and behaviors of the people in the high geographical risk areas.

The Effects of Cigarette Smoke on Serum Immunoglobulin Levels of Patient with Chronic Periodontitis (Comparative Study)

Lekaa M. Ibraheem[1], Ziyad Nizar Al-Talib[2], Ayat M. Dhafer[3]

[1]MSc. Prof. Periodontology, Department of Dentistry, Al-Esraa College, [2]PhD, Lecturer, Periodontology, Faculty of Dentistry,University of Babylon, [3]B.D.S, College of Dentistry, University of Baghdad, Iraq

Abstract

The aim of the present study was to determine and compare the periodontal health status and the concentration of serum immunoglobulins by using clinical and immunological analysis between smokers and non-smokers with chronic periodontitis. Total sample composed of forty participants, twenty subjects smokers with chronic periodontitis (group 1) and twenty subjects non-smokers with chronic periodontitis (group 2). All periodontal parameters and serumsample for immunological analysis for (IgA, IgG, IgM) were taken in the same visit. The periodontal parameters include: Plaque index (PLI), gingival index (GI), Probing Pocket Depth (PPD) and Clinical Attachment Loss (CAL) were recorded. The result showes that there was non-significant difference for mean of PLI, G.I and PPD between group 1 and group 2, but with highly significant difference in the mean of CAL the inter group comparison of serum IgA IgG concentration showed a significant different between group 1 and group 2. But there was no-significant difference between group 1 and group 2 considering the mean of serum IgM concentration. The present study indicate that there is association between cigarette smoking and increase periodontal parameters which include PLI.GI, CAL, and PPD with the suppression of immunoglobulin production.

Keyword: *Smoking, periodontal parameters, Immunoglobulins.*

Introduction

Periodontitis is a chronic multifactorial inflammatory disease and manifested through present of periodontal pocketing, gingival bleeding, clinical attachment loss (CAL) and assessed alveolar bone lossradiographically[(1)]. Tobacco smoking is one of the most important risk factors that associated with the destruction of the alveolar bone and loss of attachment in patients with periodontitis [(2)]. In addition, smoking was found to be a good predictor for further bone loss and attachment loss in smoker patients with periodontitis when compared to non-smoker counterparts[(3,4)]. Smoking as an environmental factor has been found that it could interact with host cells and affect inflammatory responses to the microbial challenge [(2)].The effects of smoking include alterations in vascular function, monocyte/neutrophil activities, expression of the adhesion molecule, release of cytokine/ inflammatory mediators and antibody production[(5,6)]. Charu Shrestha et al. showed that the long-term effects of smoking could lead to significant decreases in serum IgG levels. Smokers were found to have lowerserum IgG levels than non-smokers with chronic periodontitis. In addition, it was shown that cigarette smoking could cause suppression in the functions of B cell and effect production of Igs. The authors suggested that alterations in the levels of antibodies can give the explanation for the aggravations found in periodontal disease[(7)]. Hersey et al found that in a group of people who quit smoking, the quantity of lymphocytes decreased and NK activity against cultured melanoma cells increased. Also their serum IgG and IgM concentrations were significantly increased. Therefore these results demonstrated an inverse correlation between smoking status and immune function[(8)].

Material and Method

Sample population was consisted of forty individuals; systemically healthy males with an age range (35-55) years old. All participants were from subjects attended department of periodontology and department of oral diagnosis, Collage of Dentistry, University of Baghdad.

All the individuals were informed about the purposes of the investigation and consented to its protocol. Smoking and non smoking status were assessed by means of a self reported questionnaire. Questionnaire was designed to include: name, age, full medical history, clinical periodontal parameters (plaque index, gingival index, probing pocket depth and clinical attachment level). Also it included information about how many cigarettes smoked per day and number of smoking years.

The participants were grouped in to 2 categories:

Group 1 included (20) smokers patients with chronic periodontitiswith mean age 40.93±5.41years

Group2 included (20)nonsmokers patients with chronic periodontitiswith mean age 39.93±4.96years. All smoker subjects regularly smoked at least 10 cigarettes per day for at least 5 years and did not quit smoking [9]. Each chronic periodontitis patient had at least 20 teeth, and more than 30% of sites with probing pocket depth ≥ 4mm and or clinical attachment loss ≥ 1mm, as defined by world workshop consensus reports [10]. Any individuals had a history of any systemic diseases, subjects who receive medications (e.g: anti-inflammatory or antimicrobial therapy within the previous 3 months), a history of regular use of mouth washes and any previous periodontal treatment for the last three months were excluded.The following clinical indicesincluding Plaque index (PL.I)[11], Gingival index (GI)[12], Probing pocket depth (PPD) and Clinical attachment loss (CAL) were measured. Five millilitres of venous blood sample were collected. The serum samples were centrifuged at 3000 rpm for 10 min and stored in plastic vials at −20°C till being assessed [13]. Immunological analysis for IgA, IgG, IgM level was estimated by radial immunodiffusion technique of Mancini et al. [14].

Statistical analysis: The data were presented as mean and standard deviation,minimum,maximum. Student's t test (unpaired) were used to determine significant differences between the means. Values of $P < 0.05$ were regarded as statistically significant

Results

The descriptive statistics for PL.I and G.I betweengroups was illustrated in Table (1) it was clearly shown that the means of PL.I were slightly elevated in group 1 (1.660 ± 0.355) in comparison with 1.504 ± 0.457 of group 2.

The mean of G.I in group 1 (0.995 ± 0.197) was slightly lower than the mean score of group 2 which was (1.06 ± 0.147).

Discussion

There was no significant difference in PL.I between groups. This result was in agreement with[15,16,17] who showed that there were no significant mean differences between smokers and non smoker, but disagreed with Ustun and Alptekin[18]; Sreedhar and Shobha[4], Ali et al[19] and Mokeem et al.[20].

The reason for the result of our study is that the amount of plaque on the teeth surfaces is mainly depend on personal oral hygiene and frequency of teeth brushing rather than smoking status. People who brushed their teeth more frequently had less plaque than people who brushed their teeth less frequently or occasionally [21]. The result showed that that smoker chronic periodontitis patients associated with lower gingival index than non smoker. This result was in agreement withÜstün and Alptekin[18] and Sreedevi et al [4] who found that gingival inflammation was less pronounced in smokers than non-smokers. The results disagreed with Johannsen et al[22], who found that the smokers associated with increase gingival inflammation. Other studies reported that there were no differences in the inflammatory status between smokers and nonsmokers [16, 4].Smokers with periodontal disease typically have less clinical inflammation and gingival bleeding than non-smokers. This is because of the effect of nicotine with a vasoconstriction that lead to reduce blood flow, edema, and clinical signs of inflammation, which mask periodontal disease in smokers[23]. Smoking masks clinical signs of gingival inflammation because it suppresses the inflammatory response to plaque challenge [2]. The results showed that there was slightly elevated level in the mean of PPD in smokers group when compared with non-smokers group. Statistically, there was no significant difference between the groups. The present findings was in agreement with Preshaw et al (24) who found no significant difference between them, but disagreement with the long term results of Johnson and slach[25].There was significant difference in CAL between groups. These results were in agreement with Luzzi et al [26], Nassrawin[15] andMokeem et al [20], they found that CAL mean score of smokers were higher than non-smokers. Smoking effects both the cellular and humoral immune systems. Its effects throughout the cytokine network and suppresses both chemotactic and phagocytic functions

of polymorph nuclear leukocytes in saliva and tissues [2]. It have been reported that smoking cause suppression in immune responses, impaired stromal cell function, and amplified inflammatory responses.

According to the results, there was significant difference in the serum IgG,IgA between groups.While the IgM concentration showed non-significant difference between both groups, with slightly elevated level in non-smokers in comparison with smokers.This results was in agreement with Graswinckel et al [13], Al-Gamidi and Anil [27] and Charu Shrestha et al [7] who found that there is a reduction in IgG2 concentration in smoker patient.Another study also found that healthy smokers have lower serum IgG levels than do non-smoking individuals; however, no differences were found in the levels of serum IgA and IgM [28]. Previous findings have indicated that no significant differences occur in serum IgM level between smokers and nonsmokers [29]. Prior research has provided evidence that Ig levels (particularly IgG levels) decreased with increased smoking, and these effects were reversible after smoking cession [30].

One of the mechanisms to explain this finding is that smoking decreases the proliferative capacity of T-cells and T-cell-dependent antibody responses which affects B-cell function and antibody generation. It is possible that B-cells are functionally compromised by the reduced proliferative responses to oral pathogens, which leads to decrease in production of serum antibodies. In addition, it has been found that alveolar macrophages from smokers exhibit reduced expression as antigen-presenting cells which leads to a reduction in the humoral immune response to fight organisms in periodontitis patients [31,7].Our study suggests that reduced salivary IgA and IgM levels in smokers with periodontitis could enhance increased susceptibility to periodontitis

Conclusion

The present study indicate that there is association between cigarette smoking and increase periodontal parameters. Also alteration in antibody levels further explains the potential mechanism by which smoking exacerbates periodontal disease.

Adequacy Level of Energy and Nutrients and Nutritional Status of School-Aged Children with Working Mothers were Lower than those with Non-Working Mothers

Lilik Kustiyah[1], Novia Purnawati[1], Naufal Muharram Nurdin[1]

[1]Department of Community Nutrition, Faculty of Human Ecology, Bogor Agricultural University, Indonesia

Abstract

The objective of this research was to analyze the relation of maternal employment status to adequacy level of energy and nutrients and nutritional status of school-aged children (SAC). This cross-sectional study conducted from March to May 2016 involved 175 fifth-grade SAC. The results showed that maternal employment status had a significant positive correlation with adequacy level of energy and carbohydrates. Mean Body Mass Index-for-Age (BAZ) of subjects with working mothers was significantly lower than those with non-working mothers. Adequacy level of energy and nutrients, and BAZ of subjects with working mothers tended to be lower than those with non-working mothers.

Keywords: *Elementary school children, maternal employment status, nutrient adequacy level, nutritional status.*

Introduction

The data of Indonesian Ministry of Health in 2010 showed that the national prevalence of underweight and overweight based on BAZ for children aged 5 to 18 years were 12.2% and 9.2%, respectively[1]. The data in 2013 indicated that the prevalence of underweight based on BAZ aged 5 to 18 years was 10.6% and the prevalence of overweight was 12.3%[2]. Underweight or overweight problems, occurring in childhood may affect growth, development, health and incidence of degenerative diseases in adulthood.

Meanwhile the increasing employment opportunities for women and the need to increase household income make more women choose to work. The economic theory states that families with working mothers must trade off the increased income with less time for home-based food production and supervision of children's activities. Such trade-off may produce a positive, negative or non-existent effect on children's nutritional condition[3]. A systematic review has indicated that negative effects of maternal employment status (i.e. overweight and obesity) on children have been proven from several studies in US, Canada and the United Kingdom[4]. However, the results outside those three countries are still inconsistent, either the absence of any influence of the presence of results indicating that maternal employment status decreases Body Mass Index (BMI) value, especially in developing countries in Africa and Asia. In Indonesia itself, there has not been many studies conducted with the main focus to identify the relation of maternal employment status to food consumption and nutritional status of school-aged children. Therefore, the present study was conducted with the aim to analyze the relation of maternal employment status to food consumption and nutritional status of elementary school children in Bogor City.

Method

Study Subjects: This study used a cross-sectional design. It was conducted from March to May 2016 in four elementary schools. The subjects were selected based on the criterias: 1) fifth-grade elementary school children, 2) had working and non-working mothers, 3) were willing to follow the study and filling out the questionnaire. From the complete questionnaires filled

out by the subjects and their parents, we got 175 subjects to be studied.

Socioeconomic, Anthropometric and Food Consumption Data: The data collected were subjects' characteristics (age, sex, pocket money, body weight and height), family characteristics (parental education and occupation, family income and size), food consumption. The data regarding subjects' and family characteristics were obtained through questionnaires filled out by the subjects and subject's parents, who were guided by the researchers, respectively. Anthropometric data were collected by taking direct measurements of body weight and height in each class of each school. Body weight was measured by using a digital scale with a capacity of 200 kg and 0.1 kg precision, while body height was measured with a stature meter with a capacity of 200 cm and 0.1 cm accuracy. Food consumption data were collected through 24-hour recall.

Statistical Analysis: The data were analyzed using Microsoft Excel for Windows 2007 and SPSS version 16.0. Subjects' nutritional status based on BAZ obtained from anthropometric measurements was then analyzed by using WHO AnthroPlus 2007 software. The associations between variables were analyzed by using Spearman's rank correlation test. Comparative analyses were used to differentiate the variables between the subjects with working mothers and the ones with non-working mothers.

Results

Subjects and Family's Socioeconomic Characteristics: Most of the subjects (71%) were at the age of 11 and more than half of them (54%) were girls. Mean daily pocket money of the subjects with working mothers was significantly higher ($p<0.05$) than those with non-working mothers.

Paternal education level was significantly higher ($p<0.05$) among subjects with working mothers than those with non-working mothers. Education levels of working mothers were significantly higher ($p<0.05$) than non-working mothers. Most of the working mothers (63%) were university graduates, while most of the non-working mothers (41%) were senior high school graduates. Family income of the subjects with working mothers was significantly higher than the ones with non-working mothers.

Food Consumption: Intake of energy and carbohydrates in subjects with working mothers (1330±393 Cal/day and 188±65 g/day, respectively) were significantly lower ($p<0.05$) than the ones with non-working mothers (1534±542 Cal/day and 225±91 g/day, respectively). The adequacy level of energy (70.71±22.58%) and carbohydrates (72.81±27.75%) in subjects with working mothers were also significantly lower ($p<0.05$) than those with non-working mothers (88.03±35.06% and 93.88±41.29%, respectively). However, protein and fat intakes and adequacy levels between the subjects with working mothers and non-working mothers were not significantly different ($p>0.05$).

If categorized by the adequacy level of energy and carbohydrates, most of the subjects (75% and 76%, respectively) with working mothers belonged to deficit category. Meanwhile, most of the subjects with non-working mothers had energy and carbohydrate deficiencies; 55% and 52%, respectively. Maternal employment status had significant positive correlations with adequacy level of energy ($p=0.001$, $r=0.251$) and carbohydrates ($p=0.001$, $r=0.252$). However, there was no significant correlation between maternal employment status and adequacy level of protein and fat.

Table 2. Distribution of subjects based on maternal employment status, intake and adequacy level of energy and nutrients

Intake/adequacy level	Working mother (n=72)		Non-working mother (n=103)		*p*

Nutritional Status: Most of the subjects with working mothers (73%) and those with non-working mothers (80%) had normal nutritional status. Nutritional problems were more commonly found among subjects with working mothers (27%) than those with non-working mothers (20%). BAZ of the subjects who had working mothers (-0.49±1.58) were significantly lower ($p<0.05$) than the ones who had non-working mothers (-0.11±1.54).

Discussion

Education level of the working mothers was significantly higher ($p<0.05$) than non-working mothers. Mothers with high education will more easily receive messages and information about nutrition and child health[5], thus they are expected to be able to determine food with better quantity and quality. Income level of a person will affect the type and amount of food they consume[6]. It is reflected in the changes in the purchase of foodstuff that was originally cheap to food with more expensive price and better quality. The number of family members also contributes to types and quantity of food available in the family[7].

This study indicated that working mothers tended to give a larger amount of pocket money. Parental education, especially the father, has a reciprocal relationship with occupation[5]. Paternal education level directly or indirectly determines family's economic condition. The larger the amount of pocket money given, the greater the chances of children to buy food in canteen or outside school[8].

Adequacy level of energy and macronutrients in children with working mothers tended to be lower than those with non-working mothers. Similar result with our study was also shown by previous study, which proved that the intake of energy and nutrients of 142 preschoolers were significantly higher in children of the non-working mothers than children of the working mothers[9]. However, another study on 350 school-aged children the majority of children with non-working mothers had low energy and protein intake patterns[10].

A significant association was found between maternal employment status and adequacy of energy and protein intakes. Non-working mothers had more time to spend with their children[11]. They could manage the dietary pattern of their children, thus the children usually ate healthy and nutritious food. Food consumption in children was influenced by tradition and habits of the environment where they lived[12]. Non-working mothers were likely to prepare healthier and more nutritious

meals than the working mothers[11]. There is a negative association between maternal employment status and the quality of child's diet[3]. Children with full-time working mothers had lower healthy eating index (HEI) scores than those with non-working mothers. They also consumed less fruit and had lower iron and fiber intakes[3]. There was a significant association between maternal employment status and healthy dietary pattern among children, which was also related to mother's time[13]. Working and non-working mothers were thought to have different impacts on nutritional levels of their children. Housewives were suspected of having more time for their children, while the working mothers might depend on their families, babysitters, and housekeepers to nurture and assured that their children got the appropriate nutritious food.

There were more subjects who fell into energy and macronutrient deficit category than those who fell into normal and excessive categories. However, there were more subjects with non-working mothers that had normal adequacy level of energy and macronutrients. There was a relationship between working mother and child's body weight. Working mothers have less time to cook and prepare food. They may decide to cook less food at home, choose to buy restaurant food or ready-to-eat food. These foods are generally high in calories and not in accordance with balanced diet guidelines[14].

The effect of maternal employment status on school-aged children occurs in terms of the availability of time to prepare food at home. It is different from the preschoolers, in which the effect of maternal employment status mainly occurs through maternal nutrition knowledge[15]. Working mothers had more negative attitudes toward cooking, and they thought that cooking was an activity that they hardly wanted to do. They strongly agreed that lack of time and energy was a barrier to prepare food, and they prepared less food for dinner on weekdays over the last one week of the study[16]. Working and/or non-working mothers with longer working hours significantly allocated less time for preparing food, having meals with children, and supervising children's physical activities than the ones with shorter working hours[4].

The subjects with working mothers tended to have lower BAZ or to be heading to under nutrition. Similar results were also shown by several other researchers. Preschoolers who had working mothers showed signs of malnutrition. In addition, there were 34% of children of working mothers skipping their meal times[17]. Full-time working mothers significantly decreased the chances of children becoming obese by 5.4% and decreased age- and sex-specific BMI by more than three percentiles. However, the risk of obesity increased by 3.7% in children of the working mothers who used child care facilities[18]. Previous studies also indicated the higher prevalence of stunting, wasting and underweight among children of the working mothers, although not statistically significant[7,19].

However, our finding was different from the result of other studies. Other study concluded that maternal working hours had a positive association with child's weight and BMI[9]. There is also positive association between maternal working hours and child's body weight was stronger in sixth-grade children than younger children[20]. The extremely busy work schedules made the working mothers become less able to supervise and participate in every children's activities. Working mothers are often unable to manage the children's dietary patterns. They let their children to eat unhealthy food. Their children also often spend more time in front of the television and do less outdoor activities. Therefore, it may result in children being overweight or obese[21]. Present study showed that the prevalence of overweight and obese subjects (21%) with working mother was one and a half time compared to non-working mother (14%).

Conclusion

Subjects whose mothers worked had more nutritional problems than the ones whose mothers did not work. Adequacy level of energy and macronutrients in subjects with non-working mothers tended to be higher (closer to the adequacy level) than those with working mothers. More attention should be given to nutritional problems (under nutrition or overweight/obese) among children, especially the ones related to the consumption that has not met the nutritional adequacy level. The working mothers should pay more attention to the provision of food that is good in terms of type and amount of food, which may influence the nutritional status of children.

Abstract

Malaria affects almost all blood components. One of the most common haematological disorders is thrombocytopenia. Plasmodium infection can cause abnormalities in platelet structure and function. This study aims to spatial/map the spread of malaria incidence, location and physical environmental conditions and chemical breeding places of malaria vectors and analyze the effect of the density of Plasmodium sp on Anemia, Thrombocytopenia and SGPT/SGOT on malaria patients in Minahasa District in 2017. Samples were malaria sufferers April-August came to check up at the existing Puskesmas in Southeast Minahasa Regency, then the data of the coordinates of the house of malaria patients and Anopheles sp habitat and the physical and chemical environmental conditions of the Anopheles sp habitat surveyed using Global Positioning System (GPS). To analyze the effect of plasmodium sp density on anemia, thrombocytopenia and SGPT/SGOT using Chi square test statistics. The results of the study Dissemination of malaria incidence and the distance of Anopheles sp habitat to the homes of malaria sufferers. Physical and chemical environmental conditions in Anopheles sp habitat. in residential areas of malaria sufferers are temperatures 25.1-27.9 0c, humidity 72%-86%, pH 6.2-6.7 and salinity 0 ‰. Plasmodium sp density in 37 malaria patients consisted of 18 + cases, 12 ++ cases, 5 +++ cases and 2 ++++ cases. Statistical test results showed no relationship between Plasmodium sp density and anemia, and there was a relationship between the density of Plasmodium sp to Thrombocytopenia and SGPT/SGOT.

Keywords: *Spatial, Malaria, Anemia, Thrombocytopenia, SGPT/SGOT.*

Introduction

About 96% of the population at risk of contracting malaria in the Southeast Asian region lives in Bangladesh, India, Indonesia, Myanmar and Thailand and causes 95% of malaria cases (both sick and dead) in the area[(1)]. Indonesia is one of the countries where malaria transmission still occurs (at risk of malaria or risk of malaria), where in 2014 there were 252,027 positive cases of malaria[(2)]. North Sulawesi Province is ranked ninth out of 34 provinces in Indonesia with malaria morbidity rate (API) 0.94 per 1000 at-risk population[(3)]. Southeast Minahasa Regency is one of the Regencies in North Sulawesi Province with a high level of malaria endemicity, which in 2015 ranked second highest API number from 15 Regencies or Cities in North Sulawesi Province with a positive malaria case was 447 cases in 2015[(4)].

Malaria affects almost all components of the blood, and thrombocytopenia is one of the hematological abnormalities encountered, and has received much attention in the scientific literature. Plasmodium infection can cause abnormalities in platelet structure and function. Some of the mechanisms postulated to cause thrombocytopenia include immune mediated lysis, sequestration of the spleen and disturbances in the bone marrow[(5)]. Research conducted by Jojera et al (2013)[(6)], in 135 patients who were malaria-positive in Gujarat, India, 89.62% of patients experienced a decrease in platelet count. Thrombocytopenia is a hematological

finding that is common in malaria and is often used as an indicator of malaria in endemic areas. The liver is the first organ involved in the reproduction of malaria parasites. Transaminase enzyme increases can be observed in malaria patients. Transaminase enzymes include serum enzymes glutamate pyruvate transferase (SGPT) and serum glutamate oxaloacetate transferase (SGOT)[7].

Material and Method

This type of research is analytic with cross-sectional design. The study population was malaria sufferers in Southeast Minahasa regency in April to August 2017. Samples were determined by accidental sampling, namely malaria sufferers from April to August who came to check in at 4 Puskesmas work areas (Tambelang, Touluaan, Silian and Tombatu) number of 37 patients. The mapping of the spread of malaria cases was carried out by observing all the cases of the house made as research subjects with the coordinates of Plasmodium positive malaria cases based on examination of blood preparations. Mapping the habitat distance of Anopheles sp mosquito larvae is done by tracking using GPS on all Anopheles larvae habitat in the research location. Make buffer cases and habitats using the Arc application. GIS version 9.3. Dividing the distance between larval habitat and malaria cases into 3 (three) zones:

1. Red buffer zone, which is the distance of the malaria case house which is closest to the habitat of Anopheles sp mosquito larvae with a radius of 0-100 meters.
2. The yellow buffer zone is the distance of the house of malaria cases which is a bit far from the habitat of Anopheles sp mosquito larvae with a radius of 100-200 meters.
3. Green potential zone (green buffer zone), is the distance of the case house of malaria incidence which is relatively far from the habitat of Anopheles sp mosquito larvae with a radius of 200-300 meters.

Results

The spread of malaria cases based on Plasmodium types in Southeast Minahasa Regency can be seen in Figure 1.

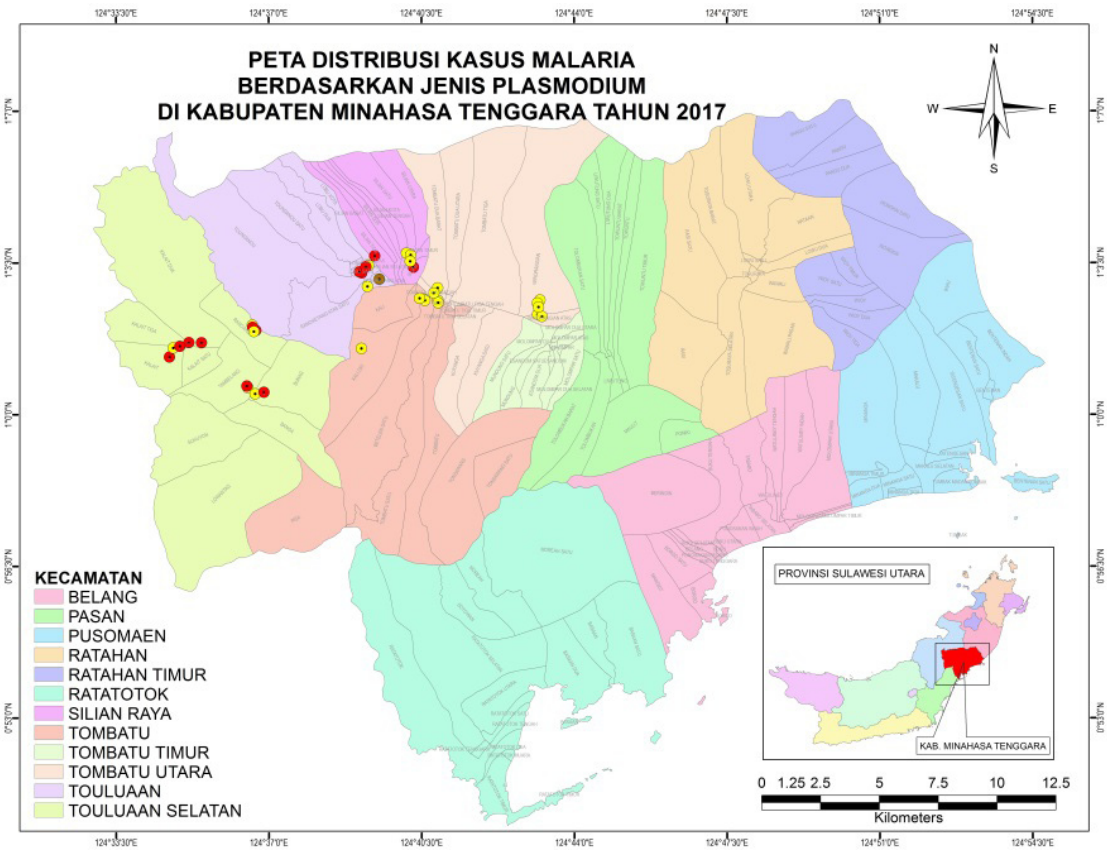

Figure 1: Map of the spread of malaria incidence based on the type of Plasmodium in the Southeast Minahasa District in 2017

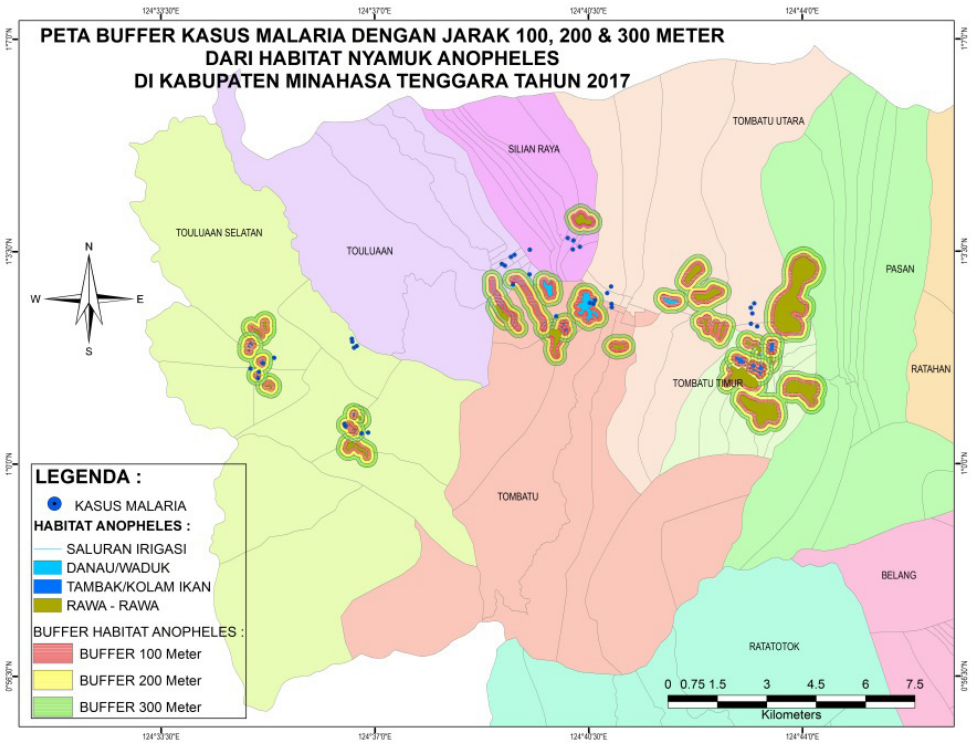

Figure 2: Distance map of Anopheles sp habitat with case houses/malaria sufferers in Minahasa District in 2017

Figure 1. Shows the spread of malaria cases in the Southeast Minahasa District in 2017 totaling 37 cases spread in 18 villages from 5 sub-districts in 4 Puskesmas areas that were the locations of the study. The most cases are in Winorangian Village, namely 5 sufferers. of the 37 patients who were sampled there were 13 patients who were Plasmodium falciparum positive, 23 patients with Plasmodium vivax positive and 1 positive patient with Plasmodium falciparum and Plasmodium vivax mixtures.

Habitat types obtained from Anopheles sp larvae located in the area of malaria cases in Minahasa Regency in 2017 consist of irrigation channels, lakes/ reservoirs, fish ponds/ponds and swamps. Figure 2, 37 malaria cases in the Southeast Minahasa Regency, 4 cases included in the green potential zone, 3 cases in the potential yellow zone, 7 cases in the potential red zone and 23 cases of malaria that were not included in the potential zone. Physical environmental conditions in the breeding places range from 25.2-27.9 (0c) and humidity 72%-86%. Whereas the results of the measurement of chemical conditions in the breeding places around the case location in Minahasa Tenggara District obtained results for the pH in the range of 6.2-6.7 and salinity of 0%.

Table 1 shows the physical environmental conditions (temperature and humidity) and the chemical environment (pH and salinity) in Anopheles sp. in the area of malaria sufferers in the Southeast Minahasa District of 2017.

Table 1: The Physical Environmental Conditionsand The Chemical Environment in Anopheles sp. in The Area of Malaria Sufferers in the Southeast Minahasa District of 2017.

Habitat Type	Physical Environment ($\bar{x}$)		Chemical Environment($\bar{x}$)	
	Temperature (°C)	Humidity (%)	pH	Salinity (Gram/kg)%
Swamps	25.2	72	6.2	0
Irrigation/Sewer Channels	26.6	81	6.3	0
Fishponds	25.1	79	6.7	0
Lake/Reservoir	27.9	86	6.3	0

a. Malaria Distribution Based on Plasmodium Types: Table 2 shows the distribution of malaria in 37 patients infected with malaria parasites in the Southeast Minahasa regency based on the type of plasmodium which found that there were two types of plasmodium with Plasmodium, the most common being Plasmodium falciparum in 23 patients (62.2,%).

Table 2: Malaria Distribution Based on Plasmodium Types in Southeast Minahasa Regency

Plasmodium	Σ	%
P. falciparum	13	35.1
P. vivax	23	62.2
P. malariae	0	0
P. ovale	0	0
Mix Plasmodium	1	2.7
Total	**37**	**100**

b. Plasmodium Density: Table 3 shows 37 samples that are positive for plasmodium and continued by calculating the density obtained with the most results is + with a number of 18 patients (48.65).

Table 3: Plasmodium density in malaria patients in Southeast Minahasa District

Density Plasmodium	Σ	%
+	18	48.65
++	12	32.43
+++	5	13.51
++++	2	5.41
Total	**37**	**100**

Hemoglobin examination results in patients infected with malaria parasites in Southeast Minahasa District. of the 37 malaria patients 23 (62.2%) had anemia because blood hemoglobin levels were below normal. More can be seen in Table 4.

Table 4: Hemoglobin Examination Results for Malaria Patients

Hb examination results	Σ	%
Normal	14	37.8
Anemia	23	62.2
Total	**37**	**100**

Statistical test results of data in table 5, the effect of Plasmodium sp density on thrombocytopenia in malaria patients in Southeast Minahasa District in 2017 using the Chi-Square test showed a relationship with p = 0.022.

Table 5: Thrombocytopenia with Malaria

Trombositopenia	Σ	%
Trombositopenia	22	59.5
Non trombositopenia	15	40.5
Σ	37	100

Statistical test results from the data in table 6, the influence of the density of Plasmodium sp on SGPT and SGOT on malaria patients in Southeast Minahasa District in 2017 using the Chi-Square test showed a relationship with each of p = 0.052 and 0.047.

Table 6: Value of SGPT/SGOT in Malaria Patients

Resultexamination	SGPT <35 u/L		SGOT <30 u/L	
Normal	21	56.8	18	48.6
Ubnormal	16	43.2	19	51.4
Σ	37	100%	37	100%

Discussion

The positive distribution of malaria cases in plasmodium at the study location was in 18 villages with different compositions. Temperature is one of the abiotic environmental factors that greatly contributes to larvae breeding in all breeding places. Based on the results of research conducted in the Southeast Minahasa Regency, the temperature of breeding places ranged from 24.2ºC-27.9ºC. the highest breeding places temperature at 27.9ºC is found in lakes/reservoirs. Temperature measurements in the range of 26 ° C-29ºC. This is a temperature that is ideal for the life of Anopheles larvae in any type of Breeding Places with varying conditions.

There is a difference in breeding places temperatures found by researchers due to differences in geographic conditions where there are breeding places that have protective plants around breeding places and there are also those that do not have protective plants that allow sun irradiation. And directly also due to differences in seasons and time of temperature measurement.

Based on the results of the study showed that the pH in breeding places ranged from 6.2-6.7. The highest pH of breeding places is 6.7 found in lakes/reservoirs. Salinity in breeding places was obtained ranging from 0-14 ‰. Examination of the density of Plasmodium amount in malaria patients from 37 respondents studied there were 18 respondents with the total density (+) (48.65%), and 12 respondents with the total density (++) (32.43%) and for (+++) amounting to 5 patients (13.51%) and 2 patients (++++) (5.41%).

The results of this study indicate that people in endemic areas have paid more attention to their health and immediately went to the health center or to the nearest hospital for the initial symptoms of the disease so that malaria cases can be detected since the initial attack. Besides that at the initial attack, the number of parasites in the peripheral blood is still low so that the parasite density is still low. Patients with ages 15-54 years are 15 people (48.65%) who are adults. This is because this age group is a productive age group where at that age it is possible to work and travel outside the house so that it is more likely to contact the malaria vector. Characteristics of malaria sufferers based on sex, showed malaria patients male as many as 18 people (63.3%) and women as many as 19 people (36.7%). The results of examination of blood smears of malaria patients showed that the most common type of Plasmodium was Plasmodium vivax, which was 23 patients (62.2%). Anemia or decrease in blood hemoglobin levels to below normal values in malaria is caused by excessive destruction of red blood cells by malaria parasites[2]. Examination of 18 patients (78.3%) with very mild anemia, 3 patients (13%) with mild anemia, 2 patients (8.7%) with moderate anemia. The malaria parasite is in the blood for most of its life cycle so it induces changes in the blood. Statistical test results showed that H0 was accepted, indicating a relationship between the type of plasmodium density and platelet count (p = 0.022). These results are supported by research conducted by Jojera et al in 2013[2] in India, where more than 80% of malaria sufferers, both pfalciparum and p.vivax infection, experienced a decrease in platelet counts and 92.48% of cases found in P. infection. falciparum. Thrombocytopenia was also found in patients with vivax malaria, in this study found 23 vivax malaria patients with complications of severe malaria.

Malaria transmission in humans is when sporozoites infect the liver. In the liver the sporozoites mature and form schizon tissue or become dormant hypnozoites. Schizonakan tissue produces a lot of merozoites and then destroys liver cells. Infection of liver cells can cause leakage of parenchymal liver enzymes (transaminases) namely SGOT and SGPT. Echo-erythrocytic cycles of malaria-causing parasitic infections invade the liver and destroy hepatocytes/liver cells thus, causing increased activity of liver enzymes as evidence of liver dysfunction and are associated with membrane integrity[8]. The results showed that there was a relationship between Plasmodium density and levels of SGPT/SGOT. This is because the amount of plasmodium density in 19 patients shows a density of more than +1, where the number of parasites that can destroy erythrocytes in the liver are many.

Damage to liver cells or hepatocytes during the schizogoni cycle results in cellular damage but that does not mean significant liver dysfunction. All types of Plasmodium experience the process of schizogoni in liver cells and then infect and destroy erythrocytes. Jaundice or jaundice can appear as a sign of severe malaria infection either due to severe hemolysis or due to liver involvement. Usually the SGPT value will increase along with SGOT, but increased SGPT indicates that liver function is happening because this enzyme is in the cytoplasm so it is easier to get out of the cell if the cell is damaged by parasites

Conclusions

Dissemination of malaria incidence and distance of Anopheles sp habitat with case houses/malaria sufferers in Southeast Minahasa District in 2017. Physical environmental conditions (temperature 25.1-27.9 0c and humidity 72%-86%) and chemical environment (pH 6.2-6.7 and Salinity 0 ‰) in Anopheles sp habitat. in the area of malaria sufferers in the Southeast Minahasa Regency in 2017. The density of Plasmodium sp consists of 18 + cases, 12 ++ cases, 5 +++ cases and 2 ++++ cases.

There was no correlation between the density of Plasmodium sp and anemia in malaria patients with p = 0.24; there is a relationship between the density of Plasmodium sp to Thrombocytopenia in malaria patients with p = 0.022 and there is a relationship between the density of Plasmodium sp to SGPT/SGOT in malaria patients with p = 0.052 and 0.047

Silver Nanoparticles that Synthesis by Using Trichoderma Orientlae and Evalute Antifungal Activity

Liqaa Y. Mohsen[1], Frial Gemeel Abd[1], Wameedh A.K. AL-Yasari[1]

[1]Department of Biology, College of Science, University of Babylon, Iraq

Abstract

Silver nanoparticles (AgNPs) have been studied as antifungal materials. AgNPs was dependent on several materials for synthesis such as; physical, chemical, and biological ways.Biological way was very important and most eco-friendly approach. In current study, we use *Trichoderma orientale* that gives good diversity and dimensions. The synthesized AgNPs are confirmed by various techniques such as; UV.VIS spectrum, FTIR analysis, and identified the antifungal activity.The peak absorbance of AgNPs for this species used in this study was 500nm. In addition, FTIR analysis was showed the presence of proteins which may responsible for the efficient reduction of nanoparticles. Also, the antifungal activity for T.orientale was identified by using several concentrations such as; 25,50,100, and 150mg/ml, the results obtained from this study revealed that the nanoparticles that responsible for silver synthesis show a significant tolerance to the antifungal activities when isolated by the concentration method. It was observed that the maximum reduction of this fungi at 150 mg/ml of AgNPs.

Keywords: *Silver nanoparticles; Antifungal activity; Trichoderma orientale; FTIR analysis.*

Introduction

Nanotechnology is the first major worldwide research initiative of the 21st century.Nanotechnologies are general purpose technologies that act as both the basis for technology solutions across a range of industrial problems or as a nexus for the convergence of other enabling technologies like biotechnologies, computational sciences, physical sciences, communication technologies, cognitive sciences, social psychology and other social sciences[1].Accordingly, these environmentally-friendly biological systems may be considered as benign nanofactories. It must be pointed out that many such microorganisms are biologically poisonous to humans, animals and plants, and care must be taken in their choice for production of nanoparticles.Nanotechnology has maximized the applications by minimizing the size of particles. The unique size dependent properties make these materials superior and essential in many areas of human activity. Nanotechnology has numerous applications in various fields like medicine, food industries, agricultural fields etc[2]. It is demonstrated that using the dissimilatory properties of an eukaryotic organism such as fungi may be used to biosynthesize and grow nanoparticles. It is shown that certain fungi have the ability of producing extracellular metabolites that serve as agent for their own survival when exposed to such environmental stresses like toxic materials (such as metallic ions), predators and temperature variations[3].In the biosynthesis of metal nanoparticles by a fungus, the fungus mycelium is exposed to the metal salt solution. That prompts the fungus to produce enzymes and metabolites for its own survival. In this process the toxic metal ions are reduced to the none-toxic metallic solid nanoparticles through the catalytic effect of the extracellularenzyme and metabolites of the fungus. The presence of hydrogenase in fungi, such as *Fusarium oxysporum*,*Trichoderma reesei*, and *Trichoderma viride*, was demonstrated with washed cell suspensions that had been grown aerobically or anaerobically in a medium with glucose and salts amended with nitrate. The nitrate reductase was apparently essential for ferric iron reduction[4].

"Several studies have shown that metal nanoparticles, such as gold, silver, gold-silver alloy, selenium, tellurium, platinum, palladium, silica, titanium, zirconium, quantum dots and magnetite can be biosynthesised by bacteria, actinomycetes, fungi and viruses revised by[5]". There are three main method of synthesizing metal nanoparticles: Chemical, physical andbiological method. The radiation-induced AgNPs synthesis is a simple, clean which involves radiolysis of aqueous solution that provides an efficient method to reduce metal ions[6.] "Antifungal activity of ionic or nanoparticle silver has a great potential for use in controlling sporeproducing fungal plant pathogens. Silver may be less toxic to humans and animals than synthetic fungicides". "In present study, we investigated the biosynthesis of AgNPs using *Trichoderma ortientale*, and its underlying mechanisms, the properties of obtained AgNPs were characterized by ultraviolet-visible spectrophotometer, and FTIR techniques. This work evaluate the efficacy silver compounds for suppression of pathogenic fungi."

Method

Fungal species: This isolation (*Trichoderma orientale*) was taken from the advanced fungi laboratory/ Department of Biology/Faculty of Science/University of Babylon.

Growth Media

Potato dextrose agar (PDA): This media was prepared according to the Indian company (HEMIDIA) by dissolving 39 gm of medium in 1 liter of distill water, mix thoroughly and then added a chloramphenicol that concentration 250mg/ml. It is then sterilized by autoclave at 121°C for 15 minutes, finally cooled to 45°C and poured into sterile petri dishes.

Potato dextrose broth (PDB): This media was prepared according to the Indian company (HEMIDIA) by dissolving 24 gm of medium in 1 liter of distill water, mix thoroughly and then added a chloramphenicol that concentration 250mg/ml. It is then sterilized by autoclave at 121°C for 15 minutes, finally cooled to 45°C and kept into sterile tube.

Biomass preparation: *T.orientale* isolate was grown in a flasks volume 250 ml, each flask containing 100 ml of liquid medium (BDB), this isolate incubated in orbital shaker at 28°C and agitated at 150 rpm for 3 days. After incubation period, fungal biomass harvested through Whatman No.1, later thoroughly wash with deionized waterto remove the effect of culture media from the biomass.After that, 20 gm of soft biomasswith deionizedwater (flask 250 ml) was incubated at 28°C for 3 days and agitated at 150rpm. Finally, the biomass was filtrated using Whatman No.1, fungal filtrate was used for manufacture of nanoparticles.

Extracellular synthesis of AgNPs: In order to manufacture of nanoparticle particle from the extracted fungal filterate, 50 ml of fungal filterate mixed with 50 ml of $AgNO_3$ solution.place the mixture in flask 250 ml and incubate the flasks at 28°C for 3 days. The reaction mixture without silver nitrate was used as control. All mixtures were kept in the dark to ovoid light events during the experiment. Finally, AgNPs were centrifuged at 10,000 rpm for 10 minutes and repeated twice, and collected for further characterization.

Characterization of AgNPs: The first step in the characterization of silver nanoparticles using the U.V-VIS spectrophotometer, where recorded wavelengths at range between 300 to 750 respectively. U.V spectroscopy is a type of analysis used to measure the intensity of light absorbed and disseminated by the sample used. The spectra was used from AgNPs solution showed a peak absorbtion at 500 nm which was designated for nanoparticle particle.

Fourier transform infrared spectroscopy (FTIR): "The chemical composition of the synthesized silver nanoparticles was studied by using FTIR spectrometer **(**perkin-Elmer LS-55-Luminescence spectrometer**)**. The solutions were dried at 75°C and the dried powders were characterized in the range 4000–400 cm-1 using KBr pellet method".

Characterization of antifungal activity: To characterize the effect of antifungal activity, different concentration of silver nitrate solution were used (25,50,100, and 150 mg/ml).Mix 5 ml of each concentration of silver nitrate solution with PDA medium and then pour into petri dishes.After that, incubate the plates that containing silver nitrate solution and PDA at 28°C for two days. After 2 days of incubation, agar disc (5 mm) containing fungi were inoculated simultaneously at the center of each Petri plates containing Ag NPs, followed by incubation at 28°C for 5 days. Finally, growth inhibition is measured by using the following equation:

$$\text{Growth inhibition} = \frac{G - g}{G} \times 100$$

G = radial growth of fungal mycelia for control, g = radial growth of fungal mycelia with silver nanoparticles

Results and Discussion

Extracellular biosynthesis of AgNPs: In the current study, the results were shown the possibility of synthesis AgNPs.*T.orientale*was used in the synthesis of silver nanoparticles based on their high efficiency, rapid growth, and production of large amounts of biomass. In order to distinguish nanoparticles, it was observed the color of fungal filterate that mix with silver nitrate changed from pale yellow to dark purple. This indicates the formation of AgNPs (Figure 1 & 2).A possible mechanism for the conversion of silver ions into nano form by using fungal biomass could be the extracellular reduction of silver ions in the solution followed by precipitation on to the cells. This may be the reason for the gradual change in color of the silver nitrate treated *Trichoderma* supernatant from pale to brown[7,8]. There is no color change noted in the control flask incubated in the same environment.

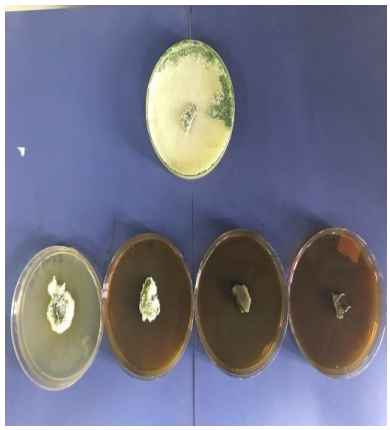

Figure 1: Agar plate of T.orientlae

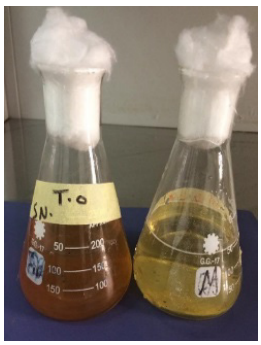

Figure 2: AgNPs biosynthesis A-control, potato dextrose broth with fingi (Negative control) B-Positive results color change AgNPs formation

Characterization by UV-visible spectroscopy: Figure 3 was shown highest absorption of *T. orientale* at 500 nm that treated with silver nitrate, Wherese no absorption of the control was observed. These results were compatible with [9]that confirmed the optimal wavelength of Trichoderma at range between 300-500 nm. According to the characteristic of nanoparticles, it was become important in many areas in recent years such as energy, health care, environment, and agriculture. Many organisms have been used to manufacture extracellular silver nanoparticles, fungi is one of the most important organism that used to synthesis silver nanoparticles by using biological method. The UV-visible spectroscopy studies could be considered as the most useful technique for structure characterization of silver nanoparticles. "[10] confirmed electrons stimulated by an interactive electromagnetic field that called surface plasmon peak.So we confirmed that these isolates have more potential to reduce Ag ions into Ag nanoparticles, which lead us for further research on synthesis of silver nanoparticles. The intensity of absorption peak increase with increasing time. The reduction of metal ions occurs on the surface by the enzymes presented in the cell wall[11] The maximum synthesis wavelength of Ag for *T.orientale*was shown at 500 nm [12].

In addition[13,14] also showed the optimal U.V absorption beak for *Trichoderma sp*at range 400-500 nm.

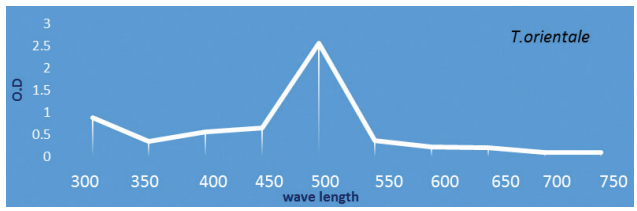

Figure-3: UV-VISSpectrumof AgNPs synthesis by T.orientale

FTIR analysis of Ag-NPs: The silver nanoparticles were analyzed by using FTIR analysis method to establish the relationship between silver and active compounds produced by fungi.These active compounds play an important role in the reduction of metal ions, stability, and AgNPs. The amide linkages between amino acid residues in proteins give a important signature in the infrared region of the electromagnetic spectrum. Therepresentative spectra of nanoparticles obtained manifest absorption peaks located at about 2360 cm^{-1} (aromatic-CH stretching) 1683.966 cm^{-1}(-NHCO of amide) and 825.16cm^{-1} (C-CI). Figure 4 showed the analysis of beaks for *T.orientale*.FTIR analysis was

used to support the presence of proteins to synthesis of silver nanoparticles. The phytochemicals may be serve as reducing agent for the conversion of Ag^+ to Ag 0 and to act as capping and stabilizing agent of AgNPs in the present study[15].

The main important potentially active functionalgroups for Ag-NPs, Ag^+ ions, andanisotropic growth are the Tyr residues from hydroxyl groups and Asp, Glu residues fromcarboxyl groups. The peaks 1384.47 may represent the residual nitrate (NO-3). Peaks at 1154.88 cm-1and 1078.10 cm^{-1}, indicates-N-H and carbonyl (C-O-) stretching vibrations respectively in amide linkages of proteins re. The peak formed at 2921.20cm^{-1} could be due to C-H stretch of methylene groups of proteins[16]. Further, it is reported to be responsible for the prevention of agglomeration of green synthesized AgNPs. Therefore, it is concluded that the phytochemicals/biomolecules present in the above plant sources played a dual role in the formation and stabilization of the green synthesized AgNPs.

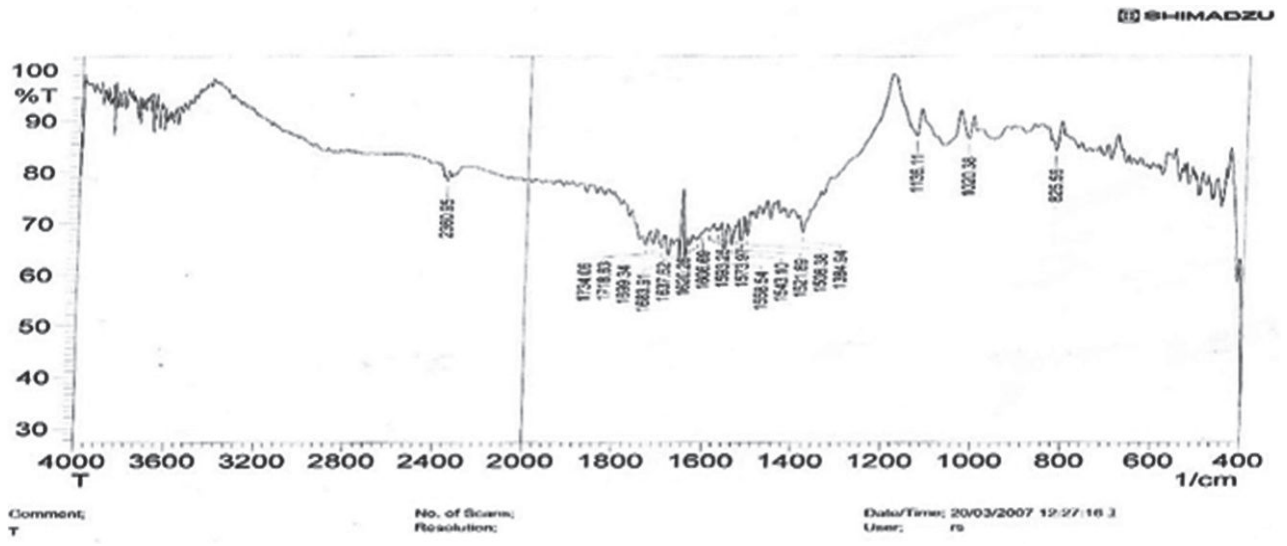

Figure 4: Detection of various functional groups by FTIR from *T.orientale*

Antifungal Activity: In the current study, the growth inhibition of *T.orientale* was tested using different concentration of silver nitrate (25,50,100, and 150 mg/ml). PDA medium was used to study the growth inhibition. After the end of incubation period, the results showed the highest inhibition of this fungus was at 150,100 mg/ml compared with other concentration which also gave inhibition but less at 81.2 and 91.2% respectively, figure 5, table 1. The current results were shown that silver nanoparticles were able to inhibit the growth of *T.orientale*, When the concentration of silver nanoparticles increases the inhibition growth also increased.. In our study, silver nanoparticles were found very effective agent against bio-control agent fungi such as *T.orientale*. There are many mechanisms of inhibitory effect of Ag on microorganisms such as DNA loses its ability to replicate[17]", "resulting in inactive expression of ribosomal subunit proteins, instead of some other enzymes and cellular proteins necessary to the adenine triphosphate production[18]". In addition, it has been supposed that silver ion primarily affects the membrane-bound enzymes functions for instance those in the respiratory chain[19]. "Similar results were previously reported by[20&21], who tested the effect of SNPs on bacteria and fungi using the same method.[21] observed SNPs antifungal activity against several fungi as *candida* spp, *Aspergillus* spp, and *Fusarium* spp, presenting the concentration that effect on fungal species are 150 mg/ml. Recently,[22] showed SNPs possess antifungal activity effects through apoptosis".In previous study, the biological synthesis of silver nanoparticles was found to be most active against the bio control isolates such as *Trichoderma*. The results proved that silver nanoparticles showed maximum activity at high concentration, which revealed silver nanoparticles as novel antifungal agent

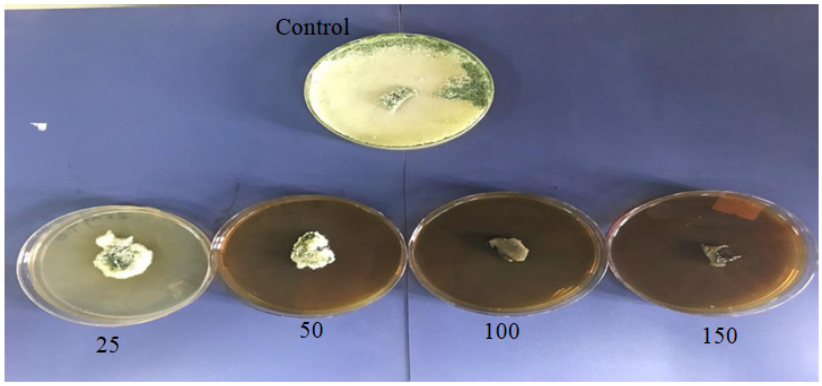

Figure 5: Growth inhibition of extracellular silver nanoparticles against plant pathogenic fungi.

Table (1): Antifungal activity of extracellular silver nanoparticles against fungi (Inhibition%)

Species	Different concentration (mg/ml)			
	25mg	50mg	100mg	150mg
T.orientale	81.2%	91.2%	100%	100%

Conclusion

In conclusion, the bio-control fungus, *T.orientale*has shown potential forextracellular synthesis Ag-NPs. Synthesis of Ag-NPs using the cell free filtrate is rapid. This indicates nanoparticle synthesis from biological process is quick suitable for larger scale production. The characterization of Ag-NPs was through UV visible spectrophotometer and FTIR analysis. Nanotechnology exhibits contemporary and revolutionary approach to formulate and to test the new approaches based on antifungal properties from the metallic nanoparticles. Ag-NPs showed remarkable antifungal activity against*T. orientale*.

Correlation Between the Level of Milk Urea Nitrogen (MUN) when Insemination with Pregnancy Rate and IGF-1 Profile on Frisien Holstein Dairy Cow

M. Ardiansyah[1], Tita Damayanti[2], Tri Wahyu Suprayogi[5], Imam Mustofa[2], Ismudiono[3], Wurlina[4]

[1]Master student of Biology Reproduction and Veterinary Reproduction, [2]Laboratory of Obstetrics Veterinary Department Veterinary Reproduction, [3]Laboratory of Fisiology Reproduction Department Veterinary Reproduction, [4]Laboratory of Reproduction Disease Department Veterinary Reproduction, [5]Laboratory of Insemination Department Veterinary Reproduction, Faculty of Veterinary Medicine; Airlangga University, Jl. Mulyorejo, Kampus C Unair, Surabaya, Indonesia

Abstract

MUN is high due to high protein content in feed, Thehigh level of MUN can affect hormonal systems including growth hormone IGF-1 and reduce pregnancy rates. The aim of this study is to determine MUN as an indicator of feed evaluation and see the corelation between MUN and IGF-1 levels and pregnancy rates. The cows according to the criteria were sampled to determine the levels of MUN and IGF-1 then processed with the application curve ekspert 1.4 and SPSS 20. Value r = 0.75 between MUN and IGF-1 stated that there was a strong correlation between the two. There were significant differences between MUN and pregnancy rates (P <0.05). High and low levels of MUN will affect pregnancy rates. All sample of MUN with levels of 17-28.5 mg/dl did not have pregnancy and MUN with levels of > 12 mg/dl was obtained in five out of eight pregnant.

Keywords: *Milk Urea Nitrogen (MUN), IGF-1 hormone,pregnancy rate, Blood Urea Nitrogen (BUN) and Dairy cow.*

Introduction

Protein as a feed substance needed by livestock to fulfill basic life needs.[1] The feed protein that enters the rumen will initially undergo proteolysis by protease enzymes into peptides, then hydrolyze to amino acids which then quickly deaminated to ammonia and α-keto acids.[2] Ammonia as the result of deamination will be absorbed through the rumen wall to the portal blood circulation, which then converted to urea in the liver. [3]Excessive urea will be absorbed by the blood and excreted in the form of urine.[4] The results of urea synthesis originating from blood urea will be used to be recycling through urine and also diffuse into the udder gland to become MUN. [5] The high Urea contained in the blood and milk exceeds the limit of 18 mg/dL, will disrupt the folliculogenesis and reproduction process. [6] And can experience the risk of reducing pregnancy. High MUN concentrations in cattle significantly reduce pregnancy rates only at the first lactation, increasing normal Urea can reduce fertility by 18%.[7] So the researchers wanted to know the correlation between the levels of MUN and IGF-1 levels and pregnancy rates.

Material and Method

Sampling Technique: The population used in this study was the Frisien Holstein (FH) lactation dairy cow obtained from field and recording data that matched the criteria. The samples taken in this study are milk, blood and pregnancy taken.

Research Locations: The sampling location was carried out on the farm in the precept, Sumbersuko village, Wager sub-district, GunungKawi-Malang.

Proximate Analysis: Proximate analysis is carried out to find out the value of the concentrate and grass given.

Collections Milk Samples: Milk samples were taken when the time of insemination, taken once in the afternoon directly from the 50 ml udder which was put into sterile milk plastic and then stored on the ice box.

Collection Blood Samples: Blood samples were taken 10 ml through the coccygeal vein using venoject and needle on day 0, day 7, and day 22 after insemination and then left in a slanted condition so that the serum could be taken.

Examination of Milk Urea Nitrogen (MUN) levels: The Urea Nitrogen Milk (MUN) referred to in this study is a by product of undigested protein metabolism in dairy cows which the levels are considered the same as BUN and examined by the Barthelot method.

Examination of IGF-1 Hormone Levels: To check serum IGF-1 levels using the ELISA sandwich method.

Data Analysis: The data obtained were analyzed by correlation and regression with expert curve software 1.4 and SPSS 20 software.

Results and Discussion

The Correlation of MUN with IGF-1 Levels: The level of urea nitrogen above 8-12 mg/dl can have a negative effect on reproduction such as: increasing service per conception, decreasing pH in the uterus and disrupting the balance of reproductive hormone levels. [8] Decreased levels of progesterone in blood serum are associated with reduced concentration of IGF-1. The results of this study indicate a correlation or relationship between levels of MUN (Milk Urea Nitrogen) (Figure 1). This study was supported by.[9] stating that dairy cows with BUN levels of ≥18 mg/dl were all not pregnant with low IGF-1 levels. the dairy cows with low BUN levels and are pregnant, they have higher IGF-1 levels, and are lower in non-pregnant cows. IGF-1 hormones are high in pregnant dairy cows, but low in non-pregnant cows. The statement shows that high levels of BUN result in low IGF-1 levels. High blood urea can increase milk urea levels, because theblood urea diffused into the udder gland. Urine nitrogen can be reflected from MUN, because high urine nitrogen will be followed by high MUN levels.[5]

The Correlation of MUNWith Pregnancy Rates: Low IGF-1 levels due to high levels of MUN can interfere with folliculogenesis and reproductive processe.[6]And can caused the risk of reducing pregnancy. High MUN concentrations in cattle significantly reduce pregnancy rates only in the first lactation, MUN ≥18 mg/dl, an increase in normal Urea can reduce fertility by 18%. [10] This study also proves the existence of a correlation between MUN levels and pregnancy rates. MUN in the range of 9-12 mg/dl pregnancy was obtained five from eight samples while MUN with a range of 17-28.5 mg/dl obtained 7 samples did not experience pregnancy (Table 3). This shows that high levels of MUN in cattle can caused the rate of pregnancy decreased.

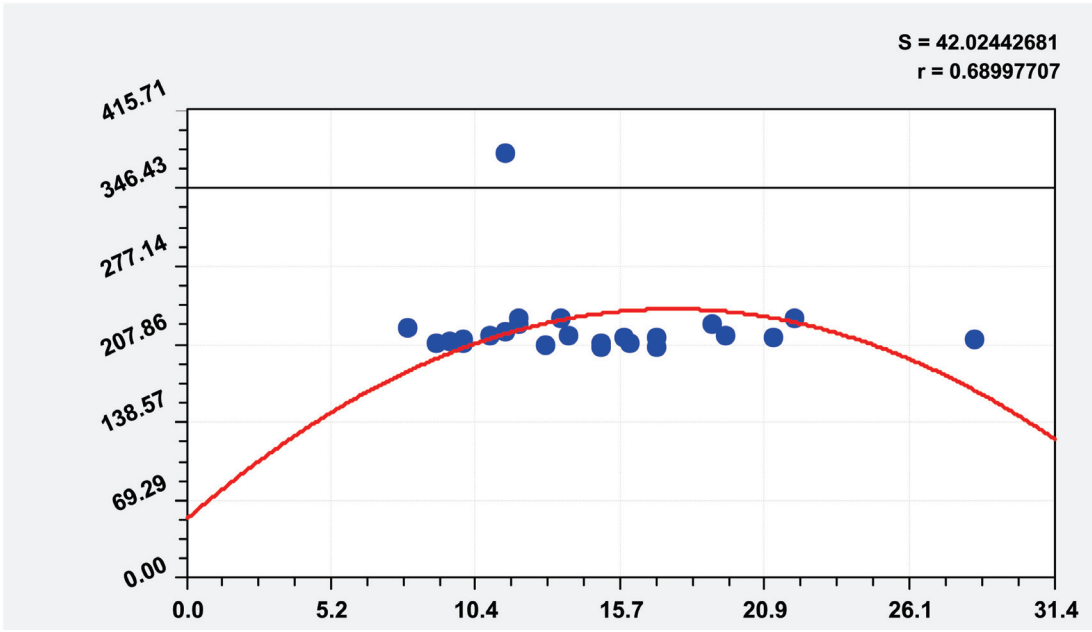

Figure 1. IGF-1 H0 correlation curve and MUN level

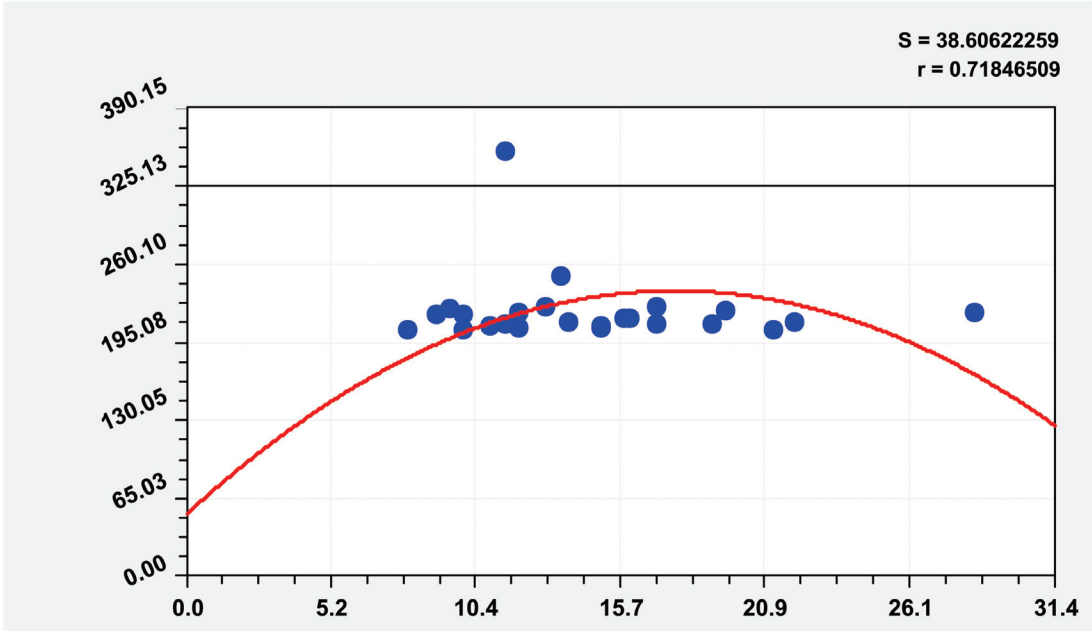

Figure 2. IGF-1 H7 correlation curve and MUN level

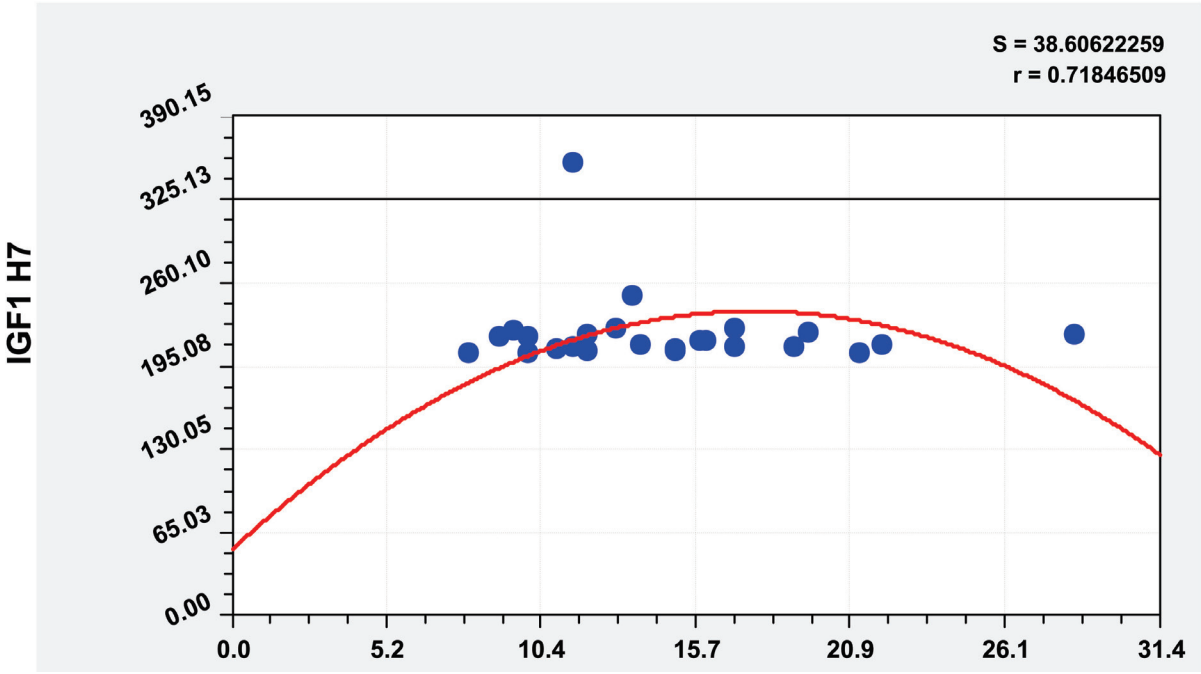

Figure 3. IGF-1 H22 correlation curve and MUN level

Conclusion

There is a high correlation between MUN levels and IGF-1 levels (r = 0.75) and there is a correlation between MUN and pregnancy rates, cows did not pregnant at MUN 17-28 mg/dl and five out of eight samples were obtained pregnant at MUN 9-12 mg/dl. Low and high level of MUN affects to the IGF-1 level and pregnancy rate.

Competing Interest: The authors declare that they have no competing interest.

Source of Funding: The authors would like to thanks the my parents, H.M Kasranto and Arliksuwati.

Ethical Approval: The research does not need ethical approval. However, samples were collected as per stand art collection method without any harm and stress to the animals.

Anxiety and its Relationship of Scoring Skill on Football Young Players

Mahmoud Abdul Jalil Abdul Zahra Tamimi[1], Imad Nasser Hussein[1], Fadhil Breesamshair[1]

[1]Faculty of physical Education, The Ministry of Higher Education and Scientific Research, University of Kufa, Iraq

Abstract

The skill is express of the ability of the individual and mastery of the work and is influenced by the factors surrounding the individual with different degrees, the football scoring of the basic skills, which is an adjective affected negatively or positively, it has a great impact on the outcome of the match where the research aims to identify psychological anxiety and its relationship to accuracy of football shooting,The sample included (20) player from team players of Furat University East Technica and has been used descriptive approach with the sample members through one of the accuracy tests where the laboratory shooting the ball on the goal and the goal is determined by three squares for each square degree and given to the laboratory three attempts for each player. Therefore It is statistically processed and reached the conclusions were The importance of a significant correlation between anxiety and scoring skill of football,as well as the accuracy of scoring is negatively affected with the high level of anxiety and the study approved some recommendations, the most important was the need of coaches and teachers to take constant attention to the levels of anxiety which affected the players and students during the matches and direct them to the lowest level.

Keywords: *anxiety, psychologically effect,cognitive.*

Introduction

The great development in the field of scientific research is one of the most important advantages of the modern age, which spread of the different fields of life. Since the sport is one of these fields in sports it has a large share in various psychological, physical, skill and other changes, The adoption of various scientific means has become very important to achieve a high progress at the sport level[1]. The use of psychological anxiety tests is an important and complementary to the training process which enables the trainer to recognize of curriculum effectiveness to create a necessary functional adaptations and the ability of the players psychologically for skill performance also the convergence of players' levels, physical, technical and planning. Hence the focus on the psychological factor of anxiety during training, competitions and official matches where levels of anxiety are different, such as the training period and official participation which subject to the situation of the player, where the basic skills and its mastery of football has an important role in the football game. Hence, the researchers wanted to highlight on the psychological state of player through the knowledge of anxiety being a personal status and its impact on the accuracy of football scoring through the use of dimensions of anxiety as a cognitive, physical and ease of emotion of the young players of Najaf Sports Club of football.

Problem of the research: It has become a good performance of skills for some players in advanced stages, but it is no longer the only indicator of the player efficiency and the effectiveness of his performance in the stadium, because the integrated preparation depends on other psychological and physical factors in addition to the skill preparation and through the researcher experience being a young football player of Iraq and doctorate in physical education, Through the investigation of research belong the anxiety in the sports side, the researcher found that there is a lack of research in the sports field of football, which attracted the researcher to study this problem and find some correct solutions and treatment it, the physical factor one of the basic elements in training field of football which did not receive enough attention in sports training field being the anxiety one of the psychological emotions which it's responses effect on accurate of skill performance, The researcher found that there is a great attention of the technical and physical aspects without enough attention to the psychological aspect, especially the anxiety and it's

dimensions of the cognitive, physical side, ease emotion and the relationship between anxiety and scoring skill of football players being the anxiety and it's dimensions one of the foundations of the integrated preparation of the player and the team.

The concept of anxiety: Anxiety is a complex emotion of internal tension and a sense of fear. Anxiety is the most important type of emotion[2]. The anxiety relate with fear of the one of the effective functions by the individual performance in any work. As defined by [3]that the anxiety as an emotional state in the case of yellowing the face or stuttering in this case the anxiety is apparently negative [1]. He suggested that " the anxiety as "an emotional state in the case of yellowing of the face or stuttering, in this case the anxiety is apparently negative [3].

Anxiety is characterized as relativity temporality (except for the anxiety of case) or at least longer at its period effect; the severity of anxiety is often greater than the real anxiety, which is unknown. Anxiety is a state of fear that has occurred in the past or may occur in the future[4].

Types of anxiety: Psychology has established evidence of anxiety that has a positive value in addition to the negative effects. It plays an important role and it can be a positive motive force or vice versa negative motive force for this purpose the anxiety is divided into[5]

1. Neurological anxiety
2. Moral anxiety
3. Substantive anxiety
4. Anxiety case
5. Feature anxiety

Anxiety levels: It is not strange to say that anxiety is associated with human life in all its details, but the anxiety found in anywhere of life, the type of anxiety and it's levels from one stage to another stages of human, but the level of anxiety in general can be divided into three levels are[6]:

- Low level.
- Intermediate level.
- High level.

Low Level: A certain degree of anxiety is a necessity for help to prepare for life's needs, so, a low level of anxiety acts as a motivation, incentive or activator for the individual because the student's anxiety before the exam will push him to study and the player's anxiety before the race will push him to the continuous exercise in preparation for the race, will motivate him and ready to make the best effort to achieve the best achievement

Intermediate Level: Sometimes the level of anxiety increases to the extent that it partially effects on the performance, in the intermediate level the athlete in general and the player in particular lose part of his ability of control and include excessive movements through excessive effort, hesitancy and fear of the opponent.

High level: Where the individual acts inappropriate behavioral method of the situations he passed result of the speed of irritability, random behavior, the inability to focus and attention, we notice sometimes negative effects begin to clear on the player's behavior and his performance, lose his ability on focus,do more mistakes, characterized his behavior by nervous and do fast and strong movements that lack the accuracy as he exert high energy without justification leading to loss of energy and lack of focus of competition in the raceearly.

Anxiety of Sports Field: The achievements of individuals and their behavior is an expression of the tendency of personal aspects and the sports achievements of the individual depends not only on the development of physical and skills capabilities, but also affected by many psychological factors such as motivations, desires, convictions, perception, thinking, psychological readiness, fear and anxiety.

We see the player proud and happy when his efforts end with the right development in order to reach the highest stages and vice versa when he gets tired, paralyzes his movement and less motivation and determination,may appear fever start or indifference.

Sports anxiety is one of the emotions and has a significant impact on the player and his field performance before competitions and important matches, during and after this matches, when evaluating the results of the player shows his level of disappointment and does not commensurate with the level of results shown during the training, this is due to the errors occurred in the skills implementation and tactical to the emotional state of the player[7].

Anxiety in sports field is a double-edged; Anxiety may be facilitated and may be disabled. In the first

case, anxiety plays the role of catalyst, which makes the player recognize the source of anxiety and prepares himphysically and psychologically to overcome it, while in the second case, anxiety disrupts work through its negative impact on the player's psychology.

We conclude that anxiety in the sports field has a positive and negative impact, The positive effect is the effect plays an important role in the required performance of the player and control his temper reverse of the negative effect of the anxiety that works on the player psychical who feel of afraid, hesitation and tension that effectson his performance in the competition.

Football: Football is a team sport played between two teams of eleven players by round ball. Football is played by 250 million players in more than 200 countries around the world; therefore football is the most popular sport in the world. Football is played in oblong stadium with two goals on each side. The goal of the game is scoring the goals by kicking the ball into the goal.

The goalkeeper is the only player allowed to touch the ball with his hands or arms, provided that he is inside the penalty area[8]. The players' non-goalkeepers often use their legs to attack or pass the ball and can also use their head to hit the ball. The team that scores more is the winner. If the two teams score equal goals at the end of the match, the result of the game will be either equivalence or the game will enter into the system of overtime or penalty shootout depending on the Championship system. Football laws in England were established by the English Football Association in 1863. International football is presided over by FIFA,The World Cup is held every four years and is the most important Championship in the world.

Football has evolved throughout the history, as well as its own rules and regulations, till retched to the current stage of modern football, which is not focus on attacking and scoring many goals as far as became focus on tactics and skill. Football represent of the general organization which uses the coach of football team to control the team's movements on the playground to achieve the planned result.

The Research goals:

1. Identify the anxiety and deportation of young players in the Najaffootballclub.
2. Recognize the accuracy of the scoring skill of football among young players in Najaf FootballClub.
3. Identify the relationship between the scoring accuracy and anxiety among young football players.

The Research hypotheses: There is a statistically significant relationship between the anxiety and its dimensions and the accuracy of scoring football among the young players of Najaf football Club.

The Research fields:

1. Human field: players of Najaf Football Club for the year 2018-2019.
2. Timefield: from 22-11-2018 to 24-2-2019.
3. Spatial field: playground of Najaf football Club.

The Research Methodology: Researchers had to use the descriptive approach in the hypothetical relationships method to determine the relevance of two variables [6] or more, because the descriptive approach works on depict the situation and determines the relationships between phenomena and trends that are on the way to growth [7].

Population and Sample Research: The most important objectives set by the researchers and the procedures that will determine the nature of the selected sample [8].

The researchers selected the research sample from the players of Najaf Youth Club for the year (2018-2019) and the sample was selected randomly numbered of (20) players.

The Research tools and devices used: Thepurpose of obtaining the correct and accurate scientific results, the researchers needs tools and means to help complete the research and how to solve the problem [9].The researchers used:

1. Arab and foreign references and scientific sources.
2. Anxiety removal form for each player.
3. Exit pollform of experts in physical education in general and physical psychology in particular.
4. Testing and measurement.
5. Legal balls.
6. Tape measure 20 m

The Research procedures: Determination of Anxiety Measurement Instruments and its dimensions: The Anxiety Measurement Instrument and its dimensions and its design shall determine by Mohammed Jassen

Allawi and applied on the Egyptian environment and the similar of Iraqi environment, Anxiety scale of the physical match 1994 [10]. It consists of three dimensions are:

1. Physical dimension
2. The cognitive dimension
3. After the speed and ease of emotion

Correction of the measure: The multidimensional anxiety scale includes (45) phase,three-dimensional words and each dimension contains (15) phase. The player answers the phases based on the graduated scale included (ABA-sometimes-often-always), the scale of positive phases is corrected by degrees of one degree (Start), two degrees (sometimes), three degrees (often), and four degrees (always).Either negative phrasescorrected as follows (four degrees (start)-three degrees (sometimes)-two degrees (often)-one degree (always), the range of degrees for each dimension ranges from (15) degrees to reach the maximum (60). The minimum theoretical degree of the scale as a whole is (45) degrees and the theoretical value of the scale as a whole (180) degrees, the closer of the player's score to the maximum score, whenever higher the characteristic, of dimension measures as follow table:

Table (1): The phase numbers which measure the multidimensional anxiety by two ways:

Measure	Positive phrases numbers	Negative Phrase Numbers	Total
Cognitive dimension	21,18,15,12,9,3 42,39,33,30,27,24	45,36,6	15
Physical dimension	31,28,22,19,16.13,7, 4,40,37,34	43,25,10,1	15
After the speed and ease of emotion	26,23,20,11,8,5,2, 44,35,29	41,38,32,17,14	15

Assessment of Iron Chelation Therapy Compliance among School Age Children with Thalassemia

Marwa A. Abdel Rahman[1], Azza A. Attia[2], Mona K. El Ghamrawy[3], Asmaa M. Hassan[4]

[1]Clinical Instructor of Pediatric Nursing, [2]Professor of Pediatric Nursing, Pediatric Nursing Department, Faculty of Nursing, Cairo-University, Egypt, [3]Professor of Pediatrics, Faculty of Medicine, Cairo-University, [4]Lecturer of Pediatric Nursing

Abstract

Background: Iron overload is the most important cause of mortality in children with thalassemia major,iron chelation therapy (ICT) is therefore a critical issue in the management of these children, so compliance with ICT is crucial in preventing iron overload related complications.

Aim: The study aimed to assess compliance with (ICT) among school age children with thalassemia.

Method: A descriptive exploratory research design was utilized. **Setting:** this study was carried out at outpatient hematology clinicat Al-Mounira Pediatric Cairo-University Hospital.

Sample: A purposive sample of one hundred school age children with thalassemia.

Tool: The required data was collected by using structured interview questionnaire which consists of three parts to assess;child and caregiver personal data, child's knowledge about thalassemia, blood transfusion and iron chelation therapy, compliance with iron chelation therapy and factors affecting compliance.

Results: More than three quarters of children their age ranged from 9 to 12 years old and nearly two thirds were males, one third of children received parenteral therapy Desferal, and about two thirds received oral chelators (Ferriprox and Exjade), the higher compliance rates were for children on Exjade,followed by Ferriprox, and thelowest compliance rates were for children on Desferal,the mean serum ferritin value was lowest in compliant children rather than non-compliant, also the lowest ferritin levels were in children on Exjade while the highest values were for children on Desferal.

Conclusion: More than half of children with thalassemia were compliant with ICT administration, compliance with oral chelators is better than parenteral and most of children prefer its convenience administration. The study recommended that factors affecting compliance with each iron chelation therapy must be examined to improve adherence to therapy through teaching.

Keywords: *Compliance, iron chelation therapy, school age children, thalassemia.*

Introduction

Iron chelation therapy (ICT) is necessary for the removal of excess iron among children with thalassemia, but treatment's efficacy and success are highly dependent on type and timing of the therapy as well as on patient compliance to treatment. Chelation therapy should be given regularly in order to work efficiently; this requires strong compliance to the chelation regimen. The more, the compliance to iron chelation therapy, more will be the life expectancy of the patient, with better quality of life and a lesser chance of iron related toxicity due to iron overload[1].

Poor compliance to chelation therapy and severe iron overload among children has been reported in both

Corresponding Author:
Azza A. Attia
Professor of Pediatric Nursing

Contact No.: 002-01068357272

developed and developing countries including United States, Pakistan, Egypt, India, Japan, Italy and Dubai. Children with poor compliance to chelation therapy develop complications of iron overload including cardiac failure, cirrhosis, growth retardation, delay in sexual maturation, diabetes mellitus, hypothyroidism, hypoparathyroidism and osteopenia, However lifelong administration of iron chelation regimens has posed challenges to the health team and patients equally[2].

Operational definitions:

- Compliance for oral chelators measured by calculation of number of doses administered in the last 4 weeks and on the basis of achieving 90% of medication administration.
- Compliance with Desferal measured by administration of medication for at least 5 nights per week for at least 8 hours/day.

Aim of the study: The aim of the current study is to assess compliance with iron chelation therapy among school age children with thalassemia.

Research question: What is the level of compliance with iron chelation therapy among school age children with thalassemia?

Method

Research Design: A descriptive exploratory research design was utilized.

Setting: The proposed study was conducted at outpatient hematology clinic which allocated at Al-Mounira Pediatric Cairo-University hospital.

Participants: A purposive sample of 100 school age children with thalassemia, who are receiving regular blood transfusion, andiron chelation therapy. Three quarters of children (76%) aged between 9 to 12 years old with mean age =10.6±1.4 years, 62% were males, and 53% ranked as the first child. Most of children (85%) attending school, 67.1% of them had primary education, three quarters of children (75%) from rural residency, and 79%lived in families more than 5 members.

Data collection tool:

Structured Interview Questionnaire: It consisted of three parts, to assess:

Part I: Child and caregiver personal data which included:

Personal data sheet for child and caregivers: child's age, gender, rank, level of education; current school year, residence, and number of family members.

Part II: Child's knowledge about thalassemia, blood transfusion and iron chelation therapy: It was adapted from Gad Allah, (2007) [3], it included: child's knowledge about normal range of Hb., and the level required for blood transfusion, normal iron in the body,complication of iron overload, food that either contains high iron levels, helps in iron absorption, or that decrease iron absorption,and knowledge about iron chelation therapy, etc…..

Part III: Compliance and factors with oral and parenteral iron chelation therapy: include type of oral chelators; (Ferriprox or Exjade), age of starting the chelators, number of doses per day or week, reminder for administration, side effects, number of missed doses per month, causes of forgetting administration, action taken when forgot to take medication, precautions of administration, route of Desferal administration; (IV./ SC./IM.), compliance with days and hours, factors of non-compliance, such as side effects, prolonged treatment time, lack of family support, medication affect body image and appearance of the child, effect on school attendance and on daily living activities,etc…..

Validity and Reliability: Content validity of the tool was been reviewed by three experts in the field of pediatric medicine nursing and pediatric hematology medicine. The experts agreed on the content of the tools, but minor changes that would make information clearer and more precise were carried-out. Reliability of tools performed to confirm its consistency by using Alpha-Coefficient test; it was 0.7 which means high internal consistency and reliability.

Pilot study: It was carried out on 10 children of the total sample to test study tools in terms of its clarity, applicability and time required to fulfill it.

Procedure: After the ethical approval obtained from the ethics research committee, an official permission was obtained from the directors of Al-Mounira pediatric university hospital and the pediatric hematology clinics. The research investigator introduced herself to the caregiver and children with thalassemia. The researcher obtained the written consent from each caregiver after explanation the purpose and nature of the study. Also oral acceptance was obtained from children to participate in the study. The researcher met each child with his/

her caregiver at a special quite room at the outpatient clinic and before entering the outpatient clinic in order to fill out the structured interview questionnaire. The duration with each child was 20-30 minutes. After that the researcher attended the follow up visit of the child with the hematologist to detect for how extent the child was compliant to iron chelation therapy administration, this information was recorded in the study tool. Also the researcher collected the needed follow-up data from each patients file about chelation history, frequency, compliance and last Ferritin level. Every child's compliance with iron chelation therapy was assessed for only one time. The researcher was available two days/ week for data collection. Field work begins from June 2017 to January 2018.

Results

Table (1) revealed that35%, 33%, 32%, and 24% of children respectively received Exjade, Ferriprox, Desferal, and combined chelation therapy. Children who received parenteral Desferal therapy, 87.5% of them administered it via subcutaneous route and 12.5% via intravenous route. Children on oral iron chelators, 51.5% of them on Exjade and 48.5% on Ferriprox.

Table (1): Percentage distribution of children with thalassemia according to type and route of chelation therapy (n=100)

Items	No.	%
Type of chelation therapy:		
Exjade (oral)	35	35.0
Ferriprox (oral)	33	33.0
Desferal (parenteral)	32	32.0
Combined therapy (parenteral + oral)	24	24.0
Chelation therapy according to route of administration:		
Desferal therapy (n=32)		
Subcutaneous route	28	87.5
Intravenous route	4	12.5

Table (2) proved that more than half (56.3% and 53.1% respectively) compliant with Desferal either by days or hours, regarding total compliance 71.9% of children were non-compliant to Desferal and 93.8% of children had side effect from Desferal.

Table (2): Compliance among children on parenteral chelation therapy (n=32)

Items	No.	%
Compliant with days (more than 5 days/week)		
Yes	18	56.3
No	14	43.7
Compliant with hours (more than 8 hrs./day)		
Yes	17	53.1
No	15	46.9
Total compliance (by days and hours/day)		
Compliant	9	28.1
Noncompliant	23	71.9
Parenteral iron chelation therapy side effects: (n=32)		
Yes	30	93.8
No	2	6.2

Table (3) delineated that, when comparing the total compliance of Exjade to Ferriprox the ratio was 85.7% versus 54.5% respectively, Ferriprox has more side effect than Exjade (75.8% and 37.1% respectively) and the differences were statistically significant, children on Exjade were more compliant with blood transfusion and follow up than those on Ferriprox (91.4% versus 85.7%respectively), and the differences were statistically significant.

Table (3) Relationship between two oral chelation therapy regarding compliance, and side effects among children with thalassemia (n=68).

Items	Treatment Type				X^2 test	p-value
	Exjade (n=35)		Ferriprox (n=33)			
	No.	%	No.	%		
Total compliance with iron chelation therapy:						
Yes (90% and more)	30	85.7	18	54.5	7.95	0.005*
No (less than 90%)	5	14.3	15	45.5		

Items	Treatment Type				X^2 test	p-value
	Exjade (n=35)		Ferriprox (n=33)			
	No.	%	No.	%		
Have side effects:						
Yes	13	37.1	25	75.8	10.27	0.001*
No	22	62.9	8	24.2		
Compliant with blood transfusion:						
Yes	32	91.4	22	66.7	6.37	0.01*
No	3	8.6	11	33.3		
Compliant with follow up:						
Yes	30	85.7	20	60.6	5.50	0.02*
No	5	17.3	13	39.4		

Table (4) illustrated that, The compliant children among the three types of chelators have lower mean of ferritin level than non-compliant with no statistically significant differences; while in comparing the total sample mean among compliant and non-compliant the lowest ferritin level was for theExjadeand the highest forthe Desferal with statistically significant difference.

Table (4): Differences in ferritin level and compliance among three types of chelation therapy among children with thalassemia

Ferritin level by treatment type and compliance						Kruskal Wallis Test	p.value
Desferal (n=32)		Exjade (n=35)		Ferriprox (n=33)

Discussion

The current study results shows that the majority of children on Exjade were compliant with its administration, these results are supported by the study done by[4]in India about "Deferasirox in Indian children with thalassemia major: 3 years' experience" who reported that, the vast majority of children recorded good compliance with administration of Exjade. Additionally, the study of[5] about "Adherence to Deferasiroxamongbeta-thalassemia major children-a cross-sectional study in a tertiary care hospital" who found that more than half of children were compliant.

The current study findings demonstrates that more than half of children who received Ferriproxreported good compliance with its administration, these results were in accordance with[6]in a study titled "Experience with combination therapy of Deferiprone and Desferoxamine in β-thalassemia major patients with iron overload at Maternity and Children Hospital, Al Madinah Al Munawarah, Saudi Arabia" who reported that half of children mentioned that they were totally compliant withFerriprox administration.

The findings of the present study clarifies that only less than one third of children on Desferal were compliant with days and hours of administration, these results are supported by[7]who reported that only about two fifth of children were compliant with Desferal administration, on the other hand, the result of the

current study is contradicted with[6]who reported that about two thirds of patient were compliant with daily administration of Desferal. Also the current study revealed that the majority of children had side effect from Desferal, these results are in accordance with[8]in a study titled "Compliance of Deferoxamine injection in beta-thalassemia major patients in Iran" who found that most of children suffered from Desferal side effects. From the researcher point of view, poor compliance with Desferal in the current study may be related to one quarter of children received combined chelation therapy (oral and parenteral) and may be dependent on oral therapy for reducing iron overload.

The results of the current study identifies that in comparing children's compliance with three treatment groups (Desferal, Exjade, and Ferriprox), the lowest compliance rates were for children on Desferal, followed by children on Ferriprox, the higher compliance rates were for children on Exjade, these results are congruent with[9]in a study titled "Compliance and satisfaction with Deferasirox compared with Deferoxamine in patients with transfusion-dependent beta-thalassemia" who found that compliance with Desferal was found only in few children while the vast majority were compliant with Exjade, These results answer the research question; what is the level of compliance with iron chelation therapy among school age children with thalassemia?

The current study findings reveals that compliance among oral chelators the Exjade is better than the Ferriprox, these results arein accordance with a study done in Egypt by[10] who found that the Exjade group had the highest compliance. From the researcher clinical observation, the difference between Ferriprox and Exjade groups may be attributed to the more frequent daily doses and side effects of Ferriprox, compared with Exjade, which was taken once daily and was devoid of these side effects.

Also the current study results stated that children's compliance with oral iron chelators is better than those who received parenteral chelation therapy, these results goes in line with[10][11]who reported that children adherence were reported to be better in those receiving oral iron-chelating agents compared with those taking subcutaneous infusions of Desferal.

The current study results reveals that the compliant children among the three types of chelators have lower mean of ferritin level than non-compliant with no statistically significant differences, these results are in agreement with [5]who reported that the mean serum ferritin level of compliant group was significantly lower than that of the non-compliant,also in relation to Desferal, there was elevation of mean ferritin level for non-compliant children rather than compliant, these results are supported by a study done in Iraq by[12] entitled "Therapeutic drug monitoring of chelating agent Desferal for β-thalassemia major patients" who reported that children who missed doses and not adhered to Desferal administration had ferritin level higher than totally compliant children.

Conclusion

More than half of children with thalassemia were compliant with ICT administration, compliance with oral chelators is better than parenteral chelators and most of children prefer its convenience administration. The study recommended that factors affecting compliance with each iron chela ti on therapy must be examined to improve adherence to therapy through teaching.

Ethical Clearance: Ethical approval was obtained from the research committee in the Faculty of Nursing, Cairo University. A written informed consent was obtained by the research investigator from the mothers of children with thalassemia after complete description of the purpose and nature of the study in order to obtain their acceptance as well as to gain their cooperation. Children under 12 years old, oral affirmative consent to participate in the study were obtained from those children. Parents were informed about their voluntary participation in the study and their right to withdraw from the study at any time without giving any reason and without any effect on the care of their children. Also parents were assured that all gathered information had been confidential and used only for the purpose of the study. The permission for adapted part from Gad Allah, (2007)[3] was attained.

The Relation between Health Literacy and Cataract Screening in Elderly People, Kalasin Province, Thailand

Metinee Methaneedol[1], Chulaporn Sota[2], Olan Suwan-apichon[3]

[1]Doctor of Public Health Program, Faculty of Public Health, [2]Department of Public Health Administration Health Promotion Nutrition, Faculty of Public Health, [3]Department of Ophthalmology Srinagarind Hospital, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand

Abstract

Vision impairment in elderly people due to cataract commonly affect including falls, confusion and reduced quality of life. Cataract screening may help in reducing their living with sight loss. This cross-sectional study aimed to study the relation between health literacy and cataract screening inelderly. Multi-stage random sampling was used to obtain data from 438 elderly people in Kalasin province. Interviewing was used for data collection. Descriptive statistic and logistic regression analyses were performed to investigate the relation between health literacy and the attendance of the cataract screening in elderly. The results revealed that 44.06% of elderly attending a cataract screening. The percentage of cataract screening attendance was greater among female (OR=2.29, 95% CI = 1.53-3.41), aged between 70-79 (OR=1.83, 95% CI = 1.22 to 2.74), with underlying disease (OR=5.45, 95% CI = 3.61 to 8.23), having annual health checkup (OR=5.21, 95% CI = 2.83 to 9.60) and distance from home to hospital less than 1 km (OR=1.77, 95% CI = 1.08-2.92). The attendance of cataract screening had significantly associated with health literacy at a good level of each skill which were access to information and services (OR= 2.42, 95% CI = 1.49 to 3.95), communication skills with professionals (OR= 2.42, 95% CI = 1.45 to 4.03), Self-management (OR= 1.90, 95% CI =1.19 to 3.04), media and information literacy (OR= 1.74, 95% CI = 1.10 to 2.75), decision-making skill (OR= 3.15, 95% CI = 1.82 to 5.46).

Therefore, to be successful in promoting public health and interventions to increase the coverage of cataract screening and the prevention blindness in the elderly, the measures should be concerned with the sociological gap, accessibility and especially, health literacy towards cataract.

Keywords: *Health Literacy, Cataract Screening, Senile cataract, Thailand.*

Introduction

Cataract is continuing to be the leading cause of blindness in the global population. Estimated almost 18 million people who were bilaterally blind from cataract[1], adults aged 50 years and older globally blind as 35% and 45% in Southeast Asia population[2]. In Thailand, a prevalence of blindness was 0.6% in people aged 50 and up[3]. Cataract was the main cause of vision loss accounted for 69.7% of blindness[4]. Vision problems due to cataract in elderly people were increasingly associated with chance of falls[5], diminished quality of life and diminished general functional living activities[6].

Cataract screening with surgical treatment are essential to correct and prevent loss of vision. “Vision 2020 Thailand”aimed to increase the coverage of visual screening in people aged 60 years and above to 80%. In 2017, an average of 76% of Thai elderly attended cataract screening at the Health Promoting Hospital[7]. In contrast, elderly in Kalasin Province shown lower rate of cataract screening,less than 65% and less than 15% in some rural areas. Consequently, many elderly people

Corresponding Author:

e-mail: chusot@kku.ac.th

have been undiagnosed for vision problems and are not received of proper treatment.

Health literacy plays a major role in promoting healthy preventive behavior[8]. The World Health Organization has defined health literacy as "the development of the cognitive and social skills which determine the motivation and ability of individuals to gain access to, understand and use information in ways which promote and maintain good health"[9]. Low health literacy had an association with poor well-being and negative health outcomes[10], particularly elderly people who have less adequate health literacy[11]. And, low health literacy also has correlated with low utilization of health services and low accessibility to health information[12].

Despite these findings, there has been little research on elderly people concerning their health literacy and its relationship to the attendance the of cataract screening. Therefore, this study aimed to investigate the relationship between socioeconomic factors and health literacy with cataract screening in elder people. The results will serve as a basis for developing programs to promote the utilization of eye care services in Thai elderly people.

Materials and Method

Study Design and Sampling: A cross-sectional study was conducted in Kalasin province, located in the northeast region of Thailand. The sample size was calculated using Krejcie and Morgan's formula[13] at a CI of 95% and further added 10% for the missing data. Thus, 438 elderly people were recruited from 18 districts by multistage sampling technique.

Data Collection: The questionnaire was adapted from the literature review and based on research questions, especially in the areas of health literacy which adapted from "Health Literacy Scale for Thais"[14] and incorporated with the Nutbeam's concept[15]. There were two parts in the questionnaire, as follows: 1) Sociodemographic characteristics, including the attendance of cataract service and 2) Health literacy toward cataract consisting of 6 skills, namely a) Knowledge and understanding; b) Access to information and services; c) Communication skills with professionals; d) Self-management; e) Media and information literacy and f) Decision-making skills. The questionnaire was validated by 3 experts and tested for reliability. Evaluation of health literacy was analyzed and interpreted according to Bloom's cut-off point[16] of 3 levels as follows: > 80% as good level, 60%-79% as medium level and <60% as low level. Data collection was carried out from May 2018 to July 2018.

Data Analysis: Data analysis was carried out using STATA (version 13; college station, TX, USA: Stata Corp). Sociodemographic characteristics were described as frequency and percentage for categorical data; minimum, maximum, mean and standard deviation for continuous data. Logistic regression was used to investigate independent variables associated with the attendance of cataract screening. A p-value ≤0.05 was considered to represent statistical significance.

Results

The overall number of those, 44.06% of the elderly attended a cataract screening. Bivariate analysis of the association between sociodemographic characteristics and the attendance of cataract screening revealed that female was likely to attend cataract screening more than male (OR=2.29, 95% CI = 1.53-3.41).Elderly people aged between 70-79 were significantly more likely to have cataract screening than aged between 60-69 (OR=1.83, 95% CI = 1.22 to 2.74). The elderly with underlying disease, having annual health checkup and having distances from home to health promoting hospital less than 1 km were significantly more likely to attend cataract screening, respectively.

Table 1: Logistic regression analysis of sociodemographic characteristics associated with the attendance ofcataract screening

Factors		n = 438				Crude OR	95% CI	p-value

Discussion and Conclusion

The study showed that more than half of the elderly in Kalasin Province attend the cataract screening lower than cataract screening rate of Thailand[7] and much lower than the aim of"Vision 2020 Thailand" project. Females were more likely to attend the cataract screening than males likewise, the cataract screening in Sri Lanka[17], it may be due to more than 80 percent of village health volunteers were females[18]. Moreover, females were more interested in and reported much more actively seeking health information and health care than male did[19]. This finding indicates the advantage of the cataract service because of the higher incidence of visual impairment was found in females than males[4,20]. This study also suggested that the older people were more likely to uptake cataract screening than the elderly in younger age. This could be clarified that the severity of senile cataract ***increasesby aging***[17], ***resulting, ina higher screening rate.***

The findings also indicated that, the elderly living near health promotion hospital were more likely to attend cataract screening than who lives far from a hospital. This can be explained that the accessibility condition played an important role for the elderly in attending the cataract screening.Additionally, long distance is one of the major barriers in accessing health services among the elderly because it related to high transportation costs and time consuming[21,22]. On the contrary,the elderly living at a shorter distance tend to obtainhealth information and were easier to travel to health service center. Moreover, elderly with the underlying disease were more likely to attend the cataract screening because of their chronic diseases[23]which usually had a regular health check-up, especially those with diabetes who have annual health screening for retinopathy[24].

The attendance of cataract screening also associated with health literacy toward cataract in 5 skills which includeaccess to information and services, communication skills with professionals, self-management; media and information literacy, and decision-making skills. The access to information and serviceshowed an important role for the elderly in attending the cataract screening because the elderly who had the high ability to seek the information had more chance to entry into health service[25]. Moreover, the poor is a one of key barriers in the access of eye care service, and Kalasin province is a one of 5 poorest province in Thailand[26]. Communication skills with professionals also played a significant role in the attendance of cataract screening. It may because of thehearing loss which common occurs in elderly[27]. And, it may be due to or the difficulty for understanding the medical words or misinterpret of the meaning[28].In addition, this study found the association between the attendance of cataract screening and media and information literacy-ability to understand, analyze and evaluate information received. Elderly in community frequently received information from words of mouth which brought them to misunderstanding such as, the difficulty in common activities of daily life and complication or bad outcome after surgery, which similar to the study in Kenya[29]. Furthermore, the elderly who had a good level of decision-making were more likely to attend cataract screening than those who had at a lower level. Decision-making skills in choosing appropriate practice to prevent cataract related to the understanding on the advantage of screening, early detection, and treatment[30].

In conclusion, this study revealed a low rate of elderly cataract screening. Factors associated with the attendance of cataract screening were sociodemographic characteristic (sex, age, distance from home to health

promoting hospital, underlying disease, obtained annual health checkup), access to information and services, communication skills with professionals, self-management, media and information literacy and decision-making skill. Health literacy could be considered as an effective strategy for promoting the attendance of cataract screening in low coverage rate, especially, in northeastern, Thailand.

Conflict of Interest Statement: No conflict of interest to declare.

Study of Dental Enamel Ions (ca^+ & sr^+) Using XRF Device-After Bleaching

Mhd. Salem Rekab[1], Raian Alzoaabi[1]

[1]*Operative Dentistry, Dentistry College, Damascus University, Syria*

Abstract

Background: Dental enamel Ca^+ and sr^+ ions were analyzed using x-ray fluorescence.

Objectives: We aimed in our research to study the effect of one application of high concentration of bleaching materials (CP 45%, HP 40%)-which contains sodium fluoride & potassium nitrate-on the mineral content of dental enamel (ca+, sr+ ions).

Method: 20 Sound Extracted human premolars with no caries were stored in distilled water at room temperature prior to the experiment, Distributed into two groups (10 teeth: its buccal surfaces were bleached by one application of 40 minutes of HP (pf) 40%, 10 teeth: its buccal surfaces were bleached by one application of 45 minutes of CP (pf) 45%).every studied enamel surface was grinded, the lingual surface of each tooth was the control sample for its buccal bleached surface. The powder taken from each enamel surface of each sample was analyzed using x-ray fluorescence which depends on electronical beam projection on enamel powder and reading results on XRF instrument screen.

Results: There was no statistical differences between ions average of bleached and control samples of dental enamel. There was no difference between HP and CP samples.

Conclusion: One application of HP 40% & CP45% bleaching materials doesn't affect dental enamel ca^+ & sr^+ ions.

Keywords: *Carbamide peroxide (CP), hydrogen peroxide(HP), pf (potassium nitrate & sodium fluoride), XRF.*

Introduction

Tooth enamel is the hardest and most mineralized tissue in the human body [1], mineral content is about 96-98% from its weight[2]. Dental enamel ions May be affected by teeth bleaching, which has become the most important, most cosmetic, well accepted procedures by most patients. Dental ions can be analyzed using several devices, the most important modern device is x-ray fluorescence (projection of electrons on enamel powder with a presence of selenium lithium ions mediator). Tooth bleaching refers to a technique where chemical bleaching materials are applied to brighten discolored teeth. Tooth bleaching materials usually contain a strong oxidizing agent that whiten teeth due to oxidation reactions.[3] Hydrogen peroxide (HP), carbamide peroxide or sodium perborate are popular oxidizing agent used to whiten teeth [4]. Bleaching occurs by peroxide decomposition into free oxygen radicals, which can break down the large pigmented molecules deposited in teeth to smaller and less pigmented molecules [5]. Studies results about the effect of teeth whitening materials on the mineral content of tooth enamel varied among researches [3,6,7,8]. Some of them did not find harmful effect of bleaching materials on formal & chemical properties[9]. Suliemanre search results showed no effect of high concentrations of hydrogen

Peroxide and carbamide peroxide on the formal properties of enamel surface[8,10]. Also, low concentrations of hydrogen peroxide 6.5% did not show any changes on enamel surface[6,11,12]. 25% and 15% concentrations of carbamide peroxide also did not affect the enamel surface[13,14]. While laboratory studies have shown an effect of low pH bleaching materials on enamel surface[15,16,17]. While no noticeable changes on enamel surface with 30% hydrogen and 10% carbamide peroxide use were noticed[18]. Goo used electronical spectroscopy for chemical analysis (ESCA) technique to study chemical changes of enamel after carbamide peroxide application[19.] many researchers studied bleaching effect on enamel chemistry and structure using different techniques: PXRF (portable x-ray fluorescence), XRD (x-ray diffraction), SRXRF (synchrotron radiation x-ray diffraction), AAS: (atomic absorption spectrometry) and XRF (x-ray fluorescence) [20,21]

Aims of study: The objective of the present *in vitro* study was to Study the effect of bleaching materials with high concentrations-containing potassium nitrate & sodium fluoride (pf)-(hydrogen peroxide pf 40%) and (carbamide peroxide pf 45%) on dental enamel ca+ & sr+ ions using XRF technique(X-ray fluorescence).

Materials and Method

40 samples of dental enamel powder were collected from 20 Extracted human premolars which were stored in distilled water at room temperature prior to the experiment. Sound premolar teeth with no caries, no enamel defects were selected in this study For electron microscopic XRF. These 20 premolars were distributed into 2 groups (10 premolars in each group) according to the bleaching materials (CP 45%, HP 40%). premolars crowns were divided perpendicularly into two parts (buccal & lingual), lingual part: is the control sample, buccal part : bleached with one of the two bleaching materials.

Teeth sample preparation: Extracted teeth were rinsed with water, cleaned mechanically with a hard brush and then left in distilled water until experiment performance mesial distal section of every premolar was performed using diamond disks to obtain 2 parts: (buccal submitted to the bleaching & lingual is control to the tooth itself). The bleached halves were rinsed completely. Then dried sufficiently to collect its enamel powder using aluminum oxide disks in order to study enamel mineral elements by XRF device the same procedure of powdering was made for control samples.

Results

Research was performed using 40 samples taken from 20 premolars distributed to 2 groups

- Group 1: 20 samples (10: submitted to carbamide peroxide 45%,10 : control)
- Group 2: 20 samples (10 submitted to hydrogen peroxide 40%, 10 : control) (table 1).

Table 1: Teeth sample distribution

HP 40% group		Cp 40% group	
Bleached Samples	**Control Samples**	**Bleached Samples**	**Control Samples**
10	10	10	10

All samples ions were analyzed using XRF device, the results showed no effect of high concentration of bleaching materials on dental enamel ions. T-test showed no statistical differences between bleached half ca^+ & sr^+ ions and control half ca^+ & sr^+ ions. (Table 2).

Table 2: Statistical t test results

Studied Ion	Bleaching Material	Tooth half	Number	Mean	Std Deviation	T value	Sig

		Non bleached	10	110.46	15.44		

Discussion

There have been many studies concerning hair and teeth sample analysis. In our work the X-ray fluorescence device was used to analyze ca^{+} & sr^{+} in dental enamel after high concentration of teeth bleaching application[23]. We used one premolar to give us the control sample & bleached sample[24,25.] research results showed no effect of teeth bleaching materials on mineral contents concentration (ca^{+}, sr^{+}) in enamel tissue, because mineral content may be affected by low ph and not by hydrogen peroxide itself [26,27]. on the other hand, fluoride & potassium nitrate-existed in studied bleaching materials-may approve enamel properties and remineralizes affected enamel [28]. These results agree with Wang results which didn't find any effect of peroxide bleaching materials on dental enamel. the researcher used 3 materials opalescence xtra boost, opalescence pf 20%,sodium perborate using following method : attenuated total reflectance infrared spectroscopy (ATR IR), with scanning electron microscopy (SEM),Raman spectroscopy, x-ray diffraction (XRD), electron probe microanalysis (EPMA), flame atomic absorption spectroscopy (FAAS) and total reflection x-ray fluorescence (TXRF [25.] results also agree with Basting 2003 and Dietschi 2006 who didn't find effect of high concentration on dental enamel ions in spite of long term application[28,29], we also agree with many researchers who didn't find any effect of teeth bleaching on enamel structure[30,31,32,35.] Whereas research results disagreed with Oltu and Tezel who found decrease in dental enamel calcium concentration using XRD[33,34] theses results returns to sample and measurement method difference[28.]

Conclusion

Within the limits of this study, no effect of teeth bleaching materials with high concentration (containing fluoride sodium and nitrate potassium) on ca+ & SR+ contents in dental enamel.

Abstract

Background and Purpose: Recently mini-implant over denture is widely used as a substitution for the conventional two-implant over denture. This study was done to evaluate the supporting structures around mini implant retained over denture radiographically when utilizing three different denture base materials.

Subjects and Method: This is a randomized controlled trial included 24 healthy completely edentulous male patients selected from the out-patient clinic and divided randomly into three equal groups according to the used denture base material. **Group I:** the conventional acrylic denture base implants were used. **Group II:** hard thermoplastic denture base implants Polyan IC (PMMA) were used and **Group III:** semi flexible thermoplastic denture base implants (bre flex 2nd edition) were used. Crestal bone loss around each mini implant was measured radiographically at 3 different follow-up intervals, baseline-3 months, baseline-6 months and baseline-12 months'. Bone density around each mini implant was measured radiographically in relative Hounsfield unit (Hu) at baseline, 3, 6, and 12 months. The collected data were analyzed by SPSS program version 20 with considering statistical significance when P value<0.05.

Results: No implant failure was detected. The bone loss values were higher significantly in the group of semi flexible thermoplastic denture bases. There was an increased bone density values in patients with acrylic denture bases than other groups but this difference was not statistically significant.

Conclusion: Under the limitations of this study we can conclude that acrylic and hard thermoplastic resins are better than semi flexible thermoplastic resins.

Keywords: *Mini implant, acrylic, thermoplastic denture base, bone loss, bone density.*

Introduction

Mini-implant is considered one of the reliable solutions to the problem of replacing missing teeth with the conventional implants. It is technically easier and less in vasive than the conventional implants. [1] These implants are used where there is no enough bone thickness for conventional ones. It can be also used to stabilize a denture until conventional implants heal. [2,3].

Mini implants were investigated as an aid for over denture. They revealed a high success degree and a good prosthetic outcome that increase their use in edentulous arches. Mini implant could be a good solution for those patients suffering from discomfort and less functioning dentures. [4]

Mini dental implants have numerous benefits as expanding the bone when they are placed as minimal osteotomy size is required. In addition they are characterized by immediate stabilization and loading on the day of placement and consequently fewer treatment visits. [5] Moreover, flapless placement leads to minimal surgical trauma, easier removal and good healing in case of failure. These implants are also characterized by decreased cost. [6]

Thermoplastic resins have various applications including partial dentures, complete dentures, performed partial denture clasps, fiber reinforced fixed partial dentures and sleep apnea appliances. [7]

Accurate and successful fitting of the denture bases is essential for the long term success of the mini implant retained over dentures. Different denture base materials have different physical properties during construction and different actions during function.[8]

The advantages of thermoplastic resins over the conventional acrylic resin are having predictable long-term performance, being more stable, exhibit high creep resistance and almost no porosity. [9]

The purpose of the article is to evaluate radiographically the supporting structures around mini implant retained over denture utilizing three different denture base materials.

Subjects and Method

The current study is a randomized controlled study that included twenty four healthy completely edentulous male patients selected from the outpatient clinic of the Prosthodontic department, Faculty of Dentistry, Minia University. The inclusion criteria included patients who were systemically free, arches provided a minimal bone height of 15 mm, all the patients are angel's class I skeletal relationship between mandible and maxilla and enough inter arch space suitable to accommodate over dentures and attachments.The exclusion criteria included clenching habits and bruxism, tempro-mandibular disorders and any intraoral soft or hard tissue abnormality.

Accurate medical history, dental history, extra oral examination, intra oral examination and radiographic examination were performed for all the patients.In this study patients were carefully selected and thoroughly examined in an attempt to reduce human variables and eliminate any factor or habit that might adversely affect the results. Standard clinical and laboratory techniques were followed for the construction of the dentures for all patients.

Also, the same materials were used as feasible as an attempt to eliminate any factor that might affect the results of this study.[10] Cross linked resin teeth were used as they act as shock absorber preventing applying undue stresses to the implant.[11]

All patients participated in the study were informed about the nature of the study and its purpose, agreed to take part in it and write an informed consent reviewed by the research ethics committee of the Faculty. All reasonable steps to protect the confidentiality and privacy of the personal and health information of the patients were taken and patients informed about the benefits of obtaining implant retained mandibular over denture.

Patient grouping: Patients were divided randomly into three equal groups (eight patients each) according to the denture base material:

Group I: Patients rehabilitated with four mini dental implants retained over denture with conventional acrylic denture base.

Group II: Patients rehabilitated with fourmini dental implants retained over denture with hard thermoplastic denture base Polyan IC (PMMA)

Group III: Patients rehabilitated with fourmini dental implants retained over denture with semi flexible thermoplastic denture base (bre flex 2nd edition)

Construction of conventional and thermoplastic complete dentures: For patients in group I, each patient had received a new set of upper and lower complete dentures, constructed with the compression molding technique used for polymerizing the acrylic denture bases.

Patients in group II, each patient had received dentures constructed from hard thermoplastic acrylic resin through injection molding technique including that when processing Polyan Ic (PMMA) hard rigid thermoplastic resin, For a safe bond to the acrylic teeth surface roughening for all the prefabricated teeth (sandblasted with aluminum oxide) was performed, with the use of the adhesion promoter poly.Link.

For patients in group III,each patient had received dentures constructed from semi flexible thermoplastic resin (bre flex 2nd edition) through injection molding technique including the same steps of hard thermoplastic resins and for a safe bond to the acrylic teeth a circumferential grooves needs to be milled in the cervical area and mechanical retention (undercut) needs to be included in the basal area (fig1).

Fig. (1) Breflex2nd edition and Polyan IC

Fabrication of the computer guided surgical stent: For each patient, a customized computer guided surgical stent was fabricated through the data obtained from the cone-beam CT (CBCT). Captured images from CBCT were imported into viewing software then sent for fabrication of the guide fig (2).

Fig. (2) Prefabricated clear acrylic surgical guide with four metal sleeves

Implant installation and loading: Four mandibular mini dental implants (Cowellmedi Co., Ltd.48 Hakgam-daero 221 beon-gl, Busan, Republic of Korea), with a standard diameter of 2.4 mm, and a length 13 mm, were placed in each of the 24 completely edentulous patients following immediateloading protocol. After the anaethesia effect has confirmed, the surgical stent was seated in position in the patients mouth (three holes were drilled in the mandible, through the provided lateral cylinders of the guides to receive the anchor pins for fixation of the guide). Flapless surgical technique was performed to the patients. Using the pilot drill, four marks were made in the mandible in the corresponding mini implant sites guided by the stent. The surgical stent was then removed from the patient's mouth, and using a 2.0 mm mini implant drill with copious saline irrigation, the four osteotomy sites were prepared in a vertical direction and parallel to each other. After finishing the osteotomy preparations, mini implants were removed from their sterile packaging using the implant insertion tool and then fastened directly to the osteotomy sites using finger until moderate resistance was felt. Then the mini implant torque wrench was applied until complete crestal flushing of the mini implants with the bone crest. Implant insertion was done under copious saline irrigation fig(3).

Fig. (3) Mini implants in position before direct pick-up

All patients were recalled one week after implants insertion for immediate loading, the metal housing caps were attached to the mini implants, glass ionomer cement was applied to block the undercuts beneath the metal housings, Lingual escape holes were opened to allow for escaping of excess pick up material and ensure proper seating of the denture on the tissue.

For patients in group I; pink cold cure acrylic resin (relining material), and in group II and III repair material uni-lign speed used as a pick-up material and after setting, the dentures checked for the accurate fitting of the metal housing to the ball abutments of the mini implants and excess material was trimmed then Patients were instructed for the proper way of denture removal and insertion, cleaning, and usage.After that, the radiographic evaluation was performed in the form of bone loss and bone density during one year follow up period.All the data were collected, tabulated and statistically analyzed.

Results

Data were gathered and tabulated for each group at baseline, 3, 6, and 12 month. The collected data were expressed by mean, and standard deviation (SD) for all variables to compare between the three study groups.

Numerical data were explored for normality by checking the distribution of data and using tests of normality (Kolmogorov and semirnov test) all showing normality distribution.

To compare the measures between the three groups Kruskal-Wallis test was used and Mann-Whitney test was used to compare between each two groups.

1. **Bone loss:** Table (1) shows increased bone loss mean values among semi flexible thermoplastic denture bases compared with other groups at different time intervals.

Discussion

Several studies revealed that injection molding techniques result in less dimensional inaccuracy and more accurate denture base than the usual conventional processing techniques. [12].In this study, 4 mini implants were used as sufficient number of mini-implants must be placed to adequately distribute loads generated during mastication. [13]

Surgical technique without incision of the soft tissue was done as the bleeding will be less, post-operative trauma is decreased, healing time and the possibility to infection during surgical procedure are less and the loading is immediate.[14] In this study, the direct pickup was performed as it is simple, economic, quick and allow patient to retain prosthesis.[15] This is particularly important to allow prosthesisimmediate functional loading.[16]

The crestal bone area is considered an important indicator of implant health. Crestal bone is the bone that bears the stress around an implant. Blood supply to the crestal bone area is reduced around an implant compared with that of the natural tooth. This is because the blood vessels from the periodontal ligament are not present. The source of blood supply is from the periosteum covering the bone. [17]

The decreased levels of crestal bone loss in the three groups could be attributed to several factors. The first factor is the flapless placement technique of mini implants which causes minimal disruption to the periosteum, preserves peri and endosteal blood supply and retains the bone height around the implants after surgery.[18] In addition, the immediate loading protocol of mini implants leads to bone compression which may act to increase bone density in the area immediately surrounding the implant and minimize crestal bone loss. [19]

Results reflected all the success criteria regarding to all parameters; these results could be explained as a result of flapless surgery with the guidance of computer guided stent which preserve the periosteum and peri implant tissues.[20]

Analysis of the results of this study reflected no statistical significance difference regarding bone loss results around the mini implants between the first two groups while there are significant increase in mean values in the semi flexible thermoplastic denture base (bre flex 2nd edition) group than other groups andbetter bone density in the acrylic group.

The 3rd group values could be explained as a result of mechanical connectionof metal housing to the denture base that may lead to some micro mechanical movement of the metal housings that enhance over denture rotation during posterior loading, with twist load transmission to the implants and increases the chance of implant overloading by rotation of the distal cantilevered portions of mandibular over denture.

Conclusion

In the present study no implant failure was detected. The mini implants were assessed radiographically throughout the study period, the three groups showed success criteria throughout the study period regarding bone loss and bone density values which may reflect theproper selection of cases, adequate mini-implant length in proportion to the height of the residual alveolar ridge, proper oral hygiene measures, proper mini-implant surgical insertion and angulations. Although thermoplastic denture bases are alternative for conventional acrylic denture bases, only the hard ones exhibited radiographically outcomes close to the conventional baseswhile the semi flex ones require more optimizations and studies.

Using of Omega 3 to Reduce the Toxic Effect of Antituberculosis Therapy on Hepatorenal Function and Some of Blood Parameters of Albino Male Rats

Moayad Mijbil Ubaid

Assistant lecturer, Department of Sciences, College of Basic Education, University of Sumer, Iraq

Abstract

Objective: Antituberculosis is anti-inflammatory drug used widely to treat tuberculosis, it is active drug but unfortunately causes harmful side effects on liver, kidney and blood. In the present study we used Omega 3 to reduce the side effects of this drug.

Method: The study was carried out on 40 males of albino rats. We divided the animals into four groups; control of healthy animals group, antituberculosis group, antituberculosis drug plus omega group and only omega group..Then after two months samples of blood were withdrawn from the animals for analyzing of some blood, liver and kidney parameters.

Results: Our study proved that *Omega-3* can significantly reduce the toxicity of "antituberculosis drug" for some hematological, liver and kidney parameters ("ALT,AST,Urea, Creatinine").

Conclusion: the results showed that "*Omega-3" have* protective characteristic to reduce the toxicity of "antituberculosis drug".

Keywords: *Antituberculosis, omega-3, toxicity, liver, kidney, blood parameters.*

Introduction:

Tuberculosis is considered a world wide which is caused by "*Mycobacterium tuberculosis",* these bacteria can infect mainly the lungs but it can cause infection to other organs and tissues of the human[1]

TB is highly resistant to treatment so that it is one of the most difficult diseases to be treated. In addition the using of this drug usually cause some dangerous side effects like liver toxicity and blood disorders [2].

To treat tuberculosis, a mixture of drugs is used to decrease drug resistance. The mixture is consist of pyrazinamide, rifampicin, and ethambutol to ensure highly effective treatment and avoid pathogen resistance [3,4]. Unfortunately this highly effective mixture can may elevate toxicity and lead undesirable side effects[5,6].

It was revealed that anti TB drugs can affect hematological parameters including WBC, RBC, Hb, HCT, MCV, MCH, MCHC, RDW and PLT[7]. Another study found that anti TB cause leukopenia especially neutropenia[8]. Number of mechanisms can mediated "drug-induced" hematological disorders like immunological effects, direct hematopoiesis inhibition and enzymatic interaction pathways. Hematological disorders include RBC aplasia, megaloblastic anemia, sideroblastic anemia, aplastic anemia and leukocytosis. Many anti-inflamatory drugs may lead to malabsorption and depression in RBC, WBC and platelet [9,10].

Aims of the study: The aim of the present study is to evaluate the "protective effect" of Omega-3 on the toxicity of anti-tuberculosis drug in albino rats.

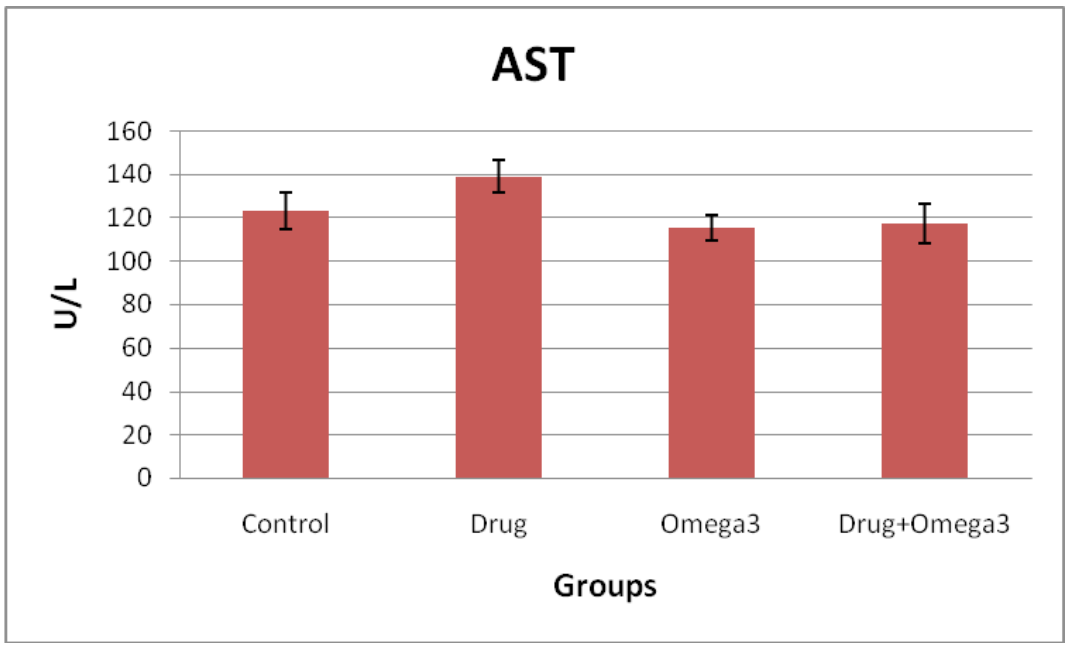
Method

Animals of the experiment: In the present study we used forty rats of male sex. the rats were housed in animal house and they were fed a standard laboratory chow with water. The rats were arranged into four separated groups.

1. Group 1: The control was nourished with only food and water.
2. Group 2: Administrated anti-tuberculosis drug (25mg/kg) in day for two months[11].
3. Group 3: Administrated Omega-3 (10 mg/kg) + Anti-tuberculosis drug (25/mg/kg) in day for two months.
4. Group 4: Administrated only Omega-3 (10mg/kg) in day for two months[12].

Biochemical measurements: For biochemical study "Aspartate aminotransferase, Alanine aminotransferase, urea and creatinin" were colorimetrically identified.

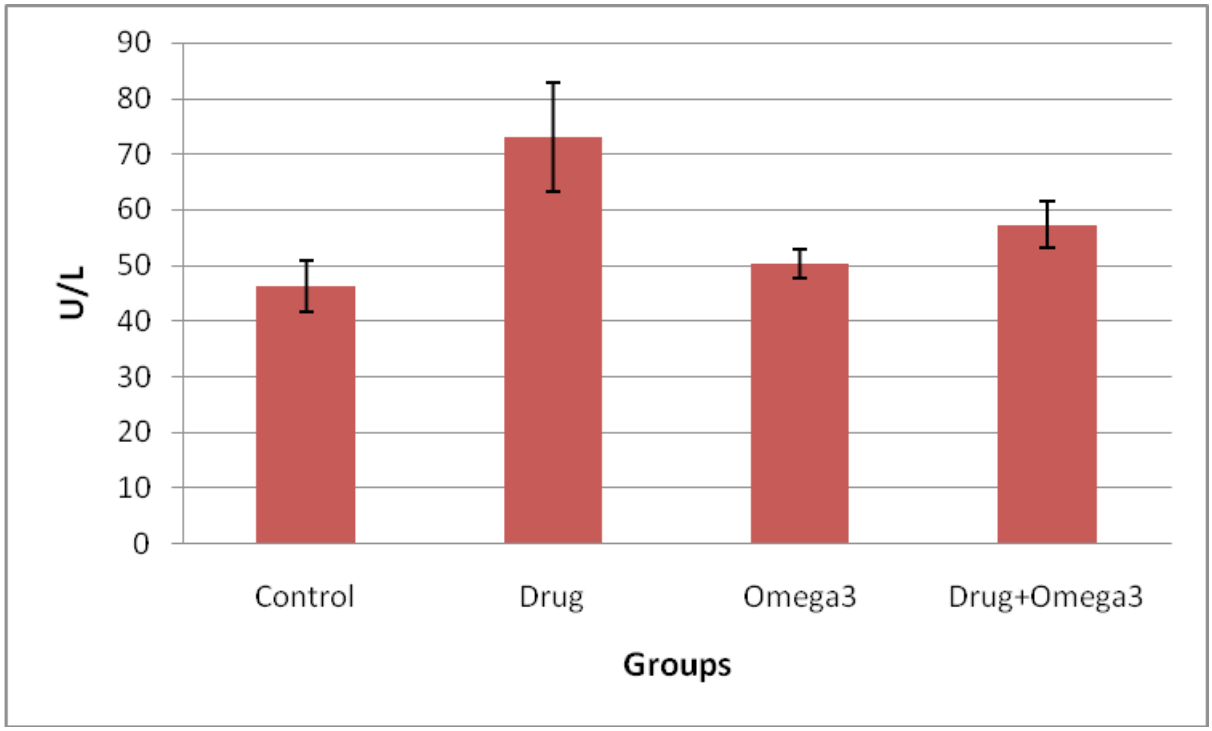
Hematological measurements: For hematological study the following tests were made : RBC_s count, WBC_s (granulocytes and agranulocytes), Platelets, HGB, HCT, MCV, MCH and MCHC.



Statistical analysis: The differences between the means of the groups were analyzed by SPSS (One way ANOVA analysis) $P \leq 0.05$.

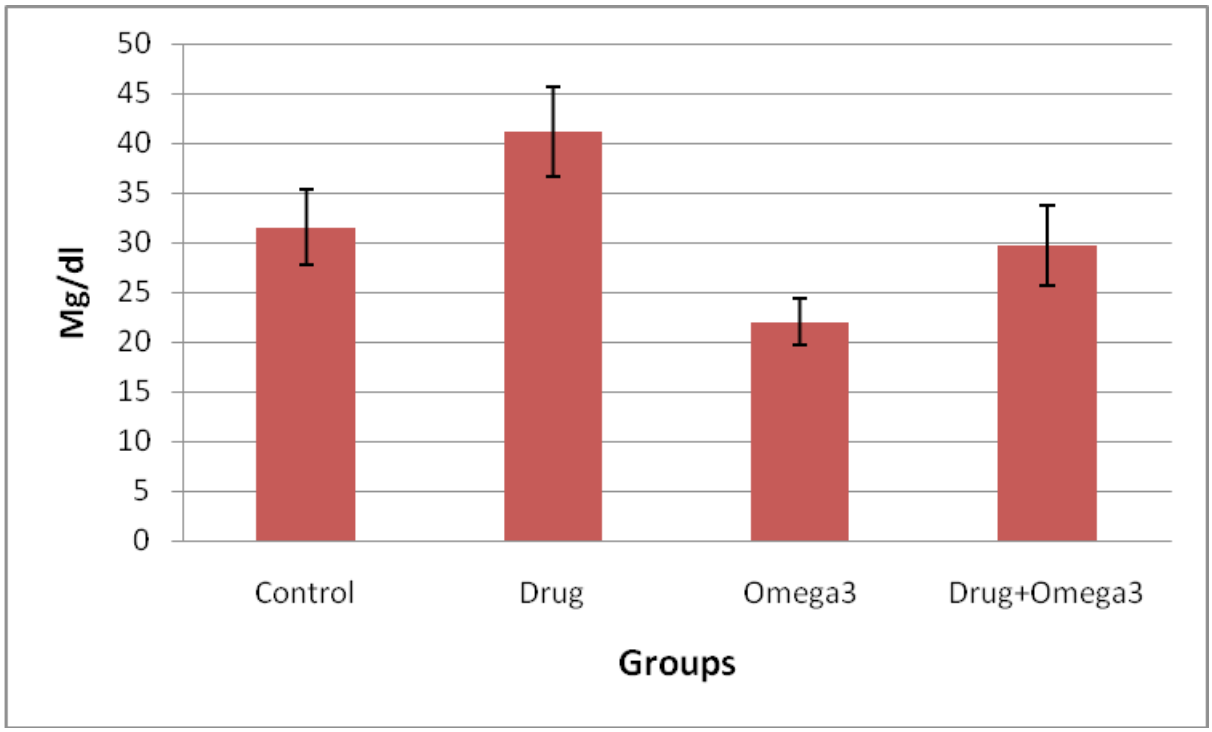
Results

Figures (1,2) show the effect of omega-3 on liver function AST and ALT respectively in rats treated with anti TB drug. The figures show significant increase at $p \leq 0.05$ in both AST and ALT in groups drenched with Anti TB drug. Both AST and ALT reduced significantly in groups treated with omega-3



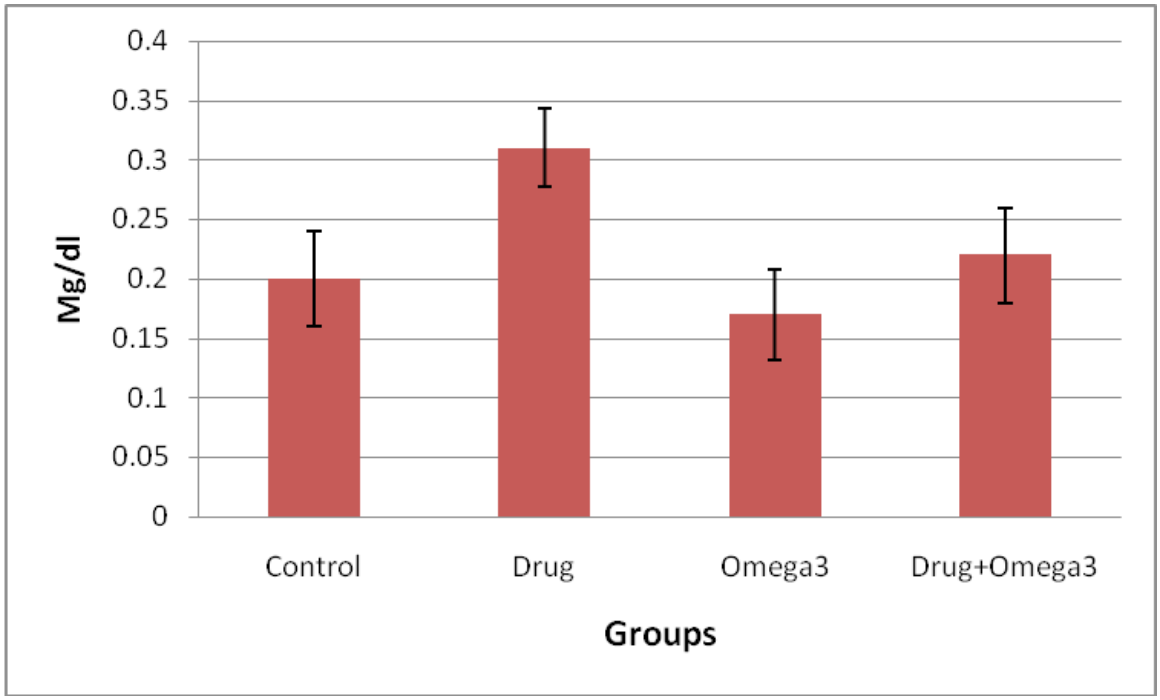
Figures (2,3) show the effect of omega-3 on kidney function urea and creatinine respectively in rats treated with anti TB drug the figures show significant increase at $p \leq 0.05$ in both urea and creatinine in groups drenched with Anti TB drug. Both urea and creatinine reduced significantly in groups treated with omega-3.

Table (1) Show the effect of Omega-3 against anti-tuberculosis drug toxicity on blood parameters. There is a significant depression at $p \leq 0.05$ in WBC count; HGB, HCT, MCH, MCHC and platelet count in groups drenched with anti TB drug. WBC count, HGB, HCT, MCH and MCHC were elevated significantly to normal in groups treated with omega-3 while the elevation in platelet count was not significant.



Values were represented by mean ± SEM at $p \leq 0.05$

Figure (1): Effect of omega-3 on AST of rats drenched with anti TB drug.



Values were represented by mean ± SEM at $p \leq 0.05$

Figure (2): Effect of omega-3 on ALT of rats drenched with anti TB drug.

Values were represented by mean ± SEM at $p \leq 0.05$

Figure (3): Effect of omega-3 on Urea of rats drenched with anti TB drug.

Values were represented by mean ± SEM at $p \leq 0.05$

Figure (4): Effect of omega-3 on creatinine of rats drenched with anti TB drug.

Table (1): Show the effect of Omega-3 against anti-tuberculosis drug toxicity on blood parameters

Groups / Parameters	Control	Drug	Drug+Omega-3	Omega-3
WBC	9.80±0.60^{a}	7.50±0.47^{b}	9.00±0.52^{a}	10.02±0.49^{a}

Values were represented by mean ±SEM, different small letters mean significant difference ($p \leq 0.05$)

Discussion

The study revealed a significan televation in liver enzymes “AST and ALT” with antituberculosis therapy compared to normal control group and this increase was significantly reduced by omega-3 when it was used as a mixture with drug. Previous studies revealed that antituberculosis drugs cause DILI by the oxidative stress in mitochondria, cholestasis and cell apoptosis [13].

The kidney function also affected by the drug. The study found increase in urea and creatinin levels. Previous studies referred to rifampicin as the main antibiotic that cause kidney injury[14,15]. Several studies explained the mechanism of rifampicin to affect the kidney by two mechanisms, these mechanisms are type ll and type lll hypersensitivity which are caused by antibodies against rifampicin “anti-rifampicin” that lead to form immune complexes, these complexes can be deposited in the glomerular epithelium, renal vessels and interstitial spaces[16]. The deposition of these complexes in the interstitial spaces can cause interstitial nephritis while deposition in renal vessels can cause vascular

degradation which lead to tubular necrosis [17]. Another studies carried out by renal biopsies proved that the most common problems were tubular necrosis and interstitial nephritis[14,15,18].

In the present study we evaluated the using of omega3 to reduce the toxic effects on liver and kidney. As shown in figures (1, 2) the using of omega3 significantly reduced the activity of AST and ALT in group 4 (Drug+Omega3) relative to group 2 (Drug) and in figures (3, 4) we also noticed that omega 3 reduced the urea and creatinin levels. Omega3 might boost the antioxidant system leading to handle treats caused by antituberculosis drug, which is pro-oxidative agent. Some studies reported the effect of omega3 in reducing the toxicity of some other drugs like anticancer drugs [19]. The antioxidant effect is done by lurking of the free radicals and frustrating lipid peroxidation[20].

The present study revealed also the effect of antituberculosis drugs on blood parameters "RBC, WBC,HGB, HCT, MCV, MCH, MCHC and platelet".

Also the number of WBC decreased significantly after treatment. Shishido*et al.,*(2003)[21]Found that agranulocytosis is caused by isoniazid and rifampicin whileKyoung & Min, (2015)[22] mentioned that ethambutol may be the cause.

The mechanism of effect may result from different mechanisms like enzymatic pathways interactions, inhibition of hematopoiesis and immune effects [23]. This may result from the effect of ashaptens to form antibodies against neutrophils which lead to lysis of neutrophils by the reaction of Gell Coombs type 2 hypersensitivity[8]. Hiwa & Falah, (2012)[19] Mentioned that omega 3 supply normal mitotic division in bone marrow in mice treated with anticancer drug. Omega 3 also increase the development of the myeloid progenitor cells of the bone marrow and regulate hematopoiesis[24.]

In the other hand the study revealed that TB therapy can cause anemia this result agreed with a study byJude *et al*., (2017)[25] which found that the syndromes induced by drug include RBC aplasia, megaloblastic anemia sideroblastic anemia, hemolytic anemia and leukocytosis. In fact two kinds of anemia are caused by TB therapy, hemolytic and aplastic anemia[26]. hemolytic anemia is caused by isoniazed and rifampicin while sidroblastic anemia is caused by pyranizimide. Anti-inflammatory drugs may cause interfering with iron absorption, malabsorption and hemolysis. Anti TB may lead to idiosyncratic reaction by lowering the number of RBC, WBC and platelets [27,28].

The present results revealed that Hb, HCT, MCV, MCH, MCHC were elevated in groups drenched with omega-3. This may belong to the supporting of the RBC membrane to increase its fluidity. MacPhail, (2012)[29] Mentioned that unsaturated fatty acids work to increase the fluidity of RBC membrane.

In The present study we also observed depression in platelet number this result agree with previous study carried out by Surya *et al.,*(2010)[30].Yakar et al.,(2013)[31] Reported that thrombocytopenia caused mainly by the effect of rifampicin. Rifampicin binds to the glycol proteins of platelets membrane leading to conformational changes and attaching of antibodies to platelets and causing increase destruction.

Conclusion

Our results revealed that omega-3 may have protective effect against the toxicity of antituberculosis drug.

Conflicts of Interest: "No conflicts of interest are existing".

Evaluation of Antimicrobial Effect of Conventional Calcium Hydroxide, Calcium Hydroxide Nanoparticle and Combined Calcium Hydroxide with Silver Nanoparticle as Intracanal Medication against Enterococcus Faecalis

Mohamed Salah Mohamed Fahmy Ali Hegazi[1], Magdy Mohamed Ali[2], Reham EL Sayed Hassan[3]

[1]Assistant Lecturer, Faculty of Dentistry, Misr University for Science and Technology, [2]Professor of Endodontics, Faculty of Dentistry, Beni Suef University, [3]Associate Professor of Endodontics, Faculty of Dentistry, Minia University

Abstract

Aim: This study was performed to evaluate the effect of three intracanal edicament Conventional calcium hydroxide ($Ca(OH)_2$), $Ca(OH)_2$ nanoparticle and Combined $Ca(OH)_2$ with silver nanoparticle on E.faecalis bacterial biofilm within infected root canals. Forty five extracted human single rooted teeth were sterilized followed by mechanical preparation Microbiological culturing of E. faecalis was performed and incubated for 7 days. After incubation period, proper irrigation and premedication bacteriological sample was taken teeth were randomly divided according to the intracanal medicament used, samples were incubated in 37°C for 7 days. Second microbiological sample was taken after 7 days and culturing was done to allow bacterial count reduction. The non-parametric Kruskal-Wallis test was performed to evaluate the bacterial count reduction and percent of reduction at significance level was set to $p \leq 0.05$.

Results: The antibacterial effect of combination of calcium hydroxide with silver nanoparticle was better than calcium hydroxide nanoparticle and followed by Conventional calcium hydroxide against E. faecalis bacteria.

Conclusion: combination $Ca(OH)_2$ with silver nanoparticle can be used instead of Conventional $Ca(OH)_2$ against E. faecalis bacteria in necrotic root canals.

Keywords: *Calcium hydroxide, E. faecalis, Silver nanoparticle, calcium hydroxide nanoparticle.*

Introduction

The goal of endodontic treatment of necrotic pulp space is to clean, disinfect the entire root canal system and to eliminate bacteria and any sources of nutrient supply such as the tissue remnants. Inadequate accomplishment of these objectives risks the short-term as well as the long term outcome of endodontic therapy, where bacteria persisting within the root canal system are the major cause of endodontic treatment failures[(1)]. The use of $Ca(OH)_2$ as an intracanal antiseptic was first suggested by Hermann in 1920[(2)]. $Ca(OH)_2$ had proven to be an excellent antimicrobial intracanal dressing, but it failed in many cases to eliminate Enterococcus Faecalis bacteria from the necrotic root canal[(3)]. E. faecalis is gram positive cocci that occur singly in pairs or in short chains. It is a facultative anaerobe present in small proportion of the flora of untreated canal as a part of polymicrobial flora. It is the predominant bacteria responsible for root canal failures and persistent infections[(1)]. When a bioflm is formed, many of the microorganisms become more resistant to disinfectant agents. Thus, the researchers emphasized on the need to find new protocols for effective removal of bacteria before obturation of the canal. In order to improve antibacterial activity of these agents against poly-microbial infections or bacterial biofilms, antibacterial materials can be combined. Based on this idea, in order to increase the effectiveness of $Ca(OH)_2$ various vehicles have been added to it

Silver nanoparticles are used in many disinfectant agents used to disinfect medical devices since they

show wide range antibacterial characteristics as well as virucidal effects[3]. Silver nanoparticles attach to the cell wall of bacterium and penetrate into the cell and cause disintegration and increased permeability of bacterial cell membrane[4,5].

A recent study has shown that a combination of $Ca(OH)_2$ with silver nanoparticle as an intracanal medicament notably decrease the number of intracanal microorganisms in short-term [6].

The aim of this study was to evaluate in vitro E.faecalis bacterial biofilm count reduction after application of 3 intracanal medicament within infected root canals. Conventional $Ca(OH)_2$paste, $Ca(OH)_2$ nanoparticle and combined $Ca(OH)_2$ with silver nanoparticle.

Materials and Method

Preparation of Calcium hydroxide nanoparticle: Nanoparticles were prepared via direct thermal decomposition method using $Ca(OH)_2$ as a wet chemically synthesized precursor. Nanocrystalline particles of $Ca(OH)_2$ have been obtained by adding 2 ml NaOH aqueous solutions to 0.5 ml $CaCl_2H_2O$ aqueous solutions at 80°C and wait till evaporation occur.

Preparation of Combined calcium hydroxide with silver nanoparticle: Nanoparticles were prepared via direct thermal decomposition method using $Ca(OH)_2$ as a wet chemically synthesized precursor. Nanocrystalline particles of $Ca(OH)_2$ have been obtained by adding 2 ml NaOH aqueous solutions to 0.5 ml $CaCl_2$ H_2O aqueous solutions at 80°C[7].

Silver nanoparticles have been prepared by chemical reduction method as reported by **Pal et al. 2009[8]**. Silver nanoparticles were prepared by microwave irradiation of silver nitrate solution in ethanolic medium using PVP as a stabilizing agent. Ethanol was observed to act as a reducing agent in the presence of microwave. $Ca(OH)_2$ were added to silver solution and mixed together till evaporation of ethanol to get the final required concentration.[7].

Characterization of nanoparticles: The optical properties of the prepared nanoparticles were characterized using UV-Vis absorption spectra which were obtained on Ultraviolet–visible absorption (UV-Vis) spectroscopy (Cary 5000 UV-Vis-NIR Spectrophotometer, USA).

The particle size and shape were determined using Transmission electron microscope which was performed on JEM-2100 (JEOL,Tokyo, Japan) high resolution transmission electron microscope at an accelerating voltage of 200 kV..

Sample selection: Forty-five extracted human single rooted teeth with straight root canals, fully developed apices, free of caries or fractures and had no previous root canal treatment were selected. Extracted teeth were collected after extraction for orthodontic or periodontal reasons from outpatient clinic, Faculty of Dentistry, Minia University. Samples were divided randomly into 3 groups according to type of medication used (n=15).

Group I: Fifteen samples were medicated by conventional $Ca(OH)_2$ paste Ultracal (Ultradent. Products. inc).

Group II: Fifteen samples were medicated by $Ca(OH)_2$ nanoparticle prepared by NanoTech Egypt for Photo-Electronics.

Group III: Fifteen samples were medicated by $Ca(OH)_2$ with silver nanoparticle prepared by NanoTech Egypt for Photo-Electronics.

Sample preparation: The anatomical crowns were removed at the cement-enamel junction using tapered diamond stone mounted on low-speed hand piece under water coolant. The roots were individually placed in separate sterilizing bag. They were autoclaved at 121 ˚C for 30 minutes. The root canals were explored with a #10 K-file (Mani, Japan) until the tip of the file was visible from the apex, working length was calculated by subtracting 1mm.. The mechanical preparation was done using crown down preparation technique with the use of protaper next rotary files (Dentsply-Sirona Endodontics) in a sequence of use of X1 rotary file (0.17/0.04), then X2 rotary file (0.25/0.06) and finally X3rotary file (0.030/0.07), all files were used to full working length using endomate endodontic motor (NSK, Japan) with adjusted torque 2 Ncm and 300 rpm according to the manufacturer instructions. 1ml of distilled water was used after each file size. After instrumentation was completed, the roots were irrigated with 5 ml of distilled water. The external root surfaces were coated with two layers of nail polish, except for the coronal opening and apical foramen. The apical foramen was then sealed with light-cured nanofilled composite resin (META, Korea).

Preparation of microbial suspension: Enterococcus Faecalis suspension was prepared by adding 1 ml of a pure culture of E.faecalis (ATCC 29212) Microbiology Department, Faculty of Medicine Cairo University, which was grown in brain heart infusion (BHI) broth for 24 hour. The inoculation suspension of Enterococcus Faecalis was standardized to 2 McFarland. Preparation of microbial suspension was performed as follows: The microorganisms were cultured on blood agar plates. The colonies of the microorganism were picked up by sterile bacteriological loop and emulsified in sterile glass tube containing 1 ml of sterile BHI broth, then vortexed for 30 seconds. This preparation was repeated till the density of the microbial suspension was adjusted to match a turbidity equivalent to 2 McFarland. Each sterilized root canal was placed in Eppendorf tube and filled with the 1ml of E.faecalis standard microbial suspension by using plastic syringe in each group. The samples were submersed in the prepared bacterial suspension in coded sealed Eppendorf and incubated for 7 days at 37˚C.

After 7 days, bacterial sampling was done by using paper point #30 all root canals were irrigated with 10 ml of sterile distilled water. The medications were placed inside the canals using plastic syringe where sufficient amount was placed until the paste was seen at the canal orifice to ensure that the canals were completely filled. After application of the medication, the root canal orifices were sealed using Intermediate Restorative Materials (Densply. Switzerland).

After 7 days, all root canals in each group were irrigated with 10ml of sterile distilled water using disposable plastic syringe. A sterile paper point #30 was placed in the root canal to the working length to get sample after 7 days.

Both pre and post intracanal medication paper point samples were inserted in weatherman tubes containing 1 ml of BHI broth. The tubes were incubated at 37˚C for one day. Each sample was carefully homogenized by being vortexed for 10 seconds. Serial 10 fold dilution (1:100 and 1:1000, 1:10000) was completed in saline, then 1ml from the third and fourth dilution was inoculated on the plate media (BHI agar plates) and incubated at 37 ؚ C for 2 days. Inoculation done by using 6 ml of BHI broth from each tube was taken by sterile pipette, BHI broth was spread on BHI broth agar media using sterile glass rods. After culturing, the plates were incubated at 37˚C for 2 days.

Colonies were counted from plates and the colony forming units CFUs/ml were calculated according to following equation:

Number of colonies X dilution X amount of infected BHI broth.

The Percentage of count reduction was calculated by following formula:

$$\text{Percent Reduction} = \frac{(A-B)\times 100}{A}$$

Where:
A is the number of viable microorganisms before treatment.
B is the number of viable microorganisms after treatment.

Results

The non-parametric Kruskal-Wallis test was performed at significance level $p \leq 0.05$. The analysis of non-parametric Kruskal-Wallis test showed that there was no statistically significant difference between the three groups in comparison referring to pre intracanal medication application, where there was a statistically significant difference between the three groups in comparison referring to post medication application.

The mean log $_{10}$ value after intracanal medication application of conventional $Ca(OH)_2$ was 68.13±35.17, while 24.40±8.01 for $Ca(OH)_2$ nanoparticle group and 7.00±2.98 in $Ca(OH)_2$ with silver nanoparticle group. Table (1).

Table (1): Descriptive statistics and test of significance of E.faecalis count reduction in tested groups for pre and post intracanal medication application.

	Conventional $Ca(OH)_2$ Group		$Ca(OH)_2$ Nanoparticle Group		$Ca(OH)_2$ with silver Nanoparticle Group		P value
	Mean	SD	Mean	SD	Mean	SD	
Pre Intracanal Medication	98.07	35.05	76.27	13.04	78.47	11.34	0.077
Post Intracanal Medication	68.13	35.17	24.40	8.01	7.00	2.98	< 0.001*

Percent of Reduction	29.93%	12.72%	51.87%	15.69%	71.47%	10.08%	< 0.001*

*Significant at $p \leq 0.05$.

Discussion

Successful endodontic treatment of necrotic root canals needs effective control of the root canal infection[9]. Chemomechanical cleaning and shaping of the infected root canal results in the reduction of microorganism counts, but cannot eliminate it completely. This is mainly because of anatomical complexity and access limitations to the root canal system by instruments and irrigants[10] [11]. In some cases where microorganisms are resistant to regular therapy and present with pain and exudation, the need for intracanal medication is increased[12].

A systematic review by **Sathorn et al. 2007**[13] on antibacterial effect of conventional calcium hydroxide as intracanal medicament showed its limited disinfection activity within the root canal system[14]. It is not equally effective against all bacteria found in the root canal. Indeed, several studies have reported the failure of conventional $Ca(OH)_2$ to eliminate Enterococci effectively, as they tolerate high pH values, varying from 9 to 11[15]. Thus, the researchers emphasized on the need to find new protocols for effective removal of bacteria before obturation of the canal.

Recently, silver nanoparticle intracanal medication has become favorable due to its effects against biofilm[16]. In a study by **Monteiro et al 2009**[17], silver nanoparticle was found to have an effect on bacterial adhesion and biofilm formation. Since, it was recommended to use silver nanoparticle in an intracanal medication rather than irrigant for effective bacterial killing[18].

Microbiological sampling was accomplished using sterile paper points to absorb the microorganisms suspended at the lumen of the root canal[19].

The injectable plastic syringe was used for application of nanoparticles intracanal medication to be sure of that the canal was fully soaked with intracanal medication, after intracanal medication application orifices were sealed with IRM to prevent leakage.

In current study results showed that combined $Ca(OH)_2$ with silver nanoparticle had higher significantly higher antibacterial effect in elimination of E. faecalis regarding to percent of reduction (71.47% ± 10.08%) followed by $Ca(OH)_2$ nanoparticle(51.87% ± 15.69%), then Conventional $Ca(OH)_2$ (29.93% ± 12.72%), which have the lowest effect as showed in. Table(2).

The results of current study may be attributed to the nanosize of the intracanal medication of $Ca(OH)_2$ with Silver nanoparticle and $Ca(OH)_2$ nanoparticle.

$Ca(OH)_2$ nanoparticle had an antibacterial effect over the traditional medicaments $Ca(OH)_2$. The mechanism of antibacterial activity of nanoparticles may be caused by an increased surface-to-volume ratio, resulting in increased surface area to contact with bacteria, increased chemical reactivity of the material, or change in the physical properties of the traditional agents, such as superior solubility, interaction, or penetration into bacteria [20].

This result came in accordance with **Javidi et al 2014** [21] who showed that $Ca(OH)_2$ with Silver nanoparticle had the better than conventional $Ca(OH)_2$ in antibacterial effect against E.faecalis.

The results of current study disagree with **Alabdulmohsen and Saad 2017** [22] who showed that the Silver nanoparticle was less effective against E. faecalis than the conventional $Ca(OH)_2$ alone or

combination of both materials this may be attributed to differences in concentration and in particle diameter as the concentration of 20 ppm with an average diameter of 2 nm in the form of colorless gel were used.

Conclusion

Combination $Ca(OH)_2$ with silver nanoparticle can be used instead of Conventional $Ca(OH)_2$ against E.faecalis bacteria in necrotic root canals.

Research Ethical Approval: This study was made with the approval of the ethical committee of the faculty of dentistry, Minia University.

Conflict of Interest: The authors declare that there is no conflict of interest.

Source of Funding: it was self funded. this research did not receive any specific grant from funding agencies in the public, commercial, or not for profit sectors.

Abstract

This study was planned to investigate the relationship between serum amylin and preptin levelsin patients with T2DM compared to healthy controls. And to study their associations together (preptin and amylin) with serum levels of insulin and HOMA-IR.Sixty-four (64) patients were recruited from the Endocrine Outpatient clinic in Al-Imamain Al-Kadhimain city hospital from March of 2018 to May of 2018. Fasting serum samples were obtained on enrolment. (Mean age, (61.73± 8.05) years;mean duration of diabetes, (8.77±2.66) years; mean HbA1c,(8.1 ± 1.7)withT2DM and body mass index (BMI) > 25.1 kg/m^2 underwent examination. Age, sex and (BMI) matched with thirty eight(38) healthy controls were also in ruled,Serum preptin and amylin levels were measured by ELISA technique.There was statistically significant difference between patients and controls serum amylin (p=0.023) and preptin (p=0.01).Patients with T2DM had significantly higher blood glucose (p=0.0001), HbA1c (p=0.0001), insulin (p=0.0001), and homeostaticmodel assessment of insulin resistance (HOMA-IR) (p=0.001)compared to healthy control,while total cholesterolwas positively related (p=0.111)triglyceride, low-density lipoprotein cholesterol values were (p<0.001 for each), and significantly lower high-density lipoprotein cholesterol levels comparedwith the control group (p<0.0001). The preptin level demonstrated asignificant positive association with insulin and HOMA-IR compared with healthy control.For healthycontrol group: r=0.381,p=0.146, r=0.133,p=0.438respectively; for T2DM group: (r=0.411,p=0.02, r=0.332,p=0.003), The amylin level also showed a significant positive correlation with insulin and HOMA-IR compared with healthy control. (for healthy control group: r= 0.188,p=0.309, r=-0.039,p=0.911) respectively; for T2DM group: (r=0.279,p=0.002, r=0.291,p=0.003),Conclusions: There were significant differences between healthy control and patients with T2DM concerning amylin and preptin levels.Serum Amylin and preptin increase in association with insulin in diabetic conditions. The present study suggests a potential role of amyline and preptin in the pathogenesis of T2DM.

Keywords: *Amylin, preptin, diabetes.*

Introduction

The term diabetes mellitus (DM) describes a metabolic disorder of multiple etiologies characterized by chronic hyperglycemia with disturbances of carbohydrate, fat and protein metabolism resulting from defects in insulin secretion, insulin action, or both.The effects of DM include long-term damage, dysfunction and failure of various organs. Diabetes mellitus may present with characteristic symptoms such as thirst, polyuria, blurring of vision, and weight loss [(1)]. T2DM results from a defect in insulin action in hepatic and peripheral tissues, especially muscle tissues and adipocytes [(2)]. The specific etiologic factors are not known but genetic input is much stronger inT2DM than type 1 diabetes mellitus (T1DM) [(2)]. Human islet amyloid polypeptide (hIAPP) which named as amylin, 37 amino acid, that is co-secreted with insulin from pancreatic islet β cells. This peptide when accumulates, and aggregates forms fibrils; Amyloid deposits is associated with β cells degeneration which considered as a hallmark of non-insulin-dependent diabetes mellitus mellitus (NIDDM)[(3)]. The The prevalence of diabetes

for all age-groups worldwide was estimated to be 2.8% in 2000 and expected to be 4.4% in 2030[4]. The total number of people with diabetes is projected to rise from 171 million in 2000 to 366 million in 2030. According to International Diabetes Federation data, there were some 425 million patients with diabetes worldwide in 2017, and this number is estimated to reach 629 million by 2045[5,6,7]. Amylin is produced via gene expression on chromosome 12. It is transcribed as an 89-aminoacid prepolypeptide, which is cleaved to form the mature peptide in the β cells of the pancreas, where it is stored along with insulin and C-peptide in the same granules [8].Amylin, which is co-secreted with insulin, regulates post-prandial glucose levels in part by inhibiting gastric emptying and suppressing the glucagon release while not affecting glucose uptake[9].Amylin Amylin has been shown to mirror insulin secretion in healthy subjects[10], obese subjects, prediabetics (subjects with impaired glucose tolerance) [11,12], and patients with T2DM(10). These findings suggest an active role for plasma amylin levels in modulating glucose metabolism [13].

As an endocrine peptide, preptin is thought to activate the insulin-like growth factor factor receptor 2 (IGF2R), and as a result, induces calcium-dependent insulin secretion in association with protein C and phospholipase C when the glucose concentration is high[14]. In addition, preptin has insulin-like effects on bone metabolism, such as boosting cellular differentiation and affecting the functions of osteoblasts and osteoclasts[15]. Preptin is a 34-amino acid peptide hormone co-secreted from the cells of the pancreas along with insulin, amylin,and pancreastatin[16,17]. Females have higher preptin levelsthan males [18]. Preptin is believed to be a pphysiological enhancerof insulin secretion induced by glucose. There is a strong correlation between obesity, hyper-insulinemia and insulin resistance, and these associations get stronger with increasing body weight[19]. Therefore, the relationship between BMI and preptin level would be a worth investigation. Hence, this study was carried out to evaluate amylin and preptin in patients with T2DM.

Subjects, Material and Method

Subjects: This study comprised sixty four consecutive patients of T2DM (26 male and 38 female) and 38 healthy controls(18 male and 20 female) were recruited from the Endocrine outpatient clinic in the Al-Imamain Al-Kadhimain city hospital from March 2018 to May 2018. All the patients were asked to provide socio-demographic data, medicalhistory, and family history.Other questions included were:theduration of disease, age of onset of the disease, anytreatment taken.

Inclusion criteria: Patients who are suffering and diagnosed as T2DM patients.

Exclusion Criteria: T1DMpatients, Pregnant women, Presence of other autoimmune diseases like Hashimoto's thyroiditis, SLE, patients with liver disease, renal disease, recent history of cardiovascular disorder, hypertension, neurological disease, or obese subjects with history of acute or chronic infections, any other chronic diseases, under cortisol treatment or suffering from any autoimmune disease, were excluded from the study.

Blood Sampling: Blood samples (7 ml) were collected from T2DMpatients diagnosed according to the WHO protocol, and control subjects in serum separatorvacutainers (BD Vacutainer Systems, Plymouth, UK).Sera was separated and immediately stored at − 20° Cuntil analysis.

Serum Amylin and preptin: The quantitative determinations of Amylinlevels and preptin were conducted by ELISA technique, using acommercial available kit, (human Amylin ELISA kit Catalog No. MBS72142 Mybiosource.com) and (human Preptin ELISA kit Catalog No. MBS764034Mybiosource.com) respectively.

Statistical analysis: All data were coded and entered using the program statistical package for social sciences (SPSS) version 25 under windows XP. Descriptive data was summarizedusing mean, standard deviation (SD), $P< 0.05$ were considered statistically significant.

Results

Serum levels of Amylin and preptinwere estimated in 64 patients with T2DM, compared with 38 healthy control, age and sex matched. As expected, the patients with T2DM had been significantly higher level of Amylin levels than the healthy controls($P=0.023$), as as shown in table (1) and Figure(1).

The concentrations of preptinlevel, are presented in Table (1) are significantly higher in T2DM patients as compared with normal subjects ($p=0.01$). As shown in figure (2), themean level of amylin and preptin in normal healthy subjects and T2DM patients was depicted in Table 1.

Table (1): the Anthropometric and biochemical variables between the studied groups.

Parameters	Healthy Control Mean± SD	Type 2 DM Mean ± SD	P-value
NO.	38	64	……..
Age (years)	58.3 ± 9.1	61.73± 8.05	0.0001
BMI	26.5 ± 3.2	29.2 ± 4.2	0.411
FPG (mg/dL)	78.8± 8.1	188.3± 38.1	0.0001
HBA1c (%)	4.1 ± 1.3	8.1 ± 1.7	0.0001
Insulin (µiU/L)	6.67 ± 4.76	4.33 ± 2.53	0.0001
HOMA-IR	1.21 ± 0.16	1.77± 0.38	0.001
Total Cholesterol (mg/dL)	165.7 ± 22.3	191.7 ± 26.3	0.111
Triglyceride (mg/dl)	96.8± 29.3	187.6 ± 63.6	0.0001
HDL-C (mg/dL)	44.3 ± 4.1	34.5 ± 2.8	0.0001
LDL-C (mg/dL)	105.4± 26.3	181.4 ± 41.8	0.293
Amylin (pg/ml)	133.46±68.47	244±73.74	0.023
Preptin (pg/ml)	383.11±18.47	546.68±19.62	0.01

Values are Mean ± SD, BMI: body mass index HOMA-IR: homeostatic model assessment-insulin resistance, FPG: fasting plasma sugar, HBA1c: hemoglobin A1C, HDL-C: high-density lipoprotein-cholesterol, LDL-C: low-density lipoprotein-cholesterol, $P < 0.05$ is considered statistically significant

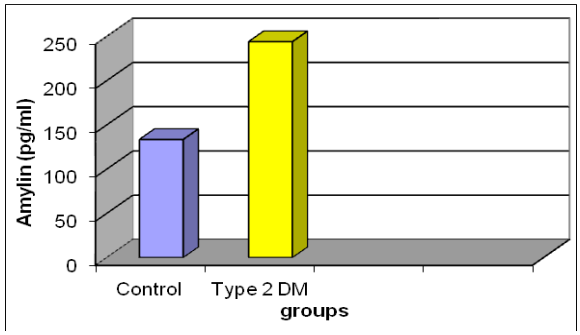

Figure (1): Mean levels of Amylin in patients with Type 2 DM compared to healthy controls.

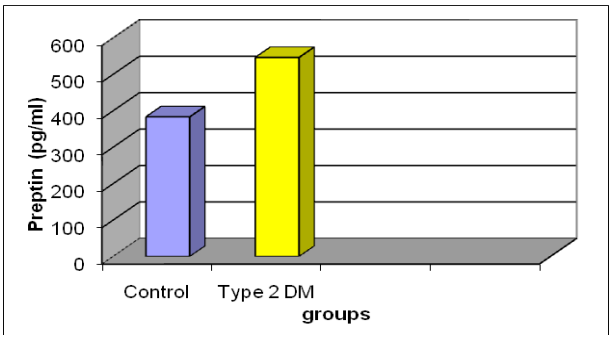

Figure (2): Mean levels of Preptin in T2DM patients compared to healthy controls

The amylin level demonstrated a significant positive correlation with insulin and HOMA-IR compared with healthy control(r=0.279,P=0.002),(r=0.291,P=0.003). Also preptin level showed a significant positive correlation with insulin and HOMA-IR compared with healthy control.(r=0.411,P= 0.02),(r=0.332,P= 0.003)

Discussion

In T2DM, the levels of amylin are raised in parallel with the increased demand for insulin, and this is thought to induce concentration-dependent amylin aggregation [20]. Islet Islet amyloid formation is associated with reduced β-cell mass [21] and human amylin 'oligomers' (small, soluble aggregates) are toxic to cultured islet cells[22] suggesting that they could contribute to progressive islet β-cell failure. Amylin oligomers can disrupt membranes [23] and inflict oxidative damage to cells [24]. In the present study amylin was measured and compared in type 2 DM and control, there was significant statistical difference between type 2 DM and control group where the p-value was 0.023. Researchers mentioned that islet amyloid deposits are found in >90% of T2DM patientsat autopsy [25], and action [26]. Amylin has been. However,the mechanisms and the precise role of amylin in the pathophysiologyof T2DM remain unclear.

In the present study the concentrations of preptin level significantly higher in T2DM patients as compared with normal subjects (p=0.01), as illustrated in Table (1).These results agree with other results done byYang et al.[27] who found higherlevels of preptin in T2DM patients compared withthe control group. Higher preptin levels have also been reported instudies of patients with gestational DM and polycystic ovarysyndrome [28,29,30]. Preptin is a physiological enhancer of insulin secretion induced by glucose. Recent studies have revealed that there is a potential association between preptin and insulin resistance in humans [31]. About diabetes mellitus, this association was also significant and this is confirmed by literature where it was shown that the concentration of preptin levels were higher in DM patients [32]. Statistical analysis revealed that Amylin significantly related to the variations seen in HOMA-IR in the present study, indicating a connection between amylin and insulin resistance in patients with T2DM.

In the present study preptin level showed a significant positive relation with insulin and HOMA-IR compared with healthy control.These results consistent with other

results that showed strong association between preptin levels and HOMA-IR in obese subjects as previously mentioned[33].

Similar to our research, thepreptin level showed a positive correlation with insulin, HOMAIR,glucose, and HbA1c levels in a study conducted by Yang etal [27]. Therefore, it is expected that a possible relation between amylin and preptin levels might exist.In the present study these two peptides(amylin and preptin) increases independently in T2DM patients; however, both indices demonstrated a positive correlation with insulin levels and HOMA-IR values.

Conclusion

Amylin and preptin may have an important role in the pathogenesis of T2DM, and ultimately in the degeneration and death of pancreatic islet cells. These findings provided a new rationale and opening up additional avenues of research into the etiology, pathogenesis and the treatment of T2DM. The findings of this investigation may provide significant data for in future research.

Impact of Occupation and Lifestyle on Prevalence of Non-Specific Low Back Pain among Common Population: A Cross-Sectional Study

Mohan Kumar. G.[1], Jibi Paul[1], Sundaram M.S.[2], Mahendranath P.[3], Priya C.[4], Premnathmargabandhu[5]

[1]Professor, Faculty of physiotherapy, Dr. MGR Educational & Research Institute, Chennai, [2]Professor, School of Physiotherapy, Vels Institute of Science, Technology & Advanced Studies, Chennai, [3]Associate Professor, ACS Medical College & Hospital, Chennai, [4]Assistant Professor, Department of Bio Technology, Dr. MGR Educational & Research Institute, Chennai, [5]Senior Physiotherapist, Physiotherapy Department, Health Service Executive, HSE, Ireland

Abstract

Introduction: Over the previous decade, musculoskeletal disorders have turned into a noteworthy ailment causing disability and expanded burden around the world. This burden will probably develop consistently, impacted by the accompanying variables, for example, age, occupation, way of life, general wellbeing, replacement, wellbeing history and so on. Earlier examinations have officially shown that age amass somewhere in the range of 34 and 51 years of age of office workers have encountered non specific low back pain in the first investigation for a year was up to 20 to 23% of office specialists.

Aim of Study: Evaluating the commonness of NSLBP among individuals of age group 18-60 years in like manner populations to contemplate the pervasiveness of NSLBP in relationship with occupational posture and way of life factors. Likewise we indent to make a self administratorquestionnaire for the examination populations utilizing computerized correspondence frameworks (Survey monkey application)

Material and Method: A cluster sample of over 480 subjects in like manner populations changing age groups between 18-60 years, where haphazardly got from office workers and drivers to be taken an interest in the examination. Overview through a survey for investigating general wellbeing, Body mass index, age, gender, occupation, rate and span of non specific LBP taken after by examination of information utilizing reasonable factual devices. We needed to reject couple of reactions from our investigation as they were either from individuals younger than 18 years old or more seasoned than 60 years old.

Conclusion: The vast majority of the members had no past history of lower back pain. Some of them could have bring down back pain because of their wellbeing conditions, some because of inactive way of life, some because of movement and so forth. Smoking and liquor addiction likewise could conceivably prompt lower back pain that is nonspecific. For this to be demonstrated, more surveys must be led taking a bigger example of around 1000 subjects.

Keywords: *Non specific, lower back pain, Prevalence, Population.*

Introduction

Non specific lower back pain is a condition that exists in numerous people from youths to grown-ups. The reason for this back pain isn't exceptionally sound. The back pain isn't caused by any conspicuous, known particular pathology. The seriousness of pain can be from mellow to extreme. Although, nonspecific lower back pain(NSLBP) has been viewed as an uncommon event

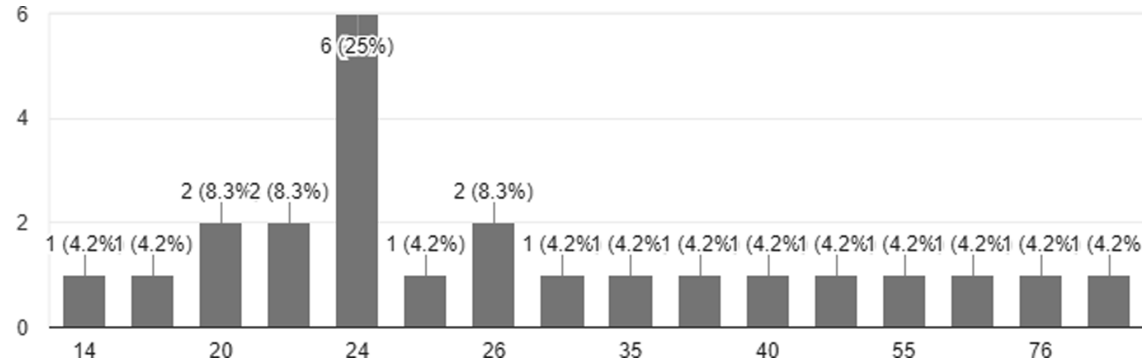
in teenagers, recent research demonstrates that there has been a noteworthy increment among young people experiencing lower back pain[1,2]. NSLBP is frequently portrayed to as a pain experienced underneath the costal edge [3]. It is thought to be a noteworthy medical issue worldwide among grown-ups with an expected lifetime commonness of more than 60% [4]. The commonness of perpetual lower back pain is around 23% [5]. The principal scene of the NSLBP can be experienced by a person as youthful as 9 years old[6]. Lifetime predominance fluctuated from young people to grown-ups, from nation to nation. For instance in low pay nations like South Africa, Kuwait and Nigeria has been accounted for as 58%, 57.8% and 25% separately[7,8,9].

Lifetime pervasiveness has been depicted to show extent of individuals who has encountered it in any event once in lifetime[10]. Lower back pain (LBP) can result in absence of execution at work front. It might prompt segregating oneself from society as the individual experiencing LBP will most likely be unable to go to social capacities and take an interest actively[11]. It is viewed as that around 85% of individuals experiencing LBP have nonspecific low back pain as the correct reason for torment isn't known [12]. It is arrangement in light of appraisal, asymmetry, arrangement and adaptability of lumbar spine, pelvis and hip [13].

The vast majority with nonspecific lower back pain recovers rapidly, on occasion; the recovery can take longer time. It tends to be said that nonspecific lower back pain varies as per the movement did and the posture of the body.

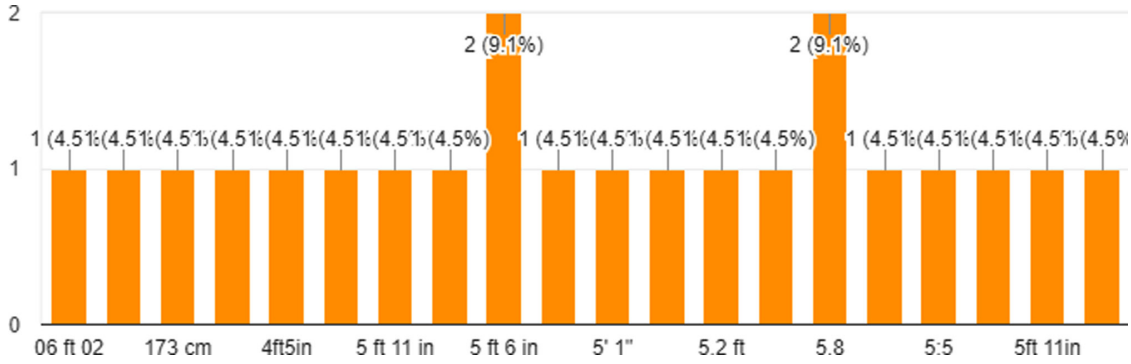
The NSLBP that goes on for over about a couple of month and a half, it is calledchronic lower back pain. Components adding to NSLBP could be inactive way of life, no break at work, travel, driving constantly for a while. The study aims to checkinfluence of occupation and lifestyle on prevalence of Non-Specific Low Back Pain among Common populationThis examination was led with the reason to ponder population amass experiencing nonspecific lower back pain in the Southern part of India



Material and Method

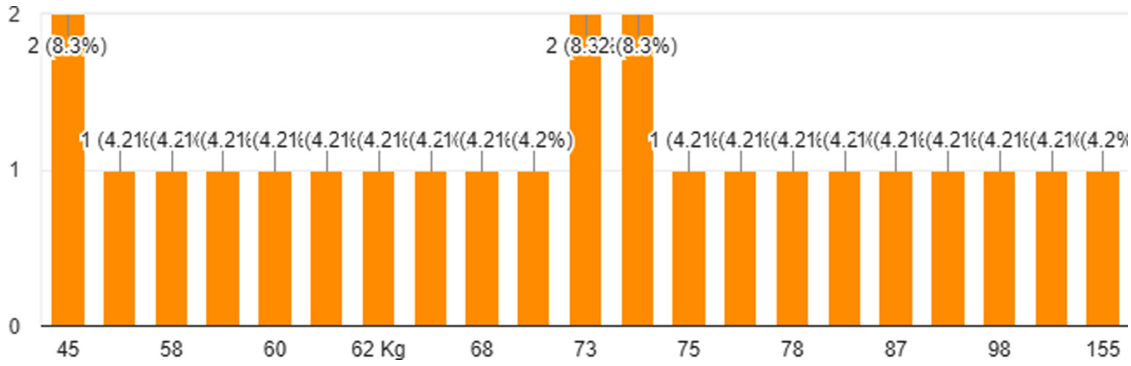
A cross sectional study survey was composed and offered out to around 480 individuals arbitrarily to fillquestionnaire. This was finished with a goal to comprehend the different variables that could possibly add to nonspecific lower back pain(NSLBP), with both genders, age group between 18 to 60 years and furthermore to limit underneath whose recuperation took longer than about a couple of month and a half. The examination would help in distinguishing hazard factors identified with occupation and way of life on growing LBP and its commonness among various age groups of individuals.

The inquiries were separated into five classes in particular Personal, Medical history, Physical wellness, business and travel. The classifications were picked in the wake of considering factors that may possibly add to bring down back pain like not taking break at work, voyaging ceaselessly, driving constantly for a considerable length of time, to what extent it takes to recuperate from back pain, liquor utilization, conjugal status, physical effort and so on.



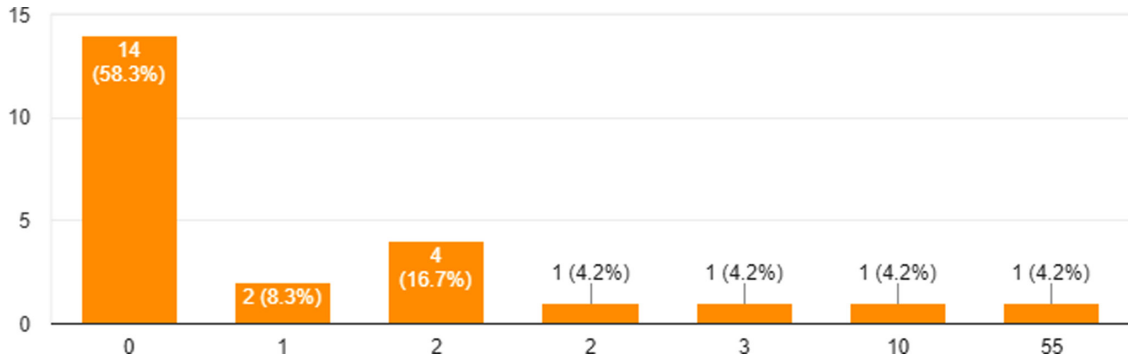
The questionnaire was outlined in such a way, it would be simple for all age'sgroups to answer the inquiries. Individuals underneath 18 years old the event may not be that clear and in the meantime, it very well may be utilized to discover bring down LBP caused by occupation.

Data Analysis



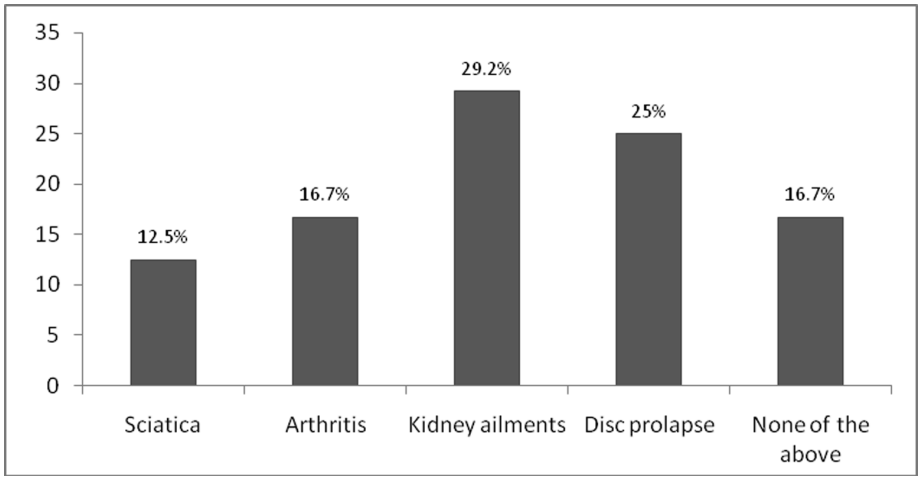
Graph 1: Age

People of age 24 years took part effectively in the survey. Around 120 individualstook part in the survey to help evaluate the occupational related dangers with NSLBP.



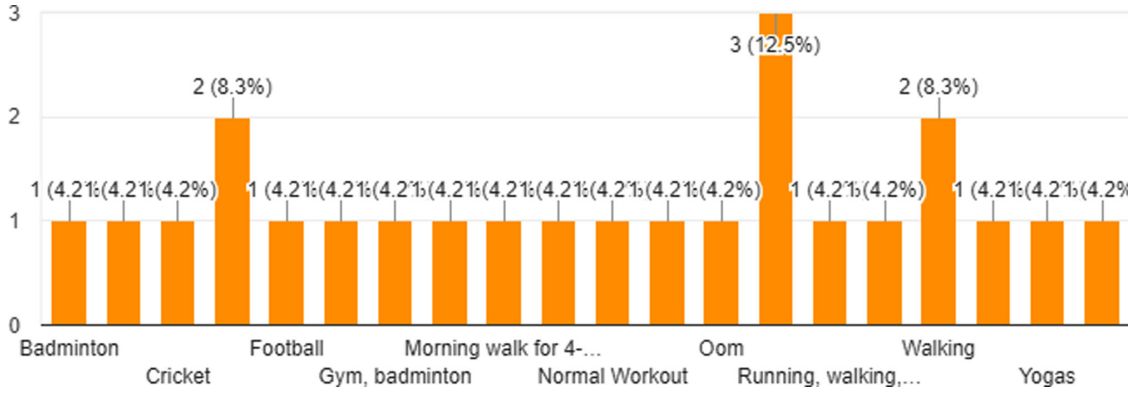
Graph 2: Height

Majority of the people was between 5 feet 6 inches to 5 feet 8 inches. The base tallness was 4 feet 5 inches and the most extreme stature was 6 feet 2 inches.



Graph 3: Weight

On a normal, individuals measured 70 kg. The most extreme weight being 155 kg and the base weight being 45kg.



Graph 4: Frequency of Back Pain and Duration

Around 58.3% had no history of LBP,around 4.2% (20) of the members experienced LBP for more than 10 years now.

Graph 5: Have You Been Diagnosed with Sciatica/Arthritis/Kidney Ailments

Individuals having kidney illnesses represented 29.2% (140 people) of the study members. Around 12.5% (60) people having Sciatica and around 25% (120) individuals with disc prolapsed. The rest of the 16.7% (80) people were not having any of the previously mentioned. The greater part of them has not had any of the conditions, like Sciatica, Arthritis and Kidney diseases. A couple has been determined to have these conditions for nearly 4 years.

Graph 6: What Kind of Fitness or Sport You Involved

Survey members were involved in different sorts of exercises like Badminton, Cricket, Football, Yoga and so forth. Some went to fitnesscenter; some were occupied with running and strolling. A large portion of them being involved in Walking/running/Jogging.

Marital Status: of members who took part in survey, 71% (340) were not married and the rest of the 29%(140) were married. Employment: of the 480 individuals, around 280 people that are represents around 58.3% were employed and the staying 200 which represents around 41.7% were not employed. Since the target of our investigation was individuals working to comprehend whether any factor in occupation is prompting NSLBP. Drinking Habits-Alcohol: Around 380 members were observed to be the individuals who don't expend liquor potential nondrinkers. This represented around 80% of the population while around 20% consumed liquor. Drinking Coffee: Around 37.5% (180 people) of the study members did not consume espresso. However, there were many members who expended espresso in excess of two times each day and rare sorts of people who consume most likely two times each week.Food Habit: Around 220 individuals who participated in the study were vegetarians. This represented 45.8% of the survey members and the staying 54.2% were non vegetarians. Smoking: of 480 individuals, around 440 people were non-smokers that is 91.7% of the survey members and 8.3% were smokers.

History of Back Pain: Around 339 individuals who took part in the survey had no history of LBP, around 8.3% (40) had NSLBP for more than 12 weeks and 16.7% (80) had bring down LBP for under about a month and a half. Around 4.2% experienced LBP that went on for 6 to 12 weeks.History of Back Pain in a Family:Around 159 survey members (i.e. 33.3%), had somebody they would say bring down back pain later in their life. The staying 321 survey members had no history of LBP in their family. Frequency of Back Pain and Duration: Around 58.3% (279) of the study members had no history of LBP. Around 37.5% of members experienced LBP at some point. Around 4.2% which is low number of members encounter bring down LBP every now and again.

How regularly you do Exercise: Around 200 survey members performed practices every day. Around 240 members performed practices now and again. Around 8% of the members did not do any kind of activities. Physical Exertion: Around 279 members experienced physical exertion around 60 minutes. Around 140 members experienced physical exertion for around 1 to 2 hours every day. Around 60 individuals experienced it for around 2-3 hours per day.About the Shoes: Around 300 individuals that took part in the survey for NSLBP did not utilize heeled footwear. The staying 37.5% (180 people), wore heeled footwear most consistently.

Work Schedule: Around 180 of the survey peoplehad a sedentary life. Around 154 members needed to travel a considerable measure in the meantime; the way of life was sedentary. Around 60 (12.5%) people went all the time. 16.5% (79) of the members were occupied with physical exertion everyday premise.Work Experience: Around 180 people were either fresher's or had 1 to 2 years work experience. Around 159 survey participants had work experience between 2 to 5 years and around 140 individuals had work experience greater than 10 years. People with greater than 10 years of work experience would better understand occupational factors contributing to NSLBP.How often you take break at Work: A standout factors in deciding components is whether a man going to work is taking breaks Around 219 people rarely enjoyed reprieve at work. Around 180 members enjoyed reprieve often 60 members enjoyed reprieve very often and a couple around 20 nevertook break at work.

How Frequently You Travel: Around 240 individuals travelled now and again. Around 140 members travelled very frequently. Around 80 individuals travelledfrequently. Generally around 4% of the members did not go by any means. Mode of Travel: The majority of them utilized two wheeler to go from place to place. Around 159 people gone by bus and around 60 people via car. The quantity of individuals going to work or to different places by walk and train were the same.Frequently of driving: The majority of the study members did not drive for a considerable length of time. A few members drove for over 2 hours.

Findings: With the approach of science and innovation, individuals depend more on machines to their work instead of working out themselves. It influences an individual mentally on the grounds that, the individual does not entertain oneself doing exercises in the fitness center for wellness or not walking to the closest grocery store. The examination was comprehendto the work relatedcomponents also; way of life factors possibly could bring down back pain. We excluded 40 responses as 20 were younger than 18 years and 20 responses from individuals more noteworthy than 60 years old. Around 339 people took part in this survey had not experienced lower back pain by any stretch of the imagination. This could be because of connecting themselves in a few sorts of activities like running, strolling, and yoga and so on. Exercise is known to diminish the quantity of repeats of lower back pain and furthermore decrease pain in individuals experiencing lower back pain[14]. A portion of people in the survey with no analysis of kidney diseases could be experiencing lower back pain either due to the utilization of heeled shoes or because of consistent travel and stationary way of life. One of the components at work that may conceivably prompt individuals getting lower back pain isn't taking break at work. Nowadays the utilization of PC isn't just confined to programming engineers, even biotechnologists, mechanical designers, structural architects; electrical specialists need to utilize PCs at work. Evidencesuggests that effective multidisciplinary management approach involves for NSLBP[15]. Hence, it tends to be presumed that back pain can be added to a great deal of variables including sitting posture. Additionally studies must be led to get an unequivocal end to find out the variables that may add to bring down back pain.

Result

The accompanying investigation was attempted so as to survey the effect of occupation on the nonspecific lower back pain. Around 480 individuals were picked

indiscriminately from various expert gatherings and were given a survey containing around 28 questions. Around 40 (8.3%) of the responses must be prohibited from the examination as the people did not meet the age criteria. Around 40 out of 480 were well more than 60 years old. Around 24 (5%) responses were from individuals more youthful than 18 years old, hence excluded from the examination.

Conclusion

Lower back pain could be consequence of an assortment of exercises. 480 individuals from Southern part of India took part in the study. We needed to reject around 40 responses 20 responses from individuals more youthful than 20 years old and 20 responses from individuals more prominent than 60 years old as it would give a reasonable picture. Out 480, around 336 members had never experienced lower back pain. Some of them could encounter it on account of working persistently without break and driving a stationary way of life alongside visit travel. It was likewise observed numerous individuals who were performing exercise all the time might be the ones who might not have had back pain. Numerous variables, for example, sitting posture, going by bikes, driving for extended periods can prompt lower back pain. The impact of smoking and liquor addiction on bring down back pain isn't exceptionally lucid. For an authoritative end, examine must be directed considering an example of a greater example of around 1000 members and by including more factors.

Conflict of Interest: None

Source of Funding: Self funded study

Ethical Clearance: Ethical clearance was obtained from Institutional Review Board of Faculty of physiotherapy, Dr. M.G.R. Educational & Research Institute.

Abstract

PCOS (Polycystic ovary syndrome) one of the endocrine disorders most often in women of reproductive age, marked menstrual disorders (amenorrhea/oligomenorrhea), hirsutism, acne, alopecia, biochemical examination results in increased androgen. The high incidence with the same phenotype in family members of PCOS patients shows that genetic factors play a role. The purpose of this study was to analyze the relationship between gene polymorphism INSR and levels SHBG on PCOS (Polycystic ovary syndrome) in the Madurese tribe.

This study was analytic observational with study design case-control, a sample of 30 patients (PCOS cases) and 30 healthy women (not PCOS) in the Madura Tribe Previously, screening of SGOT, SGPT, BUN, Creatinin and GDA, PCR and RFLP was examined in the INSR gene and examination of SHBG levels by ELISA kit.gene research results INSR have 16.67% TT genotype, 63.33% TC and 20.00% CC, control group has 38.24% TT genotype, TC 44.12% and CC 17.65%, whereas in the case group T 48.33%, C allele 51.67% and control group 56.67% T allele and 43.33% C allele, based onstatistical tests chi-square in the case group and control of both genotypes and alleles there was no significant difference (P> 0.05). This study was first carried out in the Madura Tribe in the INSR gene and in the examination of SHBG levels, the results showed no INSR gene differences between PCOS and healthy women.

Keyword: *PCOS (Polycystic ovary syndrome), polymorphism, INSR, SHBG.*

Introduction

PCOS (Polycystic ovary syndrome) is an endocrine disorder in women of reproductive age characterized by menstrual disorders (amenorrhea/oligomenorrhea), hirsutism, the appearance of acne, alopecia and biochemical examination androgen (testosterone) which increases by[1]. The long-term impact of PCOS infertility, insulin resistance, increased risk of diabetes and cardiovascular disease[2]

Basedon diagnostic criteria *National Institutes of Health* 1990, PCOS prevalence is 6 to 10% of women of reproductive age, but Rotterdam's prevalence is twice as high as[3]. Based on research revealing 75% of infertility with anovulation causes were caused by PCOS, and the prevalence of PCOS in Surabaya in women of reproductive age was 4.5% [3]. Based on research in Sampang and Bangkalan regencies on May 20, 2017, for 5 months; January to May 2017 in WijayaKusuma and RSIA RoudatulHikmah clinics, around 5.2% and 4.7% of women of reproductive age, and 60% of cases of infertility caused by PCOS.

Thegene In Iranian Turkish women revealed there was no relationship between thegene*INSR* and SOP[4.] polymorphism*INSR* was a genetic predisposing factor for PCOS. Based on several studies have been conducted to examine the relationship between *Single nucleotide polymorphismsINSR(SNPs)* and PCOS[5].

The results of gene research underlying the occurrence of PCOS are still contradictory, due to

Phone: 082231230066

regional, ethnic and racial differences, so further research is needed to prove the gene causing PCOS. The genetic role of PCOS supports, the genes involved in the etiology of the syndrome have not been fully investigated until now[3] genetic risk factors can detect PCOS early, thus avoiding risk factors for PCOS. The gene *INSR* study in PCOS patients has the potential for tribes because it has a high carbohydrate-consuming lifestyle, and marriage tends to be non-mixed.

Material and Method

This study was an observational analytic *case control*. The number of samples of 30 samples of PCOS and healthy women of 30 samples was taken by *purposive* sampling technique according to the criteria of case and control groups. Case group criteria are native Madurese (3 generations), married women aged 20-40 years, pregnancy program, there are Rotterdam criteria of at least 2 clinical symptoms, normal kidney function and liver physiology, 3-5 days of menstruation and control group criteria are genuine Madurese (3 generations), women married and aged 20-40 years, regular menstruation at intervals of 21-35, no diabetes, kidney and liver physiological disorders, 3-5 days of menstruation, no hormonal therapy or hormonal contraception 3 previous month. Screening Initial examination of SGOT, SGPT, BUN, Creatinin, and blood sugar, if normal further Body Mass Index Measurement is continued, followed by SHBG examination using an ELISA kit. Taking 8 mL of blood using EDTA tubes for DNA extraction was then taken by plasma for examination of SHGB levels from PCOS patients and healthy women.

Findings: All PCOS patients were 30 patients and controlled 34 healthy women, both cases and controls come from the Madura tribe. Based on (Table 3) it was found that clinical and biochemical examination characteristics for age, BB, BMI there were significant differences between case and control groups (P <0.001), whereas biochemical examination *SHBG* there was no significant difference in (P> 0.05). but it was seen from the mean of the two groups that there was a difference, the level *SHBG* was lower than the PCOS group of the healthy women group.

Gene polymorphism was *INSR* analyzed using *PCR-RFLP*. The results of the frequency distribution of genotyped and alleles in the gene *INSR* can be seen in (Table 4). Analysis of the genotype statistical test andgene allele *INSR* found no significant differences (P> 0.05) between the PCOS group and the control group.

Based on (Table 5) shows that from the results of the Logistic Regression statistical relationship of thegene *INSR* and levels *SHBG* there was no significant relationship P> 0.05.

Discussion

Genetic research on ethnicity that is different from China, Caucasian but says there is no significant relationship between FSHR (Ala370Thr) gene, INSR gene,and LHCGRgene. The results of the study of the characteristics of PCOS patients and healthy women obtained age, BB, BMI there was a significant relationship, BB and BMI in PCOS patients were higher than the control group, this is in accordance with Bassiuny study, 2014 that age and BMI were significantly higher in the PCOS group[7,8]. Obesity and overweight are manifestations of PCOS, especially obesity that occurs in the abdominal area, even 50% of women who are obese or overweight will experience PCOS[9, 27, 28.]

The results of the SHBG examination in this study found no significant relationship but seen from the mean more SHBG low PCOS patients compared to the control group, the control group of SHBG levels was higher, and in the PCOS group the levels of SHBG were lower, from five studies said that SHBG levels were not significant with PCOS[10.19]. PCOS patients SHBG levels were lower than in the control group[11]. Low levels of SHBG are a risk factor for the occurrence of hyperandrogenism and insulin resistance.[12] SHBG is a glycoprotein that is in testosterone and other steroid hormones in the blood, many studies linking low SHBG levels with PCOS[13]. Research revealed that SHBG levels were also found in PCOS women compared with controls.[14]

The results of this study showed no significant differences in INSR genes between PCOS women and healthy women. Based on research on Turkish women, it was found that the INSR gene with PmIlenzyme *restriction* showed that there was no difference between the case group and control of both genotype and allele[4]. The INSR gene study had no significant differences in genotypes and alleles between case and control groups. But it was seen from the relationship of INSR gene alleles with PCOS that there was a significant relationship with the PCOS group. Research on Madurese tribes is not in line with research in Iranian women, found that there was a significant association of INSR genes with PCOS[15.20]. Research on American women shows that there is an association between the INSR gene and PCOS found in thin women, but it is also necessary to describe the environmental factors that influence the occurrence of PCOS[16.]The results of research on the Madurese tribe found no significant relationship with PCOS in the INSR gene. very significant was found in PCOS women compared to the control group. But from the relationship test, the results of the INSR gene allele were significantly associated with the incidence of PCOS in the Madura tribe.

Thegene is *INSR* located on chromosome 19 and consists of 22 exons, measuring 120 kb. INSR studies in knockout rats show extreme insulin resistance. Insulin resistance stimulatessecretion*LH* from the pituitary and testosterone production from theca cells and cytochrome p450 activity from granulosa cells thereby disrupting follicular maturation and becoming PCOS. Polymorphism of *Allele INSR* genetic predisposing factors for PCOS.

There were no significant differences in the INSR gene (Pm*I*I) between 50 sample PCOS patients and 47 control groups in Iranian women. PCOS has various etiologies including gene and environmental gene interactions. PCOS is associated with insulin resistance, type 2 diabetes mellitus, hyperinsulinemia, hyperandrogenism, inflammation, cardiovascular disease, and hypertension. PCOS women are diagnosed with hyperandrogenism, menstrual irregularities,and infertility, and are usually overweight or obese[4,21,22,24,25]. There was a significant association of the INSR gene with PCOS patients in 677 participants, the INSR gene had risk factors for PCOS and the INSR gene relationship. INSR gene has an important role for the occurrence of PCOS regulate insulin, a study in China found an increased risk of insulin resistance and PCOS is associated with the group of patients emaciated by RFLP analysis, it is also consistent with studies conducted in the United States[17].

Research shows that there is a relationship between the INSR gene and the incidence of PCOS. Obese women develop insulin resistance so hyperandrogen

affects follicular development and PCOS occurs, and PCOS pathogenesis differs between thin and obese women[8]. A Korean women's study reported that there was no significant association between the INSR gene and PCOS, the frequency of allele T was higher in PCOS patients compared to the norm group[18,23]. Different research in Madura tribe found allele C was higher in PCOS patients than in healthy women.

Conclusion

Research on the INSR gene had no differences in INSR between PCOS and healthy women, and from the SHBG level there were no differences between the case and control groups, but the results from the mean were found to be lower in PCOS compared to the control group, so further research was needed. genes that are a risk factor for PCOS with a larger number of samples.

Accuracy of 3D Ultrasound in the Diagnosis of Uterine Pathology in Patients with Postmenopausal Bleeding

Nihal M. El-Demiry[1], Hassan M. Gaafar[1], Mohamed F. Ibrahim[2], Hany M. El-Didy[1]

[1]Department of Obstetrics and Gynecology, [2]Department of Pathology, Faculty of Medicine-Cairo University, Egypt

Abstract

Objective: To evaluate the diagnostic accuracy of 3-Dimensional transvaginal sonography (3-D TVUS) in detection of myometrial and endometrial lesions compared to uterine histopathological assessment in patients with postmenopausal bleeding(PMB).To estimate the accuracy of transvaginal Power Doppler of the endometrium and subendometrial space in predicting endometrial pathology in PMB patients.

Material and Method: Prospective observational study conducted on 80 postmenopausal patients presenting with PMB.All patients were subjected to 2-dimensional (2-D) and 3-D TVUS of the uterus to detect the presenceof any cavitary or myometrial lesions.Power Doppler sonography was done to detect vascular flow to the endometrium and subendometrial space to measure RI (Resistance Index), PI (Pulsatility Index) and PSV (Peak Systolic Velocity) of remarkable vessels.Histopathological diagnoses were obtained in all cases.

Results: The corresponding sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) of 3-D TVUS as a diagnostic test for Fibroid were 94.11%, 93.6%, 80% and 98.33% respectively and for Adenomyosis, were 88.88%, 95.77%, 80% and 98.55% respectively.

The accuracy of 3-D TVUS in diagnosing myometrial lesions is of 88.46% sensitivity & 55.56% specificity with accuracy 75% however in diagnosing endometrial lesions is of 77.36% sensitivity & 90% specificity with accuracy 81.93%.

The receiver operating characteristic(ROC) curvesrevealed that the cut-off values of RI=0.76, PI=1.26 & PSV=6.25 (cm/sec) for prediction of abnormal endometrium yielded sensitivity of 98.15%, 73.6% & 75.5% respectively.

Conclusion: 3-D TVUS is an accurate tool in diagnosing the cause of bleeding in postmenopausal patients; it shows high correlation with the histopathological results.

Power Doppler examination of the endometrial and subendometrial space can be used to differentiate normal from abnormal pathology through cut-off values with high sensitivity specially when examining RI values.

Keywords: *Postmenopausal bleeding, 3-Dimensional transvaginal sonography, Power Doppler, PSV, RI, PI.*

Introduction

PMB is a common problem that affects 1 in 10 postmenopausal women older than 55 years and representing 5% of all gynecology outpatient attendances.[1]

Although PMB usually has a benign cause, the priority is to exclude malignancy. Endometrial atrophy, submucosal fibroids, endometrial polyps, endometrial hyperplasia, endometrial carcinoma and estrogen withdrawal were considered knownCauses of PMB.[2]

At present, endometrial sampling is the gold standard for the diagnosis of Uterine/Endometrial

pathology however; endometrial sampling is an invasive procedure. Sampling may be performed via office biopsy, dilatation and curettage (D & C) or in some cases, hysteroscopically guided biopsy. Endometrial tissue sampling resulting in findings insufficient for diagnosis is common. D & C misses 2% to 6% of endometrial lesions, with even higher miss rates for office biopsy in which less tissue is sampled. Hysteroscopically guided biopsy is more expensive and requires considerable physician expertise.[3]

Consequently, guidelines were developed to consider these issues in evaluating women with PMB.[4] The guideline development group recommended endometrial sampling or transvaginal ultrasonography for initial management of spontaneous PMB. This will enable patients with endometrial thickness of 4 mm or less to be managed expectantly.[5]

The recent advent of Three-dimensional volume ultrasound (3-D US) of the female pelvis, specifically using a transvaginal approach, has been one of the most important advances.[5,6]

3-D US permits a more selective approach to endometrial biopsy in women with PMB by finding those who truly need to be sampled and directing the choice of the best sampling technique in each individual patient.[7]

Material and Method

The current prospective observational study was conducted at department of Obstetrics and Gynecology, Kasr Al-Ainy Hospital, Cairo University between March 2016to December 2018. It included 80 patients with PMB recruited from the attendees of the outpatient Gynecology clinic. The study was approved by the Kasr Al-Ainy ethical committee. All patients were counselled about the procedure and an informed consent was obtained from all cases.

The included women were menopausal (Menopause; defined as 1 year of absence of menstruation in women older than 50 and the amenorrhea was not explained by medication or disease) complaining of PMB; defined as any vaginal bleeding in a postmenopausal woman not on hormone replacement therapy. Women on hormonal therapy, with coagulation disorders, thyroid and liver diseases, neglected intra uterine device or pessary or any cervical abnormality were excluded.

All participants underwent the following: full history taking, complete physical examination (general examination including BMI & gynecological examination), laboratory investigations (complete blood count, liver function tests, kidney function tests and a coagulation profile), 2-D TVUS to measure Endometrial Thickness (ET) and presence of any endometrial and myometrial focal lesions,Power Doppler ultrasound is done to detect vascular flow to the endometrium and the sub-endometrial space to measure RI, PIand PSV of remarkable vessels, 3-D TVUS to acquire multiplanner view of the uterine cavity and detect presence or absence of any cavitary or myometrial lesions and Pathological diagnosis (after curettage or hysterectomy) for histopathological examination & assessment.

Transvaginal sonography was performed for all patients using GE Voluson E10 (GE Healthcare, Milwaukee, WI, USA) transvaginal volumetric probe transducer with frequency range of 5-8 MHz equipped with color, power and pulsed Doppler capabilities.

First, 2-D TVUS was performed to measure maximum ET and to detect the presence of any endometrial and myometrial focal lesions.

Then, 3-D TVUS to acquire multiplanner view of the uterine cavity to notice the presence of any focal endometrial or myometrial lesions.

Thereafter, the power Doppler gate was activated for blood flow mapping of the endometrium and endometrial-myometrial interface (subendometrial area).

Once the vessels have been identified, the pulsed Doppler sample volume was activated to obtain a flow velocity waveform (FVW). RI, PI and PSV were automatically calculated from three consecutive FVWs. The lowest RI and PI, and the highest PSV found were recorded.

Patients were then admitted for either endometrial sampling or for total Abdominal Hysterectomy. All removed tissues were sent for histopathological assessment. Data were statistically described in terms of mean ± standard deviation (± SD), range, or frequencies (number of cases) and percentages when appropriate. Comparison of numerical variables between the study groups was done using Student t test for independent samples. Agreement between the different diagnostic techniques was tested using kappa statistic.

Accuracy was represented using calculated values of sensitivity, specificity, PPV, NPP value, and overall accuracy.

ROC curves analysis was used to determine the optimum cut off value for the studied diagnostic markers. p values less than 0.05 was considered statistically significant. All statistical calculations were done using computer program SPSS (Statistical Package for the Social Science; SPSS Inc., Chicago, IL, USA) release 15 for Microsoft Windows 2006.

Findings: The characteristics of the patients included in this study are represented in Table 1.

Table 1: Patient characteristics

Variable	Mean ± Standard deviation		
Age (years)	54.33 ± 3.634		
Gravidity	6.33 ± 2.916		
Parity	5.19 ± 2.797		
BMI (kg/m^2)	36.93 ± 6.603		
Age at menopause (Years)	50.41 ± 2.114		
PMB Presentation	**Number**		**Percent**
	Primary	32	40
	Recurrent	48	60
Medical disorders among the study group	**Number**		**Percent**
	Hypertension	14	17.5
	Diabetes Mellitus	8	10
	Hypertension & Diabetes	10	12.5
	Others	6	7.5
	Free	42	52.5
Type of operation subjected to the study group	Hysterectomy	45	56.25
	Dilatation & Curettage	35	43.75

The 3-D TVUS and histopathological examination findings in the myometrium and the Endometrium are shown in tables 2, 3.

Table 2: Myometrial lesions as detected by 3-D TVUS and Histopathology (In patients underwent Hysterectomy):

Lesions	Number	%
By 3-D TVUS		
Fibroid	20	44.5
Adenomyosis	11	24.4
Free	14	31.1
Total	**45**	**100**
By Histopathology		
Fibroid	18	40
Adenomyosis	9	20
Free	18	40
Total	**45**	**100**

Table 3: Endometrial appearance and lesions as detected by 3-D TVUS and Histopathology:

Lesions	Number	%
By 3-D TVUS		
Endometrial Polyp	16	20
Endometrial Hyperplasia	25	31.3
Endometrial Carcinoma	3	3.8
Free	36	45
Total	**80**	**100**
By Histopathology		
Endometrial Polyp	15	18.8
Endometrial Hyperplasia	33	41.3
Endometrial Carcinoma	5	6.3
Free	27	33.8
Total	**80**	**100**

The accuracy of 3-D TVUS in diagnosing myometrial and endometrial lesions is shown in table 4.

Table 4: The accuracy of 3-D TVUS in detection of Myometrial and Endometrium lesions:

	Sensitivity	Specificity	P PV	N PV	Accuracy
Myometrium	88.46	55.56	74.19	76.92	75.00
Endometrium	77.36	90.00	93.18	69.23	81.93

Velocimetric parameters & endometrial thickness: Malignant endometrium had a much lower RI (mean =0.316±0.0196), and higher PSV (mean = 10.91 ±0.55) than other benign causes of PMB (Table 5)

Table 5: Velocimetric parameters & endometrial thickness According to pathology:

Pathology	ET (mm, mean±SD)	PI (mean±SD)	RI (mean±SD)	PSV (cm/mean±SD)
Endometrial Polyp	18.33 ± 4.11	1.1± 0.395	0.56± 0.16	6.9± 1.2
Endometrial Hyperplasia	10.97± 3.5	1.0632±0.57	0.61± 0.168	6.57± 1.9
Endometrial Carcinoma	16.6± 5.12	0.69±0.05	0.316±0.0196	10± 0.55
Free Endometrium	6.98± 2.39	1.35±0.49	0.7± 0.22	4.7± 1.4

ROC Curves revealed that the cutoff values of RI = 0.76, PI = 1.26 & PSV = 6.25 (cm/sec) (AUC ROC 0.761, 0.682 and 0.783 respectively) for discriminating between Normal and Abnormal endometriumhad sensitivity of 98.1%, 73.6% & 75.5% respectively (Fig. 1)

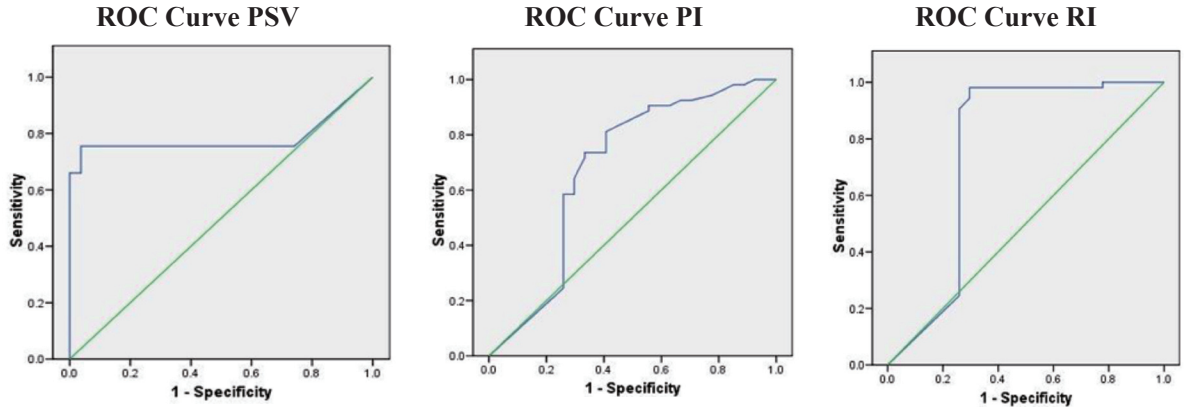

Fig. 1: ROC Curves showthe cutoff value which differentiates the normal from the abnormal endometrium according to PSV, PI and RI values

Discussion

At present, TVUS is used as a first step in the evaluation of women with PMB. In this prospective study, the corresponding sensitivity, specificity, PPVand NPV of 3-D TVUS as a diagnostic test for leiomyoma were 94.11%, 93.6%, 80% and 98.33% respectively.These results are similar to those of other previous studies that evaluated the accuracy of ultrasonography in enabling the diagnosis of leiomyoma. Hanafi, in 2013reported sensitivity and specificity of TVUS as a diagnostic test for leiomyoma of 96.38% and 96.00%,respectively with accuracy of 96.32%.[8]

Adenomyosis is a relatively frequent disease that is difficult to diagnose. Both magnetic resonance (MRI) imaging and ultrasound (US) are non-invasive tests with equivalent accuracy in diagnosing adenomyosis.[9]

Similarly,for the initial 3-D TVUS diagnosis of adenomyosis, current study findings are similar to those of other studiesthat reported sensitivity of 65% to 98% and specificity of 86% to 97%.[10]

Endometrial polyps are one of the most common etiologies of abnormal genital bleeding in both premenopausal and postmenopausal women.[11] Borges et al., 2015 observed the prevalence of endometrial polyps in 79% of postmenopausal women. In their study, ultrasonography had a sensitivity of 88.7% and specificity of 25.4%.[12] The prevalence rate of malignancy associated with endometrial polyps ranges from 0.8% to 8%, depending on the sample analyzed and the resection method used.[13]

Accordingly, in our study, it was observed that via 3-D TVUS, an endometrial Polyp was detected in 16 (20%) patients, with a mean ET of 18.33 mm.

Histopathological examinations confirmed the presence of hyperplasticendometrial polyps in15of 16 patients. Well differentiated Endometrioid endometrial adenocarcinoma with an irregular/thick endometrium of 12 mm on 3-D TVUS was evident inone patient. The mean ET in endometrial hyperplasia, endometrial carcinoma and free endometria were 10.97± 3.5, 16.6± 5.12, and 6.98± 2.39, respectively. There was

a statistically significant difference in the mean ET between women with endometrial carcinoma and women with free (normal) endometrium (P-value= 0.001).

ET of ≤ 5 mm associated with a low endometrial cancer risk had been reported.

In two large studies, using < 4 mm thickness as normal, the sensitivity was 98% with a range of specificity between 36% to 68% for the detection of endometrial cancer.[5]

Women with PMB and a thick endometrium must undergo endometrial sampling because of the high risk of endometrial cancer. [14]

In the present study, the diagnostic performance of 3-D TVUS in predicting endometrial pathology hada sensitivityof 88.46%, specificity of 90%,PPVof 93.18%,NPP of 69.23% and adiagnostic accuracy of 81.93%.

Shiva et al. (2018) reported,TVUS had a sensitivity of 50% and specificity of 98% for the diagnosis of myoma and a sensitivity of 54% and specificity of 80% for polyps.[15] Zafarani and Ahmadi (2013) reported that endometrial hyperplasia could be suspected sonographically. The principal findings are a thickness of> 15 mm or >8 mm after menopause and the presence of a non-homogenous echo pattern with microcysticchanges.[16] Meanwhile, Reported sensitivity of endometrial biopsy varies from 82% to 94%, with false negative rates as high as 15%.[17]

Regarding Velocimetric Parameters, the cut off values of RI=0.76, PI=1.26 & PSV=6.25 for discriminating between Normal & Abnormal endometrium had sensitivity of 98.1%, 73.6% & 75.5% respectively. RI and PI values of benign lesions (0.66 ± 0.19 and 0.92 ± 0.27 respectively) were significantly higher than that of carcinoma (0.33 ± 0.03 and 0.45 ± 0.15 respectively) (p value < 0.05).

In cases with endometrial polyps, a higher RI was reported (mean =0.56± 0.16) than in cases with endometrial carcinoma.

The results were in agreement with those of previously reported studies where the RI and PI values were significantly lower in malignant endometrium than in benign diseases of the endometrium in postmenopausal women[18] Bano et al, (2013), using RI = 0.81 and PI = 1.83as cutoff values for discriminating benign and malignant endometrium,sensitivity was 62.5% and 75% respectively.[19]

Conclusion

In the present study by correlating ultrasonography findings with histopathological findings, we have demonstrated that 3-D TVUS evaluation of uterine volume can enable accurate identification of uterine pathology, and should be considered for all patients with PMB. The accuracy of 3-D TVUS was 75.00% and 81.93% in diagnosing myometrial and endometrial lesions respectively.

Also Power Doppler examination of the endometrial and subendometrial space can be used to differentiate normal from abnormal pathology through cut-off values with high sensitivity specially when examining RI values.

Antibacterial Activity of Zinc Oxide Nanoparticles on the Growth of Enterococcus Feacales, Candida and Total Root Canal Microbiota (in Vitro Study)

Salah A. Hadi[1], Abbas S. Al-Mizraqchi[2]

[1]M.Sc., [2]Ph.D., College of Dentistry, University of Baghdad, Iraq

Abstract

Severalendodontic irrigants,medication can eliminate endodontic pathogens,the possible development of resistant bacterial species, the anatomic complexity of the root canal system and limitation of cleaning and shaping protocols making the achieving of complete elimination of the pathogens is difficult. Antimicrobial nanoparticles show promising effect against pathogens The concept of using nanoparticles in endodontics as a new treatment modality was developed recently and their antibacterial efficacy against endodontic pathogens was evaluated by several researchers in many in vitro studies. The aim of this study to evaluate the antimicrobial activity of zinc oxide nanoparticles against E.feacales, candida and total root canal microbiota.30 patients diagnosed with necrotic root canal and failed endodontic treatments was selected, microorganisms were isolated from root canals andcultured, After identification and isolation of bacterial species, agar diffusion method was used to assess the antibacterial action of ZNO NPs, Zones of inhibition (no growth of bacteria) were examined around the wells containing ZNO NPs & diameters of the zones were measured in mm. The mean of inhibition zones was measured and statistically analyzed among groups using ANOVA. Znonps showed increase in diameter of the inhibition zone as the concentration increased, 2% concentration showed the larger inhibition zone, When comparing between the diameter of the inhibition zone of the ZNO NPs on the bacteria using F-test for all concentration the result was highly significant except for 0.25% concentration it was non-significant. It can be conclude that the zinc oxide nanoparticles in different concentrations have inhibition effects on *E. feacales, candida, T. aerobic* and *T. anaerobic*, the sensitivity of the bacteria to ZnO NPs increase with increasing of the concentration.

Keywords: *endodontics, zinc oxide nanoparticles, Enterococcus faecales,candida,agar diffusion test.*

Introduction

The root canal system is, in its healthy and intact state, free from microorganisms, once bacteria inter the root canal by caries lesion the consequences may vary from a simple reversible pulpitis to the necrosis of the pulpal tissue and eventually formation of a periapical lesion(1).Although fungi and most recently archaea and viruses have been found in association with endodontic infections(2)bacteria are the major microorganisms implicated in the pathogenesis of root canal infection. In advanced stages of the endodontic infectious process, bacterial organizations resembling biofilms can be observed adhered to the canal walls(3) Consequently, apical periodontitis has been included in the roll of biofilm-related oral diseases.Enterococci have been implicated in endodontic infections..its occasionally isolated from primary endodontic infections but frequently recovered from treatment failures (4). The rapid emergence of antimicrobial resistance among enterococci makes it difficult to treat the chronic infections.Enterococcus faecalis is a nonspore-forming, fermentative, facultatively anaerobic, Gram-positive coccus. Enterococcus faecalis cells are ovoid and 0.5 to 1 µm in diameter. They occur singly, in pairs, or in short chains, and are frequently elongated in the direction of the chain. Most strains are nonhemolytic and nonmotile. Surface colonies on blood agar are circular, smooth,

and entire. The G+C content of the DNA ranges from 37 to 40mol% [4].*E. faecalis* may cause secondary infections that later become persistent[5].*E. faecalis* can survive in endodontically treated teeth, it has to resist intracanal disinfection procedures and to escape the action of chemomechanical preparation and adapt to the harsh environmental conditions caused by treatment[6]. Antibacterial nanoparticulates are found to have high antibacterial activity. because of the increase in the surface area and charge density of nanoparticulates, which give greater degree of interaction with the negatively charged surface of bacterial cells[7].Zinc oxide nanoparticles have high antibacterial effectiveness, its mechanisms similar to that of other types of nanoparticles, causing increased permeability of the cell wall membrane, a release of cytoplasmic content and cell death[8]. The objective of this study to analyze in vitro study the antibacterial activity of the ZNO NPs on *E.feacales*, candida and total root canal microbiota.

Materials and Method

Patient selection and isolation of bacteria: 30 patients aged (20-40) years with infected root canals which were diagnosed clinically and radiographically. Rubber dam used in order of isolation of the teeth before sample collecting. After access opening and all caries removed the working length confirmed radiographically and instrumentation by sterile files then sterile paper point introduced in the canals to collect microorganisms and then removed and placed in transported media (phosphate buffer saline) (PBS) to preserve microorganisms and send to microbiological lab[9].

Isolation of microorganisms: the bacterial strains were used in the study which were Enterococcus faecalis, which were isolated and cultured on Brain heart infusion agar (Oxoid.uk) and Pfizer selective enterococcus agar (Himedia.india), fungal strain Candida which was isolated and cultured on a Sabouraud agar media(T mast.uk),total bacteria isolated on brain heart infusion agar and cultured aerobically for aerobic bacteria and anaerobically for anaerobic bacteria.

Identification of bacterial species: Microorganisms were identified at microbiology department in (college of dentistry–university of Baghdad), Biochemical tests by gram stain were used to distinguish between G+ve and G-v,catalase test to distinguish between catalase negative and positive, vitek 2 compact (**Biomerieux) used to diagnosed E.*feacales*.**

Activation of the isolates: Inoculoms of bacterial strain were activated by addition of pure isolates of each type of 10 ml of sterile BHI broth which were incubated aerobically for 24 hrs at 37 C and anaerobically for an aerobic bacteria.

Determination of viable count: Viable count (CFU/ml) were done for all types of microorganisms using serial delution with (PBS) and 0,1 ml from 10^{-3}–10^{-6} were inoculated on (BHI-A) and incubated aerobically except total anaerobic incubated anaerobically for 24 hrs at 37 C

Zinc oxide nanoparticles

ZnO NPs properties used in the study: in the study the ZnO NPs used was prepared by sol gel method from the Corporation of research and industrial development, Iraqi Ministry of industry and minerals that prepared by[10].

Characteristics of ZnO-NPs: ZnO NPs solution were identified by the Scanning Electron Microscope SEM (CM 10 Philips) showed in fig.In Centre-College of medicine, University of Al-Nahrain, Iraq.

Also identified by scanning probe microscope(SPM) and (AFM) in the *College of Science*, *Department of Chemistry*, *University of Baghdad*

The average diameter 46 nm: Determination of antibacterial activity of Zinc oxide nanoparticles to microorganisms (agar diffusion method)

Procedure:

- 0.1ml of fourteen activated E,feacales $3x10^6$cfu\ml, ten candida albicanes $1,5x10^5$cfu\ml, thirty total aerobic$7x10^6$cfu\ml and thirty total anaerobic $5x10^6$cfu\ml isolate were spread on BHI agar plates was taken respectively and, left at room temperature for 10 minutes, then wells of equal size and depth made with sterile stainless steel Cork borer in the BHI agar 6mm in diameter were prepared in the agar
- Five wells in each plate. Each well was filled with ZnO NPs in different concentration (2, 1, 0.5, 0.25)% and last well for solvent (ethanol 1-3 water mixture) as negative control. Plates left in the room temperature for 10 minutes and then incubated aerobically for 24hrs. at 37°C for aerobic bacteria, and anaerobically for total anaerobic bacteria plate

placed in anaerobic jar with a gas pack for 24hrs at 37 C.

- Inhibition zones were across the diameter of each well. The diameter of inhibition around the wells containing the test materials were measured and recorded after the incubation under aseptic condition.
- The inhibitory zone was considered to be in (mm) measured by Vernier caliper.

Results

Antibacterial activity of Zinc oxide nanoparticles on bacteria(agar well diffusion method).

The mean values and standard deviation (SD) values of the inhibition zones in millimeters (mm) of the zinc oxide nanoparticles against the bacteria are presented in the table(1).

Table 1: Diameter in (mm) of inhibition zone of ZNO NPs%

Bacteria	No. strain		2%	1%	0.50%	0.25%	Control
E.feacales	14	Mean	30.07143	20.64286	14.5	9.928571	0
		SD	0.730046	1.150728	0.518875	1.491735	0
Candida	10	Mean	18.9	12.4	9.8	9.5	0
		SD	0.875595	1.173788	1.398412	1.178511	0
T.aerobic	30	Mean	26.6	20.6	15	9.6	0
		SD	1.037238	1.037238	1.43839	1.037238	0
T.anaerobic 30	30	Mean	22.8	18.6	14.6	9.8	0
		SD	1.186127	1.037238	1.037238	1.186127	0

Znonps showed increase in diameter of the inhibition zone as the concentration increased, 2% concentration showed the larger inhibition zone while the solvent (negative control)showed no inhibition zone see Figure(1) and figure (2).

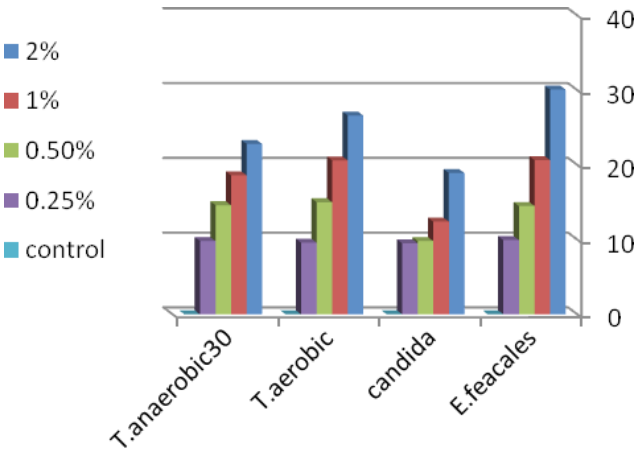

Figure (1): Bar chart showing differences between the mean of inhibition zones of ZNO NPs

When comparing between the diameter of the inhibition zone of the ZNO NPs on the bacteria using F-test for all concentration the result was highly significant except for 0.25% concentration it was non-significant see table (2).

Table (2): ANOVA between groups (bacteria) of diameter of inhibition zone of ZNO NPs%

	F-test	P-value	Sig

Discussion

The purpose of endodontic therapy is to eliminate bacteria and their by-products from the infected root canal system and prevent subsequent reinfection[11]. Chemomechanical preparation and intracanal medicaments significantly reduce microorganisms inside the infected root canal. However, it is virtually impossible to completely eliminate all microbes from root canal system in every case [12].The possible development of resistant bacterial species is one of the problems related to the efficacy of the currently available irrigants and medicaments. In addition, the complex anatomy of the root canal system allows endodontic pathogens to be hidden in areas inaccessible to the action of the irrigating preparations. Antimicrobial nanoparticles show promising effect against resistant pathogens in pharmaceutical science as a result of their unique physio-chemical properties. Unlike traditionally used antimicrobial agents, these nanoparticles destroy bacterial cells through multiple mechanisms. The concept of using nanoparticles in endodontics as a new treatment modality was developed recently and their antibacterial efficacy against endodontic pathogens was evaluated by several researchers in many in vitro studies[13].Zinc oxide nanoparticles showed high antibacterial effectiveness, destroying microbial cells in a higher pH environment[14].The antibacterial mechanism of zinc oxide nanoparticles is similar to that of other types of nanoparticles, causing increased permeability of the cell wall membrane, a release of cytoplasmic content and cell death[15].The bactericidal effect of zinc oxide nanoparticles was shown to be related to size, the smaller the size the higher the antibacterial effect and the

production of reactive oxygen species such as hydrogen peroxide when in contact with an aqueous medium[16]. Additionally, zinc oxide nanoparticles can produce zinc ions inside the bacterial cell causing disturbances in its enzymatic system and the mechanism of amino acid metabolism, resulting in further damage[17].The antibacterial effect of zinc oxide nanoparticles has been shown to depend on concentration, higher levels resulting in the maximum antibacterial effect.

The result of antibacterial assessment by disk diffusion method from which observed the antibacterial activity (the size of inhibition zone) depended strongly on the concentration of the ZNO NPs on the bacteria this agreed with Arabi et al[18]who conducted that the size of inhibition zone strongly depends on the concentration of ZNO NPs and also this agreed with study of Azam et al[19].who conducted that Zinc oxide NPs have greatest antimicrobial activity against both gram positive and negative bacteria it was also demonstrated that ZNO NPs poses excellent bactericidal activity and depend on concentration. The diameter of inhibition zone directly increased when the concentration is increased also.

Conclusion

Zinc oxide nanoparticles in different concentrations have inhibition effects on *E. feacales*, *candida, T.aerobic* and *T. anaerobic*,the sensitivity of the bacteria to ZnO NPs increase with increasing of the concentration. Zinc oxide nanoparticles are more appropriate for use as a root canal irrigant solution, intra-canal medicament, or even bioactive root canal filling material, which is still an area of further investigation. Also, the antimicrobial effects of the ZNO nanoparticles need to be tested against a large variety of persistent endodontic pathogens. Indeed, more studies are needed to evaluate the biocompatibility, safety, cost and ease of use of these innovative materials.

Behavioral Risk Factors Associated with Intestinal Parasitic Infestations among Children in Rural Areas

Samar G. Selim[1], Azza A. Attia[2], Sanaa A. Mahmoud[3], Azza I. Ismail[4]

[1]Clinical Instructor of Pediatric Nursing, Pediatric Nursing Department, Faculty of Nursing, Suez Canal University, [2]Professor of Pediatric Nursing, Pediatric Nursing Department, Faculty of Nursing, Cairo-University, 11562, [3]Assistant Professor of Pediatric Nursing, Pediatric Nursing Department, Faculty of Nursing, Cairo-University, 11562, [4]Lecturer of Pediatric Nursing, Pediatric Nursing Department, Faculty of Nursing, Suez Canal University, Egypt

Abstract

Background: Intestinal parasitic infestations (IPIs) still remain an important public health problem among children in developing countries including Egypt. Identification of behavioral risk factors among children is important for the effective prevention and control of these infestations.

Aim: This study aimed to assess behavioral risk factors associated with intestinal parasitic infestations among children in rural areas.

Design: A descriptive exploratory design was utilized.

Sample: Convenient sample of 120 children suffering from intestinal parasitic infestations and their mothers.

Tool of data collection: A structured interview questionnaire sheet included questions about behavioral risk factors.

Results: More than half and more than two fifths of children do not wash their hands either before eating or after using toilet respectively, about three quarters and most of children suffering from IPIs for the first time and more than one time respectively were exchanging personal hygienic instruments with their family' members, more than two fifths and slightly more than three fifths of children suffering from IPIs for the first time and for more than one time respectively were buying food from street vendors.

Conclusion: Neglecting washing hands before eating and after using toilet, sharing personal hygienic instruments with family' members and eating from food handlers were the behavioral risk factors associated with IPIs among children.

Recommendation: Develop educational programs to increase public awareness regarding behavioral risk factors associated with intestinal parasitic infestations among children.

Keywords: *Intestinal parasitic infestations, behavioral, risk factors, children, rural areas.*

Introduction

Intestinal parasitic infestations (IPIs) are endemic worldwide, it is estimated that 3.5 billion people have been affected, and 450 million are ill as a result of these infections with the largest majority of them being children [1]. Behavioral factors associated with IPIs include open defecation, neglecting hand washing after defecation and prior to eating food, eating street

Corresponding Author:
Azza A. Attia
Professor of Pediatric Nursing, Pediatric Nursing Department, Faculty of Nursing, Cairo-University, 11562, Egypt

food, eating unwashed food and pica, walking barefoot and handling animals that could be source of infective agents[2].

The deleterious effects of intestinal parasites on children are varied and terrifying such as growth retardation and the impairment of neuro-psychomotor development, immune function, productive ability and intellectual capacity that all will affect negatively on school performance and academic achievement. As well as, IPIs have been shown to affect nutritional status, physical development, mental function, verbal ability and cognitive behavior in children[3]. Assistance with identification of the parasites, assessment of risk factors, prevention of initial infection and treatment of current infection are considered major nursing responsibilities related to IPIs among children[4].

Aim of the Study: The aim of the present study was to assess behavioral risk factors associated with intestinal parasitic infestations among children in rural areas.

Research Question: What are the behavioral risk factors associated with intestinal parasitic infestations among children in rural areas?

Subject and Method

- **Research design:** A descriptive exploratory research design was utilized in the current study.
- **Research Setting:** The study was carried out four primary at health care units in rural areas that affiliated to Ismailia governorate, namely: Abu Atwa, Aldobaia, Nefesha and Ain Ghusein. Egypt.
- **Sample:** A convenience sample of 120 children aged 4-12 years old, suffering from intestinal parasitic infestations and their mothers.
- **Tool of data collection:**

  A structured questionnaire sheet:

  - **Part (I):** Socio-demographic data about the children and their parents.
  - **Part (II): Part (II):** Related to behavioral risk factors associated with IPIs among children including questions related to healthy and unhealthy hygienic behaviors of children.

Validity: The tool was revised by three experts in pediatric nursing and community health nursing for clarity, relevance, applicability, and comprehensiveness.

Reliability: Internal consistency reliability of the tool was done according to Cronbach's alpha coefficient and it was 0.85.

Pilot Study: A pilot study was conducted on 10 children with their mothers.

Procedure: An official letter was issued from the Dean of the Faculty of Nursing-Ismailia/Suez Canal University to the director of each study setting to seek their approval for carrying out the study. An official permission was obtained from the director of each study setting. The aim of the study and its expected outcomes had been illustrated. The actual field work was carried out over a period of 6 months, which started from 1st of October 2017 and ended in 1st of April 2018. The researcher was available 2 days per week (Saturday and Thursday) from 9.00 am to 1.00 pm in each setting of the above mentioned study settings for 6 weeks. The researcher introduced herself to the mother and the child and informed them about the purpose of the study. Oral affirmative consent was obtained from children aged 7-12 years old and written consent from mothers to participate in the study and then the researcher interviewed them in order to fill the study tool, the approximate time spent with each mother and her child dual to complete the study tool was 25 to 35 minutes across one session.

Statistical analysis: Descriptive statistics including frequency distribution, mean and standard deviation were used to describe different characteristics. Univariate analyses including: t-test was used to test the significance of results of quantitative variables and Chi-Square test was used to test the significance of results of qualitative variables. The significance of the results was at the 5% level of significance.

Results

Table (1) reveals that 58.3% of children their age ranged between 6 to less than or equal to 12 years old with mean age score mean ±SD = 6.7±2.4 years, slightly more than half of children (51.7%) were females. Less than half of children (47.5%) are ranked as the third child or more, the most of children (82.5%) are going to either school or nursery.

Table (1): Percentage distribution of children suffering from IPIs according to their personal characteristics (n=120)

Items	No.	%
Age (Years)		
• Preschool (4-<6)	50	41.7
• School age (6-≤12)	70	58.3
Mean ± SD	6.7±2.4	
Gender		
• Male	58	48.3
• Female	62	51.7
Rank of the child		
• First	35	29.2
• Second	28	23.3
• Third or more	57	47.5
The child goes to school or nursery		
• Yes	99	82.5
• No	21	17.5
Kindergarten	36	30.0
Primary school	63	52.5

Table (2) clarifies that 54.2% of children reported that they do not wash their hands before eating, 44.2% of children reported that they do not wash hands after using toilet and slightly less than half of children (48.3%) reported that they do not trim their nails weekly.

Table (2): Percentage distribution of children suffering from IPIs according to their healthy reported hygienic behaviors (n=120)

Items	No.	%
Wash hands before eating		
Yes	55	45.8
No	65	54.2
Wash hands after using toilet		
Yes	67	55.8
No	53	44.2
Used material for hand washing		
Water only	78	65.0
Water and soap	42	35.0
Wear trousers during sleep always		
Yes	117	97.5
No	3	2.5
Trim his nails weekly		
Yes	62	51.7
No	58	48.3

Table (3) reveals that 25.4% of children infected for the first time do not exchange personal hygienic instruments with their family' members, while 88.5% of children suffering from recurrent infestations reported that they exchange personal hygienic instruments with their family' members and the difference between the two groups is statistically significant, 94.9% of children suffering from IPIs for the first time do not deal with cattle in home or barn, while 27.9% of children suffering from recurrent' infestations deal with cattle in home or barn and the difference between the two groups is statistically significant, 79.7% of children suffering from IPIs for the first time do not play with cats and dogs outdoors, while 47.5% of children suffering from recurrent' infestations play with cats and dogs outdoors and the difference between the two groups is statistically significant. Also, 57.6% of children infected for the first time do not buy food from street vendors, while 60.7% of children suffering from recurrent infestations buy food from street vendors and the difference between the two groups is statistically significant.

Table (3): Relationship between the unhealthy reported hygienic behaviors of children and the recurrence of parasitic infestations (n=120)

Items	Recurrence of infestations				X^2	P
	First time (n=59)		More than one time (n=61)

Figure (1): Types of intestinal parasites

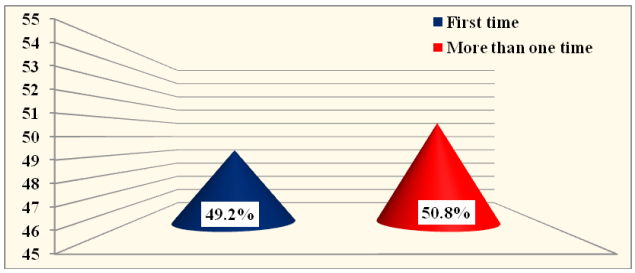

Figure (2): Recurrence of intestinal parasitic infestations

Discussion

The results of the current study revealed that more than half of children do not wash their hands before eating. This finding was in accordance with the study done by[5] titled "Prevalence of intestinal parasitic infections and risk factors among school children at the University of Gondar Community School, Northwest Ethiopia" who reported that more than two thirds of children infected with intestinal parasites do not wash their hands before eating. The present study results illustrated that more than two fifths of children do not wash their hands after using toilet. This result was supported by[6]in a study titled "A study of prevalence of intestinal parasites and associated risk factors among the school children of Itahari, Eastern Region of Nepal" who revealed that the likelihood of acquiring IPIs in children who did not wash their hands after using toilet was higher than among those who wash their hands.From the researcher point of view, neglecting washing hands either before eating or after using toilet among children in the current study may be due to lack of children awareness about the importance of hand washing in interrupting parasite transmission and low socio-economic status which play a role in the lack of resources such as soap necessary for washing hands.

The current study results revealed that slightly less than half of children reported that they do not trim their nails weekly. This finding was emphasized by[7] in a study titled"School-based prevalence of intestinal

parasitic infections and associated risk factors in rural communities of Sana›a, Yemen**"**who reported that the risk of being infected by intestinal parasites was increased among children with untrimmed and unclean finger nails as compared with children who have trimmed clean fingernails. As regards the unhealthy reported hygienic behaviors of children, the results of the current study revealed that most of children suffering from recurrent infestations reported that they exchange personal hygienic instruments with their families, while slightly more than one quarter of children infected for the first time do not exchange personal hygienic instruments with their families and the difference between the two groups is statistically significant. These results were inconsistent with the study conducted by[8] in a study titled" Life style related to parasitic infestation among primary school children in rural area" who revealed that about three quarters of families of children infected with intestinal parasites reported that they never shared in personal equipment. From the researcher point of view, exchanging personal hygienic instruments among family members may be increase the transmission of infection and the recurrence also.

The present study results revealed that less than half of children suffering from recurrent infestations play with cats and dogs outdoors, while more than three quarters of children suffering from IPIs for the first time do not play with cats and dogs outdoors and the difference between the two groups is statistically significant. These findings were consistent with[9]who found that more than two fifths of children infected by parasites were playing with cats and dogs outdoors and that it was considered the independent risk factor associated with parasitosis among children living in Damanhur city, Elbehera governorate, Egypt.

The present study results revealed that slightly more than three fifths of children suffering from recurrent infestations buy food from street vendors, while less than three fifths of children infected for the first time do not buy food from street vendors and the difference between the two groups is statistically significant. These findings were in accordance with[10]who found that slightly less than two thirds of children suffering from IPIs their mothers were dependent on street food in their homes.

Regarding the types and recurrence of IPIs among children, the present study results revealed that more than two thirds of children are infected with Entrobius vermicularis followed by more than two fifths infected with Entameba histolytica. These findings were in accordance with[11]who reported that Entrobius vermicularis was the most prevalent type of parasites among children as about two thirds of children were infected by this type of parasite. The current study results illustrated that slightly more than half of children are suffering from recurrent infestations. This finding was in accordance with[12] who noted that less than two thirds of children were suffering from recurrent IPIs. From the researcher point of view, recurrence of infestation among children may be due to their unhygienic practices and their immature immune system which put them at frequent risk of infestations.

Conclusion

Neglecting washing hands before eating and after using toilet, sharing personal hygienic instruments with family' members and eating street food were the behavioral risk factors associated with IPIs among children.

Recommendations:

1. Implementation of health education programs about behavioral risk factors and prevention of IPIs for the already diagnosed children with IPIs and their mothers at primary health care units or outpatient clinics.
2. Increase of public awareness regarding behavioral risk factors predispose to IPIs and its' control method through mass media, social media and others.
3. Regular screening and treatment of IPIs for children in rural areas.
4. Further researches are recommended to determine behavioral risk factors associated with IPIs among children in other rural areas with large sample size to generalize the results.

Ethical Clearance: Primary approval was obtained from the research ethical committee in the Faculty of Nursing, Suez Canal University. The researcher explained the aim and nature of the study to children and their mothers for gaining their cooperation. Oral affirmative consent was obtained from children aged from 7-12 years old while written consent was obtained from their mothers to participate in the study after informing them about their voluntary participation and their right to withdraw from the study at any time. The topic of this study doesn't touch religious, ethical, moral and cultural issues among participants. Mothers and

children were assured that all gathered information will be confidential and will be used only for the purpose of the study.

Conflict of Interest: The authors declare that there is no conflict of interest.

Source of Funding: There are no resources of fund.

Legal Perspective about the Management of Fishery and Marine Investment Management in Indonesia

Samsul Wahidin

Faculty of Law, University of Merdeka Malang, Malang, East Java, Indonesia

Abstract

The constitutional perspective provides the basis that the earth and water and natural resources contained therein were controlled by the State and used for the greatest prosperity of the people. This means that the government policy as the elaboration of this constitution must take sides to the people, in the sense of improving their standard of living. Policy as stipulated in Regulation of the Minister of Finance of the Republic of Indonesia No. 159/PMK/011/2015 about Tax Holiday Social Economic Condition and Policy and Fishermen's Welfare in Indonesia. In the field of economy is processed into several fields, namely the field of the state that implements the scope of large (public utilities); the field of cooperatives working on a small scope starting from the bottom. For the private sector acting between two so-called national private or national private sectors by cooperating with the foreign private sector in the line specified by the Government on its application is not in favor of the people. The tendency to side with entrepreneurs with various motivations. This causes the management of fishery and marine investment in Indonesia is not correlated with efforts to improve the welfare, especially for the fishermen.

Keywords: *Management of Investment, Fisheries, Legal Aspects.*

Introduction

Indonesia is the world's largest archipelagic country with 17,504 islands and 5.8 million km^2 of marine waters (consisting of 0.3 million km^2 of territorial sea, 2.95 million km^2 of archipelagic waters and 2.55 million km^2 of Indonesian ZEE).[1] Geo-politically Indonesia has a very strategic role because it is between the Continent of Asia and Australia, as well as between the Pacific Ocean and Indian Ocean. The position places Indonesia as the world's maritime axis in the context of global trade linking the Asia-Pacific region with Australia.[2,3]

Indonesia's archipelagic waters include oceans that contain biological resources that are very important for the prosperity of the people of Indonesia.[4] Indonesia's marine area including the Exclusive Economic Zone of Indonesia is an area of 2.7 million km^2 surrounded by tropical ecosystems such as mangrove forests, coral reefs, and biological and non-biological resources contained therein.[5]

Fisheries biological resources are strategic economic resources to improve the welfare of the Indonesian people. The marine and fisheries sector can be one of the most important sources of economic growth because of its huge supply capacity, while demand continues to increases, in general output can be exported, whereas inputs from local resources can generate large upstream and downstream industries.[6] These effects can absorb a lot of manpower, generally in the area and the fishing industry, biotechnology and marine tourism can be renewable (renewable resources) so as to support sustainable development.[7]

In 2014, the Ministry of Marine Affairs and Fisheries of the Republic of Indonesia implement various development policies with the following results: Gross Domestic Product (GDP) of Fishery in 2014 grew by 6.97%. This figure is higher than the national GDP growth of 5.1% and the growth of agricultural GDP in the broad sense of 3.3%. If viewed from the magnitude of its economic value, GDP Fisheries in 2014 reached IDR. 340.3 Trillion.

Increased fisheries production each year has supported national food security, especially in the provision of animal protein for the improvement of community nutrition; The export of fishery products in 2014 reached USD 4.64 billion. The export result was dominated by the export value of shrimp commodity

which reached USD 2.09 billion and followed by Tuna, Tongkol and Cakalang fish commodity amounting to USD 0.69 billion in 2014. In line with the above, it is necessary to elaborate more on how the arrangement of marine development investment in Indonesia. Similarly, about the socio-economic aspects and the level of fishermen's welfare as a result of foreign investment in Indonesia.

Investment Management and Marine Development Investment Arrangement.

Investment Activities: Investment is an activity to invest capital now to gain profit in the future, which always depends on the consideration in terms of managerial. In the investment activity, there are two approaches, namely macro approach and micro approach.

The macro approach is an investment activity in which there is government interference, and the micro approach is the legal relationship of the parties that is brought together in a position that is faced between the investor and the beneficiary.[7] Generally, investment can be interpreted as an activity undertaken by individuals and legal entities in an effort to increase and/or maintain their capital value in the form of cash, equipment, fixed assets, intellectual property rights, or expertise.

Law investment is the legal norms concerning the possibility of investment, investment conditions, protection and most importantly directing investment to bring prosperity to the people. Government policies to increase investment will affect the number of catches and patterns of utilization of fishery and marine resources.

Investment activities either in the framework of Foreign Investment (FI) or Domestic Investment (DI) implemented with the aim of improving national economic growth. In order to further stimulate investment for development, it is deemed necessary to simplify investment system and procedures including the review of the duty of the Capital Investment Coordinating Board, the Investment Bureau of the relevant departments with the development of the investment business field, and the Investment Coordinating Board.[8]

The location can be located at (a). Certain industrial estates and/or certain bonded areas; (b). outside a certain bonded industrial zone/region Investment and Marine Development in Indonesia Based on Article 3 paragraph (1) letter (a) of the Investment Law, it is stipulated that investment activities shall be organized on the basis of legal certainty.

According to Ida Bagus Rahmadi, there are 11 factors into consideration before conducting investment activities namely (a). risk of investing; (b). bureaucratic range; (c). transparency and legal certainty; (d). transfer of technology; (e). guarantee and protection of investment; (f). employment; (g). availability of infrastructure; (h). the existence of natural resources; (i). market access; (j). tax incentives; (k). effective dispute resolution mechanisms.[7]

Basically, investors, both domestic and foreign investors who invest in Indonesia are given various facilities. The granting of easiness is intended for domestic investors or foreign investors to invest in Indonesia.

Investment in Marine Fisheries Sector: The definition of maritime development is regulated in Article 1 number (6) of the Maritime Law, namely development that provides direction in the utilization of marine resources to realize economic growth, equity of welfare, and keppeliharaan carrying capacity of coastal and marine ecosystem.

Marine economy Under Article 15 paragraph (2), marine economic policy aims to make marine as the basis of economic development. Article 15 paragraph (4) stipulates that to make marine as the basis of nation's economic development, the Government shall include the sea area as the basis for the allocation of marine development budget.

Marine Management Based on Article 14 paragraph (1) of the Maritime Law, it is stipulated that the government and regional government shall be in accordance with the authority to conduct marine management for the greatest prosperity of the people through the utilization and exploitation of marine resources using blue economic principles. Based on Article 14 paragraph (2) Marine is stipulated that the utilization of marine resources as referred to in paragraph (1) may include: (a). fishery; (b). energy and Mineral Resources; (c). coastal resources and small islands; (d). non-conventional resources.

While the exploitation of marine resources under Article 14 paragraph (3) of the Marine Law can be: (a). marine industry; (b). Marine tourism; (c). sea transportation; (d). building of the sea. Fisheries Based on Article 16 of the Maritime Law it is stipulated that

the Government regulates the management of fish resources in the territorial waters and jurisdiction areas and exercises the regulation of fish resources on the high seas based on cooperation with other countries and international law as joint vessels, fishery resources have interconnectivity, indivisibility, and subtraction.

The nature of interconnectivity is a fishery resource having interconnectedness between a component. Indivisibility is the nature of fishery resources are not easily divided into parts or areas of certain waters. Basically, the utilization of marine biological resources is done directly or indirectly. Direct utilization is intended as the utilization of resources to meet the physical needs of humans, such as food, clothing, shelter, and religious-cultural needs, as well as recreation. While indirect use is related to the function of resources concerned with the ecosystem, for example as a coastal protector, producer of organic matter, and place of care of biotic puppies. Marine information systems and data.

Based on Article 41 Paragraph (1) of the Maritime Law it is stipulated that cooperation in the maritime sector can be implemented at the national, and international level by prioritizing the national interest for national independence. Defense, Naturity, Law Enforcement, and Safety in the Seas Defense and security are very important for a nation's sovereignty, especially Indonesia with its vast sea.

In the framework of law enforcement in the territorial waters and jurisdictional areas, especially in carrying out security and safety patrols in the territorial waters and jurisdiction of Indonesia, established the Marine Security Board, hereinafter referred to as MSB. Under Article 62, MSB has a function to develop national policies in the field of security and safety in the territorial waters of Indonesia and the jurisdiction of Indonesia, and under article 63 of the Marine Law, MSB has the authority to dismiss, examine, arrest, carry, and submit ship to the relevant authorities authorized for further legal process execution.

Governance and Marine Institutions Under Article 69 of the Maritime Law, it is stipulated that: The Government establishes marine governance and institutional policies (para.1); The marine governance and institutional policies referred to in paragraph (1) include the development plans of the legal and governance system as well as effective and efficient marine planning, coordination, monitoring and evaluation systems (paragraph 2).

In preparing governance and marine institutional policies as referred to in paragraph (1), the Government shall undertake the arrangement of the law of the sea in a system of national law, both through public and civil aspects with due regard to international law (paragraph 3); Further provisions on governance and marine institutional policies as referred to in paragraph (1) shall be stipulated in a Government Regulation.

About Marine Development in the National Medium Term Development Plan 2015-2019 The Ministry of National Development Planning has drafted the targets and maritime development Regulation of the Minister of Marine Affairs and Fisheries of the Republic of Indonesia Number 25/PERMEN-KP/2015 on Strategic Plan of the Ministry of Marine and Fisheries Year 2015-2019 To follow up and implement the Strategic Plan of the Ministry of Marine Affairs and Fisheries Year 2015-2019, the Ministry of Marine Affairs and Fisheries issued Regulation of Minister of Marine and Fisheries No. 25/PERMEN-KP/2015 on Strategic Plan Ministry of Marine and Fishery Year 2015-2019.

As a national policy, the President of the Republic of Indonesia has declared that the sea is the future of national civilization. It shows that the sea can not dipunggungi, it's time the Indonesian nation to see the sea as a source of human life. Therefore, marine and fisheries development must be undertaken by all stakeholders to transform a situation into a better state by utilizing marine and fishery resources optimally, efficiently, effectively and accountably, with the ultimate goal of improving the welfare of the community in a sustainable manner.

Concerning the socio-economic aspects of the Fishermen's Welfare, when discussing the rights of coastal communities, especially traditional fishermen, traditional fishermen form the right to develop their economic, social and cultural progress. At the international level, the livelihoods of local communities are an integral part of sustainable development.[9] Traditional rights to fish are exercised on the high seas by freedom on the high seas as regulated in the law of the open sea law.

Problems of Indonesian Fishermen: Fishermen in Indonesia have quite complex problems. The main problem faced by fishermen is in the framework of the development of their business, especially the international access. Fishermen have limited business

capital support from banks and other financial institutions and access coverage. Therefore, fishermen still have difficulty accessing capital or credit due to constrained by fulfillment of banking procedural requirements.

The Ministry of Marine Affairs and Fisheries (MMAF) has a mission to promote fisheries and to make prosperous fishermen. The mission is Kedauluatan/ sovereignty that is to realize sustainable marine and fisheries development, to sustain economic independence by securing marine and fishery resources, and reflecting the personality of Indonesia as an archipelagic country; Sustainability/sustainability, ie realizing sustainable management of marine and fishery resources; Prosperity/ prosperity, which is to realize marine and fishery community prosperous, advanced, independent, and personality in culture.

Development in the marine and fisheries sector, can not be viewed only as a way to eliminate poverty and unemployment. However, more than that, the marine and fisheries sector is the basis of the national economic, it is only natural that the fisheries and marine sector developed into a leading sector in the international trade arena.[9]

Development of marine and fisheries by MMAF has been implemented in order to realize the 3 pillars of development, namely pro-poor (poverty alleviation), pro jobs (employment), pro growth (growth). The development of marine and aquaculture should be able to make the nation of Indonesia better than what is now. According to the authors, Indonesian fishermen are not prosperous, and capital difficulties. Activities in business in the fishery sector generally still use their own capital/family, and not much capital from the bank, it is the main cause.

The Minister of Fisheries and Marine Affairs of Indonesia affirmed that the Indonesian sea should belong to Indonesian fishermen completely. The new Presidential Regulation on Negative List of Investment is a good step to restore Indonesian citizenship rights over marine municipality and fishery economy of Indonesia.[10]

The Cause of Poverty of Fishermen According to the Directorate of Coastal Community Empowerment, Ministry of Fisheries and Marine Affairs of the Republic of Indonesia: The causes of the poverty of fishermen in Indonesia are: the absence of policies, strategies and implementation of coastal development programs and integrated fishermen communities among development stakeholders; The inconsistency of production quantity (catch), so that the sustainability of socio-economic activity of fisheries in fishing villages is disturbed.[11] This is due to the condition of fisheries resources that have reached the conditions of over fishing, a prolonged famine, and rising fuel prices; The problem of geographical isolation of fishing villages, making it difficult for the flow of goods, services, capital and people to flow in and out, which disrupts socio-economic mobility; There is a limitation of business capital or investment capital, making it difficult for fishermen to increase their economic activities; The existence of exploitative socio-economic relations with boat owners, brokers (middlemen), or fisheries entrepreneurs in the lives of fishermen; The low level of income of fishermen households, so that it has a negative impact on efforts to increase business scale and improve their quality.

Based on Law Number 7 Year 2016 concerning Protection and Empowerment of Fishermen, Cultivators of Fish, and Fisherman of Salt, the Government guarantees that by Law no. 7 of 2016 aims for the following:

1. Providing the necessary infrastructure and facilities for developing a business;
2. Provide a sustainable business certainty;
3. Increasing the capacity and capacity of fishermen, fish farmers, and salt farmers; strengthen institutions in managing fish resources, and marine resources and in conducting independent, productive, advanced, modern and sustainable business, and develop environmental sustainability principles;
4. Developing a system and institutional financing that serves business interests;
5. Protect from risks of natural disasters, climate change, and pollution;
6. Provides security and safety guarantees and legal assistance.

Conclusions

That the arrangement of marine development investment in Indonesia is based on the Constitution of the State of the Republic of Indonesia Year 1945. Article 33 paragraph (3) stipulates that: “The earth and water and natural resources contained therein are controlled

by the State and used for the greatest prosperity of the people. This constitutional basis is fundamental in further regulation of investment in the marine and fisheries sector.

Abstract

Aim: The aim of this study is to find out the difference in setup errors when registering cone beam conventional tomography on couch with planning CT simulator images with 2 different registration method in ca breast patient treating with 3DCRT technique

Objective: following study is to compare the patient setup uncertainties using two different registration method, one with standard clip box registration method and other with mask registration method.

Methodology: Ten patient with ca breast are taken for the study. All patients are undergone standard 3dcrt planning and pushed to xvi for further analysis. CBCT scans were taken and two types of registration were done each under by mask based and clip box based method. Shifts on all 3 axes such x,y,z is noted with rotational shift. Comparison were done on systematic error (Σ), random error (σ), mean displacement vector (R), mean setup error (M).

Result: Out of all this registration method mask based grey registration (T+R) shows some superior quality for soft tissue verification. But again One can use any of the registration method for patient setup verification depending on their institution protocol and site to be treated

Keywords: *EBRT, CBCT, 3DCRT, xvi, ca breast.*

Introduction

Ca breast is one of the common carcinoma found in women after ca cervix worldwide over. There are different modes of treatments now, for treating such type of carcinoma. Such as chemotherapy, surgery, hormone therapy, brachytherapy, external beam radiotherapy etc. EBRT is One of that kind, using radiation to kill the tumor cells and save the surrounding normal tissue. 3DCRT is one of the standard treatment method used for treating ca breast in external beam radiotherapy from long time ago. Even though today advance treatment modalities and technique are present, 3dcrt planning technique are widely accepted for treating ca breast all over the world due to its benefits compared with other technique. For the successful treatment delivery, the patient setup error needs to be minimized as low as possible before treatment execution, to save surrounding normal cells. So verification is very important steps in radiotherapy to increase the accuracy of target localization and reduce toxicity. It is done by comparing the planned CT image with the treatment image set using 2D or 3D acquisition. The nature of breast,breathing motion, supraclavicular nodes and itsregion of avoidance contours, especially for the breast conservative surgery cases makes it's a difficult process, to retain the same position on every single treatment delivery time. For that purpose, image-

guided radiation therapy (IGRT)are commonly used to minimize patient setup errors mainly systemic and random error in the treatment session. This was achieved by using an onboard KVcone beam attached to the linac gantry or by using MV beam for imaging in our setup we have ELEKTA HD versa with x-ray volumetric imaging (XVI) verification system. With the help of onboard KV cone beam it is possible to create a three dimensional reconstructed images of patient on couch and can be used for verifying the positional shifts with the reference CT images, where treatment planning was done already. In some center MV electronic portal imaging device are also used for image registration purpose. Each verification system has their own pros and cons, but forbetter contrast and accuracy of soft tissue, kv CBCT offer better view than mv imager[1]. A study done by Hawkins et al. shows that by using 3D cbct it is possible to increase the accuracy of the treatment delivery and should be used for image guidance radiation therapy[1]. There was study done by Batumalai et al.who compared setup errors between EPI and CBCT imaging method for patients undergoing tangential breast RT. There results show both method are same in detecting the setup error[2].

Verification radiotherapy will help us to be certain that we are not missing our target, it also helps in identifies the setup error and helps in assessing the adequacy of ptv margin[5]. In our center majority of the cases are verified using XVI cone beam ct. Mainly two types of registration protocol method are available in xvi cone beam CT for verification, such as mask type and clip box type. In each protocol again four different types of registration are possible, such as manual, gray value (translational), bone (translational + rotational), gray value (translational + rotational).The selection of which registration method is used are depend on the reviewer and the specific site. In this study we are comparing four registration method such as bone (T+R), gray value (T+R) of clip box, and bone (T+R), gray value (T+R) of mask registration protocol.

Methodology

There are studies done in various department in different site using different registration method[1,6]. This study conducted at Kasturba Hospital using ELEKTA HD versa XVI cbct. Ethical approval was granted by the Institutional Ethics Committee, Kasturba Medical College, Manipal. The study is approved and registered under CTRI. Ten breast cancer patients who were treated with 42.5 Gy in 16 fractions were chosen for this study. Contours, prescription are done based on ICRU protocol[3]. Standard tangential 3dcrt beam planning was generated using 6 mv photon with wedge. Plans are evaluated by experienced radiation oncologist before sending for verification and treatment. Patients were imaged with CBCT on first consecutive three days and every third day during their course of treatment. CBCT was taken before and after during each fraction. In all, 7 CBCT image sets were acquired for each patient for 3 weeks. The total image sets of 70 are obtained. A total of 280 registrations were performed using four registration method for patient setup error. Patients were positioned supine, with both arms raised above their head and immobilized by thermoplastic mould[5]. During the mould making process, three fiducial markers were placed on the patient's body with the support of laser for isocenter reference mark. CT was taken with slice thickness of 3 mm for delineation of the targets and OAR using Monaco™ TPS V5.11.02 treatment planning system (TPS). once plan was done, all plans were approved by a radiation oncologist and transferred from TPS to CBCT system for the treatment delivery along with the corresponding planning CT datasets which will be used as the reference image data sets.The planning CT-scan was imported into the XVI database via DICOM.XVI system consisted of kilo-voltage X-ray source arm and amorphous silicon flat panel imager, is together with Elekta HD versa® (Elekta Ltd, UK) linear accelerator was used as the IGRT system to acquire onboard CBCT images. Patient's 3D-CBCT images are acquired at isocenter after applying the shift from the origin, which we got from the treatment planning station.Rotational shifts such as pitch, yaw and roll are not considered in this study. If the rotational error is more than 3°, patients are repositioned and images are taken once again

Images in cbct were acquired withinone-minute time span, 360-degree rotation with the patient immobilized in the treatment position same like during CT acquisition. M20 collimator cassette was used on all patients giving a nominal irradiated scan length at the isocentre of approximately 26 cm and reconstruction diameter of approximately 40 cm. the acquisition parameters were 120 kV, (with clinical filter F1), maintaining the lower dose to the patient's skin but improving image quality. The image acquisition parameter of xvi is given in table 1 below. Commissioningand calibration of the CBCT isocentre to the linear accelerator isocentre was performed prior to this study according to recommended guidanceAAPM TG 58[7].

Table 1: The image acquisition parameters of XVI CBCT

KV	120
MAS	140
Gantry rotation	Clockwise (360°arc)
Collimator	M20
Filter	F1
Frame	660
Reconstruction filter	wiener
XVI software	Version 5.0.3
Nominal scan dose	3.8 mGy

Image registration protocol: In Clip-box registration (CBR) method, the volume of interest is defined on the CT image in the form of a box drawn around the anatomy of interest[4]. The registration between image sets is limited only to the voxels within the clip box which contains the volume. It is a rigid registration process and does not include any margins during image matching.inMask registration (MR) Image registration is done by soft-tissue volume. The mask sets an irregular 3D region of interest around the chosen volume.in our study we created a mask on prescribed ptv contour with a default margin of in each direction. The registration is again limited only to the voxels inside this volume same like in clip box registration, which must include the target volume. In both the protocol,manual matching and automatic matching are present. In manual registration we use mouse to move the reference image with translational and rotations.Even though Manual matching is a time taking registration, it is superior than automatic one[4]. Out of automatic matching, the gray value (T + R) registration use grayscale intensity values of the voxels in the registration volume. The algorithm used here is correlation ratio procedure. The bone (T+R) mode of automatic registration use chamfer matching algorithm[11], to calculate the same as bone densities. Since the algorithm is not very sensitive to image noise, this registration can have done very quickly.

The deviation between the actual and intended position in a patient treatment is called the setup errors. Mainly two types of setup errors are present while treating a patient in external beam radiotherapy, such as systematic and random error. Systematic part of an error is one which occur systematically (same direction and magnitude) throughout the delivery[5]. This types of errors may be introduced into the treatment during immobilization preparation, planning, while transferring the data, during delivery etc.so Systematic errors are sometimes called as treatment preparation errors It can be calculated by standard deviation of the mean error of individual of that population and is represented by the symbol $\sum$. whereas random error which is represented by σ, is one which direction and magnitude of error will vary from each fraction during the treatment. This type error is usually occurring during treatment delivery phase may be due to patient's setup, tumor position, intrafraction movement and sometimes called as daily execution errors. Which can be calculated by the root mean square of the standard deviation of each patient. It is easy to reduce the random error to some extent than systematic error[5].The residual errors are calculated from data obtained from the post-treatment CBCT scans[12].

The mean setup error (M) is the average of the setup error in each direction. Whereas mean displacement vector which quantifies the distance and direction of patient setup errors can be calculated using

$$R = \sqrt{\left(d^2_{ML} + d^2_{CC} + d^2_{AP}\right)}$$

Where d_{ML},d_{CC},d_{AP} is deviation in three axis of patients respectively[5].

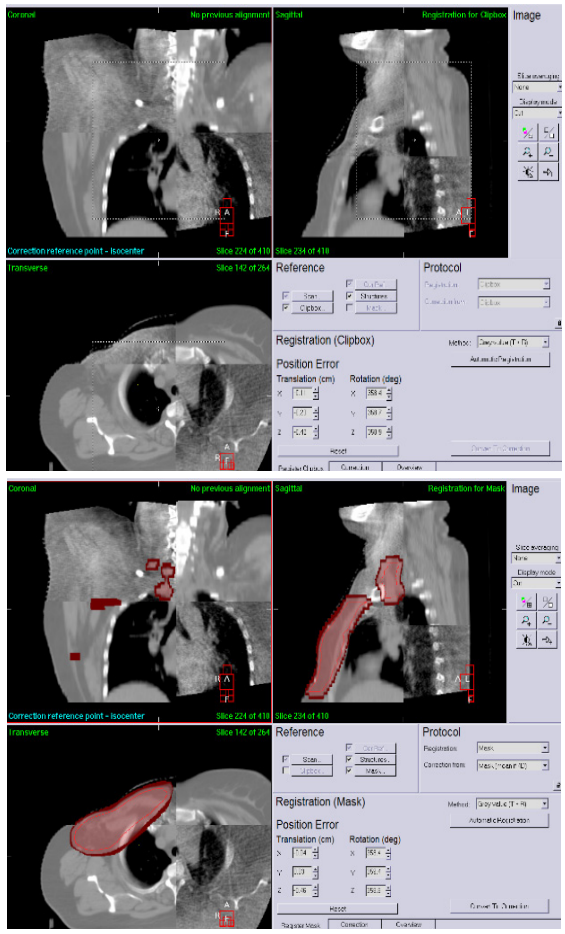

Fig 1: Clip box registration mask based registration

Results and Discussion

The result of present study is expressed in tables and chart given below.No manual match was performed in this study Furthermore no additional observers were used, as the purpose of this study was not to address inter-observer variability. It is found thatsoft tissue registration is very good in matching the tumor position and bony registration for the vertebral bodies. The systematic and random errors for each of the 'clip-boxes' and mask were calculated and showed below in table 2. It is found that in both systemic and random error most deviation occurred in (y) craniocaudal direction. It is also noted that while using mask with gray (T+R) registration the systemic and random error is less. The mean and standard deviations were calculated. The mean value expressed the systematic error and the standard deviation describes the random error. The residual systematic setup errors data's are shown in fig 2.

Table 2: Systematic (Σ) and random (σ) errors calculated for four different registration method.

	Systematic error (Σ)			Random error (σ)		
	ML	CC	AP	ML	CC	AP
Clip-box grey (R+T)	1.8	2.8	1.5	2.8	4.5	2.3
Mask grey (R+T)	1.1	1.9	1.2	2.6	3.2	2.3
Clip-box bone (R+T)	1.8	2.2	1.2	2.9	4.5	2.1
Mask Bone (R+T)	3.1	2.6	1.8	2.8	4.6	2.7

(X (ML): Medio lateral, Y (CC): Craniocaudal, Z (AP): Anteroposterior) all reading are in mm)

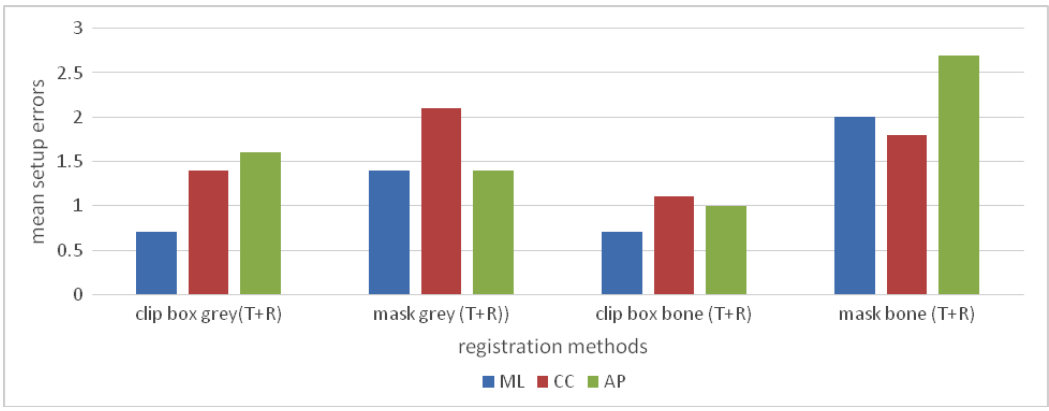

Fig 2: The residual systematic setup errors from data obtained from the post-treatment scans

The mean setup errors for clip box grey, mask grey, clip box bone and mask bone in ML direction (2.2 mm, 1.6 mm,1.8mm and 2.5 mm), in CC direction (1.3 mm, 1.9 mm, 0.3mm and 0.8 mm), and in AP directions (-0.1 mm, 0.5 mm,-1.0 mm and 1.2 mm) were observed. The mean vector displacement of four registrations are shown below in chart (fig 3). Again the vector displacement value is less in mask based grey registration when compared with other types.

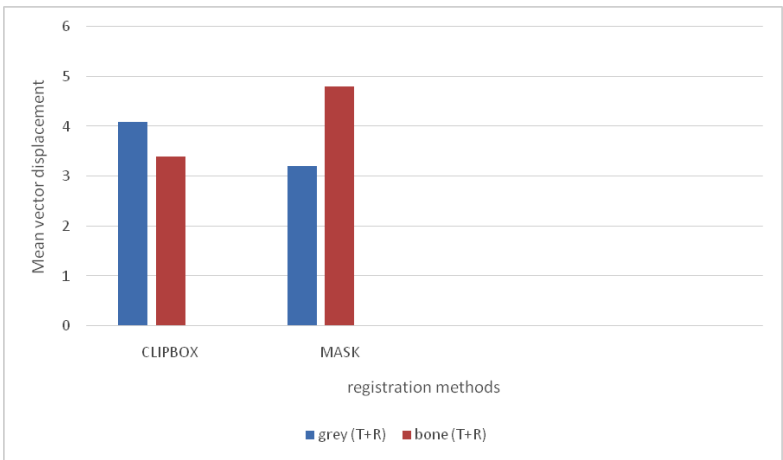

Fig 3: Comparison of Mean vector displacement of registration

A good knowledge about the patient's anatomy and well training in three dimensional registrations is also needed for an accurate image registration. Each institution has to develop their own registration clinical protocol for each site they are treating.

Conclusion

From this study, in our clinic it is found that for soft tissue such as breast, mask based grey registration shows some superior benefits than other types of registration. Appropriate clinical protocols and personnel training needs to be a developed for each clinic. Good knowledge of patient 3D anatomy is a must for a good registration

Effect of Coordination Training on the Ability to Distribute Attention in Children with Different Types of Nervous System

Georgiy Georgievich Polevoy

Candidate of Pedagogical Sciences, Associate Professor, Department of Physical Education, Vyatka State University, Kirov, Russia

Abstract

The aim of the study: was to determine the effect of coordination training on the development of the coordination abilities of children aged 7-8 years in physical education classes and to reveal its influence on the ability to distribute attention among schoolchildren with different types of nervous system.

Method and Material: Children from 7 to 8 years old who attended the regular school participated in the pedagogical study. Distribution of attention was determined using the "Different counting" method, coordination abilities were determined by the "Running Run" test, the type of the nervous system was determined by the "Tapping-test" methodic. The method of statistical and mathematical processing of the results was the T-Student test.

Results: The duration of the study was 7 months, a total of 59 physical education classes were held. After the pedagogical experiment, some changes took place in the indicators. In KG the indicators in the "Shuttle Run" test have deteriorated from 10,3±0,6 s. to 10,4±0,6 s. ($p>0,05$). However, in the test "Different counting" their indices slightly improved from 37,9±1,8 s. to 37,2±1,9 s. ($p>0,05$). In EG-1, distribution attention indicators improved from 39,3±1,9 s. to 36,7±1,7 s. ($p>0,05$). The indicators of the level of development of coordination abilities improved by 0,2 s. ($p>0,05$). In EG-2 schoolchildren significantly improved their results. In the "Shuttle Run" test, the indices improved from 10,3±0,6 s. to 9,7±0,5 s. ($p<0,05$). In the test "Different counting" from 36,5±1,7 s. to 29,6±1,5 s. ($p<0,05$).

Conclusion: If the children of 7-8 years develop coordination abilities in each physical education class, then the coordination of the movement will improve, while such exercises will improve the ability to distribute the attention of schoolchildren. Indicators will be significant if children are differentiated into groups with a typology in mind.

Keywords: *Distribute attention, coordination abilities, differentiated approach, type of nervous system, children.*

Introduction

Coordination abilities are very important for human life and activity.[1,2] Coordination of movement means a person's ability to quickly, accurately and completely solve motor problems, especially those that arise suddenly.[3] The types and variety of coordination abilities are surprising, there are classifications of coordination abilities.[4,5] It is impossible to single out the main coordination ability, which would develop separately from others.

In order to develop special or specific coordination abilities, it is necessary to bring to a high level the general coordination abilities that are more developed in the younger school age.[6,7]

Separately, one should say about the ability to distribute attention. This is the ability to spread attention to a significant space, in parallel to perform several different actions, that is, the ability to focus on several objects simultaneously.[8,9]

The interaction of different mental processes and physical qualities is constantly being studied. At the same time, we were not able to find data that establish the effect of coordination training on the ability to distribute attention in younger schoolchildren.

In the pedagogical process, in a regular school or sports section, there is a differentiated approach. The effectiveness of such an approach is not to be doubted, it maximizes the ability to reveal the full potential of the children's body.[10,11] In this case, the differentiation of children into groups can be based on different criteria.[12,13,14] One of these criteria is the typology of the nervous system.[15,16,17]

The aim of the study was to determine the effect of coordination training on the development of the coordination abilities of children aged 7-8 years in physical education classes and to reveal its influence on the ability to distribute attention among schoolchildren with different types of nervous system.

The hypothesis of the study is the assumption that differentiated coordination training raises the level of development of the coordination abilities of children of 7-8 years, and effectively influences the indicators of distribution attention of younger schoolchildren who engage in physical culture with using typological criterion.

Material and Method

In the pedagogical experiment, junior schoolchildren of 7-8 years (1st grade) took part, who were healthy and admitted to physical education classes. A total of 60 boys and girls participated, who were differentiated into 3 identical groups of 20 people each.[18]

1. Control group (CG), children were engaged in the standard program for schoolchildren who are in grade 1.[19]
2. Experimental group-1 (EG-1), the children were engaged in the same program, but at the beginning of the lesson for 12-15 minutes they performed exercises to develop coordination abilities.[3]
3. Experimental group-2 (EG-2), the children were engaged in a standard program, but, when performing coordination exercises, they were differentiated into subgroups taking into account the strength of their nervous system.[16,17,20,21]

During the study period, only 59 sessions were conducted for 45 minutes each lesson, classes were 2 times a week. Classes in EG-2 differed in that the load during the exercise was different. For children with a strong nervous system, the load was intense, and for children with a weak nervous system–a volume. At the same time, the volume increased due to an increase in the rest time and the number of repetitions of exercises. The intensity was increased by reducing the rest time and increasing the number of exercises.

To develop coordination abilities, the simplest and most accessible physical exercises were used (running, jumping, rolling, and moving with the ball, using a rope and other gymnastic objects). New physical exercises were learned using the repeated method. Then, a variation method of performing the exercises was used. The complexity increased due to changes in the location of objects, their weight, height, the external conditions also changed, exercises were used with catching objects in motion, a combination of running with jumps and many others. Equally effective were method–game and competitive.[3]

Before and after the pedagogical experiment, all children took control tests. Distribution of attention was determined using the "Different counting" method, coordination abilities were determined by the "Running Run" test, the type of the nervous system was determined by the "Tapping-test" methodic.

"Different counting"–is a method for determining the ability to distribute attention. Especially effective is the method for children 6-10 years old.[8] The essence of the method: on the command "GO" the schoolchildren write on a sheet of paper numbers from 1 to 20 in ascending order. At the same time, the schoolboy considers in the rumor the number from 20 to 1 in descending order. It is important that if the child starts to error immediately, the distribution of attention is developed very poorly.

Result: The amount of time the schoolchildren spent on the job (accurate to 0,1 sec.).

"Shuttle run" is a test that determines the level of development of general coordination abilities.[19]

Two lines "Start" and "Finish" are shown 10 meters from each other. By the "GO" command, the schoolboy runs from the line "Start" to the line "Finish" and touches her hand, after which he returns back and touches the line "Start" and performs the last jerk toward the Finish line without touching the line. Result: amount of time the schoolchildren spent on the exercise (accurate to 0, 1 sec.)

"Tapping-test" is a test that determines the strength of the nervous system through the excitation process.[22]

Paper A4 sheet is located horizontally and is divided into 6 squares (3 below and 3 above). By command "GO", a schoolchildren places points (using a pencil) in the first square for 5 seconds, then the "transition" command goes. The schoolchildren moves to the second square and performs the same moves. Exercise ends 30 seconds after the sixth square. The sum of points in each square is calculated and a graph is drawn up. The type of the nervous system is determined according to the graph

Statistical analysis was performed using T-Student, and the result was significant at $p<0,05$. Correlation analysis was performed using the Bio-stat program 2009.[23,24]

Results

Before the start of the study, all the schoolchildren were differentiated into 3 identical groups in such a way that the average coordination abilities in the "Shuttle run" test were approximately the same ($p>0,05$). Children in EG-2 were differentiated into 2 subgroups, taking into account the type of nervous system in the excitation process. After 59 training in physical culture (7 months), new results of the study were obtained (Table 1).

Table 1: Indicators of coordination abilities and ability to distribute attention among schoolchildren 7-8 years old (M±m)

Indicators	Group	Before	After	P
Shuttle run (s)	KG	10,3±0,6	10,4±0,6	>0,05
	EG-1	10,3±0,6	10,1±0,5	>0,05
	EG-2	10,3±0,6	9,7±0,5	<0,05
Different counting (s)	KG	37,9±1,8	37,2±1,9	>0,05
	EG-1	39,3±1,9	36,7±1,7	>0,05
	EG-2	36,5±1,7	29,6±1,5	<0,05

Analysis of Table 1 shows that there has been a change in the overall study period. In the KG, in which the schoolchildren were engaged in the standard program "Physical culture for schoolchildren of the first grade", the indicators in the "Shuttle run" test deteriorated from 10,3±0,6 s. to 10,4±0,6 s. ($p>0,05$). However, in the "Different counting" test, their performance slightly improved from 37,9±1,8 s. to 37,2±1,9 s. ($p>0,05$).

In EG-1, the indices improved in both tests. The indicators of distribution attention have improved from 39,3±1,9 s. to 36,7±1,7 s. ($p>0,05$). The indicators of the level of development of coordination abilities have improved by 0,2 s. ($p>0,05$).

In EG-2, in which schoolchildren performed coordinating exercises and used a differentiated approach based on the strength of the nervous system, significantly improved their results. In the "Shuttle Run" test, the rates have improved from 10,3±0,6 s. to 9,7±0,5 s. ($p<0,05$). In the test "Different counting" from 36,5±1,7 s. to 29,6±1,5 s. ($p<0,05$).

The results of the new study indicate the effectiveness of using a differentiated approach based on the typology of schoolchildren.

Discussion

The level of development of coordination abilities of a person reflects his ability to quickly and precisely solve motor tasks, especially those that arise unexpectedly, therefore it is difficult to overestimate their significance.[1,2]

It is impossible to single out and develop one coordination ability, their uniqueness is in interaction with each other.[4,5]

Taking into account the results obtained during the study (improvement of the indicators in the groups in which coordination training was implemented), one can agree with the authors' opinion that the favorable period for the development of coordination abilities is the younger school age.[6,7]

Separately we should say about the meaning of the ability to distribute attention to a person. Distribution of attention is the dispersion of attention to several objects at one and the same time, the ability to perform several actions immediately. It depends on the individual characteristics of the person. Of course, nobody will be able to do two things at the same time if one does not know how to do each one individually.[8,9]

There is enough facts about the existence of the relationship between physical qualities and psychic processes.[25,26,27] Despite this, we have not been able to find data that reflects the influence of coordination capabilities on the distribution of the attention of schoolchildren. In the new study, we managed to install it. Indeed, the indicators of ability to distribute attention depend on the level of development of coordination abilities.

This research confirms the authors' opinion on the effectiveness of using a differentiated approach in the educational and training process.[10,11] At the same time,

the effectiveness of using a different load on physical education classes for children with different types of the nervous system has been proved. The findings are confirmed by earlier studies in this area.[15,16,17] And the data we received in our previous studies.[20,21]

The peculiarity of differentiated load considering the typology is that the intensive load will be more effective for schoolchildren with a strong nervous system. Volumetric load will be more effective for schoolchildren with weak nervous system. At the same time, a person who has a strong nervous system is not necessarily stronger than the weak, these people go to one goal in different ways.

For the first time, a study was conducted on the effect of coordination training on indicators of the ability to distribute the attention of younger schoolchildren who have different types of nervous system. The aim of the study was achieved, and the hypothesis was solved and confirmed by the results that were obtained after the pedagogical experiment.

If at the beginning of each training in physical training for 12-15 minutes to perform physical exercises to develop coordination abilities, then indicators of not only coordination of movement, but also indicators of ability to distribute attention will improve. At the same time, the result will be more effective if you differentiate the schoolchildren by type of nervous system

Conclusion

Several conclusions can be revealed on the results of the study. First, in physical education lessons, younger schoolchildren need to develop coordination abilities. Secondly, coordination training can improve indicators of not only coordination abilities, but also indicators of mental processes, such as the distribution of attention of schoolchildren. Thirdly, the effect of coordination learning will be higher if we use a differentiated approach based on the strength of the nervous system through the excitation process.

The article is relevant for trainers, teachers and educators. The results of the study are new, they are perspective for studying new interactions of physical and mental abilities of schoolchildren.

Molecular Characterisation of B-Casein Gene in Cattle Breeds of Kerala (Genetic Polymorphism and Comparative Analysis of β-Casein (Exon 7) Gene in Crossbreed and Vechur Cattle)

Pranamya C. Haridas[1], Varuna P. Panicker[2], K.K. Jayavardhanan[3], Raji K.[2]

[1]M.Sc., Scholar, [2]Assistant Professor, [3]Professor & Head, Department of Veterinary Physiology, College of Veterinary and Animal Sciences, Mannuthy, Thrissur

Abstract

Casein and whey protein are the major proteins present in milk. Among 13 different genetic variants of casein proteins A1 and A2 β-casein are the most common. Polymorphism studies of β-casein gene became one of the most important groups of researches in recent years because of its close relation with the milk quality. Hence a study was undertaken to investigate the genetic variation of β-casein (partial exon 7) in crossbred cattle and Vechur cattle. DNA was isolated and casein gene was amplified by polymerase chain reaction (PCR) using suitable primers. PCR products were sequenced and analysed using suitable softwares. Nucleotide sequences obtained, were showing both synonymous and non-synonymous variations.

Keywords: *β-casein, Polymorphism, Vechur cattle.*

Introduction

Milk and dairy products are the richest source of proteins and minerals in our diet, forms an important role in human nutrition(1). Caseins and whey proteins are the two major groups of proteins present in milk. Caseins are family of phosphoproteins, synthesized in the mammary gland in response to lactogenic hormones and secreted as micelles. Casein contributes 80% of total bovine milk proteins(2,3). The four casein proteins present in bovine milk are casein alpha s1 (CSN1S1, 39–46% of total caseins), casein alpha s2 (CSN1S2, 8–11%), beta casein (CSN2, 25-35%), and casein kappa (CSN3, 8–15%)(4). Casein genes are located as a cluster on chromosome 6(5,6,7). Caseins have an appropriate amino acid composition that is important for growth and development of the nursing young. Characterization of milk protein variants in different species gained importance with the discovery of milk protein polymorphism and its impact on milk production(8). Single nucleotide polymorphism (SNP) analysis is a well-established tool for the identification of genes associated with traits of economic importance in livestock populations.

The present study was undertaken to investigate the genetic variation of beta-casein protein gene, which is strongly related to economically important milk quantitative and qualitative traits. Polymorphism study will promote selection programs that are depending on the use of genetic markers which will help in improving breeding strategies. This study aimed at molecular characterisation of β-casein gene in cattlebreeds of Kerala.

Materials and Method

A total of six animals were used for the study (three crossbred cattle and three Vechurcattle). Animal maintained in livestock farm, College of Veterinary and Animal Sciences, Mannuthy, Thrissur were randomly selected for the study. About 5 ml of blood samples were collected from unrelated animals aseptically from jugular vein. Genomic DNA was isolated using standard Phenol: Chloroform: Isoamylalcohol (PCI) method(9). Isolated DNA was then quantified by Nano-drop spectrophotometer at 260/280 nm.

Polymerase chain reaction (PCR) was employed in a total volume of 25µl with 50-100 ng of genomic DNA. PCR was performed using KAPAG2G Robust Hot Start Ready Mix contains an engineered DNA polymerase. The primer pair reported by add reference[10] was used for the study to amplify 400-500bp long exon-7 region of β-casine gene. PCR was carried out in a thermal cycler machine with an annealing temperature of 52.5^0C. PCR products were then purified using PCR purification kit (Invitrogen by life technologies) and products were then sequenced. The sequences were analysed by BLAST (Basic Local Alignment Search Tool) search at NCBI site for homology using BLAST programme.

Results and Discussion

Genomic DNA was isolated from peripheral blood leukocyte by standard Phenol chloroform method. The purity and deproteinization of the obtained DNA was indicated by ratio of optical density at 260 and 280 nm ranged from 1.7 to 2. Partial exon 7 region of beta casein gene was amplified by PCR with optimum annealing temperature of 52.5 °C for 1 minute in crossbred and Vechur cattle. The amplified products were then checked on 1 per cent agarose gel. The amplified products found to have size range between 400-500bp

Amplicons were sequenced by automated dideoxychain termination method. The sequencing results revealed an amplified fragment size ranges between 400-500bp. Nucleotide sequence analysis was carried out by using NCBI Basic Local Alignment Search Tool (BLAST)–blastn. Crossbred cattle D183CB cattle showed sequence similarity to the nucleotide sequences of Bosindicus breed Sahiwal beta-caesin (Accession no. KY290551.1) with sequence similarity of 97% with query coverage of 95%. This may be due to fact that the exotic blood is comparatively less in this animal when compared with other cross breeds. It may be present to a level that is there in Sahiwal cattle[11]. All other crossbred cattles showed sequence similarity to the nucleotide sequences of *Bostaurus* EF628290.1. Nucloetide sequences of the Vechur cattle breeds indigenous to Kerala showed 99% similarity to Sahiwal breed of cattle (Bosindicus Accession no KY290551.1) with 99% query coverage.

Multiple sequence alignment of the selected nucleotide sequence data of cattle breeds studied with the sequence available in NCBI (Accession nos. EF628290.1 and KY290551.1) showed sequence variations within breeds and between breeds. Indigenous Vechur cattle breeds showed only single nucleotide variation at position 409. Nucleotide sequence variations found to be synonymous in nature as these variations did not result in amino acid variation. All these variations in crossbreed were natural variations which may occurred due to inappropriate cross breeding programme followed. Amino acid sequence analysis of both crossbred cattle and Vechur cattle under study showed that the casein is of A2 variant[12]. A1 variant could not be identified even in crossbred animal. A through screening based on allele specific PCR-RFLP is needed in this mixed population to know the presence of A1 variant which is proved to be deleterious to health [13,14]

Casein genetic polymorphisms are important and well known due to their effects on quantitative traits and technological properties of milk [15]. Polymorphism occurring within exon VII giving rise to A1 and A2 alleles was reported to increase both protein yield and content and simultaneously to decrease the content and yield of milk fat [16,17,18,19].

Polymorphic study of the milk protein gene will help to achieve a tailored genetic improvement in both quality and quantity of ruminant milk by efficient breeding and selection programme. All these variations noticed is due to single nucleotide polymorphisms in the nucleotide sequences which can be used as tool for more efficient selection of livestock breeds. Non synonymous nucleotide changes in the nucleotide sequences can bring about new beta-casein variants. All the amino acid sequence analysis of cattle breeds showed the A2 variant in our population. It is suggestive that a wide population study is needed to identify animals with A1 milk in the livestock herd of the state.

Conclusion

The present study was undertaken with the objectives of molecular characterisation of partial β casein gene in crossbred and Vechur cattleby PCR amplification and sequencing. DNA was extracted by both phenol chloroform and kit method, and all downstream processes were standardized by using DNA isolated with kit method. Single amplicon specific to exon 7 region of the β-casein was amplified by standardizing suitable PCR protocols. The cyclic parameters were similar for all breeds expect in anneling time. Amplicons were sequenced by Sanger's method and analysed by blastn suite of NCBI and clustal-W. All sequences were

showing similarity to NCBI submitted sequences of CSN2. One among the crossbred cattle studied showed nucleotide sequence similarity to the sequence of *Bosindicus* breed Sahiwal and others showed similarity to the sequence of *Bostaurus* breed. This shows the difference in the level of exotic blood in the same population of crossbred cattle. Nucleotide sequences of Vechur cattle an indigenous breed of Kerala showed 99% similarity to Sahiwal breed. All these variations noticed is due to single nucleotide polymorphisms in the nucleotide sequences which can be used as tool for more efficient selection of livestock breeds.

Abstract

Introduction: Adolescents are very susceptible to HIV transmission. Junior high school students, in particular, should be equipped with HIV & AIDS information in order to avoid risky sexual behavior. *Kelompok Siswa Peduli AIDS dan Narkoba* (Student Group with Awareness of AIDS and Drugs)-KSPAN is one of the student organizations established in schools in Bali to help provide more comprehensive information about HIV & AIDS, including how to prevent HIV transmission. The purpose of this study was to identify the relationship of participation in KSPAN with the knowledge of HIV & AIDS among junior high school students in Denpasar, Bali.

Method: This was a cross-sectional study using secondary data from Kisara IPPA Bali Chapter. Descriptive analysis was used to present the proportion of the students' participation in KSPAN and knowledge about HIV & AIDS. Chi-square analysis was applied to identify the relationship.

Results: More than half of juniorhigh school students had sufficient knowledge of HIV & AIDS (59.8%) and most of them participated in KSPAN (81.5%). Moreover, the proportion of students with sufficient knowledge on HIV & AIDS was higher among those who participated in KSPAN compared to who did not (67.2% vs 27.0%) The result of bivariate analysis using Chi-square test showed that participating in KSPAN was associated with having sufficient knowledge of HIV & AIDS (p-value <0.001).

Conclusion: Participating in KSPAN had a positive impact on knowledge on HIV & AIDS since students were provided with comprehensive information on HIV & AIDS. Therefore, increasing the participation of students in this organization is essential to expand the HIV & AIDS information.

Introduction

HIV & AIDS remains a pressing issue in many developing countries due to a lot of new infections and AIDS sufferers are well-documented. Given this problem, governments in many affected countries set targets and made commitments as outlined in the Sustainable Development Goals (SDGs). One of the targets of the SDGs related to HIV & AIDS is to decrease HIV infections every year by three quarters by 2030 and to ensure universal access to treatment by HIV & AIDS patients by 2040.[1]

New HIV cases in the Asia Pacific regions in 2017 were estimated at 2.8 million among people aged 15 years and above whilst 10 thousand new sufferers were attributable to those aged 0-14 years.[2] In Indonesia, there were 34.5 million HIV-positive adults out of a

total of 36.7 million people living with HIV (PLHIV) from all age groups in 2016, indicating that a number of adolescents have been infected with HIV.[3] Bali as one of the provinces in Indonesia was first known to report HIV patient in 1987. The data from Provincial AIDS Commission showed that 500 people aged <19 years were infected with HIV from a total of 9,027 PLHIV from 1987 to December 2016. Meanwhile, data obtained from the Bali Health Office in 2010 showed a significant increase in HIV cases in each district in Bali. The district with the highest growth of HIV & AIDS cases was Denpasar, by 45.83% with a total of 679 AIDS cases and 920 HIV infections.[4]

Adolescents aged 10-19 years experience physical development accompanied by sexual maturation so that it leads to their vulnerability to drugs use and risky sexual behavior.[5] Therefore, they are susceptible to HIV infection since drugs use and risky sexual behavior are the mode of HIV transmission.[6] It indicates that adolescents need to have sufficient knowledge of HIV & AIDS in order to prevent HIV transmission.

Junior high school students are part of adolescents who need to have qualified knowledge since the misconceptions of HIV & AIDS-related issues are more likely to occur among them.[7] Provincial AIDS Commission of Bali initiated to establish *Kelompok Siswa Peduli AIDS dan Narkoba* (Student Group with Awareness of AIDS and Drugs)-KSPAN as one of the extracurricular activities implemented in schools in Bali. It aims to provide comprehensive information on HIV & AIDS and develop peer educators.[8,9] This present study aimed to identify the association between the participation in KSPAN with knowledge of HIV & AIDS among junior high school students in Denpasar, Bali.

Material and Method

This study was a quantitative study with a cross-sectional approach using secondary data from a project, entitled "Sexual and Reproductive Health Knowledge, Attitude, and Behavior among Adolescents in Denpasar, Bali" conducted by Kisara IPPA Bali Chapter from July to September 2016. It has successfully recruited 1,200 students out of 24 schools using multi-stage cluster random sampling. For this study, we employed all records of junior high school students, making a total sample of 400 students.

The dependent variable was knowledge of HIV & AIDS, measured using some statements or questions such as 1) HIV is a virus that attacks the immune system; 2) HIV can be transmitted through vaginal fluid and sperm, blood, breast milk, and the use of unsterile syringes; 3) HIV is the same as AIDS; 4) HIV-positive people tend to not show symptoms; 5) AIDS is a set of symptoms after being infected with AIDS; 6) HIV can be transmitted by HIV-positive people apparently look healthy (window period); and 7) HIV can be cured. Meanwhile, the independent variable is the participation in KSPAN by questioning whether the student was a member of KPSAN or not. For the analysis, Chi-square test was used to identify the relationship between the participation in KSPAN with knowledge of HIV & AIDS with the significant level (α) at 0.05. The results were presented by p-value and coefficient Cramer's V to show the magnitude of relationship.

Results

Table 1 shows that from 400 junior high school students in this study, the average age was 14 years and 56.3% of the respondents were female. For a variable of the participation in KSPAN, 81.5% of students have participated in KSPAN and the remaining of 18.5% did not participate. The total score of knowledge was grouped, and 59.8% had sufficient knowledge of HIV & AIDS.

Table 1: Characteristics, participation in KSPAN, and knowledge of HIV & AIDS among junior high school students

Variables	n = 400 (%)
Age (Mean; SD)	(14.18; 0.77)
Sex	
Male	43.7
Female	56.3
Participation in KSPAN	
Yes	81.5
No	18.5
Knowledge of HIV / AIDS	
Sufficient	59.8
Poor	40.2

Knowledge indicators of HIV & AIDS are described in detailed as presented by Figure 1. It was measured using seven questions and responses are given as "yes" and "no" by junior high school students. It shows some misconceptions among students such as more than half of them agreed that HIV can be cured (65.5%); they disagreed that HIV-positive people will not show the

symptoms and almost a half argued that at least one of these modes of HIV transmission (vaginal fluid, sperm, blood, breast milk, and the use of unsterile syringes) was incorrect (49.75%).

Other indicators showed that the majority agreed with the given definition of HIV (79%) and AIDS (61.8%). In addition, they could differentiate between HIV and AIDS (67%) and knew that HIV sufferers who apparently look healthy are able to transmit HIV (53.5%).

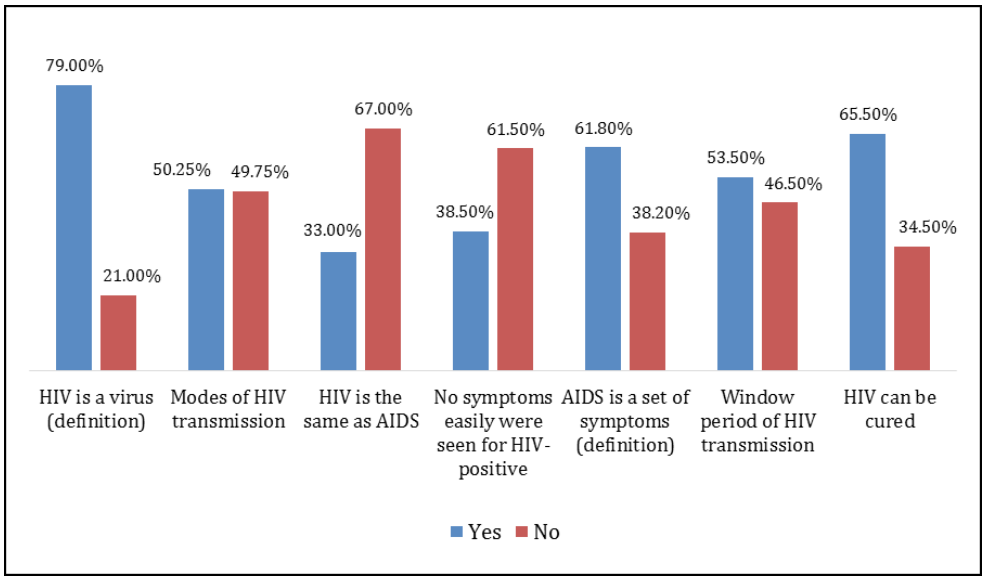

Figure 1. Knowledge of HIV & AIDS among junior high school students

Table 2 shows the result of Chi-square test between students' participation in KSPAN and their knowledge of HIV & AIDS. Based on cross-tabulation, 67.2% of students who participated in KSPAN had sufficient knowledge while only 27% who did not join KSPAN had sufficient knowledge. There was a significant association between the participation in KSPAN and sufficient knowledge of HIV & AIDS among junior high school students (p-value <0.001). According to the Cramer's V coefficient which shows 0.32 means that the relationship is quite strong.

Table 2: Association between the participation in KSPAN with knowledge of HIV & AIDS

Participation in KSPAN	Knowledge of HIV & AIDS		p-value	Coefficient of Cramer's V
	Sufficient (%)	Poor (%)		
Yes	67.2	32.8	<0.001*	0.32
No	27.0	73.0		

*significant level (α) at 0.05

Discussion

Obviously, HIV transmission is preventable, as well as, the stage of AIDS among HIV-positive people can be prevented as early as possible. Unfortunately, a lack of knowledge and incomprehensive information often results in an increase of new HIV infections and stigma and discrimination among PLHIV accelerate to AIDS. According to the Health Belief Model theory, knowledge is one of the several important modifying factors which can affect personal belief related to health, in which, can

lead to a change in one's attitudes and behavior.[10]

This study can provide information on the current situation of students' knowledge of HIV & AIDS in some aspects, such as HIV and AIDS definition, the difference between HIV and AIDS, and the window period of HIV transmission. This study found that 67% of the students argued HIV is different from AIDS. It is different from a previous study which found that 64.9% were still unable to distinguish between HIV and AIDS.[11]

However, students gave the wrong answer to some knowledge indicators, such as 65.5% of students said that HIV can be cured, but, in fact, currently no drugs available to cure HIV & AIDS. Nowadays, there is only antiretroviral virus (ARV) drug to suppress HIV and prolong the quality of life of PLHIV.[12] By contrast, a finding from a similar study showed that 69.8% reported that HIV & AIDS could not be cured.[11]

Another indicator of HIV knowledge was 61.5% of the students stated that people who are HIV-positive can be identified easily from several symptoms, although only VCT can ensure whether people have been infected with HIV or not.[13] HIV-positive people who apparently look health are also able to transmit HIV because of a window period of HIV which can last 5 to 10 years preceding the symptoms.[14]

Another important aspect of knowledge which students should have is HIV mode of transmission. Someone can be infected with HIV through vaginal fluids, sperm, blood, breast milk, and the use of unsterile needles.[15] The results of this study showed that 49.75% did not know the whole method of HIV transmission. A previous study found that most of the respondents (> 90%) knew that body fluid containing a virus, male and female sexual secretions were the main sources of infection.[16] In addition, a similar study reported that 91% and 92% of the respondents knew that HIV could be transmitted from infected mother to baby and through contaminated needles and syringes, respectively.[14] Among adolescents, the easiest HIV transmission is through risky sexual behavior or injecting drugs. Previous published literature also mentioned that sexual intercourse is a common mode of HIV transmission among adolescents.[7]

Based on the findings, providing information related HIV & AIDS that were less known by students is essential to enhance their knowledge and address their misconceptions. KSPAN is one of the extracurricular activities in schools which potentially contributes to increase the knowledge of HIV & AIDS among junior high school students. More importantly, students are also trained to be peer educators as part of KSPAN's activities. It might be underlying reasons for the moderate-to-strong relationship between the participation in KSPAN and sufficient knowledge of HIV & AIDS among junior high school students (p-value <0.001 and Cramer's V coefficient = 0.32). A similar previous study also reported that the proportion of sufficient knowledge of HIV & AIDS among KSPAN members was 68.7%, higher than students who were not members of KSPAN, at 31.3%.[9] In addition, another evidence pointed out that the existence of special programs aiming to provide health information for adolescents in schools was able to increase students' knowledge of adolescent health, including HIV & AIDS knowledge.[10] Therefore, it is essential to increase students' participation in KSPAN and teachers should support and promote this extracurricular to students to expand the HIV & AIDS information. In addition, the activities of KSPAN should be designed with a lot of interesting activities to attract students and retain members' participation.

Conclusions

Participation in KSPAN can help students to obtain trustworthy HIV & AIDS information that can increase their knowledge of HIV & AIDS. Information of HIV & AIDS must be provided in an early stage of adolescents in order to have qualified knowledge to prevent the HIV transmission. KSPAN as one of the extracurricular activities is promising to take this duty. Increasing students' participation to join this extracurricular is essential to expand HIV & AIDS information. It should be supported by a strong commitment from teachers to promote KSPAN to students.

Conflict of Interest: The authors declared that there is no conflict of interest.

Measurement and Simulation of Noise in Manufacturing Industry in Malang City, Indonesia

Qomariyatus Sholihah[1], Dewi Hardiningtyas[1], Ishardita Pambudi Tama[1], Oyong Novareza[1], Sylvie Indah Kartika Sari[1]

[1]Departement of Industrial Engineering, Faculty of Engineering, University of Brawijaya, M.T. Haryono Street 167, Malang, East Java, Indonesia

Abstract

Noise is one form of pollution that occurs in big cities. Increased noise pollution is influenced by various noise sources, for example construction activities or the number of motorized vehicles in certain areas. Continuous noise exposure with a noise level higher than 85 dB can cause effects on humans in general are physiological and psychological. In this study noise measurements and will be carried out in the manufacturing industry. It is expected that in this study, not only can produce noise simulations, but also provide scientific contributions to both engineering and social sciences. The results showed that the sound intensity generated by the factory machine at location 1 gave a maximum value of 103.5 dB on Thursday, while at location 2 the maximum value on Thursday is 82.1 dB and the minimum value is 58.3 dB on Tuesday for each total for one week. This difference is caused by the accumulation of noise levels with increasing time and outside noise activity that can affect the measurement value. Measurements made for one week gave an average value of 92.29 dB at location 1 and 67.59 dB at location 2.

Keywords: *Noise, Manufacturing Industry, Malang City*

Introduction

The production process in the manufacturing industry is required to be able to compete in order to meet demand targets and achieve the expected quality targets. This condition causes, the industry is then designed using machines to increase productivity and accuracy [1]. Machinery in the industry has a positive impact on increasing company productivity, but also has a statistical impact on the health of workers. Industrial machines that are operating will certainly cause noise or noise due to the work process between machine parts [2].

Noise is a form of potential health hazard that often occurs in the industry. The production process that runs continuously will provide continuous exposure to workers, especially the ear. Noise is a disturbing sound because it has an impact on human physical, mental and psychological health [3].

Continuous noise exposure with a noise level higher than 85 dB can cause hearing loss. Hearing loss is the most common effect of physiological effects. It is all possible to divide the effects of noise on the ear into three groups: acoustic trauma, temporary hearing loss, and permanent hearing loss. The psychological effects of noise are more common than physiological and it can all be seen from the form of resentment, stress, anger and concentration disorders due to difficulty in resting [4].

From this description, this research will identify noise levels in the industry, especially in manufacturing industries, by making direct measurements. It is expected that this research will produce recommendations to reduce noise in the manufacturing industry environment and create a more conducive industrial environment.

Method

This research was carried out by following the method flow, namely preliminary studies, data collection, noise data processing, drafting, evaluating, and drawing conclusions. The importance of this study is to provide the basis, reference or benchmark for researchers in solving the problem, so that the urgency of the problem and the objectives that have been formulated are achieved.

Data collection is done through recording information related to the object under study to support the research conducted. Researchers will conduct observations by direct observation of the object under study, namely academics, recording (documenting, and conducting interviews related to relevant information.

Calculate the noise level equivalent using the Decree standard. No. 48 / Minister of Environment RI / 11/1996. After knowing the equivalent noise level of the engine then noise mapping is made using the Surfer program. The questionnaire will be presented with descriptive statistics [5].

According to the Minister of Manpower Regulation of RI No. PER.13 / MEN / X / 2011, noise is all unwanted noise sourced from the tools of the production process and / or work tools which at a certain level can cause hearing loss [6]. According to Harun quoted by Sasongko et al. (2000) noise is an unwanted sound that is disturbing and can be dangerous [7]. According to Sataloff, noise is a very complex sound consisting of random frequencies that are related to each other [8]. From these definitions, it was concluded that noise is an unwanted sound that comes from the means of production that interfere with and can endanger health, especially hearing loss..

According to the Minister of Manpower Regulation of RI No. PER.13 / MEN / X / 2011 concerning the threshold value of physical factors and chemical factors in the workplace states that the NAV is a hazard factor standard in the workplace as a weighted average intensity of time that can be accepted by the workforce without causing illness or health problems, in daily work for a time not exceeding 8 hours a day or 40 hours a week.

The instrument used in measuring noise in the work environment is sound level meter (SLM). Sound level meter (SLM) consists of reading displays, microphones, amplifiers and electronic circuits. Microphones on sound level meters are used to detect variations in small air pressure associated with sound and turn into electrical signals that will be processed by electronic circuits from the instrument. To measure noise in the work environment can be done using a sound level meter.

Results

Noise measurement

1. **Noise level at day and night at location 1:** Noise caused by machinery measured by day and night time differences is shown in Table 1 to Table 2. Noise levels measured at locations 1 comes from the measurement of the sound intensity generated by the machine. Measurements were made at the center of the sound source, namely in the engine room for 7 days from 07.00-17.00, (Table 1) and from 17:00 to 22:00 (Table 2).

02.00-03.00	83	84.2	84	85.2	84.6	84.3	83.8
Average	90.91	93.64	94.34	94.2	93.67	93.75	93.35

Table 1 and Table 2 show the relationship between sound intensity measured by the observation time interval for one week. The table shows that the highest noise intensity increase occurred on Thursday with the average noise intensity being 93.84 dB, while the lowest intensity value occurred on Friday with an average value of 90.57 dB. This proves that the tendency of the sound intensity generated by machines for Thursday is increasing, but provides almost the same characteristics for other days. In general, the sound intensity of the machine results in maximum value measured on Thursday. This maximum value is caused by the influence of activities other than machines such as trucks carrying goods that also operate on that day.

External noise activities that can affect come from truck cars carrying goods, as well as heavy equipment working around location 1. The highest noise level occurs on Thursday, thus the external factors mentioned above are more dominant on Thursday.

During one week during the daytime measurements it turned out that the sound intensity measured on the machine had a value away from the quality standard price for the industry, which was 70-85 dB, with the highest difference of 33.5 dB to 18.5 dB on Thursday.

The relationship between the value of the sound intensity generated by the factory machine at night is to show the relationship is almost the same as the measurement during the day (Table 1 and Table 2). The highest measured intensity at night occurred on Wednesday at 94.34 dB, while the lowest occurred on Monday at 90.91 dB.

This is because on Wednesday the accumulation of noise levels increases with time. On Monday the intensity value is between the value of the interval. Sound intensity does not experience much change at night during one week the difference in intensity measurement is 1.1 dB (on Thursday and Wednesday night). When compared with the afternoon it turns out the difference in night value is greater, this is because at night the atmosphere of silence is also added by the difference in the air layer so that the sound experiences curvature downward, besides because of differences in pressure and temperature, if the small temperature is large then the greater the speed of sound and vice versa the large temperature of small density, the smaller the speed of sound. So the sound you hear will feel clear and loud at night. That the sound intensity generated by the factory machine at night gives a difference with a maximum quality threshold of 32.5 dB and the lowest is 17.5 dB.

2. **Noise level at day and night at location 2:** Noise in location 2 in the office area is also caused by factory machinery and the activities of employees in the office. The noise value for this office area is measured based on day and night time differences shown in Table 3 and Table 4

Table 3. Noise levels during the day in the office area

Period	Noise Level						
	Monday	Tuesday	Wednesday	Thursday	Friday	Saturday	Sunday
07.00-08.00	58.3	58.3	59.2	62.5	59.4	58.7	58.8

09.00-10.00	63.4	63.4	64.4	66.4	62.1	64.1	64.1
10.00-11.00	64.6	64.6	65.7	66.6	64.5	64.5	64.5
11.00-12.00	68.5	66.5	65.8	67.5	65.1	64.1	66.1
12.00-13.00	70.2	70.2	71.2	73.2	71.3	72.3	72.3
13.00-14.00	73.1	71.1	72.1	75.1	72.4	72.4	73.4
14.00-15.00	72.6	72.6	73.6	74.6	72.6	74.6	71.6
15.00-16.00	74.9	74.9	74.9	77.9	73.7	74.7	74.7
16.00-17.00	77.1	75.1	74.3	82.1	76.2	75.7	76.3
Average	68.37	67.77	68.19	71.06	67.79	68.17	68.44

Table 4. Noise levels during the night in the office area

Period	Noise Level						
	Monday	Tuesday	Wednesday	Thursday	Friday	Saturday	Sunday
17.00-18.00	57.8	58.8	58.4	56.8	58.5	63.6	57.4
18.00-19.00	63.1	61.5	62.5	62.5	62.3	65.8	61.5
19.00-20.00	63.5	61.7	62.7	62.2	62.1	67.2	62.1
20.00-21.00	64.2	63.3	62.4	63.3	62.3	68.7	63.3
21.00-22.00	64.5	63.5	64.4	64.7	64.7	71.5	64.5
22.00-23.00	66.3	66.5	66.1	66.2	67.1	74.5	66.1
23.00-24.00	67.1	64.3	64.3	66.2	65.2	75.3	64.3
24.00-01.00	67.8	67.8	66.9	67.8	67.6	76.6	67.8
01.00-02.00	69.2	70.2	71.5	72.5	72.1	78.8	71.2
02.00-03.00	76.4	77.3	76.3	74.3	75.1	85.5	75.3
Average	65.99	65.49	65.55	65.65	65.7	72.75	65.35

Table 3 and Table 4 show that the pattern of noise levels at location 2 during the day and night is the same, which tends to increase with time. The pattern of noise at night is relatively more stable than the pattern of noise during the day. This is because the external noise source is not very influential at night compared to the noise source from the factory machine.

Table 3 and Table 4 show the relationship between sound intensity measured by observation time interval and for one week. The highest increase in noise intensity occurred on Thursday with an average noise intensity of 71.06 dB, while the lowest intensity value occurred on Tuesday with an average value of 67.77 dB.

This proves that the tendency of the sound intensity generated by factory machinery and employee activity for office areas on Thursday is increasing, but provides almost the same characteristics for other days. In general, the intensity of sound at location 2 from the results of factory machinery and employee activity is measured maximum on Thursday. This maximum value is caused by the possibility of the influence of activities other than plant machinery such as heavy equipment machines that are operating on Thursday, in addition to the activity of trucks carrying goods that also operate on that day whose frequency is high enough to contribute to measured intensities. While the sound intensity on Tuesday the smallest value is 58.3 dB smaller than

the intensity of sound on other days. During one week during the afternoon measurements it turned out that the sound intensity measured in the office area had a value that avoided the quality standard for the industry, namely 65 dB, with a difference of 17.1 dB on Thursday. On Monday the deviation from quality standard is 10.1 dB, while for other days other than Thursday and Tuesday the deviation from office quality standards is at both of these intervals.

The highest intensity value measured at night occurs on Sunday at 72.75 dB. While the lowest occurred on Sunday at 65.35 dBC. When compared with the afternoon it turns out the difference in night value is greater, this is because at night the atmosphere of silence is also added by the difference in the air layer so that the sound experiences curvature downward.

Discussion

Noise levels that exceed the Threshold Value are very influential with the incidence of hearing loss. In this study most of the noise measurement results are above the threshold value of 85dB [9].

Other effects of noise such as disturbed sleep, some mental tension caused by noise, will cause rapid pulse rate and hypertension, which can lead to another danger where the sufferer cannot hear shouts or warning sounds so that it can lead to accidents [10]. Constantly in the midst of workplace noise and traffic can result in loss of listening sensitivity leading to deafness [11].

In general, high-pitched noise is very disturbing, especially if it breaks up or comes suddenly. Disorders can be an increase in blood pressure (± 10 mmHg), increased pulse, constricting peripheral blood vessels, especially in the hands and feet, and can cause pale and sensory disorders. Psychological disorders can also occur, in the form of discomfort, lack of concentration, insomnia, irritability. If noise is received for a long time it can cause psychosomatic diseases such as gastritis, stress, fatigue, and others [12].

Besides that noise can cause communication disruption usually due to masking effect (clear hearing noise) or noise clarity. Communication of the conversation must be done by shouting. Disruption can cause work disruption, to the possibility of errors due to not hearing signals or alarms; This communication disruption indirectly endangers the safety of the workforce[13]. Noise in a long time can also cause the impression of walking in space or floating, which can cause physiological disorders in the form of vertigo or nausea[14].

Conclusion

Measurement of noise intensity is known that the factory machine is above the threshold value of > 85 dB or around 77 dB-103.5 dB where in this location there are machines that have high noise levels such as kernels, boilers, and the powerplant which is a source of noise and based on the noise level at each point, the length of exposure time recommended by NIOSH varies depending on the level of noise produced. The higher the noise level, the shorter the exposure time, and the lower the noise level, the longer the exposure time.

Evaluation of Serum Thyroid Hormones and its Effect/Complications During Pregnancy

Raakad Kamel Saadi[1], Mohammed Mohammud Habash[2]

[1]Assistant Professor in Gynecology and Obstetrics, College of Medicine, [2]Assistant Professor in General Surgery, College of Medicine, Diyala University, Diyala, Iraq

Abstract

Thyroid hormone viz, triiodothyronine (T3), thyroxine (T4) and thyroid-stimulating hormone (TSH) plays an important role during pregnancy to both the mother and fetus. This study included 60 pregnant women enrolled in the Al_ Batool teaching hospital in February to July 2019. The enrolled patients are between the age group between 25-35 years. The fasting blood was collected in the plain vacutainers from the vein after getting participant oral consent. Serum were used to evaluate the serum T3, T4 and TSH level. About 96.72%response rate was observed. The average respondent age was 27.37±3.52 years. About 36 (60%) and24 (40%) women were included in the age group of 25-30 and 30-35 years, respectively. About 82.32% women were under overt hypothyroidism category i.e. they showed increased levels of TSH as compared to the healthy pregnant women. The serum TSH levels were found to be 7.076±2.01mIU/ml and 4.146±0.37mIU/ml in thyroid hormone deficiency (TD) and normal groups, respectively. In the TD groups, about 80.32% women showed a caesarean delivery while about 97.45% women showed normal delivery. Normal delivery time takes about 39.22±0.34 weeks while TD groups showed a premature delivery at about 36.64±1.93 weeks. Iraqi women showed overt hypothyroidism. This abnormal levels of the thyroid hormones can be lead to miscarriage caesarean delivery with high weight infants.

Keywords: *Thyroxine, Triiodothyronine, Thyroid-stimulating hormone, Overt hypothyroidism, Caesarean delivery.*

Introduction

Pregnancy is associated with intensealterations in thyroid physiology and function to deliveradequate thyroid hormone (T3 and T4) to both the fetus and mother. During the first trimester of pregnancy, human chronic gonadotropin (hCG) stimulates the thyroid gland. These hormones play significant role in fetal development and embryogenesis as fetal thyroid start to produce thyroid hormone (TH) in the gestation (about 20 weeks old). Therefore, in early pregnancy, maternal source of TH to fetus evidenced through increased thyroxine-binding globulin concentrations[1]. As a result of this, serum free thyroxine (FT4) level increase and thyroid-stimulating hormone (TSH) level decrease. This occurs from eight weeks to throughout the first half of pregnancy, leads to the different reference intervals for FT4 and TSH as compared to the nonpregnant women. In early pregnancy, triiodothyronine (T3) and thyroxine (T4) levels are reported to be increased and attain a plateau in the second trimester and increased is about 30-100% as compared to prepregnant women[2].

Around 2%–4% prevalence rate is observed in thyroid disorders and around 0.1-0.4% prevalence is observed for hyperthyroidism in pregnant women. Out of which, around 2-3% showed hypothyroid, 0.3-0.5% have overt hypothyroidism and 2-2.5% have subclinical hypothyroidism. Thyroid antibodies are found in the at least 5-10% of womenand prone to developed thyroid insufficiency during pregnancy[3]. On the basis of serum FT4 concentration in the mother, the pregnant women is categorized into either overt hypothyroidism (OH)

or subclinical (SCH)[4,5]. Subclinicalhypothyroidism is defined as a patient with normal serum FT4 level and TSH levels is range in 2.5 and 10 mIU/L.In case of overt hypothyroidism, women showed increased in TSH level in the trimester-specific reference interval and /or decreased in serum FT4 levels[6].

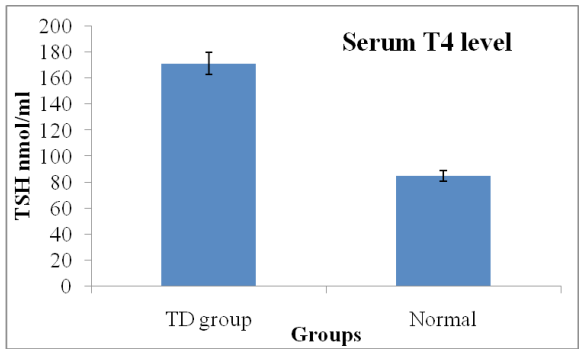
Thyroid hormone abnormality is relatedto an increased threat of various adverse maternal and child outcomes, including intrauterine growth retardation, a decreased child IQ miscarriage, preterm delivery, hypertensive disorders etc,[7]. Thus, it is very crucial to check thyroid status during pregnancy, for the assessment of suspected thyroid abnormalities and/ or status of pre-existing thyroid disease. With this background, in the present study, we evaluate the serum T3, T4 and TSH hormone levels in the Iraqi women with its associated complications.

Material and Method

This study included 60 pregnant women enrolled in the Al_ Batool teaching hospital in February to July 2019. The women with abnormal serum thyroid hormone was grouped as TD group. The age match women, which had normal thyroid hormone was considered in the healthy group.

Fasting blood (n=20) was collected by a single puncture form patients, after obtaining informed consent. The enrolled patients are between the age group between 25-35 years. The patients with the gestitional diabetes and high blood pressure were excluded from this study.

The fasting blood was collected in the plain vacutainers from the vein after getting participant oral consent. The samples were kept at room temperature for 30min. Followed by the centrifugation at 3000rpm for 15min. The serum was separated and kept at 20°C for further study. Serum sample was used to evaluate the serum T3, T4 and TSH level by commercially available kits (Sigma, USA).



Statistical analysis: Results were denoted as Mean ± Standard Error (SE). One way Analysis of Variance (ANOVA) along with Dunnett Multiple Comparison Test was done to estimate the statistical significance.

Results

In the current study, we evaluate the serum T3, T4 and TSH levels of Iraqi pregnant women visited to Al_ Batool teaching hospital from February to July 2019. The reference range was considered as given by American Thyroid Association (ATA). About 96.72% response rate was observed. The average respondent age was 27.37±3.52 years. About 36(60%) and 24(40%) women were included in the age group of 25-30 and 30-35 years, respectively. Table 1 shows the details of socio demographic characteristics.

About 82.32% women were under overt hypothyroidismcategory i.e. they showed increased TSH levels as compared to the healthy control. The serum T4 levels were171.36±9.25 and 84.83±2.58 nmol/ml.

Figure 1: Serum T4 level in the enrolled groups

The serum TSH levels were found to be 7.076±2.01 m IU/ml and 4.146±0.37 m IU/ml in TD and normal groups, respectively. The serum TSH levels are depicted in the Figure 2.

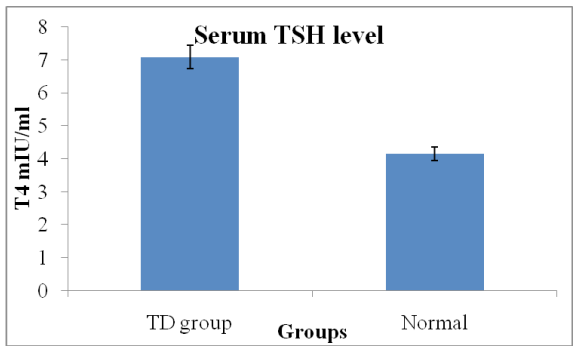


Figure 2: Serum TSH levels in he enrolled groups

In the TD groups, about 80.32% women showed a caesarean delivery while about 97.45% women showed normal delivery. Normal delivery time takes about 39.22±0.34 weeks while TD groups showed a premature delivery at about 36.64±1.93 weeks.

Discussion

During pregnancy, thyroid function is stimulated by human chronic gonadotropin (hCG). Thus, any abnormality associated with thyroid function results

in abnormality in maternal and fetal development such as miscarriages and preterm delivery[8]. However, information regarding levels of thyroid hormones T3 and T4 in pregnant women is scant and display variation depending on the ethnicity of study population. Decrease serum levels of free T3 and T4 was reported by some authors while unchages or even elevation was also reported previously. So, the thyroid hormone change during pregnancy is controversial. But many of the authors reported lowering of free-hormone concentrations as compared to nonpregnant women. Thus, it is imperative to determine levels of T3 and T4 hormones in pregnant women of a particular geographic location.

In the cohort population-based study conducted in Isfahan, Iran, in the first trimester of gestation,serum FT3, FT4 and TSH, levels were 4.50 ± 0.64 pmol/L, 1.01 ± 0.15 ng/dL, and 1.84 ± 1.32 mIU/L, respectively. While in nonpregnant women, these levels were 4.49 ± 0.57 pmol/L, 1.10 ± 0.21 ng/dL and 2.58 ± 1.77 mIU/L, respectively[8]. Mehran et al.[9]has reported that in Iranian women reference intervals of T3, T4 and TSH were first (137.8–278.3ng/dl; 8.2–18.5 g/dl; 0.2–3.9mIU/l), second (154.8–327.6ng/dl; 10.1–20.6 g/dl; 0.5–4.1mIU/l) and third (137–323.6ng/dl; 9–19.4 g/dl; 0.6–4.1mIU/l) trimestersrespectively[9]. Similar reportsare reported by Yan et al.[10] and Soldin et al.[11]. First trimester showed maximum T3 and T4 levels and it gets decreased by third trimester. Soldin et al.[11] evaluated the trimester i.e. first, second, and third specific ranges. He found that first, second, and third trimesters value of T4 ranges from 6.3–14.6, 6.4–14.8, and 6.3–16.7 g/dL and for T3 92–218, 112–278, and 111–265 ng/dL, respectively.

On the other hand, a case-control study from Dhaka, Bangladesh, reported significantly higher levels of serum TT 4 level in pregnant women during third trimester compared with non-pregnant women[12].Rajput et al.[13] determined TSH, T3 and T4 levels in pregnant women from Hrayana, India, wherein, TSH increased with simultaneous decrease in serum FT3 as gestational period progress. The significant FT4 decreased was observed from trimester 1–3rd, while nonsignificant decrease from 2nd-3rdtrimester.

Conclusion

In the present study, we found that in the TD groups, about 80.32% women showed a caesarean delivery while about 97.45% women showed normal delivery. Normal delivery time takes about 39.22±0.34 weeks while TD groups showed a premature delivery at about 36.64±1.93 weeks. Iraqi women showed overt hypothyroidism. This abnormal levels of the thyroid hormones can be lead to miscarriage caesarean delivery with high weight infants.

Ethical clearance: The blood was collected from the Al_ Batool teaching hospital after their investigation. Oral consent was taken before enrolled the patients in the study.

Comparative Study between Mesh Repair Versus Mayo's Repair in Surgical Treatment of Paraumblical Hernia

Rabah Ali Hussein[1], Basim Ghaib Hussein[1], Jameel I. Azzawi[1]

[1]M.B.Ch.B.F.I.M.C.S (General Surgery), Department of Surgery, Collage of Medicine, Tikrit University, Tikrit, Iraq

Abstract

Background: Para umbilical hernia has many causes and it is a complex process, they are most commonly found along the midline. This study aims to assess the efficacy of mesh repair in comparison toMayo'sRepair and toanalyse the complications associated with the management.

Method: The study was done in Samarra general hospital, with clinical features suggestive of Paraumbilical hernia (Minimum 30 cases each) from October 2014 to October 2016. This study not include Paediatric age group and those patients requiring emergency surgery. 30 patients underwent Mayo's repair and 30 patients underwent Mesh repair. Follow up period ranged from 2 months to 24 months.

Results: Paraumbilical hernia was found more commonly between the age of 30 years to 50 years with female: male 3:1. Most common presenting symptom was swelling with cough impulse (36 %) and reducibility present. Commonest predisposing factors were multiparty and obesity. Percentage of early postoperative complications in Mayo's repair was 18% and in Mesh repairs 6%. Percentage of recurrence following Mayo's repair was 13.3% and following mesh repair was 0%. Postoperative complications like seroma, infections were similar in both procedures (Mayo's repair and Mesh repair).

Conclusions: Prosthetic mesh repair is a technique with good post-operative outcome, low recurrent rate and Good patient satisfaction.

Keywords: *Mesh repair, Mayo's repair, surgical treatment, paraumblical hernia, Medical techniques, features suggestive.*

Introduction

Midline hernia occurring through linea Alba either superiorly or inferiorly to the umbilicus is called asparaumblical hernia.(1) Paraumbilical hernias present one of the common hernias of adulthood. Formation of Paraumbilical herniais a multifactorial and complex process they are most commonly found along the midline line a Alba. Though they are typically supra umbilical in location. Paraumbilical hernias are relatively common in adult population, more common in female with ratio of 3:1.(2) In 90%of the patient it isan acquired defect that is a direct result of increase abdominal pressure include multiparous status, obesity, older age, emphysema, asthma and other chronic lung conditions, benign prostate hypertrophy, abdominal distension, steroid use, coughing and lifting heavy weight. Para umbilical hernia is often asymptomatic or produces intermittent complaints. Discomfort or a ventral bulge is the most common initial symptom, most common content isomentum, but bowel obstruction can also be the first symptom that forces a patient to seek medical attention. Incarceration and strangulation are more common if the hernia neck defect is small. Repair of paraumbilical hernia was earlier performed bymayo's repair,but it has high recurrence rate up to 28% to 30%.(1)

Thus it has been replaced with Mesh repair as standard procedure for paraumbilical hernia repair, it has low recurrence rate compare to Mayo's repair. Umbilical hernias are amongst the commonly occurring abdominal wall defects, not much work has been done to record the incidence. Western studies quote an incidence 4.65% among all types of hernias.(3)

The management of paraumbilical hernias remains one of the common surgical problems.(4) a number of operations are presently employed in the management of paraumbilical hernia. Hence, this study taken up to assess the efficacy of mesh repair in comparison toMayo's Repair and to analyze the morbidity associated with the management.

Method

This is a Prospective study done at Samarra General Hospital for the treatment of paraumbilical hernia from October2014toOctober2016. All the materials for this study have been taken from 60 patients who got admitted to Samarra General Hospital. Informed written consent was obtained after explaining the surgical procedure and its results.

The study criteria include, randomly selected 60 para umbilical hernia patients and excludes Patient with severe co-morbid conditions (severe cardiopulmonary disease), recurrent hernia, pediatric patients and patients undergoing emergency surgery are excluded.

Clinical history regarding duration of hernia, progression,associated complaints like pain in the swelling orabdomen, vomiting, reducibility, chronic cough, constipation, difficulty in micturition, abdominal distension-history suggestive of ascites and other causes of abdominal distension, number of pregnancies, previous surgery for same problem is collected. In local examination special attention was given to the position, size, shape, composition, cough impulse, reducibility, skin over the swelling and size of defect inlinea alba.

Pre-surgical technique Cases were prepared for surgery after preoperative correction of anemia, hypertension, diabetes and localskin conditions. All patients underwent surgical procedure after preoperative preparation. All patients received one dose of preoperative antibiotic 1 gm of 3rd generation cephalosporin during or immediately after induction of anaesthesia. The anaesthesia of choice was spinal anaesthesia with mild intravenous sedation. On operative table betadine 10%scrub given toanterior abdominal wall. Surgical procedures done were Mayo's repair and Prosthetic mesh repair. 30 patients were selected for particular procedure randomly. Patients who underwent Mayo's repair and 30 patients who underwent polypropylene mesh repair.

Surgical technique

Mayo's method

Mayo's repair

After anaesthesia patient is laid on supine position, parts painted, and drapes are applied to allow access to the umbilical area. A transverse elliptical incision is made enclosing the umbilicus and the skin covering the hernia.

It should extend laterally on each side for at least 5cm beyond the protuberance. It is deepened through subcutaneous fat until the surface of the aponeurosis is exposed. The neck of the sac is generally free from adhesions and is opened first. Before doing so, the aponeurosis is cleared centrally from all directions, until the neck of the hernia is exposed of the level where it emerges through linea Alba. A small incision is made in the fibrous coverings of the neck of any convenient point on its circumference and is carefully deepened until the sac itself has been opened. A finger is introduced and is passed round the in side of the sac to determine the presence of any adhesions. The remaining circumference of the neck of the sac is then divided with scissors, the finger being used to protect the contents from injury. The central island comprising the sac together with attached ellipse of skin and fat is now joined to the abdomen only by contents is carefully examined. If they consist of omentum, which is chaemic, it can be ligated and excised, if it is healthy, it can be reduced into peritoneal cavity. If bowel is the content, sac is opened upas far as possible. The sac is now gradually turned inside out, and contents gently peeled off its interior. Adherent omentum removed along with the sac. Adhesions between adjacent coils of intestine are released as far as possible and the hernial contents are returned to the abdominal cavity.

Mesh repair: Steps for surgery are similar to Mayo's repair till the hernial sac and its contents are managed. Polypropylene mesh is used for repair. Most commonly used size of mesh is 6" x 3".If defect is larger, larger sized mesh is used. After exposing the defect and excising excess part of hernial sac, peritoneum is closed using vicryl, mesh is placed beneath the peritoneum. It

is fixedto rectus sheath using prolene suture. Incision closed after keeping suction drain. In all patient suction drain was kept and skin closed with nylon.

Results

Paraumblical hernia is more common between 4th and 6th decade of life,more common in females (65%) than in males(35%).there is no difference in age distribution of cases between male and females age distribution in mesh is (44_70) years. Most common symptom was swelling around umbilicus,may or maynot be associated with pain. Swelling was reducible and cough impulse was present in 93% of patients. Skin changes were present in 8,5% of cases.

Table 1: Size of defect

Size of defect (cm)	Mesh	Mayo's
4	13	18
4-6 13 11	4-6 13 11	4-6 13 11
>6	04	01

Most common precipitating factor in females is multiparity 87%, next common factor is obesity is 33 %.Most common precipitating in males is smoking 62 % followed by COPD as stated in international literature paraumbilical hernia is more common in obese and corpulent women. This has been substantiated by our result. Size of defect was <4cm in 52 % of patients, between 4-6 cm in 40% of patients >6cm in 8.5% of patients.

Table 2: Complication of procedure

Complication	Mayo's repair (n=30)	Mesh repair (n=30)	Significance
Seroma	4	2	p>0.05(NS)
Wound infection	2	1	p>0.05(NS)

Diabetes mellitus (20%) the most common associated disease followed by Hypertension (16%) and Hyperthyroidism 3.33%.Most common postoperative complication were seroma-13.3% in Mayo's repair and 6.6% in mesh repair.wound infection 6.6% in mayo's repair, 3.3% in Mesh repair there is no statistical difference between mean size of defect for which mayo's repair and mesh repair was applied.

Table 3: Recurrence of the procedure.

Procedure (n=30)	Recurrence	Percentage
Mayo's	4	15%
Mesh	00	00

Size of defect for which Mesh repair was done is mean 4.88+-1.32 cm. There was one recurrence (3.33%) following 30 cases of Mayo's repair. There were no recurrence following mesh repair there is no significance in recurrence following mayo's repair and mesh repair, P value =0.2, but there is statistical trend towards the difference between procedures regarding recurrence.

Discussion

Paraumbilical hernia ismore common in patients aged between 40-60 years in this study. Youngest patient was 20 years old. It is found that paraumbilical hernia is rare after 70 years as only one patient was >70 years old in both mayo's and mesh group. Paraumbilical hernia is more common in females. Inmayo's group (n=30), 18 female 60% and 12 were male 40% and in mesh group (n=30), 21 were female 70% and 09 were male 30%. There is no significance difference in age distribution in males and females, as disease is more common between 4th and 6th decade in both sex. All 60 (100%) patients were presented with chief complaint of swelling around umbilicus, 25 (41%) patients had pain in the swelling and 8(13.3%) patients had skin excoriation along with pain and swelling.

Most of the patients had swelling for more than 6 months before they presented to hospital. Maximum duration of symptoms was 2 years and minimum duration was 1 month. Even though it was stated in literature that most of the paraumbilical hernias are irreducible or partially reducible, in this study cough impulse was present and swelling was reducible in 93% of patients. Only 4 patients had absent cough impulse and irreducible swelling. Overlying skin changes were presented in long standing cases 8 (13.3%). In females, most common precipitating factor was multiparty. Out of 40 patients 35(87.5%) were multipara. This can be attributed to stretching and weakening of anterior abdominal wall Next common precipitating factor was obesity-13 patients (33 %). Pathogenesis can be attributed to theory explained by Mayo-obesity causes downward traction on the abdominal wall bearing on a fixed point on umbilicus associated with an increase of vertical dimension of abdominal wall. [1,2] Fat penetrates muscle bundles and layers, weakens aponeurosis and favours appearance of hernia.

Other less common precipitating factors were diabetes, hypertension, chronic cough and constipation.

In males most, common precipitating factor was Smoking–13 patients (62 %) followed by COPD patients. Smoking is an important predisposing factor in development of hernia as it causes degeneration of collagen fibers. Other factors are obesity and heavy manual work. Some patients had more than one precipitating factor and some patient did not have any precipitating factor. 12 patients were diabetic, 10 patients were hypertensive, and 2 patients were hypothyroidism. These associated diseases were treated adequately before surgery; hence there was no much effect on the outcome following surgery. In this study, 30 patients underwent polypropylene meshrepair and 30 patients underwent Mayo's repair. Out of 30 patients who underwent Mesh repair, all were Inlay (preperitoneal) procedure. Although cases were randomly selected for particular surgical procedure, size of defect and age of patients has been considered. Among 30

patients who underwent mesh repair 13 patients haddefect size of <4 cm, 13 patients had defect size of 4-6cm and 4 patients had defect size of >6 cm. Mean size of defect was 4.88 cm with small defect 1.77cm. Among 30 patients who underwent Mayo's repair 18 patients had defect size of< 4 cms,11 patients had defect size of 4-6 cms and one patient had defect size of >6cm. Mean size of defect was 4.08cm with SD 1.32cm. There isno statistical difference in defect size for which Mayo's and Mesh repair has been done. In this study, most common postoperative complications were Seroma-13 % in Mayo's repair, 7 % in Mesh repair, Wound infection–6 % in Mayo's repair, 3 % in Mesh repair. No patient required removal of mesh because of infection, as infection was superficial and responded well to antibiotics. There is no significant difference in percentage of postoperative complications between Mayo's repair and Mesh repair.

In this study, out of 30 patients who underwent Mayo's repair one patient had recurrence of paraumbilical hernia (3.33%), there were no recurrence following Mesh repair.

Conclusion

Prosthetic mesh repair is a technique with good post-operative outcome, low recurrent rate and excellent patient satisfaction. It could become the gold standard in adult umbilical and paraumbilical hernia repair, in the future.

The Relation between Bullying Workplace, Organizational Support, and Work Engagement as perceived by Staff Nurses

Rasha Mohamed Nagib Ali[1], Ebtsam Ahmed Mohamed[1]

[1]Lecturer of Nursing Administration, Faculty of Nursing. Minia University, Egypt

Abstract

Aim: The present study aimed to assess the relation between bullying workplace, organizational support, and work engagement as perceived by staff nurses.

Setting: This study was conducted at Minia university hospital, and Gynecology, Obstetric, and Pediatric University Hospital.

Research Design: A descriptive correlation comparative design was utilized to achieve the objective of the present study.

Sample: All nurses who accepted to cooperate in this study at the time of data collection were included (N=300) from Minia university hospital and from gynecology, Obstetric and Pediatric University Hospital.

Tools: The following instruments were used: Bullying workplace was developed by(15) II: (8)developed organizational Support questionnaire III: Work engagement questionnaire was formed by(16).

Results & Conclusion: The conclusions of the current study showed that there signified an adverse correlation between perception of nurses' regarding bullying workplace and organizational support plus work engagement (R=.461-**), (R=.265-). Finally, work engagement and perceived corporate support positively correlated (R=.298).

Recommendations: The organization should encourage nurse supervisors to use practical communication skills and support for nurses' staff, which helps to reduce workplace bullying.

Keywords: *Bullying workplace, Perceived organizational support, Work engagement, Staff nurses.*

Introduction

Motive, assurance, and maintenance of staff nurses have developed as concerns of meaningful interest for healthcare providers.(1) Every day nursing duties are physically and emotionally requiring and depend not so much on regulated rules but situational bases.(2) The essence of the work in the healthcare organizations entails nurses to be sincerely interested in their work performances and voluntarily go beyond the call of their duty.(3) Workplace bullying (**WPB**) is perceived as a severe problem in the nursing profession. **WPB** has been designated as repeated behaviors directed at one or more workers that create embarrassment, offense, and distress, and that may interfere with job fulfillment such that the contradictory effects may lead to an unpleasant working environment.(4)

The healthcare sector may very well be a model of a set at significant risk of **WPB**, **WPB** becomes a severe negatively affects both, organizations and individuals., for an organization, this may result in the raised rate of absenteeism, which then negatively influences productivity, efficiency, and profitability. The repeated exposure to negative behavior at work may lead to a depletion of coping resources, thus preventing

the individuals' ability to cope with daily work tasks, in addition, it may increase operator turnover affecting the health care organization financially as novice staff recruitment and retraining is a costly process.[5] **WPB** can results in various adverse consequences for individuals,, including distress, tension, irritation, marks of trauma, and diminished interpersonal functioning. Additionally, it may lead to lower levels of self-confidence and lower levels of contentment with life. Studies indicate that not only victims of **WPB** but also the individuals who observed it had raised levels of tension.[6]

Receiving support from an organization directs staff nurses to be more productive and more committed to duty.[7],[8] represented the construct of perceived organization support (POS) as workers 'global expectations concerning the degree to which the health care organization values their contributions and cares about their well-being'.[9] POS one of the core concepts that have a considerable impact on organizational, it affects all regulatory policies. Creating appropriate work conditions, Supervisor assistance, appropriate rewards, and justice in the workplace that are individual values leads to the improvement of one's self-esteem, hope, and personal growth of employees. Appearing in the existence of physical, mental, emotional, and spiritual well being.[9][10]advised that supporting from an organization is returned to worker and employer in terms of a better level of staff production, job pleasure, and condition of patients' care. Highly perceived level of organizational support may aid to revive the equilibrium between the benefits awarded by the organization plus the benefactions of the individual.[11]enlightened that organizational support considers one of the great predictors to discriminate low and high accomplishing employees.

Work engagement refers to a convinced work-related state of thought that is designated by dimensions of vigor, dedication, and absorption and trust and results in more reliable, cost-effective patient outcomes.[12]" Work engagement has been linked to numerous affirmative organizational consequences such as job satisfaction, job completion, organizational commitment.[11] Given these positive outcomes, nurturing work engagement is of famous value for health care organizations, particularly in a setting where workplace bullying might be at action. Employees who are engaged in their work can work long hours and put their hearts into their practice.[13] According to the studies by[14] which exhibited that job sources are combined with engagement in work include social support from supervisors, feedback for one's performance, autonomy and opportunity for learning.

Significance of the Study: The study is significant because workplace environments and the dynamics that exist within them affect everyone involved, especially coworkers, and to provide further evidence on the implications of **WPB**. **WPB** has been linked to many unfavorable outcomes that can be very costly to organizations. On another hand, other studies have suggested, work engagement is a vital component for a healthy work environment, and workplace bullying is a significant, unresolved problem that affects workers and neighboring bystanders. Therefore, It is, necessary to examine how **WPB** affects the work environment and how these concepts are interrelated. So from the researcher's point of view, it is essential to investigate the concept under investigation to identifies the means of retaining, engaging, and supporting ways to facilitate engagement and unusual behaviors for staff nurses. Therefore the following study will be conducted to assess the relation between bullying workplace, organizational support, and work engagement as perceived by staff nurses.

Subjects and Method

The study aim: The present study was offered to assess the relation between bullying workplace, organizational support, and work engagement as perceived by staff nurses.

Research question: What is the relation between bullying workplace, organizational support, and work engagement as perceived by staff nurses?

Research Design: A descriptive correlation comparative design was utilized to achieve the objective of the current study.

Sample: All staff nurses who agreed to cooperate in the study at the point of data collection were included. The total number was (n=300) staff nurses divided into (175) nurses from Minia Hospital and (125) staff nurses from Gynecology, Obstetric and Pediatric University Hospital

Setting: The current study was conducted at Minia university hospital and. Gynecology, Obstetrics, and Pediatrics University Hospital within these hospitals include critical care units, medical units, surgical units, and kidney dialysis units, obstetric units, and plastic surgery units.

Tools for data collection:

To reached the aim of the current study, data were collected using four tools:

a. **Personal data questionnaire:** This developed by the researchers to collect data such as marital status, age, qualification, plus years of experience.

b. **Bullying workplace questionnaire:** Developed by the[15], it composed of (22) items which operates on five possible answers (1) never, (2) occasionally, (3) monthly, (4) weekly, and (5) daily referring to contrary acts and it is based on the frequency an individual experiences negative behaviors which relate to workplace bullying. Cronbach's coefficient alpha was .95

c. **Perceived Organizational Support Scale:** Evolved by[8] It consisted of (33) items to value levels of recognized organizational support among nursing staff about their settings. Responses ranged from (1) strongly disagree to (5) strongly agree. Cronbach's alpha coefficient was.91

d. **Work engagement questionnaire:** was formed by[16] It consisted of (17) items using the 5-responses Likert scale, ranged from (1) strongly disagree to (5) strongly agree. And Cronbach's coefficient alpha was .92.

Tools validity and Reliability

Validity: Study tools content validity was established through a jury of three specialists, two professors and one assistant professor from the Faculty of Nursing Miniauniversity. Each expert on the group was asked to examine the instrument for content, coverage, clarity, wording, length, format, and overall appearance.

Reliability: The reliability test was measured utilizing Cronbach's Alpha Coefficient for the three tools which indicate that questionnaires were highly reliable. Test results for the inquiries workplace bullying, organizational support, and work engagement were (0.86, 0.79, and 0.84), respectively.

The pilot study: The pilot study was conducted on (10%) from the current sample to ensure the clarity and applicability of the items, and to estimate the time needed to complete the questionnaire. The result showed that the time spent in filling the survey was ranged between 25-30 minutes. Based on the pilot study analysis, no modifications were done in the questionnaires. So the number of the pilot study was included in the total number of the study sample.

Procedure:

- Official permission was obtained from the director of the hospitals after explaining the nature of the work.
- The researcher explained the aim, quality, and significance of the study for every nurse to get better cooperation during the implementation phase of the research
- Oral consent was obtained from each participant in the research after clarifying the scope of the study
- During data collection, the researcher handed the questionnaire sheets individually to the participant nurses in their units, then the investigator told the questionnaire sheets to them and asked them to fill it.
- The time spent to fill the questionnaires ranged between 25 to 30 minutes.
- The researcher waited until the participants completed the sheets and were ready to answer any question.
- After completion of filling the questionnaire sheet, the researcher collected them. Data were collected in a period of nearly two months from March to April 2019

Statistical design: Data entry and statistical analysis were done using computer software the statistical package for social studies (SPSS), version 21. Suitable descriptive statistics were used, such as frequencies, and percentages for qualitative variables, means, and standards deviations for quantitative variables. The correlation coefficient (r) test was used to estimate the closeness association between variables. For all the criteria used, statistical significance was considered at p-value <0.05.

The Finding:

Table (1): Distribution of staff nurses personal data characteristics (No =300)

Personal data	N= (300)				
	No	%	Personal data	No	%
Age			**Marital status**		
18-28	74	24.7	Single	57	19
29-39	121	40.3	Married	207	69
40-50	68	22.7	Divorce	18	6
·<50	37	12.3	Widowed	18	6
Sex			**Qualifications**		
Male	72	24	Diploma	128	42.7
Female	228	76	Institute	136	45.3
			Baccalaureate	36	12
Years of experience					
1-10	114	38	21-30	66	22
11-20	104	34.7	>31	16	5.3

Table (1), More than one third (40.3%) between 29-39 years, more than three quarter (76%) of them were females, more than half (69%) were married, less than half (45.3%) of them had technical degree of nursing and more than one thirds(38%) had 1-10 years of experience.

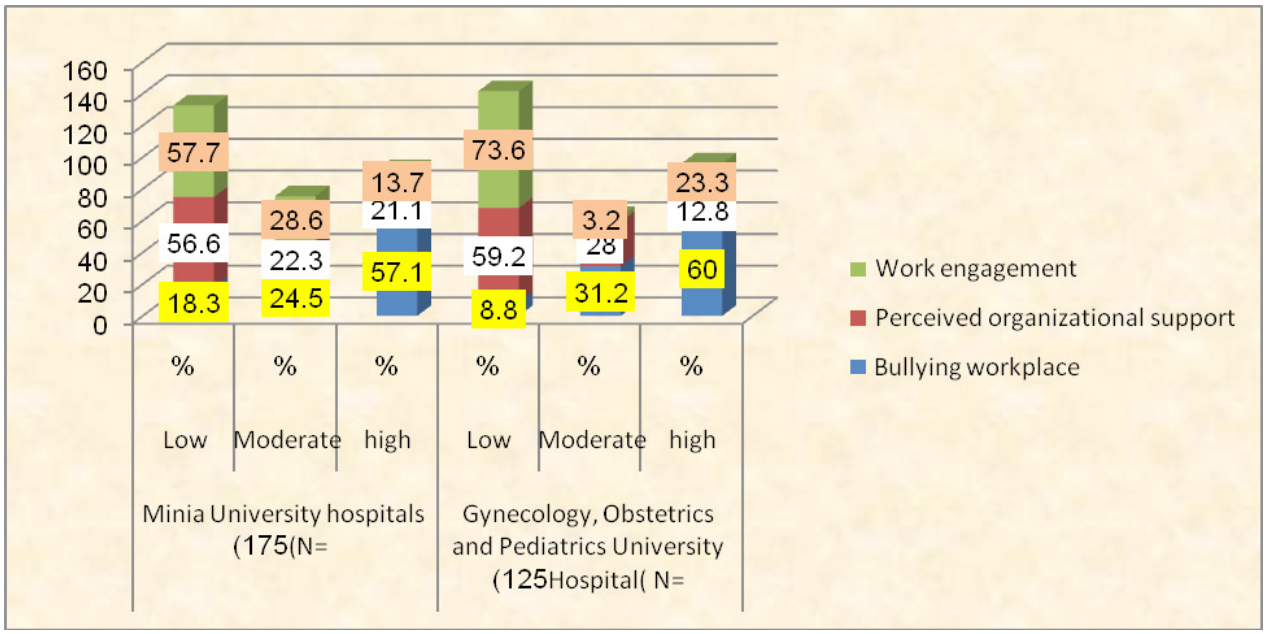

Figure (1): Percentage distribution regarding staff nurses perception of the studied variables (n = 300)

Figure (1), About sixty percent of staff nurses from the two Hospitals had the highest percent regarding perception toward bullying workplace (60%, 57.1%), in addition, the majority of staff nurses from two hospitals had low percentage regarding perceived organizational support by percent (59.2%,56.6%). Also, they have a little interest regarding perception toward work engagement by percent (73,6%),(57.7%) sequentially.

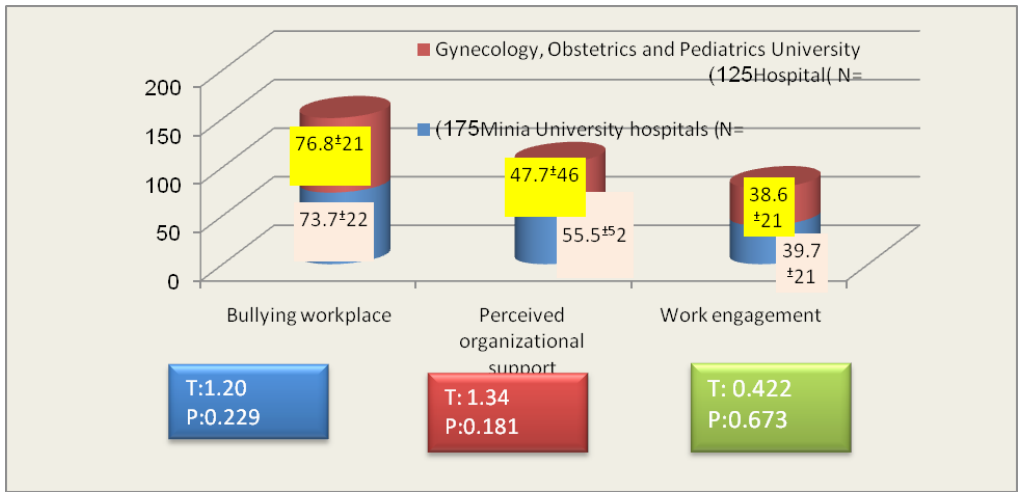

Figure (2): Analysis of variance among hospitals regarding staff nurses perception of bullying workplace, organizational support and work engagement (n = 300)

Figure (3), there was no statistically significant difference between the two hospitals in bulling workplace and organizational support, and work engagement.

Table (2): Correlation between staff nurses perception of bullying workplace,organizational support and work engagement (n = 300)

Variable	Bulling workplace	
	R	P
Organizational support	.461-**	.000
Work engagement	.265-	.000

Table (2),there was a negative correlation between staff nurses' perception of bullying workplace and organizational support (R=.461-**) besides where a negative correlation between staff nurses' knowledge of bullying workplace and work engagement (R=.265-).

Table (3): Correlation between staff nurses perception of Perceived organizational support and work engagement (n = 300)

Variable	Work engagement	
	R	P
Perceived organizational support	.298**	.008

Table (3) showed a positive correlation in work engagement and perceived organizational support(R=.298).

Discussion

The current study revealed that the majority of staff nurses from Minia University Hospital and Gynecology, Obstetric and Pediatric University Hospital had the highest percentage regarding their perception toward bullying workplace, and more than half of them from two hospitals had the lowest rate regarding their opinion toward organizational support and work engagement. From the researcher view of point, this result might be due to absence or lack of support from their organization which leads psychological problems of staff nurses such as distress, anger, anxiety, embarrassment, discouragement, feelings of inadequacy, hopelessness, depression, burnout, and lower job satisfaction all psychological problem affected negatively on work outcome which results poor performance, and staff nurses not engaged with their work.

This supported by the point of view of [17]which stated that staff nurses who are bullied in their workplace always evolve psychological side effects like stress disorder, anxiety, depression, and insomnia, all of that could result in poor work performance. Also, another author, [10]added that employees who gain organizational support would have more involvement and stronger feelings of faithfulness and allegiance towards the organization, which leads to employee engagement. Also[18] demonstrated that nurse's exposure to bullying workplace was highly related to somatization, depression, anxiety, and negative affectivity among victims of bullying, and fear among those who witnessed the bullying behavior.

Besides this current study explored that, there was no statistically significant difference between two hospitals in bulling workplace and organizational support, and

work engagement. The interpretation from the researcher view of point, this result might emphasizes that, the head nurses followed autocratic style in their leadership, and the most of the head nurses like to take the final decision-making authority within their department because they believe if they didn't do that they can be lost their control on staff nurses; and they may do not have enough experience in management, and they didn't have enough training program on leadership and how to lead staff members.

These findings were consistent with the work of the [17]which concluded that autocratic leaders have absolute power over their subordinates and the latter have little opportunity to make suggestions, Also this result confirmed by a study conducted by[19] which reported that most of the study subjects had autocratic style, and there was a connection between bureaucratic, authoritarian, and authority compliance management styles that followed an autocratic leadership style.

In addition this finding may be due to, that a result of the shortage in the nurses numbers in the hospitals and lack of training programs, and poor hospital environment in which this increase the workload for the nurses; and thus lead to reduce their ability to cope with daily challenges; and ability to deal with recent technology which reduce their job performance efficiency. This was inconsistent with[20] that there is a remarkable significant negative correlation between job stress and work overload which affect job performance efficiency; as when there are work overload and tension in the work environment; the employee affected physically and psychologically and thus consequently decrease their job performance efficiency.

The current study illustrated that there was a negative correlation between nurses' perception of bullying workplace, organizational support, and work engagement (R =.461-, R =.265-). From the researcher's view of point, this result might due to; the bullied employees are less likely to have their fundamental psychological demands (i.e., autonomy, relatedness, competence) met and therefore lost their inherent motivation to be engaged with their profession. They also may have a lack of support from their supervisors and first-line managers, which results in a negative work environment (poor performance, low quality of patient care). This agreement with[21] stated that nurse managers who have the stability of organizational support and work engagement promote a work environment conducive to an excellence culture. So, this healthy work environment fosters quality care, patient security, and staff retention. Also, this result was congruent with[22] which found that bullying workplace was negatively related to organizational support, assistance and work engagement.

Finally, the finding result of the present study indicated that there were a positive correlation among work engagement and organizational support (R=.298). This result was supported by[23] stated that there was a strong correlation between staff nurses' perceived organizational support, work engagement. Also, this was congruent with[24], detected a meaningful association between recognized organizational support and work engagement and appointment.

Also[17] added that employees who gain organizational support would have more involvement and stronger feelings of faithfulness and allegiance towards the organization. This led to employee engagement and proved that there is a meaningful and positive correlation between perceived organizational support and employee engagement.individuals will be motivated to match their obligations and kept fully engaged at work when there is recognized organization support–empirically demonstrated organizational support is an antecedent to work engagement. Moreover, work engagement is critical because recent research findings suggest that engaged employees practice: happiness, joy, and enthusiasm, good physical and psychological health, and better job performance, increased the ability to create jobs and different personal capacity and capability to transfer their engagement to others.

Conclusion

The findings of the current study affirmed that the majority of staff nurses from the two hospital had the highest percentage regarding their perception toward bullying workplace, and more than half of them from two hospitals had the lowest rate regarding the understanding of organizational support and work engagement.

Also, there were a negative correlation between the perception of staff nurses' toward bullying workplace and organizational support and work engagement. Finally, work engagement and perceived corporate support positively correlated.

Recommendations:

- Hospitals should create a supportive practice

environment within the implementation of policies, anti-bullying, and continuous training programs.

- The organization should encourage nurse supervisors to use practical communication skills and support for nurses' staff, which helps to reduce workplace bullying.

Socioeconomic Disparities in Hospital Utilization among Elderly People in Indonesia

Ratna Dwi Wulandari[1,2], S. Supriyanto[2], Bagus Qomaruddin[3], Agung Dwi Laksono[4]

[1]Doctoral Program, Faculty of Public Health, University of Airlangga, Surabaya, [2]Department of Health Policy and Administration, Faculty of Public Health, University of Airlangga, Surabaya, [3]Department of Health Promotion and Behavioral Science, Faculty of Public Health, University of Airlangga, Surabaya, [4]Indonesian Agency for Health Research and Development, Ministry of Health, Republic of Indonesia

Abstract

The pattern of diseases in the elderly people usually is degenerative diseases which often catastrophic and high cost. Unfortunately, a large financial intervention is often having the wrong target, precisely because of the more utilized by high socio-economic groups. This article is devoted to an analysis of hospital utilization disparity based on the socioeconomic status on the elderly in Indonesia. The data processed from the 2013 Indonesian Basic Health Survey (Riskesdas) with a sample size of 199,653 elderlies. Estimation by using multinomial logistic regression test used to explore the disparity between socioeconomic characteristics of the elderly in hospital utilization. Quintile 1 likelihood 0.355 times utilizing hospital outpatient than quintile 5 (OR 95% CI; 0.355 0.302-0.418). Quintile 1 likelihood 0.414 times utilizing hospital inpatient than quintile 5 (OR 95% CI; 0.414 0.366-0.468). Quintile 1 likelihood 0.247 times utilizing outpatient inpatient at once than quintile 5 (OR 95% CI; 0.247 0.184-0.332). The better the socioeconomic status is getting better the hospital utilization of the elderly.

Keywords: *Elderly, socioeconomic disparities, hospital utilization, Indonesia, inpatient-outpatient.*

Introduction

The elderly is one of the groups that are vulnerable according to the attention of the World Health Organization (WHO). Other vulnerable groups are children, pregnant women, people who are malnourished, and people who are ill or impaired immune[1]. The elderly is getting increase and require more attention as an impact of the development of better health. Indonesia's population dynamics also shifted towards the population elderly groups. As evidence is the life expectancy in Indonesia that is continually increasing. The year 2010 life expectancy 69.81 years. The number then rose to 70.90 years (man 69.09 years, women 72.8 years) in 2016. Life expectancy 70.90 years showed that babies born in the year 2016 can live up to 70 years of age[2].

The dynamics of population shifts to the elderly age group also promoted the shift pattern of the disease. The pattern of disease that often follows the elderly is a type of degenerative diseases that often this type of the catastrophic disease. The types of diseases that topped a catastrophic, that disease absorbs the high cost, are the heart, stroke, diabetes, kidney, cancer, hepatitis, leukemia, hemophilia, Thalassemia[3]. Unfortunately, the financial intervention of the catastrophic disease is often the wrong target, because of more utilized by high socioeconomic groups[4]. Elderly people on low incomes have more diseases, which more require medical care than their counterparts who are higher income earners[5].

The claim type of catastrophic disease seized a considerable amount of the share of the budget of the National Health Coverage (JKN). The year 2017, one-half of the costs spent on catastrophic disease has reached IDR 12.7 trillion or equivalent 24.81% of total hospital

costs that are claimed to Social Security Administrator (BPJS)[6].

Based on the description of background then the writing of this article is devoted to the analysis of hospital utilization disparity based on the socioeconomic status on the elderly in Indonesia. The results of this research are important for consideration of equitable health care on the elderly in Indonesia.

Method

The analysis unit in this study was Indonesian citizens aged 50 years and over. The sample size in this research paper was 199,653 elderly respondents. The processed data comes from the 2013 Riskesdas. Riskesdas was a national scale survey conducted by the Ministry of Health.

The hospital utilization was public utilize to the hospital, whether it did an outpatient or inpatient. Limits on outpatient variables were hospital utilization one last month. Limits on inpatient variables were hospital utilization one last year. Assuming the use of these time restrictions due to respondents could still remember well the events of outpatient or inpatient.

Chi-Square was used for the dichotomous variable and the t-test for continuous variables. This test is used to assess whether there was a difference between the elderly's socioeconomic statistically significant. Estimation used multinomial logistic regression test used to study the influence disparity between socioeconomic characteristics of the elderly in hospital utilization and to check the level of his significance.

Findings: The chi-square test results showed that there were differences between each of the elderly's socioeconomic status at hospital utilization, which was confirmed as statistically significant. In proportion, the better socioeconomic status (getting rich), then the better hospital utilization. This condition applies to all categories of hospital utilization, both in outpatient, inpatient, and outpatient inpatient at once.

The chi-square test results also showed that the very poor elderly more living in a rural area. Contrary, the very rich elderly more living in an urban area. Based on the gender of the elderly is dominated by women. However, the difference is thin, and this was confirmed with no significant gender differences on each quintile. The education level indicated directly proportional to socioeconomic. Based on the type of work, the poor elderly (quintile 1 and 2) are dominated by those who worked as a farmer/fisherman/labor, while the rich elderly (quintile 3-5) dominate those who don't have jobs. When viewed on the category of insurance ownership, the elderly is already more than half which have insurance.

The T-test results shows that those who are on quintile 1 have an average age of older (61.82 years) compared to the elderly who have the quintile 5 (58.99 years).Overall, only gender variables that show no significant relationship with hospital utilization in the elderly in Indonesia

Note: The reference category was "no utilization"; 95% Confidence Interval for OR; *Significant at level 95%.

Table 1 is the multinomial logistic regression test results to detect hospital utilization disparity between elderly in Indonesia. Selected as a reference category "no utilization". Table 1 shows the significant disparity between socioeconomic at elderly that utilizes the outpatient or inpatient. Table 1 shows the better socioeconomic then the better hospital utilization of the elderly. This condition applies to all utilization. Quintile 1 likelihood 0.355 times utilize hospital outpatient than quintile 5 (OR 0.355; 95% CI 0.302-0.418). Quintile 1 likelihood 0.414 times utilize hospital inpatient than quintile 5 (OR 0.414; 95% CI 0.366-0.468). Quintile 1 likelihood 0.247 times utilizing outpatient inpatient at once than quintile 5 (OR 0.247; 95% CI 0.184-0.332). The results of this research are consistent with several studies in various countries. A study in Brazil found that the elderly who have a socioeconomic good have better access than the elderly with low socioeconomic[7]. Similar results were also obtained with research in South Africa[8], Rwanda[9], Europe[10], Bangladesh[11], and USA[12].

Based on Table 1 it can be known that the elderly in the urban has a better utilization compared to the elderly who live in rural. The elderly in urban likelihood 1.544 times more utilize than rural (OR 1.544; 95% CI 1.420-1.679). Based on the categories of marital status, the elderly with "divorce" status (as reference) has a better utilization than the single, but lower than are married. Comparing an urban area with rural in the hospital utilization are also carried out by researchers in several countries. A study in Brazil found that the elderly living in urban had better access than the elderly who live in rural[7]. The same conclusion is also produced in several studies in China[13], Ethiopia[14], Taiwan[15], USA[16], Egypt[17], and India[18]. Better transportation in urban areas is predicted to contribute to hospital utilization.

Based on the level of education, the better education level means the better in hospital utilization for the elderly. Elderly with no passed primary school is likelihood 0.500 times utilize the hospital outpatient than elderly with a college education (OR 0.500; 95% CI 0.434-0.575). A better level of education is closely related to the ability to receive better information, and end up with the utilization of better service anyway[19]. Based on the work type, the not working elderly have a better hospital utilization than elderly who worked on another's category. This condition applies to all categories of hospital utilization. The possibility is the elderly who do not work is the poor that covered by Government insurance.

Table 1 shows good consistency on ownership categories of insurance, especially in outpatient utilization. The elderly who have a Government-run insurance has better utilization than who have no insurance. The elderly who have a private-run insurance better than the elderly who have a Government-run insurance. This is in line with a research in China that aimed at studying the impact of access repair through elderly insurance that found positive results. Proven that the elderly have better access to health services[20,21]. The same study also was done in five African countries (Ghana, Nepal, Sierra Leone, Zambia, and Zimbabwe), and the results show the same impact[22]. Although there are other studies in low-and middle-income countries that have different results[23].

Conclusion

It can be concluded that the socioeconomic status of the elderly is directly proportional to the utilization of hospital services in Indonesia. This condition applies to all services provided by the hospital. The better the socioeconomic status, the better the hospital utilization of the elderly.

Ethic and Consent: The 2013 Riskesdas had an ethical clearance that was approved by the national ethical committee in the NIHRD (ethic number: 01.1206.207). Informed consent was used during data collection, which considered aspects of the data collection procedure, voluntary, and confidentiality.

Abstract

Aim: The purpose of this study was to evaluate and compare the area of voids in calcium hydroxide, epoxy-resin and tricalcium silicate-based sealers when employed with single cone obturation technique.

Materials and Method: Fifteen extracted single-rooted mandibular premolar teeth were cleaned and shaped and divided into three groups according to the three different sealers used. Single cone obturation was done using gutta-percha and three sealers: Sealapex, AH Plus, and Bioroot RCS sealers, respectively. These teeth were decoronated at the cementoenamel junction and the roots were sectioned at apical, middle, and coronal third, and a stereomicroscope was used to assess the area of sealer voids and digital images were taken and was analyzed by image J software. The results were statistically analyzed using SPSS software and Kruskal–Wallis and Mann–Whitney tests.

Results: All three groups showed voids in all the sections. Significant differences were found between these sealers regarding their section wise area of voids ($P < 0.05$). Similarly, there were significant differences in their overall area of voids ($P < 0.05$) with AH Plus showing significantly least area of voids followed by Sealapex.

Conclusion: Single cone obturation with AH Plus showed least mean area of voids, whereas Single cone obturation with BioRooot RCS had significantly the most mean area of voids.

Keywords: *Sealapex, AH Plus, BioRoot RCS, voids, single cone obturation, stereomicroscope.*

Introduction

The three-dimensional obturation of the root canal system is one of the foremost necessary steps in endodontic treatment which remains as a challenge in the root canal procedure and affects the long-term successful prognosis[1]. Gutta-percha itself cannot completely seal the canal. Hence,the homogeneity of root fillings must be enhanced by using root canal sealers in conjunction with gutta-percha to fill the irregularities and minor

discrepancies between the core filling material and canal walls, thus reinforcing remaining tooth structure[2,3].

The single cone (SC) obturation technique comprises packing the canal with a single gutta-percha cone employed with sealer in which its thickness varies depending on the fit of the single cone to the walls of the canal. Since spreader is not used with SC obturation, the risk of damaging dentin is totally reduced. As a result of the quantity of sealer needed in SC obturation is larger than the quantity of sealer necessary for many compaction techniques, a spare volume of a dimensionally stable sealer ought to be placed into the canal[4].

The standard of the ultimate root canal filling directly depends on the properties of root canal sealers, where they assist to resolve the periapical pathosis by preventing microleakage, thus reducing the likelihood of residual microorganisms from apical percolation. An ideal root canal sealer should have sufficient working time and when set should provide an excellent seal with the canal walls[5].

Studies conducted by Ingle and Beveridge concluded that the bulk of endodontic failures occur principally due to microleakage which results from incomplete sealing of the root canal. Thus, the sealers which produce a fluid-tight seal between the root canal system and the periapical tissues must be promoted to use. Aside from glass ionomer cement-based sealers, none of the sealers have the flexibility to bind chemically to canal walls. The smear layer produced on the root canal walls should be eliminated from the root canal walls for the better penetration of sealers into tubular dentin, which successively reduces the microleakage[6].

It might be fascinating to use a sealer which can stimulate hard tissue formation and it is well established that calcium hydroxide stimulates the healing of periapical tissues and induces hard tissue formation. Sealapex (Kerr Sybron, Romulus, USA) is a calcium hydroxide polymeric based non-eugenol root canal sealer. It is composed of calcium hydroxide, sulfonamide, zinc oxide, zinc stearate, colloidal silica, barium sulfate, resin, isobutyl salicylate, colloidal silica, titanium dioxide, and iron oxide and sets in about 40 minutes[7].

AH Plus (Dentsply, Konstanz, Germany), a well-known epoxy-resin sealer had overcome the disadvantages of formaldehyde release and extended setting time of AH 26 sealer. It consists of two paste system, Paste A consists of Bisphenol A epoxy resin base, while Paste B consists of Dibenzydiamine as catalyst[7]. AH Plus has comparatively short setting time, low solubility, and high tissue compatibility. AH Plus demonstrated good sealing and adaptation properties[8].

Bioroot RCS, a tricalcium silicate-based hydraulic sealer has been introduced recently. It is available as powder/liquid combination, in which the powder comprises tricalcium silicate, zirconium oxide, and povidone; whereas, the liquid consists of polycarboxylate and calcium chloride. Since the tricalcium silicate phase is bioactive, it is popular today. It induces hard tissue deposition and has lower cytotoxicity than alternative standard root canal sealers and has antimicrobial activity[9]. However, the impact of Bio Root RCS sealer voids in single-cone obturation has not been evaluated much. Therefore, this *in vitro* study was conducted to determine and compare the presence of voids in Sealapex, AH Plus, and Bio Root RCS sealers when employed with single cone obturation technique.

Materials and Method

The study was done after obtaining clearance from the ethical committee. Fifteen single-rooted human mandibular premolar teeth extracted for periodontal or orthodontic reasons were used as samples in this study. Access opening was done and the working length was determined by subtracting 1 mm from the inserted no: 15 K file which was just visible through the apical foramen. Pro Taper Gold (Dentsply Maillefer, Ballaigues, Switzerland) Ni-Ti rotary files were used in the crown down technique up to size F3 to clean and shape the root canals. Sodium hypochlorite (5.25%), 17% EDTA and saline were used as irrigants.

The prepared teeth were randomly divided into three groups, with five teeth in each group (n = 5), for single cone obturation using different sealers as follows:

Group	Sealer used	Manufactured
A	Sealer sealapex	Kerr Sybron, Romulus, USA
B	Sealer AH Plus	Dentsply, Konstanz, Germany
C	Bioroot RCS	Septodont, Saint Maur Des Fosses, France

The groups were then obturated by single cone technique using the corresponding F3 sized Pro Taper Gutta-percha cone (Dentsply, Switzerland) with tug back along with their root canal sealers respectively. In order to ensure the complete set of the sealers, all the

obturated teeth were stored in 100% relative humidity at 37° for 7 days. Then, decoronation of all these samples were done at the cementoenamel junction, and the roots were marked with shallow cuts on the buccal and lingual aspects at an approximate level of 1 mm, 4 mm, 8 mm, and 12 mm from their apices using a diamond disc. A total of 15 sectioned samples were obtained in each group by sectioning of the roots through the marked cuts with a chisel. Thus, apical, middle, and coronal third sections, each with an approximate thickness of 3 ± 0.5 mm, were obtained from a single tooth.

Each sectioned sample was observed using a stereomicroscope with a magnification ×40 and digital images were taken. Image J software (National Institutes of Health, Bethesda, MD, USA) were used to analyze the images for calculation of the area of voids. The results were statistically analyzed using SPSS software (version 15, SPSS Inc, Chicago, IL, USA) and Kruskal–Wallis and Mann–Whitney tests.

Results

All sealers showed voids in all the sections, but AH Plus sealer showed least voids in apical, middle and coronal third among all the sealers and had a least overall mean area of voids. Single cone obturation with Bioroot RCS sealer also showed a lesser area of voids in the apical and middle sections and greatest overall mean area of voids when compared to those with Sealapex sealer. The differences in mean area of voids between Sealapex and AH Plus sealers in the middle and apical section were significant ($P < 0.05$).Section-wise mean area of voids in the sealer is demonstrated in table 1.

Table 1: Mean area of voids in mm^2

Section	Groups	No of samples (n)	Mean area of voids±SD (mm^2)
Coronal	Sealapex	5	.0272±.0278
	AH plus	5	.0094±.0097
	Bioroot	5	.0388±.0245
Middle	Sealapex	5	.0154±.0099
	AH plus	5	.0024±.0028
	Bioroot	5	.0068±.0044
Apical	Sealapex	5	.0080±.0050
	AH plus	5	.0016±.0020
	Bioroot	5	.0064±.0048

Discussion

Single cone obturation of the straight root canals with a tapered gutta-percha master cone that matches the shape of nickel-titanium rotary instruments eliminate complete bacterial penetration effectively and reduces chairside time. Since the adaptation of a single cone to the canal walls depend on the quantity and property of sealer used, the area of voids in the sealer should be least to prevent microleakage[1].

Single cone obturation technique, the most frequently used root filling technique was selected for use in the present study, due to its simplicity and it is less operator-dependent and time consuming when compared to other root filling techniques. The ability to create a tapered circular preparation, as well as the shape of the canals, determine the quality and use of single cone gutta-percha points[10].

In this study, there have been significantly fewer sealer voids and better seal of the root canals was found

in the canals obturated using the epoxy-resin sealer, AH Plus when compared with calcium hydroxide and tricalcium silicate-based sealers. This study was in agreement with certain studies (Viapiana et al, Siboni et al)[2,9]. Adhesion to the root canal dentin of epoxy-resin based sealers are high and they penetrate deeper into the dentinal tubules. Their creep capacity and period of prolonged polymerization allow their better penetration into the micro-irregularities (Topcuoglu H S et al)[3]. Presence of resin in the sealer explains its better flow. The superior adaptation of AH Plus to the root dentin can be explained by their chemical bonding to dentin by forming covalent bonds between the collagen and the epoxy resin (Arikatla S K et al)[12]. This difference could also be related to sealer properties as BioRoot RCS has a shorter working time and less flow than AH Plus[2].

The AH plus penetrated completely in the dentinal tubules in the coronal, mid-root and apical region, whereas the sealer penetration pattern of Bio Root RCS was different to that of AH Plus. Tricalcium silicate-based sealers may enhance the seal of the root fillings due to their biological activity. Biomineralization may be potentially induced due to their interaction with dentin fluid. Thus, the mineral plugs form within the dentinal tubules enhances the biological activity within the root canal (Viapiana et al)[2].

Sealer voids on the apical third of all groups were less when compared to the middle and the coronal third, whereas it was significantly higher on the coronal third of Bioroot RCS. The hydrophilic nature of Bioroot RCS had produced greater porosity and solubility values. Since AH Plus is a hydrophobic material, they do not adsorb water; and therefore, their porosity and solubility values are significantly reduced than for the tricalcium silicate-containing materials. High Ca2+ and OH^{-} release in Bioroot RCS resulted in their high values of voids (Siboni F et al)[9].

A calcium-hydroxide based sealer, Sealapex, which is a paste-paste preparation was selected for this study, as it improves the biological properties and guarantees a proper seal to the root canal system. Voids with sealapex sealer were more when comparing with AH Plus sealer and were less comparing with Bioroot RCS sealer. Our findings are supported by Janavathi et al, who found better results with AH plus than Sealapex. Vasconcelos et al, in their study, have shown that initially, Sealapex had presented with good sealing ability, then the sealing was found very poor after being stored in water for an extended time. Initially produced satisfactory results may be related to the volumetric expansion of sealapex while setting due to water sorption caused by calcium oxide in the sealer; whereas the sealer dissolution over time explains the later sealing ability loss. The rapid, but limited release of hydroxyl ions may be related to the disintegration and solubility of the sealer and in an aqueous environment[13,14]. The alkaline environment created during the liberation of hydroxyl ion is responsible for the antimicrobial activity of the sealer[7].

Stereomicroscopic examination was chosen for this study as this was simple and at the same time, provides a three-dimensional view of the surface to be examined, it needs no pretreatment of the specimen as in the Scanning Electron Microscopic Examination and is related to an image analysis software system, which eliminates human errors while the interpretation of the parameters[11].

Even though it was a three-dimensional microscopic study, this methodology leads to the destruction of samples and structural loss while sectioning. Greater sample size associated with nano-computerized tomography would assist in the better results of this study.

Conclusion

In the present study, all the groups showed sealer voids and single cone obturation with AH Plus showed least voids in all the sections when compared to other groups and had a least overall mean area of voids and that with Bioroot RCS showed greatest overall mean area of voids when compared to those with Sealapex sealer.

Abstract

Fifty subfertility couples were involved in the present study during their attendance at the fertility clinic at Al-Sadder teaching hospital in Al-Najaf/Iraq throughout a period from January 2018 to January 2019 to undergo intracytoplasmic sperm injection (ICSI). Details history and physical examination were done for every subject participated in this study. Fertilization rate (FR) was calculated as percentage transformation of microinjected oocytes into two pronuclei. A categorical variable of FR defined based on 50% FR grouped couples; Group I with FR>50% and Group II with FR>50%. The objective of this study was to investigate the influence of fertilization rate on ICSI outcome and pregnancy rate for unexplained subfertile couples. Main results of this study revealed that there was a significant difference ($p<0.05$) in ICSI outcome and pregnancy rate between different study groups. With increasing fertilization rate, there was an increase in the ICSI outcome and the pregnancy rate. It was concluded that increased fertilization rate have a positive impact on the ICSI outcome and pregnancy rate for unexplained subfertile couples.

Keywords: *Intracytoplasmic sperm injection, Fertilization, Fertilization rate.*

Introduction

Infertility could be defined as the couples inability to achieve spontaneous conception after one year or more of a regular, unprotected sexual relationship[(1)]. Infertility is a growing concern affecting globally up to 15% of couples trying to conceive, and it represents a source of social and psychological suffering for both men and women and can place high pressure on the relationship within the couples[(2)]. Fortunately, progresses in the assistive reproducing technologies (ART) have assists many subfertile couples to achieve conception[(3)]. In Vitro Fertilization (IVF) is a well-established procedure as a treatment of various types of infertility, including tubal obstruction, endometriosis, idiopathic infertility and some cases of mild male infertility. However, those couples suffering from severe male factor infertility represent the leading cause of failed fertilization in IVF[(4)]. The need for a more efficient procedure to achieve normal fertilization ended with the development of ICSI, where a single viable sperm was introduced directly into the ooplasm[(5)]. The first human pregnancy and live birth using this technique were achieved in 1992. Since then, ICSI has become the common treatment of choice for couples presenting with male infertility[(6)]. Fertilization rate (FR) is the percentage of the transformation of microinjected oocytes into two pronuclei[(7)]. The implantation rate (IR); the number of pregnancies per embryo transferred, has been reported to vary from 10% to 40% in different clinics. Fertilization process involves that, the ovulated or retrieved oocyte is activated by sperm entry either by normal conception in vivo or artificially with ICSI. Events happen during fertilization include sperm-oocyte membrane fusion,

then polar body extrusion and completion of the second meiotic division[8]. The first week of preimplantation development starts from fertilization and continue up to blastocyst hatching. This involves repeated mitotic division of zygote in the tubes and uterus before the blastocyst hatches and implants in the endometrial cavity on day 6 or 7[9].

The most important morphological criteria to evaluate cleaved embryos in vitro are blastomere size and shape, whether even or not, fragmentation and multinucleation[10]. Nuclear structure, especially of nucleoli, change after embryonic genome expression between the 4-cell and 8-cell stages, where compact nucleoli in early embryos become progressively reticulated in later embryos[11]. Failure of treatment after ICSI a to a long list of factors which vary depending on the cause of infertility. In 25% of the cases, the aetiology of infertility cannot be found. This unexplained infertility is described with normal semen counts together with optimal ovulatory functions, presence of patent tubes and a normal uterine cavity[12]. It has been observed that failure of fertilization and cleavage is more likely to occur in couples with unexplained infertility as compared to tubal factor infertility, and male sperm problems [13].

Materials and Method

Patients: A total of fifty subfertile couples who approach the clinic of fertility centre at Al-Sadder teaching hospital in Al-Najaf/Iraq for their inability to conceive and undergoing ICSI were included in this study, throughout a period from January 2018 to January 2019. Couples with unexplained infertility for more than two years with female's age ranging from 20 till 35 years were included. Details history and physical examination were done for every subject participated in this study. Subfertility due to male factor and females with polycystic ovaries, endometriosis, and endocrine abnormalities were excluded from the study. Fertilization rate (FR) was calculated as percentage transformation of microinjected oocytes into two pronuclei. A categorical variable of FR defined on the basis of 50% FR grouped couples; Group I with FR $\leq$ 50% and Group II with FR $>$ 50%.

Sperm preparation for ICSI: Semen analysis and preparing, damage to sperm must be minimized by avoiding large fluctuations in temperature and unnecessary centrifugation[14].

Intracytoplasmic sperm injection (ICSI): All-female partners were subjected to controlled ovarian hyperstimulation with different protocols, including long agonist, short agonist, and antagonist programs. Ovulation was induced by intramuscular injection of 10,000 IU of human chorionic gonadotrophin. Oocyte retrieval procedure was performed under ultrasound guidance at about 36 hr. after triggering. The oocytes were denuded by hyaluronidase enzyme and the mechanical way by repeated aspiration through a sequence of denuding pipettes. Then the oocytes were washed with the culture medium, and the maturity of oocytes was assessed.

Oocyte Culture and Evaluation of fertilization: The normal standardized routine method was used for all patients 16-18 hours after injection oocytes were inspected for fertilization (finding of two pronuclei and two polar bodies). The fertilization rate was calculated from the number of oocytes normally fertilized divided by the number of injected oocytes. Subsequent evaluation of the embryo quality depended on blastomere number, shape, equality, mononucleated and proportion of fragmentation. Embryos were incubated individually in drops and transferred daily to fresh cleavage medium. Embryos were classified as 'good quality' if they were at the four-cell stage at forty-eight hr. after injection or at the six-to the eight-cell stage, seventy-two hr. after injection with even-sized blastomeres and little or no fragmentation[15].

Pregnancy Evaluation: In this study, pregnancy was reported as positive when serum hCG (IU/mL) concentrations were more than 10 IU/mL on day 10 post-transfer, and clinical pregnancy was confirmed by the presence of cardiac activity on transvaginal ultrasound scan (TVS) two weeks afterwards[16].

Results

In this study, we evaluate the impact of fertilization rate on ICSI outcome and pregnancy rate for unexplained subfertile couples.

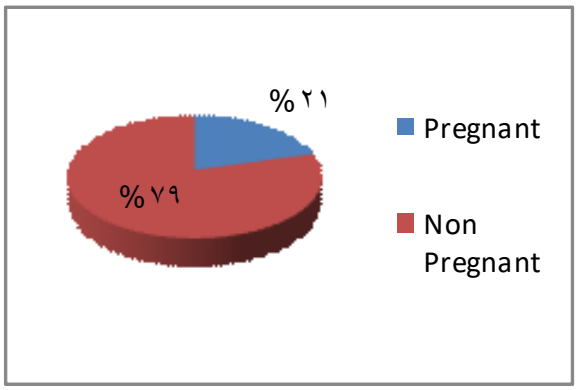

Figure 1: Distribution of patients according to the pregnancy rate (PR).

Figure 2: shows the pregnancy rate among different studied groups. The clinical PR was 15.9% in group I and 29.4% in group II. Thus, a higher rate was achieved in group II.

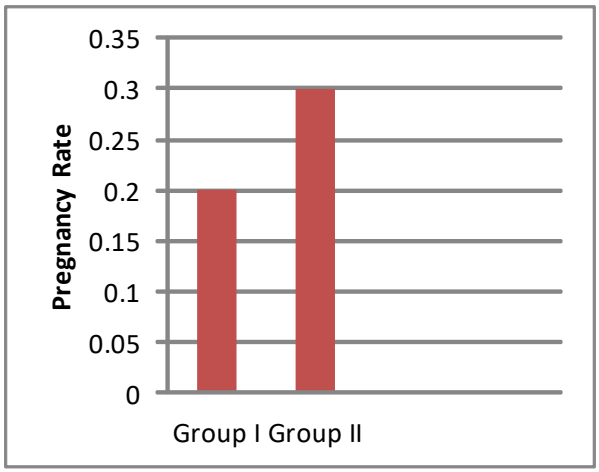

Figure 2: pregnancy rate among different studied groups.

Table-1 shows that Group II had higher basal E2, LH and FSH levels than Group I, but the results were not significant.

Table 1: Hormonal profile of the studied groups

Hormone	FR		P-value
	<50%	>50%	
Basel E2 (pg/ml)	38.41	39.57	0.783
E2 at the day of HCG injection (pg/ml)	1768.32	1693.88	0.785
Basel FSH (Miu /ml)	5.41	5.48	0.916
Basel LH (Miu /ml)	3.15	3.33	0.688

Table 2: shows that Group II had higher ICSI outcomes than Group I, there was a significant difference.

Table 2: ICSI outcomes of the studied groups.

ICSI outcome	FR		P-value
	<50%	>50%	
No. of follicles	8.35	9.73	0.304
No. of retrieved oocytes	5.85	6.77	0.438
Good injected oocyte	5.20	5.77	0.545
2PN	1.80	5.10	0.00
No. of embryos	1.75	4.83	0.00
Grade I embryo	0.8	1.5	0.67
Grade II embryo	0.65	2.4	0.002
No. of embryos transferred	1.75	3.87	0.00
Cleavage rate	83%	93%	0.289

Discussion

The introduction of intracytoplasmic sperm injection (ICSI) in 1992, a technique of in-vitro fertilization using direct insertion of a single sperm into an egg, offered the ability to bypass even some of the most severe etiologies of male subfertility[4]. ICSI procedure need a single life sperm with ability to activate oocyte and form pronuclei is necessary but morphology, motility and acrosome status not important[15]. It is documented that fertilization of oocytes involves a complex series of events requires growth, development and cytoplasmic maturation of oocytes microinjected with spermatozoa. Implantation of the human embryo is a well co-ordinated sequenced event of apposition and adhesion of the invading blastocyst in the endometrial bed during the window of implantation[17]. The sensitivity of antral follicles to gonadotropic drugs, response to stimulation, oocyte maturity, fertilization, embryo quality and endometrial thickness, all contribute to the magnitude of success rates of ART. In all procedures, failure of fertilization is the stage which stops the process and wipes the hopes and expectations of the infertile couples. The problem is intensified more in the couples to whom the reproductive endocrinologists have no true explanation of the cause of infertility. It is established that low FR results in poor IR and pregnancy outcome in comparison to patients with greater FR[18]. During ICSI, a number of oocytes estimated by TVS as preovulatory follicle count (PFC) is the strongest predictor of number of oocytes obtained during oocyte pick up. In the present study, the oocytes number and basal FSH was high in group II. E2 produced during the follicular phase of female reproductive cycle improves endometrial receptivity for implantation of the blastocyst. A good number of oocytes and high E2 measured on the day of hCG administration reflects response and pregnancy outcome that has been subjecting

of debate by several researchers[19]. In a previous study, it is reported that females with higher peak E2 had more significant number of retrieved, mature and fertilized oocytes with increased FR and IR[17]. In this study, peak E2 gives a positive predictor of FR in patients of unexplained infertility. Our results in this study show that the quality of the embryos at the time of ET has a critical effect on the outcome of ICSI, as was the case with conventional IVF.

Total oocyte retrieved, PN, grade II embryo, the total number of embryos, and the number of ET were significantly higher in pregnant women when compared with non-pregnant women. These results agreed with Van Loendersloot and his co-workers in 2014 who found a direct relationship between the increasing number of oocytes retrieved, ET, embryo quality and pregnancy rate after ART [20]. Also, he discovered that pregnancy chances had a significant association with ICSI parameters [20].

Cai and his co-workers (2011) found that the total number of grade I and II embryos was a superior predictor for ART success [21]. Also, they established that embryonic parameters, including a total number of grade I & II embryos and the total number of embryos, ordered as the first most important and second most important predictors for ART success. These results recommend that the total number of embryos give additional information to predict ART success if there was a lack in the determination of the total number of good-quality embryos. It may be a substitution marker for hormonal factors and may work through the uterine receptivity [22].

It is clear that in ICSI, different sperm indices do not affect the fertilization rate, PR, or the outcome of pregnancy as long as a morphologically well-shaped motile sperm is used for injection [23]. Although poor-quality embryos failed to demonstrate the same PR as those derived from mature oocytes, the cause was not the quality of the sperm, but the quality of the oocyte and particularly the maturity of the cytoplasm. In general, the ICSI fertilization rate is lower than expected despite the mechanical injection of one sperm into a mature oocyte, possibly because sperm that is selected may have defects in their DNA [24]. That is to say ICSI procedure bypass the natural selective process although the most normal-appearing and motile spermatozoa are selected there is always a small percentage of sperm used in in vitro fertilization (IVF)/ICSI that contains varying degrees of DNA damage and due to the high apoptotic activity during development into a blastocyst the chance of a successful ongoing pregnancy is significantly low[24].

Conclusion

It was concluded that increased fertilization rate have a positive impact on the ICSI outcome and pregnancy rate for unexplained subfertile couples.

Development of Score Computation Concept of Desirable Dietary Pattern as a New Approach for Measurement of Consumption Quality

Sabila Fabi Hanida[1], Dadang Sukandar[1], Hidayat Syarief[1]

[1]*Department of Community Nutrition, Faculty of Human Ecology, Bogor Agricultural University, Bogor*

Abstract

The concept of calculating DDP which is use of maximum scores even though the AKE score is higher can be biased on the quality of consumption of some food groups, especially grains, oils/fats, and sugars because they are considered to be in line with the recommendations, but the fact exceeds from consumption recommendations. Development of the concept of DDP (Desirable Dietary Pattern) score using a new method that evaluates the deviation score is aimed to get a valid result of quality of food consumption. This research is a development research with quantitative multiple method used the secondary data of Calorie and Protein Consumption Report March 2017. The results showed that the quality of consumption has decreased according to the new method of DDP score. The average deviation of DDP score the difference between the old and new scores of the all areas is 7,25 and especially in food group grains and oils-fats. Excessive food consumption generally in the food group of grains, oil/fat and sugar affect decreased in consumption quality which is at risk for the emergence of degenerative diseases and also higher risk to death. The development concept of DDP score is in line with the actual quality of the population's consumption by considering health problems arising from excessive food group consumption.

Keywords: *Consumption, DDP, Development, Deviation.*

Introduction

Related to the problem of food in national scale, it can be done with changes in the system that integrated by doing food diversification [1]. The size of food consumption through food diversity of the population in an area can be seen from the Desirable Dietary Pattern (DDP) score. Desirable Dietary Pattern is a combination of type and quantity of the main food groups that are recommended to meet the needs of energy and nutrients[2]. Food Security Agency (BKP) performance report in 2017 states that the high consumption of grains and oil fats then low consumption of fruit and vegetables, animal food, beans, tubers impact on less diverse of food consumption. Excessive food consumption generally in groups of oil/fat and sugar affects a decrease in consumption quality which is become risk for the degenerative diseases and death[3,4].

The BKP concept of calculating DDP in the use of maximum scores even though the adequacy of energy intake (AKE) score is higher can be biased on the quality of consumption. Some of food groups, especially grains, oils/fats, and sugars are considered to be in accordance with the recommendations, but the fact exceeds ideal consumption recommendations. The development of the concept of calculating DDP using a method that evaluates deviations aims to obtain valid results of quality of food consumption by taking into account irregularities that occur. The development of the concept of calculating the DDP score is expected to be able to assess the quality of population food consumption according to actual consumption.

Material and Method

This study used the secondary data from the Report of Calorie and Protein Consumption of Population of Indonesia and Province March 2017 issued by Statistics Center of Indonesia (BPS RI). The data were nation-wide food consumption survey data which include data variable of food consumption of population (calorie/capita/day) with data type are quantity and type of food consumed[5]. This research is a development research with quantitative multiple method. The primary method used are content analysis of extant data based on two

measurement method and descriptive of literature for validation. This research were conducted at Bogor Agricultural University for three months in January until March 2018.

The data were processing and analysis using Microsoft Excel 2013. Food groupings and DDP score calculations were done with the guidelines from the guide book of DDP by BKP 2015 with standard of adequacy of energy intake is 2.150 kkal (table 1). Calculation of DDP score according to old concept (BKP) has the following formula[6]:

DDP Score (i)=SAKEi,if SAKEi <Ei

DDP Score (i)=Ei,if SAKEi >Ei

Description: i = type of food, SAKEi = Energy adequacy score of food type i, Ei = Standar score/maximum score DDP

Table 1: Examples of calculating a score of DDP food consumption with the concept of national

No	Food Groups	Energy (kkal)	% AKE	Weights	AKE Score	DDP Score	Max score of DDP (Ei)
1.	Grains	1083.1	50,4	0.5	25.2	25.0	25.0
2.	Tubers	35.3	1,6	0.5	0.8	0.8	2.5
3.	Animal source foods	213.6	9,9	2.0	19.9	19.9	24.0
4.	Oils and Fats	266	12,4	0.5	6.2	5.0	5.0
5.	Oily fruit/seed	64.6	3,0	0.5	1.5	1.0	1.0
6.	Pulses	35.3	1,6	2.0	3.3	3.3	10.0
7.	Sugar	104.1	4.8	0.5	2.4	2.4	2.5
8.	Vegetable and fruit	75.5	3.5	5.0	17.6	17.6	30.0
9.	Others	26	1.2	0.0	0.0	0.0	0.0
Total		**1903.6**	**100**			**75**	**100**

The old concept has a point of view that the DDP score is still ideal even though the AKE score exceeds the ideal. The principle of development a DDP score is to evaluate the deviations that occur when the score is more than the standard/maximum calculated as a standard score. The calculation equation of development PPH score becomes:

$$\text{DDP Score}\,(i) = \sum_{i=1}^{n} \text{Ei} - |\text{SAKEi} - \text{Ei}|$$

$$\text{DDP Score}\,(i) = 0, \text{if SAKEi} \geq 2\text{Ei}$$

Description: n = The number of food groups

Analysis of deviation of DDP score can be seen from:

Deviation (absolute different) = Old DDP Score – New DDP Score

Validation of the concept of calculating the DDP score by development method using theory-based validation. The analysis included in the validation is a literature study related to the estimation of health risks due to unbalanced food consumption (excess from standards).

Results

Based on the results of calculating the DDP score in all regions, the DDP score with the development concept has a lower value when compared to the DDP score calculated by the BKP (Food Security Agency of Indonesia) concept.The change in the DDP score concluded that there was a decrease in levels when calculated using the development concept. The average absolute difference between the DDP score and the BKP concept and DDP score of the development concept was 7.25 with an average standard deviation of storage in the entire region of 2.68 (table 1).

Table 2: The absolute difference in provincial DDP scores according to the old method with the development method

Results of	Desirable Dietary Pattern Score		
	Old (BKP)	New	Absolute Difference
Median	79.72	71.39	7.64
Average	78.42	71.17	7.25
Standard Deviation	4.90	5.00	2.68
Minimum	66.39	57.30	0.37
Maximum	87.94	81.86	11.57

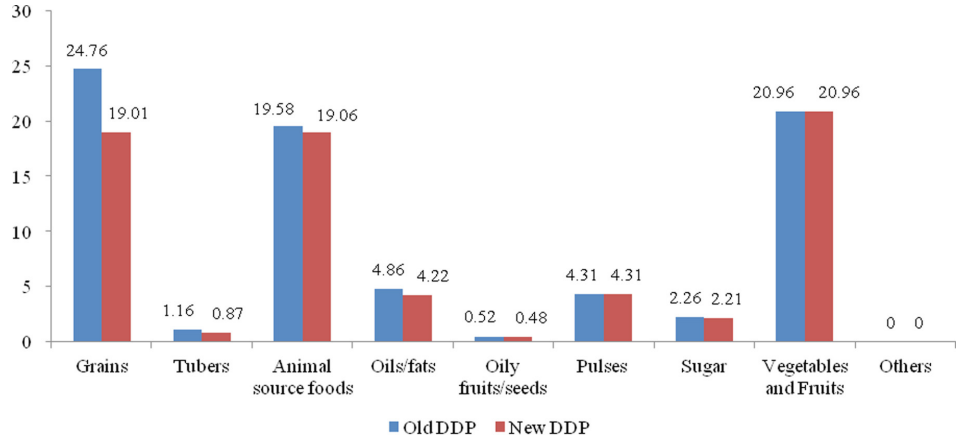

Diagram 1: Average value of deviations in each food group

The concept of calculating DDP scores according to BKP has an average of 78.42 with an average score in the grains group reaching 24.76. Whereas in the development concept, the average DDP has a lower average score of 71.17 with a DDP grade of 19.01. The food group with the highest value is owned by the grains group with an average absolute difference in the entire region of 5.74. Oil and fat in second place of biased food consumption with an absolute average value of 0.64 I then followed by animal food groups with an absolute difference of 0.52 (diagram 1).

Discussion

National concept of calculation of the DDP according to BKP guidelines will cause a deviation/bias, because of excessive scoreare considered to be in line with the recommendations. But according to the new concept (development) excessive scorefrom recommendations will be evaluated so that the more score will not be counted as the ideal DDP score. The principle of developing DDP calculations with similar concepts is also carried out in China. Study of Zhou *et al.*(2013) stated that the DDP score category that previously calculated using the traditional concept showed the "desirable dietary pattern", but showed decline in levels when using the concept of development, became a "good dietary pattern".The results of the development DDP scores by Zhou were positively correlated with the NRF9.3 index and considered more accurate and sensitive for evaluating dietary patterns for the Chinese population [7].

Almost all food groups show an absolute difference when calculated using the concept of development except the food group of pulses, vegetables and fruits and other food groups (spices). The results of the PPH scores of the three groups doesn't have biased because there were no excessive consumption from recommendations. The highest absolute difference value is found in the grains group with an average of 5.74, conclude that consume of grains reaching 5 points above the recommendation.

The low diversity of consumption is a trigger hidden hunger phenomena (micronutrient deficiency)and lead to disruption of physical growth and learning processes, limiting productivity, and ultimately perpetuating poverty in a sustainable cycle[8]. Excessive food consumption is generally in the food group sources of, grains, oil/fat and sugar affect the decline in quality of consumption at risk of emergence degenerative diseases that progress to death[9].

Grains and Tubers: Foods that are largely based on staple foods, such as corn, wheat, rice, and cassava, which provide most of the energy but with relatively low amounts of important vitamins and minerals and often result in hidden hunger[8]. Excessive consumption of rice is not enough to meet the needs of micronutrients because white rice is a low source of folate (vitamin B9), low level of β-carotene, and selenium[10,11].

The phytat acid group, pesticic acid, and dietary fiber contained in grains and tubers has a negative effect against other minerals such as calcium, zinc, iron, and magnesium [12,13]. Some tubers such as potatoes are found to contain trypsin inhibitors and chymotrypsin inhibitors which interfere with digestion, absorption, and utilization of trypsin and chymotrypsin. Potato foods are also found to contain lectins which when consumed excess can be goitrogenic [13].

Animal source food: Meat is the main source of fat in human consumption patterns, especially saturated fatty acids (SFA) which is also a significant factor of degenerative diseases in some developed countries [14]. In line with this, Sartika's research (2008) states that every 4 ons of beef or chicken meat contain 100 mg of cholesterol and saturated fatty acids. The increase levels of K-LDL (LDL cholesterol) is a predictor of coronary heart disease if being balanced by other diverse foods [15].Animal foods are also iron-rich foods, but overfilling iron stores can damage the liver, pancreas and heart[12]. High iron status in the human body combines with LDL cholesterol can be a significant factor in the incidence of atherosclerosis [13].

Fish and marine products are important natural sources of omega-3 fatty acids, selenium, iodine and vitamin D for human. Fish and marine products are also a source of dioxin, mercury, marine biotoxins and endocrine disruptors for human[16].

Oils and fats: The consumption of food groups of oil and fat is inseparable from the effect of the taste of fat from the food itself [17]. The taste of fat will encourage or trigger continuous consumption and tends to overdo it. Excessive consumption of fat in the body can allow too much calorie intake consumed by the body and has a very significant impact on obesity [18].Coconut oil and palm oil initially contain unsaturated fatty acids and will turn into saturated fatty acid content after being used for frying. It also has the ability to increase LDL cholesterol levels and a trigger for coronary heart disease (CHD) and arteriosclerosis which are the main contributors to death[14,15].

Oily fruits/seeds: Food groups of oily fruits/seeds such as chocolate have a nutritional content that has a negative impact if consumed in excess. Oxalic acid in chocolate can be like pitatic acid which has the effect of reducing absorption of calcium and some other minerals[13]. Phytate and deep polyphenols can inhibit nonheme iron absorption with absorption inhibition of 71% in chocolate [19].

Pulses: Research by Tosh and Yada (2010) stated that in raw conditions, legumes can have a dietary fiber content of 15-30% of the total food fiber needed by the body in a day [20]. Excessive food fiber content in food consumption a day when accumulated will cause interference with absorption and utilization of other minerals such as calcium, magnesium, zinc, and iron [12]. Research by Mc Crory et al. (2010) and Omaye (2004) state that pulse has antiprotein content which can inhibit the action of trypsin and chymotrypsin as evidenced in the study [13,21].

Sugar: Sugar is important as a substance that capable of releasing opioids and dopamine and allows it to have the potential like opiate. In some circumstances, intermittent access to sugar can cause behavioral and neurochemical changes that mimic the effects of substance abuse such as bingeing, withdrawal signs, craving, and cross-sensitization [22]. It is estimated that each additional can or a glass of sugary drink consumed daily increases the risk obese by 60% and higher the caries incidence in children. Some studies also show that deaths caused by obesity amount to more than 300,000 and result in related medical expenses of $ 100 billion per year [23].

Vegetables and fruits: Some nutritional content in vegetables and fruits has anti-nutrients properties, which makes some of these nutrients unable to be absorbed other nutrients maximally. Anti nutrients in this food including oxalate, phytate, tannin and dietary fiber that can interfere with absorption minerals, especially calcium[24]. Fruits and vegetables tend to contain a lot of potassium (potassium) when intake exceeds (about 18 g/day) will cause hyperkalemia and have a fatal impact due to heart attack. The risk of hyperkalemia will be very high in patients with renal failure[12].

Conclusion

The DDP score when calculated using the development concept show deviation value, especially in the grains group. The quality of consumption also decline in categories according to the developing concept of calculation of DDP score. The concept of DDP with reference to the diversity of consumption, nutritious, and balanced foods is still not achieved when viewed from the high contribution of calories from grains and oil/fat groups. When considering health problems that arise due to excessive consumption of food groups which is resulting in imbalance of nutrients contained such as a description of the theory above, then the development concept of calculation DDP score is considered appropriate for measure of the quality of food consumption.

Parental Style and Its Relation to Adolescents' Self-Concept and Depression

Safaa Mohammed Zaki[1], Manal Hassan Abo Elmagd[2], Nagat Farouk Abo Elwafa[3]

[1]Lecturer of Psychiatric and Mental Health Nursing, Faculty of Nursing, Minia University, Egypt, [2]Associate Professor of psychiatric and Mental Health Nursing,Faculty of Nursing, Umm Al Qura K.S.A. & Minia University, [3]Lecturer of Pediatric Nursing, Faculty of Nursing, Minia University, Egypt

Abstract

Background: The adolescents' growth and development can be developed by the style of parents. Parenting style has been discussed to influence on psychological status of adolescent in which it may produce depression or decrease self-concept.

The aim of the study: Was to assess parental style and its relation to adolescents' self-concept and depression

Research design: Descriptive correlation research design was used.

Research question: Is there a relation between Parental style and adolescents' self-concept and depression?

Setting: This study was carried out in Zohra preparatory and El-Fath preparatory schools at Minia City.

Sampling: A convenient sample consisted of 200 adolescent students.

Tools: Three tools were used; Parental style (MOPS), Self-Concept Clarity Scale, and Birleson depression scale.

Results: There was significant negative statistical correlation between self–concept and total parent style; **Conclusion**: the current study concluded that most of the studied adolescent pained from depression symptoms. Parents with abusive behavior their adolescent self-concept decreased and become depressed.

Recommendations: Parents training regarding parenthood had a power on self-concept of their children which as a consequently induced the depression.

Keywords: *Adolescents', Depression, Parental Style, Self-Concept.*

Introduction

The master component of each society and the smallest public unit is the family. As well, the climate of family is the most significant and initial tool that affect the growth of family individuals[(1,2)]. The basic of developing any individual is resting in the family womb; and the family environment as well its atmosphere is the basic for developing and growing the child's personality.

Parenting is sophisticated and multiplex action that encompasses numerous special behaviors as well as it is working autonomously to impact their children outcomes. Parenting contains two major and distinguishing roles as the mothering and fathering[(3)]. Loving, sympathetic, authoritative, legitimate fathering develops the child autonomous, individualistic, and emotional stability as well establishes their positive attitudes and behaviors toward the society. If mother's anticipation is true, having love, and suitable in caring, ascendancy or punishing; the development of child become more gainful, useful and fanciful. While, ideal and exemplary mother expectation, over protection and more soldiers like mother's attitude can be seen as the responsible for the modes of parenting problems [(4)].

At times, self-concept has been defined as an individuality characteristic. Modern researches about personality has been displayed that great five personality

features (extraversion, neuroticism, agreeableness, conscientiousness, and openness) are essence and root characteristics that cannot be changed. While self-concept realized as the biddable and tractable characteristics of person. These researches had seen self-concept as changeable personality characteristics because it can be affected by status, situations, events of life, and environment factors. Therefore, self-concept considered as multidimensional structure and it has been specified that the causative impact of personality on one behavior and attitude can be more probably interpose to some scope by self-concept [5, 6].

There are many studies concluded that there is a reverse relation between self-concept and depression. By another way when self-concept dwindling, the average of depression will be excessed [7]. revealed in their study that depression and self-concept had correlation; as well as they displayed a comparable correlation for another variable like ethnic/racial group, physical look, and sex in their study. Also, they revealed that adolescents with Hispanic ethic had low self-concept and high depression level than other ethnic categories.

The negative feelings about own bodies were higher between Hispanic females adolescent than White and African American and these feelings were shared in increasing the depression symptoms as well decreasing self-concept. Self-concept, depressed mood, and body image have a mutual distinction between emigrant and acculturated Hispanic girls. As the negative feelings among Hispanic females for their bodies' image may be directed to marginalization outcome[8, 9].

Therefore, depression which is the most widespread status of emotional problems is more practiced during adolescence; it can be described by feelings of anxiety, anger, fear, sadness, guilt, disrespect, grief, chagrin confused or troubled thinking [10,11]. Personality features can be explicate as the continual characteristics which can discriminate between persons, and some words that can be used to characterize personality are "passive, " "extrovert, " "outgoing, " and others. On the other hand, personality features or traits refer to how the person can reply to events that is temporary[12].

Depression is utilized as a subscale for determining the clinical and nonclinical citizens of children with the behavior disorders[13].There are many aspects of adolescent's life can be influenced by the presence of depression such as, family and social relationships, self-worth, schoolwork, and decision making. Specially, depression can affect negatively different domains of cognitive function in children and adolescents. Thus, inability to treat depression in adolescents, this can lead to a growing in suicides; as the greatestdecisive predictor for suicide is depression [14].

Significance of the study: One of most important aspect of individual is self-concept which is a key of psychological luxury that build in and of itself. Also, self-concept had been evident to have an effect on various and many of critical wellbeing results and outcomes and serve as an influential cornerstone for developing full of one's potential. Also, it was reported from various studies that many of individual who have low self-concept had negative or high psychological disorders such a fear, anxiety, stress and depression. Thus this study was done to assess parents' styles and its relation to self-concept and depression.

Aim of the study: To assess parental style and its relation to adolescents' self-concept and depression

Research question: Is there a relation between Parental style and adolescents' self-concept and depression?

Subjects and Method

Research design: Descriptive correlational research design was used in this study.

Setting of the study: This study was conducted at selected sample of Minia schools in (Zohra preparatory school and El-Fathpreparatoryschools) at Minia City.

Subjects: A convenient sample of 200 adolescent their ages ranged from 12 to16 yrs. students was recruited in the study. Data collection started from March to May 2017.

Tools of data collection: Three tools were used

Tool one: It contained two parts

First part: Personal data, which covered the following items: age, gender, address, and birth order and family income.

Second part

Measure of Parental Style (MOPS)[15]: This self-assessment tool usedto assess the perceived parenting styles by parents. This tool comprised of 15 items

divided into three styles as: Indifference style contained (6 items), Abuse style contained (5 items)and over control contained (4 items). The sum of thestyle items scores provides the total score for each style. There is no severance of score; the style total score show to which that parental style was dominated by parents.

Self-Concept Clarity Scale [16]: This scale was used by researcher to assess the self-concept of adolescent. This scale contained 12 statements measured by five points likert scale ranged from (1 strongly disagree to 5 strongly agree). The scoring system was as follow: low self-concept when adolescent is less than 20, from 21 to 40 is moderate and high self-concept is from 41 to 60. The scale statements are reversed items except statement number 6 and 11.

Birleson depression scale[17]: This scale was utilized by researchers to determine the depression level among adolescents. It encompassed from 18 statements measured by three point likert scale ranged from (0=never to usually=2). Statements are reversed in 3,5,10,14,15,17and 18.Scoring system was the adolescent who had less than 11= is not depressed; and adolescent who had 12 and more are depressed.

Pilot Study: It was applied on 10% from the study subjects (20 adolescents). Based on the pilot study analysis no modifications were done in the questionnaires. So number of the pilot study was included in the total number of the study sample.

Validity and reliability: The tools were submitted to a panel of five experts in the field of pediatric nursing and psychiatric nursing at Minia and Assuit University to confirm content validity. Reliability of the tools were done and calculated statistically. The reliability of tools was measured by Cronbach's alpha test and was for tool I (0.87), for tool II (0.90)and for tool III (0.89).

Procedure: A review of related literature was done for covering various aspects of the problem using available journals and books to be acquainted with the research problem and to select the appropriate study tools. Official permissions were granted from the director of schools to conduct the study. The researcher selects these two schools because only these schools agree to participate in the study. The researchers went to El-Fath preparatory school every Sunday from 9am to 11 am and take adolescents in lab room then explain the purpose of the study and then fill in the sheet. Regarding Zohraschoole, it's a village affiliated to Minia city, the researcher went to it by bus, the researchers went to Zohra preparatory school every Wednesday from 9am to 11 am, and the aim of the study was explained by the researcher to adolescents for getting their approval prior starting their participation in the study. The data collection was lasted for three months. Their ages were ranged between 12-16 yrs, majority of them in class 3 preparatory school, their number was 200 who agreed to participate in the study.

Statistical Analysis: Subjects' responses to each category were analyzed, categorized and coded by investigators then tabulated separately by using the statistical package for social science (SPSS) version 20. Descriptive statistics were calculated as frequency, percentage, mean, stander deviation. T-test and ANOVA test and Pearson correlation were also used among studied values. Probability (p-value) less than 0.05 is considered significant and less than 0.001 is considered highly significant.

Results

Table (1): Distribution of the studied adolescent according to socio-demographic data, shows that, more than two thirds of the study adolescents (68.5 %) aged between 14-16year, with mean age (13.73 ± 0.95). Regarding gender, about three quarter (73 %) of adolescents were females and (27 %) of them were male. 50.5% of adolescences live in urban area. 50% of adolescences have low family income. Also, it reveals that, the highest percentage of adolescent (36.5 %) was ranked as second child in their families.

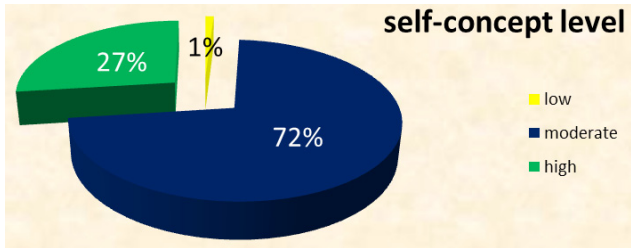

Figure 1: Distribution of Studied adolescent According their self-Concept levels (n= 200).

Figure (1) shows that most of adolescent 72 % had moderate self–concept level and more than on quarter 27% had high self-concept level.

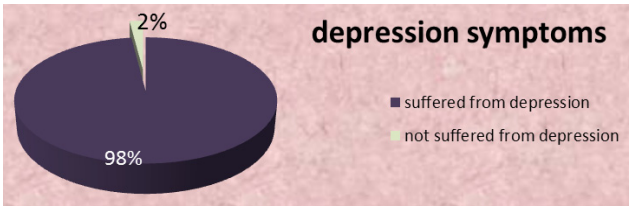

Figure 2: Distribution of Studied adolescent According to Presences of depression symptoms (n= 200)

Figure (2) clarifies that the vast majority 98 % of studied adolescent suffered from depression symptoms, but only 2% of them not suffered from depression.

As regard mean Score differences of adolescents' Parent style, Self-concept and Depression, According to gender, result shows that, there was statistically significant difference between total parent style and adolescent gender (t=0.96, P=0.03).

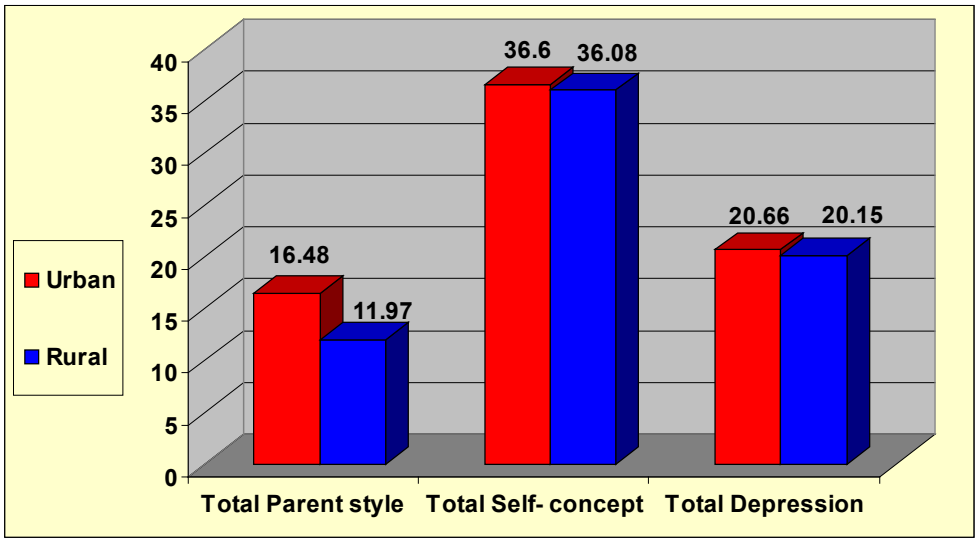

Figure 3) Mean Scores differences of adolescents' Parent style, Self-concept and Depression, According to place of residence (n=200)

Figure (3) shows that, there was statistically significant difference between total parent style as well as total self-concept with place of residence (t=5.01, p=0.00** and t=0.66, p=0.02**) respectively.

Table 1: Relation between adolescents' gender and both depression and self-concept levels (n=200).

Tested Items	Total	Male		Female		X^2 P-value
		No.	%	No.	%	
Level of depression • Nnormal non-depressed "less than 11"	5	1	0.5	3	1.5	0.96 0.00**
• Ddepressed "12-and more"	195	53	26.5	143	71.5	
Level of self-concept • Llow "≥ 20"	1	1	0.5	0	0.0	2.76 0.25
• Mmoderate "21-40"	145	38	19	107	53.5	
• Hhigh "41-60"	54	15	7.5	39	19.5	

Table 1: Clarifies that there were 71.5 % of female adolescents suffering from depression compared with 26.5% of male adolescents with statistically significant difference between the two groups (X^2 = 0.96/p-value 0.00). Additionally, 53.5 % of female adolescents had moderate level of self-concept and no one had high level; compared with 19% had moderate self-concept level and 7.5% had high level among male adolescent with not significant statistically difference between the two groups.

Also, results display that the highest mean scores "16.25 ± 8.09" of total parent style score and its'

domains; indifference parent style and over control parent style "6.00 ± 3.74" and "7.00 ± 2.58" were reported by adolescent's who don't have depression symptoms. Also, it can be noted that the highest mean score was "4.41 ± 3.21" of abuse parent style reported by adolescent's who had depression symptoms.

Table (2): Correlation between Adolescents' Perceived Parent Style and both of self-concept and depression

Variables		Total Parent Style	parent style domain 1	parent style domain 2	parent style domain 3	Total depression	Total Self concept
Total Parent Style	R P-value	1					
parent style domain 1	R P-value	0.855** 0.000	1 -				
parent style domain 2	R P-value	0.842** 0.000	0.610** 0.000	1 -	.		
parent style domain 3	R P-value	0.436** 0.00	0.098 0.166	0.121 .074	1 -		
Total depression	R P-value	-0.146-* 0.039	-0.166 0.019	-0.074 0.300	-0.069 0.332	1 -	
Total Self concept	R P-value	-0.174-* 0.014	-0.123- 0.083	-0.195- **0.006	-0.047- 0.509	0.296** 0.00	1 -

Table 2: Shows that there were statistically significant negative correlations between self–concept and total parent style and its sub scale of abuse parent style (R=-0.17, p-value 0.01) & (R=-0.19, p-value 0.00) respectively. Additionally there was a statistically significant negative correlation between depression score and total parent style & Parent Indifference style (R=-0.14, p-value 0.03) & (R=-0.16 p-value 0.00) respectively.

Discussion

The current study revealed that there was more than two thirds (68.5 %) of the adolescents aged between 14-16 year, while there was 31.5 % of them had age between 12-< 14 year, with mean age of 13.73 ± 0.95. Regarding gender, there was 73 % of adolescents were female and 27 % of them were male. Also data revealed that, the highest percentage of adolescent 36.5 % ranked the second child in their families.

The current study displayed that most of adolescent 72 % had moderate self-concept and more than a quarter 27 % had high self–concept. The vast majority 98 % of studied adolescent suffered from symptoms of depression, but there only 2% had no experiences or symptoms of depression according to Birleson depression scale. As the adolescent who has low level of self-concept, was in risk to be depressed. This can be explained as result of the strong relation between self-concept and depression.

Actually when there is a support provided from parents and peers to the adolescents, their self-concept will be enhanced and maintained. In the same respect, [18]displayed that there 56% of their studied adolescents had an average level of self-concept and about third 30.75% had good level of self-concept, 8.25% had poor self-concept, and 0.75% had very poor self-concept, while only 4.25 had very good level of self-concept. Thus, it can be consummated that low level of self-concept is linked to the high level of depression; in other words, when the level of self-concept diminished, the level of depression rates excessed. Also, [5]stated in their research study among 77 adolescents, that there was strong negative correlation founded between depression level and self-concept level.

Moreover, in the current study it was revealed that there were statistical significant differences between male and female adolescents in regarding to the perceived parent style. It was noted that the highest mean scores were for the indifference and abusive parent style "4.22 ± 3.20"and "4.60 ± 2.99" respectively in favor to female adolescent. While, the highest mean score "6.59 ± 2.53" of over control parent style was reported by male adolescent. This result was in agreement with the findings of[19] who displayed that there are two parent

styles as indifference and abusive had significant relation with level of depression among adolescents. Also, the result advocates the hypothesis about the significant relation between parent styles and level of depression in adolescents.

It also observed that there were 71.5 % of female adolescents had high level of depression compared with 26.5% of male adolescent; indeed 53.5 % of female adolescent had moderate self-concept. This result was congruent with the study result of [12]revealed that, the most commonly psychological disturbance among adolescent was depression, in which it was appear that up to one of each three girls and one out of each five boys can had minimally one episode of depression disorder when reach the age of eighteen.

In the same context [20]supposed that the adolescents with high depression level had self-concept with negative view, which can affect negatively on their cognitive capabilities and had an effect on academic ability. Also, this result was consistent with the findings of [21] found that the level of depression is higher and raised more among female (35%) than male (23.1%) adolescent. As well as it was reported that the incidence of depression symptoms is higher in women than in men[22, 23]. Also, in 2010 the annual global incidence of depression mentioned that depression was 5.5% in female and 3.2% in male[24].

The current study also revealed that the highest mean score was "4.41 ± 3.21" for the abuse parent style which was reported by adolescent's who had depression symptoms. [25]Reported that; adolescents with manifestation of depression had the higher mean score for the abuse parent style. Also, [26]mentioned that the abuse parent style was the most common style reported among adolescents who had symptoms of depression.

Moreover, it was reported from different researches that the mostly effective aspect that influence on the establishment and enhancing personality of adolescent was the parents' activities in parenting. Style of parent's parenting can determine the prosperity or dud of the adolescent. The most important issues in parenting style were; the amount of emotion, softness and smoothness that children had; also, the amount of agreement, conformity and monitoring or dominance that utilized by parents[27].

The current study also revealed that, there were statistically significant negative correlations between self–concept and total parent style & its subscale of abuse parent style. As when abusive behavior increases as a parent style, the self-concept of adolescents decreases consequently. The negative self-concept among adolescent can lead them to do not good during their life. Commonly, they not successes in their life as they often do problems and turmoil in their life; as well as they failed to manage effectively their life.

Therefore, the persons who had negative or low self-concept can absolutely be unsatisfied about them in everything as well they cannot be happy about the surrounding. Further[28] agreed that one who has self-concept in negative manner can be easily and permanently gain criticism from the parents, teachers, peers, and friends. This can help adolescent to be further unfavorable and passive, as well they don't realize how to have relations with people who live with; in which this can influenced and effect on them to be more less self-confidence and timid.

Additionally, there were statistically significant positive correlations between depression score and total parent style & parent indifference style. This result was in congruence with the finding of[29] who pointed that, there was negative relation with statistically significance between the parenting style and adolescents' self-concept in favor to indifference style.

Indeed, correlation between adolescents' self-concept and parenting style did not show any statistically significant relations with all the three dimensions. This was not congruence with[27] mentioned that, parenting styles had statistically significant correlation with depression. As there were two styles of parenting had significance correlation; and the parenting style of authoritarian was the mostone had positive correlation, while parenting style of permissive was correlated negatively with depression.

It also, found that there was a statistically significant relation between total depression and total self-concept. This finding was in accordance with the finding of[12] displayed that, there was a strong relation with significance between self-concept and depression.

Conclusion

The parents' style has crucial role in shaping their children behaviors, attitudes and outcomes. Therefore, when the abusive behavior increased due to parent style the self-concept of adolescents decreases consequently

Recommendations: According to the findings of the present study, the relation between depression and parenting style is actually significant. Thus, it is recommended that the training of parents for parenthood can influence their children self-concept which has adverse effect on depression. As well there should be suitable attention given to adolescents, as when they have the necessary assistance and proper feelings and emotions they can be more self-concept and be less depressed.

Source of Funding: Self-funding

Conflict of Interest: Nil

Ethical Clearance: An official permission was obtained from the directors of the two schools after explaining the nature of the work. Also, an official permission was obtained from the ethical committee in faculty after explaining the nature of the work, and then the study aim was explored for every interviewed adolescent (males & females). An ethical right to agree or refuse participation in the study was granted to the adolescent. They informed that their information will kept confidential and used only for the purpose of the study and there was no harm for their participation.

Leader Empowering Behavior and Faculty Stress and their Relationship to Job Satisfaction among Faculty Staff

Safaa Mohammed Zaki[1], Rasha Mohammed Nagib[2], Ebtsam Ahmed Mohammed[2]

[1]Lecturer of Psychiatric and Mental Health Nursing, [2]Lecturer of Nursing Administration, Faculty of Nursing, Minia University, Egypt

Abstract

Background: Leader empowering behaviors have been shown to influence staff work engagement because social identification with managers positively influenced the staff's level of work engagement and satisfaction.

Aim of the study: To assess leader empowerment behavior and faculty stress and their relationship to job satisfaction among faculty staff. Subject and method: Correlational comparative research design was done to fulfill the aim of this study.

Subject: A sample was selected conveniently, which meeting the inclusion criteria. Setting: The study was conducted at both faculty of nursing and faculty of early childhood in Minia university. Tools of data collection: 1st personal data questionnaire 2nd: The Leader Empowering Behaviors Scale (LEBS)(3). 3rd: The Faculty Stress Scale (8), 4th: Job Satisfaction Scale (NSOPF) (10). Results: there was a statistically significant difference in the faculty of nursing staff regarding the dimension of "Creating meaningful of work." There was a negative correlation between both leadership empowering behavior and faculty stress and both faculty stress and job satisfaction.

Conclusion: It can be concluded that, when leader enabling behavior is increasing, the faculty stress will decrease so; the level of job satisfaction will increase.

Recommendation: It is recommended that it is essential to continue leader empowerment for faculty staff to achieve the optimal level of goal achievement and decrease faculty stress level which in return increases job satisfaction level among faculty staff.

Keywords: *Leader Empowering Behavior, Faculty Stress, job satisfaction, faculty staff.*

Introduction

Empowerment is "a tool to encourage workers to think for themselves about the requirements of the job and to move beyond blindly doing what they are told." Empowering employees refers to helping the staff to work best to achieve organizational goals, which requires an understanding of their needs. Leaders' use of allowing behaviors is essential in the development and retention of a capable work team. Effective leader empowering practices make employees feel empowered, autonomous, motivated, and rewarded, and yields a sense of fairness and community in the workplace. Empowered employees are more likely to self-manage, take greater responsibility within their organization, and work more effectively(1).

Leaders' use of empowering behaviors includes "enhancing the meaningfulness of work, fostering participation in decision-making, facilitating goal accomplishment, expressing confidence in high performance and providing autonomy from bureaucratic constraints." A systematic literature review by(1) identified leaders' behaviors that affected employees' motivation and performance. The authors noted that nurses were empowered to perform when they had autonomy for decision-making when effective and robust communications to build trusting relationships where available, when reasonable and accessible resources were available, and when their leaders used effective leadership behaviors such as mentoring and coaching. Also,(2)noted that providing autonomy and expressing

confidence in staff performance caused employees to feel more empowered to work efficiently.

Stress is defined as a state of mental and physical; or organism›s response and a great worry towards the problematic situation or environmental demands[3]. Stress is basically focused on two significant factors which are stressors in terms of environmental conditions and on how the person reacts and response towards the challenging events. Stress is a 'global epidemic' in this decade where there are more than 50% of the population in many countries who were reported to have anxiety related to work[4]. Academician was recorded as a stressful job compared to the accident and emergency (A & E) staff who deals with a substantial amount of ongoing occupational stress. [5] reported that the prevalence of job stress among lecturers in 2 universities in Malaysia as 17.5% and 23.3%. The stressful conditions increase their distress causes low productivity, which leads to a negative impact on their family's life, negative behavior and chronic health problems.

Job satisfaction is ''an overall affective orientation on the part of individuals toward work roles which they are presently occupying'' [6]. Job satisfaction has a deep knowledge base and theoretical foundation. There is a multitude of variables that have been tested about job satisfaction; however, many of the variables may be explained by Herzberg's Two Factor Theory of job satisfaction[7]. The theory asserts that intrinsic factors ('motivators') and extrinsic factors ('hygiene's') affect job satisfaction.

Significance of the Study: Job satisfaction is a multifaceted concept associated with many factors such as working conditions, organizational support, leadership styles, leader empowering behaviors (LEB), structural empowerment (SE), and psychological empowerment (PE). The leaders' use of practices that allow staff contributes to work effectiveness by enhancing employees' performance. Leader enabling behaviors directly affect the ability of the team to accomplish organizational goals, and this enhances organizational effectiveness. The use of leader empowering practices in faculty is essential since it creates supportive working environments where staff can perform best. This, in turn, can lead to increased job satisfaction. [2] So, it is crucial to assess leader empowerment behavior and faculty stress and their relationship to job satisfaction among faculty staff.

Aim of the Study: To assess leader empowerment behavior and faculty stress and their relationship to job satisfaction among faculty staff

Subjects and Method

Research Design: The correlational comparative research design was done to fulfill the aim of this study.

Sample: A sample was selected conveniently, which meet the inclusion criteria

Setting: The study was conducted at both faculty of nursing and faculty of early childhood in Minia university.

Inclusion Criteria:

Doctorate degree

Assistant professors

Professors

Tools for data collection:

Four instruments were used for collecting data for this study

1st: personal data questionnaire which included gender, age, experience in the present job and specialty

2nd: The Leader Empowering Behaviors Scale (LEBS)[3]: it was used to assess staff perceptions of their leaders' use of empowering behaviors. This questionnaire consists of 27 items covering the five dimensions of Creating Meaningfulness of Work (6 items), Encouraging Participation in Decision Making (5 items), Expressing Confidence in High Performance (6 items), Facilitating Goal Accomplishment (5 items), and Fostering Autonomy from Bureaucratic Constraints (6 items). Responses were measured on a 5-point Likert scale ranging from 1(strongly disagree) to 5(strongly agree). With the system, the score ranged from 27-135. Higher mean scores on the LEBS indicate higher levels of leader empowering behaviors. Cronbach's alpha 0.97 found for the total scale.

3rd: The Faculty Stress Scale: it was developed by[8]. The index is based on both items from the Administrative Stress Index Koch,[9] and items suggested via stress logs kept by twenty faculties for a week. The resulting 45-item FSI examines five dimensions. The instrument reflects five dimensions: reward and

recognition, time constraints, departmental influence, professional/identity, and student interaction. A sample item for each aspect is: "Indicate to what extent each is a source of pressure": Scoring for the instrument was on a five-point scale: 1= rarely or never stressful, 2= occasionally stressful, 3= sometimes, 4= often stressful, 5= always or frequently stressful. Cronbach's alpha is reported as 0.83.

4th: Job Satisfaction Scale (NSOPF)[10]. It consists of eight items rated on a four-point scale. The participant is asked to rate their level of job satisfaction on eight subjects, including salary, the authority to make decisions about content and method in instructional activities and overall job satisfaction with score 1= very dissatisfied, 2= dissatisfied, 3= satisfied and 4= very satisfied. The total score range that a participant could obtain is eight (8 items * 1 score on each) to 32 (8 items * 4 ratings on each). Cronbach's alpha was 0.85 for this scale.

Tools validity and Reliability

Validity: Study tools content validity was established by a panel of five experts, two professors of the psychiatric department and three professors of the Administration department Faculty of Nursing, Minia University. Each expert on the board was asked to examine the instrument for content, coverage clarity, wording, length, format, and overall appearance.

Reliability: The reliability test was estimated using Cronbach's Alpha Coefficient for the three tools which indicate that questionnaires were highly reliable. Test results for the questionnaires The Leader Empowering Behaviors Scale, The Faculty Stress scale, and Job Satisfaction Scale were (0.86, 0.79, and 0.84) respectively.

Pilot study: The pilot study was carried out on (10%) of the current sample to ensure the clarity and applicability of the items and to estimate the time needed to complete the questionnaire. Based on the pilot study analysis, no modifications were made in the questionnaires. So the number of the pilot study was included in the total number of the study sample.

Procedure:

- Official permission was obtained from the dean of the two faculties after explaining the nature of the work.
- The researcher explained the aim, nature, and significance of the study for every participant to get better cooperation during the implementation phase of the research
- Oral consent was obtained from each participant in the study after explaining the purpose of the study
- The time spent to fill the questionnaires ranged from 20 to 30 minutes for each participant.
- After completion of filling the questionnaire sheet, the researcher collected them. Data were collected from September to November 2018.

Statistical design: Data entry and statistical analysis were done using computer software, the statistical package for social studies (SPSS), version 21. Suitable descriptive statistics were used, such as frequencies and percentages for qualitative variables, means, and standards deviations for quantitative variables. The correlation coefficient (r) test was used to estimate the closeness association between variables.

Results

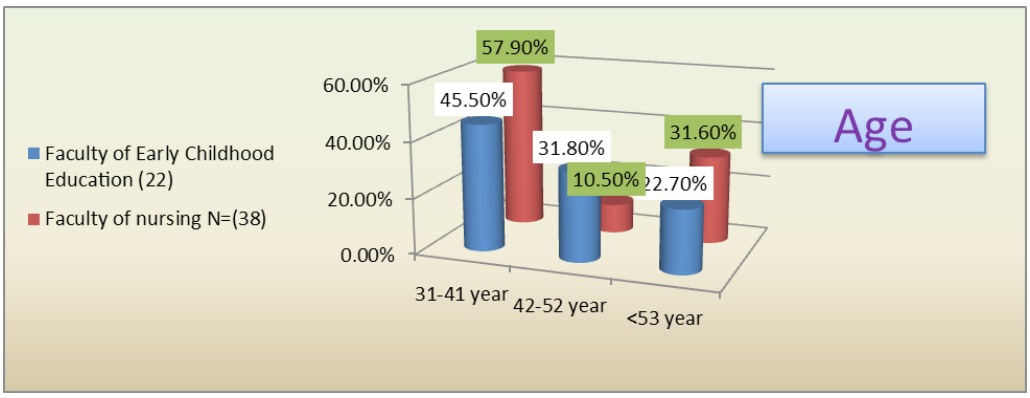

Figure (1): Distribution of the faculty staff members according to their personal data characteristics (n=60).

Figure (1) illustrates that more than half (57.9%) of faculty nursing staff their ages were ranging from (31-41) years old, while less than half (45.5%) of faculty of early childhood education staff their ages were ranging from (31-41) years old.

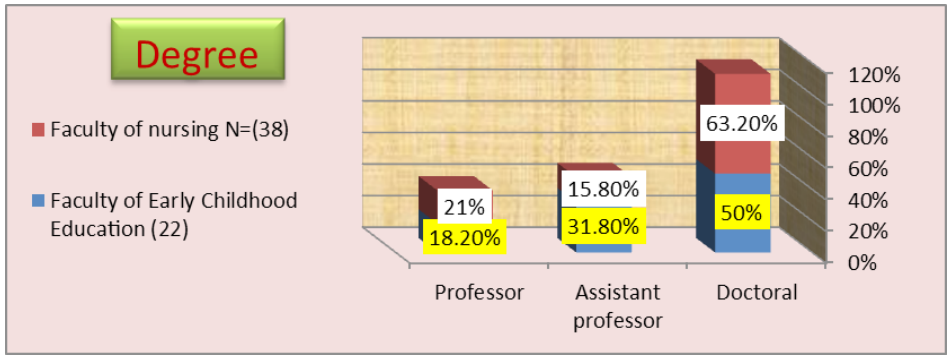

Figure (2) the distribution of the faculty staff members according to their job degree (n=60).

Figure (2) reveals that remarkable percent (63.2% and 50%) of both faculties of nursing and early childhood education staff were lecturer, followed by (31.8%) of early childhood education staff were assistant professor, while faculty of nursing had just only (15.8%) were associate professor and (21% and 18.2%) of both faculties were professors

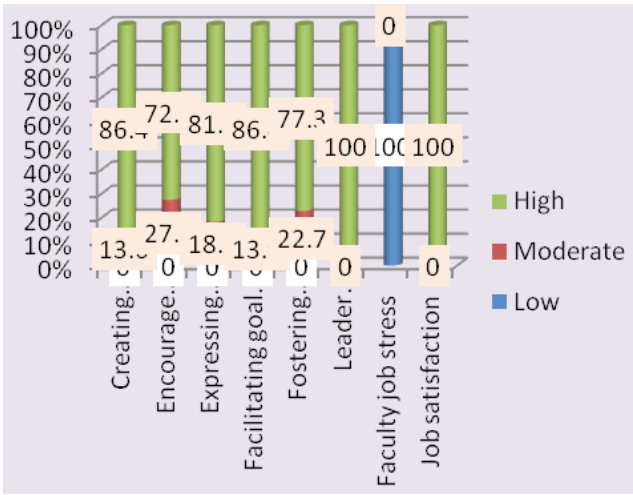

Figure (3) frequency distribution regarding the opinion of the Faculty of Early Childhood staff members concerning the variables (N=22)

Figure (3) demonstrates that, the faculty of Early Childhood staff members had the highest percentage regarding leader empowering behavior (100%), also all faculty staff members had percentage (100%) regarding job satisfaction highly.

Figure (4) frequency distribution regarding the opinion of the Faculty of Nursing staff members concerning the variables (N=38)

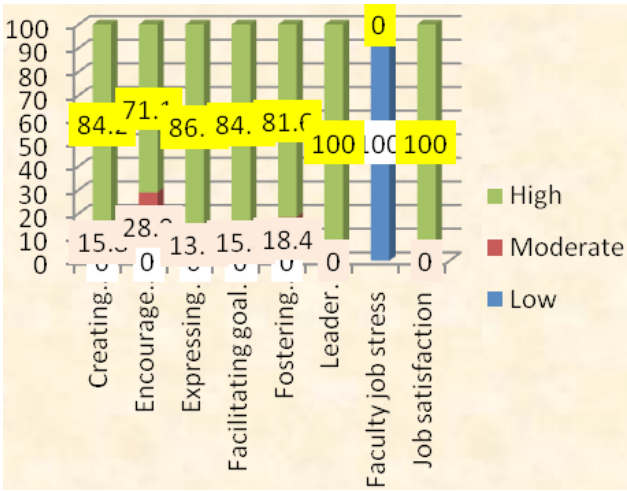

Figure (4)illustrates that the faculty of Nursing staff members had the highest percentage regarding leader empowering behavior (100%), also all faculty staff members had percentage (100%) regarding job satisfaction highly. Also, faculty staff members had the lowest percentage as regards to faculty job stress

Table (1) Difference between Faculty of early childhood and Faculty of Nursing about the variables (N=60)

Dimensions	Faculty of Early Childhood N= (22)	Faculty of Nursing N=(38)	T	P
	Mean±SD	Mean±SD		
Creating meaningful work	24.4 ±3.12	24.6±3.21	0.252	0.802
Encourage participative in decision making	21.23±3.05	21.2±3.06	0.020	0.984
Expressing confidence in high performance	24.2±2.93	24.4±2.76	0.281	0.780
Facilitating goal accomplishment	22.3±2.73	22.1±2.78	0.252	0.802
Fostering autonomy form buracturatic constraints	22.1±3.07	22.4±2.86	0.443	0.659
Leader empowering behavior	114.1±6.70	114.7±6.24	0.365	0.717
Faculty job stress	54.9±12.5	54.5±11.8	0.142	0.887
Job satisfaction	26.5±3.64	26.2±3.70	0.221	0.826

Table (1), shows that there was no statistically significant difference for all dimensions of leader empowerment behavior, faculty job stress, and job satisfaction for both Faculties.

Also. Result demonstrates that there was a statistically significant difference as regards to facilitating goal accomplishment and expressing confidence in high performance" p =.012* in the faculty of early childhood staff and job degree.

Table (2) Correlation between leader empowering behavior, faculty stress and job satisfaction (60)

Variable	Leader empowering behavior	Faculty stress	Job satisfaction
Leader empowering behavior	1	.287- .153	.282 .164
Faculty stress	-	1	.290- .887
Job satisfaction	-	-	1

Table (2) illustrates that there was a negative correlation between leadership empowering behavior and faculty stress and both faculty stress and job satisfaction. There was a positive correlation between leader empowering behavior and job satisfaction.

Discussion

Regarding to the distribution of the faculty staff members according to their personal data characteristics, the current study revealed that more than half of faculty nursing staff their ages were ranging from (31-41) years old, while less than half of faculty of early childhood education staff their ages were ranging from (31-41) years old, a remarkable percent of both faculty of nursing and early childhood education staff were lecturers respectively, followed by (31.8%) of early childhood education staff were assistant professors, while faculty of nursing had just only (15.8%) of assistant professors, also (21% and 18.2%) of both faculties were professors.

As regards to opinions of both faculties "Faculty of Early Childhood, and faculty of nursing" staff members in relation the studied variables, it was observed that all of both faculties had the highest percentage of leader empowering behavior level and job satisfaction. Indeed, both faculties had the lowest rate of faculty job stress levels. From the researcher view, this result might be due to support from their top-level management (deans or managers) of both faculties (e.g. helps faculty staff members to identify and understand the mission and vision of department and their organization, helping them understand the purpose of what they do at work, encouraging staff members to participate in decision making through using of democratic leadership style.

This result is supported by [11] who stated that leaders are responsible for the organization's moral climate and that corporate values flow from leader beliefs and moral character. The leader must display moral strength, honesty, courage, and integrity in all interactions with others. The faculty members should also consider the university culture in which he or she is working. The leader should respect different cultures and be a positive influence on others. Cultural differences require different leadership styles for success. [12], [13]stated that ethical leadership encompasses the leader's moral character, the legitimacy of the ethical values the leader proclaims, and the morality of the organizational mission and purpose.

The current study revealed that there were no statistically significant differences for all dimensions of all variables among both faculties. This might be due to the Faculty of Early Childhood have got academic accreditation and the Faculty of Nursing also try to finishing the process of accreditation, so both faculties work hardly with soul of cooperation and goal achievement desire through support from their top-level management, empower working condition of the faculty staff members, and treat fairy with them which lead to faculty staff members of both faculties more satisfied and less stress.

This result is supported by[8] who asserted that effective leaders should possess clinical/technical, organizational, human relations, and critical thinking competencies that motivate and contribute to the quality goal of their organizations.[14] reported that an academic leader's style of leadership impacts faculty job satisfaction. Effective leaders can lead to better productivity and better outcomes for faculty.[15] stated that faculties had expressed decreased organizational commitment in the absence of good leadership. Successful leaders have a significant positive impact on the retention of faculty. Indeed,educational leaders have a moral responsibility to treat everyone fairly, respect individual needs, maintain trust, display integrity in all dealings, and create a class culture that facilitates growth and development for all staff. Honesty and integrity helps build the confidence needed to facilitate the respectful relationship that creates a quality learning environment

Also, [16] stated that effective management of academic dean leadership styles might increase higher education student success through faculty improvement. On the same line [17] stated that in dynamic working environments, employee empowerment could give organizations advantages in acquiring and sustaining competitive positions in their markets if it results in favorable employee attitudes, motivation, and behaviors.

In the current study, it was observed that there was statistically significant difference between Faculty of Nursing staff as regarding to dimension of «Creating meaningful of work «. Also, they had a great experience of the faculty members at the faculty of nursing and cooperation of others helps them to improve work. This result is consistent with the outcome of [18]who reported that staff members working with empowering leaders are more likely to have autonomy and positive work experiences, and thereby they may feel less burnout and tension or stress from their job as well as possess less cynical attitudes.

On the same context, [19] stated that subordinates who experienced empowering leadership reported higher levels of job satisfaction, probably because empowering leaders to emphasize their discretion in setting goals and determining work procedures, which help employees, understand and perform whole pieces of work and eventually makes it possible for subordinates to derive meaning from the job. Also, [20] revealed that leader's empowering behavior played a significant role in enhancing employee's work engagement and influenced work meaningfulness. Empowering leaders created more meaningful jobs by allowing employees to be responsible for their tasks through the autonomy given to them.

The current study shows that there was a statistically significant difference p =.015* as regards to facilitating goal accomplishment and expressing confidence in high performance" p =.012* in the faculty of early childhood staff and staff job degree respectively. This result could be attributed to, whatever the job degree of the team, all of them able to facilitating goal accomplishment and expressing confidence in high performance. This finding was supported by [21-22-23] suggested that consequences of empowering leadership on performance especially facilitating goal accomplishment and expressing confidence in high performance include creativity and innovative behaviors, in-role performance, contextual performance, and with-drawl behaviors. On the same line, [24, 25] found that individuals who possess a high level of job satisfaction tend to be more productive and dependable and are critical parts of high-performing organizations and their level of job satisfaction was increased.

Finally, the results of the present study illustrated that there was a negative correlation between (both leadership empowering behavior and faculty stress) for (both faculty stress and job satisfaction). This might be due to increased support from deans of both faculties, deans play essential role in organizational achievement which helps staff members feel more empowered, they become actively engaged in their jobs, feel more satisfied and less stressful, This result was supported by [26] who stated that there were negative relationship between servant leadership, job stress, and job satisfaction.

In addition, the present study also found that there

was a positive correlation between leader empowering behavior and job satisfaction. This could be interpreted as when managers support their staff in any agency, the team will achieve a high level of job satisfaction. This agreed with the study of [27]who showed that positive relationships between the five dimensions of leadership empowerment behavior and overall job satisfaction. Also,[28]stated that satisfied employees play a crucial role in organizational success. Higher job satisfaction may result in the more top quality of instruction, increased productivity, and more time spent with students. Conversely, lower faculty satisfaction and engagement may result in lower student performance, decreased student retention, and lower graduation rates[29,30].

Conclusion

Leader empowering behavior has a direct positive effect on decrease faculty stress and increase job satisfaction; additionally; enhancing leadership practices and educational leaders may be able to raise the job satisfaction levels among faculty members in community colleges. Moreover, when the leader empowering behavior is increasing, the faculty stress will decrease so; the level of job satisfaction will increase.

Recommendation: It is recommended that it is essential to continue leader empowerment for faculty staff to achieve the optimal level of goal achievement and decrease faculty stress level this in return increases job satisfaction level among both faculty staff.

Diagnostic Study and Some Pathological Aspects of Parasites Associated with Appendicitis in Al-Najaf Al-Ashraf Governorate

Sahira Ayed A. Al-Musawi

Medical Lab. Analysis Department, Kufa Technical Institute, Al-Furat Al-Awsat Technical University, Iraq

Abstract

The study is intended to investigate the parasites that existenec and accompany appendicitis after its removal in the surgical department at al-Sadr Educational hospital and Al-Hakim General Hospital in Al-Najaf Al-Ashraf Governorate for the period from October 2017 to April 2018. The results of the current study of the appendectomy samples showed that 45 parasite samples were infected with 128 parasites (35.15%), the highest percentage of enterobius vermicularis (28.8%), and Ascaris lumbricoidis (22.2%). Entamoeba histolytica (17.7%), Entamoeba coli (13.5%), Giardia lamblia (11.3%), Cryptosporidium (6.5%), and male infection The parasite appendicitis was 55.6%, while the female infection rate was 44.4% 6 years had the highest incidence of parasitic appendicitis (33.3%), and the lowest rate of infection was in the 65-56 age group (4.4%).

Keywords: *parasites,inflammation,appendicitis, Al-Najaf Al-Ashraf, worms.*

Introduction

Acute appendicitis is one of the most common cases of invasive surgical surgeries worldwide[1]. The appendix is known It is a tubular structure or a small, irregular cavity. There is a lot of lymph nodes in the wall, which is like a large intestine. Of four primary serological layers (serosa) Outside and then the muscle layer (muscularis) and under mucous (submucosa) And to the mucous layer inside (mucosa), The Appendix differs from the large intestine by containing fewer and fewer glands and the hollow walls of the coliform strips, as well as the internal tissue content of the appendix is not as new as the other histological content of the digestive tract. In addition to being a closed cavity, it is a suitable place for the growth and multiplication of different types of pathogens Including parasites, and for these and other reasons they are often susceptible to inflammation that may develop to a degree leading to inflammation of the abdominal cavity [23]Considered a protozoa And worms are a cause of many symptoms and disorders such as vomiting, abdominal pain, diarrhea, intestinal obstruction, rectal rectal inflammation, appendicitis and intestinal ulcers [45]**.** the presence of intestinal parasites in the appendicitis cavity and subsequent activity may cause in some cases symptoms of appendicitis without infection by[6], I pointed out a lot of Studies have shown a close relationship between appendicitis and the presence of types of parasites in them such as ***Ascaris lambricoides*** and ***Enterobius vermicularis*** **and Schistosoma spp and Taenia spp**[7]

Materials and Method

Collection of samples: Was collected 128 Of appendicotomy samples after resection in the surgical section of Al Sadr Teaching Hospital and Al Hakim General Hospital In the province of Al-Najaf Al-Ashraf Governorate for the period of October 2017 Until April 2018, And the samples were placed in special containers containing NaCl 0.9% Until diagnosis.

Examination of samples: The appendectomy was performed longitudinal and was visually examined using a magnifying hand lens to diagnose and observe mature worms in the appendage cavity. The samples

were then examined in several ways to identify the types of parasites present and their stages. precipitation And Direct smear method And the method of Floatation According to **[9,10]** Data on the sex and age of patients were recorded.

Results

Numbers and percentage of parasites that cause appendicitis: The results of the current study of the appendectomy samples showed that 45 parasite samples of 128 samples were infected with 35.15%. The highest incidence of *Ebterobius vermicularis* was 28.8%, while *Ascaris lumbricoidis* was 22.2%, *Entamoeba histolytica* was 17.7%, *Entamoeba coli* was 13.5%, *Giardia lamblia* was 11.3*%, Cryptosporidium* was 6.5%, as shown in Table (1).

Table No. 1: Numbers and proportions of parasites that cause appendicitis.

Type of parasite	Number of injured	Percentage
Enterobius vermicularis	13	28.8
Ascaris l umbricoidis	10	22.2
Entamoeba histolytica	8	17.7
Entamoeba coli	6	13.5
Giardia lamblia	5	11.3
Cryptosporidium	3	6.5
Total	**45**	**100%**

Relationship of appendicitis with parasites by age and sex: The results of the current study showed that the incidence of male appendicitis was parasitic 55.6%, While the percentage of infection in females 44.4%, And recorded age group 45-36 The highest incidence of parasitic appendicitis was 33.3% The lowest incidence was in the age group 65-56 year it was 4.4%, as shown in table (2).

Table (2): Relationship between parasitic appendicitis, age and sex

Age categories	Sex	Samples infected		Total infected samples	Per-centage
		The number	%		
15-10	Female	1	2.2	4	8.8%
	Male	3	6.6		
25-16	Female	4	8.8	7	15.4%
	Male	3	6.6		
35-26	Female	5	11.1	10	22.2%
	Male	5	11.1		
45-36	Female	6	13.3	15	33.3%
	Male	9	20		
55-46	Female	4	8.8	7	15.4%
	Male	3	6.6		
65-56	Female	0	0	2	4.4%
	Male	2	4.4		
Total	Female	20	44.4%	45	100%
	Male	25	55.5%		

Discussion

Results of the current study showed that the ratio of 35.15 % Of appendicitis is caused by a parasite, and this result is consistent with some studies, where he noted [8] That the percentage of renal parasites in cases of appendicitis reached 64%, As consistent with the results a study [9] Which showed rates of injury of 39.7% Samples of excised, recorded [10] Proportion of its approach to infection with parasites to study samples reaching 34.8%, While the results of the current study did not agree with other studies such as the study [11] As it recorded a lower percentage 16.2%, As well as record [12] Percentage of total injury hit 8%, While recording [13] The highest injury rate reached 79%.Although parasites are present in the tapeworm tissue, this does not mean that the cause of the appendicitis is always due to the effect of parasites. It is common knowledge that people with appendicitis mayshow symptoms only after parasites enter the waste into the appendix [14],However, to discharge the role of parasites in the incidence of infection, however, should be treated with parasites in excess ofinjuries appendicitis confirmed the parasite after surgery, in addition to a diagnosis of parasites of the family and those around the grave who are directly with him in contact, and should pay attention to personal hygiene and health care For people working in food factories and restaurants to reduce the spread of parasites as well as attention to water sanitation plants and the provision of safe drinking water, these factors help to reduce rates of appendicitis caused by parasites [14] Poor economic and social conditions such as poverty, low drinking water supply, environmental and climatic conditions such as high temperatures and population density, as well as the biological and mechanical resistance to phylogenetic growth are all factors contributing to the transition and survival ofprotozoa And intestinal worms in the environment, and spread in different age groups and in

both sexes, [15]The record in the twentieth century atheist and high injury rates for appendicitis in industrialized countries in Asia, South America andthe Middle East, compared with Western countries because of different environmental factors and exposure to injury [16].

The current study showed that the incidence of the most common parasitic worm was *E.vermicularis* this result is in agreement with other studies [17] Bowel injury *E.* The most common vermicularis in all parts of the world between the parasitic worms injuries [18], it should be noted that the eradication of APPENDICITIS does not necessarily mean appendicitis syndrome, because there is ambiguity and symptoms associated with some of the situations that could lead to an error in the diagnosis. Therefore, there must be increased vigilance in identifying possible cases of APPENDICITIS, especially the very young patients and adults because they have a high rate of complications which overlap with symptoms of APPENDICITIS [19].

It may be due to the difference in the rates of infection between males and females to the nature of community life where the presence of males outside the home and thus exposure to various types of microbes, including parasites, as well as eating fast food, which are often the cause of various types of injuries.

The results of the present study showed that the age group with the highest incidence is 36-45 Year where it reached 33.3% Of the total infection rate, while the age group 56-65 Year is the least injury where it reached 4.4%, And this result corresponds to its findings [2], In his clinical, clinical and pathological study of acute appendicitis cases in Babel governorate where the incidence rate was in the age group 40-31Year 34.3% The highest rate of infection among the total infection rates for the other age groups, and is not consistent with the results of the study reached [14] Where the age group most affected in their studies are 20-35 Year.

Conclution

It is concluded to Diagnosis of parasitic infections in appendix samples and their relationship with appendicitis surgically removed in Al-Najaf Al-Ashraf Governorate As well as to studyof some pathological variables related to infection rates such as age and sex of the infected.

Supporting Factors that Influence of Mental Health Cadres in Implementing the Role in Wonokromo Village Surabaya

Sahriana[1], Merryana Adriani[2], Hanik Endang Nihayati[3]

[1]Magister of Nursing, Faculty of Nursing, [2]Faculty of Public Health, [3]Faculty of Nursing, Airlangga University Surabaya

Abstract

Mental health cadres have an important position in public health programs because cadres as part of the community have easier access to reach other community members. Cadres play a role in improving the degree of public health both physically and mentally. The active role of mental health cadres helps to prevent an increase in mental disorders through early handling in the community. This study aims to explore the supporting factors that influence mental health cadres in carrying out roles in Wonokromo Surabaya. Used a qualitative approach with phenomenological studies, 18 participants were interviewed and observed. Data were analyzed using the Colaizzi analysis method. The research findings obtained 4 themes namely 1) cadre characteristics, 2) knowledge, 3) motivation and 4) expectations. Supporting factors are important factors that influence the role of mental health cadres in carrying out their roles.

Keywords: *Mental Health Cadre, Qualitative, Role.*

Introduction

Mental health problems continue to increase both in the world and in Indonesia. Mental illness is a major cause of morbidity and mortality and an increase in the burden of the State[(1)], this causes of disability and premature death, decreasing quality of life from non-communicable diseases[(2)]. There are differences in life expectancy for individuals who have no mental illness with individuals who experience mental disorders[(3)]. The gap between availability and need for mental health services exceeds 75% in most parts of the world and extends in the lowest income countries by as much as 90%[(4)].

WHO reports in 2016 there were around 35 million people experiencing depression, 60 million people have bipolar disorder, 21 million have schizophrenia and 47.5 million experience dementia. The prevalence of mental-emotional disorders indicated by symptoms of depression and anxiety for ages of 15 years and overreach around 14 million people or 6% of the total population of Indonesia. This means that there are more than 1 million people in Indonesia who suffer from mild mental disorders, while the prevalence of severe mental disorders, such as schizophrenia, reaches around 400,000 people or as many as 1.7 per 1,000 inhabitants[(5)].

Severe mental disorders in East Java province showed 2.2% of the total population of 38,005,413 people or as many as 83,612 people experienced severe mental disorders. The mental-emotional disorder of the East Java province shows a fairly high number of 6.5% 4. Cases of mental disorders in the Wonokromo Community Health Center work area were 99 cases out of 42,620 residents[(6)].

The high mental health problems require active participation from various parties including the government, health care providers etc. because currently there are still lack of trained human resources, mental health service facilities that are still lacking and it is not possible for the government to provide mental health workers in the near future.

The global mental health challenge is to increase knowledge and literacy about mental health disorders to the community, improve and expand ways to identify

e-mail: sahriana014@gmail.com

and treat mental disorders effectively. The things that can be done is to increase training and conduct community empowerment such as the formation of cadres. The formation of mental health cadres will be very helpful in programs to deal with mental health problems in the community[7]. Mental health care in the community requires commitment and partnership with the community, especially stakeholders as community leaders[8].

Efforts to deal with mental health problems carried out include primary, secondary and tertiary prevention. Primary prevention, mental health cadres identify risk groups, provide information about mental health problems to the community, provide social and emotional support for clients or families in stressful situations. Secondary prevention, mental health cadres involved in conducting early detection, motivating families or communities to be involved in mental health programs. Tertiary prevention, mental health cadres can help clients in the rehabilitation process and motivate clients to exercise control and get therapy[9].

Wonokromo Village has enormous potential both from economic potential, socio-cultural potential, and human resources. The survey in March 2018 found 23 mental health cadres in Wonokromo village. This shows that there are quite a lot of mental health cadres compared to other community Health centers in the city of Surabaya. Mental health cadres in Wonokromo village were formed in 2017, but in the implementation of the role of cadres is very active, such as integrated mental health service posts that are routinely carried out every month

This study aims to explore the supporting factors that influence mental health cadres in carrying out roles in Wonokromo village using the Preced-Proceed Model approach.

Method

This study uses a qualitative approach with phenomenology studies. Mental health cadres who meet the inclusion criteria are conducted interviews and observation activities. Data obtained were analyzed using the Colaizzi method, data validation using source triangulation techniques.

The first step that was carried out before the research was to submit a research permit application to the Surabaya City Health Office, then the initial data collection to the Responsible Staff of the Mental Health Program at the Wonokromo Health Center. The researcher came to the participants one by one to explain the objectives of the researcher and to contract time for conducting interviews and observing participant activities. 18 participants expressed willingness to be interviewed while 1 participant stated that they were not willing to be interviewed and 4 people who were not included in the inclusion criteria. Interviews were conducted at different locations and times.

Findings: The Preced-Proceed behavior model from Lawrence Green and M. Kreuter (2005) states that there are two factors that affect the health level of a person or society, namely behavioral factors and non-behavioral factors. In health promotion programs it is known by the existence of a review and follow-up model[9].

Supporting factors are factors that influence and underlie the occurrence of certain behaviors. Based on the results of the interviews found several themes namely cadre characteristics, knowledge, self-motivation and expectations of participants.

a. **Characteristics of cadres:** The results of this study obtained 18 participants with an average age of 46-55 years (9 people) with the highest level of education namely high school (10 people). Most jobs are IRT (17 people), and are dominated by women (17 people). All participants are Muslim.

b. **Knowledge:** Knowledge is the result of "knowing" that occurs after people have sensed a particular object. Knowledge becomes an important basis for someone to take action. Notoatmojo (2007) a person's knowledge is influenced by the level of education, experience, culture, and economy[10].

   The highest level of mental health cadres education is the level of high school education. Mental health cadres gain knowledge about mental health through training. Mental health cadres are taught about, causes of mental disorders, how to conduct early detection and how to deal with mental disorders in the community. The following is the narrative of mental health cadres during interviews

   "We were first made into mental health cadres, we took part in the 2017 training around June... (R02)

   "We were given a briefing on how to get closer to the people with mental health disorders and also the patients detected the risk of having mental disorders.

So we are taught how to meet the real people with mental disorders, (R16) "

a risk factors like the burden of life, the economy, it could also be the burden of school children with the burden of so much learning that eventually becomes stressful (R01)

"A chronic person who does not recover, it will lead to it, because the problem is, how come I am sick, not cured. it made it hinder his thinking (R04)

"We provide assistance to patients and their families, we ask the medicine, what activities have been carried out (R15)

Kurniawan & Sulistyarini (2016) has examined the relationship of providing training to help cadres improve knowledge in dealing with mental health problems in the community. Research conducted by Rosiana et al. (2016) found that the results of training on mental health cadres, namely cadres were able to realize the existence of mental health problems, explained mental health and how to manage them, cadres were able to do early detection, move the community to participate in counseling[12]. Research conducted by Sutarjo et al. (2016) in line with the results of Lucy Maconick et, al (2018) study that there was an increase in cadre skills after being given training[13],[14]. Mental health training succeeded in increasing knowledge, confidence and attitudes of social health workers [15].

c. Self Motivation: Motivation affects individuals in doing to achieve the goals to be achieved. Interviews conducted with mental health cadres found that mental health cadres in carrying out the role in the community have a lack of motivation. The following are excerpts of interviews with participants:

"Maybe that's what, just say anything, aims, he will, I'll pay the one above right (R04)

"We just enjoy it, we help what" social "is easy-hopefully, it will be a blessing"

"I sincerely do activities like that, indeed, I am happy, like social activities."

"The experience of my father was killed people with mental disorders, I joined this caretaker so that people with mental health disorders did not all kill or feel cruel, so it can be handled, treated so it can recover as before"

"My soul is actually touched to see someone like that, someone like that must be embraced"

"For experience, that's it. I am happy to know the cases of people who seem healthy, but there are those who have problems "

Cadres have diverse motivations in carrying out roles. There are cadres who say they are happy with social activities, happy to be various, useful for the community, happy to get knowledge about mental health problems. In addition, cadres are also say that the activities carried out as alms to get a reward, Cadre performs her role with a sincere heart without expecting rewards, feels touched after seeing and interacting with patients. One cadre wants his bad experience not to happen to other people.

Motivation is a concept that describes extrinsic conditions that stimulate certain behaviors and intrinsic responses that reveal human behavior, motivation is also defined as beliefs and emotions that affect a person's behavior[16].Research conducted by Prang, et al (2013) showed a significant relationship between cadre motivation and activeness of cadres, this factor is the most dominant factor in carrying out an action. The theory of motivation for new directions for theory states that motivation represents a psychological process that will cause responsibility and is the initial stage of willingness to act to achieve the goal. Everyone wants to be trusted, included and recognized as a potential person so that self-confidence arises and is ready to assume responsibility[17].

Motivation possessed by mental health cadres is able to move cadres in carrying out roles in society. The cadre's caring attitude was based on the motivation of the cadre to be happy to help others, the community's needs for themselves also motivated the cadres to carry out their roles in the community health center.

d. Hope: This theme illustrates the hopes possessed by mental health cadres related to mental health problems in the community. The following is the presentation of the results of interviews with cadres:

"Hopefully, in the future, it will be like that, so that it can be received in the community again, it is more humane, sometimes there are people who are ostracized, and there are family members who feel it is a disgrace or something..."

"Yes, I want the government to guarantee people like that"

"My passion is even though I don't recover completely, but at least I don't know, I can control myself, take care of myself"

"Well, we want all the people in this area to be healthy, there are no one people with mental disorders"

"Yes, the hope that people with mental disorders have been routinely going to menur (Hospital) has been improved, healed, if possible. all people with mental health disorders here can be cheerful, not moody. can hang out with the surrounding neighbors,"

"The hope is to recover even if it's not 100%.

"Our patients get medical care like other general patients.

"Don't be cornered, exiled. Still able to embrace, the only way we did before was the result of not widening "

Cadres have hopes for the community not to stay away from, limit, isolate patients who have mental disorders. The purpose of the caretaker is to help patients care for patients so that patients can socialize with the surrounding community. Participants hope that mental health problems in the community can be reduced, people with mental disorders can recover, can control themselves. In addition, participants hoped that the government would pay attention to patients regarding treatment and fulfillment of their daily needs.

Participants have hopes of increasing the role of mental health cadres, along with excerpts of interviews with cadres :

"Yes, I hope it can be more advanced, if we can, the cadres can be eager to advance this, so the cadres of the caretaker will do it because we are sometimes confused"

What can we do or not? ". But I believe, we hope that these tenants can move forward, more fun, more compact to advance the caretaker, here we can coordinate, detect, we can mingle with the sufferers so that they can be familiar, happy like that,

Hope for mental health cadres to be able to progress, cadres remain enthusiastic, compact and able to perform their roles optimally to continue to help deal with mental health problems in the community by providing assistance to patients and families, controlling the health development of patients, helping patients to be independent so that patients are able to operate independently and no longer dependent on others.

Expectations arise from a cognitive assessment that meaningful goals are possible in the future[18]. Emotions such as expectations arise when an event is valued as important and important to be considered by the individual thereby strengthening cognitive perceptions only the possibility and adding elements of motivation, manifested in the planning path to achieve desired goals[18].

Conclusion

Supporting factors influence mental health cadres in carrying out the role, supporting factors namely knowledge, self-motivation and expectations of mental health cadres.

Conflict of Interest: There is no conflict of interest in research

Organoleptic Quality of Nugget Products Seluang Fish and Gabus Fish with Tempe Formulation as Food Products of Protein Sources for Toddler Kep

Yasir Farhat[1], Ermina Syainah[1], Sari Novita[1], Niken Widyastuti Hariati[1]

[1]Nutrition Department, Health Polytechnic of the Ministry of Health Banjarmasin, Indonesia

Abstract

Protein deficiency in the diet is the most serious nutritional problem in cases of malnutrition, which is often known as Protein Energy Deficiency (KEP). Children and toddlers need more protein for more active growth and energy exchange. Therefore, an alternative source of energy and high protein is needed which has been known by all levels of society as raw material for brownies such as kepok bananas and seluang fish. It is expected that these products can overcome and prevent KEP problems such as malnutrition and malnutrition in infants.

This research is an experimental research conducted in two stages of research. The first stage was processing seluang fish and cork fish tempe formulations with a ratio of 25%: 75%. At this stage organoleptic tests were carried out with Mann Whitney analysis with a significance of 0.05%, and supporting data for proximate and amino acid tests.

The supporting data of the highest essential amino acid test results in cork fish, tempe formulation, which is a lot of 1.08% leucinese and in seluang fish, tempe formulation is 0.80%, the highest essential amino acid content in seluang fish is as much as 2.64% amino glutamic acid and cork tempe formulation 2.21%.

Keywords: *Nugget, seluang fish, cork fish, tempe and organoleptic test.*

Introduction

Protein deficiency in the diet is the most serious nutritional problem in cases of malnutrition, which is often known as Protein Energy Deficiency (KEP). Toddlers are more vulnerable to KEP cases. The impact of PEM on toddlers causes abnormal growth, decreased immunity, and a low level of intelligence. In severe stages, PEM in infants can cause kwarshiorkor to death.[1] The prevalence of cases of malnutrition in Indonesia continues to increase from year to year. According to data from Basic Health Research (RISKESDAS) in South Kalimantan Province the prevalence of underweight and malnourished children under five in 2013 was 19.2% malnutrition and 8.2% malnutrition.[2] According to Astuti (2014) tempe protein is classified as easily digested so that protein can be used to gain weight, especially in toddlers. Overall soybean tempeh contains a fairly high nutrient element: 25% protein (17 grams protein / 100gram), 5% fat, 4% carbohydrate and 60% water, a source of vitamin B12 which is high enough, low fat, cholesterol free. Besides being able to be given also processed fish as an additional food for toddlers.[3] The main advantage of fish products is that the digestibility of fish protein is very high (more than 90%) so that the fish are easy to digest because fish meat is softer than other animals.[4] Seluang fish (Rasbora spp.) Is one of the edible small fish his whole body.[5]Seluang fish contains 361 Kcal of energy, 10 grams of protein, 5.3 grams of carbohydrates, 3.2 grams of fat, 80

milligrams of calcium, 224 milligrams of phosphorus, and 4.7 milligrams of iron. In addition, Seluang Fish also contains 86 IU of vitamin A, 0.03 milligrams of vitamin B1 and 0 milligram of vitamin C. Cork fish (synonym channastriataophiocephalusstriatus) is a predatory fish and is an authentic Indonesian aquatic fish. In cork fish contains proteins, especially albumin and essential amino acids, fats, especially essential fatty acids, special minerals zinc / zinc and some vitamins that are very good for health.[6] The processing of high-protein food products such as nuggets made from seluang fish and fish cork with tempeh formulation, is expected to be effective in overcoming and preventing PEM problems such as malnutrition and malnutrition in infants.

Method

This research is an experimental research because it is done by setting the treatment, where the researcher can arrange the treatment. There are two types of nugget formulations namely nugget namely seluang fish nugget tempe (P1) formulation and cork fish tempe formulation (P2) with a ratio of 70%: 30 %. Furthermore, organoleptic quality tests of nuggets were carried out, and as supporting data a nutritional value (proximate and amino acid) test was carried out. This study was carried out at the Food Technology Laboratory and Laboratory of Organoleptic Test at the Department of Nutrition of Banjarmasin Polytechnic for the process of making tempe nugget formulations with additional Seluang Fish and Fish Cork. Organoleptic quality test using the hedonic scale test test form in the form of a panelist response to preferences or vice versa. Processing and analysis of data using the Mann Whitney test to determine the difference in organoleptic quality, seluang fish nuggets tempe and cork fish nuggets formulation tempeh formulations with a significance level of 0.05. The data obtained was processed using the Microsoft Excel 2010 program and SPSS for Windows 16.0. The received data on nugget formulation products was presented descriptively. Proximate tests and amino acids will be analyzed descriptively.

Results

Organoleptic quality tests for the acceptability of celluang fish cork formulations and cork fish nuggets were obtained using 35 students as semi-trained panelists. The components assessed are color, taste, aroma, and texture. From the organoleptic test based on color, the average color values of seluang fish nugget tempe formulations were lower at 3.30 compared to cork fish nuggets with tempeh formulations which had an average value of 3.83. The distribution of panelists with criteria that are very fond of seluang fish nuggets tempe formulation (0%) is also lower than cork fish tempe (16.7%) formulation. In general, both Seluang fish and nugget fish nuggets are preferred by more than 50% of the panelists in terms of color, namely 53.3% and 63.3% respectively. However, in Seluang fish nuggets there are 3.3% who say they are very dislike. Seluang fish nuggets tempeh formulations have a dark brown color, compared to cork fish nuggets tempeh formulations are yellowish brown in color. The color difference of the two products is very striking. Can be seen in Table 1.

Table 1 : Distribution and Average Value of Organoleptic Quality Score Color of seluang fish nuggets and cork fish tempe formulation

Criteria	Nugget Ikan Seluang		Nugget Ikan Gabus	
	N	%	N	%
Very Like	0	0	5	16.7

Do not like	3	10	2	6.7
Very Do not like	1	3.3	0	0.0
Average	3.30		3.83	

Source : Data Primer 2018

In terms of aroma, the average value of the aroma of seluang fish nugget tempeh formulation was 3.67 higher than that of cork fish nuggets in tempe formulation which had an average value of 3.60. Distribution of panelists with criteria very like on seluang fish nuggets tempe formulation (20%) greater than cork fish nuggets formulated tempe (16.7%). The results of seluang fish nuggets tempe formulations and cork fish nuggets tempe formulations produced are savory scented.

In terms of nugget texture, where the average value of texture preference on seluang fish nugget tempe formulation was higher, which was 3.53 compared to cork fish nugget tempe formulation which had an average value of 3.36The distribution of panelists with criteria very much like the seluang fish nugget tempe formulation (16.7%) also has a higher value than cork fish nuggets, can be seen in Table 2.

Table 2 :Distribution of Quality Score of the Texture Organoleptic of Seluang Fish and Cork Formulation of Tempe Fish

Criteria	Nugget IkanSeluang		Nugget ikangabus	
	N	%	N	%
Very Like	5	16.7	1	3.3
Like	13	43.3	18	60.0
Neutral	8	26.7	6	20.0
Do not like	3	10.0	4	13.3

Table 3 : Distribution of Organoleptic Quality Score Value of Seluang Fish Nugget and Cork Formulated Fish Tempe

Criteria	Nugget IkanSeluang		Nugget ikanGabus	
	N	%	N	%
Very Like	0	0	3	10
Like	18	60.0	17	56.7
Neutral	4	13.3	6	20
Do not like	5	16.7	7	23.3
Very Do not like	3	10.0	4	13.3
Average	3.17		3.50	

Source : Data Primer 2018

Table 4 :Average Quality of Organoleptic Seluang Fish Nugget and Cork Formulation Fish Tempe

Criteria	Nugget Ikan Seluang	Nugget Ikan Gabus
Color	3.30	3.83
Aroma	3.67	3.60
Texture	3.53	3.36
Taste	3.17	3.50
Total Value	13.67	14.29
Average	3.42	3.57

Source : Data Primer 2018

The resulting value is a combination of seluang fish and tempeh formulations and cork fish and tempeh formulations. Texture differences are caused by differences in the basic ingredients used in making nuggets, where Seluang fish contains 13.9 grams of protein per 100 grams of material weight, 642 mg of calcium / 100 grams of ingredients while tempeh contains 18.9 grams of protein per 100 grams of material weight, fish cork containing 13.9 gr per 100 gr weight of ingredients and amino acids and calcium 290 mg / 100 gr high material weight and albumin (3) Then in terms of taste, seluang fish nuggets tempe formulation is lower, which is 3.17, compared to Nuggei cork fish tempeh formulation of 3.50. This shows that in terms of the taste of cork fish nuggets the tempeh formulation is more acceptable. Can be seen in Table 3.

We did the total score of the results of the quality assessment and organoleptic acceptability of the two nugget formulations. It was found that the cork fish tempe nugget had the highest average value of 3.57 compared to the Seluang fish nugget tempe formulation of 3.42. In both cellulite and cork fish nugget formulations, an analysis of the composition of nutrients and amino acids can be seen in Table 5 and Table 6. Proximate test for nutrient composition showed that the water content of seluang fish nugget tempeh formulation was 43, 53%, this value is lower than cork fish nugget tempe formulation which is 46.96%. This will affect the shelf life / expiration. Carbohydrate content (KH) in Seluang fish nuggets is higher by around 2.2%, which is 30.4% compared to cork fish nugget which is only 28.2%.

Table 5 : Proximate Content of Seluang and Gabus Fish Nugget

Protein (%) *	11,08	10,8
Carbohydrate (%)	30,4	28,20
Rough Fiber(%)	0,74	1,31

Discussion

KEP is one of the main nutritional problems that is often found in toddlers in Indonesia and other developing countries KEP has an impact on growth, intellectual development and productivity between 20-30%, besides that it also has a direct impact on morbidity and mortality[7]. One of the factors that influence the quality of nuggets is the amount of binder added and supporting materials needed in making fish nuggets such as salt, sugar, spices including garlic and pepper pepper.[8]Some studies show that tempe nutrients are easier digested, absorbed and utilized by the body compared to that in soybeans.[9]This has been proven in infants and toddlers suffering from malnutrition and chronic diarrhea. By giving tempeh, the growth of body weight of sufferers of malnutrition will increase and diarrhea heals in a short time.[10]Seluang fish contains energy equal to 361 Kilocalories, protein 10 grams, carbohydrates 5.3 grams, fat 3.2 grams, calcium 80 milligrams, 224 milligrams of phosphorus, and 4.7 milligrams of iron. In addition, Seluang Fish also contains 86 IU of vitamin A, 0.03 milligrams of vitamin B1 and 0 milligram of vitamin C. These results were obtained from conducting research on 100 grams of Seluang Fish, with an edible amount of 89%.[11] Cork fish also has a very good nutrient content for health. The content consists of high protein content, especially albumin and essential amino acids, fats, especially essential fatty acids, minerals, especially zinc / zinc (Zn) and some vitamins that are very good for health. Overall, the acceptance of seluang fish and cork fish nuggets with tempe formulations in terms of color, aroma, taste and texture was received quite well by the panelists.

Conclusion

The proximate analysis of nutritional value, cork fish nugget tempeh formulation has a higher protein content and higher crude fiber. The carbohydrate content is higher in seluang fish nuggets compared to cork fish nuggets. The highest essential amino acid test results on cork fish nuggets, tempe formulations, which are many leucinese 1.08% and on seluang fish nuggets tempeh formulations of 0.80%, the highest non essential amino acid content in seluang fish nuggets tempe formulations namely amino glutamic acid as much as 2.64%, in cork fish nuggets tempeh formulation is 2.21%. As for the assessment of organoleptic test results (color, aroma, texture and taste, cork fish nuggets tempeh formulations are preferred in terms of color and taste, while in terms of aroma and texture of Seluang fish nuggets are preferred. The results of this study illustrate that processed fish nugget products seluang or cork fish with tempeh formulation can be used as an alternative supplement for toddlers who are KEP.

Grateful Greeting: Our thanks go to the Director of the Banjarmasin Ministry of Health Polytechnic and the Banjarmasin Ministry of Health Polytechnic Research and Community Service Unit who have provided Lecturer Research funds in order to carry out the Tridharma of Higher Education.

Association between Social Capital, Mental Health and Quality of Life among Migrant Workers in Myanmar

Yi Myint Swe[1], Kittipong Sornlorm[3], Wongsa Laohasiriwong [2]

[1]Dr. PH student, Faculty of Public Health, Khon Kaen University, Thailand & Lecturer, University of Public Health, Yangon, Myanmar, [2]Faculty of Public Health, Khon Kaen University, Thailand, [3]Thakhantho District Public Health Office, Kalasin Province, Thailand

Abstract

Introduction: During these decades, Myanmar has faced mass internal migration as a result of pull and push factors. The concepts and concerns related to Quality of Life on internal migrant workers are different from the general population. Migration gives rise to huge stresses and depression.

Methods and Materials: Cross-sectional study was conducted among 1,182 migrants. To assess socioeconomic status, health behaviors, mental health status, social capital, accessibility to health care services, and QOL. The Generalized Linear Mixed Model was used to determine the association between social capital, mental health and QOL after controlling the other covariates.

Result: About one third of respondents were factory workers and had low level of education. Regarding the level of good, fair and poor QOL were 26.82% (95% CI: 24.37-29.42), 71/74% (95% CI: 69.10-74.24) and 1.44% (95% CI: 0.89-2.30) respectively. Cognitive social capital (AOR=2.51, 95%CI: 1.14-5.55 p value<0.05), structural social capital (AOR= 2.14, 95%CI: 1.22-3.76, p value=0.008) and depression (AOR= 2.13, 95%CI: 1.25-3.62, p value=0.006) were associated with QOL. Not like the other studies, stress was not associated with QOL. The other factors associated with good QOL were monthly family income, living with related family members in a house and burden of medical services costs.

Discussion: Only one-fourth of internal migrant workers had good quality of life. The findings highlighted to develop policies aimed to improve QOL in order to reducing stress and depression among migrants by promoting social capital. In order to achieve the sustainable development goals, it is important to make investment on health of the migrant workers.

Keywords: *Quality of Life, social capital, mental health, migrant workers.*

Introduction

Like migrants are increasing trend globally[(1)], Myanmar has seen the significant internal migration, 20% of total Myanmar population[(2)]to seek job opportunities and pursue a better life[(3)]during these last few decades[(4)].The rural to urban migration has contributed to the explosive growth of cities all over the world[(5)]. Migrants are principally vulnerable to health problems[(6)].Migration gives rise to unambiguous stress, nevertheless most immigrants behave well in new settlement[(7)].

Rogers explored that socially isolated migrants were at increased risk for poor health outcomes because of their limited access to resources[(8)].The impact of human migration on mental health is complex and has cross-cultural differences[(9)]. Stress and depression could have an impact on overall health[(10)] and not recognized or treated, depression can profoundly impair their quality of life[(1)].

QOL is one of the essential aspects of human health, which includes physical, mental and social context. Over the past few decades, measuring QOL has become a familiar approach in health research[(11)].

Currently, there are limited data available regarding the level of QOL and its associated factors among internal migrant workers who were chosen as a priority

group because they were living under highly stressful situations and needs to be addressed because 25 % of those migrate to Yangon.

Hence, the aims of this study were to investigate the levelof quality of life and association between social capital, mental health and QOL among internal migrant workers in Myanmar. The findings of the study will contribute to formulate specific measures to improve quality of life among migrant workers even though they are vulnerable population.

Methods

This cross-sectional study was conducted in 2018 at North and East Districts among four districts namely East, West, North and South of Yangon Region.

Study participants: Migrant workers with the aged between 18 to 59 years living in Yangon Region and could verbally communicate were included in this study.

The multiple logistic regressions used to estimate the sample size. The approximate sample size was 600. In order to control the over-fitting, we used ρ and VIF. Therefore, total samples was 1182. A multistage random sampling method was used.

Firstly Yangon was purposively selected then 2 districts were randomly selected namely, East and North among 4 districts. After that two townships (sub-districts) from each district were randomly selected namely Hlaingtharyar and Shwepyithar from North District and Dagon East and Dagon Seikkan from East District. Therefore 4 townships (sub-districts) were included in the study. Finally, 2 community were randomly selected from each township. Then simple random sampling was applied to select 1,182 individuals proportionate to the size of the population. All participants were interviewed face-to-face by trained interviewers.

Research tools: A structured questionnaire which was developed from reviewing literature. The questionnaire underwent content validation by 3 experts and then it was revised to improve validity. The questionnaire was tested for reliability using Conbach alpha coefficient, 0.80. The questionnaire consisted of six parts: (1) socioeconomic (2) Health behavior (3) social capital (4) mental health (5) accessibility to health services and (6) quality of life.

Assessment of quality of life: QOL was assessed by using WHOQOL– BREFquestionnaire, consisted of 26 items within the 4 domains. The scores are categorized into 3 groups: poor (26–60), moderate (61–95) and good (96–130).

Assessment of Stress: By using Perceived Stress Score, contains 10 questions, each scored from 0 to 4. The higher and longer the duration of self-perceived stress, indicated by a higher score. The scores are categorized into 3 groups: low (0-13), moderate (14-26), high (27-40).

Assessment of Depression: Burmese version of the Centre for Epidemiological Studies Depression Scale (CES-D) which is a 20-item self-report questionnaire using a four-point rating scale. A cut point of 16 or greater is defined as depression in Myanmar migrant population.

Assessment of Social Capital: Structural Social Capital included; Unity, Transparency, Responsibility of leaders, Participation and Responsibility, Parallel Organization. Cognitive Social Capitalincluded; behavior, attitude, trust, reciprocity and sharing the norms. For each part, using the 5 scores: Never, Often, average, frequently, mostly. After summing the total marks, according to Kiess's theory, total score were divided into 3 groups such as high, median and low.

Socio-economic status (SES) and Health service accessibility factors: Socio-economic status composed of gender, age, marital status, educational, occupation, house ownership, relationship with family members, monthly income, adequacy of income, burden of transportation cost and medical service costs were treated as covariates in the analysis.

To minimized information bias, we trained interviewers and standardized the data collection competency in the study area. They were structured questionnaire interviewed by well-trained and standardized interviewers.

Data analysis: STATA® (ver. 13; College Station, TX, USA: Stata Corp). The categorical data were presents as frequency and percentage whereas the continuous data as mean, standard deviation, median, and range. The GLMM was operated to model the random effects and correlations inside clusters. In the modeling, the residential area, community set as the random effect. Bivariable analysis was utilized to define the association of each independent variable with quality of life. In bivariate analysis that had $p \leq 0.25$ were chosen and continue to the multivariable analysis.

The final model results presented the magnitude of association of independent variables and good quality of life were adjusted odds ratio (adjusted OR) and 95% CI.

Results

The average age of migrant workers in this study was 31.42 years and gender distribution was not much different but more than half of respondents were married. Nearly three fifth of participants were primary and secondary school education level. Only 11.24% owned their houses. Among the migrants, nearly 90% were related and breathed in a house.

Nearly three fourth of migrants responded that their monthly family income ranged between USD 130 – USD 230 with median monthly family's income of USD 200. Nearly half of the respondents said that they had no financial problem but can't save money.

Most of migrants responded that they felt moderate level of: stress, total social capital, cognitive social capital, structural social capital, QOL and no burden of medical services costs. Nearly two fifth of the respondents suffered depression.

Table 1: Number and percentage of QOL among migrants in the Myanmar (n=1,182).

Quality of Life	Number	Percent	95%CI
Poor QOL (≤60)	17	1.44	0.89-2.30
Moderate QOL (60-90)	848	71.74	69.10-74.24
Good QOL(≥90)	317	26.82	24.37-29.42
Mean ± standard deviation Median (Min : Max)	83.12± 9.62 83 (52 : 110)		

Most of the migrants had moderate QOL (71.74%), 26.82% had good QOL and the rest, 1.44% had poor QOL.

The bivariate analysis revealed that total social capital (COR= 1.95, 95%CI: 1.38-2.75, p value <0.001), cognitive social capital (COR= 2.30, 95%CI: 1.68-3.13, p value <0.001), structural social capital(COR= 1.95, 95%CI: 1.37-2.78, p value <0.001), depression (COR= 2.33, 95%CI: 1.75-3.11, p value <0.001) and stress (COR= 1.52, 95%CI: 1.02-2.25, p value <0.001) were strongly associated with Good QOL. Also, gender,house ownership, relationship of family members, time to reach the health service center, burden of transportation cost and medical service costs,support for medical servicecosts were associated with good QOL. But in contrast to previous studies that age, marital status, education, occupation,monthly family income were not associated in this study.

Multivariable analysis for associated factors of good QOL, GLMM was performed to control the clustering effect of the sampling selection of the participants. The association between multiple independent variables and good QOL was determine by using multivariate analysis to control the effect of covariates.

Table 2. Adjusted Odd ratio for the factors on good quality of life based on GLMM after controlling the random effect (n = 1182)

Characteristics	No	% of Good QOL	Crude OR	Adjusted OR	95%CI	p-value
1. Cognitive Social Capital						0.023
Low and moderate	970	23.61	1	1		
High	212	41.51	2.30	2.51	1.14-5.55	
2. Structural Social Capital						0.008
Low and moderate	1027	24.93	1	1		
High	155	39.35	1.95	2.14	1.22-3.76	
3. Depression						0.006
Depression	452	17.26	1	1		
Without Depression	730	32.74	2.33	2.13	1.25-3.62	
4.Monthly Income						

<USD 130	264	21.59	1	1		
USD 130- 200	578	27.68	1.39	1.41	1.03-1.92	0.032
≥USD 200	340	29.41	1.51	1.49	1.05-2.13	0.024
5. Related with family members						<0.001
not related	135	25.50	1	1		
Related	1047	37.04	1.71	2.15	1.59-2.92	
6.Burden of medical services costs						<0.001
Some what a burden & Very burden	296	20.27	1	1		
Not a burden	905	28.51	1.57	1.34	1.14-1.56	
7. Stress						0.643
Moderate and severe stress	1076	25.56	1	1		
Mild stress	125	34.40	1.53	1.18	0.58-2.40	

Discussion

The prevalence of good QOL among migrant workers was 26.82%. These findingwas consistent with the study, one third[12]were felt as good QOL. But a study showed that 94% were moderate level of QOL[13]. It was less than all level of QOL in compared with two studies among Myanmar migrant workers in Thailand. It was not consistent with the study done in Chiang Rai, 56% demonstrated moderate QOL, high (43.8%) and low (0.20%)[14]. It was not similar in a study done in Dhaka city, low QOL (94%), moderate (3.25%) and high (2.75%)[15]. Inconsistent with the study was done at construction site, 14.6% were rated as having poor QOL[16].

After GLMM analysis, cognitive social capital, structural social capital and depression, monthly family income, living with related family members and burden of medical services costswere strongly associated with good QOL.But stress was not significantly associated in this study.

More socially connected female expressed higher QOL[17]. The presence of social capital among adolescents and establish associations with their QOLin Brazil[18]. Hosseini, S. M et al suggested that enhance social capital for improving QOL among breast cancer patients[19].

Social support is very important to health outcomes and has a positive effect on QOL[20]. For the cognitive social capital, migrants with high cognitive social capital were 2.51 times more likely to get good QOL than those with moderate and low cognitive social capital. Regarding structural social capital, migrants with high structural social capital were 2.14 times more likely to get good QOL than those with moderate and low group. These findings were consistent with the study done among elderly in north east of Thailand[21].

On seeing the mental health status, migrants did not suffer depression were 2.13 times more chance to get good QOL than migrants suffered depression. The finding was consistent with other study[12].

Stress was not significant, migrants with mild stress were 1.18 times more chance to get good QOL compared to moderate and severe stress group. It had similar agreement with the study[16] but inconsistent with the study done in Singapore[1].

Regarding socioeconomic and demographic characteristics of the respondents, living with related family members was the strongest variable (AOR=2.15, 95% CI= 1.59 to 2.92, p<0.001). It was similar with the study done in Myanmar[22].

High monthly income group got good QOL than the other groups. It had agreement with the studies[23].

Burden of medical service cost associated with good QOL. The participants with financial hardship were 1.34 times more chance to get good QOL than those without (AOR= 1.34; 95% CI= 1.14 to 1.56; p-value < 0.001). It had similar agreement with the study done in northeast of Thailand[21].

Conclusion

Only one-fourth of internal migrant workers had good QOL. Cognitive social capital, structural social capital and depression were strongly associated with good QOL. But stress was not associated with good QOL.

Limitation of the Study: Cross sectional study was not allowed the cause and effect relationships between various factors and QOL. This study was conducted among migrant workers (18 to 59 years old) living in Yangon Region thus it could not generalize the all migrant workers in Myanmar.

Conflicts of Interest: The authors declare no conflict of interest.

Ethics Clearance-: Taken from Khon Kaen University Ethics Committee in Human Research (the approval number, HE 612079) and University of Public Health, Yangon, Myanmar (ITERB-2018/Research/17). A coding scheme was used and every document were destroyed on completion of research.Written consent was obtained from all participants prior to participation.

Faculty of Dentistry, Minia University, [4]Professor of Removable Prosthodontics Department and Vice President, Sinai University, Egypt

Abstract

Background and Objective: Long-term success of dental implants depends on implant abutment connection. This prospective study aims to assess the implant stability of self locking conical connection and traditional platform implant abutment connection with mandibular telescopic supported overdenture.

Material and Method: This study is a randomized controlled study included twelve completely edentulous patients selected from the Outpatient Clinic of the Prosthodontics Department, Faculty of Dentistry, Minia University.Two root form implants were inserted in canine area bilaterally in each patientone is self -locking implant abutment connection while the other is traditional platform. Telescopic overdenture was constructed over the two implants. The stability was evaluated at 3, 6, 9 and 12 months. The collected data were analyzed by SPSS program version 20 with considering statistical significance when P value<0.05.

Results: There was no significant difference in implant stability regarding mean implant index when evaluated at delivery and various intervals with self locking conical implant abutment connection. While with traditional implant abutment connection there was significant difference in implant stability when evaluated at delivery and 6 months interval.

Conclusion: The self locking conical implant abutment has more stability rather than traditional platform implant. This is may be explained by that the self locking conical implant abutment interface optimize the ability of an implant-to-abutment joint to resist bending forces and micromotion increasing implant secondary stability.

Keywords: *Stability,telescopic over denture, self locking conical connection implants.*

Introduction

The introduction of modern dental implant leads to many problems which were solved in case of complete edentulism. Dental implants improve the problem of support and retention of complete denture. Moreover; utilization of dental implants has many benefits. The balance and effectiveness of prosthesis has positive effects on oral structures and aesthetics. They also improve the quality of life of the patients by reducing their total healthcare costs in the long run.[1]

Many factors affect the success of the implant treatment. These factors include the bone–implant, implant–abutment and abutment–prosthesis interfaces.[2] A major difference between implant systems is the type of connection between implant and abutment. There are two types of implant abutment connection external

connections and internal connection. The internal connections prevent the complete tilting of the abutment even in the absence of a connecting screw during the extra axial loading[3,4] in peri-implant bone[5,6].

In this study we tried to evaluate the reliability of the implant/prosthesis system using conical connection between implant and abutment in comparison to the traditional platform implant abutment connection.

Patients and Method: The current study is a randomized controlled study that included twelve completely edentulous patients selected from the Outpatient Clinic of the Prosthodontics Department; Faculty of Dentistry, Minia University.

For each patient medical history, clinical examination, mounted diagnostic casts and radiographic assessment were carefully done.

The inclusion criteria were:age above 50 years old, angle Class I relationship between maxilla and mandible, adequate oral hygiene, firm and adequate mucosal thickness and without highly frenal attachment, physically and psychologically able to tolerate conventional implant surgical protocol, sufficient bone height and width as well as adequate bone quality as confirmed radiographically, proper tongue size and sufficient inter-arch distance to accommodate the future prosthesis and attachment.

The exclusion criteria include:alcoholic or drug abusers, health condition precluding surgery, logistic or physical reasons that could affect follow-up, psychiatric problems, disorders to the implant area related to a history of radiation therapy to the head and neck, neoplasia, or hematological diseases.

All patients participated in the study were informed about the nature of the study and its purpose, agreed to take part in it and write an informed consentre viewed by the research ethics committee of the Faculty. All reasonable steps to protect the confidentiality and privacy of the personal and health information of the patients were taken and patients informedabout the benefits of obtaining an implant.

Source of Funding: Self-funding.

Patient Grouping: The patients were randomly divided into two equal groups. Both groups of patients were treated by implant supported mandibular overdenture retained by telescopic crowns,and divided according to the implant abutment connection type into:

Group I: Include patients treated by implant with self-locking conical implant -abutment connection.

Group II: Include patients treated by the same implant system with traditional platform implant abutment.

Traditional complete dentures were constructed to the patients according to the regular manner using heat activated acrylic resin.

Surgical guide construction: For each patient, a customized surgical guide was fabricated using 3D printing technology. Patients were scanned by the cone-beam computed tomography(CBCT)machine, with lower denture contains gutta perch markers. After that, the lower dentures with gutta percha markers were scanned. Captured radio-opaque markers were imported into viewing software then sent for fabrication of the guide.

Overdenture construction: Two root form implants"implant direct: Reactive® no. 753716, interactive™ no. 653716, USA" were inserted at the mandibular canine areas in each patient using the surgical guide. After one week of implant insertion, two straight contoured abutments were fixed to the implant. The abutments with impression coping were unscrewed. The impression with elastomeric impression material was taken for construction of telescopic crowns connected with the framework.

As illustrated in Fig. (1), the metal try in was done. A jaw relation was taken. Setting of artificial teeth was preformed and try in of the trial denture was checked out. The waxed trial denture and processing cast were flasked, packed and processed as usual. The overdenture checked for accurate fitting on the abutments. The patients were instructed for proper way of denture removal and insertion, cleaning, and usage. Fig. (2,3).

Fig.(1):Two telescopic crowns connected meshwork mesially and distall

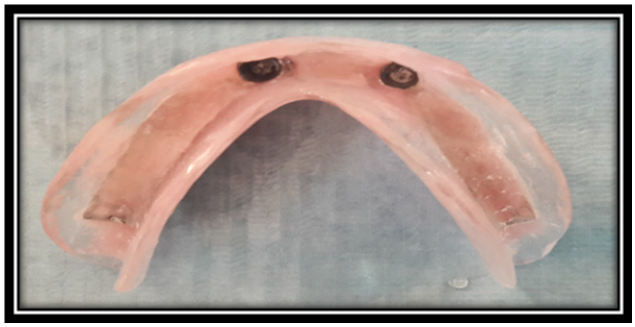

Fig. (2): Fitting surface of finished and polished denture

Fig.(3): Delivery of implant supported overdenture

Measurement of implant Stability: Implant stability was measured using osstell^{TM}. The Smart Peg was attached to the implant. The measurement probe was hold close to the top of the Smart Peg without touching it. The peg has a small magnet attached to its top, which is excited by magnetic pulses from a handheld computer. The peg vibrates in two directions, which are approximately perpendicular to each other. The vibration takes place in the direction that gives the highest resonance frequency (first mode) and in the direction that gives the lowest resonance frequency (second mode).
The values above 65 indicate a favorable response, whilst below quotient 45 implant stability may be indicative of overload and ongoing failure.[7] The measurements were at time of implant insertion 6,9, and 12 months Fig.(4,5).

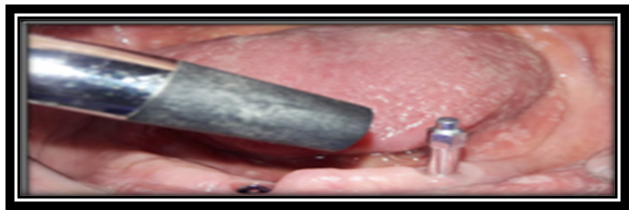

Fig.(4): Measurement of implant Stability using osstell^{TM} The mearment prob directed to smart pegs.

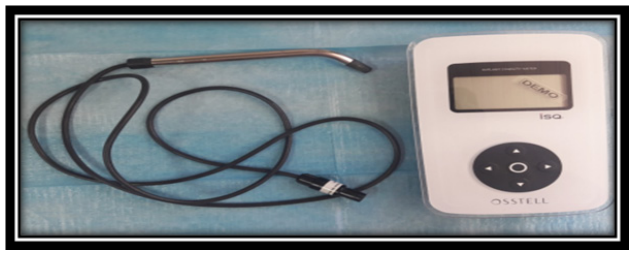

Fig.(5): Osstell™ ISO

Results

Regarding the mean implants stability at different intervals self-locking (interactive) implants, there was no significant difference regarding mean implant stability between delivery and other intervals. Regarding the mean implants stability at different intervals in traditional platform(reactive) implants, there was only significant difference between delivery and 6 months of follow up (p= 0.007).

During comparison between both groups, there was significant increase of mean implant stability among self locking conical abutment implant connection than traditional platform at different interval Fig. (6).

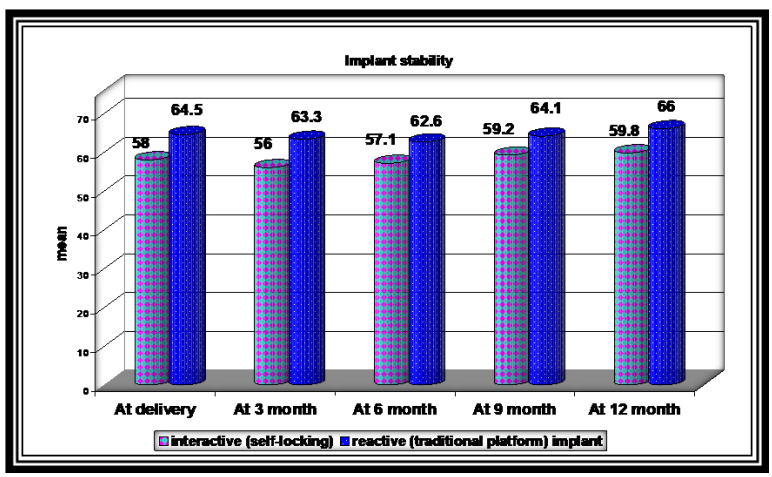

Fig.(6): Comparison of implant stability at different interval between both groups

Discussion

The criteria of success of Osseo integration are the absence of clinical mobility, no peri-implant radiolucency or infection, no pain, no neuropathy or parasthesia or crestal bone loss exceeding 1.5 mm at the end of the first year of function or 0.2 mm per year subsequently.[7, 8]

Accordingly, patients were scheduled for follow-up after 3, 6, and 12 month of implants placement and loading time to implant stability.

Implant abutment connection (IAC) is the point of transition from surgical to prosthetic phase. It is the primary determinant of strength and stability of the implant interface away from the crestal bone and consequently giving better biologic and aesthetic results. Over the years, different IAC have been developed with an aim to decrease stress on the prosthetic component and on bone-implant interface and ensure adequate prosthetic stability. [8]

Osstell^{TM}is non-invasive resonance frequency analysis (RFA). It is an easy practicable method of measuring quantitative stability that can be used in the intra-operative and post-operative settings. The resultant Hertz waves are converted into a numeric value which is called implant stability quotient (ISQ). This will deliver values which can be compared independently of the implant system used. The scale used ranges from 1 to 100 with the correlation to the resonance frequency value being almost linear. This means that the higher the ISQ value, the more securely the implant is retained to be anchored in the bone. [8]

Primary stability of an implant comes from the mechanical engagement with the cortical bone[11]. This is affected by the quantity and quality of bone. Secondary stability is developed from bone and tissue regeneration and remodeling around the implant after its insertion.[12,13]

In this study there is a significant increase of mean implant stability among self locking implant connection than traditional platform at different interval. This due to the absence of an implant–abutment microgap and consequently associated with reduced micro motion.

The same results were concluded by several studies which revealed that incidence of both mechanical and prosthetic complications observed during the loading period was minimal and there was high mechanical stability.[14,15,16]

Conclusion

The implant -abutment interface determines the lateral and rotational stability of the implant -abutment joint which in turn determine the prosthetic stability of the implant supported restoration.The self locking conical implant abutment interface optimized the ability of an implant-to-abutment joint to resist bending forces, micro motion. That led to increase in implant secondary stability.

Conflict of interest: Nil

Ethical Clearance: Every patient in this study had given their informed consent for inclusion before their participation. Which is conducted in accordance with the declaration of Helsinki, it was approved by the Ethics Committee of Minya University

Vernadsky Crimean Federal University, Simferopol, Russia

Abstract

Nowadays, gender medicine generates the great deal of discussion in a modern society. However, more attention is given to on female health in comparison to male health. It is undoubtedly true that men have many physical and mental peculiarities and public health should consider these facts. *The aim of the study* is to access how different stress factors of childhood influence on male health in the Crimean Republic.

Materials and Method: Our investigation included 1144 men, from ages 18-65 living in different Crimean region from 2010 to 2016. They answered questionnaires, including 12 chapters and it consists of 233 questions. *Results* - The results of our investigation proved that stress factors from childhood negative effects on male health. Firstly, men without any psychological problems in childhood showed a low level of chronic diseases in adult life. It is on 87, 8% less than in other respondents (P<0, 05). Moreover, the frequency of hypertonic disease less on 34, 5% (P<0, 02); the number of other health problems is less by 64, 0% (P<0, 01). Secondly, in adulthood the frequency of hyper tonic diseases has a weak correlation with negative events (Q=0,159); at the same time the frequency of other problems with health is deviated from 836, 8‰ of hands and legs fracture to 1234, 6‰ of parents violence. *Conclusion* - The current findings prove that male health in the Crimean region was influenced by stressful factors, and elimination of these factors can possibly improve male health in general.

Keywords: *Stress, childhood, adolescence, male health, Crimea Republic.*

Introduction

Notwithstanding that, nowadays gender medicine is shared all over the world, the main attention is spent on female health problems. Specific aspects of male health care were being researched last since the decade for some reasons. The most persuasive reason is the different medical care needs conditioned on reproductive function, as a result they have varied risk of specific diseases. The second and third crucial reasons are the variability of risk of developing specific diseases and different realization of personal health in these groups [1]. Males have high social and economic status than females; meanwhile men have high risk of serious chronic diseases and death in different age period of life. Russian, Ukrainian and Belarusian men die 10 - 11 years earlier than women do. In comparison to Europe and USA, this indicator is significantly high [2]. Public health system should detect these differences and additional biological, psychological, social and behavioral factors influencing on male health. The research purpose is to defineinfluence of stress factors on the health of men living in theCrimean.

Material and Method

Our investigation included 1144 men, ages 18-65, from different region of Crimea from 2010 to 2016. They answered a questionnaire, which included 12 chapters and consisted of 233 questions. The frequencies of chronic diseases, diabetes mellitus, and hypertension were assessed among male health indicator. A special psychological scale was created and tested with the purpose of comprehensively estimating

the respondents' neuropsychological condition in correlation with negative emotional experience in their childhood. As a result, the scale comprises such groups: balanced (minimal influence of stress factors on child), unstable(stress factors impact on child periodically), anxious (child develops in chronic stress). Statistical analysis of received data was realized by variation method of statistics. Relationship between health indicators and risk factors was accessed by the calculation of pair correlation (r), the Yule association coefficient (Q), and Pearson rank correlation coefficient (C). The reliability of differences among compared health indicators was evaluated by Student's t-test (t), the dispersed method (F), dispersion index (χ 2),authenticity (P) and Pearson's chi-squared test. Distinctions were statistic reliable in probability detection 95% ($p<0,05$). Database was processed by using Microsoft Excel 2010.

Findings: International statistical data proved that men during their life have mental disorders more often than women. Boys have significant risk of mental problems, which was diagnosed in their childhood and teenage years, than girls [3]. Social limited connections between men decrease level of their social adaptation. Under great stress, men commonly have weaker social support than women do. Among youngsters boys often do not have moral support after stress, nervous shock and depression [4].

Our investigation demonstrates the influence of stress factors in early childhood and adolescence of men on the health level in adulthood. Table 1 shows main consequences for men health after psychological problems in childhood.

Table 1. There are the frequencies of some diseases and other health problems in Crimean men according to their mental and psychological condition in childhood and adolescent years.

Mental and psychological condition	Cases amount 1000 persons			
	Chronic diseases	Diabetes mellitus	Hypertension	Other problems in men health
Balanced	107,3±11,7	22,7±5,6	188,3±14,7	804,8±14,8
Unstable	129,6±20,4	--	-	-
Anxious	201,5±35,5	20,0±7,0	253,1±21,6	1320,1±57,2
Total	123,9±9,9	21,7±4,4	211,9±12,3	991,8±2,8
χ^2	4,86	0,08	6,43	125,7
Q orC	Q= 0,200	–	Q = 0,187	C = 0,318
P	<0,05	>0,05	<0,02	<0,01

χ^2- dispersion index; C- Pearson rank correlation coefficient; Q- the Yule association coefficient; P- authenticity.

Table 1 showed that frequent emotional suffering in childhood and youth years have negative impact on their adult health. On one side, if the childhood was without stress factors, the frequency of chronic diseases was only 107, 3‰. On the other side, when male children have a lot of stress in childhood the number of diseases - 201, 5‰ (Δ=87, 8%, P<0, 05). The frequency of hypertension comprises 188, 3‰ and 253, 3‰ respectively, then more than (Δ=34, 5%, P<0,02). Moreover, the number of other health problems were 804, 8‰ and 1320, 1‰ respectively in previously mentioned groups, then more than (Δ=64, 0%, P<0, 01). This factor does not influence on the increased frequency of diabetes mellitus.

Male behavior is a serious factor, which correlates with the premature increase of mortality and morbidity indicators. Approximately half of male death cases can be prevented by changing the model of individual behavior. Results of the last cohort investigations, statistical data, meta-analyses showed that boys and men chose behavioral strategies leading to morbidity, injury and death [5]. Boys and men have become victims of physical violence. Around 50% men are injured by other men in majority cases [6]. Violent attitude to boys in age from 12 to 19 years on 50% often then the same to girls. According to official statistics in the USA, men have traumas often than women to two times. Some reports showed that in 12% adolescents were violated in physical and moral ways [7].

Table 2. Influence of negative events from childhood on their health level in adulthood. There is the frequency of some diseases and other problems with Crimean men health depending on negative consequences in their life.

Unfavorable cases in life	Cases amount1000 persons			
	Chronic diseases	Diabetes mellitus	Hypertension	Other problems in men health
Burns	130,4±40,5	0	194,4±46,6	985,7±14,2
Drowning	122,8±43,4	0	229,5±53,8	935,5±31,2
Domestic traumatism (injury fracture of hands, legs)	92,8±20,8	(20,6±10,2)*	190,5±28,6	836,8±26,8
Road and traffic accidents/car accidents	141,3±36,3	(32,6±18,5)*	241,7±44,9	1054,9±107,7
Sports injury	101,9±21,1	(13,7±8,1)*	183,6±26,9	893,7±21,4
Trauma in the fight	120,8±26,7	(14,8±9,9)*	203,9±32,7	967,1±14,5
Autoaggression	109,6± 25,8	(20,5±11,7)*	210,1±34,7	1101,4±89,3
Domestic violence	150,0±39,9	0	151,7±39,8	1234,6±123,4
Peer physical violence	116,8±27,4	(21,9±13,3)*	226,3±35,7	1087,6±31,3
Total	115,4±9,4	22,7±4,4	210,7±12,1	997,4±1,5
χ^2	14,82	4,55	29,64	117,17
C	–	–	0,159	0,305
P	>0,05	>0,05	<0,01	<0,01

χ^2- dispersion index; C – Pearson rank correlation coefficient; Q - the Yule association coefficient; P – authenticity; *- a tripled error exceeds the indices

Data from table 2 describe that stressful situation in lives of respondents produce negative consequences, which decreased male health level in different ways. The frequency of chronic diseases respondents were not connected with stressful events in the past. In average their numbers were registered in 115,4‰ and have deviation from 92,8‰ of fracture hands and legs to 150,0‰ of violence in childhood, however differences between these indices were not reliable (P>0,05). Correlation with these factors and diabetes mellitus was not detected (P>0, 05). Meanwhile the frequency of hypertonic diseases was considerably presented (p<0, 01), but (Q=0,159) depended on stressful events. It varies from 151, 7‰ of domestic parent's violence to 241, 7‰ of car accidents. Considerable impact on this factor (P <0, 01; Q=0,305) shows the development of other health problems. It deviates from 836, 8‰ of hands and legs fracture to 1234, 6‰ domestic parents' violence.

Discussion

It envisages that a psychophysiological reaction after emotional stress is connected with angina pectoris [9]. Investigation proved that men recover slowly after stress. This can partly explain high level of cardiological diseases, especially angina pectoris. Systolic blood pressure reactivity was more notable in men then in women. Autonomic nervous system activation and following cardio-vascular system answer discussed like one of the main mechanism stress impact on physical health. Furthermore, strong evidences of correlation between stress and immune system were presented in search papers [8]. New findings suggest that children exposed to stress mature into adults with altered corticolimbic responsively to emotional stimuli. These individuals also tend to be vigilant for threat and mistrusting of others. They engage others in a manner that leads to abrasive exchanges and makes it difficult to garner social support from others. They have persistent difficulties forming and keeping close social ties [10]. Nevertheless changing in pathophysiological reactions on emotional stress was detected extremely difficult, but behavioral and situational factors are easy to change [9].

Research reviews prove that basis of human health were formed in childhood and depend on grownup and development conditions. According to our analysis the leading position among male health risk factors were stress factors in childhood and adolescent period of their life. If we eliminate stress factors, frequencies of different health problems in Crimean men would decrease by 19%. It is important to note that 322,

1 Crimean man was influenced by aforementioned factors. We suggest that childhood adversities give rise to lifelong behavioral proclivities, like vigilance for threat, poor social ties, ineffective self-regulation, and unhealthy lifestyle choices. These proclivities lead to frequent activation of the body's stress– response systems, creating a hormonal milieu that requires adaptations by the immune system. Ultimately, these adaptations serve to exacerbate the pro-inflammatory tendencies already programmed in cells by childhood stress [11]. For instance similar research was conducted in 2017, a composite measure of threat of victimization that includes three components; cognitive (perceived risk), emotional (stress) and behavioural (precautionary behaviour) which they consider to be important in the measurement of health problems in men [12].

Various scholars have argued that the relationship between stress factors and health is complex as it includes direct and indirect effects. For instance, higher levels of stress might increase heart rate, leading to cardiovascular effects; higher levels of stress can, however, cause physical inactivity (through avoidance of outdoor activity), which may negatively influence individual health and overall well being in men [13,14]. There was a study based on a large sample of men, and used validated instruments [15, 16] to collect an array of social, demographic and health-related states. The outcome variables self-reported health and self-reported stress are well validated within the Health and Equal Terms survey [15, 16].

Conclusion

Influence of stressful events in childhood, on male health was proved during our research work and, as result, can give us innovative conclusions, which possibly resolve main issue connected with this topic.

Firstly, males without childhood problems have low level of chronic diseases in adult life. It is on 87, 8% less than in other respondents (P<0, 05). Moreover, the frequency of hypertonic disease less by 34, 5% (P<0, 02); the number of other health problems less by 64, 0% (P<0, 01).

Secondly, in adulthood the frequency of hypertonic diseases has low level correlation with negative events(Q=0,159); at the same time the frequency of other problems with health deviated from 836, 8‰ of hands and legs fracture to 1234, 6‰ of parents violence.

The current findings prove that male health of Crimean region was influenced by stressful factors and the elimination of this affect possibly can improve male health in general way. It is important to note that the significant problems with male health were because of up gradable factors. The suggested solution for resolving such issues is modification of behavioral habits, life style and prophylaxis against development of risk factors.

Assessing Local Issues Related to Drug Used Behavior among Students in Makassar

Shanti Riskiyani[1,2], Sabarinah[3]

[1]Doctoral Student of Public Health Faculty, Universitas Indonesia, Depok, West Java, [2]Lecturer of Public Health Faculty, Hasanuddin University, Makassar, South Sulawesi, [3]Lecturer of Public Health Faculty, Universitas Indonesia, Depok, West Java, Indonesia

Abstract

Out of 100 students there are 4 students who have been using drugs, three students are using drugs in the past year, and 2-3 students in the past month. The first time using drugs appears to be getting younger from year to year(1).A school-based program for young people are more effective, because most of the students spend their time in school. A local issues related to drug-used among students became a crucial to considered in developing prevention program for young people. Three FGD among students and stakeholders performed in this study to gathered an information about drug-used behavior among youth.

Findings of this study shows that being popular in school is one motif to doing bullying and harassment in school. Calling friend with his/her fathers name became a beginning of bullying. Consuming drugs, like analgesic is a common situation among youth in school. Even thereis a punishment in school, not every student could be in a teacher supervision. However, most student choose to be good in academic rather than popular. Popular students identic with negative attitude, image and social life.A prevention program for youth in school should be suitable for young people and accommodate an update and local issue associated to their behavior including using drugs not for medical purpose.

Keywords: Drug-used, student,local.

Introduction

In Indonesia, it is projected that approximately 1.2 million students use drugs and 31 thousands of them are in South Sulawesi. The prevalence of people who use drugs is higher for senior high school especially male students(2,3). Provincial National Narcotics Board on their monitoring and evaluation report shows that most of the prevention program doing in senior high school and university. Therefore, this study held on junior high considered that the prevalence rate of people who use drugs is increase among age 10-19 years old from 0,7% (2010) to 0,9% (2015). Moreover, some research says that an effective school-based intervention had to be done to 2nd grade student in junior high school, also considering that 13-19 years old was the first time of people using drugs(4,3).

A qualitative study in Jakarta and Makassar on junior high student shows that prevention program in Jakarta must have more creative and varies media for students in Jakarta. While students in Makassar prefer to had a new method on drugs education. The strategy of providing information with a one-way communication model is considered unattractive and boring for students. In addition, the information also had to consider the current situation and conditions of drug use in Makassar(5,6).

Several studies show that the implementation of a program which considering a social context such as students family condition or culture is proved in improving the effectiveness of drugs prevention activities in school(7,4). Furthermore, local culture or values are a strong factor in a process of adaptation

e-mail : shantiriskiyani@gmail.com

of an innovation. Employed components of social factors in the curriculum is also considered to be very influential on behavior change, compared to programs that not consider the social conditions of the program objectives[8,9].

In addition, knowledge, skills and availability of facilities are also supporting factors in a process of introducing a new behavior. Considering the social situation and values in the community is also important to had a context of the process[10]. A combination of knowledge and skills about drugs would be a supporting factor in building self-awareness. Likewise, the ability of students to interact with their environment and avoid themselves from the risk of using addictive substances is important to be included in a prevention activity[11].

Program implementation for adolescents is relatively more effective and easy to do in a school-based. Most of their times was spend in school, so teachers should be involved to preparing a strategy in developing good information for students. Furthermore, networking with community organizations or health facilities is a good breakthrough, especially if schools are faced with students who had problems with drug use[12,8,13,7,14].

The objective of this study is to gathered and describing a local issue and updated drug-used behavior among young people in Makassar. Findings of this study will be base-line data for developing an instrument for interventions program to educate students to had an ability in facing drugs misuse behavior.

Materials and Method

Data of this study collected from 2 focus group discussion (FGD), conducted with students from two different schools and 1FGD with stakeholders. First school is located in urban area of Makassar and the other school is in rural area. We choose two schools with a similar status; they are a public school with no accreditation. The participants of the two FGD are students from 2nd grade. They were recruited by their teacher after we explained the objective of this study. The participants came from different class and also had a variety in after-class activity. Participants of FGD among stakeholders, recruited because of their knowledge and expertise related to education for junior high students and their activities associated with drugs prevention in Makassar. All discussions were recorded and conducted in Indonesian.

We employed a thematic approach to analyze FGD transcripts, then coded and categorized to thematic classification[15].Procedure of ethic was performed to get a consent from the participants by informing all the participants about the objective of this study and the confidentiality applied by not using their real name. This study also already had an ethical approval from The Researchand Community Engagement Ethical Committee Faculty of Public Health University of Indonesia.

Findings

Characteristic of FGD participants: A focus group discussion performed to get a local context of drug-used behavior among young people in Makassar. In this event, we discussed about the perception of became popular, perception of bullying, perception of addiction and knowledge around drugs and addictive substances.

Table 1. Characteristic of FGD Participants in Junior High School "A" Makassar

No	Name	Gender	After School Activities	Grade
1.	Eri	Female	National Flag Ceremony Troop	II-4
2.	Ani	Female	Student Guild	II-3
3.	Dadang	Male	Islamic Organization	II-2
4.	Mustafa	Male	Football	II-8
5.	Amir	Male	Football	II-6
6.	Oki	Male	Scout	II-7
7.	Sarif	Male	National Flag Ceremony Troop	II-1
8.	Anita	Female	Student Guild	II-6
9.	Ayu	Female	Youth Red Cross Organization	II-5
10.	Nini	Female	Youth Red Cross Organization	II-9

In Junior High School "A", FGD performed for two hours and it was going fruitfully especially when we discussed about drugs including all the over-counter drugs. Our discussion also accompanied by a teacher of student affairs.

Table 2. Characteristic of FGD Participants in Junior High School "B" Makassar

No	Name	Gender	After School Activities	Grade
1.	Rita	Female	Student Guild	2nd-6
2.	Anya	Female	Student Guild	2nd-2

3.	Rianti	Female	National Flag Ceremony Troop	2nd-2
4.	Rani	Female	Scout	2nd-3
5.	Hanafi	Laki-laki	Scout	2nd-3
6.	Arya	Laki-laki	Student Guild	2nd-3
7.	Fahrul	Laki-laki	National Flag Ceremony Troop	2nd-6
8.	Asyanti	Female	Youth Red Cross Organization	2nd-2
9.	Nana	Female	Youth Red Cross Organization	2nd-2
10.	Tati	Female	Scout	2nd-2

In school "B", our discussion take place in library for 2 hours without any teacher around us. Most of participants is female students and sometimes became dominanton discussion. When we are talking about bullying, female students had more experience become a victim of the perpetrator. While male students often become perpetrator than a victim, except those who are smaller or weaker than others.

Table 3. Characteristic of FGD participants among stakeholders

No	Name	Gender	Institution
1.	Uni	Female	Head of Local Boarding School (Education Practitioner)
2.	Rani	Female	Psychologist
3.	Hartono	Male	Provincial Narcotics Board
4.	Randy	Male	Counsellor of Addiction
5.	Rini	Female	Local Family Planning Office
6.	Amri	Male	Department of Psychology, Universitas Negeri Makassar

Inviting all the participants for this FGD, was a long process because we had to rely on their schedule then finally choose a proper date to have a discussion with them. We agreed to had a discussion in one working space downtown so everybody could reach that place easily. After giving a brief explanation about the topic which we'll be discuss, we started the FGD with asking about their perception about young people's lifestyle. Our discussion going very well because all of participants was very updated with young people's life particularly student activities and their behavior related to drug misuse.

Perception on gaul (a slang group among youth) and bullying: Being accepted, famous and popular among friends was identic with *anak gaul* terms. Became *anak gaul* sometimes had to passed a particular process that applied by some students in school. A negative behavior such *malak* (asking for some money to others with violence) was a common practice in school. Taking picture with sexy clothes then published it in social media also one of the characteristic being *anak gaul*. Even being *gaul* will make them famous and popular, some participants choose to be an ordinary student rather than being *gaul*. They prefer had a normal social life, not too popular in school but had a good reputation in academic report.

Among girls, there was a term named *anak rawanggang* (a female student who didn't good in academic and sometimes makes trouble in school). Most of them coloring their hair, modified their uniform so it looks fashionable (short skirt, slim-fit blouse and tighten their skirt). *Anak rawanggang* also a part of being 'gaul' in school and in teenage social life. *Anak gaul* also identic with having a not-cooperative behavior related to relationship with their parents. Many of *anak gaul* had a problem in school and should attending a counseling session with counsellor in school. In Makkasar language, words *rawangngang* used to describe a place located lower than the other. Thus, life of *anak rawangngang* believed byother student as a condition with a lot of problem and bad attitude; not better with other students who is not *gaul*.

Other phenomena among young people life's is bullying and it was another way for being popular or admitted between young people. In this study, bullying is calling others by using a harsh word or their parents name. When bullying then became a fight, teacher from counselling affairs will ask the student to had their parents in school. Parents-teachers meeting will look at for solution and there will be consequences for students who involved in a bullying situation. A study that examine experience of bullying among Swedish students show that it is a common behavior between student and it also associated with abuse. Still, actor of bullying are also reporting as a victims of bullying and violence[16].

Information on addictive substance and perception on addiction: Most informants more familiar with drugs term than addictive substance. They are aware that some students consumed soft drink with the over-counter drugs to get fly. Addiction also known as a behavior of using marijuana and an amphetamine type-stimulant (ATS)known as *sabu-sabu*.

Table 4. Types of Substances Recognized by Informants

Substances	Price/pcs	Details
Tramadol	Rp 3,000 – Rp 5,000	Mix with soft drink
THD	Rp 20.000 – Rp 30.000,-	
Dobol (double) Y	Rp 10.000 – Rp 20.000,-	Mix with energy drink
PCC	Start from Rp 2,000	No logo on the tablet
Somadril	Rp 5,000	
Ganja	Rp 15.000 – Rp 20.000	
Cigarette	Rp 1,500	
Ballo' (a local alcoholic beverages)	Rp 10,000 per liter	Sometimes free

From discussion with students shows that it was easy to get drugs in school. They even know who is the seller and how much the price. The seller also came from other school, sometimes students from senior high. From **Table. 4** we can see the price is very cheap and they even mix their drugs with soft drink or energy drink. According to NNB survey report in 2017, there are approximately 3 million people in age 10-49 years old using drugs. Twenty four percent of them are students. The over-counter drugs and analgesic are types of drugs that being favorite. A study about chemical used in South Sulawesi shows that program on harm reduction which is implemented in this province not really focused on chemicals that are not narcotics but they are available in market and easy to get[17,18].

Social life: Nowadays, student facing many challenge in their daily life. They had to get a good grade for every subject in school. Being smart in academic is another way to make parents proud. Furthermore, going to school with good looking outfit and accessories also another thing to accomplished. Student with great look, fashionable outfit and had a latest gadget would be acceptable in every group or *gang* in school. A competition among students sometimes become negative activities such as bullying, smoking, drinking and using drugs. Even it was not a narcotic, consuming drugs excessively is already common issues among junior high student. Those activities happen when they are in a birthday party, in a hang-out place, and sometimes in school. Interaction between with students from senior high often become an introduction to new behavior including drug taking.

From **Table. 1** and **Table. 2** most of the students prefer to had a physical activity rather than being a member of a science group or student guild as their extra-curricular. In sport- activities they thought had more chance to exist and being accepted among their friends. Most of the informants believed that group activities is more fun and enjoyable. Some studies indicated that students who participated in extracurricular activities had higher grade point averages than students who didn't[19-21].

Conclusion

In a local context, drugs term is more familiar rather than addictive substance. Most of the students already know and seen a drug-used practice in their environment. Mixing drugs with soft drink or energy drink become a common practice among students. A competitive environment was deliberately employed in school just to meet several targets to get an award as 'The Best' school in town which is labeling by local department of education. School with many trophy from several student-competition bring proud to the teachers and at once had a great image in society.

Abstract

The prevalence of fall increases with increasing ages. Falling is significant health problem in elderlyand the risk increases significantly when they have chronic diseases such as, cardiovascular diseases, metabolic problem, urogenital diseases, digestive diseases, respiratory diseases, musculoskeletal and malignant diseases. elderly also vulnerable on suffering multiple chronic illness. This study aimed to identify the influence of multimorbidity to the incidence of fall in elderly.

A cross sectional approach was used for this research, and, based on simple random sampling, a total of 427 elderly individuals (>60 years old). The data collection was based on the use of one set of questionnaires consisting of the demographic characteristics (age, gender, education background and economic status), the list of fifteen common chronic illness including suffered by the elderly as the risk factor for fall, and the incidence of fall within the las 12 month as the outcome.

This study demonstrated that fall incidence among the elderly is significantly linked to the presence of chronic illness. The number of chronic conditions is significantly influencing the incidence of fall among elderly. The elderly who have more than two of chronic illness likely to have fall 2 times higher that those who have less than two chronic illness.

Keywords: *Chronic illness, multimorbidity, elderly, fall.*

Introduction

The number of older persons (those aged above 60 years old) in Indonesia is expected to increase to 28.8 million (11% of the total population) in 2020, and 80 million (28.68%) in 2050 . Life expectancy from 66.7 years in 1990 to 70.5 years in 2015, would increase to 71.9 in 2025,and 72.8 in 2045[(1)]. The increasing number of the elderly in Indonesia is followed by the increasing number of non-communicable diseases[(2)]. Moreover, elderly is at a high risk of suffering from disability and dependability that increase the burden of the elderly and decreasing their quality of life.

The increasing number of elderly population presents special challenges in the health sector with the emergence of degenerative problems and non-communicable diseases (NCD'S) such as diabetes, hypertension, and mental health disorders namely depression, dementia, anxiety disorders, and insomnia[(3)]. On the other hands, the elderly also vulnerable on suffering chronic illness such as, cardiovascular diseases, metabolic problem, urogenital diseases, digestive diseases, respiratory diseases, musculoskeletal and malignant diseases. Multimorbidity is often defined as the presence of 2 or more chronic co-occurring conditions[(4,5)]. Although this is the formal definition, most clinicians consider multimorbidity to be particularly vexing when it involves a broad array of conditions and is also accompanied by functional limitations, cognitive impairment or mental health concerns, as well as interactions between the conditions themselves and their treatments. Multimorbidity is associated with a number of negative health outcomes, including accelerated declines in functional status, increased symptom burden, reduced

quality of life, and mortality[5]. The increasing number of chronic conditions puts older adults at a higher risk of hospitalization and placement in nursing homes.

Cardiovascular diseases is one of the chronic condition that linked to multimorbidity situation. Aside from the chronic condition itself, the medication for cardiovascular diseases may increase the risk of fall. One of the most common symptoms is hypertension that treated with antihypertensive medicines. National record for Hypertension showed that the only 60% of recorded hypertensive cases are currently taking medication[6]. Approximately 40% of hypertensive person are irregularly taking hypertensive medication. This situation can lease a postural hypotensive side effects that are at risk of falling.

Physiologically, elderly experience physical changes in musculoskeletal such as decreased muscle strength, especially the lower extremities, endurance and coordination as well as limited range of joint motion [7]. Weakness of the lower limb muscles can cause disturbance in the body's balance, resulting in slowness of movement, short strides, feet not tread strongly, and late anticipation when slipping or tripping. This condition can increase the risk of falling in the elderly.

Elderly people face weaknesses, limitations and disabilities that increase the risk of fall. Fall-related injury in older adults has been recognized as a major public health issue. Risk factors for falls include muscle weakness, a history of falls, use of four or more prescription medications, use of an assistive device, arthritis, depression, age, gender, and impairments in gait, balance, cognition, vision, and activities of daily living [8].Main characteristic of the elderly is experiencing several symptoms due to aging. The multifactorial health conditions that occur when the accumulated effects of impairments in multiple systems of elder person vulnerable to situational challenges called geriatric syndrome. One of the most common complaints at the geriatric syndrome is falling [9]. Fall is not an illness but an accident that results in disability in old age. Falling is the second leading cause of death due to injuries or accidental injuries worldwide([10]). Every year, 24,000 people die from falling globally and 80% are in low to middle income countries[11]. Old people aged 65 years and over are the main sufferers of fatal falls. The elderly must be prevented from falling by identifying risk factors. In principle, preventing falls in the elderly is very important and more important than cure.

A study on the risk factors for falling in older people shows that certain health conditions and impairments contribute independently to the risk of falling or experiencing a fall injury[12]. Falls and chronic disease are both important health issues in older adults. This study aimed to identify the number of chronic diseases suffered by the elderly, here in after multimorbidity as the risk factor of fall.

Method

This study using cross sectional approach with the primary outcome was self-reported falls in the previous twelve months (binary: yes/ no). We also include socio-demographic characteristics including age (for 60-69 age group and 70 or more age group), gender, education background (obtained formal education and not obtained a formal education), economic status (whether they have fixed income or not having a fixed income), living places (living in community or living in elderly home). In order to measure multimorbidity, we included fifteen frequently reported chronic diseases (hypertension, cardiovascular diseases, chronic obstructive pulmonary disease (COPD), stroke, diabetes mellitus, depression,chronic gastritis, cancer, osteoporosis, Parkinson diseases, vision impairment, urinary problem (urgency, incontinence), constipation, Osteoarthritis, and hearing loss[2,6]. The status of the chronic condition of the illness listed in the interview questionnaire was based on a diagnosis from a health professional. Presence or absence of each condition as well as total number of conditions was calculated. Those who have more than 2 diseases categorized as Multimorbidity.

The sample size calculation for the logistic regression analysis was based on Van Voorhis and Morgan[13]. The overall model is $50 + 8k$, where k is a number of independent variables and an analysis for the individual variables model is $104 + k$. In this study, the overall model sample size was $50 + 8 \times 6 = 98$, and the overall was $104 + 6 = 110$. Thus, the minimum sample size for this study was 110 per model. Thus, the minimum sample size was $98 \times 4 = 392$. Additional 10% of cases were collected to prevent any missing data with total 431 targeted study participants. This study was conducted from July to October of 2018 in Yogyakarta, West Java and Jakarta provinces.

Written informed consent was obtained from the participants before their start of the study. The study was approved by the Ethical Committee of Faculty of

Public Health, University of Indonesia, Indonesia. The approval number is 125/UN2.F10/PPM.00.02/2018.

Results

A total of 427 out of 431targeted study participants are involved this study with response rate 98%. The average ages of the study participants are 73 years old with minimum age 60 years old maximum 102 years old, SD ±10.12.

Table.1 Sociodemographic characteristics of the study participants

Variables	Categoric	n	Percentage
Ages	>70	242	56.7%
	<70	185	43.3%
Gender	Female	290	67.9%
	Male	137	32.1%
Living place	Elderly home	213	49.9%
	Community	214	50.1%
Education	With formal education	210	49.2%
	Without formal education	217	50.8%
Economic condition	Without fix income	333	78.0%
	With fixed income	94	22.0%
Multimorbidity	No	168	39.3%
	Yes	259	60.7%

More than half of study participant are above 70 years old. 67.9% of them are female, 50%of them living in elderly home and 50.8% of them are educated in formal school, and 78% of them having no fixed income. 60.7% of the study participants are having more than 2 chronic illness herein after identified as multimorbidity.

Table.2 Chronic condition and the incidence of fall

Condition	Prevalence Weighted %	% people with condition with fall	% people with condition without fall	p value
Hypertension	44.7%	14.3%	30.4%	0.235
Cardiovascular diseases	7,3%	1,6%	5,6%	0.537
COPD	11.0%	3.5%	7.5%	0.722
Stroke	3.7%	1.2%	2.6%	0.843
Diabetes mellitus	10,8%	3,3%	7,5%	0.825
Depression	74,9%	19,7%	55,3%	0.028*
Digestive problem	25,5%	8,9%	16,6%	0.121
Cancer	0.9%	0.2%	0.7%	0.824
Osteoporosis	9,8%	3,5%	6,3%	0.316
Parkinson	4.9%	1.2%	3.7%	0.766
Vision impairment	24.1%	10.2%	13.9%	0.001*
Urinary problem	10.1%	4.0%	6.1%	0.110
Constipation	11,7%	5,2%	6,6%	0.012*
Osteoarthritis	58.3%	19.9%	38.4%	0.006*
Hearing problem	21.5%	8.7%	12.9%	0.008*

Table.2 described the prevalence of the chronic condition and fall. Depression is the highest chronic illness suffered by the elderly by 74,9% and 19,7% of the elderly with depression are falling in last 12 month ($p<0.05$). Osteoarthritis is the second the chronic illness suffered by 58.3% of the elderly and independently correlate with the incidence of fall ($p<0.005$), whereas 19.9% of the elderly with Osteoarthritis are experience of falling within the last 12 months. Moreover, vision impairment (24.1%), Hearing problem (21.5%) and constipation (11.7%), also significantly correlate with the incidence of fall ($p<0.05$).

Table. 3 Predictor model for Multimorbidity adjusted to sociodemographic characteristics

Variables	B	Wald	Sig.	Exp (B)	95% Confidence Interval	
					Lower	Upper
Ages	0,650	7,057	0,008	1,915	1,186	3,093
Gender	0,580	4,950	0,026	1,786	1,072	2,978
Multimorbidity	0,815	11,536	0,001	2,260	1,412	3,618
Living place	-0,339	1,740	0,187	0,712	0,430	1,179
Education	-0,234	0,987	0,320	0,791	0,499	1,256
Economic condition	0,079	0,063	0,802	1,083	0,582	2,014
Constant	-1,962	24,062	0,000	0,141		

Prediction model analysis showed that ages, gender and multimorbidity are the predictor for the incidence of fall among elderly. Whereas Incidence of fall; logit(p) = -1.962 + (0.650 × ages) + (0.580 × gender) + (0.815 × multimorbidity). Those who are above 70 years old likely to fall 1.9 times higher than those under 70 years old. Male elderly are 1.78 times at risk to fall compare to female elderly, those who have multimorbidity have 2,26 times higher risk to fall compare to those who have not.

Discussion

This study demonstrated that fall incidence among the elderly is highly linked to the presence of chronic disease. The number of chronic conditions is significantly influencing the incidence of fall among elderly. The elderly who have more than two of chronic illness likely to have fall 2 times higher that those who have less than two chronic illness. Importantly, both number and type of chronic condition played a role in falls. Several chronic condition such as Depression, vision impairment, constipation, Osteoarthritis and hearing problem are independently correlate with the incidence of fall. This study also identifies gender and ages as the risk factors of fall in elderly. Female elderly are likely to have twice risk of fall, and those who ages more than 70 are likely to have fall compare to those younger.

This finding is in line with the previous study, which proved that the incidence of fall are increase with the number of chronic medical conditions [(14)]. Although chronic diseases are commonly suffered by the elderly, suffering from two or more chronic diseases, will becomeanother burden for both physically and psychologically. Aside from physical and psychological burdens, suffering from more than two chronic illness can make the elderly weaker and frailer. Not to mention the medication for some chronic illness that may cause orthostatic hypotension or dizziness. This condition can increase the risk of occurrence of falling the elderly. Therefore, further observation is needed regarding the increasedrisk of fallingfrom antihypertensivemedication. This medication consumption can be associated with an increased risk of falling events compared to the absence of antihypertensive consumption [(15)].

The elderly Age was an independent risk factors for falls. In this study, we found that increasing age increased the risk of falls in the elderly by 1.9 times and that elderly with advancing age (over 75 years) had higher odds of falling than the younger elderly (<70 years old). Age is one of the key risk factors for falls in elderly [(16)]. Older people have the higher risk of death or serious injury arising from a fall and the risk increases with age. As the elderly get older, they have a tendency to experience frailty and muscle weakness, that may increase the risk of falling. This result indicates that a variety of effects of aging increase the risk of falling [(17)].

This study also identified gender as the predictor of fall, whereas male elderly likely to fall 1.7 times higher compare to female (OR : 1.76 (95% CI 1.072 – 2.978)). WHO revealed that across all age groups and regions, both genders are at risk of falls(16).However, in this study as it is found in some other countries, male are more at risk than female and it has been noted that males are more likely to die from a fall, while females suffer more non-fatal falls[(11).] Possible explanations of the greater burden seen among males may include higher levels of risk-taking behaviours and hazards. Another explanation is that the effects of chronic diseases differ between men and women[(18,19)]which will have an impact on the body's response in dealing with the chronic illness and ultimately affects weakness and frailty which has implications for the risk of falling.

As the surveywas cross-sectional, cause-and-effect cannot be determined.All variables were derivedfrom self-report data, notobjective measures. Falls were identified by retrospectiverecall over the previous twelve months.Our analyses relied on self-reported data, which are potentially subject to recall bias and misclassification. It is also possible that the recall of falls was underreported because of difficulty remembering, which is a particular concern in an older population.

Conclusion

This study confirms that multimorbidity was markedly related to falls in the elderly and increased the risk of falling. In addition, a low education level, the use of a walking aid and receiving care from caregivers were riskfactors that contribute to falls in geriatric patients. This situation requires an integrated patient-centred rather than disease-centred approach. The majority of chronic diseases of these multimorbid elderly patients are fall within one year.Therefore, it is important to study the risk association between comorbidity and falls. Further research should focus on monitoring the elderly with risk factors of fall and aims to develop effective prevention and intervention measures, which can be

applied and improve the quality of life of older adults in the community.

Conflict of Interest: The author declare that this study has no potential conflict of interest.

Impact of Serum Apolipoprotein B Measurements on the Risk Management of Atherosclerotic Cardiovascular Disease

Tahrir Etihad Kadium[1], Lewai S. Abdulaziz[2], Abdulhadi Alrubaie[3], Omar J. Ahmed[4], Wail A. Abd Al-Hassan[4]

[1]Lecturer, Dept. of Clinical Biochemistry, [2]Assistant Prof., Dept. of Clinical Biochemistry, [3]Assistant Prof. Head of Obesity Research and Therapy Unit. Alkindy College of Medicine, University of Baghdad, [4]Fourth Grade Medical Student, Iraq

Abstract

Background: Studies have indicated that serum Apolipoprotein B (Apo B) was superior to LDL-C and Non-HDL-C in risk management of Atherosclerotic Cardiovascular Disease (ASCVD).

Objectives: The present study was designed to explore the impact of introducing serum Apo B measurement as an additional target, on antilipidemic treatment policy.

Methods: Patients attended the obesity research and therapy unit (ORTU), besides staff and undergraduate students at Al-Kindy College of Medicine, were participate in this cross-sectional study. Lipid profile and Apo B analysis were performed. Participants were stratified according to the classic major ASCVD risk factors endorsed by guidelines.

Results: Comparing (75) obese to (36) non-obese subgroups, significant differences were demonstrated in lipid profile parameters ($P< 0.05$). Serum Apo B levels were evidently higher in obese patients, ($P> 0.05$). In multiple regression model, Non-HDL-C was the only significant independent predictor of serum Apo B levels. According to guidelines, serum Apo B was a treatment target only for (9) patients. When serum Apo B was introduced as a third treatment target, additional antilipidemic treatments were need to be initiated in (36) out of the (69) participants already achieving treatment targets.

Conclusions: Introduction of Apo B measurement in the management of ASCVD increases the number of patients in whom antilipidemic treatment should be initiated. The extent of this increase is partially determined by the discordance rate between Apo B and LDL-C in the studied population.

Introduction

Atherosclerotic cardiovascular disease (ASCVD) is the leading cause of death worldwide, as coronary heart disease, stroke, and peripheral arterial disease.[1] Lowering Low Density Lipoprotein Cholesterol (LDL-C) has been shown to decrease the risk of ASCVD and mortality. Patients who are inadequately treated, or responded poorly to treatment, were reported to have increased ASCVD risk and suboptimal prevention.[2] Cumulative evidence from studies has described an altered composition of Low-Density lipoprotein particles (LDL-P) in the presence of elevated Triglycerides (TG).[3] In such condition, measurement of the altered LDL-C levels may underestimate the LDL-P, and the atherogenic burden. In such patients the achieved LDL-C targets may not fully reflect the residual cardiovascular risk conferred

by the actual LDL-P burden. In presence of high TG (200–499 mg/dl), the Adult Treatment Panel III (ATP III) has recommended Non High-Density Lipoprotein-Cholesterol (Non-HDL-C), as an indirect estimate of Apolipoprotein B (Apo B) particles.[3] Recently assays for Apo B, and its concentrations should be considered as a better surrogate for LDL-P, than Non-HDL-C.[4] Several studies have indicated that serum Apo B was superior to LDL-C and Non-HDL-C in the management of ASCVD risk, this view lacks a generalized full acceptance.[5-10] Moreover, discordance between population for achieved LDL-C, Non-HDL-C and Apo B targets was reported by many therapeutic studies, illustrating how patients with optimal LDL-C levels may still be at high risk of CVD events secondary to an undetected high LDL or Apo B particles number. Suggesting that achieving optimal or near optimal Apo B levels could result in more effective prevention of cardiovascular events.[11]

Since 2008 and despite this controversy, the combined consensus statement by the American Diabetes Association (ADA) and American College of Cardiology (ACC) panel recommended and provided risk- specific cut-offs for both Apo B and Non-HDL-C, to be considered as treatment targets.[8] The above panel also stated that the two measurements are highly correlated, but with some discordance in patients with hypertriglyceridemia. Thereafter, the statement from the American Association of Clinical Chemistry (AACC) Lipoproteins on Best Practices has addressed similar recommendations.[6]

The Expert Panel of the National Lipid Association (NLA) suggested aggressive Apo B targets of <70 mg / dl, in contrast to ADA/ACC and AACC recommendation of (<80 mg/dl) in patients with very high cardiovascular risk.[12] The most current guideline issued by the American Association of Clinical Endocrinology (AACE) recommended a similar optimal Apo B value of (< 70 mg/dl), only for patients with extreme risk. Two optimal level suggested for very high and high risk (<80 mg/dl and <90 mg/dl, respectively). Yet; no Apo B targets were recommended for moderate and low risk categories.[13]

Aim of the study: the present study was designed to explore the impact of introducing serum Apo B measurement as an additional target, on antilipidemic treatment policy, in terms to initiate treatment in patients already achieving the optimal LDL-C and Non-HDL-C, by the latest AACE guidelines.

Subjects and Methods

Study Setting and Participants: Patients attending the Obesity Research and Therapy Unit (ORTU), staff and undergraduate students at Al-Kindy College of Medicine, were invited to participate in the present cross-sectional study. Inclusion criteria were history of hypertension, type 2 diabetes, obesity and smoking. Exclusion criteria was history for use of antilipidemic medications, renal, liver and infectious diseases. Pregnant females were excluded. According to the classic major ASCVD risk factors by AACE guidelines[13], participants were stratified into five categories designated as: extremely high, very high, high, moderate and low risk.

Biochemical Assay Methods: Fasting venous blood sample was obtained from participants. The routine lipid profile and Apo B analysis were performed on serum samples by readymade kits (Human Diagnostics-Germany) using Optizen kinetic spectrophotometer (Mecasys Co. Ltd, Korea).

Non-HDL-C is calculated as = TC - HDL-C [14] and LDL-C is calculated using the Friedewald equation.[15] Framingham risk score for Coronary Heart Disease[17] was applied using online calculator.[18]

Concordance and Discordance between serum Apo B with LDL-C and Non-HDL-C Levels: Framingham Offspring study databases[6] were used to determine the discordance between levels of Apo B, LDL-C, and Non-HDL-C.

Impact of Apo B measurement on Treatment Policy: The levels of serum LDL-C and Non-HDL-C treatment targets proposed by the AACE management algorithm[13], and position statement from the AACC Lipoproteins [6] were taken as Medical decision cut points identifying the need to initiate antilipidemic therapy.

The scenario was redone, adding the serum Apo B levels as the third medical decision cut point.

Statistical Analysis: Participants were divided into two subgroups according to BMI cut point of 30 kg/m^2, and all statistical tests were conducted for both subgroups. Concordance and discordance results were expressed as frequencies and percent. Statistical significance was determined using chi square test. Independent *t*-test was performed to compare variables, and linear multiple regression models were used to explore any significant contribution of independent variables on serum Apo B

levels. All statistical procedures performed by statistical package SPSS version 17.0 (SPSS, Inc.).

Results

A total of (111) Eligible participants were enrolled in the present study, (75) were classified as obese and (36) were non-obese. As illustrated in Table.1, significant differences were demonstrated in lipid profile parameters (P<0.001). Although serum Apo B levels were higher in obese patient, the difference is statistically insignificance (P >0.05). Adopting the AACE risk stratification approach, three patients were categorized as very high risk, while the other (9, 48 and 51) patients were categorized as high, moderate and low risk, respectively. The numbers of participants with very high, high and moderate risk were significantly higher in obese subgroup.

As presented in Table.2, the rate of discordance between Apo B and LDL-C was significantly higher as compared to the discordance in to Non-HDL-C (P<0.001). The rates of discordance in obese subgroup were insignificantly higher than that of non-obese subgroup (Data do not show); (P = 0.051). Non-HDL-C was the significant independent predictor for serum Apo B levels in all participants, discordant and concordant subgroups. The details of the linear regression model are presented in Table.3

According to AACE, antilipidemic treatment should be initiated, in (42) out of the (111) patients to achieve treatment target. Serum Apo B was a treatment target only for 12 patients ((3) with very high and (9) with high risk). For the other (48) moderate risk patients Apo B is not recommended as a treatment target (Table.4). In (36) out of the 69 patients achieving AACE treatment targets, treatment should be initiated to achieve AACC targets (Data do not show). Apo B was the only treatment target in 15 patients (3 moderate and 12 low), while Apo B in conjunction with Non-HDL-C were the treatment target for another 12 (3 moderate and 9 low risk). For the last participant Non-HDL-C was the only treatment target. However, for the 30 moderate risk patients in whom treatment should be initiated according to AACE guideline, the introduction of serum Apo B measurement will not affect treatment policy (Data do not show). Significant association was observed between discordance rate and the number of antilipidemic treatments that were to be initiated due to the introduction of serum Apo B measurements (P< 0.001) (Data do not show).

Table.1: Anamnestic and clinical data of the participants enrolled in the study.

Parameter	Obese	Non-obese	P value

Discussion

Most of ASCVD risk management guidelines, including the AACE and AACC adopted in the present study, the actual decision of initiating antilipidemic therapy is determined on the basis of serum lipids and lipoprotein concentrations, as well the presence of other modifiable and non-modifiable risk factors such as age, gender, hypertension, diabetes or evidence of coronary disease. A considerable amount of information must be integrated to reach an appropriate decision. The present results of lipoprotein measurements were in accord with the well-recognized association of obesity with high levels of TG and Apo B-containing lipoproteins, and low levels of HDL-C.[19] These abnormalities were thought to be the metabolic consequences of obesity-induced insulin resistance, which may by caused by a combination of overproduction and/or decreased catabolism of Apo B-containing particles.[19]

However, the accumulation of excess adipose tissue in obesity has been reported to have a clear association with other cardiometabolic risk factors such as hypertension and diabetes.[20] The above may provide a decent explanation for the higher prevalence of very high, high and moderate ASCVD risk, observed among obese patients enrolled in this study.

The recently reported higher discordance rates of Apo B with LDL-C, as compared to Non-HDL-C in patients with diabetes and hypertriglyceridemia[21], were reestablished in the present study. Further support for this concept was delivered simultaneous by the linear multiple regression analysis, illuminating Non-HDL-C as the only significant independent predictor for serum Apo B levels in all participants, as well in discordant and concordant subgroups.

Despite the significant high TG levels and the increases in Apo B discordance rates demonstrated among obese as compared to non-obese subgroup, no significant associations were found between obesity and Apo B discordant rates. Nevertheless, taking into account the relatively small number of participants enrolled, such association, if exists, might be unveiled by future studies recruiting much larger samples. Participants with extreme risk were completely absent, with only three participants stratified as very high risk and another 9 with high risk. Such setting has fortunately been responsible for a high number of participants achieving AACE treatment targets, and thus provide us with a better opportunity to investigate how the addition of Apo B as a third medical decision cut-point can affect antilipidemic treatment policy. Several reported studies suggesting that Apo B is a significant predictor of recurrent cardiovascular events independent of LDL-C or Non-HDL-C [22], and others which proposed it as a stronger predictor of death from acute myocardial infarction, as compared to LDL-C.[23,24]

The increased initiation of antilipidemic therapy specifically targeting optimal Apo B levels in patients already achieving LDL-C and Non-HDL-C may provide additional beneficial long-term preventive measures. The significant logical association observed between Apo B discordance rates and the number of patients in whom antilipidemic treatment should be initiated may suggest the utility of this measure to identify groups in which introduction of Apo B measurements are of legitimate healthcare priority.

Conclusions: Introduction of Apo B measurement in the management of ASCVD will increases the number of patients in whom antilipidemic treatment should be initiated. The extent of this increase is partially determined by the discordance rate between Apo B and LDL-C in the study.

Recommendations: Comparable future studies with larger samples of different patients' characteristics are necessary to identify groups in which introduction of Apo B measurements are of legitimate healthcare priority.

Acknowledgments: The authors appreciate all participants who took part in this study, especially Alkindy College of Medicine students, staff members and the employees of the ORTU for assisting and facilitating this research study.

Conflict of Interest: The authors have no conflicts of interest in this work.

Source of Research Funding: Self-funding.

Ethical Clearance: The study protocol was approved ethically and scientifically by the Scientific Affairs Unit of Alkindy College of Medicine. All patients and healthy volunteers gave their approval and consent to be included and participated in this study.

Protective Effects of Omega3 on CCl_4-Induced Oxidative Stress and Nephrotoxicity in Female Albino Rats

Tahseen A. Abdullah[1], Hawzheen K. Othman[2]

[1]Department of Health Prevention /Medical Technical Institute/Erbil Polytechnic University,
[2]Department of Biology/College of Science/Salahaddin University, Iraq

Abstract

In the present study, twenty one female albino rats were used and they were divided in to three groups. This was carried out and designed to study the effect of omega 3 poly unsaturated fatty acid on carbon tetrachloride (CCl_4) induced oxidative stress and kidney damage in female albino rats. However, the antioxidant activity of omega-3 were determined by assessing biochemical parameters (serum creatinine, urea, uric acid, and malondialdehyde (MDA)). Carbon tetrachloride caused significant increase in serum creatinine, urea, uric acid, and MDA level while, omega 3 significantly prevented the increase of the serum levels of creatinine, urea, uric acid, and MDA.

Keywords: *Omega-3-Fatty acids, Carbon tetrachloride, Free radicals, Malondialdehyde.*

Introduction

Free radical is an atom or ion possessing an unpaired electron that can be considered as fragments of molecules, these unpaired electrons make free radicals very reactive towards other substances, or even towards themselves [1]. It was generally accepted that free radical seek to pair with a new free electron, and free radicals would be generate and it is unstable and can react with another one to generate a new free radical. Thus, this chain reaction of free radical subsequently damage biological systems and tissues [2].

However, reactive nitrogen species (RNS), reactive oxygen species (ROS) and their generation are two kinds of biologically active free radicals, their generation, chemical reactions, and in vivo effects are closely interrelated. Harman was the first person who recognized the pathogenic role of oxygen free radicals in diseased states [3]. The studies of free radical and antioxidants in biology demonstrated that free radical played a role in chronic diseases including atherosclerosis, cancer[4] neurodegenerative (e.g. Parkinson's disease, Alzheimer's disease, multiple sclerosis) [5], asthma and diabetes [6].

Exposure to heavy metals, ultraviolet (UV) radiation, environmental pollutants, drugs, cigarette smoking, alcohol consumption[7] and xenobiotics e.g., CCl4 [8] lead to metabolic activation of ROS, which in turn causes cellular injuries[9].

Carbon tetrachloride intoxication in animals is an experimental model that generates oxidative stress in many pathophysiological states [10]. The long term CCl4 exposure generates reactive oxygen species and different free radicals in many tissues such as liver, heart, kidney, brain, lung and blood. Also, it defects antioxidant enzymes activities and increased thiobarbituric reactive substances concentrations [11]. Inaddition, [12] reported that CCl4, distributes at greater concentrations in the kidney than in the liver and it has a high affinity to the cortex part of kidney which contains cytochrome P-450 predominantly.

Epidemiological studies investigate that certain that long chain highly unsaturated omega 3-fatty acids which derived from the tissues of oil fish are known to reduce the oxidant status of various tissues. Diet rich in long chain omega-3 fatty acids has been shown to help in the development of healthy brain, heart and immune system [13]. Omega-3 fatty acids are considered as strong antioxidant and have an anticancer role in most of the human malignancies[14]. Furthermore, regular consumption of omega-3 fatty acids, particularly docosahexaenoic acid, has been reported to ameliorate cardiovascular disorders, including endothelial dysfunction, platelet aggregation, elevated blood pressure and triacylglycerols, and

arrhythmia [15]. The present investigation was conducted to study the evaluate the mechanism of omega-3 fatty acids on kidney function test parameters in CCl4 induced nephrotoxicity in female albino rat

Experimental animals: Twenty one adult female albino rats (*Rattusnorvegicus*) were used in the present study. Animals bred in the animal house of Biology Department, College of Science, Salahaddin University. All rats were weighing about 150-250 gms and 9-12 weeks old. The experiments achieved under the standard laboratory conditions (12h light: 12h dark photoperiod) and 22 ± 4 Cº, the animals were supplied with standard rat diet and tap water *ad libitum.*

Experimental design: One experiment was carried out and designed to study the effects of omega-3 fatty acid on malondialdehyde (MDA**)** and some renal function test parameters including serum creatinine, urea and uric acids) in CCl4 induced nephrotoxicity in female albino rats. The experimental rats were divided into three groups, each with seven individuals and the treatments were continued for 4 weeks.

The group one received standard rat chaw and tap water [16] and represents control rats. The rats in the second group received CCl_4 (0.25 mL/kg) body weight intraperitoneally and normal rat chaw with tap water. The rats in third group received standard rat chow supplemented with omega-3 (1gm/Kg) body weight and intraperitoneally administration of CCl4 (0.25 mL/kg) body weight.

Samples collection

Collection of blood samples: The rats were anesthetized using a combination of ketamine hydrochloride (35 mg/kg) and xylazine (5mg/kg) [17]. Blood samples were taken by cardiac puncture into chilled tubes with EDTA (4.5 mM as an anticoagulant) and centrifuged at +4Cº for 15 minutes; then plasma was stored at -80ºC (Sony, Ultra low, Japan).

Determination of serum malondialdehyde (MDA): Serum malondialdehyde (MDA) concentration, one of the end products of lipid peroxidation, was determined by the method of [18]. The level of serum MDA was determined spectrophotometrically. In brief: To 150 μl serum sample the followings were added: 1ml of 17.5% trichloroacetic acid (TCA) and 1ml of 0.66% (TBA), mixed well by vortex, incubated in boiling water for 15 minutes, and then allowed to cool. One ml of 70% TCA was added and the mixture was allowed to stand at room temperature for 20 minutes, and then centrifuged at 2000 rpm for 15 minutes, and the supernatant was taken for scanning spectrophotometrically at 532nm. The concentration of MDA calculated as follow:

MDA (µmol/L) = Absorbance at 532nm×D/L×E0

L: light path (1cm), E_0: Extinction coefficient 1.56×10^5 M^{-1}.-Cm^{-1}, D: Dilution factor = 1 ml Vol. Used in ref./0.15 =6.7

Biochemical determination

Determination of serum creatinine: Serum creatinine level was determined by spectrophotometer Creatinine kit (Biolab, France). Creatinine in alkaline solution reacts with picrate to form a coloured complex; the intensity of the colour is proportional to the concentration of the creatinine in the serum and urine. The absorbance was measured at 500 nm using spectrophotometer.

Determination of serum uric acid: Serum uric acid was determined by uricase method, using colorometric test kit and the absorbance was measured at 492 nm using spectrophotometer (Biolab,France).

Determination of serum urea: Serum urea was determined by using colorometric test kit and the absorbance was measured at 600 nm using spectrophotometer (Biolab,France).

Statistical analysis: Analysis of data was performed by using {statistical package for social science (SPSS) version 24}. Results are expressed as mean ± standard error (mean ± SE). Statistical differences were determined by Ducan's test for multiple comparisons after analysis of variance (ANOVA).

Results

Serum MDA: The serum MDA level of CCl_4 treated rats increased significantly and reached (10.939 ± 1.3µmol/L) as compared with control rats (4.206 ± 1.1 µmol/L). While, serum MDA level decreased significantly in animals that were provided with diet supplemented with omega-3 (6.418 ± 0.5 µmol/L), compared with CCl_4 treated rats (Table 1 and figure 1).

Serum uric acid level: Statistical analysis revealed significant increase in serum uric acid level (14.61±7.05 mg/dL) of CCl_4 treated rats when compared with control group (9.99±0.55 mg/dL). On the other hand, rats treated with (omega-3 and CCl_4) showed significant decreases

in serum uric acid (9.61.96±0.71 mg/dL**)** compared to CCl_4 treated rats (Table.1)

Serum urea: Carbon tetrachloride caused significant increase in serum urea level (31.12 ±0.76 mg/dL) when compare with control rats (21.00± 0.48 mg/dL).on the other hand, rats treated with (omega-3 and CCl_4) showed significant decreases in serum urea (23.57±0.64 mg/dL) when compare withCCl4 treated rats(Tabe. 1 and figure 2).

Serum creatinine: Carbon tetrachloride caused a significant elevation in serum creatinine level (147.43±24.2 mg/dL) in CCl_4 treated rats when compared with control rats (42.52±10.5 mg/dL), while, serum creatinine level significantly decreased when rats treated with CCl_4 and omega 3 (65.64±6.1 mg/dL) when compared with CCl_4 treated rats (Tabe1 and figure 3).

Discussion

Treatment with CCl4 for days elevated serum MDA level. MDA has been reported to one of the secondary products produced following exposure to reactive oxygen species and free radicals, and it can be used to check out oxidative damage through measuring serum levels of thiobarbituric acid reactive substance [19]. However our results confirm those of [20] as they concluded that, CCl4 enhances lipid peroxidation through increases free radical formation. CCl4 is metabolize by cytochrome p-450 and produce highly reactive free radical which initiates lipid peroxidation of the endoplasmic reticulum s cell membrane and causes a chain reaction.

Our results were correlated with [21] who reported that omega-3 caused significant reduction in lipid peroxidation induced by CCl4 in different organs of rats. The decrease in the MDA level by fish oil may be due to its antioxidant properties. Omega-3 could maintain normal levels of Superoxide dismutase and catalase activities [22] Inaddition, the anti inflammatory and anti-oxidant properties of omega-3 may be through it is ability to inhibiting lipid peroxidation and scavenging of free radicals [14].

The present results reveal that, intoxicated rats with CCl4 showed a significant increase in serum creatinine, urea and uric acid levels as compared to normal control rats. These pathological changes indicate the potential damage to kidney cells induced with CCl4 treatment since the observed increase is indication of an impairment of glomerular function and renal disorder [23]. Our results are agree with earlier reports reported by [24], who attributed these increases to the pathological changes observed in the kidney tissue and to the damage in kidney glomeruli as a result of CCl4 injection. Moreover [25] recorded that CCl4 induced elevation in serum urea could be related to the impairment of renal blood follow as well as reduction in glomerular filtration rate. However, creatinine production, infact, has a strong relationship with muscle mass and increased it is level indicates the muscular wasting occurred during CCl_4 intoxication [26]. Although, CCl4 causes depletion and deamination of muscle proteins but associated renal disorder prevents normal excretion process and therefore, causes accumulation and elevation serum levels of creatinine and urea [27].

Oral administration of omega-3 produces significant nephroprotective effects in CCl4 intoxicated rats. Our results are in agreement with [28] who suggest that Omega-3 may find clinical application in a different condition where cellular damage is a result of oxidative stress. The nephroprotective effects of omega-3 may be explained by the antioxidant effect of omega-3 fatty acids. The antioxidant or anti-inflammatory effects of omega- through inhibiting lipid peroxidation and scavenging of free have been reported previously [14]. However, omega-3 protects rat from CCl4 induced kidney injury as evident from significant decrease in serum creatinine, urea and uric acid. [29] suggested that the ameliorative effects of omega-3 on kidney function may be due to the improvement of glomerular filtration.

Moreover, it was generally accepted that fish oil reduce hyperlipidemia by decreasing serum total cholesterol and low density lipoprotein cholesterol concentration, so, creatinine might be decreased due to glomerulosclerosis reduction [30]. In addition, in a study [15] demonstrated that elevated serum level of creatinine, urea and uric acid were improved in the hypothyroid treated rats with fish oil, they concluded that the protective effects of omega-3 in in the concentration of creatinine, uric acid and urea may due to that omega-3 ameliorated concentration of thyroid hormones and improved glomerular filteration.

Conclusion

In conclusion, from this study it was concluded that omega-3-fattyacids, protects the kidney against CCl4 induced hepatotoxicity in female albino rats.

Risk Assessment on BTEX Exposure at Fuel Storage Tank Area in Gasoline Station

Thawatchai Dacherngkhao[1], Sunisa Chaiklieng[2]

[1]Doctor of Public Health Program Candidate, [2]Department of Environmental Heatlh Occupational Health and Safety, Faculty of Public Health, Khon Kaen University, Khon Kaen, 40002, Thailand

Abstract

Volatile organic compounds (VOCs; BTEX) cause health effects and polluting ambient air working at a gasoline station. This cross-sectional study aimed to study health risk assessment (HRA) to BTEX exposure at fuel storage tank area for forty-seven gasoline stations in Thailand. There was collected gasoline stations characteristics by questionnaire, BTEX concentration measuring by active sampling followed NIOSH number 1501 (NIOSH 2003) methodology analyzed by gas chromatography with flame ionization detector (GC-FID).Health risk assessment for non-cancer effect was calculated by hazard quotient (HQ) which estimated BTEX exposure concentration was calculated following the US.EPA-IRIS. The result measuring found that 0.023(0.0003-0.6821), 0.07(0.0032-1.49), 0.0039 (0.0008-0.0552), and 1.12 (0.05-29.50)ppm for mean (min-max) concentration in benzene, toluene, ethyl benzene, and xylene (BTEX) respectively. Benzene concentrations measurement for two stations (4.26%) exceeded the NIOSH-TWA standard (>0.1ppm). Furthermore, the health risk assessing was estimated 2 stations (4.26%) as more than one for hazard quotient (HQ≥1) for benzene and 2 stations (4.26%) for unacceptable risk as to more than one the summary of hazard index (HI>1).The non-cancer human health risk assessing by HI for exposure to BTEX compounds, did not significant correlation with all risk parameters. However, installed area of the fuel storage tank (right side of gasoline stations; above wind direct), fuel loading frequency, the located zone of gasoline stations, and service type, closer buildings of residential (<8 meters) and station borderline (<3 meters) distance from installed fuel storage tank of gasoline stations were increasingly health risk by considered safety action or HI≥0.5.

Therefore, as this study, suggests that entrepreneurs must be strictly controlled personal protective equipment wearing, safety work instruction, and safety training for gasoline station workers (truck drivers and loading examiners) to raise awareness of intake BTEX exposure by inhalation protective, including adding health surveillance program.

Keywords: *Health risk assessment, BTEX exposure, Fuel storage tank, Gasoline station.*

Introduction

BTEX (benzene, toluene, ethylbenzene, xylene) are volatile organic compounds (VOCs) and well known can also affect health. Especially, benzene is carcinogen[1-3] including cause hematopoietic, the central nervous system (CNS), and reproductive disorders[4-6]. Toluene is a cause of reproductive and CNS abnormalities[3]. Ethylbenzene and xylene are harmful to respiratory and neurological[4,7]. Those were one reason for inducing hazardous conditions contributed from polluted fuel vapors on ambient air[8] which gasoline station workers are exposed intake to BTEX while working. Thailand, gasoline stations has risen by an average of 4-5 percent a year to 28,753 stations[9].

The former study of BTEX measuring in gasoline station, was reported that 29.7, 47.7, 23.3 and 46.9 μg/m^3 for benzene, toluene, ethylbenzene and xylene at gasoline station atmosphere in Brazil, respectively[10]. There were average 1.922, 1.173, 0.868 and 1.866 μg/m^3 for BTEX in the gasoline stations of India[11]. In Thailand, there was 709, 1,984, 114 and 496 μg/m^3 for benzene, toluene, ethylbenzene, xylene, respectively at gasoline stations of Bangkok[12]. Benzene concentration were found 144.94±37.39 μg/m^3 in urban, 144.14±42.29

$\mu g/m^3$ in sub-urban and 108.94±69.01 $\mu g/m^3$ in rural zone in Khon Kaen province, the Northeast, Thailand[13].

Gasoline station workers were causing a high health risk[14], 64% of fuel service attendants had risk higher than an acceptable level[15] and some workers (12%) has risk higher than acceptable risk on benzene exposure via biomarker t, t-MA monitoring[16]. Although the long-term health risk of non-cancer were acceptable risk which the health risk assessing of non-malignant were less than hazard quotient (HQ) reference level (HQ<1)[17].

Vapor recovery systems (VRS) had used to reduce concentration of fuel vapors at fuel depots or industrial petroleum plants[18]. It was determined installations for vapor reduction in Bangkok, perimeter are as[19]. There was efficiency reduced evaporation at 80-99% of fuel vapor[20-21].

Despite these findings, there have not been adequately studied related to human health risk assessment in the fuel storage tank area at gasoline stations. This cross-sectional study was aimed at comprehensive assessing health risk all hazardous area that BTEX emission, investigate between the relationship fuel storage tank factors and health risk assessment (HRA) at gasoline stations.

Materials and Method

Study Design and Sampling: The result of cross-sectional study was conducted among 47 gasoline stations in Khon Kaen province, located in the northeast region of Thailand. The sample size was calculated by using Cochran (1953) under the known number of population in small size. The selected gasoline stations criteria 1) located in an area along either side of, or within 5 km of Mittraphap Road in Khon Kaen province 2) having more than eight dispenser nozzles.

Data Collection: This study were collected though a gasoline station questionnaire and a survey for 47 gasoline stations. BTEX concentration on ambient air a fuel storage tank working area, while fuel loading and non- loading, was measuredactive sampling followed NIOSH number 1501 (NIOSH 2003) methodology analyzed by gas chromatography with flame ionization detector (GC-FID) of Hewlett Packard 1996, Germany. It was collected during work shifts of working hour (8 hrs.) by active sampling with charcoal tube at a flow rate of 0.2 L/min in dispenser area. All charcoal tubes were kept at 4 ^{0}C while transported to the laboratory. There was extracted with carbo-disulphide (CS_2), and analyzed by GC-FID detector (Varian,CP3800) and column CP 52 wax (30 m x 0.25 µm x 0.25 mm). The BTEX concentrated on this method was determined health risk assessment by hazard index.

The human health risk assessment for non-cancer effect was estimatedby hazard quotient (HQ) according to HQ=EC/RfC, where; EC refersexposure concentration in $\mu g/m^3$, RfC refers exposure concentration for 30, 5,000, 1,000, and 100 $\mu g/m^3$ of benzene, toluene ethylbenzene, and xylene, respectively. The hazard quotient was considered "adverse non-malignant effects of concern" for HQ≥1 and "acceptable level" for HQ<1. The non-cancer health impact was expressed at the hazard index (HI), which was determined by the HQ of BTEX summation.

The BTEX exposure level was calculated following US.EPA-IRIS 2009 to EC=(CA x ET x EF x ED)/AT, where; CA refers contaminant concentration in $\mu g/m^3$, EF refers exposure frequency in day/year (324 day/year), ET refers exposure time in hours/day (2 hrs./day), ED refers exposure duration (25 year), and AT refers averaging time (194,400).

Data Analysis: Data analysis was carried out using STATA version 10 software, and descriptive statistics were used to define fire risk and classify hazardous zones. The Kruskal–Wallis test and a chi-squared test were used for correlation analysis of factors and health risk assessment. There was calculated the statistical significance was identified at a p-value <0.05.

Results

The overall of forty-seven gasoline stations, the basic characteristics found that located in 14.89% of the inner city and 85.11% of the outer city area. Each gasoline station had an average of 10±5 gasoline station workers. The time service of twenty stations (57.45%) were opened 16 hours (06.00 am - 10.00 pm) and twenty-seven (42.55%) were opened for all day. Gasoline station classification according to service type showed that 12 stations (25.54%) for type I+II, provides service dispenser house, fuel storage tanks, office, maintenance store and 37 stations (74.46%) type III+IV, fuel dispenser house, oil storage tanks, office, maintenance store, minimart, coffee shop, and food court. There were average 23±12 dispenser nozzles (min: max=8: 48). Daily fuel sold were average about 9,060±5,028 liters (min: max=2,300: 24,200).

The fuel storage tank contains average 44,121 liters, 18,000 liters for lowest, and 212,000 liters for maximum for stocked. The most located fuel storage tanks were built in left side of a gasoline station, above wind direction which was 34 stations or 72.34%.Frequency loading in the fuel storage tank was 40 stations (85.10%) for reloading every day and average 2 hours of spending time. The distance of located fuel tank was measured median 9, 20, 3.5, and 11 meters away from the dwellings area line, services building, gasoline station borderline, and fuel dispensers, respectively.

BTEX concentration at fuel storage tank ambient air was indirectly measured by active sampling and analyzed by GC-FID. The result found that average at 0.023, 0.07, 0.0039, and 1.12ppm for concentration on benzene, toluene, ethylbenzene, and xylene, respectively. There are only two station that the concentration was exceeded the NIOSH-TWA standard (>0.1 ppm)for benzene vaporization. BTEX exposure concentration was estimated at average 24.93, 88.54, 5.78, and 17.47 µg/m3 for inhalation exposure as Table 1.

Furthermore, the human health risk assessing for non-cancer effect was estimated by hazard quotient (HQ), which was calculated BTEX exposure level as fuel loading into a storage tank and non-loading with measured BTEX concentration by the above methodology. Hazard quotient more than or equal to 1 (HQ≥1) was assessed 2 stations (4.26%) for benzene exposure. Also, hazard index (HI) measured on working ambient atmosphere fuel storage was estimated average of 0.26 and 0.012-6.81 for minimum-maximum, which summarized with HQ form BTEX exposure intake by respiratory system as Table2.

The non-cancer risk for BTEX exposure assessed by safety action of hazard index (HI≥0.5) presented as Table 3, found that all the studied factors did not significantly different between hazard index (HI). However, those factors were positively associated with increased health risk assessing (hazard index; HI).

Table 1. Characteristic of gasoline stations and fuel storage tank

Characteristics	n (%)
Location zone of gasoline stations	
inner city	7 (14.89)

Discussion and Conclusion

The compared BTEX between fuel storage tank area in this study and other gasoline stations studies showed that was lesser than the inner gasoline stations and roadside area[11-13]. However,benzene concentration was 2 gasoline stations that was exceeded the NIOSH-TWA standard (>0.1 ppm).

The non-cancer risk for BTEX exposure as assessed by hazard index; HI (summarized with HQ of BTEX), the estimated hazard index was higher in fuel storage tank area than another area on gasoline stations[17]. There was two gasoline station for un-acceptable limits on humans, which may be related to frequency loading in the fuel storage tank a day which found that 40 gasoline stations (85.10%) in this study.

These assessed the health risk of non-malignant found that, all risk factors disparity effects increased trends of hazard index (HI).Particularly, an installed area of the fuel storage tank (right side of gasoline stations; above wind direct), building residential distance, station borderline, and daily loading frequency have not been adequately studied in truck drivers and loading examiners because they had to be directly exposed in numerous fuel vapor quantities in a few hours as petroleum loading per day.

Therefore, entrepreneurs must be strictly controlled personal protective equipment (PPE) wearing, safety work instruction, and safety training for gasoline station workers (truck drivers and loading examiners) to raise awareness of intake BTEX exposure by inhalation protective. Extremely, important adding health surveillance programto them.

Relationship between Talkativeness and Transformational Leadership among Management & Science University Students

Thin Thin Aung[1], Nur Hanis Shahnon[1]

1Senior Lecturer, International Medical School, MSU, Nur Hanis (BMS Student at MSU)

Abstract

Talkativeness is defined as talking a lot while a leadership trait refers to characteristics of a successful leader. Recent studies show lack of prove regarding the correlation of talkativeness and leadership trait among people. Hence, this research is a quantitative study which utilizes self-administered questionnaires to analyze the correlation of talkativeness and leadership traits among the students of Management & Science University. The data was collected using questionnaires which consist of 3 parts known are demographic survey, talkativeness survey and leadership traits survey. A total of 204 students from various faculties were randomly selected to participate in the survey. Data was entered on the SPSS version 17.0. The result obtained shows a significant correlation between talkativeness and leadership traits among Management & Science University students as the p-value is 0.01 which is less than 0.05. Talkativeness does effect on ability to be a leader. Thus, students should always practice more talking in order to create a better leader in the future.

Keywords: *Talkativeness, Leadership, Students, University.*

Introduction

Are leaders usually talkative or taciturn? Are leaders such as Tun Mahathir and Barack Obama talkative or are they the type of people who would stay quiet in discussions? Some people are born to be very talkative but do these people like to take the role of a leader. According to the Cambridge Dictionary, talkativeness is defined as talking a lot. Talkativeness is also to measure whether someone is talkative or the opposite. Talking is a fundamental human behaviour that reflects a range of underlining traits and behaviours.[23] The average rate of speech ranges between 140 – 160 words per minute.[11] Psychologically, talkativeness is under extraversion, the Big Five personality trait. Other personality traits included in the Big Five personality trait are openness to experience, neuroticism, agreeableness and conscientiousness.[7] Extraversion is associated with the trait such as sociable, talkative, friendly, outgoing and energetic. In most cases, the person who is the most talkative is usually picked as the leader. This is also known as the big mouth theory of leadership. A study found that a mouth width correlates with leader selection.[4]

In addition, leadership is the process of influencing others in a manner that enhances their contribution to the realization of the group goals.[25] Example of leadership traits that are popular include honest, confident, team-oriented, respect the followers, highly motivated, responsible, acts as a coach of the team, provides training for the followers and expects followers to work together to create the best possible results. There are many types of leadership such as Laissez-Faire leadership, Autocrat leadership, Transactional leadership, Transformational leadership and Participative leadership. Transformational leadership is the most common type.[20] Transformational leadership is defined as a leadership approach that causes change in individuals and social systems. In its ideal form, it creates valuable and positive change in the followers with the end goal of developing followers into leaders. Transformational leadership enhances the

motivation, morale and performance of followers through a variety of mechanisms. These include connecting the follower's sense of identity and self to the mission and the collective identity of the organization, being a role model for followers that inspires them, challenging followers to take greater ownership for their work, being very well-organized and expect their followers to be creative and understanding the strengths and weaknesses of followers so the leader can align followers with tasks that optimize their performance.

This study is done to determine the association between talkativeness and leadership trait. Since students are the future leaders of the world, it is important to train and develop the leadership trait in them since young adulthood. If there is relationship between being talkative and these leadership traits, we should train these future leaders to become more talkative. With this study, we could identify association of talkativeness with the leadership trait. To enhance talkativeness in students, we can suggest and provide more programs that can enhance communicating skillsby introducing public speaking classes and activities. This study is chosen on MSU students and not on a specific faculty because there are many students from various faculties who have portrayed their leadership skills by leading activities arranged in MSU.

Objective: To find the relation between talkativeness and leadership trait among Management & Science University students

Literature Review: Since Burns first introduced the concept of transformational leadership in 1978, a great deal of research has been devoted to exploring the behaviors of leadership styles.[5] Leadership is grouped into three distinct dimensions: transformational, transactional and laissez-faire leadership.[5] According to Burns, transformational leadership is a process in which leaders and followers help each other to advance to a higher level of morale and motivation.[10] Burns related to the difficulty in differentiation between management and leadership and claimed that the differences are in characteristics and behaviors. He established two concepts of leadership which are transformational leadership and transactional leadership. Burns stated that the transformational leadership approach creates significant change in the life of people and organizations. It redesigns perceptions and values and changes expectations and aspirations of employees. Unlike in the transactional approach, transformational leadership is not based on a give and take relationship but on the leader's personality, traits and ability to make a change through example, articulation of an energizing vision and challenging goals. Transformational leaders are idealized in the sense that they are a moral example of working towards the benefit of the team, organization or community. Burns theorized that transforming and transactional leadership was mutually exclusive styles. Transactional leaders usually do not strive for cultural change in the organization but they work in the existing culture while transformational leaders can try to change organizational culture.

Moreover, in a research study done by Stang and Castellaneta, it is proved that there are positive correlations between talkativeness and peer judgments of leadership.[24] This point is also strongly agreed by a study done in 2004 by Bono and Judge who state extraversion was the strongest and most consistent correlate of leadership compared to neuroticism, openness, agreeableness and conscientiousness.[3] This study proves that the extraversion characteristic which includes talkativeness has a strong correlation with leadership trait. In addition, Harrison L.M. in the year 2011 supports that transformational leadership behaviors are a more significant in cognitive learning, affective learning, perceptions of instructor credibility and communication satisfaction than instructor transactional leadership behaviors in his study.[13] However, a research study done in the University of Ghana does not support all these statements. This research done by Boateng proves that student leaders at the university researched do not perceive themselves as having transformational leadership characteristics.[12]

Extraverts are most often characterized as assertive, active, energetic, upbeat, talkative and optimistic individuals.[18] Extraverts experience and will express positive emotions to their surrounding[17] which were revealed in assessments of job satisfaction[8] and subject well-being.[14] Extraverts' optimistic views of the future allow extraverts to emerge as group leaders.[8] Extraverts are also to be perceived as "leader like" [22] and exhibit behaviors consistent with the transformational model of leadership.[3] It is therefore no surprise that Bono and Judge (2004) recognized extraversion was the strongest and most consistent correlate of leadership compared to neuroticism, openness, agreeableness and conscientiousness.

Materials and Methods

The study design used for this research is a quantitative study which utilizes self-administered questionnaires. The questionnaires were constructed based on talkativeness and leadership qualities according to Multifactor Leadership Questionnaire and the Big Five Inventory Questionnaire.

The study area of my research is at the compound Management and Science University, Seksyen 13 Shah Alam.

The study population for this research will be the students of Management & Science University.

The sample size was calculated using a formula of $n = z\ 2p\ (1-p)/\ d2$

The standard deviation value, p value of 0.24 is taken from the previous study.[3] In the formula, n is the minimal sample size, z is the standard normal deviated of 1.96 which corresponds to 95% of confidence level, d is the detectable difference which is 0.05 and P is the expected prevalence which is 0.5. The value obtained is then added with 20% to include the drop up numbers. Thus, the maximum sample size obtained is 204 respondents.

Sampling methodused was choosing the male and female students of Management & Science University randomly. The questionnaires were distributed to the MSU Students randomly. The questionnaire consists of 3 sections which are the demographic survey, talkativeness survey and leadership survey. Descriptive and inferential statistics were used to analyze the data. Descriptive statistics includes frequency and percentages. The Pearson correlation test was used to measure the association between the variables which are the talkativeness and leadership trait. The significance level was set at P value less than 0.05.

Data analysis will be performed with the Statistical Package for Social Sciences (SPSS) 17.0 for Windows. The inclusion criteria for this research include all MSU Shah Alam students with valid university identification card while the exclusion criteria are MSU Shah Alam staffs and students with no valid university identification card.

Discussion

Fig.1 until Fig.5 show the results of demographic survey of the participants. In this research there were 67 males (32.80%) and 137 females (67.20%). Female participants are higher than male participants. Fig.1 shows a bar chart portraying the ethnicity percentages of people participating this research. It shows that Malay (70.60%) was the highest followed by Indian (28.43%) and Chinese (0.98%). Majority of the participants are Malay. In addition, according to Fig.2, IMS students were the majority subject for this research with 72 people. The second highest number of subject is from the faculty of FBMP by 44 people. It is followed by SESS (28 people), SHCA (17 people), FISE (17 people) and FHLS (16 people). The least number of people are from the faculty of SPH with only 10 people. The survey proves that majority of the participants are among the age of 18 years old to 24 years old (93.6%). There are only 6.40% of people from the age group of 25-35 and none was with the age above 35 years old. The education levels of the participants are shown in Fig.3 26 students (12.70%) are studying in foundation, 39 students (19.10%) are studying diploma and the majority of the students, 139 students (68.10%) participated are studying in degree. Fig.4 shows that most of the students speak in Malay when conversing. Next, 46 students (22.50%) usually speaks in English in their daily conversation and only 34 students (17.0%) of the students speak other languages such as Tamil. Fig.5 shows the talkativeness level and leadership level of the participants. The results shown are parallel to the alternative hypothesis which states that there is high prevalence of talkativeness level and high prevalence of leadership trait. The scoring to measure the level of talkativeness and leadership traits were divided into three which are low level for scores below 25, moderate level for scores between 26-50 and high level for scores above 50. None of the students scored below 25. This means the students of MSU are not quiet people. 15 males (7.35%) and 55 females (26.96%), a total of 70 students (34.31%), scored between 26 to 50 meaning they have moderate level of talkativeness. 52 males (25.49%) and 82 females (40.20%) scored above 50 and this proves that a total of 134 (65.69%) out of 204 students have high talkativeness level. Other than that, for leadership trait level, it also shows that no students scored below 25 meaning MSU students do have leadership traits in them. It is just a matter of time whether they have shown the leadership trait or not. 2 males (0.98%) and 28 females (13.73%), a total of 30 students (14.71%) scored 26 to 50 which is the

moderate level of leadership trait. Lastly, 174 (85.29%) students which consist of 65 males (31.86%) and 109 females (53.43%) have scored above 51. This means 174 students have high leadership skill and that is a very big number as it is more than half of the total respondent number. This result contradicts with a research study done by Boateng in 2014. His result proves the mean score of 2.97 shows that student leaders did not perceive themselves as having transformational leadership qualities.[12]

Last but not least, Pearson Correlation test proves that there is a relationship between the talkativeness level and leadership trait level of MSU students. This is also parallel to the alternative hypothesis which states that there is a relation between talkativeness and leadership trait. Table.1 shows that the significant p value is 0.01 which is below 0.05. This proves that the result obtained is significant. The correlation coefficient r value is also positive which 0.533 is. This result can be supported by a recent. The study results indicate that extraversion or talkativeness may be an important trait in predicting and understanding transformational and transactional leadership. Extraversion correlated with transformational leadership. Extraversion is a trait that shows robust relations with both leadership outcomes and rated leadership behaviors. Thus, it seems worthwhile for future leadership research to focus on extraversion.[3]

Conclusion

According to this study, there is a significant correlation or relationship between talkativeness and leadership trait among MSU students. The leadership traits found in MSU students include highly motivated, confident, reliable and honest. This means that talkative students have a higher chance to be a leader as they have the leadership traits. However, there were lack of previous researches on talkativeness and leadership trait.

Conflict of Interest Statement: We certified that there is no conflict of interest with any financial organization regarding the material discussed in the manuscript.

Application of Cognitive and Behaviour Framework Module in the Treatment for Mental Games among Golf Athletes: A Study of UUM National Golf Academy

Zainudin Omar[1], Siti Rozaina Kamsani[2], Noor Azniza Ishak[3], Azmi Shaari[4]

Senior Lecturer[1,2], Professor[3], Associate Professor[4], School of Applied Psychology, Social Work & Policy (SAPSP), UUM

Abstract

This article discusses the continued effects of using the counselling approach module, ABC Rational Emotive Behaviour Therapy (ABC REBT) in reducing the psychological problems of golf athletes, especially athletes who are facing problem especially mental game and yips. Symptoms of this problem include anxiety and loss of self-confidence, shown through sweating and clumsy conditions when putting and chipping in critical situations. As a result, athletes face low self-confidence especially during major championships. In identifying the effectiveness of the module,the study conducted on the same athlete in previous years as respondents. This study also uses qualitative approach, involving three golf athletes. The views of coach who train them full time are also taken to support any changes in the results of the study. The theme of analysis and content analysis has been used. The findings show that the using of ABC REBT module treatment to overcome the mental game and the yips of golf athletes is effective in the long run. The result of theme analysis and content analysis reinforces the effectiveness of the ABC REBT treatment module on respondents. The result of this study are important in expanding the scope of counselling services in sports, and also proves the effectiveness of counselling approaches to athletes. Therefore, involvement of counselling practitioners in sports is also recommended. The article also illustrates the potential of cognitive and behavioural counselling approaches in reducing the problem.

Keywords: *Counselling, Treatment module, mental game, athletes.*

Introduction

The mental game problem refers to psychological problems faced by sports athletes that include personal problems, pressure in the competition, burn out, relationship problems with coaches and teammates and other problems involving the athlete's psychology[1,2,3]. Mental game is a state of anxiety experienced by the athletes during certain manoeuvres in sport. It stems from the way the athletes responded to the difficulty level as well as the importance of movement or a shot that they will attempt. In addition, the over thinking symptoms before starting the shot can also affect a player's skills and achievements. Thus mental game is considered to be a wide aspect in the field of sports. In golf specifically, mental game aspect is significant when a player is susceptible to the changes in the psychological aspects.

Therefore, a study entitled "The impact of ABC REBT brief counselling approach framework in addressing the mental game and the yips among golfers"[4] has been conducted in order to improve the mental game treatment among golf athletes. In his study, the ABC REBT brief counselling approach framework was applied to a number of golf amateur athletes who were involved in a series of local and international golf competition. The study found that the approach has a significant impact in terms of control of the mental game that they face. At a glance, the results of the study are in line with the findings of other researchers who found that counselling approach can be implemented in the

field of sports[5,6,7]. This association is primarily caused by the psychological, mental and spiritual aspects of the athlete[8].

Past Research: Among the earliest problems that affect athlete's psychological growth is the result of' sports commercialization which started in the 1970s[9]. According to Scott[9], athletes are faced with various problems such as lost self-confidence and mental stress, especially when it comes to unreasonable coaches' expectations. They are also faced with the pressure to meet the expectations of the parties who are sponsoring them. Thus, Scott[11] suggested that the problems faced by athletes such as stress and lost self-confidence are relatable with counselling services.

Hinkle[10] estimated that there are around ten percent of student athletes who are associated with psychological problems at universities in the United States. Hinkle[9] also attested that sports psychologists, different from sports counsellors focus on the athlete's performance. Sports counsellors on the other hand focus on the psycho-emotional problems experienced by athletes, by reviewing the emotional and psychosocial development of the athletes in a more comprehensive manner compared to sports psychologists. Such differences can be considered as the boundary between sports psychology and sports counselling fields. Further, a sports counsellor refines the athlete's problems and tries reducing them, while professionals in other fields may not have these capabilities[9].

The cross field research on counselling and sports fields starts with the application of theory and counselling based approaches into the game aspects[10]. Among them are behavioural theories such as Solution Focused Behaviour Therapy and Therapy and Rational Emotive Behaviour[10]. Counsellors may not be an expert on the best *performance* for athletes, but the sports counsellors have their own method to handle their problems[9]. Sports Counsellor concentrates on the development of an athlete through lifestyle counselling, career and development programmes, as well as stress management.

Further to this, sports counsellor can engage in programmes such as problem prevention programmes, coping skills and competitive response, decision-making method, life management, therapeutic strategies and crisis management. However, that doesn't mean that sports counsellors are not involved with athletes' performances. Sports counsellors could provide services that support both aspects indirectly[9]. Thus, sports counsellor sports need to be savvy or at least familiar with a specific type of sports activities of their clients[11].

One of the biggest challenges in the sports development is the lack of emphasis on a holistic approach in the aspect of training and development programmes for athletes[3]. More emphasis has been put on the development of skills, physical appropriateness, health and fitness aspects, and rewards and achievement[11]. Unfortunately, serious attention in the athlete's psychological aspects is rarely given. This is due to the rapid development of immediate and continuous result-oriented sports industry that is expected by the stakeholders. They include the sponsors, the sports institutions or countries who expect that the athletes would collect medals from the tournaments in which they participate[3].

For example, when the commercialization era started to enter the American sports industry, sponsored athletes were involved in several of psychosocial and psychological problems including the use of drugs and alcohol. These problems were believed to be the effect from high expectations from coaches, sponsors and fans[8]. It is estimated that ten percent of the athletes were involved in problems that requires counselling interventions[7].

Thus, the development of counselling services in sports have a great potential to be further developed[11] and will continue to grow that can also imply the current developments of sports psychology is at the stage of maturity and will continue take into place in the long run[12]. This fact is important to support the continuity of research on the field of counselling in sports.
