The increased risk of UTI among diabetic patients, coupled with the increase in the incidence of type 2 diabetes mellitus worldwide in recent years, may impose a substantial burden on medical costs. In addition, the high rates of antibiotic prescription, including broad-spectrum antibiotics for UTI in these patients may further induce the development of antibiotic-resistant urinary pathogens. There are likely several reasons for people with diabetes more prone to UTIs. First, people with diabetes may have poor circulation, which reduces the ability of white blood cells to travel in the body and fight off any kind of infection. Second, high blood glucose levels can also raise the risk of a UTI. And third, some people with diabetes have bladders that don't empty as well as they should. As a result, urine stays in the bladder too long and becomes a breeding ground for bacteria. Diabetic patients are at a high risk of development of UTIs, so it is recommended that special attention is paid to them, especially for the management of bacterial UTIs.[7] The aforementioned literature motivated the researchers to assess the effectiveness of structured teaching programme on prevention of UTI among women with type 2 diabetes.

Objectives

- To assess the pretest level of knowledge on prevention of Urinary tract infection among women with type 2 diabetes mellitus.
- To assess the Urinary tract infection symptom severity within 24 hours and past history of Urinary tract infection.
- To determine the effectiveness of structured teaching programme regarding prevention of urinary tract infection in terms of gain in knowledge among women type 2 diabetes mellitus.
- To find out the association between the post test level of knowledge on prevention of Urinary tract infection among women with type 2 diabetes mellitus in the selected demographic variables.

Method

A Quantitative approach, pre experimental one group pretest and post test design was used for this study and conducted in selected tertiary hospital, Chennai. A pilot study was conducted prior to the main study with 10 samples and Reliability and practicability of tools and method was identified. The study was conducted in Out patient department after the written permission from the higher authorities. 32 Samples was selected using simple random sampling technique who was diagnosed with Women with Type 2 Diabetes. The objective of the study was explained and Informed consent was obtained from the Samples. Demographic data and Pretest was collected by using structured questionnaire. Urinary tract infection symptom severity assessment scale used to evaluate the UTI symptom within 24 hours and past one month history of Urinary tract infection. The Structured teaching programme on Prevention of UTI was conducted for 20 minutes.The Post test level of Knowledge was assessed by investigator after seven

days. The nurse investigator thanked the participants for their cooperation throughout the data collection period.

Results and Discussion

Majority 53% of the samples age was between 41-50 years, 57% of women having 5-6 years duration of diabetes mellitus and 50% of women are experienced urinary tract infection in the past one month. Majority of patients 26(82%) had inadequate knowledge, 3(9%)of patients had moderate and 3(9%)of patients had adequate knowledge on prevention of urinary tract infection in pre test. After the post test the majority of sample 21(66%) had adequate knowledge and only 8(25%)of patients having moderate and 3(9%) were under the category of inadequate knowledge. The study result also shows that fifty percentage samples having history of UTI and remaining 50% of people did not had History of UTI. Among 50% of the history of UTI samples majority that 50% of had history of severe symptom of urinary tract infection, 31% were had of mild symptom and 19% of moderate symptom of urinary tract infection in the past one month period among type 2 diabetes mellitus women. The pretest mean score for knowledge on prevention of urinary tract infection was 4.62 and standard deviation was 2.36. The post test mean score was 9.37 and standard deviation was 1.56. The mean difference was 4.8. The t value 10.68 was greater than the table value and therefore its significant at $p<0.05$ level. This study result reveals that the structured teaching programme on prevention of urinary tract infection is effective in increasing the knowledge level among type 2 diabetic women. There was no association between demographic variables and knowledge on prevention of urinary tract infection at 0.05 level.

A similar study conducted in Bangalore to assess the effectiveness of structured teaching programme on prevention of micro vascular complication among patient with diabetes mellitus at KC General Hospital. The research design selected for this study was quasi experimental design. The sample size consists of 50 diabetic patients. Purposive sampling technique was used to select the respondents. A structured knowledge questionnaire was administered to assess knowledge in pre test among experimental group on the first day. Structured teaching programme was administered on the same day of pre test to experimental group.After 7 days of administration of structured teaching programme a structured knowledge questionnaire was administered to assess the effectiveness of STP. The results of major findings indicate that the DM patients had inadequate knowledge regarding micro vascular complications and its prevention's. The study concluded that the STP on prevention of micro vascular complications of diabetes mellitus was an effective method for providing moderate to adequate knowledge and help the DM patients to enhance the knowledge to prevent vascular complications. The teaching programme content was different in the above study but both the study results indicates that structured teaching programme increase the knowledge among type 2 diabetic patients.

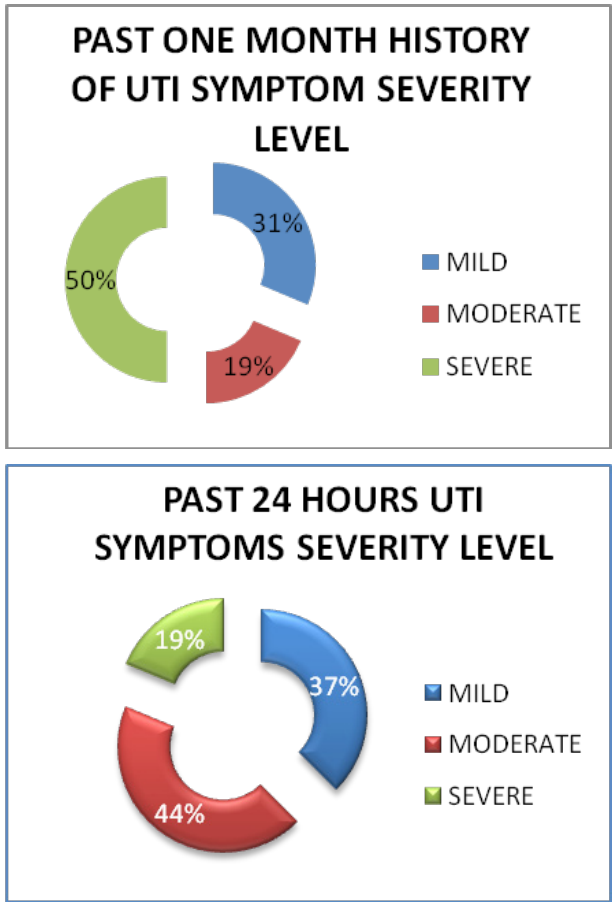

FIG 1: Percentage distribution of patients experienced symptoms severity Level of UTI past one month and within 24 Hours.

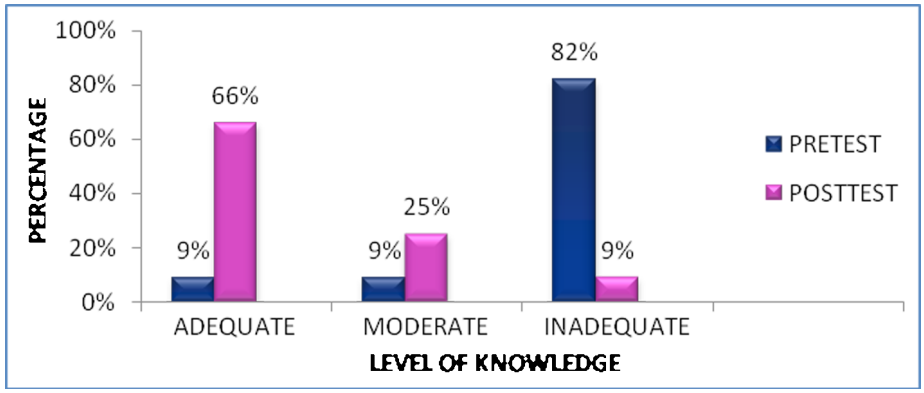

Fig 2: Percentage distribution of knowledge on prevention of urinary tract infection among type 2 diabetes women.

Table 1: Comparison of Pre test and Post test Knowledge on Prevention of Urinary Tract Infection Among Women with Type 2 Diabetes Mellitus. N=32

Sample	Group	Mean	Standard Deviation	Mean Difference	't' Value
Women with type 2 diabetes mellitus	Pre test	4.62	2.36	4.8	10.68* Significantat p<0.05
	Post test	9.37	1.56		

Implications for Nursing Practice and Research: The present study will enable, nurses to apply theory into practice as the educative material and IEC are currently playing major part in clinical area and use this in their daily practice on patients to reduce the recurrence of UTI. Nurses can conduct more research studies to demonstrate prevalence of urinary tract infection among diabetic and non diabetic women and the effects of Structured teaching programme on prevention of urinary tract infection can be evaluated. There is a need for extensive and intensive research in this area to provide evidence based care since the increased prevalence of Diabetes and the increasing incidence of UTI among Diabetic Women gives red alarm to the health care professionals.

Conclusion

Urinary tract infections frequently occur in diabetic patients due to an impaired immune status and increased glucose content of the urine, among other reasons. This makes UTI very important to investigate. Complicated cases of UTI may be infrequent but are more common in diabetics with far more severe consequences, and so warrant further investigation. The proper management of UTI in diabetics is crucial, as prompt diagnosis and correct treatment is essential. Prevention is better than cure.So,the present study concentrated on prevention of UTI among diabetic women. In conclusion the discussion of the study findings shows that there was a significant difference in the level of knowledge among type 2 Diabetic women after receiving the Structured teaching programme on prevention of urinary tract infection. So it can be used as a routine teaching programme in the medical out patient department.

Ethical Clearance: The ethical clearance obtained from "Institutional Human Ethics Committee" Chettinad Academy of Research and Education,Proposal No.34/ IHEC/3-18.

Migrant Labour Resource Management a Channel for Sustainable Development in Tamil Nadu

R. Bharathi Rajan[1], R. Lakshmi[2], S. Thangamayan[3]

[1]Assistant Professor, Dept. of Commerce, [2]Associate Professor, Dept. of Commerce, [3]Assistant Professor, Dept. of Economics, Vels Institute of Science, Technology & Advance Studies (VISTAS), Pallavaram, Chennai

Abstract

Seasonal migration for work is a pervasive reality in rural India. An overwhelming 120 million people or more are estimated to migrate from rural areas to urban labour markets, industries and farms. Migration has become essential for people from regions that face frequent shortages of rainfall or suffer floods, or where population densities are high in relation to land. Areas facing unresolved social or political conflicts also become prone to high out migration. Poverty, lack of local options and the availability of work elsewhere become the trigger and the pull for rural migration respectively.

Migration is a form of geographical mobility or spatial mobility between geographical unit and another, generally involving a change in residence from the place of origin or place of departure to the place of destination or place of arrival. Such migration is called permanent migration and should be distinguished from other forms of movements, which do not involve a permanent change of residence. Migration is a very selective process. Migration is not for a pleasure. Migration is not merely the physical movements of individuals and groups involve a lot of strain in their social, economic, cultural and other aspect of life. It is a subject of keen interest not only to the demographers but also to sociologist, anthropologist, economist and political scientist movements of people, specially rural people from the land to the cities, from one country to another and from one continent to another is an international phenomenon and not a phenomenon of modern times. It concerns not only developing countries but also those which are highly industrialized and affects not only the more or capitalized countries but also the socialist change of the move or open the voluntary and involuntary nature of the act and destination. Is made between external and internal migration.

Introduction

Tamil Nadu is home to more than a million migrant workers, a government-commissioned survey has found[1]. The just-concluded survey conducted by a private consultant on behalf of the state labour department shows that a majority of the 10.67 lakh migrant workers in the state are unskilled workers. About 27% are employed in the manufacturing sector, 14% in textile industries and 11.41% in the construction sector. The numbers may be under-reported, say social workers, but the data will help them get healthcare and other benefits[2].

Experts say relatively better wages and employment opportunities in TN draw workers from West Bengal, Odisha, Bihar, Jharkhand and Assam. "Migration has been so much that Hindi and Bengali have become languages of communication in urban areas. Workers from West Bengal have proved their skill in laying granite floors, while those from northeastern states are sought after for security and hospitality services," he said. In the construction sector, activists complain, several migrant workers are not registered under the Tamil Nadu Construction Workers Welfare Board, leaving them at the mercy of builders and contractors[3]. A senior official in the labour department said the survey

e-mail: hellobharathi@gmail.com

was but a beginning. "This will help us keep a tab on the working and living conditions of migrant labours across the state," he said.[4] According to the migrant worker survey, 20.9% of migrant workers in Tamil Nadu live in Kancheepuram district. Most of them work in manufacturing companies. Kancheepuram has units including Ford, Hyundai, BMW and Nissan where several migrant workers are working. The top three districts-Kancheepuram, Chennai and Tiruvallur-house 51.3% of the migrant worker population. Real estate projects and the metro rail work have attracted migrant labour.

The second maximum number of jobs are offered by textile and allied industries which employ 1.5 lakh workers, evidently why Coimbatore has 12.1% and Tripura has 9% of the state's migrant population.

Tamil Nadu now home to 1 million migrant workers: Tamil Nadu is home to more than a million migrant workers, a government-commissioned survey has found[5]. The just-concluded survey conducted by a private consultant on behalf of the state labour department shows that a majority of the 10.67 lakh migrant workers in the state are unskilled workers. About 27% are employed in the manufacturing sector, 14% in textile industries and 11.41% in the construction sector. Migration has been so much that Hindi and Bengali have become languages of communication in urban areas. Workers from West Bengal have proved their skill in laying granite floors, while those from northeastern states are sought after for security and hospitalityservices.

In the construction sector, activists complain, several migrant workers are not registered under the Tamil Nadu Construction Workers Welfare Board, leaving them at the mercy of builders and contractors. A senior official in the labour department said the survey was but a beginning[6]. According to the migrant worker survey, 20.9% of migrant workers in Tamil Nadu live in Kancheepuram district. Most of them work in manufacturing companies. Kancheepuram has units including Ford, Hyundai, BMW and Nissan where several migrant workers are working. The top three districts Kancheepuram, Chennai and Tiruvallur house 51.3% of the migrant worker population.

Objectives

- To study the socio economic status of migration workers.
- To analyses the reasons for migration.
- To identify the problems faced by migrant labors.

Methodology: The researcher came to know about the large scale out migration from Kanchipuram districtand also the surrounding areas. Experience the same in the past by means of focus group discussion the respondent was confirmed the same and select Kanchipuram purposively for this study. Researcher has adopted the systematic random sampling technique[7]. To select the respondents for collecting the primary data. By adopting random start technique the researcher has selected the head of the households as respondents for the purpose of field investigations. Researcher has used the structured interview schedule as tool of data collection which was supplemented by observation technique for primary data collection. These are two types of data collected for his research which are primary data, and secondary data. Researcher had collection primary data by means of interview schedule. Researcher collected the secondary data through various sources like books, journals, magazines and News paper.

Analysis and Interpretation

Table: 1. Age of Daily Migrant wage Laborers

Age group of years	No. of Respondents (%)
16-25 15	(12.50)
25-35 54	(45.00)
35-45 40	(33.33)
45-55 6	(5.00)
55 and above	5(4.17)
Total 120(100.00)	**120(100.00)**

Source: Primary Source

The above table shows that out of 120 (100.0%) there are 15 (12.50 %) respondents belong to the age group of 16-25 years. 54 (45.00 %) respondents belong to the age group of 25-35 years, 40 (33.33%) respondents belong to the age group of 35-45 years. 6(5.00 %) respondents belong to the age group of 45-55 years and 5 (4.17%) respondents belong to the age group 55 and above years. Thus, it indicates that majority (45.00 %) of respondents are in the age group of 25-35 years and lowest number (4.17 of respondents are in the age group of 55 and above years. It means that more migrants are of younger (25-35 years) age group

Table 2: Education Status of Daily Migrant wage Labourers

Educational Status	No. of Respondents (%)
Illiterate	15(12.50)
Primary	17(14.17)
SSLC	39(32.50)
Hr. Sec	25(20.83)
Degree	6(5.00)
Others	3(2.50)
Total 120	120(100.00)

Source: Primary Source

The above table shows that out of 120 (100.0%) there are 15 (12.50) respondents have no education, 17 (14.17) respondents belong to primary education group, 39 (32.50) respondents belong to SSLC education group, 25 (20.83) respondents belong to Hr. Sec education group, 6 (5.0) respondents belong to graduate and 3 (2.5%) respondents are any other education. This indicates that majority (32.50) respondents are SSLC and short number (2.5%) respondents in any other education. It means that migrant has been there connected with illiterate group.

Table 3: Nature of Job of Daily Migrant Wage Labourers

Nature of Job	No. of Respondents (%)
White Wash	25(20.83)
Contractor	19 (15.83)
Wages Labour	76(63.33)
Total 120	Total 120(100.00)

Source: Primary Source

The above table shows that out of 120 (100.0%) there are 25 (20.83%) respondents doing white wash work, 19 (15.83%) respondents are doing the Contractor work and 76 (63.33%) respondents are doing the wage labour work. This indicates that majority (79.5%) respondents are doing the wage labour work and lower number (9.5%) of respondents are doing the Contractor work. It means that migrant has been there connected with wage labour works.

Table 4: Causes of Daily Migrant Wage Labourers

Causes	No. of Respondents (%)
Non-Availability of work	24
Less wage	16
Seasonal cause	45
Conflict in family	21
Any other (hesitation, ego, Problem)	14
Total 120	100

Source: Primary Source

The above table shows that out of 120, 24 respondents are migrating due to non-availability of work in their villages, 16 respondents are migrating due to less wage in the villages, 45 respondents are migrating due to seasonal lack of work, 21 respondents are migrating due to conflict in family and 14 respondents are migrating due to other problems. Thus, the above facts show that majority of respondents (45 out of 120) are migrating due to non-availability of work in the villages. Other causes are numerically lesser but still important e.g. less wage, seasonal unemployment and family conflict.

Major Findings

- The majority (45.00%) of respondents is in the age group of 25-35 years and lowest number (4.17%) of respondents is in the age group of 55 years and above. It means that more migrants are of younger (25-35 years) age group which is the most productive age group.
- The majority of the male respondents‟ (61.67%) live in the thatched houses, whereas, majority of the female respondents‟ dwell in the sheet form of houses.
- The majority (32.50)of respondents are SSLC and very small number (2.50)of respondents have any other education. It means that migrants largely SSLC or very less educated.
- The majority (53.33)of respondents have daily income of 60 to 80 rupees per day and smaller number (10.0%) of respondents have daily income of 120 rupees and above. It means that large majority of migrants get less wages i.e. 60-80 rupees daily.
- The large number (30.83)of respondents gets work for 15 to 20 days per month and the smaller number (13.33) of respondents get work for minimum 6-10 working days. It means that larger number gets work for 15-20 working days.

Conclusion

The contribution of migrant workers, both high-skilled and low-skilled, has led to India’s top remittance position in the world. Interstate migrant workers seem

to travel in an invisible carriage way to Chennai. The carriage way has been built over time by the friends and relatives of the migrant workers that carry more and more streams of migrant workers to Chennai.[8] The most prominent carriage way evident from our survey is the one that originates in North East and runs through the Eastern states to reach Chennai. However, a sizable section hail from marginal small farmer households and could mobilize the required financial resources to migrate. They are not educated much nor or they skilled to readily fit into the requirements in the destination. They leave behind their families and keep remitting most of their wage earnings and visit them at least once in a year. Thus one can conclude that these migrations are not driven by distress and despair. Thus there is a moral obligation for the state to bestow the complete citizenship to the migrants by instituting appropriate policies. As of now, it remains a silent spectator leaving the migrants at the mercy of the employers.

The Impact of Natural Disasters on Economic Growth: A Study of Kerala Floods

R. Bharathi Rajan[1], R.V. Suganya[1], S. Thangamayan[2]

[1]Assistant Professor, Dept of Commerce, [2]Assistant Professor, Dept of Economics, Vels VISTAS, Chennai

Abstract

Natural disasters have potentially large economic impacts on developing nations. There is a small, but growing literature analyzing these impacts on variables such as gross domestic product. In this study the state of Kerala are studied to measure the impact that disasters have had on economic growth especially tourism industry. It is hypothesized that the number of natural disasters that a country faces has a negative impact on economic growth rate as measured by GDP. As the quantity of disasters experienced in any given year increases the overall disruption of the economy is predicted to be greater, thus leading to lower levels of economic growth in the short term. The causes of the high frequency of severe natural disasters have become popular research topics, and the findings have improved the understanding of the relationship between human activities and the environment. However, the exploration into the relationship between natural disasters and long-run economic growth in Kerala tourism has not been minimal. This paper fills this gap by investigating the economic effects of post-disaster rebuilding activities in the current Kerala economic environment.

Keywords: *Natural Disasters, Economic Growth,Tourism, Kerala.*

Introduction

In late August 2018, severe flooding affected the south Indian state of Kerala due to unusually high rainfall during the monsoon season. It was the worst flooding in Kerala in nearly a century Over 445 people died, 15 are missing within a fortnight, while at least a million 45 people were evacuated, mainly from Chengannur, Pandanad, Aranmula, Aluva, Chalakudy, Kuttanad and Pandalam. All 14 districts of the state were placed on red alert.According to the Kerala government, one-sixth of the total population of Kerala had been directly affected by the floods and related incidents. The Indian government had declared it a Level Calamity or 'Calamity of a severe nature[1]. Thirty-five out of the fifty four 13 dams within the state were opened for the first time in history. All five overflow gates of the Idukki Dam were opened at the same time, for the first time in 26 years. Heavy rains in Wayanad and Idukki have caused severe landslides and have left the hilly districts isolated[2]. The situation was regularly monitored by the Prime Minister and the National Crisis Management Committee coordinated the rescue and relief operations

Table 1: Rain Fall from 1 June 2018-17 August 2018

District	Rainfall (mm)	Normal (mm)	Increase %
Alappuzha	1648.1	1309.5	29%
Ernakulam	2305.9	1606	48%
Idukki	3211.1	1749.1	89%

Causes Heavy Flood In Kerala: Kerala received heavy monsoon rainfall on the mid evening of August 8 resulting in dams filling to capacity; in the first 24 hours of rainfall the state received 310 mm (12 in) of rain. Almost all dams have been opened since the water level has risen close to overflow level due to heavy rainfall, flooding local low-lying areas.18 For the first time in the state's history, 35 of its 13 dams have been opened[3].

Most of the regions affected by this monsoon were classified as ecologically-sensitive zones (ESZs) by the Western Ghats Ecology Expert Panel, the Gadgil Committee. Most of the recommendations and directions by the committee was either neglected or rejected. Chairman of the committee Madhav Gadgil accused the state government and its irresponsible environmental policy for the recent landslides and floods. The Government of Kerala argued in the Supreme Court that the sudden release of water from the Mullaperiyar Dam by the Tamil Nadu government was one of the reasons for the devastating flood in Kerala[4]. The Tamil Nadu government rejected the argument saying that Kerala suffered the deluge due to the discharge of excess water from 80 reservoirs across Kerala, spurred by heavy rains from within the state; It also argued that the flood surplus from the Idukki dam is mainly due to the flows generated from its own independent catchment due to unprecedented heavy rainfall while the discharge from Mullaperiyar dam was significantly less.

Though it is difficult to attribute a single event to climate change, its possible role in causing the heavy rainfall event over Kerala cannot be discarded24. Recent research indicates that rising temperatures have led to huge fluctuations in the monsoon winds carrying the moisture from the Arabian Sea, resulting in heavy-to-extreme rains over the Western Ghats and central India, lasting for two to three days.

Impact of Flood in Kerala: A state official told AFP that 370 people have died, while The Economic Times has reported that 33,000 people have been rescued. 82627 The Kerala State Disaster Management Authority has placed the state in a red alert as a result of the intense flooding. 28 A number of water treatment plants were forced to cease pumping water, resulting in poor access to clean water, especially in northern districts of the state. Over 5,645 relief camps4 have been opened at various locations to accommodate the flood victims. It is estimated that 1,247,496 people4 have found shelter in such camps.3031 The flooding has affected hundreds of villages, destroyed an estimated 10,000 km (6,200 mi) of roads and thousands of homes have been damaged or destroyed[5]. The Government has cancelled Onam celebrations, whose allocated funds have been reallocated to relief efforts.

Kerala Economy and Tourism: Tourism is an important contributor to the growth of service sector in Kerala. The total revenue (including direct and indirect means) generated from tourism during the year 2015 comes to 26,689.63 crores showing an increase of 7.25 per cent over the last year. During the last decade, the total revenue from tourism registered a compound annual growth rate (CAGR) of 11.33 per cent. It grew from 7,738 crores in 2005 to 26,689.63 crores by 2015. The annual growth rate of income from tourism reveals a fluctuating trend between 2005 and 2015. Between 2013 and 2015, a declining tendency of the growth rate was noticed: from 12.22 per cent in 2013 to 7.25 per cent by 2015.

Table 2: Contribution of Tourism Sector to Total Employment between 2009 and 2015, in per cent

Share in Employment (in per cent)			
Country/ State	**Direct Impact**	**Indirect + Induced Impact**	**Total Impact**
India	4.4	5.8	10.2
Kerala	9.9	13.6	23.5

Foreign Exchange Earnings: The foreign exchange earnings from tourism increased from 1552.31 crores in 2005 to 6949.88 crores by 2015 registering a CAGR of 14.6 per cent. The earnings from foreign tourism showed a steady increase over the years, except for the year 2009 when the global financial crisis affected the flow of foreign tourist Arrivals and led to a decline in foreign exchange earnings. Figure 9.8 captures the data on foreign exchange earnings of Kerala over the last ten years[7].

Table 3: Allocation and Expenditure on Tourism in the State Plan over Various Plan Periods, in lakh

Period	**Total Plan Outlay**	**Outlay for Tourism**	**Percentage share of Tourism**	**Actual Expenditure**
I Plan	3003	--	--	--
II Plan	8701	13	0.15	8
III Plan	17000	50	0.29	22

Objectives of Paper:

- To study the impact of Flood inthe State of Kerala.
- To analyze the impact of Flood on Tourism Industry in Kerala.
- To compare the impact of Kerala and Other State

Research Methodology: The paper is based on secondary data. The data has been collected from internet and News papers, Graph and percentile method has been used to analyze the data.

Research Method :Netnography: Netnography is online ethnography conducted in a specific manner. It is an interpretive research method that adapts the traditional, in-person participant observation techniques of anthropology to the study of the interactions and experiences that manifest through digital communications (Kozinets 1998). The word "netnography" is a portmanteau combining "network" and "ethnography" and was a particular kind of research process which was developed and named in 1995 by Robert Kozinets during his dissertation research at Queen's University on Star Trek fans. Netnography was originally a consumer research method, but use of the method has spread to a range of other disciplines, including education, library and information sciences, hospitality, tourism, computer science, psychology, sociology, anthropology, geography, urban studies, leisure and game studies, and human sexuality and addiction research.

Data Collection: In a netnography, data takes two forms: data that the researcher directly copies from the computer-mediated communications of online community members, and data that the researcher inscribes. Although some netnographies have been conducted using only observation and download.

Data Analysis: Netnography is based primarily upon the observation of textual discourse, ensuring trustworthy interpretations requires a different approach than the balancing of discourse and observed behavior that occurs during in-person ethnography. Although the online landscape mediates social representation and renders problematic the issue of informant identity, netnography seems perfectly amenable to treating behavior or the social act as the ultimate unit of analysis, rather than the individual person.

Findings: Kerala Floods 2018: Flood-Hit Kerala's Tourism Industry Grinds to a Halt. Kerala is reeling under the aftermath of the devastating flood, so do the tourism industry, which has been hit hard by the deluge. The southern state, which is considered as one of the top tourist destinations, is still recovering from the impact of floods that claimed lives of over 300 people.

The tourism industry in Kerala, which accounts for 12 percent of the state's economy, has come to a grinding halt as the floods damaged roads, airports, rail lines, forcing tourists to cancel their trips."International flights are cancelled. Since its Onam, and at the same time we have monsoon tourism, we expected good business but suddenly hotels, restaurants, and home-stays are empty," he added.As the situation has subsided, the locals and the government are trying to bring Kerala back to normalcy. Tourism industry estimates losses worth Rs 20 billion due to Kerala floods.

The tourism industry in Kerala is estimating losses worth Rs 20 billion due to the floods which include Rs 15 billion as the opportunity lost during the last two months and another two to three months. Sabarimala, one of the major pilgrim centres in South India, has seen a loss of around Rs One billion and is expecting the situation to remain bleak during this pilgrimage season if at least a bridge is not built for the pilgrims to travel to the Lord Ayyappa Temple.

The properties were not affected except for Kumarakom. While the damage was massive in the hill stations of Munnar and Wayanad, properties were not affected, but the road connectivity has been affected. Tourism in Kerala is a Rs 300-350 billion industry. Opportunity lost due to the floods is expected to be at Rs 15 billion for the last two months and the next couple of months.

Conclusion

Kerala had witnessed 10.94 per cent growth in 2017, compared to the previous year, with 1.91 million foreign travellers and 14.6 million domestic tourists visiting the state[8]. Tourism contributes over 10 per cent to the state GDP. Kerala was promoting the Neelakurinji blooming in Munnar, which is still cut off from the rest of the state due to many landslides. The Neelakurinji blooms once in 12 years and has been a big draw for local public and of late, the tourism department has been promoting it to incoming tourists as well. Flooding on the scale seen in Kerala could have killed 10 times more people a decade ago, but India's disaster management capacity has improved significantly in that timeKerala received over 40 per cent more rainfall than usual this monsoon, forcing authorities to release water from dozens of dams, which compounded the flooding. But other man-made problems were also to blame. Kerala is one of India's wealthiest states and has seen rapid unplanned development in recent years, with luxury resorts, residential complexes, power plants and mines built on floodplains, often in violation of the rules.

Impact of Self-Efficacy of Middle-Level Managers on Implementing Innovation

R. Vimaladevi[1], D. Ganesan[2]

[1]Research Scholar & Assistant Professor, Vels University, Pallavaram, Chennai,
[2]HOD & Research Supersivor, Government Arts College, Villupuram, Tamilnadu, India

Abstract

The paper explores to know the impact of self-efficacy of middle-level managers towards implementing innovation in their work The researcher has chosen the leading 4 private sector banks in Chennai city namely ICICI, Kotak Mahindra, Axis and HDFC. The researcher has directly visited the branches for collecting the primary data through well structured questionnaire. The researcher has used the stratified random sampling method for collecting the data from 345 respondents. The data analysed using percentage analysis, one sample t-test, Chi-Square analysis and Karl Pearson Correlation. The study inferred that middle-level manager who has high sense of self-efficacy could have high level of implementing innovation in their job. The study also proved that there is strong correlation among self-efficacy of middle-level manager and implementing innovation in their job.

Keywords: *Middle-level manger, self-efficacy, implementing innovation, impact.*

Introduction

In changing scenario, banking sectors plays crucial role in the economy. Hence, the banking sectors have to be innovative and creative in order to meet the customers' needs. The success of any organization lies in the hands of effective management. This can be possible only by the managers who have high sense of self-efficacy. Self-efficacy of the person can greatly help to create impact in their thinking, behaving, motivating, coping the behaviour to take situation in perspective way. Luszczynska (2005) opined Psychologist Albert Bandura view on self-efficacy as "one's belief in one's ability to succeed in specific situations or accomplish a task. One's sense of self-efficacy can play a major role in how one approaches goals, tasks, and challenges".[1] Self-efficacy of the manager helps to accomplish the organization goal effectively in competitive environment. The managers who have high sense of self-efficacy can tackle the tough situation where as the person who with low level of self-efficacy get frustrate easily in the tough situation and drop out from the responsibility. Thus, there is a greater demand to improve the self-efficacy of the managers in order to sustain in the competitive world.

Objectives:

- To identify the self-efficacy of the middle-level managers of selected private sectors
- To identifythe implementation of innovation of the middle-level managers of selected private sectors in Chennai city.
- To study the association between the level of self-efficacy of the middle-level managers and level of implementing innovation among the middle-level managers in selected private sectors banks in Chennai.
- To study the impact of self-efficacy of middle-level managers on implementing innovation.

Review of Literature: Bessant, J. & Tidd, J. (2011) according to them, effective change management is inevitable to implement innovations. The skills consist of highly developed understanding of the process and its various components, project planning and management, teamwork skills in uncertain conditions, leadership–having a vision and the ability to implement innovation, learning skills–the ability to analyze, identify positive and negative events and their causes, the ability to correct the process on their basis[2]

Cherian and Jacob (2013) the study explores the impact of self-efficacy on motivation and performance of employees. The study revealed that theory of self-efficacy could influence work related performance.[3]

Grauet al. (2001) emphasis that self-efficacy is a moderator in the occupational stress process. Specifically, it analyses the complementarily between two self-efficacy measures: generalized and professional. The study was conducted with 140 workers who performed their task on new technology. The study revealed that self-efficacy controls the stress strain association. i.e, low levels of self-efficacy is related to high degree of occupational stress. It was also found that individuals with low levels of self-efficacy expressed more emotional excretion.[4]

Katarzyna et al. (2014) the study focused to identify essential managerial competencies would promote and enhance innovation in companies. The study carried among managers of top, middle and operational management level in companies operating in Poland. The research has found key competencies of managers in the context of implementing innovation in the company as well as differences resulting from the level of management in the organization. It also to identify discrepancies between the current levels of competencies needed to achieve organizational objectives, and the expected level ensuring maximum efficiency during their implementation of innovation.[5]

Persing (1999) explores that individual creative and innovation idea create employee to higher level in the organization.. The findings indicate that the task of the manager in the innovation process is not to generate new products, concepts, new ideas, but to strengthen and increase creativity of team of employees. Important skills include the ability to motivate others, to persuade orders and build relationships and trust. The manager's personal motivation has to come primarily from aspiration, excitement, persistence and perseverance.[6]

Quinn et al.(1990) asserted that the manager's awareness make inevitable changes in the business environment and provide opportunities for innovation and development. An organization which is readily adapts change and innovation will meet demands and changes of contemporary society. The innovator envisions change and a more effective way of doing things.[7]

Ruba Osama Hawi, Dina Alkhodary and Tareq Hashem (2015) the study investigate relationship between the managerial competencies and the firms' performance in Jordan. The data collected from 4 reputed airways organization and distributed to 62 managers. The result shows that strong association with the organizations performance in the airline sectors in Jordan. Further, it asserts that organizations innovations have linked to the strategic competency, while client focus linked with the organization competitive advantage.[8]

Hypothesis:

- There is no self-efficacy among the middle-level managers of selected private banks in Chennai city.
- There is no implementing innovation among the middle-level managers of selected private banks in Chennai city.
- There is no association between level of self-efficacy and level of implementing innovation among the middle-level managers in selected private sector banks in Chennai city
- There is no correlation between overall self-efficacy and overall implementing innovation among the middle-level managers in selected private sector banks in Chennai city

Scope of the Study: The study aims to identifyself-efficacy of the middle-levelmanagers, implementation of innovation in the selected private sectors banks in Chennai and also to know the association between the level of self–efficacy of middle-level managersand level of implementing innovation. The study emphasised to know the impact of self-efficacy of the middle-level mangerson implementing innovation.

Methodology: The study consists of both primary data and secondary data. The primary data are collected from 345 respondents from the selected private sector bank of middle-level managers in Chennai such as ICICI bank, HDFC bank, Kotak Mahindra bank and Axis bank. Stratified random sampling method was used for collecting the data. Percentage analysis, one sample t-test analysis, chi-square analysis and Karl Pearson correlation analysis has been used to analysis the data. The secondary data were collected from books, websites and journals.

Limitation: The sample which used pertains to select four private sector banks in Chennai city only. Therefore, it is considered as the prime limitation. The study constraints only middle-level managers of the banks.

Data Analysis and Interpretation

Null Hypothesis: There is no self-efficacy among the middle-level managers of selected private banks in Chennai city.

Table 1: One-sample test for self-efficacy

Factors	N	Mean	Std. Deviation	t-value	P-value
I will be able to achieve most of the goal that I have set for my self	345	3.25	1.207	3.881	0.000**
When facing difficult tasks, I am certain I will accomplish them	345	3.26	1.246	3.846	0.000**
In general, I think I can obtain outcomes that are important to me	345	3.19	1.161	3.106	0.002**
I believe, I can succeed at most any endeavour to which I set my mind	345	3.18	1.304	2.560	0.011*
I will be able to successfully overcome many challenges	345	3.21	1.187	3.265	0.001**
I am confident that I can perform effectively on many difficult tasks	345	3.21	1.232	3.102	0.002**
Compared to others, I can do most of the tasks well	345	3.33	1.230	4.990	0.000**
Even when things are tough, I perform quite well	345	3.19	1.220	2.957	0.003**

Source: Computed from primary survey
Note: **denotes significant at 1% level, *denotes significant at 5% level

The above table shows the results of one sample t-test for self-efficacy of the respondents of the middle-level managers of selected private banks. The factors of self-efficacy of the middle level manager's p-values are less than 0.01 and statistically significant at 1% with respect to following aspects such as "In general, I think I can obtain outcomes that are important to me" (3.19), "Even when things are tough, I perform quite well" (3.19), "I will be able to successfully overcome many challenge" (3.21), "I am confident that I can perform effectively on many difficult tasks" (3.21), "I will be able to achieve most of the goal that I have set for myself" (3.25), "When facing difficult tasks, I am certain I will accomplish them" (3.26), "Compared to others, I can do most of the tasks well" (3.33). The p-value of the following statements "I believe I can succeed at most any endeavor to which I set my mind" (3.18) is less than 0.05. Thus, it proved that statistically significant at 5% level. The study concluded that self-efficacy exist among the middle-level managers of selected private sectors banks in Chennai city and also the mean value of all the variables are more than (3.00) which means all the variables of self-efficacy are agreeable. Hence, it inferred that self-efficacy of the middle-level managers is high among the middle-level managers of selected private sectors banks.

Null hypothesis: There is no implementing innovation among the middle-level managers of selected private banks in Chennai city.

Table 2: One-sample test for implementing innovation

Factors	N	Mean	Std. Deviation	t-value	P-value
I focus on developing solutions in day-to-day operations	345	3.13	1.146	2.161	0.031*
I feel reliable operation has the highest priority at our workplace	345	3.15	1.177	2.380	0.018*
I am good at collaborating across the workplace	345	2.43	1.063	-9.928	0.000**
I emphasis on developing own solutions	345	2.53	1.289	-6.806	0.000**
I work by learning systematically from our mistakes	345	2.80	1.425	-2.569	0.011*
I value people who come with new ideas	345	3.65	1.479	8.154	0.000**
I find that it is easy to reuse good ideas	345	3.69	1.271	10.080	0.000**
I work by systematically incorporating the employee's differences(Education, Age and Gender)	345	3.20	1.443	2.537	0.012*

Factors	N	Mean	Std. Deviation	t-value	P-value
I work by systematically incorporating citizen's and/ or companies points of view	345	3.28	1.183	4.413	0.000**
I work actively in comparing ourselves with other workplaces that are similar to us	345	3.18	1.489	2.206	0.028*

Source: Computed from primary survey
Note: **denotes significant at 1% level, *denotes significant at 5% level

The above table indicates the results of one–sample t-test for implementing innovation. The result highlights the mean value, standard deviation, t-value and p-value of the all the statements of implementing innovations. The mean range of all the variables 2.43 to 3.69 and standard deviation range from the 1.063 to 1.289. From the above table, the p-value of "I am good at collaborating across the work place "(2.43), "I emphasis on developing own solution'' (2.53), "I value people who come with new ideas"(3.65), I find that it is easy to reuse good ideas"(3.69,) " I work by systematically incorporating citizen's and/ or companies points of view"(3.28) are less than 0.01 and statistically significant at 1% level. Therefore, the null hypothesis is rejected at 1% level of significance. The p-value of "I work by learning systematically from our mistakes" (2.80), "Ifocus on developing solutions in day-to-day operations" (3.13), "I feel reliable operation has the highest priority at our workplace" (3.15), "I work actively in comparing ourselves with other workplaces that are similar to us" (3.18) and "I work by systematically incorporating the employee's differences" (3.20) are statistically significant at 5% of level. Therefore, the null hypothesis rejected at 1% level of significance. The study found that there is implementing innovation exists among the middle-level managers of selected private sectors banks in Chennai city.

Null Hypothesis: There is no association between level of self-efficacy and level of implementing innovation among the middle-level managers in selected private sector banks in Chennai city

Table 3: Chi-square test for level of self-efficacy and level of implementation innovation

Level of Self-efficacy	Level of Implementing Innovation			Total	Chi-square value	P-value
	Low	Medium	High			
Low	108 (89.3%) [61.0%]	13 (10.7%) [11.4%]	0 (0.0%) [0.0%]	121 (100.0%) [35.1%]	118.700[a]	0.000
Medium	54 (32.1%) [30.5%]	68 (40.5%) [59.6%]	46 (27.4% [85.2%]	168 100.0%) [48.7%]		
High	15 (26.8%) [8.5%]	33 (58.9%) [28.9%]	8 (14.3%) [14.8%]	56 (100.0%) [16.2%]		
Total	177 (51.3%) [100.0%]	114 (33.0%) [100.0%]	54 (15.7%) [100.0%]	345 (100.0%) [100.0%]		

Source: Computed from primary survey
Note: Figures in () indicates row percent; Figures in [ ] indicates column percent

The table denotes the results of chi-square between level of self-efficacy and level of implementing innovation. The calculated chi-square value is 118.700 and p-value is 0.000 which is lesser than 0.01 and statistically significant. Hence, it proved that there is significant association between level of self-efficacy and level of implementing innovation.

Hypothesis: There is no correlation between overall self-efficacy and overall implementing innovation among the middle-level managers in selected private sector banks in Chennai city

Table 4: Karl Pearson correlation between overall self-efficacy and overall implementing innovation among the middle-level managers

Correlation			
		Overall Self-Efficacy	**Overall Implementing Innovation**
Overall Self-efficacy	Pearson Correlation	1	.491**
	Sig. (2-tailed)		.000
	N	345	345
Overall Implementing Innovation	Pearson Correlation	.491**	1
	Sig. (2-tailed)	.000	
	N	345	345
**Correlation is significant at the 0.01 level (2-tailed).			

Source: Primary Data

The above table shows the results of Karl Pearson correlation analysis between overall self-efficacy and overall implementing innovation among the middle-level managers. The p-value is 0.000 which is less than 0.01 and statistically significant at 1% level. The mean value indicated that about 49% of correlation between overall self-efficacy and overall implementing innovation. The study inferred that self-efficacy of the middle-level managers have strongly influence the implementation of innovation among the middle-level managers. Hence, it concluded that there is an association between overall self–efficacy and overall implementing innovation.

Findings and Conclusion

- The study found that 65.8% of the respondents are male and 34.2% of the respondents are female from the total respondents of 345.
- The study established that 25.2% of the respondents are from the age group of below 30 years and 30.4 % are from the age group of 31-35 yrs.
- The study originated that 25.8% of the respondents are from ICICI bank, 25.2% of the respondents are from HDFC bank, 24.9% of the respondents are from Axis bank and 24.1% of the respondents are from Kotak Mahindra Bank. It reveals that nearly equal responses are received from the selected private sector banks
- One sample t-test analysis shows that self-efficacy of the middle-level managers is high among the middle-level managers of selected private sectors banks.
- One sample t-test analysis found that there is implementing innovation exists among the middle-level managers of selected private sectors banks in Chennai city.
- Chi-square analysis proved that there is significant association between level of self-efficacy and level of implementing innovation.
- The Karl Pearson correlation analysis showsthat there is an association between overall self–efficacy and overall implementing innovation.

It concluded that middle-level managers possessed high sense of self-efficacy, the study also shows that implementing innovation exist among the middle-level managers in selected private sector banks and also it creates greater impact on implementing innovation. Hence, the self-efficacy of middle-level managers placed important role in implementing innovation in the respective field. So, the study recommended that banking sector should give importance to improve self-efficacy of the employee through giving proper training, mastery in their field in order to sustain in the competitive business world.

A Cognitive-neuroscience Module to Enhance Spiritual and Physical Well-being

Rajarethinam Emmanuel[1], Chithirai Rajan[1], S. Saravanan[1], Telu Suvarna[1]

[1]Asst. Professor, Vels Institute of Science, Technology and Advanced Studies, Velan Nagar, Pallavaram, Chennai

Abstract

Despite the fact there is a huge advancement in cognitive-neuroscience, it hasn't brought about any substantial change in the way human beings think and feel. The estimation we have of ourselves is almost the same as the people of the prescientific era. However there are vast potentials, if only we would start applying the findings of science to our own mind processes. By culling out the essential discoveries of neuroscience that can contribute to a deeper understanding of our own psychology, this article argues that there is a close agreement between the tallest aims pitched by Religions and the functional design of brain as brought out through a large number of studies.

Keywords: *Learning, Memory, Synapse, Plasticity of Brain.*

Background

The modern scientific era began with the discoveries of the celestial system and it had remarkable ripples on the conventional beliefs of Religions founded a few millennia earlier. The victory march of science, ever since, has revolutionized our knowledge of the stellar universe as well as life on planet earth and it has led all the way to the impressive discoveries on the structure and function of human brain. However, belying all expectations, cognitive-neuroscience can hardly claim to have made as much of an impact in human psychology as has been the case with biological and technological innovations.

The complexity, of course, is much greater here. The rift that has come about between the pursuers of science and the followers of religion over the past few centuries is yet another reason as to why substantial attempts in applying the fruits of neuroscience to the traditional belief system has not come about in the expected way.

However this is an arena of huge significance. A vast field of opportunities lie open largely unutilized. There's a crying need to come up with the points of convergence as well as clarifications at the crossfire of the recent findings on brain and the traditional ways of constructing our personality.

One of the major discoveries of neuroscience is that the plasticity of neural links has allowed the formation of specialized locations in human brain for speech comprehension and production. Language, as is well-known, is a social arrangement of communication and it has found an adequate support system in the structural evolution of human brain. Such major modification of brain structure that occurred in less than two million years indirectly implies that any new conclusive insights obtained by human beings redefining their perception of themselves as well as the mighty reality of existence will definitely make similar impressive changes in the already existing neural connections. At the level of consciousness, these changes might be experienced as the generation of a higher level of positive emotions and self-confidence born of increased mental certainty.

This article in fact would present a module of such a program. Even if the topic of this nature is too vast for a single experimental set-up and consequently for a single article of this kind, we would make some introductory attempts by briefly summarizing the advances made in cognitive-neuroscience and projecting a set of implications that would assist the pursuit of self-knowledge, joy and ethical values.

Material and Method

Neuroscience has made impressive progress in the last two centuries. The physical input starting off at a specific part of the body gets converted as low voltage electric signals and it is passed on through a one-way

stretch of neural links to some specific destination of the brain. Cognitive-neuroscientists have identified the major functions of the different destination areas of the brain. It has also been basically established that once the signal reaches the brain system, multiple circuits triggering multiple actions get initiated, although each of it still maintains the fundamental characteristic of one way link between any two neurons. And this trigger can happen both voluntarily as well as involuntarily starting right from brain processes themselves.

In his seminal book, *In Search of Memory*, Eric R. Kandel[1] captures the major developments of neuroscience over the past two centuries. By examining the neural basis of sensitization, habituation and classical conditioning, Kandel has adequately dealt with the brain regions and functions of implicit and explicit memory, both in their short term and long term modules.

And there's an astonishing similarity of neural mechanisms experimentally verified across species, starting from very simple systems. Indeed the breakthrough for Kandel came via experimental studies on the marine snail, which was later expanded to the mammalian system. The action potential of neural firing across all species is just one and the same-A rest potential of-70 millivolts shoots up to +30 millivolts, if and when the action occurs. And the signal is carried on to the successive neuron lying in an extreme proximity called synapse and this is achieved through the exchange of chemical signals called neurotransmitters. The mediatory synaptic action between any two neurons is accomplished through the release of glutamate from the pre-synaptic terminal to the post-synaptic one. A modulatory circuit is also found across most species enabling the effective learning processes of sensitization and conditioning. This circuit acts on the central body of the signal carrying neurons without directly interfering at the synaptic connections.

As per the remarkable summary of Kandel, serotonin plays the modulatory role in shaping the memory of involuntary behavior and dopamine plays the modulatory role in shaping the memory of voluntary attention and behavior. Attention, however, is always to a specific sensation or a group of sensations. The human ability to acquire knowledge and the ability to control emotions are indeed built around the basic neural system of learning and retaining memory. Since language is nothing but a group of sound, gesture or pictorial format, these sensations could be registered as memory and the connections found in the law of nature could be expressed verbally with the support of the short-term and long-term brain memory system.

According to Kandel, short term memory is a functional optimization of existing synaptic connections, while long term one is a result of the growth of new synaptic terminals. Kandel has also described how repeated pulses of dopamine induced through training leads to long-term explicit memory. In such cases, gene expression followed by protein formation results in the growth of new synaptic terminals.

The modulatory circuit releasing dopamine is thus responsible for short-term memory caused by a single powerful incident and long-term memory produced out of training or emotional rapture.

Kandel's study on explicit memory was restricted to the action of hippocampus to form spatial memory in mammals like rodents. But as we know, the explicit memory of human beings is certainly lot more than the spatial memory of escape routes. Language which is essentially a memory of the sound and picture of words has enabled human beings to move into the stage of abstract thinking and reasoning and one must extend the molecular study on explicit memory to the language process and apply it even to the practice of self-talk that goes on within a human being. In recent times, cognitive-neuro scientists[2] have turned their focus towards the role of hippo campus in forming semantic memory.

Apart from the generic studies on memory, more especially the semantic memory required for our purpose, specific experiments on cognitive generation and control of emotions have also yielded some uniform results. In an excellent review of the available studies on "The Cognitive Control of Emotions", Kevin N. Ochsner and James J. Gross[3], have succinctly described the evidence for both attentional influence[4, 5, 6] and cognitive control of emotions[7,8,9]. A clear map of the different regions that are activated in such processes of generating, controlling or avoiding emotions is also given in this excellent review.

The studies on placebo effect[10,11], for instance, have clearly shown the evidence for the reduction of pain when the subject generates the belief that the placebo cream or drug blunts pain. The experimental studies have established the plasticity of brain to accommodate any new learning that takes place. The cognitive control of emotion, a traditional skill undertaken by all human

beings across all cultures, was upheld scientifically by instructing the subjects to ruminate over an upcoming emotional stress event or joyful event or by observing the neural reappraisal system while the subjects attempt to reinterpret the meaning of an emotional stimulus. The brain evidence for the conditioning of mind with the objective of avoiding an existing habit of emotional arousal has also been established. Studies on the effect of training on compassion leading to a better sharing of resources have also been undertaken.[12]

The challenge, however, is this. While experimental studies are restricted to some controlled types of learning and regulation of emotions, they can't be uniformly applied to each and every human context. The complexity here hardly allows mathematical extension or model replication of the kind seen in physical and biological technologies. And yet human culture has immensely distinguished itself from the rest of the species, by simply making use of the sensations and the language built on sensations.

After enriching oneself with the knowledge of neural structure and functions, it is therefore entirely left to the individual to take the findings as examples and to start applying them in the larger context of their life. Each human being is indeed capable of evaluating much more than a simple emotional cue generally taken up for an experimental study. With the availability of the senses and the facility of language, we can in fact go ahead and make some definitive statements about the structure and nature of the whole of cosmic evolution, including the way our own mind has evolved over time. It is this kind of holistic search for meaning that brought about faith systems in olden times. Many of the physical truths found in the religious systems might have been proved wrong given the extraordinary scientific instruments developed in modern era. But despite all discoveries, science is still unable to explain the fact of fine-tuning observed in the universe leading to such extraordinary developments as the sustained expansion of cosmos, the wonder of life and the birth of consciousness. A holistic explanation is possible only under the assumption that there's an intricate planning similar to our own setting up right from Big Bang mutually relatable components that continue to evolve on their own terms to bring about even more complex components in an endless progress of change.

The universal pattern of evolution substantiates some of the tallest teachings of Religion. Under the common paradigm of little components building complex constructs, there can be noseparate thing such as 'atom', 'molecule', 'cell', 'self', 'caste', 'religion', 'race' or 'nation', although for all practical purposes they have been facilitated to evolve and function as separate entities. By imbibing the facts discovered by science, the human mind would necessarily become far more capable of moving in and through all these carefully-built-up entities and to discover the manner in which they can be assembled and the manner in which they can be disintegrated. To top it all, the findings of neuroscience have enabled us to verify for ourselves how through bits and pieces of memory chemically stored in different regions of our brain, an individual self or an individual memory system has been constructed.

A Module for Change of Perception from the findings of Neuroscience

- As different regions and molecular systems have been implicated both for the arousal of emotion, speech and their control and regulation, the traditional judgment built by our memory system can often be on a mistaken platform. Each individual must reassess the directly experienced mental state acquired largely through culture and tradition by breaking it down to the simple sensations from which the entire construct has been built right from childhood.
- Once we focus on the fact that there are universal features in our brain systems supporting learning, the generation of emotion and memory, it becomes that much easier for us to mingle into the entire evolutionary development, rather than just holding on to our memory as if it has come from nowhere.
- The evidence found in our brain system for the cognitive control of emotion and reappraisal of a situation instantly validates the tireless effort carried on by Religion and Wisdom literature in training human beings to evolve into socially responsible individuals each developing a mental fortitude of their own. The modulatory circuit playing a crucial role in brain functions has only been taken a step further through the relentless teachings of Religion and our own individual efforts of conscious control of life to excel as exemplary human beings. Indeed with the extent of knowledge that we already command, we need to aim at far greater ideals of the kind given to us through religions.

- Thanks to the symbolic sensations called language, we are now capable of understanding the connections and commonalities of the entire flow of cosmic events. Yet our emotions and touch sensations causing pain and pleasure are largely dictated by the immediate and close reality, which in any case is mighty little in comparison to the whole universe. It now becomes incumbent on the individuals to repeatedly remind themselves of the utter paucity of the judgments and emotions the neural system manages to present to them. The current system of the natural flow of emotions and judgments definitely calls for revolutionary corrections in the context of the integrally connected expansion of the universe.
- If the placebo effect has been scientifically verified, it immediately follows that the traditional religious statement inviting human beings to feel as if they are the secretive plan and strength of the entire universe, can indeed make remarkable changes in the build-up of their own psychic strength. Smaller the belief that we entertain, smaller will be the results as well.
- We have been jumping from one argument to another without realizing that there's a chemical basis for each of the statement that we make. The repeated attention paid to this simple fact would necessarily make it clear that we have no distinctive existence of our own and that whichever effect we reflect upon is nothing but a continuation of our brain activities.
- Each sensation including the sensation of language does indeed have a unique feel and an exclusive nature of self-intelligibility. Just reflecting over this specialty that has come our way via physical evolution and by reflecting over the strong possibility that the entire universe might be dependent on such exclusive feel of intentional plan and arrangement, the individual can bring about a secret union between their own ability to learn the structure of everything and the mysterious ability to move all things as per a constructive scheme of its own.
- Ultimately the individual can easily understand that the current emotions he or she experiences must be vastly upgraded in accordance with the fact that the meaningfulness he or she experiences and the intricate planning that has brought about the entire universe can easily be seen as one and the same root and sprout.

Conclusion

When human beings keep up the journey of discovering the real nature of connections of all things outside and inside one's own consciousness and throw away the myths, exaggerations and the misplaced priorities and orders, this would necessarily reflect itself in the new pathways of neural connections as well. The special arrangements our brains have made to retain language memory offers definite hope that the emotional wirings would also undergo significant changes with the additional discoveries, insights and the conscious efforts that we take up to improve our psychic health.

Does Season Worsen Air Quality: Comparison of Pollutant Levels for Summer and Winter in New Delhi

Rudraksh Gupta[1], Manju Rawat Ranjan[2], Usha Mina[3], Rajul Kumar Gupta[4],

Abstract

The present study endeavours to compare pollutant levels for summer and winter season at selected sites in Delhi, namely-Pusa in Central Delhi, ITO in East Delhi, Dwarka in South West Delhi and Rohini in North West Delhi. The 24 hour average of prevailed ambient levels of Particulate Matter ($PM_{2.5}$), Nitrogen dioxide (NO_2) and Nitrogen oxide (NO) air pollutants were documented. Results indicate that ambient levels of selected pollutants in winter season were significantly higher than summer season. Pollution levels were lowest in Pusa (in summer and winter) followed by Dwarka, Rohini and ITO.Crop stubble burning, crakers during festival of Diwali and adverse ambient atmospheric conditions makes the winter air worse. Effective political will, implementation of regulations, awareness amongst residents and tree-plantation could help offset winter pollution.

Keywords: *Air quality, Pollutants, Seasonal change, Summer, Winter, Vegetation, Delhi.*

Introduction

Since the enactment of Air (Prevention and Control of Pollution) Act, 1981, air pollution control programs have focused on point and area source emissions, and many communities have benefited from these control programs. Nonetheless, most cities in the country still face continuing particulate non-attainment problems from aerosols of unknown origin (or those not considered for pollution control) despite high level of control applied to many point sources.

Being a major centre of commerce, industry and education, Delhi has experienced a phenomenal growth in recent years. Like many other large cities, Delhi is adversely affected by problems of urbanization. The burgeoning population coupled with rapid growth in terms of vehicles, construction, and energy consumption has resulted in serious environmental concerns in Delhi.

Air pollution in Delhi is caused mainly by industry and vehicular traffic present both inside and outside Delhi. Delhi's annual average concentration of PM_{10} is highest among major Asian cities, and was between three and four times the Indian standard in 2001–2004. Balachandran et al (2000)[1] and HEI, (2004)[2] reported that PM_{10} concentrations exceeded national standards, and that roughly half the PM10 mass in Delhi could be attributed to fine particulate matter. The number of vehicles in Delhi is ever increasing causing great concern regarding concentration of NO_x.

In some studies, the pollution levels were reported worse in winter compared to other seasons due to emissions from heating and unfavourable meteorological conditions for dispersion. (Guttikunda and Gurjar, 2012).[3] At the beginning of winters, fog starts to set in and at this time the farmers resort to crop stub burning, leading to formation of smog thus increasing the

pollutant levels and compromising air quality. Cracker burning during festival of Diwali too coincides with the same season further worsening the situation. This spurt in pollution during winters has definite deleterious effects on air quality, health of people and the environment. On the other hand, rains may precipitate the pollutants, thus reducing the pollutant levels. It is therefore important to study the effect of seasons on the pollutant levels in the city.

The present study endeavours to quantify this worsening of air quality, through ascertaining the levels of pollution during winters and comparing them with summers and also analysing the health effects.

Methodology: This Observational-analytical study was undertaken at New Delhi, India, which has an elevation of 216 m above sea level, The area of NCT Delhi is 1484 sq km (latitude 28°.64'N, and longitude 77°.21'E). The study was undertaken over five months and ambient air pollution levels were monitored during winter (January-March 2018) and summer (April-May 2018).

Four sites were selected, to cater for the four directions of Delhi, i.e. North, East, Central and South-West. They were located far away from each other, namely:

1. Dwarka (DAV School)-South West Delhi
2. ITO (Metro Station)-East Delhi
3. DTEA Senior Secondary School, Pusa Road-Central Delhi
4. Rohini (Delhi Technical University)-North West Delhi.

Data of $PM_{2.5}$, NO_2 and NO levels, on daily basis was downloaded from Central Pollution Control Board (CPCB) nearbymonitoring sites displayed on website (https://app.cpcbccr.com/ccr/#/caaqm-dashboard-all/caaqm-landing/data)for the entire study period.[5]

Results

Pollutant Concentration: Winter

Average pollutant concentration for the three pollutants, namely $PM_{2.5}$, NO_2 and NO for winter from the four sites is depicted in Table 1.

Table 1: Mean Pollutant concentration for winter months (January-March 2018)

Site	Level of Pollutant		
	$PM_{2.5}$(µg/m^3)	NO_2(µg/m^3)	NO(µg/m^3)
Pusa	91.5	24.5	29.0
Dwarka	157.4	40.0	27.0
Rohini	205.4	26.8	41.2
ITO	146.2	73.5	129.6
Standard	60.0	80.0	80.0

From Table 1 it is observed that pollutants were highest in ITO except for $PM_{2.5}$ which was highest in Rohini. $PM_{2.5}$ at all four sites exceeded standard values, and also exceeded prescribed standard (60 µg/m³). NO_2 levels were highest at ITO and lowest in Pusa. However none of these exceeded the standard. NO levels were highest at ITO and lowest in Dwarka. At ITO, NO levels exceeded standard.

Mean Pollutant Concentration: Summers

Table 2: Mean pollutant concentration for Summer months (April-May 2018)

Sites	Level of Pollutant		
	$PM_{2.5}$ (µg/m^3)	NO_2(µg/m^3)	NO(µg/m^3)
Pusa	53.8	53.5	31.5
Dwarka	104.5	35.5	16.0
Rohini	97.3	7.3	16.4
ITO	81.7	138.1	142.7
Parameter	60.0	80.0	80.0

Table 2 depicts pollutant level for summer being highest in ITO except for $PM_{2.5}$ which was highest in Dwarka. $PM_{2.5}$ value at Pusa was lower than standard. But for other three sites $PM_{2.5}$ value exceeded standard.

NO_2 levels were highest at ITO and lowest in Rohini. NO_2 values at ITO exceeded standard, while being lower than standards at other three sites. NO levels were highest at ITO and lowest in Dwarka and Rohini. At Pusa, Rohini and Dwarka, NO levels were below, while at ITO it was higher than prescribed standards.

Table 3: Difference of Means (Winters & Summers) in Level of Pollutants and Statistical Significance (p) [n=66]

Sites	Seasonal Difference of Means and Statistical Significance (p)					
	$PM_{2.5}$ (µg/m^3)	p	NO_2 (µg/m^3)	p	NO (µg/m^3)	p
Pusa	37.75	<0.05	28.99	<0.05	2.47	>0.05
Dwarka	52.89	<0.05	4.48	<0.05	11.02	<0.05
Rohini	108.14	<0.05	19.52	<0.05	24.81	<0.05
ITO	64.49	<0.001	64.61	<0.001	13.14	0.84

The seasonal difference of means and statistical significance (p) were obtained for the three pollutants at four selected sites. **Table 3** depicts a significant difference of means between winter and summer pollutant levels for $PM_{2.5}$, NO_2 and NO at Dwarka and Rohini ($p< 0.05$).The same exists for Pusa and ITO sites for $PM_{2.5}$ and NO_2 levels. However, the difference of means for NO levels(summer and winter) at Pusa and ITO are not significant ($p> 0.05$).

Discussion

There are many types of pollutants present in the air namely, Sulphur Dioxide, Nitrogen Oxides, PM_{10}, $PM_{2.5,}$ Carbon Monoxide, Carbon Dioxide, Lead, etc. Three major pollutants were chosen for the study i.e. $PM_{2.5,}$ NO_2 and NO, as these are dangerous for health and environment.

Pollution Levels in Delhi: The site at ITO had the highest level of pollutants followed by Rohini, Dwarka and Pusa. In January 2017, the pollution levels at ITO were maximum. According to Times of India, $PM_{2.5}$ average at ITO between December 18, 2016 to January 2, 2017 was 309µg/m^3, more than five times the 24 hour standard and more than 12 times the WHO guidelines.[6]

Levels are highest at ITO being a traffic intersection and most of the land is concretized. An IIT study found that Pusa was one of the least polluted areas in Delhi followed by Dwarka and Rohini.[7] Present study also depicts similar results. Pusa and Dwarka have lower pollution levels due to high abundance of trees, lesser construction activities and lower traffic. Rohini is an industrial area with lots of construction work and smoke being emitted from industries.

Seasonal changes in level of Pollution: Pollutant levels were significantly higher in winter as compared to summer. Apart from NO and NO_2 values of summer at ITO; $PM_{2.5}$, NO_2 and NO values at the four sites were also significantly higher for winter. One of the major reasons for increased pollution levels in winter is crop-stubble burning in Haryana and Punjab which release excessive smoke. Certain specific reasons for increased pollution in winters are elaborated further:

Fog and Smog: North Indian planes undergo a sudden change in weather during November-December. The visibility goes down and even flight schedules go hay-wire due to fog! People resort to burning wood/ stubs/coal for warmth. This generates smoke, which was not present till then. Fog and smoke merge forming smog. This impedes sunlight, hampering dissipation of smoke and encased pollutants. The vicious cycle continues, worsening the situation.

Diwali: The festival of Diwali, observed at outset of winters, worsens the situation. Crackers add harmful chemical pollutants to the already compromised winter environment. This not only harms the environment, but also compromises health esp. the elderly and young children.

Crop-stubble Burning: Punjab and Haryana generate 30 million tonnes of paddy straw which are later burnt to reduce the time between harvesting paddy and sowing the winter wheat crop. This burning of crop residue results in smog, lots of smoke and increased levels of $PM_{2.5,\ 10}$ etc which are harmful for humans and environment. Despite repeated ban orders issued by courts and National Green Tribunal, this practice continues unabated. As per farmers, there is no affordable alternative to stubble burning. Increased mechanisation of harvesting process has also contributed to the problem. The use of mechanised harvesters result in stubble of 10-30 cm in the field, which was not the case earlier with manual harvesting, which used to be smaller (thus less polluting).[8]

Health and Environment Effects: Particles in the $PM_{2.5}$ size range travel deeply into respiratory tract, into lungs. Exposure causes short-term health effects such as eye, nose, throat and lung irritation, coughing, sneezing, runny nose and shortness of breath besides affecting lung function and worsening asthma,chronic bronchitis, and

increased mortality from lung cancer and heart disease.

When nitrogen is released during fuel combustion, it combines with oxygen forming nitric oxide (NO) and nitrogen dioxide (NO2), together referred to as (NOx)[4]. NOx gases react to form smog and acid rain besides formation of fine particles (PM) and ground level ozone, both of which compromise health.

High NOx levels have negative effect on vegetation, including leaf damage, reduced growth, making vegetation more susceptible to disease and frost damage. Pollution is likely to significantly influence forest-ecosystems as well.

Tackling Winter Pollution: Controlling crackers during Diwali, through public awareness and legislation could help tackle the problem. Equipment that processes the stubble and convert it to fuel for biomass based power plant can be an alternative to stubble burning. Crop residue can also be used for mushroom cultivation, bedding for cattle, paper production, etc. Other solutions include government offering subsidies to make these implements accessible to larger number of farmers or alternatively, the co-ownership models for these agri-implements. In Punjab, farmers have started using environment friendly waste decomposer solution. The small bottle of solution costs Rs 20 and is developed by National Centre for Organic Farming and Ministry of Agriculture and Farmers Welfare. Officials claim that it can decompose 10000 tons of bio-waste in 30 days. The emphasis must be on ways in which authorities can scale up implementation of such solutions. This requires political will. Any success on this front will make it easier for farmers to dispose or utilise crop residues without polluting air[8].

Conclusion

Delhi is one of the most polluted cities in the world. Every year the pollutant level rises to such a level the it becomes almost impossible to go out for work, school or have fun. This study evaluated concentrations of three important pollutants, $PM_{2.5}$, NO_2 and NO at four sites in Delhi ie. Pusa, Dwarka, Rohini and ITO over summer and winters. It was found that in winter, pollutant levels were significantly higher as compared to summer. This is due to the excessive burning of crops in Haryana and Punjab and Diwali festival. The crop burnings and crackers burnt during Diwali causes smog leading to ill health and harm to trees and environment. Delhi government has taken steps to reduce pollution levels, like, launching plantation drives, odd-even rule for vehicles, use of CNG in vehicles, green-cess, banning old diesel cars etc. The government also considered alternatives to crop burning like crop residue use for mushroom cultivation, bedding for cattle, paper production, etc, offering subsidies for implements for farmers. If these steps are implemented correctly and under good supervision by the authorities, the pollution concentration especially in winter will reduce significantly.

Implementation Challenges of Universal Health Coverage– Arogya Karnataka in a Tertiary Care Hospital

Ramya Y.P.[1], Khyathi G.V.[2], Narendranath V.[3]

[1]Post-graduate Student, Department of Hospital Administration, M.S. Ramaiah University of Applied Sciences, [2]Assistant Professor, Department of Hospital Administration, Faculty of Management and Commerce, M.S. Ramaiah University of Applied Sciences, [3]Chief Hospital Administrator, Ramaiah Medical College Hospital, Bengaluru

Abstract

This paper explores the importance of the Universal Concept of Health which is emerging globally, is achieved through implementation of different disciplinary perspectives for the long-term sustainability. It also represents the multi-dimensional concept of the Universal Health Coverage in terms of Population coverage, financial protection and accessibility to the quality of health care needs. As a health economic study, which explains the emanation of the Out-of-pocket expenditure, comprehensive medical services, minimum basic health package through implementation of shared fiscal systems for the effective function of the Universal Health Coverage. It also emphasizes on the implementation challenges regarding the hospital charges in empaneled private hospitals with the Arogya Karnataka (UHC) scheme package rates to the complex secondary and tertiary care treatments. A descriptive study was conducted to determine the average hospital charges for complex secondary and tertiary care treatments for the period of six months in a tertiary care hospital, where the secondary data is collected from the IT Billing Department. The Quantitative analysis is done by using the pie charts and pareto's diagram for the average total charges of hospitalization. The results showed the average total hospital charges for the complex secondary and tertiary care treatments are 32% and 54% where the Arogya Karnataka packages covered for the selective procedures respectively. The Comparative analysis of the subsumed existing schemes into one comprehensive Arogya Karnataka scheme showed that only Trans Urethral Resection Prostate (TURP) procedure has been revised and relatively increased when compared to selective procedures. Based on the result analysis, there is requirement of reformulating the health policy and regulations as the Out-of-pocket expenditure continues for more than 50%. In a long run, it's not viable for the hospital to accept the government insured patients without any revised package rates of Arogya Karnataka.

Keywords: *Universal Health Coverage, Arogya Karnataka, Complex Secondary and Tertiary care, Out-of-Pocket expenditure, Package rates.*

Introduction

All over the World has declared that the Health as a Fundamental Human Right by the World Health Organization's (WHO) in 1948 and the prime objective of the Constitution is to provide 'Health for all' by the Declaration of Alma-Ata in 1978 were pragmatic behind the Universal Health Coverage. In 2005, the World Health Assembly introduced the concept of UHC for the financing systems of healthcare sector to emphasis on the predefined and sharing mechanisms aimed to achieve the Universal Health Coverage. Based on this principle, the WHO defined the UHC as "access to key promotive, preventive, curative and rehabilitative health interventions for all at an affordable cost, thereby achieving equity in access''. According to the World Health Report 2013 states the well-structured and defined foundation based on the research evidence would lead to facilitate the evolution of UHC to all the countries. The United Nations, the United Nations Children's Fund, International Labor Organization, the World Bank, United States Agency for International Development, the Gates Foundation, the Rockefeller Foundation and other health institutes took the initiative to promote the UHC across the countries and also considered as the rational approach to achieve the overall health outcomes

of the Sustainable Development Goals by many leading health agencies. Universal Health Coverage by 2030 has been widely recognized as the primary health related concept defined under the Sustainable Development Goals on the occasion of United Nations Summit held in September 2015.[1]

The WHO has stated the Universal Health Coverage as "the desired outcome of health system performance whereby all people who need health services receive them, without any undue financial hardship". The Universal Health Coverage concept is a multi-dimensional which requires the healthy perspectives covering the three main dimensions, they are Populace coverage, fiscal protection and accessibility to health care services.

Expanding the Health Insurance to the Unaffordable in India: Generally, the extending the health Insurance coverage is major venturing thirst in the UHC which ensures the individual from the financial risk for the health care facilities by the pooling mechanisms of the health care systems. Out-of-pocket payment is another type catastrophic health expenditure among the poor families. According to the WHO study showed that in 2007, most of the low-economic countries does the direct Out-of-pocket expenditure showed more than the 50% of the total health expenditure.[2]

The National Governments are most reliable on the domestic resources for the Universal Health Coverage like domestic tax revenue, because the poor nations always depends on the governments to provide the fiscal support for the basic health needs. Expansion of the financial occupancy for the health budget and proper allocation of the pooling funds with continuous monitor is important even for the high income countries to sustain the Universal Health Coverage.[3]

Due to high Out-of-pocket expenditure which lead the huge population to the poverty and poor quality of health. Based on radical restructuring of the health care system with an integrated approach will build the equity in health and reducing the poverty has been drafted in National Health Policy 2015 by the Indian Government.

Arogya Karnataka Implementation: Karnataka government took the initiative as first state to implement the Universal Health Coverage and has decided to introduce the UHC under "Arogya Karnataka" from 23rd February 2018, bringing all government health schemes under one comprehensive health scheme by subsuming the following Yeshaswini Scheme, Vajpayee Arogyashree Scheme,Rajiv Arogya Bhagya Scheme, Rashtriya Swasthaya Bima Yojana including senior citizens, Rashtriya Bala Swasthaya Karyakram,Mukhyamantri Santwana Harish Schemeand Indira Suraksha Yojane health schemes, are reimbursed through the Suvarna Arogya Suraksha Trust.

Literature Review: The study describes about the effectiveness of the essential health package as per UHC. Due to the poor implementation and inequitable distribution of both public private partnership which led to the inequities in the populace coverage and fiscal protection among the Malawi people. The gaps identified such as no emergency services, inadequate medical personnel, no medical supplies and difficulties in transportation should be addressed by the Malawian Government to the local context reforming the strategic reformation of appropriate demand and supply interventions for the health care services.[4]

Universal Health Coverage defines Health as legal right which is essential to provide the health care services for all. It also describes on basic health needs in access to health care services without any barriers on both demand and supply with appropriateness and quality, health infrastructure, health financing, qualified health care professionals, resource allocation and medical supplies to deliver the quality of health as per Universal Health Dimensions.[5]

To ensure the UHC globally, there is requirement of health policy reforms and sustainability in the health financing system, equity, quality of care, efficiency and cost control strategies. The restructuring of the health care reforms may become barrier for the long-term sustainability of the health financing and market failure if the health care cost and quality control measures decreases simultaneously. Thus, the health financing systems does not sustain, if the high out-of-pocket extends further leading to the inequity in the healthcare.[6]

The study conducted in China demonstrated the Challenges in the Universal Health Coverage to the health insurance sector by the managers and administrators. There is lack in resources management of public healthcare facilities, huge inequity in healthcare and limited financial protection. However, there is requirement to increase the pooling of funds and develop the health policy and to reduce the out-of-pocket expenditure among the people.[7]

The Disproportionate distribution of the health financing leads to inequity and out-of-pocket expenditure among the poor and vulnerable population. Thus, robust constructive and emphatic regulatory policy frameworks by the Government can help in minimizing the gaps in the current health care sector and adopt to improve on the notion of the Universal Health Coverage.[8]

In Asian region, many low and middle economic countries are aiming towards the UHC finding the variations in the health care system–structures, resources and competences and identifying the leading challenges to the health care delivery. Indonesia introduced the UHC in its country in assurance mode which led to face the barriers in the logistic and administration with regards to the inadequate supply of medicines, human resources, health financing, weak governance in the health care service delivery.[9]

Methodology: This study was conducted in a Tertiary care hospital, Bengaluru which is 850 bedded hospital. This study includes the quantitative analysis of the secondary data collected during the study period for about six months. Two procedures were selected based on the highest rates done during the period of 3 months under seven different departments from the Medical Record Department and Operation Theatre in the complex secondary and tertiary care services provided by the hospital. The secondary data collected from the IT Billing department which contains the average of total hospital charges including the procedure cost, ward charges, food charges, pharmacy charges, post-hospitalization charges (post discharge medicines, travel conveyance and review) admitted in the general ward for the selected procedures.

It includes the patient data of an annual year from 01/04/2017 to 31/03/2018 who were admitted to the general ward (cash paying category) and also general concession patient (as per hospital concession policy) adding 20% to the gross total to get enough data on general ward patients. The Average total of hospitalization charges includes pharmacy charges which were collected from the private ward for the same procedures as they do not intend the medicines to general ward (25% of the total hospital charges).

The Arogya Karnataka patients are eligible for accessing the medical care for complex secondary and tertiary care treatments in government empaneled private hospitals subjected in predetermined package rates only for General ward.

Results and Analysis

Table 1: Differential amount between the Arogya Karnataka package rates and total hospital charges for the selected Complex secondary and tertiary care treatments

Procedures	Arogya Karnataka Package rates (Rs./-)	Grand Total of Hospitalization- (Rs/-)	Differential amount b/w AK and Hospital charges (Rs/-)
Lap. Assisted Vaginal Hysterectomy (LAVH)	11500	44789	33289
Vaginal Hysterectomy with Pelvic floor repair (Cystocele, Rectocele & Perineorraphy)	15000	34123	19123
Arthroscopic Cruciate Ligament (ACL) Reconstruction	19000	67016	48016
Simple Compound Fracture with internal/external fixation along with implants (ORIF)	21000	63729	42729
Tonsillectomy + Styloidectomy	12500	27871	15371
Cortical Mastoidectomy	6250	38090	31840
Lap. Hiatus Hernia Repair Abdominal	20000	61054	41054
Lap. Appendicectomy	10000	27811	17811
Percutaneous Nephro Lithotomy (PCNL) inclusive of stent	10000	37458	27458
TURP (Trans Urethral Resection Prostatectomy)	30000	32270	2270
Gastro Jejunostomy	30000	65597	35597
Splenectomy	45000	88828	43828

Table 2: Complex secondary care treatments of Arogya Karnataka package rates coversaverage of 32% of the total hospital charges

Departments	Complex secondary Treatments	A K rates to the Total hospital charges
Obstetrics and Gynaecology	Lap. Assisted Vaginal Hysterectomy (LAVH)	25.68%
	Vaginal Hysterectomy with Pelvic floor repair (Cystocele, Rectocele & Perineorraphy)	43.96%
Orthopaedics	Arthroscopic Cruciate Ligament (ACL) Reconstruction	28.35%
	Simple Compound Fracture with internal/external fixation along with implants (ORIF)	32.95%
ENT	Tonsillectomy + Styloidectomy	44.85%
	Cortical Mastoidectomy	16.41%
General Surgery	Lap. Hiatus Hernia Repair Abdominal	32.76%
	Lap. Appendicectomy	35.96%
Average Total Percentage		**32.61%**

Table 3: Tertiary care treatments of Arogya Karnataka package rates covers average of 54% of the total hospital charges.

Departments	Tertiary care Treatments	AK rates to the Total hospital charges
Genito Urinary	Percutaneous Nephro Lithotomy(PCNL) inclusive of stent	26.70%
	TURP (Trans Urethral Resection Prostatectomy)	92.97%
Oncology GI Tract and Oesophagus	Gastro Jejunostomy	45.73%
Neonatal and Paediatric Surgery	Splenectomy	50.66%
Average Total Percentage		54.01%

The results showed the Out-of-pocket expenditure for the complex secondary and tertiary care treatments continues to be 68% and 46% respectively.

The Hospitalincurring the additional benefits of providing the food charges and post-hospitalization to the Arogya Karnataka insured patients. Thus, the hospital has to initiate cost-cutting strategies in diagnostics and pharmacy like generic medicines or Janaaushadis on pharmacy provision as it incurs the 25% of the total hospital charges.

The Comparative analysis of the Arogya Karnataka and other subsumed schemes showed that excluding the Trans Urethral Resection Prostate (TURP) procedure has been increased and other procedures are comparatively decreased and some are unrevised for the selected procedures.

Discussion

Universal Health Coverage has been introduced as 'Health for all' objective under the Sustainable Development Goals as imposed on all the states of the country that stratified as legal right to the health for the delivery for the delivery of the Universal Health Coverage on National Governments after the failure to achieve Millennium Development Goals.

Due to low spending on the health resulted in inadequate supply of resources, lack of skilled human resources, huge inequity in health and high financial rick protection by the weak governance and poor accountability which created the large chaos for the Health care services providers. These identified barriers may not sustain for the long term by the modified design for the existing funds and not enough to provide the satisfactory solution. However, there is significant need to increase the capacity of the funds by the pooling mechanisms to develop unified and consistent health regulatory and policies for both the public and private sectors of the health system in terms of Out-of-pocket expenditure.[10]

People centered political decisions regarding the betterment of health were not successful and stable in the previous objectives of the Health agenda.As a result, frequent changes in the health policy reform have led to poor sustainability, low efficiency, large inequity causing

the poor quality of health care leading to the market failure in terms of the cost control and accessibility in the healthcare sector.[11]

Conclusion

By the considerable facts, the Universal Health Coverage still continues to be Out-of-pocket expenditure more than 50-60% for the people. Hence, increase the public health expenditure to 2-3% of gross domestic product and pubic private partnerships in case of adequacy in delivering the service with proper planning and monitoring would help in the assessment of the Universal Health Coverage program.

The Government of India has taken the initiative in introducing the 'Ayushmann Bharat', a central government insurance scheme announced in the Union Budget 2018.

The Government has to rule out the health policy and regulations pertained to the unauthorized private sector and increase the shared mechanisms and strategic purchasing with pooling the funds and allocate the resources optimally and increase the expenditure on health would bring the expected change in the health outcomes.

The Universal Health Coverage (Arogya Karnataka) has to take the initiative to define the package rates accordingly without any hardships to the patients and health care service providers with prioritized budget for the health care system.

Limitations: The obtained data was limited to calculate the pharmacy charges in the general ward and considered the general concession patients are included for the general ward cash paying patients. No proper data available to determine the average hospital charges for the other procedures. Thus, actual costing of the procedures would overcome the financial barriers of the Arogya Karnataka scheme.

Abstract

Chronic inflammation isthe hallmark of periodontitis. The inflammatory events are suggested by the action of microbes in tissue cells that lead to release of several cytokines and soluble mediators. Among them TNF alpha and Interleukine-21 are known to play an important role.C-reactive protein is an acute phase protein, highly sensitive marker used to indicate inflammatory tissue. This study evaluates serum levels of Il-21, TNF α, hsC-reactive protein in patients with chronic periodontitis and periodontally healthy individuals. Total 46 participant, 30 cases of chronic periodontitis, 16 systematically healthy subjects, with age and sex matched were included in study.The serum levels of IL-21, TNF alpha, were assessed by using Enzyme Linked immunosorbant assay. hsC-reactive protein assessed by particle enhanced immunoturbidometer. Statistical analysis was performed using statistical software. Data were expressed as mean ± SD and interquartile ranges and comparison of controls and cases by Mann Whitney Test. Levels of IL-21, TNF α, hsC-reactive protein were notably higher in chronic periodontitis group than control. ($p<0.001$). IL-21, TNF α, hsC-reactive protein, highly expressed in patients with chronic periodontitis than control subjects and linked. Therefore these markers can be used for diagnosis of chronic periodontitis.

Keywords: *Interlukine-21, TNF α, hsC-reactive protein, chronic periodontitis, Diagnostic biomarker.*

Introduction

Periodontitis is one of the most common chronic inflammatory diseases worldwide. It is a persistent polymicrobial infection of multi-factorial etiology which evokes both innate and adaptive responses leading to irreversible destruction of periodontal ligament and alveolar bone.[1-2] It has been shown that exaggerated disproportionate immune response of host responsible for tissue destruction and bone loss. The host immune response is due to production of proinflammatory cytokines produced by activated T-cells in diseased gingival and periodontal tissue[3] These include tumor necrosis factor alpha (TNF-α),IL-1β,IL-6,IL-7,IL-11and prostaglandins.

Interleukin-21 (IL-21) is a recently discovered proinflammatory cytokine, member of the type-1 cytokine family and expressed by activated Th-1 and Th-17 lymphocytes[4]. IL-21 regulates innate and adaptive immune responses. It plays a key role in antitumor and antiviral responses, and has major effects on inflammatory responses[5-6].

The acute-phase response is part of innate immune response which is a nonspecific process responding to injuries to host including infections. Among several acute phase proteins,TNF-α is a dominant cell signaling protein involved in systemic inflammationand itregulates immune cells, induction of apoptosis and inflammation[2]. It is key periodontal pathogens-induced

early inflammatory cytokine in destructive periodontal disease[7-8].

Another important acute phase protein is C-reactive protein used as a marker of tissue inflammation and damage and regulated by several cytokinesincluding tumor necrosis factor-α[9]. TNF-α and C-reactive proteins are present in low levels in healthy but markedly raised in tissue injury [10-11].

The objective of the study was to investigate the role of IL-21, TNF-α and C-reactive proteinin periodontitis and compare the levels with healthy to evaluate their use as a diagnostic marker of chronic periodontitis.

Materials and Method

The study was carried out in the Department of Microbiology ofour Institute in association with Department of Oral Medicine & Radiology.Study was approved by the Institutional Ethical Committee. Written informed consents were obtained from participants before enrollment and collection of samples.

Study involved 46 participants, 16 healthy subjects, 30 chronic periodontitis of both genders with age group of 25-55 years. Periodontal parameters such as probing depth and clinical attachment loss were measured by using UNC-15 probe.Subjects with known systemic disease, malignancies, blood disorders, smoking, alcoholism and drug abuse were excluded. Those with <20 teeth and or had undergone any dental treatment or received antibiotic therapy were excluded. Inclusion criteria for chronic periodontitis were presence of at least 4 sites with >5mm pocket probing depth and attachment loss. The criteria for healthy group were no sites with >3mm pocket probing depth and attachment loss.

Blood sample collection and storage: Standard operatingprocedure was followed for collection of blood samples. 5 ml blood samples was collected from subjects from cubital vein by using aseptic technique and transferred to serum separator tubes. Blood was allowed to clot for 15 minutes andcentrifuged for 10 min at 3000 rpm. Serum was separated and aliquoted kept at-80°cuntil laboratory analysis.

IL-21quantification: IL-21was assessed by ELISA kit (Krishgen Biosystems 15375 Ashley Ct. Whittier,CA; Lot No 1211015).Manufacturer's instructions were strictly followed during the assay. Results were calculated using standard curve produced in assay and expressed as pg/ml.The sensitivity of the assay was 8.0 pg/ml

hsCRP quantification:Serum hsCRP levels were assessed by particle enhanced turbidimetric immunoassay technique (PETIA) on Dade Dimension clinical chemistry system.Results were expressed in mg/dl.The assay range of the kit was 0.05-25.0 mg/dl.

TNF alpha quantification:TNF-αwas assessed by ELISA (Booster Biological technology Co, Ltd.).Results were calculated using standard curve produced in assay and expressed as pg/ml. The sensitivity of the assay was, 1pg/ml.

Statistical analysis: Mean and standard deviation were calculated for both the groups. Pearson's correlation was used to assess the correlation between chronic periodontitis and healthy for serum IL-21, TNF-α and hsCRP. In this study, *P* value of 0.05 was considered as significant. Statistical (SPSS) version 15 was used for statistical analysis. For comparison of mean IL-21, TNF α and hsCRP between chronic periodontitis and control by Independent samples t test and Mann-Whitney test was performed.

Results

Group I 30 patients with chronic periodontitis with mean age 31.5± 4.3. Group II comprised of 16 healthy controls with mean age group 36.6 ± 6.5. Difference between both sexes could not evaluate since of small sample size.

Figure 1 shows results of all three parameters in both the groups. Serum levels of IL-21 in healthy subjects ranged from 15.8 to 193.3 pg/ml (mean 65.34 pg/ml) where as in chronic periodontitis patients the levels were much higher with a range from 67.0-694.5 pg/ml with a mean of 497.78pg/ml (Fig 1a).The concentrations of TNF-α in group I and group II were and 17.94 ± 10.5 pg/ml (6.8 to 29.0 pg/ml)and 70.37 ±18.5 (28.0 to 138.0 pg/ml)respectively (fig 1b).Levels of hsCRP in group I were 0.96 ± 0.46 mg/dl (0.1 to 1.46mg/dl)and in group II were 3.57 ± 2.27 (1.2 to 6.92 mg/dl)respectively (fig 1c). It could be seen that all three parameters were significantly increased in patients with chronic periodontitis when compared to healthy subjects.

Fig. 1,2 & 3. Distribution of IL-21 (Fig.no.1), TNF α (Fig.no.2), and hsCRP (Fig.no.3) in the blood samples of healthy and chronic periodontitis subjects.

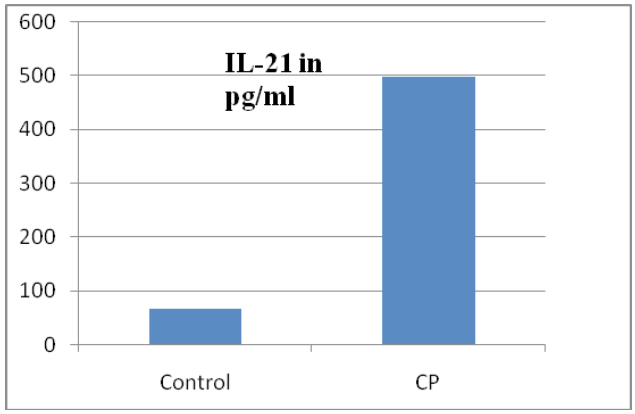

Fig. No. 1

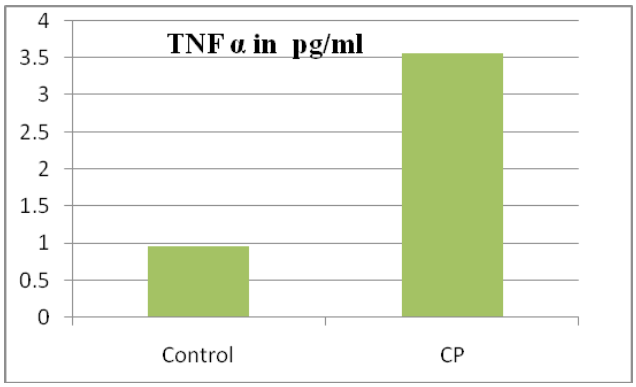

Fig. No. 2

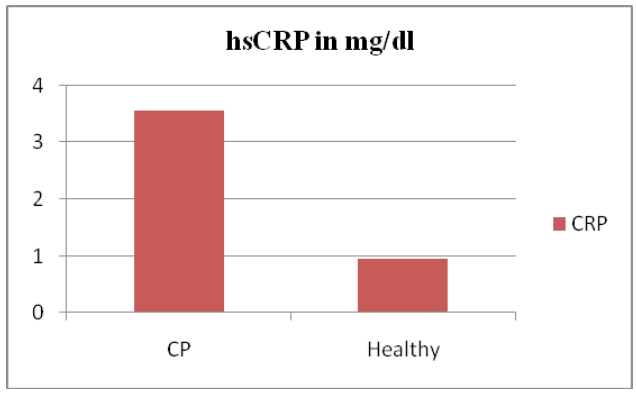

Fig. No. 3

The difference in the levels of IL-21, TNF-α and hsCRP between the two groups was highly significant with p< 0.001 by Mann-Whitney test and independent sample T test (Table 1).

Table 1: Comparison of parameters done by independent sample T test and Mann Whitney test.

Serum Marker	Group	N	Mean	SD	t-value	p-value and significance	Mann-Whitney test
IL-21	Periodontal disease	30	497.78	297.06	10.18	<0.001, Significant	<0.001, Significant
	Control	16	65.34	42.66			
TNF	Periodontal disease	30	70.3767	18.50515	10.43	<0.001, Significant	<0.001, Significant
	Control	16	17.9438	10.55045			
hsCRP	Periodontal disease	30	3.5757	2.27008	4.50	<0.001, Significant	<0.001, Significant
	Control	16	0.96	0.46			

SD-Std. Deviation, P<0.001-highly significant

Pearson's correlation showed highly significant positive correlation between the IL-21, TNF-α and hsCRP in Periodontal disease (p= 048). However, there was no significant relation when only healthy groups were analyzed (0.506) (Table 2).

Table 2: Correlation between IL-21, TNF-α and hsCRP analyzed by Spearman's correlation coefficient

		Periodontal disease	Control
IL-21 TNF α hsCRP	Correlation Coefficient	0.364*	0.179
	p-value and Sig. (2-tailed)	0.048, Significant	0.506,not Significant
	N	30	16

*p<0.0500 significant

Discussion

Periodontitis is the most common infections affecting gingival and tooth supporting tissue[12].During progression of periodontitis, endotoxins released that lead to periodontal inflammation, characterized by macrophage activation, production of cytokines, inflammatory mediators and acute phase proteins[13]. Cytokines play an important role in triggering the acute phase response mainly these are TNF-α,IL-1β,IL-6,IL-7,IL-11,IL-17 and Prostaglandins. Among them, we chose three molecules IL-21, CRP and TNF-α which are known to play a role in the inflammatory process of periodontal disease, but so far, their synergistic role has not yet been studied. According to our literature survey this is the first study conducted in India which has included IL-21, TNF-α and CRP to assess their collective role in chronic periodontitis patients.

Interleukin-21 is a member of common-γ chain (γc) family of cytokines, produced by activated T cells but it targets lymphoid and myeloid cells of immune system. It has the potential to impact innate and adaptive immune responses, recognized to contribute to the development of Th17 cells which have been shown to play an important role in the pathogenesis of periodontitis[14-15]. TNF-αis considered as a major inflammatory mediator produced by activated macrophages, CD 4 Tcells, NKcells, neutrophils and mast cells[16].TNF-αis the key periodontal pathogens-induced early inflammatory cytokines in destructive periodontal disease[7,17].

CRP isone of the major acute-phaseproteins synthesized in response to pro-inflammatory cytokines. It belongs pentraxin family of proteins and plays a significant role in immune reaction[18]. The serum levels increase rapidly within 24 to 72 hours in conditions of inflammation[19, 20]. CRP also is increased in chronic periodontitis[9,20-21].

Present study shows that levels ofIL-21, TNF-α and hsCRP significantly raised in patients with chronic periodontitis in comparison to those of healthy individuals.

Several investigators have studied IL-21 levels in GCF, saliva and gingival tissue from patients with chronic periodontitis and used different method as Immunohistochemistry, western blot, PCR and ELISA [21]. Very few studies have analyzed IL-21 in serum samples [5-6].Inall of these studies, the levels of Il-21 were significantly higher in chronic periodontitis patients when compared to healthy subjects. The results of our study are in agreement with these findings. Some investigators have also shown significant correlation of IL-21 levels with periodontal parameters[5,21.]

Studies have also been conducted to assess the levels of TNF-α in periodontal health and disease[7-9,16].A cross-sectional study attempted to correlate periodontal disease with risk indicators for high levels of systemic inflammatory markers and showed that higher TNF-α is associated with periodontal disease[22].

Studies shown significant association between TNF-α and CRP and decrease in levels after periodontal treatment[10,17.]Another recent report describedserum CRP and TNF in pseudoexfoliation syndrome and suggested TNF alpha is a proinflammatory cytokine and hsCRP is a predictor marker of inflammation and endothelial dysfunction while and both involved in pathogenesis of PEX[23].

In thepresent study IL-21 and TNF-α were assessed by ELISA method. It is one of the most sensitive and reproducible assays, used for the detection and quantitation of antibodies against specific molecules. Literature survey shows that ELISA has been the most popular method for the study of cytokines from various body fluids in health and disease [24].

We investigated hsCRP levels in the present study by Particle enhanced turbidometric immunoassay (PETIA) with detection limit of <1 mg/dl. This technique is regarded as the most rapid, sophisticated, accurate and sensitive method of detecting, and measuring CRP in body fluids [18]. Other investigators have used different method such as nephalotubidimetry, turbidometry, enzyme immunoassay and PETIA [10-11,18,20]. Our results are in concurrence with the findings of other authors.

Currently, diagnosis of periodontal disease relies primarily on clinical and radiographic parameters. These measures are useful in detecting data of past disease, or verifying periodontal health, but offer only incomplete information about sites at risk for future periodontal crash[25]. Hence there is a search for appropriate biomolecules which can aid in diagnosis as well as predict future onset of disease at periodontal sites. In this connection, our data demonstrate that IL-21 TNF α,hsCRPcan beused as diagnostic and prognostic marker in chronic periodontitis. However, more studies with larger sample size are needed to confirm our findings.

Conclusion

Overall the present study suggest that IL-21,TNF α and hsCRP are predictive markers of inflammation and involved in pathogenesis of periodontitis. These marker can be used as diagnosticaid.

Community Household Survey Utilization of EPI Cluster Sampling Style

Renu G.[1], Asha Kamath[2]

[1]Principal, Pushagiri College of Nursing, Thiruvalla, [2]Professor and Head, Department of Statistics, MAHE, Manipal

Abstract

This is an article trying to explore the utilization of EPI cluster sampling style in the prevalence survey for childhood injury. The EPI cluster sampling provides the researcher a low cost way for performing the household survey. There can be a bias in the prevalence estimation because of meeting the participants at a single point of time and the limitation associated with cluster sampling.

Keywords: *Cluster sampling, survey.*

Introduction

The monitoring of health status of the population and planning interventions for them is only possible with very accurate and most recent information. Cross sectional surveys are the best choice to answer these needs.

Children and injuries represents an important global health problem[(1)]. Unintentional injuries among children gives a high impact on mortality morbidity and the health care costs. These type of injuries contribute to the top 15 causes of deaths in all age groups of children world wide[(2)].

Children of age 2 years to 5 years spend a very long time in the home, and this place is crowded with a variety of hazards, hence a major amount of childhood injuries occur there [(3-5)].

Unintentional accidental injuries occur at home in various severity majority doesn't need a hospitalization and management so they become unnoticed [(6)]. These are actually a threat to the health of any country. World health organization report of 2004 warns out injuries in children as the sixth leading cause of morbidity and mortality [(7)].

Many studies have been carried out in India and in various parts of the world to find the epidemiology of injuries in children. Majority of them happened at a hospital basis [(8)]. The present cross sectional survey was planned in a household basis. The aim of this survey was to establish a baseline information prior to the planning of a community based intervention.

Sampling Strategies for Community Survey: There are so many sampling strategies which can be used to estimate the prevalence of injuries among children in a community. The simple random sampling is the simplest but often the most difficult sampling method to perform. Simple random sampling being the most simplest method is often difficult to execute. Each member of the population gets involved in the sampling frame and gets equal chance of being selected. Generating a sampling frame of all eligible members is often a difficult task. To some extent, the census system in India provides the frame of a population. However, the completeness of the census is limited due to the inaccuracies in the enumeration and recording of migrants and new births.

The diversity of India's geographical distribution makes the selected sampling units to be widely disperse. Contacting one or two such isolated samples in the remote areas diverts the resources from major areas of concern or from other health programmes. All these makes simple random sampling a less preferred measure[(9)].

One of the sampling method which eases the administration of simple random sampling is the cluster

sampling. In this method the primary sampling units are clusters [10]. The clusters in a survey can be various blocks in the city if it was planned in an urban setting, villages if it is in a rural setting.

The cluster sampling requires a complete list of clusters. Generation of sampling frame for cluster sampling comprising of the list of clusters along with the cluster size is relatively easier than that of individual members for a simple random sampling. The complete list of individuals in the selected clusters is needed. Simple random sampling is often the most commonly used method to select individuals within the clusters [11]. One of the major advantages of this method is, as the cluster size increases the amount of resources needed to list the elements are considerable.

The cluster sampling method assumes that the selection of one household in a cluster is not independent of the selection of other households, the members of the cluster are similar. The "design effect" may give a serious effect in situation where one particular infectious or communicable disease is prevalent in that cluster.

One of the example which was talked over time was the one developed as a part of Expanded Programme on Immunization (EPI) by the World Health Organization[12,13]; with an aim to estimate the vaccination status among young children. In this project a 30 clusters (villages or the like) are identified and 7 children of required age selected from each of the selected clusters.

The ideal EPI cluster surveys consisted of 30 clusters of 7 children each (for immunization coverage surveys)[13,14]. Various modifications of this method were done as selecting 20 clusters with 14 children from each clusters was used for immunization coverage, oral rehydration and breast feeding and dietary information [15,16], clusters of hypertension in Guinea [17], 125 children in 8 cluster used for iron fortified complimentary treatment for Malaria [18], 14 cluster with 7 sample in a tuberculosis study [19], 30 cluster of 70 children survey on Goitre (at present this is 90 children with 45 each of males and females) among children in Jamnagar [20], 30 cluster 23 children diarrhoeal out break mortality study at Botswana [21], 30 cluster 98 children obesity assessment study at Pondicherry [22].

A cluster sampling design is the best practical solution for most of the community surveys to cover wider geographical areas. When the study need to assess multiple centers multistage cluster sampling could be a choice.

Many studies have altered the selection 30 clusters to larger or smaller number of clusters. Eg. 46 cluster with 118 new births in a breast feeding financial incentive study at UK [23] and 16 cluster 60 sample counselling intervention for asthmatic children [24].

A cluster sampling most of the time uses simple random sampling within clusters, but EPI cluster sampling uses convenient sampling technique for the second stage sampling.

The present article report the utilization of modified 30 cluster EPI sampling technique for the selection of households in a household survey in Karnataka.

Method

Survey population: The survey population was children between 2 years to 5 years of age and their primary caregivers.

Definitions

Respondent: The respondent of the survey was the primary caregiver of the child.

Household: A group of people living together under one roof and eating in the same place.

Injury: Any unintentional or accidental harm which affect the child physically, psychologically and or socially.

Sample Size: Sample Size was calculated by using the formula $n = \frac{(Z\alpha)^2 P(1-P)}{d^2}$ X Design effect.

The prevalence of injury among children in India was 24.5 (3). Considering this as the anticipatory injury rate for children with a relative precision of 10% at 95% confidence level and a design effect of 1.5 the sample size was estimated. The estimated sample size was 1780.

Selection of the area: Karnataka state is divided into 30 districts and 4 administrative divisions. As per 2011 census, the state is having a population of approximately 6.11 crores. Among these 30 districts, Udupi is one of the highly literate (86.4%) district with a population of 1,177361 with 562,131 males and 615,230 females ((COI))[25]. The total under-five population estimated was 35401.

Description of Udupi: This district was formulated in 1997, the three taluks Udupi, Kundapur and Karkala merged together to form Udupi District. The administrative headquarters is Udupi. The press reports Brahmavar and Byndoor also will become separate taluks[26]. At the time of planning of the survey there were only three taluks with Udupi as headquarters. Udupi taluk consists of 108 villages comprised of 16 census towns, 6 out growth areas and 86 villages. The population among the villages vary from 867 to 144960.

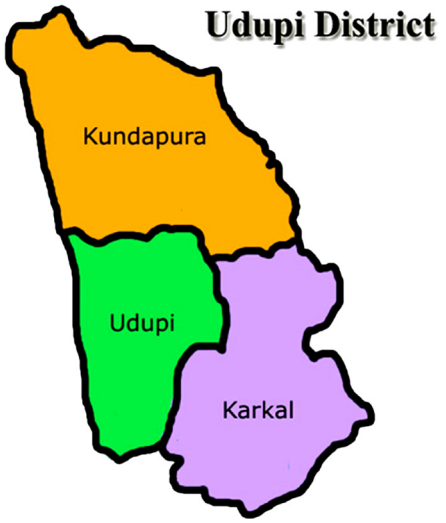

Figure 1. Udupi District Map

Sample Selection: This can be done in various stages: a nation divided into states, districts, taluks and choose villages from taluks. Villages may be treated as clusters and households can be selected from them. In order to make sure the adequate representation of the area as a whole, a multistage cluster random sampling technique was adopted.

Selection of clusters: The selection strategy used for the selection of village is the same as that of EPI method. A list of all villages from the intended region of where the survey coverage was retrieved from the census 2011. The data provided average population size as well as the number of children in the area. It is very important to have the average community size. The average village size was estimated based on the 2011 census. In case the size of any village is too small, it is clubbed with the adjacent village.

Selection of the villages was done using *Probability proportional to size.* In EPI methodology, this is carried out after creating a cumulative list of community population and selecting systematic sample of clusters with a random start.

The village (cluster) selection was done as described below.

Udupi taluk has 108 villages and it was decided to include one third of the total villages that is to select 34 villages (clusters). The total under 5 population estimated was to be 35401. The sampling interval was obtained by dividing the total under 5 population by the number of villages to be selected. Thus, the sampling interval was (35401/34 = 1041.2 rounded to1042. The random start for the systematic selection of the clusters was done by selecting a random number from 1 to 1042. A person not involved in the study, selected the random number to be 856. The village corresponding to a cumulative population equal to or greater than 856 is identifies as the first sampled village. In the list 856 lies between the cumulative population of 503 and 949 and thus the village number 2 was selected as the first cluster. The second village is identified by adding the sampling interval to the first random number (1042+856 = 1898), the number got is 1898 which lies between 1506 and 1913, hence the village number 6 got selected. This process was continued till the selection of 34 villages (Table 1).

This procedure very well leads to the selection of villages with a probability proportion to size. This procedure will automatically bring a representation of all types of villages in the survey.

Table 1: Cumulative method of village selection

Village number	Population size	Cumulative population size
1	503	503
2	446	949
3	307	1256
4	89	1345
5	161	1506
6	407	1913
7	186	2099
8	302	2401
9	243	2644
10	151	2795

Selection of Households: The survey defines household as a group of people living together under one roof and eating in the same place by sharing a common kitchen. The survey considered this as a sampling unit. Since the survey expecting to have equal chance for all households, it was decided to have a constant number

of households to include from each cluster. The sample size calculation estimated a size of 1780 children. This type of sampling procedure is known as *self-weighting.*

The EPI suggests to select the first household with some selective measure like identifying a central point, or locating a landmark and move either right or left, or use the "spin the bottle technique". Once the procedure is clear then in a straight line all the houses which meet the inclusion criteria need to be surveyed.

The cross sectional survey estimated a sample of size 1780 requiring 1780/34 = 52.3 rounded to 55 or 60 under five to selected per village. The sampling frame consisted of villages having more than 55 eligible members. Only one eligible member from each household was included in the study.

Conclusion

EPI cluster sampling is a simple, faster and low cost measure of performing cluster surveys compared to simple random and stratified random sampling method. One of the important things to remember is that the sampling error decreases as the number of clusters increases. At the same time this measure can result in estimation bias and differences compared with simple random or stratified random sampling. The household survey was conducted in a District of Karnataka state. The selection of villages and the household selection is the description in this article.

Radiological Study on the Anterior Loop of Inferior Alveolar Nerve

Roshene R.[1], Jayanth Kumar V.[2]

[1]Graduate Student, Saveetha Dental College, [2]Reader, Department of Oral Medicine and Radiology, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, SIMATS, Saveetha University, No. 162, Poonamallee High Road, Vellapanchavadi, Chennai, Tamil Nadu

Abstract

Aim: The inferior alveolar nerve, branch of the mandibular nerve consists of an anterior looping at its end which acts an important factor during certain dental procedures such as implant placement. The principle aim of this study is to scrutinise the anterior loop of inferior alveolar nerve using cone beam computed tomography.

Methodology: Thirty CBCT scans were evaluated among which, 16 of them were males and 14 of them were females and was visualised with Planmeca romexis software. The anterior loop was measured bilaterally. In the axial slices, the radiolucent canal was traced beyond the mental foramen. This measurement was reconfirmed by taking measurements in the panoramic scale by tracing the canal anterior to the mental foramen using the nerve tracing tool.

Results: From the data obtained, it was seen that the maximum length of the inferior alveolar nerve on the left side was 12mm and the maximum length of the inferior alveolar nerve on the right side was 15mm. The mean length of the loop on the left side was 1.07mm and 2.217mm on the right hand side. The mean length of the inferior alveolar nerve on the left side was found to be 2.21mm and on the right side, the mean length of the nerve was 5.04mm.

Conclusion: The anterior loop of inferior alveolar nerve is discernible in the orthopantamograph. This study helps to establish the anterior loop more clearly in the CBCT and also ensures the safe placement of implant away from the mental foramen.

Keywords: *Mental foramen, CBCT, paraestheisa, planmeca, romexis.*

Introduction

The mental foramen is one of two foraminain the body of the mandible at an equal distance from the superior and the inferior border and it is located below the interval between the premolars, and mental nerves and vessels passes through it. They occur as a pair and are either round or oval. The mean vertical diameter on the right and left are 2.3±0.64mm and 2.29±0.6mm and the mean horizontal diameter are 2.63±0.85mm and 2.61±0.85mm.[1] The mental nerve, a terminal branch of inferior alveolar nerve and the mental vessels leave the mandibular canal through it.[2] The mental foramen has a tendency to migrate inferiorly with ageing.

The mandibular nerve is the third and most inferior division of the trigeminal, or fifth, cranial nerve. The upper branch of the trigeminal nerve is the ophthalmic nerve, which innervates the forehead.The middle branch, the maxillary nerve, innervates the maxilla and the midface. The lower branch, the mandibular nerve,

Corresponding Author:

Reader, Department of Oral Medicine and Radiology, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, SIMATS, Saveetha University, No.162, Poonamallee High Road, Vellapanchavadi, Chennai-600077, Tamil Nadu
e-mail: doctorjayanth@gmail.com
Mobile: 8056135807

innervates the teeth and the mandible, the lateral mucosa of the mandible, and the mucosa and skin of the cheek, lower lip, and chin.[3] The Inferior alveolar nerve (IAN) is a branch of the posterior division of the mandibular nerve that contains both sensory and motor fibers. It enters the mandibular foramen, runs in the mandibular canal, and supplies the mandibular teeth. It leaves the mandibular canal through the mental foramen as the mental nerve. Within the canal, the nerve is about 3 mm in diameter, and its course varies. It can run with a gentle curve toward the mental foramen, or it can have an ascending or descending pathway. [3]

The inferior alveolar nerve may extend beyond the mental foramen in an anterior and inferior direction, curving back to the mental foramen and forming a loop, which has been termed the anterior loop of the inferior alveolar nerve of the mental nerve or of the mandibular canal. Although it is a benign anatomical variation, its accurate identification is very much essential for surgical planning, particularly for dental implant placement, in order to prevent iatrogenic complications. [4] Damage to the anterior loop of the inferior alveolar nerve will result in mental nerve damage which in turn may result in paraesthesia, dysthesia, or even overt pain in the area innervated by the mental nerve. The mental nerve supplies sensation to the labiomental area and gingival tissue upto the mandibular second premolar.[5] Altered sensation in the region may impede the ability to perform routine activities like eating, shaving, speaking, tooth brushing etc. Therefore, the anterior loop of inferior alveolar nerve should be identified accurately so as to enhance the outcome of the surgical procedures done in that area. [6]

Cone-beam computed tomography (CBCT) presents various advantages, such as allowing the three-dimensional (3D) assessment of craniofacial structures without distortion or overlapping images, in addition to a lower radiation dose than multislice CT. [7]

It is very important to precisely identify and to preserve neurovascular bundles in order to avoid sensorineural damage in the interforaminal region. The aim of this study was to use the CBCT scans to evaluate the prevalence and extent of the anterior loop of the mandibular canal.

Materials and Method

In this study, the anterior loop of inferior alveolar nerve was identified using the cone beam computed tomography. Thirty CBCT scans were evaluated and visualized with Planmeca romexis software.

The anterior loop was measured bilaterally. In the panoramic slices, the radiolucent canal was traced beyond the mental foramen. Then, panoramic slices were moved upwards or downwards according to the requirement. This measurement was reconfirmed by taking measurements in the panoramic scale by tracing the canal anterior to the mental foramen using the nerve tracing tool.

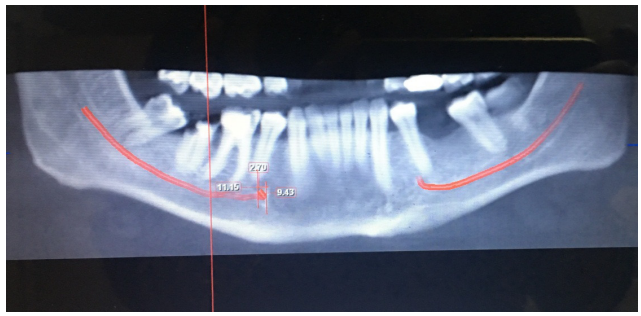

Figure 1: Panoramic slice showing the loop

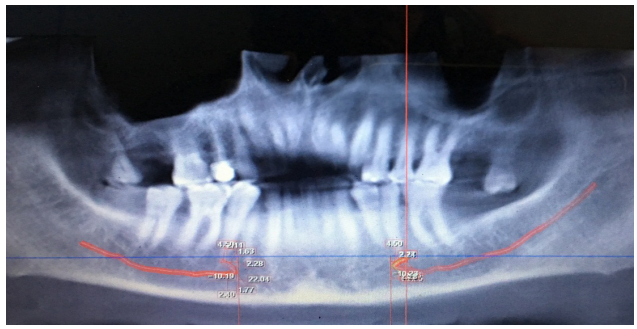

Figure 2: Panoramic slice showing the loop

Results

Among the thirty CBCT scans that were evaluated, 16 of them were of males and 14 of them were of females. The minimum age group of the participants was 16 years and maximum was 72years. The mean age group was found to be 53.50. The maximum length of the anterior loop on the left side was 6cm whereas the maximum length of the anterior loop on the right side was found to be 6.4mm. On the other hand, the maximum length of the inferior alveolar nerve on the left side was 12mm and the maximum length of the inferior alveolar nerve on the right side was 15mm. The mean length of the loop on the left side was 1.07mm and 2.217mm on the right hand side. The mean length of the inferior alveolar nerve on the left side was found to be 2.21mm and on the right side, the mean length of the nerve was 5.04mm.

On comparing the length of the loop on the right and the left side, the p value was found to be p<0.05. The length of the inferior alveolar nerve on the right and the left side was compared and the p value was p<0.01

Table 1: The mean length of the loop and nerve for the left and right side

	N	Mean	Std. Deviation
Length of Loop-Left	30	1.07	2.001
Length of Nerve-Left	30	2.21	4.112
Length of Loop-Right	30	2.217	2.3984
Length of Nerve-Right	30	5.04	5.477

Discussion

The inferior alveolar nerve enters the mandibular bone through the mandibular foramen and runs inside the mandibular bone in the mandibular canal, which ends at the mental foramen, although it may present an anterior loop and which has ethinic variations. [8]At that location, the mental nerve emerges to innervate the inferior lip, chin and buccal gingiva. A smaller branch (i.e. the incisive nerve) continues within the mandibular bone to innervate the anterior teeth. The inferior alveolar nerves supply sensation to the lower teeth. The terminal portion of the inferior alveolar nerve may pass beyond the anterior rim of the mental foramen, before curving back to exit the mental foramen. The portion of the inferior alveolar nerve anterior to the mental foramen is termed the anterior loop of inferior alveolar nerve. [9]

One of the most severe complications when performing intraoral surgical procedures is the injury of the inferior alveolar nerve.[10] Nerve damage can be manifested as paresthesia, dysesthesia, analgesia or anesthesia. The predominant nerve injuries have occurred secondary to surgical procedures in the mental foramen area.[11-13] Although panoramic radiography may be useful, it is not completely adequate to identify the mental foramen. Hence a multiplanar imaging like CT /CBCT is essential to study its morphology.

In the study conducted by Xiao Li et.al, on sixty-eight Chinese,patients were scanned by 64-slice spiral computed tomography, and the prevalence, length, and position of the anterior loop were assessed. An anterior loop could be identified in 83.1 % of the cases, with a mean length of 2.09 mm. The mean distance from the superior border of the mental foramen to the alveolar crest was 13.00 mm, and the mean distance from the superior border of the origin of the anterior loop to the alveolar crest was 17.83 mm.[14] However, this study is in accordance with our study.

Another study conducted by Zeba et al, a cross-sectional study was conducted in which a total of 1075 patients reported for CBCT scan at randomly selected Diagnostic and Research Centre (Delhi-NCR), India, during the period of study (January 1, 2014 to December 31, 2014. In this study, out of 193 CBCT scans evaluated, anterior looping of IAN was identified in 72 (37.3%) CBCT scans. Prevalence of anterior looping of IAN was 40.4% among male and 33.7% among female study subjects.[15] In our study, the mean length of the anterior loop on both sides were compared and analyzed which is indifferent from the study conducted by Zeba et al.

Kheir MK et al, had done a study in an Iranian population 180 projections were analyzed in different sectional planes. The results showed that 32.8% of images had anterior loop. The mean lengths of anterior loop in the right and left sides were 2.69 mm deviation and 2.36 mm, respectively. [16] There were no statistically significant differences between the mean lengths of the anterior loop in both sides. However, in our study the mean length was different between the sides probably due to ethnic varation

Eduarda Helena Leandro do Nascimento et al, had conducted a study in a Brazilian population. CBCT images from 250 patients obtained for various clinical indications were randomly selected and evaluated to determine the presence and length of the anterior loop. The length of the anterior loop was then compared based on gender, age, and the side of the mandible. The data were analyzed using the Pearson chi-square test and linear regression analysis. An anterior loop was identified in 41.6% of the cases, and its length ranged from 0.25 mm to 4.00 mm (mean, 1.1±0.8 mm). The loop had a greater mean length and was significantly more prevalent in males (p=0.014). [17] No significant differences were found between the right and left sides regarding length (p=0.696) or prevalence (p=0.650).The p value in our study after comparing the length of the loop on both the sides was found to be p<0.05.

In the study conducted on Mexican participants by Del Valle Lovato Juan et al, Fifty-five computed tomography (CT) scans were made and were visualized with In Vesalius software. Anterior loop measurements were made on 3-dimensional surfaces. Ninety percent of participants showed the anterior loop of the inferior

alveolar nerve. The length of the anterior loop ranged between 0 and 6.68 mm, with a mean of 2.19 mm. No significant differences were found between the left and right sides or between men and women.[18] In our study the length of the anterior loop ranged between 0 and 6.4mm, with a mean of 1.07mm on the left side and 2.217mm on the right side.

Maryam Rastegar Moghddam et al conducted a study in the Iranian population. The anterior loop was observed in 106 quadrants (23.5% of 451 quadrants) of 95 patients (40.6% of 234 patients), of whom 11 had bilateral anterior loops. The mean anterior loop length was 2.77 ± 1.56 mm (95% CI: 2.5-3.1 mm), without significant sex differences. [19]This research is in absolute accordance with our study.

Conclusion

There are various studies conducted to determine the location of inferior alveolar nerve prior to the implant placement procedure and there are very few studies regarding the anterior loop of inferior alveolar nerve.In this context, this study is an important addition to the existing literature. This study indicates the presence or absence of the loop using the cone beam computed tomography scan. The anterior loop on right and left side of the mandible was evaluated and measured. The longest length of the anterior loop was found to be 2.77mm whereas the minimum length of the anterior loop was 1.07mm. The measurement was typically made easier by the three-dimensional method of CBCT. The inferior alveolar nerve on both the sides of the mandible was also measured and compared.

Ethical Clearance: The data used for the study was from the retrospective data available in the Radiology department. Further the patients sign a consent form to use their clinical data except photographs for research purpose, the Institutional Ethical Committee, SIMATS felt that a clearance is not required.

Refugee Women: Problems and Health Concerns

Rubina Grewal[1], R.L. Koul[2]

[1]Research Scholar Under the Supervision of Professor, [2]Professor, Amity Law School, Amity University, Uttar Pradesh

Abstract

Record numbers of people, across the world, are forced to be displaced because of conflict or other violations of their human rights, thus becoming refugees. Often, refugees not only have a higher burden of disease but also compromised access to healthcare, as they face many barriers, such as limited knowledge of the local language. However, there is very limited knowledge on the lived experiences of this population. Moreover, the strategies people might develop in their efforts to access healthcare have not been explored in depth, despite their value in establishing peer-support, community based programs.

This paper is an attempt to discuss the issues concerning the refugee women and children and the steps taken by the Government of India and other organizations in addressing such issues in order to stabilize the socio-economic status and attainment of basic human rights for such women and children.

Keywords: *Access to healthcare, Disadvantage, Refugees, Refugee and asylum seeker healthcare, Women's health.*

Introduction

On 10.12.1948, the Universal Declaration of Human Rights proclaimed that "all the human beings are born free and equal in dignity and in rights without distinction of any kind."[1] Yet, displacement since 1948 has risen on account of armed conflict within the states, persecution and other serious human rights violations. Such unstable environment further leads to sex discrimination and inequality wherein women and children are identified as most vulnerable. These women and childrenare exposed to particular protection problems related to their gender, cultural and socio-economic position and legal status. International displacement especially, weakens the existing community and family protection mechanism and exposes such refugees to a range of human rights violations, including sexual and gender-based violence ("**SGBV**"), abuse and exploitation[2]. As of 2014, India has been a host to more than 2 lakh refugees in India according to the United Nations High Commissioner for Refugees ("**UNHCR**")[3] from Tibet, Sri Lanka, Bangladesh, Afghanistan, Myanmar, Iran, Iraq and even to the Pakistani Hindus, (many of these refugees being women & children) even though India does not have any particular national refugee protection legislation in place. Thus, it is the Indian Foreigners Act, 1946 applies to all classes of non-nationals, including refugees and asylum seekers, and the refugee policy is determined on an ad hoc basis, however, in general India respects the principle of non-refoulement of the UNHCR.

Status of Women and Children Refugees in India: Since India is not party to the Conventions relating to the Status of Refugees, 1951 and Protocol Relating to the Status of Refugees, 1967 (collectively referred to as "**1951 Convention**"), the status of refugees in India is governed mainly by political and administrative decision rather than any codified law[4] on an *ad hoc* basis as stated above. The *ad hoc* nature of the Government's approach results in varying treatment of different refugee groups. The lack of a strong teethed refugee policy means the refugees may be at the subjective and ideological discretion of every incoming government. For instance, the current government in India is more adamant on refusing migrants belonging to the religion of Islam from entering the country from the eastern borders without appropriate permissions and approvals. Some groups are granted the entire gamut of benefits including, legal residence and the ability to the legally employed, while the others are criminalized and denied access to the basic social resources. To enable the refugee and asylum-seekers basic support, the UNHCR set upits operation in New Delhi[5], India in 1981. UNHCR in India conducts Refugee Status Determination

("**RSD**") procedures, which involves a detailed process to registration of individual refugees in order to enable them the protections and provisions meant enabled for refugees in India. UNHCR also provides a range of services to support the refugees and asylum-seekers in health, education, legal counselling, vocational skills and livelihood. UNHCR has certain centers across India, which implement the aforesaid services:

a. Socio-Legal Information Centre (Delhi): provides legal assistance to protect persons under the UNHCR mandate;

b. Bosco (Delhi): Assists refugees in accessing government hospitals, dispensaries and other medical facilities;

c. Gandhi National Memorial Study (Pune): assists refugees and asylum-seekers in Pune;

d. Confederation of Voluntary Agencies (Hyderabad): assists refugees and asylum-seekers inHyderabad;

e. Development and Justice Initiative (Jammu, Mewat and Jaipur): assists refugees and asylum-seekers in Jammu, Mewat and Jaipur;

f. UNHCR along with its partner, Delhi Police, has been organizing self-defense training for refugee women;

g. UNHCR also endeavors that all refugee and asylum-seeker children attend public schools. This has been corroborated by the passing of the Right of Children to Free and Compulsory Education, 2009, under which every child between the age of 6-14 years has the right to free and compulsory education.

a. Sri Lankan Refugees:

(i) Even though the Indian Government provides basic medical care and free education till Class XII, including free course readings, uniforms, bicycles, noon meals, transport passes and tablets to school-age Sri Lankan Childrenas well as subsidized food grain for the camps' inhabitants, they are not permitted the free movement within India. Furthermore, these camps are generally poor with insufficient health and sanitary facilities.

b. Burmese Refugees:

(i) While the access to education is formally ensured for every child, however, educational institutions require a birth certificate and papers for registration and fees, which refugees cannot always provide. In government schools, the medium of instruction is Hindi, which acts as a barrier to education. Further, the cultural differences and language barriers prevent assimilation, and cases of bullying and safety concerns result in the children being sent to school catering for Burmese Community such as Prospect Burma.[6]

c. Majority of the Burmese women are from the Chin state–and they are uneducated, unskilled, with no abilities and thus lack the skills to adapt to the day to day skills of city life. They are also poor, are usually widows and/or the heads of families and are forced to live in overcrowded accommodation in highly unsanitary conditions. In addition to taking care of the family members, these women also work to provide for them. Such women refugees are regularly harassed at work, and if they work at night shifts, the risk of harassment and assault increases even more. Because of their peculiar status, they are wary to approach for police protection, even if they are victims of crime.

d. Somali Refugees:

(i) Majority of the Somali community in India cannot speak English or Hindi and are even discriminated against, because of their ethnicity. Somali women face, particular problems in accessing transport, healthcare and education, they are subjected to prejudicial treatment and unwarranted scrutiny on the suspicion of human trafficking, prostitution and drug rackets.

(ii) In the *"Urban Profiling of Refugee Situations in Delhi: Refugees from Myanmar, Afghanistan and Somalia and their Indian Neighbours: A Comparative Study"*, 35% Somali refugees do not have any education. And Somali refugees have reported that they frequently need to face discrimination at the government schools and sit in a class without seats and at alternate times, they were made to sit at the back of a classroom. Further, they even have to confront verbal and physical abuse by their classmates and even instructors and returned with wounds from school.[7]

e. Afghan Refugees:

(i) A large population of the Afghan community are widows and single mother Workers in

the informal sector and work very long hours and Afghani Muslim women are particularly discriminated against.

(ii) Even though education is open to all Afghan refugee children, most Afghan boys only study up to primary level before startingwork to support their families. The dropout rate among Afghan girls is also high in the primary level, in order to take care of ill relatives, they are engaged/married off, or for financial reasons.

f. Pakistani Hindu Refugees:

(i) Even though the children of Pakistani Hindu Refugees are born in India and are natural citizens of India, however, they are not eligible for jobs in the government sector.[8]

g. Rohingya Refugees:

(i) Out of all the Refugees, the Narendra Modi-led government has taken the most stringent stand on the Rohingya refugees. Thus, the conditions for such refugees are abominable, where women are afraid to step out of the camps, and during the monsoon the children reportedly got bitten by snakes[9]. Because the Rohingya do not have identity documents, they cannot send their children to government schools or even use health services at government hospitals.[10]

(ii) Further in Salehdi, a refugee camp in northern India, the situation is dire for pregnant women, mothers and their new-born children apart from the general population where hunger is a constant. The women are falling sick with diarrhea from the dirty water they have to drink, robbing their fetuses and breastfeeding children of critical nutrients. Others are deprived of iron in their diets, leading to anemia and heightened risk of giving birth prematurely.The nutritional status of the Rohingya refugees has suffered without guaranteed access to housing and public relief and assistance programs.[11]

(iii) Most expectant Rohingya mothers are blocked from access to a basic maternity benefit program that provides pre-and post-delivery care and vaccinations for new-borns. They are also locked out of the *Pradhan Mantri Maternity Scheme*, which provides lactating mothers with roughly $100, which they could use to buy food and improve their diet.

With lack of any detailed refugee laws, the refugees from different nationalities have varying treatment in India. Even thoughthe Constitution of India, 1950 ("**Indian Constitution**") is empowered to regulate citizenship and naturalization. Accordingly, the Parliament passed the Citizenship Act of 1955 ("**Act**"), which has been amended twice since, once in 1986 and later in 2003. Section 3 of the Act regulated the citizenship by birth between 26.01.1950 to 01.07.1987, however, one such parent ought to be an Indian. Thus, despite the refugee children having been born in India are not granted the Indian citizenship and have even fought their basic fundamental rights. One such case is of Namgyal Dolkar. Even though she was born in Kangra, Himachal Pradesh in April, 1986, she was denied many opportunities on account of being a foreigner. However, the Delhi High Court vide its order[12]explicitly stated that Ms. Dolkar was indeed a citizen under the Indian Constitution.

I. Steps Taken by the Indian Government & Other Organizations

1. Despite such failures, the Indian Government has taken various steps to mitigate the risk that basic fundamental rights are not deprived to the refugees in India, with particular attention to women, girls & children. Firstly, the 2013 Criminal Law (Amendment) Act ("**Amendment Act**") that came into effect on 03.02.2013, whereby the Indian Penal Code, 1860 ("**IPC**") was amended as well as certain new sections were included with regard to various sexual offences, including acid attack, sexual harassment, voyeurism, stalking.

2. Further, as per the Amendment Act, the police will be penalized for failing to register First Information Reports. The Amendment Act introduced unprecedented provisions in the IPC which amended the legal provisions to protect the privacy of individuals. The reported instances of SGBV affecting refugee women & girls have reduced by 20% in 2015 due to improved national response on SGBV and inclusion of refugees in national DGBV prevention and response mechanism and programs.[13]

3. Another key facet which one needs to take a note of is the proactive support of the Indian Judiciary to these communities as a flag bearer

of human rights and custodian of the Indian Constitution. The Indian Judiciary, especially the Supreme Court of India has progressively interpreted Articles 14 and 21 of the Indian Constitution, particularly bearing in mind the tenets of Universal Declaration of Human Right, 1948, resulting in effective protection of refugees in India. For instance, the Apex Court in *Vishaka v. State of Rajasthan (1997)*, stated that international law and the municipal law ought to be interpreted harmoniously, in conjunction with each other, and in the absence of any domestic law occupying the field, the contents of International conventions and norms are significant for the purpose of interpretation of Articles 14 and 21 of the Constitution of India.

4. The Apex Court has been sympathetic towards the cause of refugees in India and has stitched many rights of the refugees within the four folds of the Indian Constitution. In the case Hans Muller of Nurenberg v. Supdt. Presidency Jail (1955), The Supreme Court has held that despite a good cause, extradition being a discretionary right of the government may refuse so. In interpreting the Foreigners Act, the Apex Court stated that the power to make order under Section 3, vests with the Central Government, and even though subordination of power is permissible, the same ought to be used judiciously, setting aside the order passed by the district superintendent of police. The fundamental rights of the foreigners in India, however, Luis De Raedt v. Union of India (1991), the Apex Court held[14] are restricted only to Article 14 and 21 of the Indian Constitution and does not include the right to reside and settle in India, as specified in Article 19(1)(e), which is applicable only to the citizens in India.

    a. *Development and Justice Initiative ("***DAJI***"):* DAJI, a registered public charitable Trust in New Delhi as a public charitable Trust, works mainly with urban poor, migrant workers, refugees and displaced people. It is particularly concerned with rights and safety of children, women, and elderly, differently abled people, Dalits, Minorities and Indigenous Peoples.

    b. *Save the Children India (***"SCI***"):* Started in 2008, SCI India is working in 18 states in India and has reached more than 9 million children, including 2.7 million in 2017. SCI strives to provide quality education, healthcare, protection from harm and abuse and life-saving aid during emergencies to children. As a UNHCR-implementing partner SCI seeks to reduce the vulnerability of refugees/asylum seekers especially women, children and youth to protection risks by enabling them to meet their basic needs.

Conclusion

We stand at a juncture where diplomatic relations amongst the International Community is at its weakest. The ongoing conflicts in the West Asia and North Africa region and countries like Venezuela, Myanmar etc. is leading to the emergence of a Global Refugee Crisis. However, the untiring efforts of the United Nations coupled with the efforts of the nations like Canada and European Union, specially Germany have stepped in right direction to give protection to these refugees and have helped keeping a check on the refugee problem. This is a ray of hope in an otherwise emerging global crisis.

But, unfortunately at the same time, the increase in the number of asylum seekers all over the world during the past few years has led to the diminishing of protection space laying a heavy burden on the economies and resulting in specific terrorist attacks supposedly based on religion. Against the broader background of the difficult socio-economic conditions, the tradition of tolerance has been undermined. This has led to countless women and children fetching for their lives on the roads. Certainly, one can understand the concerns of the government relate to the limited resources and the land mass which is already overburdened by the ever-growing population and the threat to national security. However, this should not be an excuse for the genuine cases. The progress made in India as a stakeholder of emancipation of refugees especially women and children is commendable. But we still have a long road ahead of us in the field of refugee rights. The key stakeholders in the International arena including India should throw light onto this problem. The plight of these vulnerable women and children should change and to bring in such change and strong teethed concrete law should be enforced. Policy makers have time and again attempted to persuade the government to

make a more liberal enactment for opening the doors of India to these refugees.

Investors Attitude Towards Investment in Private Insurance Companies in Madurai City, Tamil Nadu State

S. Chandrachud[1], M. Ramesh[1], E. Rajarethinam[1], Telu Suvarna[1]

[1]*Associate Professor, Department of Economics, VISTAS*

Abstract

The business of insurance is concerned with the economic values of assets. Every asset has a value. The asset would have been created through the efforts of the owner, in the expectation that, either through the income generated there from or some other output, some of his needs would be met. The main objective of the study is to analyse the various investment options of the investors and to study the customers' perception on investing in private sector insurance companies. The secondary objectives of this study include analysing, the investing habits of the investor, the factors influencing the investor in investing in insurance. This study is compiled with the help of primary data and secondary data. Primary data were collected from 260 respondents with the help of structured Questionnaire method in various places in Coimbatore city. Cluster Random sampling technique has been adopted to select the respondents. The Secondary sources of data are company profile, organization Website and other related library books. The Simple Percentage analysis, Weighted Average Method for ranking was used for analysing the collected data.

Keywords: *Private Insurance, Investment, Individual attitude, market risk, insurance policy.*

Introduction

The business of insurance is concerned with the economic values of assets. Every asset has a value. The asset would have been created through the efforts of the owner, in the expectation that, either through the income generated there from or some other output, some of his needs would be met. However, the assets get lost earlier being destroyed or made non-functional, through an accident or other unfortunate event, the owner and those deriving benefits there from suffer. Insurance is a mechanism that helps to reduce such adverse consequences.

Importance of Insurance: Assets are insured, because they are likely to be destroyed or made non-functional through an accident occurrence. Such possible occurrences are called Perils. Fire, floods, breakdowns, lighting, earthquakes, etc., are perils. The damage that these perils leads to the asset known as the risk. The risk only means that there is a possibility of loss or damage. It may or may not happen. There must be an uncertainty about the risk. Insurance is done against the contingency that it may happen.

Objectives

1. To identify the investors' attitude towards various investment alternatives
2. To study the customers' perception on investing in private sector insurance companies.
3. To analyze the factors influencing the investor in investing in insurance
4. To determine the Sector and Plan Preferred by investors.
5. Toanalyze the factors influencing the investor in investing in Private insurance companies.

Need for the study: The last few years have been a watershed for assured return plans. As the insurance sector has developed, there's been a growing acceptance by most policyholders that the assured return era is a thing of the past. The private insurance companies are focusing on the Market Linked Plans. This study aims to

study the investors' attitude towards various investment alternatives and to study the customers' perception on investing in private sector insurance companies. The study would also analyse the acceptance level of Market Linked Plans, which is being the current era. This has been done by preparing the questionnaire which contains questions put forth to the perspective investors which would help in analyzing the profile and investing habits of the investor, factor influencing the investor in investing in insurance and level of acceptance of private insurance companies.

Limitation of the Study: The area of study is limited to various places Madurai city; hence the results may not be true for other geographical areas. Validity & Reliability of the data are obtained depends on the responses from the customer.

Research Methodology: Research is an intensive study in a particular field to achieve at a better conclusion of a problem. Research Methodology is a systematic way of solving the problem. The methodologies followed for this study are as follows.

Nature and Sources of Data: Both primary and secondary data is used in this study in order to meet the requirements of the purpose. Under this study primary data was collected by using Questionnaire. The primary data was collected from individuals residing in Madurai city with the help of questionnaire. The secondary data are sourced from Life Insurance Companies, Magazines, Books, Pamphlets, Periodical Surveys and Websites etc. The data collection has been done through questionnaire by means of personal interview. A questionnaire is consisting of a number of questions printed in a definite order on a form.

Sample size: Since the population of Madurai city is large in number, researcher was unable to collect information from all individuals due to limitation of time, so part of the population is taken for analyzing and generating the findings, which is applicable for total market. The size of the sample is 260.

Sampling Method: Cluster Random Sampling Method is used, as data are collected according to the clusters divided. The city is mainly divided into four clusters, like North, South, East and West. A total of 65 samples were collected from each cluster due to the limitation of time by the researcher.

Tools Used: The collected data were analyzed with the help of Simple Percentage analysis, Chi-and Weighted Average Method.

Review of literature

Brigid Goody Sc. D, Renee Mentnech M.S and Gerald Riley M.S.P.H[1] in their article, over the last decade, various laws have been passed to increase the likelihood that lower income individuals and families would have access to health insurance coverage. Through the Health Insurance Premium Payment Program enacted in 1990, States could use their Medicaid funds to pay the employer-sponsored health insurance premiums of Medicaid eligible individuals and families.

Chang Hoon You, et al[2] in their research article, It was confirmed that diabetic patients insured by SPHI had more use of hospital services than those who were not insured. People insured by SPHI seem to be more likely to use hospital services because SPHI lightens the economic burden of care.

Avi Dor, Joseph Sudano and David W. Baker[3] In this paper we investigate whether the presence of private insurance leads to improved health status. Using the Health and Retirement study we focus on adults in late middle age who are nearing entry into Medicare.

Subba Lakshmi Tirukoti[4] The paper explores the reasons for purchasing private health insurance and to identify the determinants of private health insurance in East Godavari District of Andhra Pradesh. Economic development programs should help enhance income to reach a higher standard of living and in doing so boosts their economic access to health insurance policies and the relevant health services.

Minsung Sohn and Minsoo Jung[5]: The moral hazard behind insurance membership, depending on how NHI maintains policies to confer benefits, may give rise to differences in medical utilization. This phenomenon must be closely monitored to find a way to reform NHI when the rights of medical service consumers are solidified through PHI.

Influencer of the Investors: There are many influencer for the insurance policy. On our study there are 5 major influencers, such as Auditors, Family influence, word of mouth by friends, Advertisement in Electronic media and Articles through dailies, magazines and other written advertisement.

Table 1: List of Influencers for Investment Decision

S.No.	Influencers	No of Respondents	Percentage
1.	Auditor	22	8.46 %
2.	Family	100	38.46 %
3.	Friends	50	19.23 %
4.	Advertisement	32	12.31 %
5.	Article	31	11.92 %
6.	Others	25	9.62 %
	Total	260	100 %

Source: Primary Data

From table 1, it can be viewed that, 38.46 % of the Respondents are influenced by Family,19.23 % of the Respondents are influenced by Friends,12.31 % of the Respondents are influenced by Advertisement, 11.92 % of the Respondents are influenced by Article,8.46 % of the Respondents are influenced by Auditors and9.62 % of the Respondents are influenced by others.

Table 2: Objectivein Investment

S.No.	Objective	No of Respondents	Percentage
1.	Return	71	27.31 %
2.	Tax Benefits	52	20 %
3.	Security	83	31.92 %
4.	Children	54	20.77 %
	Total	260	100 %

Source: Primary Data

From table 2, it is clear that 32 % of the respondents choose Security as their Objective in Investment,27.31 % of the respondents choose to return as their Objective in investment,21 % of the respondents choose Children as their objective in Investment, 20 % of the respondents choose tax benefits as their objective in investment.

Table 3: Sector Preferred by the Respondents

S.No.	Sector	No of Respondents	Percentage
1.	Public	192	73.85 %
2.	Private	66	25.38 %
3.	Nil	2	0.77 %
	Total	260	100 %

Source: Primary Data

From table 3, it can be viewed that,74 % of the respondents prefer only Public-Sector Insurance Companies,25 % of the Respondents prefer only private sector insurance companies,1 % of the respondents does not prefer any sector.

Table 4: Factors Influencing to Gofor Private Life Insurance Company

S.No.	Factors	No of Respondents	Percdntage
1.	Service	58	22.31 %
2.	Return	69	26.54 %
3.	Security	40	15.38 %
4.	Premium Amount	20	7.7 %
5.	Flexibility	23	8.85 %
6.	Market Linked Plans	32	12.31 %
7.	Nil	18	7 %
	Total	260	100 %

Source: Primary Data

From table 4, it can be viewed that, 26.54 % of the Respondents has given Return as the Influencing Factor to go for Private Life Insurance companies,22.31 % of the Respondents has given Service as the Influencing Factor to go for Private Life Insurance companies,15.38 % of the Respondents has given Security as the Influencing Factor to go for Private Life Insurance companies,12.31 % of the Respondents has given Market Linked Plans as the Influencing Factor to go for Private Life Insurance companies, 8.85 % of the Respondents has given Flexibility as the Influencing Factor to go for Private Life Insurance companies, 7.7 % of the Respondents has given Premium Amount as the Influencing Factor to go for Private Life Insurance companies,

Table 5: Expectation overinvestment Using Weighted Average Method

Rank Weight (X)	1 5	2 4	3 3	4 2	5 1	Total	Weighted Average	Rank
Rate Of Return (y1)	69	74	62	36	19	260		
x.y1	345	296	186	72	19	918	3.53	2
Security (y2)	123	62	28	34	13	260		
x.y2	615	248	114	68	13	1058	4.07	1
Liquidity (y3)	9	29	54	63	105	260		
x.y3	45	116	162	126	105	554	2.13	5
Tax Benefit (y4)	37	65	53	54	51	260		
x.y4	185	260	159	108	51	763	2.93	3
Service (y5)	22	30	63	73	72	260		
x.y5	110	120	189	146	72	637	2.45	4

From table 5, it is inferred that,the respondents have ranked security as first in respect to expectation over investment. The respondents have ranked Rate of Return as recond in respect to expectation over investment and they have ranked Liquidity as Fifth in respect to expectation over investment.

Table 6: Ranking of Private Life Insurance Companies Using Weighted Average Method

Rank Weight (X)	1 11	2 10	3 9	4 8	5 7	6 6	7 5	8 4	9 3	10 2	11 1	Total	WA	Rank
HDFC	30	84	44	22	15	10	7	6	12	5	8	243		
X.Y1	330	840	396	176	105	60	35	24	36	10	8	2020	8.3	1
MAX	4	7	11	29	32	26	16	27	37	36	18	243		
X.Y2	44	70	99	232	224	156	80	108	111	72	18	1214	5	9
ICICI	71	29	34	17	20	12	9	11	9	18	13	243		
X.Y3	781	290	306	136	140	72	45	44	27	36	13	1890	7.8	2
KOTAK	15	14	14	20	31	32	27	22	37	17	14	243

BIRLA	19	18	21	27	27	26	31	27	18	13	16	243		
X.Y5	209	180	189	216	189	156	155	108	54	26	16	1498	6.2	4
TATA AIG	10	29	17	25	17	34	31	28	25	16	11	243		
X.Y6	110	290	153	200	119	204	155	112	75	32	11	1461	6	5
SBI	47	28	25	17	27	14	22	16	11	20	16	243		
X.Y7	517	280	225	136	189	84	110	64	33	40	16	1694	7	3
ING VYS	21	15	23	13	19	28	30	36	18	18	22	243		
X.Y8	231	150	207	104	133	168	150	144	54	36	22	1399	5.8	6
BAJAJ	7	7	19	34	22	25	27	20	40	25	17	243		
X.Y9	77	70	171	272	154	150	135	80	120	50	17	1296	5.3	8
AVIVA	8	6	28	14	22	12	17	25	26	40	45	243		
X.Y10	88	60	252	112	154	72	85	100	78	80	45	1126	4.6	10
METLIFE	10	6	8	25	12	24	24	24	13	32	65	243		
X.Y11	110	60	72	200	84	144	120	96	39	64	65	1054	4.3	11

From table 6, the respondents have ranked HDFC Standard Life Insurance Company as first in private life insurance companies, ICICI Prudential Life Insurance Company assecond, SBI Life Insurance Company as third in Private Life Insurance companies. Likewise, the respondents were not much aware of the two new

recently entered insurance companies, AMP Sanmar Life Insurance Company Ltd and Sahara India Insurance Company Limited, so default these companies were ranked last.

Findings: From the study the following findings have been made:

1. Most of the respondents are salaried people.
2. Most of the respondents choose Security as first and rate of return as their second it expectation over investment.
3. Most of the respondents are influenced by family and friends to make the investment decision,
4. Majority of the respondents' objective on investment is Security and Return.
5. 78 % of the respondents accept insurance as agood investment Option.
6. 74 % of the respondents prefer only public sector.
7. Majority of the respondents do not have a plan to go for private life insurance in future.
8. Majority of the respondents are influenced by benefit factor to take life insurance policy.
9. The respondents have ranked HDFC and ICICI private life insurance as the mostly preferred companies.
10. Majority of the respondents i.e., 62% preferbonus-based plans.

Suggestions: Since Security and Return is the main expectation of investors, it is suggested that this aspect be reinforced while wooing prospective investors. The annual income of most of the respondents are below 1 lakh and this segment goes for investment in insurance. It is suggested that while marketing this segment be considered. The awareness of LIC is most and other private insurance companies remains untapped. It is suggested that an attempt be made to bring out the advantages of other companies and schemes. Only few Respondents have plan to go for private life insurance, so the schemes and advantages of private insurance companies must be promoted greatly. While dealing with prospective investors, according to their occupation the objective on investment varies, so this factor should be considered the most. The awareness of market linked schemes to the people is low. The respondents who prefer return as their investment option will prefer Market linked pans when its advantages known, so steps should be taken in this area to create good awareness.

Conclusion

It has been found that the salaried person is more interested in having insurance as an investment avenue for various reasons. LIC and money back are the well-known company and scheme. The private insurance companies are accepted to certain extent only and it has to be tapped to greater extent. It has also been found that insurance advisor is the one, who are the main source of information on schemes and advantages of private insurance companies, to the investor.

Ethical Clearance: Completed.

The Economic Impact of FDI in Indian Chemicals Sector

S. Chandrachud[1], S. Thangamayan[2], R. Premalatha[2], Telu Suvarna[2]

[1]Professor, [2]Assistant Professors, Department of Economics, VISTAS

Abstract

With the increasing demand for the chemical products in global scenario, India has witnessed the significant growth in both chemical and petrochemical sector in the past decade. The increased flow of Foreign Direct Investment in the Chemical Industry in India has helped in the development, expansion and growth of the industry. The current study throws light on the economic impact of Foreign Direct Investment in Chemical and Petro-chemical industry. Chapter 1 exposes the current position of Indian Chemical Industries. Chapter two enlists the review of literature. Chapter three narrates the sector policy of Chemical industry. Chapter four analyses the Economic impact of FDI in Indian Chemicals Sector through SWOT analysis. Chapter five portrays the future scope of Chemical Industry. The last chapter concludes with imperative economic effects of FDI in chemical and petro-chemical industries.

Keywords: *Chemical industry, SWOT, FDI, Economic growth, PCPIR, Petrochemical.*

Introduction

The Indian Chemical industry is sixth largest in the globe and third largest in Asian continent by output and India is the fourth largest producer of agro chemicals after US, Japan and China, in case of the supply side. On the demand side, the Indian chemical industry is the sixth largest consumer of the chemicals of the world. The Chemical and petro chemical sector in India is an integral part of many major sectors like agricultural sector, Construction sector, leather industries etc. The highlighting criteria of Indian chemical industry growth are sufficient irrigation facility, innovation in indigenous research, raw materials availability, demand growth, low labour cost, largest peninsula and proximity to the Middle East countries, and low-cost production. Encouraging potentials of Agro chemical industry enlighten the performance of Indian chemical industry. The modern era of chemical industry has grown with investment regions scheme.

Review of Literature: The following studies supports the current research article with respect to FDI.

Corresponding Author:
S. Chandrachud
Professor, Department of Economics, VISTAS
e-mail: prof.chandrachud@gmail.com

Nadide Sevil Tuluce and Ibrahim Dogan[1] The influence of FDI not only affect the labour and capital market but also the trade patterns and economic growth. The FDI effects in the receiving country, extended to multinational enterprises (MNE) with specific economic advantages which is higher than the host country. The main specific advantage is the technology transfer from the parent firm to local firm which in turn the economy.

Mohammed Amin Almfraji and Mahmoud Khalid Alumsfir[2] The relation between the Foreign Direct Investment is significantly positive in most of the cases, while in few cases it is negative or even null. There are many factors which are influencing the relation between FDI-EG, such as Adequacy of man power, the well-built financial markets and services, Provision of exchangeability between domestic and foreign investment and the open trade operations, etc.

Jorge Bermejo Carbonell and Richard A Werner[3] The lion share of global FDI inflow directed to developed economy rather than developing economy.. Single-country case studies are to be conducted, due to the Complexity relationship between FDI and economic growth, and due the global impact of FDI on growth is said to be largest in liberlized, advanced developed countries with an educated and skilled workforce and well-built commercial and capital markets.

Majid Mahmoodi and Elahe Mahmoodi[4] The current study expresses the connectivity of developing economies of Europe indicates indicate bidirectional connectivity between GDP and FDI, and unidirectional connectivity from GDP and FDI to exports in limited time intervel. On the other hand, the developing countries of Asia, there is bidirectional connectivity between exports and economic growth in limited time intervel.

Niels Hermes and Robert Lensink[5] This study counter that the well-developed financial system is the pre-requisite for the Foreign Direct investment and which will result in positive significance, on economic growth. State of financial system is directly proportion to the process of technological diffusion with the FDI and collaborations.

V N Balasubramanyam, S Salisu and David Sapsford[6] This article is witness that, Foreign Direct Investment gains its importance in economic growth. Construction of theoretical framework, pave way to understand the role of FDI in the growth and size of the domestic market and secondly, the competitive climate in relation to local producers.

Sector Policy of Chemical Industry: FDI Inflows to Chemicals industry in India has increased over the last few years due to the several incentives that have been provided by the government of India. The increased FDI Inflows to Chemicals industry in India has helped in the growth and development of the sector. 100% FDI is allowed in chemicals under the automatic route in India.

In order to promote the foreign Direct investment, the Ministry of Chemical and Petro chemicals has set up set up PCPIRs (Petroleum, Chemicals and Petrochemical Investment Regions) as an integral part of Special Economic Zones. Under the PCPIR policy, Government of India has conceptualized PCPIRs in a cluster approach for promotion of Petroleum, Chemical and Petro chemical sectors in an integrated and environment friendly manner on a economies scale. It is to be noted that the PCPIR unit is a specifically delineated investment region having a land area of 250 sq. km approximately and minimum of 35 to 40 percent allotted for the processing activities. Chemical and petro-chemical ministry has constructed PCPIR in Vishakapatnam in the State of Andhra Pradesh, Dehej in the State of Gujarat and Paradeep in the State of Odisha and Cuddalore and Nagapattinam in the state of Tamilnadu. The expected Foreign Direct Investment out of these PCPIR about USD 117 billion, and planning to generate 34 lakh employment opportunities. As of now, we have received nearly USD 28 billion and 2.93 lakh persons are employed through these PCPIR.

The scheme aims to set up necessity based plastic parks and progress of a strong ecosystem along with provision of common facilities through cluster development approach. Indian government provides endowment finance up to 50% of the project cost, subject to a upper limit of USD 6 million per project. And, the rest of the project cost is to be financed by State Government or State Industrial Development Corporation. Four States of the economy initiated the Plastic Parks, Madhya Pradesh, Odisha, Assam & Tamil Nadu respectively, are being implemented under the scheme of Plastic Parks. However, all the project must be subject to the industrial license and approval from the environmental protection legislation.

There are several schemes for the purpose of export promotion to grant incentives. Some of the schemes are export promotion capital goods scheme, Duty drawback scheme and Merchandise Export from India Scheme etc. The other financial incentives for the this chemical industry with respect to research are discussed in the future scope of Chemical industry chapter.

SWOT Analysis–Economic Impact of FDI on Indian Chemical Industry

Strength

1. 6th largest producer of chemicals in the world
2. Third largest producer of ASIA
3. Key industry for agriculture, construction and leather industries.
4. 6th largest consumer of chemicals in the world
5. Proximity of Middle East
6. 100 percent automatic route for FDI approval.
7. Economies of Scale

Weakness

1. Currency devaluation,
2. Political instability,
3. Environmental Issue,
4. Water pollution
5. Air and Sand Pollution.
6. Adverse to health status
7. Environmental pollution.
8. Hazardous chemicals injuries to health
9. Abandonment of plastic products

Economic Impact of FDI on Indian Chemical Industry

Opportunities

1. Special Economic Zone
2. PCPIRs (Petroleum, Chemical and Petrochemical Investment Regions)
3. CoEs (Centre for Excellence)
4. Plastic Park
5. Raw materials availability
6. Low cost of production
7. Abundance of labour supply
8. CIPET (Central Institute of Plastic Engineering and Technology)
9. Chemicals Promotion Development scheme

Threats

1. Skilled workforce are in scarcity
2. Infrastructural problem prevailing in the private sector
3. Colourant chemical industry
4. Environmental pollution,
5. Environmental degradation,
6. Hazardous Chemicals
7. Problems of Agro-Chemical Industry.

Source: Prepared by author.

Future Scope of Indian Chemical Industry: Provision of Grant-in-aid to educational/research institutes for setting up Centre of Excellence (CoE) with a view to improve existing petrochemicals technology and promote development of new applications of polymers and plastics. The Department of Chemicals and Petrochemicals has set up five Centre of Excellence (CoE).

1. CoE for Sustainable Polymer Industry through Research, Innovation and Training (CoE-SPIRIT) at National Chemicals Laboratory, Pune.
2. CoE for Green Transportation Network (GREET) at Central Institute of Plastics Engineering & Technology (CIPET), Chennai.
3. CoE for Advanced Polymeric Materials at IIT, Delhi.
4. CoE on Sustainable Green Materials at CIPET, Bhubaneswar.
5. CoE for Sustainable Polymers at IIT, Guwahati.

A new scheme called CPDS, called Chemicals Promotion Development Scheme, in which our central government provides Grant-in-aid for creation of intellectual products through educations, investigation,

data bank, preferment materials etc. in order to enable development of the sector. Under the scheme of CIPET, Central Institute of Plastic Engineering and Technology, the government instigated sector framework to strengthen civil and technical infrastructure, research and development capacities and academic and training initiatives, budgetary allocations are made in the Union Budget.

There are two provisions from Income tax act encourages more economic activity in Chemical and petro-chemical industry. A weighted tax deduction is given under section 35 (2AA) of the Income Tax Act and Weighted deduction of 200% is granted to assess for any sums paid to a national laboratory, University or institute of technology, or specified people with a specific direction and that the said sum is used for scientific research within a program approved by the prescribed authority.

Section 35 (AB) of the Income tax act, 1961 provides Section 35 (2AB) of the Income Tax Act, 1961 provides weighted tax deduction of 150% of expenditure incurred by a specified company, on scientific research in the in-house R & D centers as approved by the prescribed authority. This does not include expenditure on the cost of any land or building. Further, the weighted tax deductions of 150% are effective till 31st March'2020. Consequent upon that, the weighted tax deductions will be 100%.

Apart from the above, each state in India offers additional incentives for industrial projects and Incentives are in areas like

1. subsidized land cost and relaxation in stamp duty exemption on sale/lease of land,
2. power tariff incentives,
3. concessional rate of interest on loans,
4. investment subsidies/tax incentives,
5. backward areas subsidies,
6. special incentive packages for mega projects etc.

Conclusion

Most successful encouragement from the government is the area based incentive, particularly, Incentives for units in Special Economic Zones (SEZ) and National Investment and Manufacturing Zones (NIMZ) as specified in respective Acts or setting up projects in special areas like the North-east, Jammu & Kashmir, Himachal Pradesh & Uttarakhand. The Economic impact of FDI on Chemical sector can be summarized with current focus of the central government. The Union budget 2018, the total budget allocation amount made towards Department of Chemicals & Petrochemicals during the year 2018-19 is USD 30 million. The following central government schemes are allotted with the project funding under the Union Budget 2018-19,

1. Assam Gas Cracker Project (USD 1,538),
2. Chemical Promotion and Development Scheme (USD 0.46 million)
3. Promotion of Petrochemicals (USD 8.53 million).
4. CIPET (Central Institute of Plastic Engineering and Technology) has been allocated USD 12.86 million.

As far as Agro-Chemicals industry is concerned the Indian agrochemical industry is worth USD 4.9 billion, and around 50% of it is export oriented.

A Study on Labour Laws with Special Reference to Industrial Dispute Act, 1947

G. Senthil Kumar[1], S. Chandrachud[2]

[1]Assistant Professor, School of Law, [2]Associate Professor, Dept. of Economics, VISTAS

Abstract

Successful implementation of any legislation depends on the need and purpose of the act and provision to reach the right destination. The current study throws light on the pre requisite for industrialization and the penalties of violation of rule in labour law. For this purpose, an attempt to make a study on Industrial Dispute Act, 1947 (IDA 47), in terms of its concepts and penalties. Chapter one initiates the basics of IDA 47. Chapter two portrays the methodology of the study. Chapter three enlists the literature review. Chapter four discusses with concepts of IDA 47 and chapter five envisages the penalties of IDA 47. Last chapter concludes with the need of voluntary arbitration.

Keywords: *Industrial Dispute, Labor laws, conciliation, adjudication, Legal framework.*

Introduction

This paper deals with the Industrial Disputes Act, 1947. The Industrial Disputes Act 1947 extends to the whole of India and regulates Indian labour law so far as that concerns trade unions. It came into force April 1, 1947. The objective of the Industrial Disputes Act is to secure industrial peace and harmony by providing machinery and procedure for the investigation and settlement of industrial disputes by negotiations. The laws apply only to the organised sector. Chapter V-B, introduced by an amendment in 1976, requires firms employing 300 or more workers to obtain government permission for layoffs, retrenchments and closures. A further amendment in 1982 (which took effect in 1984) expanded its ambit by reducing the threshold to 100 workers. The Act also lays down the provisions for payment of compensation to the workman on account of closure or lay off or retrenchment, the procedure for prior permission of appropriate Government for laying off or retrenching the workers or closing down industrial establishments, unfair labour practices on part of an employer or a trade union or workers.

Methodology

Objectives:

1. To critically analyze about the concept of the Industrial disputes Act, 1947
2. To critically analyze about the penalties under the Industrial disputes Act, 1947

Hypothesis:

H_0: Industrial Dispute Act is settling the labour issues to make the industries to run in good and efficient way.

H_1: Industrial Dispute Act is not settling the labour issues and make the industries to run in good and efficient way.

Source of study: As the current study analysis with the particular act of labour laws, it uses only the secondary data sources and researchers have referred books, journals, and research articles, unpublished thesis, working papers, conference proceedings, dailies and online sources.

Limitations: Non availability of firsthand information always remains a limitation while doing this assignment and the assignment consumes lot of time and efforts since the information is not direct and time is consumed in the transformation of the indirect facts.

Chapterisation :

1. Introduction
2. Methodology
3. Review of Literature
4. Concepts of Industrial Dispute Act, 1947

5. Penalties under Industrial Dispute Act 1947
6. Conclusion

Review of Literature:

K.M. Pillai[1] in his book, Labour & Industrial Laws, has dealt with various kinds of Acts and rules made by the parliament of India. This book deals with the Industrial disputes Act, 1947 and relating case laws, latest relevant judicial decisions and legislative amendments.

Palak Varma and Aditya Tomer[2] in their article, discussed the concepts of industrial disputes and individual disputes under the Industrial Dispute Act, 1947. A dispute is an industrial dispute even where it is sponsored by a union which is not registered where as an individual dispute is espoused by union the question of employee being a member of the union when the cause arose is immaterial.

The Indian Express[3] "With the proposed amendments in the Industrial Disputes Act, the state government is trying to change the definition of labour and diverting it to increasing the compensation. By putting a three-year bar on raising an industrial dispute, it is throwing the labourers out of the legal framework," said Vishwas Utagi, convener of the Trade Union Joint Action Committee.

Richard Mitchell, Petra Mahy and Peter Gahan[4] in their study, a survey of the literature in the field, examining the various periods through which Indian labour law has evolved up the present time and extent to which the labour law system can be seen to have fulfilled its two core objectives: protection of labour and maintenance of industrial peace.

Concept of Industrial Disputes Act, 1947: The Industrial disputes Act,1947 is the first effective measure of all India application for tye settlement of industrial disputes. Under this Act, various tribunals have passed awards regulating wages and other relations in many industries. The Act regulates the relationship of the employers and employees in many matters irrespective of whether the employer is the State or not. This Act makes provision for delegation of powers to the State and Central Government in the matter of making rules. This invariability enables the State Government to make amendment to the Act so as to suit the local conditions.

Definitions: Clauses (a) to (s) of Section 2 provide for defining the important terms and phrases which have a bearing on the Industrial Disputes Act, 1947. The section opens with the qualifying words "unless there is anything repugnant in the subject or context' so as to give emphasis to the natural or ordinary meaning as well as to the context in which it is made. The Industrial Disputes Amendment Act, 1982 has redefined the concept of industry by recasting S. 2(j). The new definition was necessitated to overcome the impact of the decisions of the Supreme Court.[5]

Industrial Dispute: The collective bargaining ideal is implicit in the definition of industrial dispute. A dispute between the employer and a workman will not be an industrial dispute under section 2(k) unless it is sponsored by the union or a substantial number of workman. This is subject to section 2A. Industrial Dispute is defined in Section 2(k) as-

(a) Any dispute or difference between the employers and employers or

(b) Between employers and workmen or

(c) Between workman and workman which is connected with

  (i) The employment or non-employment or

  (ii) The terms of employment or

  (iii) With the conditions of labour of any person[6]

Employer: Employer is defined in section 2(g) to mean in relation to an industry carried on by or under the authority of any department of the central government or state governments., the authority prescribed in this behalf or when no authority is prescribed, the head of the department and in relation to an industry carried on by or on behalf of a local authority prescribed in this behalf or when no authority is prescribed, the head of the department and in relation to an industry carried on by or on behalf of a local authority, the executive of the authority. Thus, the definition of employer is very comprehensive to include the government, their agencies and private individuals. In *Heavy Engineering Mazdoor Union v. State of Bihar,* the Supreme Court made it clear that the central or state Government is the employer in relation to industries carried on directly by a department under its control and authority, or one carried by such department through the instrumentality of an agent. Rule 2(g) of the industrial Disputes (Central) Rules, 1957, in this connection makes it clear that in relation to an industry carried on by or under the authority of a department of the central Government or State Government, the

officer in charge of the industrial establishment shall be 'employer' in respect of that establishment, and in relation to an industry concerning railways, carried on by or under the authority of a department of the central Government, the officers mentioned in rule 2(g)(ii)(a)(f) and (c) shall be 'employer'

Industry: The Industrial Disputes Act, 1982 has redefined the concept of industry by recasting S. 2(j). The new definition was necessitated to overcome the impact of the decisions of the Supreme Court in the late 70s particularly that of in the *Bangalore Water Supply and Sewage Board v. Rajappa.*

In this case the Supreme Court evolved a triple test, namely:

1. There is systematic activity with the co-operation between the employer and employees for the production and distribution of goods and services calculated to satisfy the human wants and wishes.
2. absence of profit motive or gainful object is irrelevant; and
3. the true focus is functional and the decisive test is the nature of the activity with special emphasis on the employer-employee relations.

Applying this test, the Supreme Court held that the Bangalore Water Supply is comprehended in the term 'industry' and that the provisions of the Industrial Disputes Act, 1947 will govern the settlement of the disputes beyond the board and their employees.

Workman: The definition of 'workman' was restricted in its present form by the Industrial Disputes (Amendment and Miscellaneous provisions) Act, 1956 and it is broadly based on the definition in the English Statute. Section 8 of the Industrial Courts Act, 1919 (English Statute) defines a 'workman' thus: "The expression 'workman' means any person who has entered into or works under a contract with an employer, whether the contract be by way of manual labour, clerical work or otherwise, be express or implied, oral or in writing, and whether it be a contract of service or of apprenticeship, or a contract personally to execute any work or labour."Under Section 2(s) of the Industrial Disputes Act, 1947, a 'workman' means any person who has entered into or works under a contract with an employer, whether the contract be by way of manual labour, clerical work or otherwise, be express or implied, oral or in writing, and whether it be a contract of service or of apprenticeship, or a contract personally to execute any work or labour.

The terms of employment may be expressed or implied. The person concerned must have been employed in an activity which is an 'industry' as defined in Section 2(j) of the Act. In other words, the persons employed or engaged in an activity which does not fall within the definition of 'industry' will not be treated as workmen When the activity in question is brought within the definition of industry, then not only the persons who are employed in the actual operation of the industry, but also those who are engaged in anywork which is incidently connected with the main industry would come within the ambit of the expression "employed in any industry" and hence would be workmen under Section 2(s) of the Act.

Penalties Under The Industrial Disputes Act, 1947: The Industrial Disputes act prohibits certain acts and penalizes the violation thereof. A complaint can be made only by the appropriate Government or under the authority of the appropriate government. No court below a first class Magistrate can take cognizance of an offence punishable under this Act.

1. Prohibition of financial aid to illegal strikes and lock-outs.

Section 25 of the Act prohibits financial aid both to illegal strikes and lock outs. It says that no person shall knowingly spend or apply any money in direct furtherance or support of an illegal strike or lock-out. It is clear that the persons spending or applying the money must know that the strike or lock-out is illegal. Thus mens rea is necessary element of an offence under this section. It will be attracted only if a strike or lock-out is illegal and not otherwise. For violation of the provisions of this section, punishment is provided by section 28. Even a person who is not a workman can be penalized under section 28 for violating section 25. The combined effect of sections 25 and 28 to sustain a prosecution and conviction requires the following factors:

(i) The strike or lock-out in question was illegal

(ii) The accused had knowledge that the strike or lock-out was illegal and the money spent or applied by him was in direct furtherance of support of strike or lock-out; and

(iii) That the money was actually spent or applied by the accused.

It is only spending of money in support of a strike or lock-out that is prohibited by the Section. Therefore, giving assistance to the strikes in any other form like supplying cloth, food, etc. is not prohibited by this section.

Penalty for commencing and continuing illegal strikes or lock-outs: Section 24 of the Act enumerates the circumstances under which strikes and lock-outs would be illegal. Section 26(i) imposes on a workman punishment for commencing or continuing or otherwise acting in furtherance of an illegal strike. Such person guilty of the above act may be imprisoned up to one month, or fined up to Rs. 50 or both. Under Section 26(2), any employer who commences, continuous or otherwise acts in furtherance of a lock-out which is illegal may be punished with imprisonment which may extend to one month, or fine which may extend to Rs. 1,000/-, or both.

Penalty for instigation: More severe punishment is imposed against instigation or commencing or continuing illegal strike or lock-out. This is with a view to deter the outsiders from disturbing industrial peace and harmony y inciting the workers to resort to strike or employers declaring lock-out Section 27 of the Act thus imposes a punishment up to six months' imprisonment, or fine up to Rs. 1,000/-or both.

Penalty for breach of settlement or award: The settlement arrived at or the award given after industrial adjudication is given sanctity under the act. Under section 29, any person who commits a breach of any term of settlement or award which is binding upon the parties has been made punishable with imprisonment up to six months, or with fine, or with both a continuing breach of a settlement is also punishable with an additional fine up to Rs. 200 for everyday during the continuance of the breach after conviction of the first breach.[7]

No offence within 30 days of award of publication: Since the award is not enforceable before the expiry of 30 days from its publication, no obligation is to be discharged by the employer within those 30 days. Therefore, no offence would be deemed to be committed by an employer within 30 days after the publication of the award if he does not implement within that time.

Penalty for disclosure of confidential information: Under Section 30 of the Act, any person who willfully discloses any such information in contravention of Section 21 is liable to imprisonment up to six months, or fine up to Rs. 1,000 or both. The word 'willfully' denotes that the disclosure must be not only knowingly but also deliberately. A mere casual or inadvertent disclosure will not be penal. Section 21 provides for certain matters to be kept confidential in general interest of industrial peace. Under the section, the Conciliation Officer, Board, Labour Court, Tribunal or National Tribunal charged with the duty to investigate and settle industrial disputes referred to them are not to include in their report and awards any information obtained by them in the course of conciliation or adjudication proceedings if a specified request was made by the trade union, person, firm or company for keeping such information confidential. But this protection is not available in giving false evidence or fabricating false evidence.

Penalty for other offences: nder Section 31(1) of the Act, the employers who contravene Section 33 are punishable with imprisonment for a term which may extend up to six months, or a fine which may extend up to Rs. 1,000/-or with both. Section 31(2) as a residuary clause provides for punishment for the contravention of any other provisions of the Act or rule made thereunder for which no penalty has been prescribed by the present Act or rule made thereunder for which no penalty has been prescribed by the present Act.

Conclusion

The Industrial Disputes Act, 1947, which provides the legal framework for the Government's intervention in Industrial disputes through conciliation and adjudication, has not undergone any major changes in this regard, despite the demand of the labour and recommendations of various commissions and committees for a thorough reform of the Act with a view to shifting the emphasis in favour of collective bargaining. Though an attempt was made to promote harmony in Industrial relations through many Act, no much changes has taken place. Disputes are characteristic of society and more so in an industrial society. The inherent conflicting interests of capital and labour in an industrial organization give rise to disputes between the employer and workmen. These disputes have to be resolved from time to time by the formula of reconciling the interests of both the parties, as they cannot altogether be eliminated. The Industrial disputes Act provides a machinery for resolving the industrial disputes through different method such as settlement between the parties works committees, conciliation, investigation, voluntary arbitration.

The Economic Impact of FDI in Indian Shipping Sector

S. Chandrachud[1], S. Venkataganesh[2]

[1]Associate Professor, Dept. of Economics, VISTAS, [2]Associate Professor, Marine Engineering Department, AMET

Abstract

A well favored Geographical position of a country is the gift of nature but economic growth and development come by state practice. The world largest peninsula, 12 Major ports, 187 minor ports, huge man power, pioneer of international business, enormous natural resources etc., are the gift of nature to India and the Government of India have initiated number of developmental policies and strategies in order to achieve economic development and growth. The current study throws light on the economic impact of Foreign Direct Investment in Indian Shipping sector. Chapter one imitates with details of Indian shipping sector. Chapter two enlists the review of literature. Chapter three narrates the FDI policy in Indian Shipping Sector. Chapter four reason out the 'why to invest in Indian Shipping sector', in terms of SWOT analysis. Chapter five portrays the investment opportunities in Indian shipping sector and the final chapter summaries the economic impact of FDI in Indian Shipping Sector.

Keywords: *Economic impact, FDI, Indian Shipping, automatic route, Coastal line.*

Introduction

India has the longest coastal line about 7500 k.m., out of which nearly 5750 k.m. is also the mainland and rest of the coast line is along with islands. The Ministry of shipping is taking care of 12 more ports and 187 minor ports. 6 major ports, Kandla (Gujarat), Mumbai (Maharastra), Jawaharlal Nehru (Maharashtra), Marmugao (Goa), New Mangalore (Karnataka) and Cochin (Kerala) are situated in West Coast line and other 6 major ports are situated in Tuticorin (Tamilnadu), Chennai (Tamilnadu), Ennore (Tamilnadu), Visakhapattnam (Andhra Pradesh), Paradip (Orissa) and Kolkata, Haldia (West Bengal). These 199 ports are handling Export Import Cargo.

The need for the study arises, as the government want act in concert with all shipping owners for the promotion of the country's economy and are looking forward to a long and mutually beneficial relationship, the government had invited 100 percent Foreign Direct investment(FDI) into the country's shipping sector. Unforutnately, more a decade not a single dollar had come in. During 2010 FDI begins with American Eagle Tankers flagging in their first vessel under Indian registry. Now the scenario is different in Indian shipping. The total cargo handling capacity of major ports during 2016-17 was 1065.83 MTPA Million metric tonnes per annum. With the substancial focus on capacity enhancement and infrastructure development, cargo handling capacity at major ports increased to 1065.83 MTPA in 2016-17 from 744.91 MTPA in 2012-13.

During 2016-17, the traffic handled by the major ports was 648.40 million tonnes, witnessing an increase in traffic by 11 percent from 2014-15. 12 major ports in India handle approximately 57 percent of the total cargo traffic specifically Petroleum, Oil, Lubricants, Containers, Thermal & Steam Coal, Iron ore & Pellets, Finished fertilizers and other miscellaneous cargo.

Review of Literature

Joseph P. Daniels and Marc von der Ruhr[1] found that transportation costs have a positive and statistically significant relationship with US total and manufacturing FDI, suggesting a substitute relationship between FDI and trade flows consistent with horizontal MNE activity.

As one would expect, these costs are insignificant for service stocks.

Joseph Fonseca[2] Foreign direct investment begins to flow into the Indian shipping sector commencing with American Eagle Tankers' flagging in their first vessel under the Indian registry. This comes almost a decade after the government having permitted 100% FDI in shipping

Girish Gujar et al[3] their study reveals that the total factor productivity of the sector might be adversely affected due to the heavy market presence of the government thus causing the FDI inflows into this sector to slow downfurther.

Atri Mukherjee[4] FDI to India has increased significantly in the last decade. However, the growth in FDI flows has been accompanied by strong regional concentration. The findings of the study reveal that market size, agglomeration effects and size of manufacturing and services base in a state have significant positive impact on the regional distribution of FDI flows in India. The impact of taxation and cost of labour is negative. While the impact of quality of labour is ambiguous, infrastructure, however, has a significant positive impact on FDI flows

S R Keshava[5] in his research paper, he compared the effect of FDI with two Asian countries, India and China. The result of the study, except GDP other variable of economic indicators are not significant but positive.

FDI and other Sector Policies in Indian Shipping Sector: The post liberalization era has witness that India significant improved in economic status. The foreign policy of Government of India enhanced the Foreign Direct Investment in terms of automatic route. 100 percent FDI is allow under the automatic route for projects related to the construction and maintenance of ports and harbours. Apart from that major ports are under the jurisdiction of the Government of India and is governed by New Major Ports Authorities Bill, 2016 replacing the Major Port Trust Act, 1963. Non-major ports are under the jurisdiction of the respective state government's maritime boards. In 2016, a New Berthing Policy for Dry Bulk Cargo for all major ports was rolled out in 2016 to drive higher cargo throughput from major ports. A new Stevedoring and Shore Handling Policy, 2016 was implemented for all major ports with a view to increase operational efficiency of ports. To increase investments into the port sector, Government revised Model Concession Agreement (MCA) for PPP projects in major ports. This includes establishment of Society for Affordable Redressal of Disputes-Ports as dispute resolution mechanism.

Why to invest in Indian shipping Sector?: There are many factors involved in Indian shipping sector which makes the investment more meaningful. Foremost is the geographical factor, the largest peninsula of the globe with more than 7500 km coast line surround by Bay of Bengal, Arabian Sea and Indian Ocean. Indian economy has 12 major ports and 187 minor ports. The total cargo handling capacity of all these 12 major ports was more than 1050 Millionmetric Tonnes Per Annum. The new policy of Ministry of Shipping started with the name National Maritime Development Policy (NMDP) to target the Foreign Direct Investment from abroad with the planned outlay of US$ 15 billion. The 12th five year plan includes port plan involving investment of over USD 10 billion has been identified for the upcoming five years and 21 dry port projects are under development. Further new non-major ports are notified for the purpose of enhancing the cargo handling capacity. In 2016-17, 57 projects worth of USD 14 billion created for the additional capacity of 103.52 MTPA. Further in 2017-18, 59 additional projects are targeted.

SWOT Analysis–Economic Impact of FDI on Indian Shipping Sector

Strength

1. Largest peninsula
2. More than 7500 km of Coastal line,
3. rapid improvement in infrastructure,
4. 12 major ports and 187 minor ports,
5. 100 percent investment in Indian shipping.,
6. Stable Cargo handling capacity
7. Abundant supply of labour forces
8. World's 6th largest Economy

Weakness

10. Currency devaluation,
11. Political instability,
12. Low per capital income,
13. Unstable government policies and their loop holes in implementation part,
14. Non-cooperation of indigenous work force,
15. Noncompliance of legal frame work and other legislations
16. Environmental pollution.

Economic Impact of FDI on Indian Shipping Sector

Opportunities

1. Automotive Mission plans,
2. Total allocation made to Ministry of Shipping in 2018-19 stands at USD 28 million, an increase of 20% from that in 2017-18.
3. An allocation of USD 25 million has been made towards development of major ports and USD 21 million towards minor ports.
4. Promotion of internal trade and reduce logistic cost.
5. The opportunity to serve the spill demand from major ports.
6. Port support services
7. Ship repair facilities in ports and dry docks and set up ancillary repair facilities.

Threats

1. Single hull tankers to operate the Coastal water
2. Nearly a decade, no 100 percent FDI investment was received after the announcement of FDI Policy
3. Hurdles in implementing FDI policy-INSA
4. Environmental pollution,
5. Environmental degradation,
6. Problems in maneuvering, dry dock and official hurdles of Register of Shipping.
7. Flooding in Manpower.(both in deck side and engine side)

Source: Prepared by author.

Investment Opportunities in India: In Indian scenario, the shipping sector has witnessed tremendous growth and it is projected, cargo traffic to be handled by Indian ports by 2021-22 is expected to be 1695 million metric tonnes as per the report of the National Transport Development Policy Committee (an increase of 643 million metric tonnes from 2014-15). Total 2422 million metric tonnes of cargo handling capacity would be required in Indian Ports by 2021-22. For this, additional cargo handling capacity of 901 million metric tonnes is required to be created in Indian Port in the next 6 to 7 years. Ministry of Shipping initiated National Maritime Development Policy (NMDP) with a planned outlay of USD 15 billion. Port projects involving Investment of over USD 10 billion identified for award for the upcoming five years. Small ports are supported with Industrial Cities and Industrial Clusters to be developed at selected ports. 21 Dry port projects

are under development. Increase trade activity and private participation in port infrastructure development. Focus on the development of terminals that deal with a particular type of cargo, for eg: LNG (Liquefied Natural Gas). India's increasing integration into Global Value Chains requires a well-established port infrastructure.

Conclusion

As far as the Indian service sector is concerned, both railways and seaways have strong base as Indian railways is the largest monopoly of the world and Indian shipping has the largest peninsula of the world. The economic impact of the FDI on Indian shipping sector can be summarized as India is the best destination for the import and export business through seaways. After liberalization policy and new industrial policy, the economic growth has witnessed significant growth in GDP and cargo handling capacity. During the last decade, the growth in the shipping sector is comparatively high, due the policy framework of Foreign Direct investment. Different promotional measures are taken, in order to improvise performance of cargo handling and logistics of specified items. There is a wide scope in the Indian shipping sector, either in terms of level of investment, Employment opportunities or both.

Interlinking of Rivers of India; Problems and Prospects

S. Suresh[1], S. Jansi Rani[1]

[1]*Associate Professor, Department of Economics, Vistas, Pallavaram, Chennai*

Abstract

The proposed Interlinking river network is a mega project comprising of a system of interlinked projects and has to be therefore subjected to multi-disciplinary scrutiny. It is a large scale Civil-Engineering project. The people involved in the decision making of rivers do not look into the holistic view of the situation but only examined it by associating it with their knowledge and expertise in special fields, democratic action enlightened self-interest by all citizens of India in the need of the hour. The ILR should be implemented in an eco-friendly manner and that the benefits will surely outweigh the cost.

Interlinking of rivers is (ILR) government of India's proposal to link 37 rivers through 30 links, dozens of large dams and thousands of miles and canals making it the largest water project in the world. It aims to transfer water from water-surplus to water–deficit areas and thus proposes to provide a permanent solution the paradox of floods and droughts. Of the thirty links proposed fourteen are in the Himalayan and sixteen in the peninsular component

Keywords: *Interlinking River, Water–Surplus, Eco-Friendly.*

Introduction;

British Colonial era;during 19th century Arthur cotton proposed the plan of Interlinking of major river in order to export of goods. **Post-Independence**; in the year former irrigation Minister K.L.Rao proposed the 'National Water Grid' He was concern about southern areas shortage of water, He suggested that Brahmaputra and Ganga have surplus water and repetitive flooding, He plans to divert that in to deficit areas in south. Several inter basin were successfully interlinked.[1] The Cauvery river water dispute between Tamil Nadu and Karnataka dates back to 19th century. The agreement is lapsed in 1974. The demand made by Tamil Nadu since 1970, In May 1990 Supreme Court directs center to constitute Cauvery water dispute Tribunal., June 2, 1990 center notifies [CWDT] Cauvery water dispute Tribunal, but it was rejected, again TN appeals in 1991, June 1991: The CWDT announced Karnataka ordered to release 205 tmcft., Karnataka government passes an Ordinance. Supreme Court intervenes, strikes down Karnataka's ordinance and upholds the interim award of the CWDT. Karnataka refuses to oblige. December 11, 1991: The Interim award is published in the Government of India gazette.[1]

Corresponding Author:
S. Suresh
Associate Professor, Department of Economics, Vistas, Pallavaram, Chennai-600117

History of ILR

1974: Garland Canal proposal by Captain Din Shaw J. Dastur, a Pilot, both plans were rejected due to technical infeasibility and huge cost and

1980: ministry of water resources frames the national perspective

Reports conducted that it saw "no imperative necessity for massive water transfer in the peninsular component" and that the Himalayan component would require more detailed study. August 15th 2002, President Abdul Kalam mentioned the need for river linking in his Independence Day speech based on which the senior advocate Ranjit Kumar filed a PIL in Supreme Court. October 2002, Supreme Court recommends that the government formulate a plan to link the major Indian rivers by the year 2012. December 2002-Government appointed a task force on Interlining of waters (ILR) led by Mr. Suresh Prabu. The deadline was revised to 2016.

Uneven water availability

1. India as highly uneven water availability in space and time
2. The country receives rain fall for only 3-4 months
3. The Brahmaputra–Barak-Ganga basin accounts for 60% of surface water resources
4. This region is also rich in ground water
5. Western and Southern India experiences water deficit in both surface and ground water
6. 60% of the country experiences water deficit, while parts of the country surface from floods

Himalayan Rivers Development/benefits: Construction of reservoirs on the principle tributaries of Ganges and Brahmaputra in India, Nepal,and Bhutan. Along with interlinking canal system to transfer surplus flow of the eastern tributaries of Ganga to the west. Apart from linking of the main Brahmaputra and its tributaries with Ganga and gang with Mahanadi

Peninsular River Development/benefits: Rivers and building storages at potential sites in these basins. Irrigation to the coastal areas in Maharashtra. Interlinking of Ken-Chambal Rivers. Diversion of other west flowing Rivers. Heavy rain falls on Weston side of the Weston Ghats. Runs down numerous streams, which empty in to the Arabian Sea.[2]

Benefits: The Peninsular component is expected to be provide additional irrigation of about 30 million hectare and is expected to generate about 4 million KW of power. Engineering works for mass transfer of water across the river basins.Basically, the scheme is convey floodwater in the Ganga and Brahmaputra river basins to the arid and semiarid area of Rajasthan and Madhya Pradesh, and to the Peninsular river of south India.There are essentially three method to achieve the same.

- Canal option to construct lengthy canals
- Pumping option–to convey the water under mountains
- Pumping option–to pump water over mountains

The enormous drain of water in to the sea.The Paradoxical and perennial storage of water for irrigation and drinking and floods in many parts of the country have prompted the idea of networking the rivers. The Former President Dr. Abdul Kalam has said that the plan must be accorded top priority. It is hoped it will kick start the economy and mitigate the problems of unemployment. This according to him will convert the country in to a developed nation. The project is also certain to integrate the rural and urban economies and bridge the gap in great rural-urban divide.Dr.Kalam had adumbrated certain requirements so that the grandiose plan is successfully implemented. They are as follows

a. The need to development greater tolerance, compassion, hard work, dedication, and an ability to feel and realize the problems of others and the readiness to help, Avoiding narrow political ambition and greed. Leaders must foster inter and intra communal harmony. The country as a whole must realize the economic need for such a project that would stimulate growth.

b. The second priority is political. Water must be moved from the state list and included in the concurrent list, with over weaning central control. The need for bringing water under central control has been amply demonstrated by the non-implementation of several river water sharing awards between the states.

c. An immediate dialogue with Pakistan and Bangladesh to seek their approval for their networking is an essential priority as per Dr. Kalam. The project will not be successful without linking the Ganga and Indus the Brahmaputra. The Ganga and Yamuna and Brahmaputra combine in Bangladesh before entering the Bay of Bengal. Similarly, the Indus and its tributaries–the Ravi, the Beas, the Sutlej, the Jhelum and the Chenab merge in Pakistan before entering the Arabian sea

d. The next priority would be to look at and review the land acquisition laws. This River-networking project would require a lot of land across the country and also would need access rights from several million land owners.[3]

e. The fifth priority is to design an acceptable management structure to plan this project and implement and monitor it. Once-completed this network would last several generations and change the face of the country this would also cost an enormous amount of money.

Expected Benefits of Interlinking of Rivers: Surface water irrigation 25 million Ha', Ground water irrigation 10 million Ha 'Hydropower generation; 34 million KW ', Improved agriculture;, It will help in ensuring food security 'Flood and Drought control',

alternative means of transport; River transport is cheap and non-polluting 'Higher GDP growth; creation of more employment opportunities will approximately lead to a 4% growth in the GDP lead to a national unity and national security

Disadvantages of this networking project: Projects have been enumerated below and later there are some details elaborating the same.

No inclusion of the people's participation

Lack of consensus among the citizens

Crises-cross construction of the dams and canal systems, which will cause displacement of people

Submergence of land forest and reserves

Negative impact on flora and fauna

Acquisition of large track of land

It controls is transferred to the center than decision might be taken under political pressure.

Arguments against interlinking of rivers: The legal angles and election tangles; at presents there are serious disputes between various states of the Indian Union concern sharing of the river water. The disputes occur on account of the chief executive of any state having to take decision and make claims in the interest of the people of his/her state since after all, that is the purpose for which he /she is elected. A central law to dictate water sharing between all the states from the network has the potential to precipitate new problem. This is because that there is no guarantee for change in the very political climate that causes interstate disputes in the first place. Despite the present of river sharing agreements and authorities. Furthermore it control is transferred to the center then decisions might be taken under political pressure.[4]

Financing: The effect of huge borrowing an enormous amount of money [estimated today at Rs. 5.6 lakhs crores as conveyed by Government of India to the Supreme Court, but it would surely increase] needs to be reconsidered. This especially India is almost in debt trap with rising debt servicing almost equaling loans received from financial institution like world Bank or Asian Development Bank. It is also necessary to consider whether we will be in the financial and physical position to maintain the huge assets. When created [dams, canals, tunnels, captive electric power generation plants etc..]In order for the system to continue to function and give the benefits for which it is designed.

If we cannot maintain the network the capital asset created will deteriorate and be lost and the benefits of the project and incomes from it will not available. Though the loan liability would remain. This will inevitably lead to take over of assets by the creditors Banks to consolidate the entry of foreign interest in to India. The political aspect of forcible project implementation is increasing disaffection among displaced people who already number tens of million since Independence

Flood period: The basic idea of networking river is to convey unwanted flood waters from one place to another where it is deficient and needed. But this idea does not consider that the period when it is surplus in the donor area [July to oct.in the Ganga Brahmaputra basins] is not the time when it is needed most in the recipient area [January to May in the peninsular rivers]. In such a situation it will be necessary to construct enormous holding reservoirs that will add to financial social environmental costs.

Desertification: Flooding parse is not desirable because it results in deposition of alluvium particularly in the delta areas of rivers to maintain the fertility of the land by compensating loss of top soil due to natural erosion. Any system that prevents or severely reduces natural flooding [by diversion of flood water] will cause land fertility will gradually reduce over the years. Thus decertifying the land. The greatest loss that land can suffer is desertification by loss of top soil. The land that will be so lost to cultivation is most fertile delta land and therefore the impact of these on total food production needs to be factored in to the discussion.

Reducing the flow in the Ganga by diversion will increase the concentration of the pollution in the river. A live example is the Yamuna. From which Haryana and Delhi draw so much water that it barely flows Delhi and water quality at Delhi is so poor as to be positively poisonous. It is relevant to note that the expensive project to clean the Ganga has not succeeded even with annual flooding. This is not argue that pollution of river water is inherent and never is checked at source, but that this factor is yet another that needs to be included in the legitimacy check for the project.

Security: India has a National electric power grid that functions with difficulty because supply does not

meet Demand. However it is kept functional. Because electric power can be switched from one circuit from another in the grid. Further it is not easy to deliberately interfere physically with the flow of very high voltage [up to 132KV] electricity on overhead conductors atop huge pylons. But a National Water Grid is entirely different because water does not flow instantaneously like electricity it cannot be switched like electric power and it can very easily be tampered with enroot to divert pump out or interrupt flow

A canal breached deliberately or due to natural circumstances combined with poor maintenance would spell disaster for the areas around the breach. Water is basic for human survival unlike electric power, and motivation for interference is that much more maintenance of network of canals, dams, etc…will have to be done under central supervision. Flow can be prevented or caused by the simple expedient of taking control of sluice gates as demonstrated by former during the recent Cauvery water problem. Thus security of the network will be an enormous load on security forces of central and state Government in contrast, decentralized system can be maintained, repaired and protected by those who benefit from them and live nearby.

Land acquisition: One cannot consider the acquisition of 8000 sq km of land when acquisition of land in acres is a vexed issue which as taken years even if fresh legislation makes it possible within a short period its implementation will cause untold misery and injustice to the displaced people in obtaining compensation due to systemic corruption. Besides land or resettlement is mostly not available. Thus we must scrutinize closely guard against our tendencies to address the political challenges of progressive policy of and law making for resolution of conflicts over natural resources with technology heavy solution.

Interlinking Rivers Projects–First Model; Ken-Betwa-Mahanadi & Santosh: In New Delhi, Sixth meeting of Interlinking of Rivers projects Union Water Resource Minister Uma Bharti addressing the special committee, Ken-Betwa would be ambitious for inter river linking projects, the process is in advanced stage, after obtaining statutory clearances Government plan to implement the National project. **Present Status of Interlinking of Rivers; Press Information Bureau, Government of India, Ministry of Water Resources, 03-March-2011 17:31 IST**

National Water Development Agency [NWDA] under the Ministry of Water Resource [MOWR] gives the feasibility report to the Government out of these 16 links in peninsular and 14 in Himalayan component. From this 2 portions of Indian portion of Himalayan rivers were linked. The five inter State rivers peninsular like1. Ken-Betwa, 2. Pārbati-Kalisindh-Chambal. 3. Damanganga-Pinjal, 4. Par-Tapi-Narmada, 5. Godavari Polavaram-Krishna Vijayawada,The one priority link Ken-Betwa was completed between the States utter Pradesh and Madhya Pradesh. Second one Par-Tapi. The Minister Shri. Vincent H. Pala said in loksabha, the proposal of NWDA gives the additional benefits of irrigation to 25 million hectare, and 34000 MW of power generation, and speaking about the Intra State. River linking it is difficult and it will take time to proceed. The NWDA has 36 intra-State river link proposal from 7 States, and 12 Intra-State river link have been completed.

Modi's $87 billion river-linking project set to take off as floods hit India: Government spends $87 billion to the scheme of connecting 60 rivers in our country.

This may sort out the problems in flood and dragging, In India larger land mass has flooded and in south people suffer in water scarcity especially the contrast between Mumbai and Tamil Nadu, This plan helps the farmers from the fickle monsoon rains, and it brings millions hectare of cultivation land under irrigation, and which also generate electricity, best one is Ken-Betwa connection, Sanjeev Balyan, the junior water resource minister said 'got the clearance in record time from the Government, The Ken-Betwa interlinking tops the priority. But some experts say India would be better off investing in water conservation and better farm practices. Environmental and wildlife enthusiasts have also warned of ecological damage.

Conclusion

The proposed river network is a mega project comprising of a system of interlinking projects and has to be therefore subjected to multidisciplinary scrutiny. The people involved in the decision making about networking of rivers do not look in to the holistic view of the situation but only examine it by associating it with their knowledge and expertise in special fields. Democratic action and enlightened and self-interested by all citizens of India is the need of the hour/the ILR

should be implemented in an eco-friendly manner and that the benefits will surely overweigh the costs.

Abstract

The demand of water is also increasing day by day not only for Agriculture, but also for household and Industrial purposes. The perennial rivers are becoming dry and ground water table is depleting in most of the areas. Country is facing floods and drought in the same year in many states. This is because, no concrete action was taken to conserve, harvest and manage the rain water efficiently. Due to the nature of the terrain and distribution of rainfall, it is estimated that only 69 million hectare meter run-off can be harnessed for irrigation 175 million hectare meter water enters soil, of which 130 million hectare meter is retained in the soil and 45 million hectare meter is added to ground water every year. The demand for water, currently estimated at 75 million hectare meters, is expected to rise to 105 million hectare meters in another 25 years. Agriculture and allied activities make the single largest contribution to the Gross Domestic Product (GDP), accounting for almost 27 percent of the total. Agriculture growth has direct impact on poverty eradication and also an important factor in contain inflation, raising agricultural wages and for employment generation. Water resource contributes to agricultural production in three ways; It raises productivity by inducing the use on complementary inputs, like fertilizer, HYV of seeds, etc., increases the cropped area by making double or multiple cropping possible, and bring out a change in cropping pattern.

Keywords: *Water, Fertilizer, Seed, Economic good, Water Infrastructure.*

Introduction

Water is the most important factors in modern agricultural production; it offers opportunities for improving livelihood, particularly in rural areas. Access to reliable, good quality irrigation reduces the cost of production and increases the quantum of food production by reducing the risks faced in rain fed agriculture. The demand for water, currently estimated at 75 million hectare meters is expected to rise to 105 million hectare meters in another 25 years. That is almost all the utilizable potential will have to be harnessed to meet the demands of agriculture, industry, energy generation and domestic consumption. These figures released by the Indian Water Resources Society in 1995, foretell the shape of things to come.[1]

Due to irrigation, India has been in a comfortable position with regard to the availability of food grains over the last ten years. The productivity differential between irrigated and un-irrigated lands being quite substantial, irrigation has acquired a pre-eminent place in the Indian Planners Agenda for agricultural growth along a stable path. As the incidence of rural poverty has been found to be inversely related to both the rate of growth of crop output and the irrigation factor investment in irrigation becomes an indirect instrument for eradicating much of the rural poverty in India. Irrigation is the essential input to increase agricultural production. The current state of agriculture provides a contrasting picture of low growth of food grain and productivity. Among the inputs, water is the basic input essential for applying new technology in agriculture.[2]

Water as an Economic Goods: Chirapunji gets more than 11,000mm of average annual rainfall but face drinking water problem before monsoon commences whereas in Ralegoan Siddhi, in Maharashtra there is no water scarcity problem though the annual average rainfall is only about 450mm. Hence to mitigate water problem drought etc., there is an urgent need to follow our ancestral way of water harvesting and the latest technologies adopted in Soil and water conservation. Need has come to harvest the rainwater including roof

water to solve the water problems everywhere not only in the arid but also in the humid region. For the improvement of water infrastructure in the developing world, subsidies are vital.[3] The principle of full cost recovery sometimes handicaps developing nations that are striving to provide basic needs by subsidizing their basic water infrastructure. However, water is a basic human need and access to minimum quantities of safe water (20 liters per person per day) should be everyone's right. Lack of access to safe drinking water, sanitation, and irrigation is directly related to poverty and poor health. For example, in South Asia 300million people have no safe drinking water and 920 million people have no adequate sanitation.

Climate Change and Demand for Water: Climate change could result in global, large scale changes in natural and social systems. In many developing countries, the very poor actually pay a great deal for water relative to their income, but these costs are often hidden. Water is priced by all urban societies, and the poor often have no choice but to pay high prices, spending between 5-10% of their income; however, in contrast in most industrialized countries, the lower-middleclass spends 1-3% of their income on potable water and sanitation. For example, in OPEC countries, households spend about 1% of their income on water; on the other hand, in Onitsha, Nigeria, the poor spend as much as18% of their income on water.[4] The application of economic principles to the allocation of water is acceptable, and provides a simple tool for the development of water services in a more efficient direction. However, water should not be treated as a market oriented commodity when it comes to domestic use for very basic needs particularly for people in extreme poverty. More discussion, analysis, study, and commitment are needed in deciding whether water is a common or an economic good. Global demand for water has tripled since the 1950s, but the supply of fresh water has been declining. Half a billion people live in water-stressed or water-scarce countries, and by 2025 that number will grow to three billion due to an increase in population. Irrigated agriculture is the dominant user of water, accounting for about 80% of global water use. Population and income growth will increase the demand for irrigation water to meet food production requirements and household and industrial demand. The global population is projected to increase to about 9 billion by 2050. In response to population growth and rising incomes, worldwide cereals and meat demand has been projected to increase by 65% and 56%, respectively. Being the largest user of water, irrigation is the first sector to lose out as water scarcity increases.[5]

Water and Agricultural Production: Agriculture takes major share of the existing water resource.Thus increasing the productivity of water used in agriculture is essential to meet the enhanced requirement of food, fodder and livelihood security. Some action plans *viz.,* change in water use of agriculture, fight poverty by improved productions, improve environment ecosystem, upgrade rain fed farming systems, conservation of water bodies and indigenous technology of water and its resources management etc., are needed to mitigate the water problems. Water management, crop genetic material, agronomic practices and economic and policy incentive to produce are the essential components of water productivity.[6] As a result of growing population, the per capita water availability is reducing day by day. The estimated annual per capita water availability which was 5177 cubic meters in 1951 has come down to less than 1700 cubic meters. At the same time, certain unplanned activities for the development of water resources have resulted in unsustainable exploitation of water, also affecting its quality. It is estimated that 69% of worldwide water use is for irrigation, with 15-35% of irrigation withdrawals being unsustainable. In some areas of the world irrigation is necessary to grow any crop at all, in other areas it permits more profitable crops to be grown or enhances crop yield. Various irrigation method involve different trade-offs between crop yield, water consumption and capital cost of equipment and structures. Irrigation method such as furrow and overhead sprinkler irrigation are usually less expensive but are also typically less efficient, because much of the water evaporates, runs off or drains below the root zone. Other irrigation method considered to be more efficient include drip or trickle irrigation, ground level. These types of systems, while more expensive, usually offer greater potential to minimize runoff, drainage and evaporation. Any system that is improperly managed can be wasteful; all method have the potential for high efficiencies under suitable conditions, appropriate irrigation timing and management. One issue that is often insufficiently considered is salinization of sub surface water.[7]

Availability of Water: The demand of water is also increasing day by day not only for Agriculture, but also for household and Industrial purposes. The perennial rivers are becoming dry and ground water table is depleting in most of the areas. Country is facing

floods and drought in the same year in many states. This is because, no concrete action was taken to conserve, harvest and manage the rain water efficiently. The availability of water in the world, in India and in Tamil Nadu is given below with rainfall.[8]

Table 1: The Availability of Water in the World, in India and in Tamil Nadu

Places	Rainfall in mm	Population	Availability of Water/Person/ Year in m^3
World	840	6.99 Billion (United States Census Bureau 2011)	700
India	1150	1.21 Billion (India's Census2011)	2200
Tamil Nadu	925	72.1 Million (India's Census2011)	750

Source: Various sources of secondary data

If the availability of water is 1700 M^3/p/y, there will be occasional water stress, and if it is less than 1000 M^3/p/y, it is under water scarcity condition. Though India is not under water stress conditions but Tamil Nadu state is already under water scarcity condition, but there is no need for panic since it is possible to manage this condition as in the case of Israel where the availability is only about 450 M^3/p/ y, by means of water harvesting, water conservation and water management.

Future Requirements of Water: The requirement of water for various sectors has been assessed by the National Commission on Integrated Water Resource Development (NCIWRD) in the year 2000. This requirement is based on the assumption that the irrigation efficiency will increase to 60% from the present level of 35 to 40 percent. The Standing Committee of Ministry of Water Resources (SCMWR) also assesses it periodically. These are shown in the following table.

Table 2: Projections of Water Requirements of Various Sectors of Indian Economy

Sector	Water demand in BCM*					
	Standing Committee of Ministry of Water Resources (SCMWR)			National Commission on Integrated Water Resource Development (NCIWRD)		
Year	2010	2025	2050	2010	2025	2050

Conclusion

Irrigation is the essential input to increase agricultural production. The current state of agriculture provides a contrasting picture of low growth of food grain and productivity. Adequate availability of water resources is a precondition for applying new types of raw materials, mechanization and modern method of cultivation. Among the inputs, water is the basic input essential for applying new technology in agriculture. While analyzing the role of irrigation, point out that in many places, the constraint on agricultural development is the supply of water for irrigation, rather than the supply of land. The major advantages of irrigation are: it helps in increasing crop yields, and hence to attain self-sufficiency in food, optimum utilization of water is made possible by irrigation, mixed cropping and multiple cropping. The timely availability of water reduces cost of production and increases output. Therefore, planning and implementation of irrigation schemes are essential.[9] The March 22nd has been dedicated as World Water Day and UNESCO is celebrated the year 2012 as International Year of Water Co-operation. The goal of International Year of Water Co-operation is to make awareness on the potential for increased co-operation in water management as there is an increase in scarcity of water. It also tries to highlight how to use water effectively and identify steaming issues on water scarcity. It is said that,

if there is any chance of third world war it will be for water. There is an increased chance of conflict between neighboring countries or state which share same water resources.

Physical and Financial Performance of Women Welfare in the Marriage Assistance Schemes of Tamil Nadu

S. Gunaseelan[1], S. Thangamayan[2]

[1]Assistant Professor, Department of Commerce, VELS Institute of Science, Technology and Advanced Studies, Pallavaram, Chennai, [2]Assistant Professor, Department of Economics, VELS Institute of Science, Technology and Advanced Studies, Chennai

Abstract

The present analytical paper has been writer for the general awareness of women welfare of the Tamilnadu. The authors have identified the certain schemes are not taken growth both the physical and financial performance in the women welfare assistance schemes. To implicate the policy maker, the authors have taken steps to identify where and when the lacking has happened. The results of the findings of the paper will implicate the society. The present analytical article is mainly concentrated on women welfare schemes, particularly marriage assistances, widows remarriage, poor widow daughter's marriage, orphan girl marriage assistance and inter-caste marriage assistance. Again the government has taken the steps to give the marriage assistance to help the poor parents financially in getting their daughters married and also to promote the educational status of poor girls. The hindrances of each scheme are also the higher affinity to accumulate the money from the government projects for future and future generation; it is the very big problems of each benefit schemes. Therefore, the policy makers should consider the above findings and suggestion to assist the women welfare and for the financial assistances for their marriage.

Keywords: *Assistance Scheme, Women welfare, Physical and financial Performance.*

Introduction

In Tamilnadu Government, various schemes are given for the assistance of women welfare. The assistances are in the form of monetary benefits, the government has been allotted the funds for every year. The target and the achievements of the select schemes are slacked many times due to various conditions prevailed in the State and also in the Central government policy for changing environments of economic, society, institutional and political. The authors have taken the secondary data available in the Tamilnadu Government Portal of document repository. The present analytical article is mainly concentrated on women welfare schemes, particularly marriage assistances, widows remarriage, poor widow daughter's marriage, orphan girl marriage assistance and inter-caste marriage assistance.[1]

Marriage Assistances Scheme: Moovalur Ramamirtham Ammaiyar Ninaivu Marriage Assistance Scheme has been started from 1989 onwards, due to financial crisis of the government of Tamilnadu it has been stopped from 2002 to 2006. Again the government has taken the steps to give the marriage assistance to help the poor parents financially in getting their daughters married and also to promote the educational status of poor girls. The beneficiary of the scheme should not entitle their annual income not exceeding Rs.24000 during the period of 2006-07 to 2009-10. It has been increased (w.e.f. 23.05.2016)and stands at Rs. 72,000 during 2017-18. The benefit amount from the scheme is Rs. 20000 during 2006-07 and it has been increased to Rs. 25000 for scheme-I and Rs.50000 for scheme-II along with One Sovereign (8 Grams) 22 carat gold coin for making *Thirumangalyam*.[2] The following table describes that the growth of the schemes during the present decade.

Table No. 1: Marriage Assistance Scheme

Year	Target	Achievement	Target	Achievement
2008-2009	65000	8999	13000.00	17999.80
2009-2010	75000	125125	15000.00	15000.00

Year	Target	Achievement	Target	Achievement
2010-2011	120000	160228	30000.00	37265.75
2011-2012	164552	163228	48638.15	62015.00
2012-2013	166687	138656	70161.38	58929.00
2013-2014	158780	130035	70161.38	56319.14
2014-2015	158500	125029	69964.85	59478.36
2015-2016	160000	149111	65170.68	62894.40
2016-2017	160000	123449	65170.68	68052.35

Source: Women Welfare, Performance and budget of Tamilnadu Government,

From the above table inferred that the financial performance of Marriage Assistance Scheme of Tamilnadu and itstargets and achievements are got the significant level of growth during the present decade. The consistency of the growth is better and also the p-value is highly significant at 0.005 percent level. It denotes that the scheme is going in a better way in its growth. Though the growth is better but there is difference of target and achievement. The achievement is lower than the target has identified. Hence, the government should take necessary steps to achieve the target at a possible ways that will help the women who poorly faced their daughter's marriage.

Widows remarriage Scheme: Dharmambal Ammaiyar Ninaivu Widows Remarriage Assistance Schemehas been started from 1975 onwards. This scheme is to give the marriage assistance to Rehabilitation of widows as well as to encourage remarriage of widows by financially helping them for re-marriage. The beneficiary of the scheme should above 20 years of age. Minimum age for bride is 20 years. Maximum age limit for bridegroom is not more than 40 years. The bridegroom should produce Death Certificate separation Certificate of his first wife / wives, in case if already married. The benefit amount from the scheme is Rs. 20000 during 2006-07 and it has been increased to Rs. 25000 for scheme-I and Rs.50000 for scheme-II along with One Sovereign (8 Grams) 22 carat gold coin for making Thirumangalyam.[3] The following table describes that the growth of the schemes during the present decade.

Table No. 2: Widows Remarriage Assistance Scheme

Year	Target	Achievement	Target	Achievement
2008-2009	166	167	25	25.15
2009-2010	167	181	33.4	36.2
2010-2011	175	154	35	33.3
2011-2012	140	117	51.09	50
2012-2013	250	142	161.8	70.22
2013-2014	170	112	161.8	43.36
2014-2015	170	75	76.25	44.05
2015-2016	170	121	76.25	56.9
2016-2017	170	52	76.25	36.65
2017-2018	170	35	76.25	18.14

Source: Women Welfare, Performance and budget of Tamilnadu Government,

From the above table inferred that the financial performance of Widows Remarriage Assistance Scheme of Tamilnadu and its targets and achievements are got the insignificant level of negative growth during the present decade. The consistency of the negative growth is obviously taken place during the study decade and also the p-value is highly insignificant at 0.05 percent level. It denotes that the scheme is not reached its growth as per the target. Though the growth is better on the target but there is highly difference of target and achievement. The achievement is in negative than the target has identified. Hence, the government should identify where the slacking has been happening in the financial performance of Widows Remarriage Assistance Scheme of Tamilnadu. After 2014-15 it has taken the sudden downtrend in its path. But since the beginning of the decade, the volatility of the beneficiaries and financial targets and achievements is existed. Therefore it expresses the mismanagement of the scheme is exposed. That should be corrected in the future.

Poor Widow Daughter's Marriage Assistance Scheme: E.V.R. Maniammaiyar Ninaivu Poor Widow Daughter's Marriage Assistance Schemehas been started from 1981 onwards. This scheme is to help the poor widows for the marriage of their daughter. The bride of the scheme should be between 18 and 30 years.

But it later there is no upper age limit. The beneficiary of the scheme should not entitle their annual income not exceeding Rs.24000 during the period of 2006-07 to 2009-10. It has been increased (w.e.f. 23.05.2016) and stands at Rs. 72,000 during 2017-18. The benefit amount from the scheme is Rs. 20000 during 2006-07 and it has been increased to Rs. 25000 for scheme-I and Rs.50000 for scheme-II along with One Sovereign (8 Grams) 22 carat gold coin for making Thirumangalyam. The following table describes that the growth of the schemes during the present decade.

Table No. 3: Poor Widow Daughter's Marriage

Year	Target	Achievement	Target	Achievement
2008-2009	1,533	1,600	230.00	320.00
2009-2010	2,000	4,899	400.00	979.80
2010-2011	5,500	7,264	1,100.00	1,846.00
2011-2012	7,244	6,145	1,810.88	3,001.00
2012-2013	8,322	6,883	3,503.07	2,580.35
2013-2014	7,490	5,608	3,503.07	2,186.96
2014-2015	7,770	7,011	3,771.09	3,582.56

2016-2017	7,770	4,941	3,771.09	2,603.80
2017-2018	7,770	5,528	3,771.09	3,354.93

Source: Women Welfare, Performance and budget of Tamilnadu Government,

From the above table inferred that the financial performance of Poor Widow Daughter's Marriage Assistance Schemeof Tamilnadu and its targets and achievements are got the significant level of growth during the present decade. The consistency of the growth is better and also the p-value is highly significant at 0.05 percent level. It denotes that the scheme is going in a better way in its growth. Though the growth is better but there is difference of target and achievement. The achievement is lower than the target has identified both the physical and financial performance. During 2009 to 2012 the achievements are higher than the target but after 2012 it has lower than the target. Hence, the government should take necessary steps to identify the slacking on the achievements.

Orphan Girl Marriage Assistance Scheme: Annai Teresa Ninaivu Orphan Girls Marriage Assistance Schemehas been started from 1985 onwards. This scheme is to help the orphan girls financially for their marriage. The bride of the scheme should be between 18 and 30 years. But it later there is no upper age limit. The beneficiary of the scheme should not entitle their annual income not exceeding Rs.24000 during the period of 2006-07 to 2009-10. It has been increased (w.e.f. 23.05.2016) and stands at Rs. 72,000 during 2017-18. The benefit amount from the scheme is Rs. 20000 during 2006-07 and it has been increased to Rs. 25000 for scheme-I and Rs.50000 for scheme-II along with One Sovereign (8 Grams) 22 carat gold coin for making Thirumangalyam. The following table describes that the growth of the schemes during the present decade.

Table No. 4: Orphan Girl Marriage Assistance Scheme

Year	Target	Achievement	Target	Achievement
2008-2009	273	285	41	42.75
2009-2010	274	509	54.8	101.8
2010-2011	530	563	105.9	128.3
2011-2012	675	682	168.81	437
2012-2013	828	846	373.75	315.52
2013-2014	1,110	717	373.75	282.36
2014-2015	1,110	796	373.75	355.82
2015-2016	2,450	4,088	1,000.00	2121.75
2016-2017	2,450	2,572	1,000.00	1,308.75
2017-2018	2,450	2,361	1,100.41	1,903.20

Source: Women Welfare, Performance and budget of Tamilnadu Government,

From the above table inferred that the financial performance of Orphan Girls Marriage Assistance Scheme of Tamilnadu and its targets and achievements are got the significant level of growth during the present decade. The consistency of the growth is better and also the p-value is highly significant at 0.001 percent level. It denotes that the scheme is going in a better way in its growth. The achievement is higher than the target that is remarkable in its performance. Hence, the government

should keep achievement in future that will help the orphan girls' marriage.

Inter-Caste Marriage Assistance Scheme: Anjugam Ammaiyar Ninaivu Inter-Caste Marriage Assistance Schemehas been started from 1967 onwards. This scheme has been renamed as Dr. Muthulakshmi Reddy Ninaivu Inter-Caste Marriage Assistance Scheme since 08.07.2011. This scheme objective is to abolish Caste and Community feelings based on birth and for wiping out the evils of untouchability and to abolish caste based discrimination by encouraging inter-caste marriages. The bride of the scheme should have completed 18 years old. There is no upper age and income limit. It has two type of schemes in which, one of the spouse should belong to SC/ST community and Marriage should be between Forward Community and BC/MBC community spouses.[4] The benefit amount from the scheme is Rs. 20000 and Rs.15000 respectively during 2006-07 and it has been increased to Rs. 25000 for scheme-I and Rs.50000 for scheme-II along with One Sovereign (8 Grams) 22 carat gold coin for making Thirumangalyam. The following table describes that the growth of the schemes during the present decade.

Table No. 5. Inter-Caste Marriage Assistance Scheme

Year	Target	Achievement	Target	Achievement
2008-2009	2075	2896	400	524.6
2009-2010	2900	2713	525	513.35
2010-2011	2,771	2,483	535.5	518.1
2011-2012	2,895	1,828	734.38	1,185.00
2012-2013	1,901	1,583	800	656.87
2013-2014	2,450	1,409	800	632.56
2014-2015	2,450	2,269	1,000	982.32
2015-2016	2,450	4,088	1,000.00	2121.75
2016-2017	2,450	2,572	1,000.00	1,308.75
2017-2018	2,450	2,361	1,100.41	1,903.20

Source: Women Welfare, Performance and budget of Tamilnadu Government,

From the above table inferred that the physical and financial performance of Inter-Caste Marriage Assistance Schemeof Tamilnadu and its physical targets and achievements are got the insignificant level of growth during the present decade. The consistency of the growth is better but the p-value is highly insignificant at 0.1 percent level. It denotes that the scheme is not performed well due to various political, judicial and government inability against of social issues inherent with the Inter-Caste Marriage forced by the non SC/ST communities. Even there is practice of higher protections given by the law many people are lost their life against of communal affinities.[5] there is no improvement in the targets of physical and finance after 2013-14 to 2017-18. The government should identify the forward community who really married with SC/ST communities. The government should give opportunities in the reservation of employment, education, election, self-employment business, government papers and stamps and income tax concessions. It will definitely create as 'all are equal'.

Table No. 6. Physical and Financial Performance of Women Welfare in the Marriage Assistance Schemes of Tamilnadu (CAGR in %)

Women welfare marriage assistances schemes	Physical Target	Physical Achievement	Financial Target	Financial Achievement
Marriage assistances	6.54	12.69	19.95	16.18
Widow remarriage	0.24	-14.36	13.51	-0.63
Poor widow daughter's marriage	17.02	7.12	34.77	20.82
Orphan girl marriage assistance	30.98	27.88	46.98	48.59
Inter-caste marriage assistance	-0.33	0.49	11.30	16.08

Source: Computed Secondary Data

From the above table the growth of the physical and financial performance of women welfare in the marriage assistance schemes of Tamilnadu is identified. Among the schemes widows' remarriage and inter-caste are not

reached better. Hence, the government should supported to the inter-caste marriage even the political hurdles are played. The poor widow daughter and orphan girl marriage are able to identify the target and possible to done the financial assistance directly without any hindrances of public. Most of the murders have done by the foreword communities. The government and the judicial systems are unable to do against of the political force and playing strength of money is determining the strength of judgment is the situation is prevailed. The support of political alone the schemes are achieved its target. The government also not bothers about the people affected in the downtrodden level in various benefit schemes.[6] The most of the schemes are not aware by people, only the political persons are aware and they do in favour of their parties and communities. The ultimate aims of the most of the schemes are created for the benefit of the people. But what happening really, the academician can only do the research and can implicate the policymaker.

Suggestions

- The government should take actions to achieve the target at a possible ways that will help the women who poorly faced their daughter's marriage.
- The government should identify where the slacking has been happening in the financial performance of Widows Remarriage Assistance Scheme of Tamilnadu. After 2014-15 it has taken the sudden downtrend in its path. But since the beginning of the decade, the volatility of the beneficiaries and financial targets and achievements is existed. Therefore it expresses the mismanagement of the scheme is exposed. That should be corrected in the future.
- The government should take necessary steps to identify the slacking on the achievements.
- The government should keep achievement in future that will help the orphan girls' marriage.
- The government should identify the forward community who really married with SC/ST communities. The government should give opportunities in the reservation of employment, education, election, self-employment business, government papers and stamps and income tax concessions. It will definitely create as 'all are equal'.

Conclusion

From the above findings and suggestions authors have concluded that the government is ready to give all the schemes to particular people. The hindrances of each scheme are also the higher affinity to accumulate the money from the government projects for future and future generation; it is the very big problems of each benefit schemes. Therefore, the policymakers should consider the above findings and suggestion to assist the women welfare and for the financial assistances for their marriage.

An Analysis of Women Empowerment through Self Help Groups

S. Sudha[1], S. Thangamayan[1], Premalatha[1]

[1]Assistant Professor, Department of Economics, VELS Institute of Science, Technology and Advanced Studies, Chennai

Abstract

The Government of India in quest of new social order and poverty free society drafted the constitution with great emphasis on equality, liberty and fraternity. Self help groups are a small group of individual members who voluntarily come together and form an association for achieving a common objective. Various intervention approaches have been developed in order to address the needs of the women which ultimately reveal modifications not only in social policy approaches to third World Development, state policies relating to women but also in the overall economic policy of the country as a whole. The human development reports of the UNDP published annually have declared that women's empowerment is not merely important but crucial if development is to be sustainable. In a developing society, women in particular and more specifically rural and illiterate women never get portrayed as agents of change. In 1970's there was shift from the welfare to development of women. In 1980's and onwards the shift took place from the development to the empowerment of women. The major land mark in the field of women empowerment was brought by 73rd and 74th Amendment Acts in the Parliament which brought 33% reservation to the women in the Panchayats and Municipalities. These amendments have empowered about 1000000 women and gave them political power for taking social, economic and other development measures for the all round growth of their women counterparts.

Keywords: *Women Empowerment, Micro Credit, Self Help Group.*

Introduction

The Government of India in quest of new social order and poverty free society drafted the constitution with great emphasis on equality, liberty and fraternity. Self help groups are a small group of individual members who voluntarily come together and form an association for achieving a common objective. In most cases SHGs are constituted by persons known to one another and coming from the same village community or neighborhood, that is, SHGs are small in size with membership ranging from 10to 20 are homogenous and has certain pre groups binding factor. This concern for low-income women's needs has coincided historically with recognition of their important role in development. Various intervention approaches have been developed in order to address the needs of the women which ultimately reveal modifications not only in social policy approaches to third World Development, state policies relating to women but also in the overall economic policy of the country as a whole. The empowerment approach is the most recent and is aimed at empowering women through greater self-reliance and internal strength. Empowerment as a concept was introduced at the International Women's Conference at Nairobi in 1985. The conference defined empowerment as "A redistribution of social power and control of resources in favour of women. It is "the process of challenging existing power relations and of gaining greater control over the sources of power".[1]

Dimensional Views on Women Empowerment: Women Empowerment refers to an increase in the strength of women such as spiritual, political, social or economic. The most common explanation of "Women's Empowerment" is the ability to excise full control over ones actions. The human development reports of the UNDP published annually have declared that women's empowerment is not merely important but crucial if development is to be sustainable. In a developing society, women in particular and more specifically rural and illiterate women never get portrayed as agents

of change.[2] Women in India constitute 48% of total population in which 43.88 lakh women are engaged in organized sector and 17.77 lakh in private sector. In the decade of 1960's the issue was for the welfare of the women. In 1970's there was shift from the welfare to development of women. In 1980's and onwards the shift took place from the development to the empowerment of women. The major land mark in the field of women empowerment was brought by 73rd and 74th Amendment Acts in the Parliament which brought 33% reservation to the women in the Panchayats and Municipalities. These amendments have empowered about 1000000 women and gave them political power for taking social, economic and other development measures for the all round growth of their women counterparts. 93rd amendment was passed in the Parliament which changed its colour from Directive Principle under Article 45 to Fundamental Right under Article 21-A for free education to all children in the age group of 6-14 years. The International conferences sponsored by the United Nations started from Rio through Vienna, Copenhagen and Beijing have generated a lot of interest on the social development and highlighted the growing feminization of poverty an possible impact on women the structural adjustment process. The 4th World Conference on Women held in Beijing (1995), reveals that women's empowerment and their full co-operation on the basis of equality in all spheres of society are fundamental for the achievement of equality, development and piece. Tamil Nadu is one of the predominate state to encourage to form SHG's next to Andhra Pradesh and Kerala. The NGOs and Banks are provident credit facilities to SHGs members. But the roles of NGOs are larger than banks to facilitating credit to poor people, because the banks are not extending to this service to the poor. Many studies estimate that the micro finance is one of instrument to remove poverty in rural areas. The promotional efforts especially under taken be NABARD in the last two years have resulted in a significant growth of programme beyond expectation. [3]

Table 1: Number of SHGS in India (2010-11 to 2015-16)

Year	Number of SHGs	Growth Rate
2010-11	2238565	109.47
2011-12	2924973	30.66
2012-13	5009794	71.28
2014-15	6121147	22.2
2015-16	6959250	13.6

Table 1 evident that the total number of SHGs is increased in the period of 2010-11 to 2015-16. SHGs were linked with the banks. In 2010-2011 the number of SHGs has been increased by 109.47 growth rate i.e. 22, 38,565. In the year 2011-12 growth rate was 30.66, in 2014-2015 growth rate was 71.28 in 2008-09 growth rate was 22.2 and in 2015-16 Growth rate is 13.6. The variation is grater in growth rate.

Table 2: Progress of Women SHGS as on 2015-16

Particulars	Total SHG's (Lakh)	Women SHG's (Lakh)	Women SHG's Total SHG's	Total Amount (Crore)	Women SHG's Amount (Crore)	% of Women SHG's to Amount to Total SHG's
Savings Linked SHG"s	50.1	22.38	44.67	3785.39	3108.65	82.12
Loan Disturbed	12.28	10.4	84.69	8849.26	7474.25	84.46
Loan Outstanding	36.26	29.17	80.45	16999.91	13335.61	78.45

Source: Status of Micro Finance 2015-16, NABARD

The purpose for which SHGs are formed varies from managing a common pool resources such as an irrigation facility and tree plantation on common land & providing such basic amenities as a school, health centre and so on. In the context of micro finance, SHGs are formed around the theme of saving and credits.

SHG phenomenon definitely brings group consciousness among women, sense of belongingness, adequate self confidence. Infact, what she cannot achieve as an individual, can accomplish as a member of group with sufficient understanding about her own rights, roles, privileges and responsibilities as a dignified member of society in par with man. When she becomes a member of SHG, her sense of public participation, enlarged horizon of social activities, high self-esteem, self-respect and fulfillment in life expands and enhances the quality of status of women as participants, decision makers and beneficiaries in the democratic, economic social and

cultural spheres of life.The opportunity provided in safe savings as well as availability of need-based credit has led to more and poorer people keen to join SHGs. The members use the credit for a variety of purposes like small businesses, agriculture, health, education of children, festivals and so on.[4]

Table 3: Progress of Women SHGS as on 2015-16

Loan Outstanding	48.51	38.91	80.33	28038.38	23030.36	82.14

Source: Status of micro Finance 2015-16, NABARD

The role of women outside the home has become an important feature of the social and economic life of the country and in the years to come this will become still more significant. From this point of view, greater attention will have to be paid to the problems of training and development of women. The education of girls, therefore, should be emphasized not only on grounds of social justice but also because it accelerates social transformation.[5]

Women Empowerment in India: The year 2001 had been declared by the Government of India as "Women's Empowerment Year" to focus on a vision where women are equal partners like men". Because the Constitution of India grants equality to women in various fields of life. In the past, the position of women was miserable in the society and even women were not ready to undertake any assignment or job due to many reasons like fear, shyness, male dominance in the society and purda system but time has been changed now. Women of today are not like the early days. Now, they are always ready to come forward and want more economic independence, their own identity, achievements, equal status in the society and greater freedom. And Government of India has provided for Self Help Groups (SHGs) to them so that proper attention should be given to their economic independence through self employment, entrepreneurial development and well being that ultimately leads to its contribution. SHGs have been emerged as a powerful instrument in order to alleviate poverty and for the empowerment of women in the rural economy. SHGs through the network of commercial banks, co-operative banks, regional rural banks, NABARD and NGO's has been largely supply driven and a recent approach in the provision of financial services to the poor and further upgrading their status in the society.[6]

Conclusion

Women empowerment aims enabling them to realize their identity, potentiality and power in all spheres of their lives. It has mainly five dimensions viz., economic, political, social/cultural, physical mobility. Woman is important part of society and her empowerment is must of development. In developed countries every member of society is in equal position. But in developing nations we need to empower people who are not receiving equal treatment. Empowerment of women is possible only when a woman has increased access to economic resources, more strength and courage for entering into the power structure, more involvement through social/ cultural relationships and participation, more self-motivation and confidence, and more say in the family matters.[7]

Agriculture and Women's Health

R. Shakeela[1], Dr. S.N. Sugumar[2]

[1]Research Scholar, VISTAS Chennai, [2]Prof. and Head, Department of Economics, VISTAS, Chennai

Abstract

Agriculture is the backbone of India and the most important sector among all. The role of Agriculture is significant in the overall Socio-economic development of India. It accounts for 18% of India's GDP and 50% of Indian population is depending on Agriculture for employment. Agriculture not only provides food and fabrics, it also helps in the development of major industries by providing raw materials and enhances the healthy life by contributing natural medicines. Health is a prime factor of a Country's development. Development of Health and development of Economics are interlinked. The Country's Economic performance is mainly depending on Health status of the people in the Country. Wealthier Countries have Healthier population. WHO (World Health Organization) has estimated that 80 percent of the people Worldwide are depending on medicines from plants. As per research data, it is found that three-quarters of the World population is relying on Agriculture for their well-being. Plants and plant extracts serve the nation by fulfilling human health care needs. Especially Women are mostly relying on herbal products for their day to day requirements. Moreover economically weak, Poor and marginalized people, who cannot access or afford to Modern medicines, depends on Traditional medicines for their Health care needs[1]. This study elaborates some of the women's problems and remedies through medicinal plants.

Keywords *Agriculture, Health economics, Natural/Traditional medicine, Women's Health, Medicinal plants, Dysmenorrhea.*

Introduction

Health is a prime factor of a Country's development. The Country's Economic performance is mainly depending on Health status of the Country. Women play a vital role in preserving the health and well being of their societies."Healthy Women leads to Healthy Children and it leads to Healthy Population which in turn creates Healthy World". Women are the caretakers of healthy family healthy society.

According to Geetha S. Iyengar, The wealth of a nation and the health of the future generation depend upon women's physical and mental well-being.[2] Woman is soft, tender and flexible and this makes her move with ease and grace. Woman's muscles are soft and light. Woman does not have broad skeletal structure like man. In spite of that, by nature's characteristic gift, she has the power to withstand physical strains and mental pressures to a far greater extent.

Nature has, in addition, endowed her with the responsibility of perpetuating mankind. To fulfill her tasks, woman is being dependent on nature. Nature helps her in maintaining her physical body, her changing physiological functions and emotional states through Traditional plants[3].

Generally speaking, the plants and plant products surrounding us will help us in solving our health issues. Himalayan sage scholars of Traditional Medicine have said

"Nanaushadhi Bhootam Jagat Kinchit" i.e. there is no plant in the world, which does not have medicinal properties.' We can get all which we desire from plant for our betterment, if we treat it to be in its own way without

disturbing the law of nature. The Health maintenance is being done by the food we take daily. The crops that we cultivate bring harmony and ensure overall development of human body[4]. There is no need to search a plant with a medicinal quality. Every plant and plant products we use for food acts as a medicine, proving "Food is Medicine". Generally the plants surrounding will definitely have the medicinal qualities to solve the health problems of the domicile as per the law of Nature[5].

Research Objective: To analyze the role of Medicinal plants in solving the Women's health disorders, in order to accelerate healthy Economy.

Stages in Women's life: There are three important stages in woman's life beginning with youth, passing through middle age, and ending in old age.

1. Menstruation
2. Pregnancy and delivery
3. Menopause.

These are the three periods and milestones of a woman's life. In all the three stages Women face lot of problems physically as well as mentally.

In human females, the menstrual cycle occurs repeatedly between the ages of menarche-when cycling begins, until menopause-when it ends. In the menstrual cycle, changes occur in the female reproductive system as well as in other bodily systems. A woman's first menstruation is termed menarche, and occurs typically around age 12-16. The end of a woman's reproductive phase of life is called the menopause, and this commonly occurs somewhere between the ages of 45 and 55.

Menstrual cycle: Themenstrual cycle is the cycle of natural changes that occurs in the uterus and ovaries as an essential part of making reproduction possible. The menstrual cycle is essential for the production of eggs, and for the preparation of the uterus for pregnancy. The average menstrual cycle takes about 28 days. It occurs in three phases: 1) Follicular phase (development of the egg), 2) Ovulatory phase (Release of the egg) and 3) Luteal phase (Implantation of fertilized egg).

If the egg is not fertilized, levels of hormones get decreased and the lining of uterus prepared for the pregnancy breaks down and sheds. Shedding of endometrium, the uterine lining is called menstruation or period. Women can experience lots of complaints during this period.

Three out of four experience menstrual discomforts. One of the problems during menstruation is extremely painful period or Dysmenorrhea.

Dysmenorrhea: Dysmenorrhea is the medical term for the painful cramps that may occur before or during the menstrual period. Menstrual cramps are caused by contractions in the uterus, which is a muscle. The uterus contracts throughout a woman's menstrual cycle. If the uterus contracts too strongly, it can press against nearby blood vessels, cutting off the supply of oxygen to the muscle tissue of the uterus. Pain results when part of a muscle briefly loses its supply of oxygen.

Prostaglandin is hormone like substance that does contraction and relaxation of smooth muscle. Higher levels of prostaglandin are associated with more–severe menstrual cramps. Endorpins counteracts Prostaglandins. It interacts with the receptors in the brain which reduces the perception of pain and also it triggers a positive feeling in the body

Medicinal plants for Women's health: During the menstrual cycle, hormone levels rise and fall in an effort to prepare the lining of the uterus to thicken for ovulation and then shed if pregnancy doesn't occur. In this period women suffer with backpain, body pain, pain in the thighs, abdomen, hip, bloating, nausea, constipation, diarrhea, tiredness, headache, vomiting, giddiness, sweating, dizziness, fatigueness, depression, stress, irritability and mood changesetc. Deficiency of vitamin B12, vitamin B6, vitamin C and vitamin D can lead to nausea and dizziness during periods[6].

The following Medicinal plants help to solve the discomforts of Dysmenorrhea[7]:

- Licorice root–Adhimadhuramver in Tamil–Can moderate spasms and alleviate pain. Contains glycyrrhizin & flavonoids which are antioxidants known to improve circulation and relieve tissues damage and also reduces inflammation.
- Foods with high Flavonoid-Onion, blueberries, black tea, green tea, bananas, all citrus fruits
- Ginger–Soothe menstrual trouble and fight the fatigue.
- Fennel–Perunjeeragam in Tamil–Contains anethole (a compound with anti-spasm effects)
- Chamomile tea–Samandhi in Tamil–Has pain relieving properties. Contains Hippurate-a natural

anti-inflammatory drug helps to decrease the prostaglandin production.

- Derris trifoliate–Angaravalli in Tamil–For painful periods
- Menthaarvensis–Mint or Pudhina in Tamil–For painful periods
- Meliaazadiracta–Common name Neem–Vembu in Tamil–Acts as a Pain killer.
- Trigonellafoenumgrace–Common name Fenugreek–Vendhayam in Tamil–Acts as a pain killer.
- Black gram–Ullundhu in Tamil–For Uterine strength.
- Dolichosbiflorus or Kollu in Tamil–For strengthening the Uterus and to reduce the menstrual pains.
- Vetiveriazizanoides–Vettiver in Tamil–Regulates Menstruation.
- Daucuscarota–Common name Carrot–Roots regulate menstrual disorder.
- Desmodiumtriquetrum–Common name Sakuli–Sakkaraivalli in Tamil–Tender leaves regulate menstrual disorder.
- Riccinuscommunis–Common name Castor–Amanakku in Tamil–For sterility after Menstruation.
- Piper beetal–Common name Betal–Vetrilai in Tamil–Gives relief from perspiration and menstrual odor.
- Allium sativum–Common name Garlic–Poondu in Tamil–Fights against bacterial and fungal infections[8].
- Vitamin B6–Can be obtained from Avacado, Sunflower seeds and Sesame seeds
- Vitamin B12–Can be obtained from Mushrooms, Broccoli, Soya beans and Asparagus.
- Vitamin C–Can be obtained from Kiwi, Guava, Orange, Papaya, Pineapple, Mango, Banana, Lemon, Grapes, Tomatoes, Strawberries, Broccoli, Cauliflower, Peas, Green bell pepper, Red pepper, Black currant, Parsley, Brussels sprouts, Honey dew.
- Vitamin D–Can be obtained from Orange juice, Soya milk and Cereals. Important in preventing menstrual cramps.

Conclusion

The traditional food and systematic lifestyle, adopting medicinal plants as food of our older generation kept their health in good condition. But present generation's food habits and negligence of the olden culture results in deterioration of self as well as future generation's health. Moreover medicinal plants do not have side effects and also it is economically cheaper. Especially at present women get Health awareness and utilize the traditional medicines for their well being.

Discussion

The general observation is that the agricultural sector feeds the population, animal population and also supplies raw materials to the development of agro-based industries. Infact, the agricultural sector also facilitate and promote women health through precious herbals. The herbal medicines are easily available especially in rural areas. When we properly cultivate herbal plants it will generate more income to the farmers as well as we can supply those precious supply of plants to prepare medicines and treat women's ill health. This effort will make people to avail herbal medicines at lesser price or at free of cost for all types of human ailments. The practice of herbal medicine will be more economical, natural and it will cut short the medical expenditure of the society. It is to say that this will lead to intergrated agricultural activities, natural way of life and healthy motherhood.

Finger Theraphy-Clensing and Revitalizing Human Health

S.N. Sugumar[1], M. Shanmugapriya[2]

[1]Prof. and Head, Department of Economics, [2]Scholar, VISTAS, Chennai

Abstract

All living and non-living beings are part and parcel of Universal system. There is an invisible energy which makes universe dynamic and it is found and present in the smallest particles as well as in the biggest sun and the moon. This is true to the smallest insects, plants, trees, animals, and human beings. The flow of Universal energy spreads everywhere in the Universe. This is the vital energy makes the human body dynamic and it vibrates constantly. Infact, obstruction in the energy flow causes ailments in human body. This is balanced by stimulating the particular energy centre on meridians under acupuncture and acupressure system. This is balanced by balancing three doshas in siddha and ayurvedic system. This is also balanced by various generic method such as varma therapy, panchakarma, hand mudras, finger therapy, yogasanas, balanced diet, breathing exercises,etc. The authors in this paper examine the impact of finger therapy to cleanse and revitalize the human energy for healthy life and healthy aging.

Keywords: *Law of nature,Universal energy, physical energy, human ailments, five elements, chakras, finger therapy and hand mudras.*

Introduction

In the process of development inventions and innovations take place in all the sectors throughout the world. People enjoy more comforts and the benefits of modern technology but each technology that we introduce to the society has sting on its tail. Therefore, all inventions and innovations have their own merits and demerits. All modern gadgets make people static and inactive which leads to life style disorder. As per law of nature especially, law of vibrations everything vibrates in nature which is indispensable for healthy life. It implies that our body needs proper movement, actions, physical exercise, such as walking, jogging, cycling, laughing, hobbies which involves hands and legs, but the modern life style is static and sedater just against the law of vibrations which results in so many non-communicable diseases.[1]

Infact, our emotions may be expressed through fingers and hands. Our inner emotions and ailments are reflected through emotions and physical complains. Chronic negative emotions such as aggression, depression, dissatisfaction, fear, anger, frustration can weaken our organs and they inturn cause non communicable physical and mental ailments such as, digestive problems, blood pressure, pain, diabets, weight gain, insomnia, poor vision and so on. Emotional fluctuations, can be balanced gradually by practicing finger therapy along with proper diet and life style.[2]

In addition, human brain should be active especially at the time of chronic illness or bed ridden. Inactive brain prone to human ailments so quickly as there is less flow of energy between universe and human. Therefore, it is through the practice of mudrabrain gets activated and regenerated. There is a positive influence on the brain waves, particularly when the fingertips touch each other.

Statement of the problem: As per the law of correspondence the individual organs and elements are associated with fingers which help to heal the human ailments. *The purpose of mudra is to activate the prana sakthi or universal energy.* Constant flow of this energy is responsible for the existence of human body by generating and balancing the vital energy with the presence of pancha poothas through five fingers. This is depicted in many Indian dance, architecture, painting, martial arts and yoga. Human body is made up of five elements and the fingers are the representatives of them. Thumb finger represents fire or sun, index finger represents wind or air, middle finger represents sky or space, ring finger represents earth and little finger represents water element. Excess of certain emotions affect organs. Infact, anxiety and joy affects heart and

lungs, fear affects kidney, pensiveness affects stomach and spleen and anger affects liver.

Objective: The authors in this article made an attempt to examine the impact of finger therapy to cleanse and revitalize the human energy for healthy life and healthy aging.

Review of literature: The origin, place, time and the practice of mudra is time immemorial This has been in practice in Asia and Europe from their age old time till now. In our tradition and culture we are using hands and fingers to show our emotions interms of clapping, applause, shaking hands, greeting others, saluting other, sending off others, and so on. In India, mudras are a part and parcel of day to day activities and it is also depicted in the statues of hindu deities too and through their hand mudras they portray the nature and the special power of the deity. In Indian traditional dances, like bharathanatiyam, kuchupudi, kathak, kathakali and other Indian folk dance and dramas, hand mudra, eyes and body movements are use to express their emotions.

The practice of mudras are effectively engaged and influenced our body and mind by bending, crossing, extending, or touching the fingers with other fingers.[2] In Hatha Yoga,there are 25 mudras and these include eye and body positions namely asanas and locks known as bandhas. It expresses the many states of mind, such as mourning,joy, anger, and serenity, through gestures and body positions and they influence our physical body and mind positively. In Kundalini Yoga, the hand mudras are used in the body postures to intensify their effect with spiritual consideration. The kundalini expert Lothar-Riidiger Liitge explains that " Kundalini Yoga assumes that every area of the hand forms a reflex zone for an associated part of the body and the brain. In this way, we can consider the hands to be a mirror for our body and mind."[3] Each mudra ultimately creates a special connection to cosmic consciousness. This is exhibited through chin mudra where the thumb is symbol of cosmic energy or divine power and the index finger is symbol of individual human consciousness and their union is ultimate or primary goal of yoga. That is union of mankind with cosmic consciousness. The human being express their desire, by intuition and inspiration through this mudra because the index finger represents inspiration i.e.energy from the outside and the thumb stands for intuition i.e. inner energy connected with cosmic world.

Mudra specialist Ramm-Bonwitt describes that," The hands are the bearers of important symbols, which are still universally understood in the East today. With his or her hands, the Indian dancer expresses the life of the universe. Through its variety of interpretive possibilities, the rich symbolism of the dance's language of gestures gains a greater significance for the mind than words could express. The spiritual meaning of the mudr as found its perfect expression in Indian art. The gestures of the deities depicted in Hindu and Buddhist art symbolize their functions or evoke specific mythological occurrences."[4]

Ways and means of doing finger therapy: Infact, hand mudras are popular among the people which is being practiced in the east and the west. There are many mudras which can heal human ailments when we practice hand mudras regularly. Hand mudras also include finger therapy which is part and parcel of exercise for the fingers. Finger therapy means holding a finger or giving gentle massage to particular finger will heal common human ailments such as anxiety, head ache, body pain, irregular blood circulation, constipation etc., Hence, the practice of mudras and finger therapy may balance energy flow in the body which may lead to normal health.

Generally, hand mudras can be done by joining the hands, joining the tips of different fingers and holding the fingers. Observing the normal flow of the breath while doing mudras is a very important way to enhance the benefits of doing mudra.

One can actually practice the mudras at any time and in any place but the good result may be enhanced when it is practiced while in a good mood and in a positive atmosphere. It is because, feelings and thoughts influence the energy fields and the flow of energy in a negative or positive manner.

A good time to practice mudras is a few minutes before getting up and a few minutes before falling asleep, before or after meals. It is good to practice one or two mudras at a time according to their ailments.

Mudras can be done while we are in padmasana, sukasana and vajrasana for good result. If we sit on a chair while doing them, our back should be straight and our feet should have good contact with the floor. It is important to be relaxed and calm while we do mudras.

For chronic complaints, the Indian mudra researcher Keshav Dev, recommends holding one mudra per day for 45 minutes. This time duration can be divided into three time periods of 15 minutes each. To heal a chronic ailment practice of mudra should be routine at the same time and for the same length of time. Acute complaints such as respiratory and circulation problems, flatulence, exhaustion, or inner restlessness mudras should be practiced till the appropriate effect is achieved[5].

The effect of a mudra may be realized immediately or only after a certain amount of time. in the way of feeling warm, the sense of freshness and pain fade away, improving mood status and refreshed mind through clear thinking and action. But some time, some people may also experience just opposite like tired, or start to feel cold and shiver. However this is also a positive sign of the effect.

Mudra is even used a symbol because it is a processes of consciousness with eye positions, body postures, and breathing techniques. So mudras engage certain areas of the brain and soul and exercise a corresponding influence on them. There is a direct relationship between the hands and the neck since the nerve paths run through the arms, hands, and fingers. The flexibility of the hands always influences the flexibility of the neck. Therefore, hand exercises relieve tensions in the neck. Moreover, spreading the ten fingers creates a reflex that causes the thoracic or chest vertebrae to spread out. This increases the tidal volume of the lungs. The hands and fingers also have an additional direct relationship to the heart and lungs. With increasing age, many people can no longer properly stretch their fingers. This shows tension in the heart area, which often indicates to heart disease or a tendency toward osteoporosis.

Finger therapy for healthy life: Finger therapy means holding gently the fingers for 10 to 15 minutes will stimulate the particular organs. Be polite and try to feel the heart beat in the finger which you hold it.As per the astrological perspectives all the planets are indicated in our hands especially fingers and palm. For example, little finger represents mercury and water element, ring finger represents to sun and venus and earth element, middle finger represents Saturn and ether element, index finger represents Jupiter and air element and thumb finger represents mars and fire element[6]. Therefore, gentle massage or holding the fingers will stimulate the respective organs. For instance;

- Joining the tips of ring finger with thumb will arrest any ailments related to stomach, joining the tips of little finger with thumb will arrest any ailments related to kidney and urinary bladder.
- Holding thumb for 10 to 15 minutes will relieve headaches, stomach pain, stress, and skin issues
- Smooth massage or gentle pressure at the base of thumb will solve the problems related to the respiratory system.
- Holding or pressing index Finger will alleviate heartburn, muscle pain, toothaches, and back pain.
- Holding or pressing middle Finger will help us to over come anxiety, indecisivenessand it will also improve the eyesight, blood circulation, and menstrual cramps.
- Gentle massage of ring finger helps to improve colon and lung function,respiratory issues, asthma, skin problems, and digestive conditions.
- Holding and pressing little finger will increase our confidence level and cure stomach bloating, throat pain, and various heart issues.
- Pressing center of the Palm will alleviate any digestive issues and stomach pain or cramps.
- Gentle massage of exterior Palm will control or reduce high sugar levels in the blood.

Managing our daily routine work through fingers: Proper exercise and work to the fingers like doing handicrafts, playing an instrument, washing the hands, or massage will have long-lasting effects.Press the four fingers of one hand together with the other hand and turn the fingers you are holding to both sides. Then make fists, open the hands again, and spread the fingers. Or vigorously rub both palms together. Cross your fingers with each other, turn the palms outward,and stretch our arms. This will refresh you, improveour breathing, and strengthen your heart.

Conclusion.

Generally, we have been using our hands and finger in some way or other by playing games, instruments, writing, drawing, and doing some other activities such gardening, cooking. grinding, cleaning vessels, washing, ironing etc, but now a days we donot practice many of these activities due to the mechanized life. This makes people static, sedater and inactive which results in life style disorder with so many non-communicable and

unknown diseases. Therefore, it is pertinent to say that along with physical exercises such as walking, jogging and cycling people can practice finger therapy inorder to keep their health in tact.

Discussion

People at present are experiencing cut throat competition in their day to day activities and they have to struggle to prove themselves in the society by compete with each other throughout the day. In addition, the so called modern machine–life leads to life style disorder and suffering from non-communicable diseases. Infact, gentle finger therapy or holding fingers will facilitate to heal physical and mental ailments. Therefore, clapping, massaging our palm, rubbing both the hands, gathering both the hands to greet along with the practice of finger therapy will cleanse and revitalize human energy for healthy life and healthy aging.

Energy Medicine & Herbal Brain–Top Five Brain Inducing Herbs of India its Impact on Health and Economy

Mouthu Kumarasamy[1], S.N. Sugumar[2]

[1]M.Sc. Varmam, MD. in Acupuncture, SJT (Sujok), SMP Siddha, Advanced Diploma in Yoga Therapy, Practioner-Above & Beyond Universal Healing Therapy Clinic, Chennai, Tamilnadu, [2]Prof. and Head, Department of Economics, VISTAS, Chennai, India

Abstract

Brain functions through its chemical secretions and electrical signals it generates, if there is excess or shortage of these signals or secretions it leads to various mental disorders. It has been observed that for treatment of Brain disorders any invasive procedure creates long term complications and unwanted side effects in majority of the cases, hence there is a clear need to look at some of the traditional and ancient healing method. This is a review article with a primary objective to trace five of the top beneficial brain strengthening herbs along with their medical and scientific properties which are currently in various stages of research both in conventional and traditional medical practices. There is an economic angle for their cultivation or wild foraging of these herbs and it plays an important role in its authenticity and efficacy of the finished herbal drug. If these herbs Vallarai, Neer Brahmi, Amukkara, Nithyakalyani and Vishnukranthi herbs are consumed as prescribed by a qualified medical doctor it produces anti-stress nervine tonic, anti demential brain tonic which helps in strengthening of the brain and prevents the brain from auto neuro degeneration. It also enhances the overall learning and memory abilities.

Keywords: *Herbal Brain, memory, Health Care Economy, Indian Herbal Medicine.*

Introduction

What drives humans? is it the healthy strong body or the agile brain, if you look around world leaders or top scientists, or leading academicians you will find them doing extraordinary things which for majority of the population is impossible to think and execute and this is possible only through the agile brain which is driving their bodies to do super human things. We have so many examples where particular race or sects of people have demonstrated significant learning or business skills compared with other parts of the population. We could trace their behavior, attitude towards the specific diet regimen they follow as one of the leading examples.

In a society every human being participates using his physical and mental abilities, based on his contribution through his faculties he gets compensated for his efforts in cash or in kind or both cash and in kind. This is the basis of economic development and defines individual, family, community, regional, national prosperity index. Each human being differs at physical and mental ability levels even though skill sets of homogenous nature is administered through education and training. Given this paradox how does one human being who has similar physical make up and similar educational background and skills training fares better or different than the other human being–this question is being taken up to find the answer as part of this research article. Healthy body and an even more optimally functioning brain become a huge asset for the possessor, for the society and the country at large for wealth and health creation thereby increasing quality of life.

Statement of the problem: This brings us back to the question if Brain leads the body to achieve

Corresponding Author:
Dr. S.N. Sugumar
Ph.D., M.D. in Acupuncture, Dip in Herbal Siddha, Homeopathy, Panchakarma & Varmam
Prof. and Head, Department of Economics, VISTAS, Chennai–117, Res: No. 7, Madhavamani Avenue, Velachery, Chennai-42

extraordinary results can the brain be kept healthy like the body through herbal diet systematically?

Materials and Method

This is a review article to analyze and examine the impact of agile Brain and its role in human health and societal economics and to understand if five of the identified medicinal herbs have direct influence on making a not so normal brain an agile and healthy one from various sources including Materia medica books, journals, old tamil Siddhars texts and from the world wide web.

Brain: The Brain is a mass of soft, spongy, pinkish gray tissue that weighs about 1200 gms in a human, it is contained in the head within the cranium comprising of Forebrain, Midbrain and Hindbrain. The human brain consumes the major portion of the entire energy that is generated in the human body. To be exact, the brain consumes 20% of that energy despite the fact that it only represents 2% of the total body weight. The brain is made up of 100 billion of nerve cells or neurons that are in constant communication with each other through electric signals, intricately connected with each other.[1] It contains nerve centers which control many involuntary functions, such as circulation, thermostat regulation, respiration, to interpret sensory impressions received from the eyes, ears, nose, skin and tongue. Consciousness, emotion, thought, and reasoning are functions of the brain. It also contains centers or areas for memory which allows for recording, recalling, and playing back past experiences.

The neurons transmit messages with the help of electrochemical processes. This electrochemical process can be understood as the movement of sodium, potassium, and chloride ions in and out of the cells with the help of flowing regulated electric current through neurotransmitters. The brain contains several hundred different types of chemical messengers or neurotransmitters. They in turn are categorized as either excitatory or inhibitory. An excitatory messenger like Serotonin, Norepinephrine, dopaminestimulates the electrical activity of the brain cell, whereas an inhibitory messenger like Gamma aminobutyric acid (GABA) calms this activity. The activity of a brain cell is largely determined by the balance of these excitatory and inhibitory process.

Brain Disease: Brain diseases are broadly classified under infections, trauma, stroke, seizures, tumors, vascular condtions, auto immune conditions and neuro degenerative conditions.

Mental Disorder: A mental disorder, also called a mental illness or psychiatric disorder, is a diagnosis by a mental health professional of a behavioral or mental pattern that may cause suffering or a poor ability to function in life. Such features may be persistent, relapsing and remitting, or occur as a single episode.

Herbal Medicine: Food as medicine and medicine as food has been the lifestyle for many cultures around the world especially the Tamil civilization which originated from the South of India has embraced this and have furthered this concept by creating its own system of medicine called Siddha which is entirely based on using different parts of Plants, Animal, metals and minerals. This system of medicine also specializes in anti-ageing by using specific herbs to increase longevity. Siddhars who were the earliest proponents of the system also have understood the chemical compounds secretion by the brain and have mapped it back to certain herbs which induces brain functions like controlling neuro degenerative diseases and mental disorder management.

Herbal Medicine and its action: Medicine entry into the body happens through Oral or mouth passage, nasal, eyes, skin, rectum and ears. The most common method of administering medicines are always oral because of its convenient quotient. The other important aspect of medicines is how well and with what its packaged and administered with ensures the delivery of the medicine for better absorption in the blood stream.

The Chemical compounds in the herbal medicine mediate their effects on the human body through processes identical to those already well understood for the chemical compounds in conventional drugs; thus, herbal medicines do not differ greatly from conventional drugs in terms of how they work. This enables herbal medicines to be as effective as conventional medicines[2].

Top Five Herbs of India Inducing Brain Power: For centuries mankind has been using herbs to improve the function and memory of the brain but it was always shrouded with mystery and secrecy for various reasons. There have been enough references in our ancient scriptures and texts about the use of specific herbs which was used by the likes of King Solomon and was called as the secret of Solomon for his mental prowess. In the Dravidian history there were three kingdoms which shaped up itsculture, arts, religion and medicinal

practices they were the Cholas, Cheras and the Pandyas between them there are numerous instances where they have used specific herbs to increase their brain power, valour, longevity etc.

From actually increasing intelligence to improving memory, tissue oxygenation, balancing chemical secretions and even regenerating neuronal connections, these five superstar herbs are in a class of their own when it comes to improving brain function and creating long lasting neurological health.

1. Neer Brahmi, Water Hyssop, bacopa monnieri
2. Amukkara, Ashwagandha, Indian Ginseng, Winter Cherry, Withania Somnifera
3. Vallarai, Gotu Kola, Brahmi, Asiatic Pennywort Centella asiatica
4. Nithya Kalyani, Periwinkle, Catharanthus roseus
5. Vishnukranthi, Sankhapuspi, Speed Wheel, Convolvulus pluricaulis

1. **Neer Brahmi (bacopa monnieri):** Neer Brahmi is a Siddha herb utilized by Indians for thousands of years. Neer Brahmi is said to work by supporting our nervous system and brain. Neer Brahmi acts as a micro-nutrient in the Siddha therapy known as Karpa Marunthu or Rasayanam was shown to retard brain ageing and help in regeneration of neural tissues. Neer Brahmi, is also believed to provide adrenal support, and helps with emotional resilience[3].

2. **Amukkara (withania somnifera):** Siddha herb, Amukkra or ashwagandha has been found to inhibit the formation of beta-amyloid plaques in preliminary research. It's also indicated that ashwagandha may benefit the brain by reducing oxidative stress (a factor that may contribute to the development and progression of Alzheimer's disease).

The herb also reduces tumor GSH levels which may contribute to the enhancement of radiation response. Amukkara can reverse paclitaxel (cancer chemotherapy drug that works by slowing or stopping cancer cell growth) induced neutropenia[4] (Neutropenia is an abnormally low concentration of neutrophils in the blood. Neutrophils make up the majority of circulating white blood cells and serve as the primary defense against infections by destroying bacteria, bacterial fragments and immunoglobulin-bound viruses in the blood. Patients with neutropenia are more susceptible to bacterial infections and, without prompt medical attention, the condition may become life-threatening).

3. **Vallarai (centella asiatica):** Vallarai or Brahmi herb is a tonic for brain. Traditionally it is used for treating brain disorders, skin diseases, neural disorders and insomnia due to its adaptogen, central nervous system relaxant, sedative, antibiotic, detoxifier, blood-purifier, laxative, diuretic, emmenagogue properties. It reduces tension, stress, anxiety and sleeplessness due to its sedative, tranquilizing and relaxant activities. Vallarai is used in Siddha, for improving memory, intelligence and speech. The intake of herb overcomes mental confusion and supports better thinking.

The intake of Vallarai herb overcomes mental confusion and supports better thinking. It has cooling, sedative and relaxing effect. The tea prepared from Vallarai induces sleep and gives relief in insomnia. Centella can elevate the level of cerebral glutamic acid and temporarily increase the gamma-aminobutyric acid (GABA) level in the brain. It is believed that the endogenous increase in brain glutamine may be helpful in the learning process.

4. **Nithyakalyani (catharanthus roseus):** Nithyakalyani or Periwinkle is used by herbalists to treat nervous disorders, epilepsy, hysteria, and nightmares. Exciting new research into this delicately beautiful plant shows that vinpocetine, a derivative of vincamine, a natural compound in periwinkle, helps transport oxygen and glucose to the brain. Since the brain needs both to function optimally, Nithyakalyani or periwinkle may be beneficial for assisting to ease brain disease.

Vinpocetine is a powerful free radical scavenger. Used regularly, periwinkle, or its active ingredient, vinpocetine, may help to prevent senility and dementia, by preventing damage to the blood vessels in the brain caused by free radicals. With around one hundred studies conducted on vinpocetine's effects on humans, mostly in Hungary, it is not surprising that it has been used by doctor's world over to treat senility and blood vessel disorders in the brain for twenty-five years. In these studies, it appears to boost memory and cognition in healthy people and in those with mild to moderate forms of dementia.

5. **Vishnukranthi (convolvulus pluricaulis):** Vishnukranthi herb works on nerves, plasma, and reproductive system. It helps in mental, nervous, excretory and reproductive disorders. It promotes intelligence, enhance memory and retention, reduces

stress, anxiety, depression, confusion and induces peaceful sleep,It is psychotropic and nootropic agent drug that cures nervous debility and dementia, it also acts as a brain tonic, alterative, febrifuge, vermifuge and anti-inflammatory. It is beneficial in rejuvenating the brain and hence works as a Psycho-stimulant and tranquilizer. It is also a known herb to induce production of Dopamine which calms the brain.

Economic burden of Brain Disease: The Economic burden of mental disorder is not very easy to ascertain due to various reporting issues, but NIMH (National Institute of Mental Health) puts the mental health care figures equal to cancer health care[5]. But unlike cancer, much of the economic burden of mental illness is not the cost of care, but the loss of income due to unemployment, expenses for social supports, and a range of indirect costs due to a chronic disability that begins early in life which can be measured through DALYs (Disability adjusted life years).[6] It is estimated that 1.46 trillion US dollar is being spent annually on global mental disorder medicine and care.

Conclusion

It is clearly understood that the identified five Indian herbs contain the saponins called bacosides and adaptogens, which appear to affect certain neurotransmitters in the brain. Brahmi seems to increase the effects of serotonin, gamma aminobutyric acid or GABA and acetylcholine. Vallarai effects on these neurotransmitters, along with its antioxidant and neuroprotective actions in the brain, they include enhancing mental function and easing anxiety and depression. Nithyakalyani or Periwinkleits active ingredient, vinpocetine, may help to prevent senility and dementia, Vinpocetine is also a powerful free radical scavenger. Vishnukranthi produces psychotropic and nootropic agent drug that cures nervous debility and dementia. Overall these five drugs[7] are shown to reduce oxidative stress and GSH levels which may contribute to the and strengthening of learning and memory abilities. As conclusion we can significantly increase the capacity to deal with stress and improve mental and physical performance with the use of these five Indian adaptogen herbs. The economic costs of these five Indian herbs are relatively much lower than conventional medical treatments for mind disorder which might include invasive and non-surgical procedures. The other significant benefit of these five Indian herbs is that it could be taken along with conventional medicines which also could lower the health care costs.

Discussion

As per the law of mentalism everything is mind and mind is in everything. All scientific advancements and developments, inventions, innovations, discoveries are the outcome of human mind and it is the replica of human brain which is the part and parcel of the human body. Body and mind are inter-related and reinforce each other butmind is more subtle and powerful than the physical body. Purity in mind will indicate healthy mind which inturn will provide healthy physical body. Unfortunately, mind is polluted by various factors in the modern life that leads to all sorts of human ailments. Hence, it is indispensable to keep our mind healthy through herbals such as Neer Brahmi, Amukkara, Vallarai,, Brahmi,. Nithya Kalyani and Vishnukranthi. If these herbs are consumed as prescribed by a qualified medical doctor it produces anti-stress nervine tonic, anti demential brain tonic which helps in strengthening of the brain and prevents the brain from auto neuro degeneration. It also enhances the overall learning, memory abilities and longevity.

Blood Pressure–Some Issues and Traditional Remedical Measures

S.N. Sugumar[1], G. Raguram[2]

[1]Prof. and Head, Department of Economics, [2]Research Scholar, VISTAS Chennai-600117

Abstract

Human ailments may be classified into communicable and non-communicable diseases. Thanks to the technological advancement in the medical field, many communicable diseases such as cholera, tuberculosis, HIV/AIDS, gonorrhea, influenza, measles, hepatitis–A, hepatitis–B, typhoid etc are in control to a large extent. In contrast, due to life style disorder, poor diet and environment the number of causalities increases due to non-communicable diseases such as cardio–vascular disease, cancer, chronic respiratory diseases, dysfunction of kidneys, diabetes, etc. Abnormal blood pressure may be the cause for most of the non-communicable diseases. Therefore, the authors examined the causes and consequences of abnormal blood pressure and also presented a few traditional remedial measures to over come the same.

Keywords: *Abnormal blood pressure, life style disorder, circadian rhythm,Physical and mental health, yoga and hand mudras.*

Introduction

In the modern world, people are very busy and active in their efforts to eke out their living. Many people spend most of the time in travel, preparation for their official and personnel works. Our social, personal responsibilities and obligations influence our physical and mental conditions which inturn imbalances body metabolism and it ends with physical and mental ailments. Human ailments may be classified into communicable and non-communicable diseases. Thanks to the technological advancement in the medical fields many communicable diseases such as cholera, tuberculosis, HIV/AIDS, gonorrhea, influenza, measles, hepatitis–A, hepatitis–B, typhoid etc are in control to a large extent. In contrast, due to life style disorder, poor diet and environment the number of causalities increases due to non-communicable diseases such as cardio–vascular disease, cancer, chronic respiratory diseases, dysfunction of kidneys, diabetes, etc. Abnormal blood pressure may be a cause for most of the non-communicable diseases.

Statement of the problem: Blood pressure, in general, is one of the major indicators of good health. It is the pressure of circulating blood on the walls of blood vessels, in large arteries with systemic circulation. Blood pressure is usually expressed in terms of the systolic pressure is maximum during one heart beat over diastolic pressure which is minimum in between two heart beats and is measured in millimeters of mercury (mmHg). Blood pressure is influenced by cardiac output, total peripheral resistance and arterial stiffness and it varies depending on situation, like emotional state, activity, and relative health/disease status. Blood pressure is regulated by baroreceptors which act via the brain to influence nervous and endocrine systems. Normal resting blood pressure in an adult is approximately 120 millimetres of mercury (16 kPa) systolic, and 80 millimetres of mercury (11 kPa) diastolic, abbreviated "120/80 mmHg".Low blood pressure is called hypotension, and high blood pressure is called hypertension. As the abnormal blood pressure leads to many human ailments, the authors in this article examined the causes and consequences of abnormal blood pressure and also presented a few traditional remedial measures to overcome the same.

Objectives of the study: Toexamine the causes and consequences and also to suggest a few traditional remedial measures to balance the Blood Pressure.

Blood circulation Mechanism in human body: Blood circulation provides nutrients and oxygen to every tissue, muscles, organs and cells through blood circulation from the heart to every part within the body. To understand healthy blood pressure range, it is necessary to know systolic and diastolic blood pressure.

Systolic blood pressure is the blood pressure number when the heart contracts (beats).Diastolic blood pressure is the blood pressure number between heartbeats (when the heart rests).The heart is a muscular pump that pumps blood throughout the body during our entire life span. Low oxygen blood enters into the lungs and reloaded with oxygen and oxygen-rich blood is sent throughout the body. The heart pumps out blood with some pressure so that it can easily reach extremes. This pumping of heart generates blood pressure.

Functions of brain and blood pressure: Baroreceptors are sensors in the blood vessels that sense the blood pressure and send it to the brain and it maintains a healthy blood pressure by communicating with the kidneys, arteries, veins, and heart to increase, decrease, or maintains blood pressure, as needed. Its function is to ensure sufficient blood supply to all the organs, cells and tissues.

If our blood pressure is too high, baroreceptors send a signal to the brain and it instructs the heart to beat slower, pump less blood per beat, relaxes the arteries that carry oxygen-enriched blood from the heart and constrict the veins that carry oxygen-depleted blood to the heart which results in a drop in blood pressure until it attains healthy blood pressure. On the other hand, if our blood pressure is too low, baroreceptors send signals to the brain and it instructs the heart to beat faster, pump more blood per beat and loosen the arteries that carry oxygen-enriched blood from the heart andrelaxes the veins that carry oxygen-depleted blood to the heart which results in rise in the blood pressure until it attains healthy blood pressure.

If the above said control loop not able to maintain healthy blood pressure, then next master control system is kidney. If the blood pressure is high, kidney pulls more water out of the blood by excreting more urine than usual thus decrease blood pressure.If the blood pressure is low, kidney keeps more water in the blood by excreting less urine than usual thus increases blood pressure.

Review of literature: Generally, an individual's blood pressure varies with exercise, emotional reactions, sleep, digestion and time of day. Blood pressure fluctuates from minute to minute and normally shows a circadian rhythm over a 24-hour period, with highest readings in the early morning and evenings and lowest readings at night.[1] Loss of the normal fall in blood pressure at night is associated with a greater future risk of cardiovascular disease and there is evidence that night-time blood pressure is a stronger predictor of cardiovascular events than day-time blood pressure.[2]

Various other factors, such as age and sex, also influence a person's blood pressure. In children, the normal ranges are lower than for adults and depend on height.[3] Standard blood pressure values have been developed for children in different countries, based on the distribution of blood pressure in children of these countries.[4] As human grows older and older systolic pressure tends to rise and diastolic pressure tends to fall.[5] Consequently, in the elderly, systolic blood pressure often exceeds the normal adult ranges,[6] this is due to increased stiffness of the arteries. [7]

Consequences of high blood pressure: Poor diet and physical inactivity among the people may cause increased blood pressure, blood glucose, blood liquids and obesity which inturn increase the risk of developing cardio-vascular disease such as heart attack, stroke, coronary artery disease, cerebrovascular disease, peripheral artery disease and congenial heart disease. It also leads to weak heart, weak bones, rigid joints, weight gain, low energy,and increased stress levels. Diabetes also leads to heart disease, vision loss and kidney injury.

Traditional remedial measures to balance the blood pressure

a. Mind-body relationship

In a normal situation breathe directs lungs, lungs influences heart, heart influences blood circulation, blood circulation influences brain, brain influences mind, mind creates thoughts and the nature of thoughts feeling and emotions create different vibrations in the body. The external objects also influence our mind and create thoughts, feeling and emotions. Feelings and emotions are also part of thought. They may be formed and expressed as love, fear, hatredness, jealousy, worries, angry, anxiety, depression, frustration and so on. These different feelings and emotions may also imbalance blood circulation in our body. These entire mental functions imbalance the physical functions of the body, because body and mind are inter-related. Depressed mind can depress the physical body. Poor physical condition can depress the mind. However, mind is more powerful than physical body. Therefore, body–mind harmony will stabilize the total health status of the man-kind. Hence, the practice of pure, satvik, positive,

neutro, optimistic,ethical, disciplined and synthesizing mind may be useful to maintain the normal blood pressure.[8]

b. Exercises

Exercise can help to increase the secretion of nitric oxide, improve blood vessel's elasticity, and lower our blood pressure. Exercise makes our heart stronger, pump more blood with less effort, the force on our arteries decreases, and lower our blood pressure. In addition, regular exercise helps to maintain a healthy weight, another important way to lower blood pressure. Some exercises like household chores such as trimming and cleaning the lawn, gardening, rake leaves, and cleaning floor/utensils, and also playing indoor and out door games. Riding bicycle,swimming or attending water aerobics class anddancing also will help to maintain blood pressure.

c. Diet

Balanced and hygienic food, proper food habits, avoiding jung foods, also keep our general health in tact. Nutrients useful to lower blood pressure are potassium, magnesium, and vitamin D. Nutrients useful for vascular health care are vitamin E, C & B3.

- Potassium rich foods include coconut water, beans, dark leafy greens, potatoes, squash, yogurt, fish, avocados, acorn squash, mushrooms, wild-caught salmon, bananas, and pomegranate seeds.
- Magnesium rich foods are Spinach, Chard, Pumpkin Seeds, Yogurt, Almonds, Black Beans, Avocado, Figs, Dark Chocolate, fish (salmon, mackerel & halibut) and Banana.
- Vitamin D rich foods include Salmon, Mushrooms, Beef Liver, Eggs, Milk, Yogurt, Butter, and Orange Juice.
- Vitamin E rich foods include Sunflower Seeds, Spinach, Peanuts, Broccoli, Asparagus, Almonds, Sweet Potato, Avocado, Wheatgerm, Palm Oil, Butternut squash, Trout, and Olive oil.
- Vitamin C rich foods include Oranges, Red Peppers, Kale, Brussels Sprouts, Broccoli, Strawberries, Grapefruit, Guava, Kiwi, Green Peppers, Peas, and Papaya.
- Niacin (vitamin B3) rich foods include Turkey, Chicken breast, Peanuts, Mushrooms, Liver, Tuna, Green peas, Grass-fed Beef, Sunflower seeds, Kidney Beans, Bell Peppers, and Avocado.and
- Proper exposure to sun light.

In addition to that we can reduce the problem of hyper tension more effectively by cutting down sodium salt intake and increasing potassium-containing vegetables, fruits, nuts, seeds, legumes,milk and milk products, meat, fish and poultry foods and coconut water.

d. Alternative therapy

- Yoga

Constant practice of morning and evening for fifteen minutes certain yogasanas may balance high blood pressure namely savasana, sethu bandasana, vibaritha karani, vajrasana and padmasana

- Mudra

Constant practice of morning and evening for fifteen minutes, certain hand mudras such as apana vayu mudra, akash mudra, Gnana mudra, prana mudra may balance high blood pressure.

- Acupressure points

Constant practice of morning and evening by stimulating the meridians for three minutes namely LI 4 (hand web), LV 3 (Leg web), K1(back of foot below the middle finger), GB-20 (below the base of the skull both sides), CV-12 (four cun above the naval point), LI 11 (Outer crease of the elbow), SP 6 (just above the crown of the inner ankle) and ST 36 (below the bottom of the knee cap and one thumb width out side of the leg)

- Relaxation technique of meditation

we can relax our body while in savasana telling that "my toes are relaxed, my feet are relaxed, my ankles are relaxed, my knees are relaxed, my hip is relaxed, my abdominal muscles such as kidney and urinary bladder are relaxed, my liver and gall bladder are relaxed, my small intestine and large intestine are relaxed, my stomach and spleen are relaxed, my pancreas is relaxed, my diaphragm is relaxed, my lungs are relaxed, my heart is relaxed, my pericardium is relaxed, my triple warmer is relaxed, my central nerve system is relaxed, my chest is relaxed, my shoulders are relaxed, my hands are relaxed, my neck and throat are relaxed, my head is relaxed, my brain is relaxed, my eyes are relaxed, my nose and mouth are relaxed and my ears are relaxed. My body and all its organs, bones, muscles, nerves, tissues and cells are relaxed. This technique

may also be practiced while we sit in sukkasana sukkasana means comfortable way of sitting on the ground or chair[9].

Hypo blood pressure: Low blood pressure is the condition where vital organs such as heart, brain, kidney and other organs receive inadequate oxygen and nutrients due to insufficient blood pressure. It may bedue to hormonal changes, widening of blood vessels, medicine side effects, anemia, heart, & endocrine problems,severe infection, allergic reaction, nutritional deficiency, and neurological disorder.

Risk of Hypo blood pressure

1. Dizziness or light-headedness
2. Fainting
3. Sleepiness.
4. Palpitations (a rapid, or irregular, heartbeat)
5. Lack of concentration or confusion
6. Blurred vision
7. Nausea
8. Cold, clammy, pale skin
9. Rapid, shallow breathing
10. Fatigue or weakness
11. Depression
12. Thirst
13. Breakage of bones due to fall
14. Stroke and other cardiovascular diseases.

Remedial measures for hypo blood pressure

Diet: Along with healthy diet with increased sodium intake raisins, almonds milk,juice made up of tulsi, beetroot, carrot, lemon, ginger and rosemary help to increase blood pressure. And also follow the below said suggestions to mange normal blood pressure.

Drink more liquids, avoid alcohol,take coffee moderately, use compression stockings,be slow in the activities,sleeping slightly head elevated position, managing proper leg movements and emotions.

Alternative medicine

1. **Herbs:** Some herbals may be used to overcome low blood pressure such as Turmeric, Cinnamon, Ginger, Pepper, Cardamom, Ashwagandha, and Indian spikenard.
2. **Yoga:** Constant practice of morning and evening for fifteen minutes of certain yoga asanas such as Uttanasana, Adho Mukha Svanasana, Supta Baddhakonasana, Viparita Karani, Savasana and pranayamas may be useful to over come low blood pressure.
3. **Acupressure:** The following acupressure points may be stimulate to overcome the problem of low blood pressure : LV 3 (Leg web), SP 6 (just above the crown of the inner ankle), ST 36 (below the bottom of the knee cap and one thumb width out side of the leg), CV 6(1.5 cun below the naval point) and H 7(located directly in line with the inside of the little finger at wrist)
4. **Hand Mudra:** Constant practice of morning and evening for fifteen minutes of certain mudras such as prana mudra, apana mudra and linga mudra may help to overcome lower blood pressure.

Conclusion

Health education and awareness among the people on communicable and non-communicable diseases and their causes and consequences of the diseases may be helpful to keep health in tact. The ideal condition of natural way of life makes man happy and keep them in harmony. But, in the modern society due to life style disorder, unhygienic environment, social economic responsibilities and obligations, deviate the people from happiness and healthy life. Therefore, it is indispensable for us to practice yogasana, meditation, hand mudra and acupressure and content, selfless and ethical life may normalize blood pressure which inturn help us to overcome the problem of any non-communicable diseases.

Discussion

Now–a–days due to complicated health issues not only increase medical expenditure in the total family budget but also reduce work hours, productivity and make people frustrated and unhappy. Of late, number of deaths due to non-communicable diseases increases and makes medical expenditure recurring in nature forever. As the problems of hypertension and hypo tension are the root cause of many dangerous non-communicable diseases, it is pertinent to arrest them with the combined efforts of conventional and alternative medicines. Definitely, the alternative way of treatment may complement the conventional treatment more effectively.

An Analysis of Health Status in Tamil Nadu

R. Premalatha[1], S. Thangamayan[1], S.N. Sugumar[2], S. Chandrachud[3]

[1]Assistant Professor, Department of Economics, VELS Institute of Science, Technology and Advanced Studies, (Deemed to be University), [2]Professor & Head, Department of Economics, VELS Institute of Science, Technology and Advanced Studies, [3]Professor, Department of Economics, VELS Institute of Science, Technology and Advanced Studies, Chennai

Abstract

Health services are an important indicator to understand the healthcare delivery provisions and mechanisms in the State and are subdivided into three categories viz. primary, secondary and tertiary health care systems. Nutritional status is one of the indicators of the overall well being of population and human resources development. Malnutrition is the cumulative effect of factors like poverty, inadequate access to food, illiteracy, large size of families, poor environmental sanitation, lack of basic minimal health care, lack of personal hygiene, lack of easy access to adequate safe drinking water and lack of awareness. In this study eighteen determinants, namely number of Primary Health Centers, population per bed ratio, number of doctors and nurses in primary health centre, population per doctor ratio, female literacy rate, per capita food availability, PHC per million population, per capita income at current prices, public health expenditure, literacy rate, employment in organized sector, provision of drinking water villages covered, couple protection rate, fertility rate, sex ratio, density of population, beds and hospitals are taken as determinants of health status in Tamil Nadu. The study period is 15 years from 2002-03 to 2016-17. The first objective of the present study, namely, to study the levels of health in the study area is based entirely on secondary statistics.

Keywords: *Health, Indicators, Life Expectancy.*

Introduction

Good health is an essential pre-requisite which contributes significantly both to the improvement in labour productivity and human resource development. Considerable achievements have been made in Tamil Nadu in health indicators like life expectancy at birth, infant mortality rate and maternal mortality rate. Among the major States Tamil Nadu ranks 'fourth highest' in terms of life expectancy at birth, 'second lowest' next only to Kerala in terms of infant mortality rate and birth rate, 'third lowest' in terms of maternal mortality rate and 'tenth lowest' in terms of death rate. Small pox, polio and guinea worm have been eradicated. Life Expectancy at Birth indicates the average number of years that a newborn is expected to live if current mortality rates continue to apply.[1] with the improvements in the prevention and control of major childhood infectious diseases, nutritional status, housing condition and modern medical care resulted in an increase in life expectancy in the State.

Health Care Institutions in Tamil Nadu: Health services are an important indicator to understand the healthcare delivery provisions and mechanisms in the State and are subdivided into three categories viz. primary, secondary and tertiary health care systems. The Primary Healthcare System consists of Primary Health Centre (PHCs) and Health Sub-Centre (HSCs). Secondary healthcare system comprises of District Head Quarters Hospitals, Taluk Hospitals, Women and Children Hospitals, Dispensaries, Mobile Medical Units, Police Hospitals and Non-Taluk Hospitals etc., Tertiary healthcare system covers multi-specialty hospitals[2]. In addition to Government efforts, the private sector is also contributing to the provision of Health Care Services. In the absence of data relating to private sector health services, an attempt has been made to assess only the efficacy of Government healthcare system.

Indian System of Medicine: Indian System of Medicine (ISM) encompasses not only Siddha, Ayurveda, Yoga and Naturopathy but also Unani and Homoeopathy systems. The increasing cost of medicine in Modern System and the incidence of toxicity with

associated side effects have once again highlighted the need importance and relevance of traditional system of medicine in the world

Nutrition: Nutritional status is one of the indicators of the overall well being of population and human resources development. Malnutrition is the cumulative effect of factors like poverty, inadequate access to food, illiteracy, large size of families, poor environmental sanitation, lack of basic minimal health care, lack of personal hygiene, lack of easy access to adequate safe drinking water and lack of awareness.[3] The manifestations of malnutrition could be seen in the prevalence of specific nutrient-deficiency disorders such as protein-energy malnutrition, anemia night blindness, goitre, susceptibility to a number of infectious diseases, low birth weight of children, high IMR and MMR, lack of resistance to illnesses among mothers and children, growth retardation (both physical and mental) and stunting among toddlers.

Trends in Indicators of Health: In the present study four health variables, namely, life expectancy at birth, birth rate, death rate and Infant mortality Rate are used for measuring the levels of health status in Tamil Nadu. These health variables are known as health indicators. The health indicators are influenced by many determinants. In this study eighteen determinants, namely number of Primary Health Centers, population per bed ratio, number of doctors and nurses in primary health centre, population per doctor ratio, female literacy rate, per capita food availability, PHC per million population, per capita income at current prices, public health expenditure, literacy rate, employment in organized sector, provision of drinking water villages covered, couple protection rate, fertility rate, sex ratio, density of population, beds and hospitals are taken as determinants of health status in Tamil Nadu. The study period is 15 years from 2002-03 to 2016-17. The first objective of the present study, namely, to study the levels of health in the study area is based entirely on secondary statistics. They are collected from various statistical reports, published by Government of Tamil Nadu, Directorate of Medical and Rural Services, Chennai, Directorate of Public Health and Preventive Medicine, Chennai, Directorate of Family Welfare, Chennai Department of Economics and Statistics, Chennai Joint Directorate of Health and Medical Services, School Health Programme mainly emphasizes on providing comprehensive healthcare services to all students studying in Government and Government aided schools. Under this programme care has been taken to identify heart diseases, eye disorders, nutritional disorders, skin diseases and dental problems.[4] The students those indentified with problems and need of higher medical treatment are referred to higher medical institution.

Objectives of the Study:

1. To analyze the health status in Tamil Nadu.
2. To examine the health care expenditure in Tamil Nadu.

Staement of the Problem: Tamil Nadu has performed well in health sector when compared with other states in India. Tamil Nadu is the leading state in implementing various government health programmes as per the observations made by UNICF AND WHO. The studies on health status in Tamil Nadu show the rosy picture of the health status in the state are based on aggregates and they conceal rather than reveal the inequalities that exist in the health conditions in the state.

Tools of Analysis:

- Simple Regression Model
- Method of Least Squares
- Multiple Regression Model

Indicators of Heath in Tamil Nadu: Table 1 reveals various data related to life expectancy, birth rate, death rate and infant mortality rate in Tamil Nadu for the period from 2002-03 to 2016-17.

Table 1: Indicators of Health in Tamil Nadu for the Period from 2002-03 to 2016-17

Year	Life Expectancy	Birth Rate	Death Rate	IMR
2002-03	64.09	20.3	8.0	54
2003-04	64.10	19.5	8.0	53
2004-05	64.14	19.0	8.0	53
2005-06	64.29	19.2	8.5	53
2006-07	65.31	19.3	8.0	52
2007-08	65.41	19.3	7.9	51
2008-09	65.09	19.1	7.6	49
2009-10	65.11	18.5	7.7	44
2010-11	65.15	18.3	7.6	43
2011-12	66.22	17.1	7.5	41
2012-13	67.11	16.5	7.4	37
2013-14	67.21	16.2	7.5	37
2014-15	67.31	15.8	7.2	35
2015-16	67.75	16.0	7.4	31
2016-17	67.98	16.3	7.6	28

Table 2: The Results of Trends in the Indicators of Health in Tamil Nadu for the Period from 2002-03 to 2016-17

Sl. No.	Health Indicators	Coefficients		R^2
		a	b	
1.	Life Expectancy at birth	63.3587	0.661* (11.948)	0.917
2.	Birth rate	20.6152	-0.3235* (-10.269)	0.890
3.	Death rate	8.2123	-0.0607* (-4.998)	0.657
4.	Infant Mortality Rate	66.7430	-1.1034* (-4.257)*	0.582

Source: Computed from secondary data.

From Table 2 the trend and the annual rate of change of four health indicators have been observed. Life expectancy at birth has registered an increasing trend and its annual rate of changes is, 0.661. The birth rate, death rate and infant mortality rate have shown a declining trend, with the annual rate of changes being-0.3235,-0.0607 and-1.1034 respectively. All these rates are significant statistically.

Table 3: Health Determinants in Tamil Nadu for the Period from 2002-03 to 2016-17

Year	Number of PHCs + HSCs	Population per Bed ratio	Number of Doctors + Nurses	Population per Doctor Ratio	Female Literacy Rate	Per capita food availability (in Kgs)
2002-03	10106	1926	22262	20511	55.41	143.00
2003-04	10102	1954	23354	20698	56.77	167.20
2004-05	10099	1977	22416	20784	58.12	107.40
2005-06	10090	1995	22470	20853	59.48	114.90
2006-07	10091	2031	22504	20978	60.84	133.00

Source: Computed from secondary data.

Determinants of Health in Tamil Nadu: From the Table 4 it has been revealed that in terms of determinants in Tamil Nadu, all the determinants were significant except one determinant namely per capita food availability which has not recorded any significant trend. All others have shown significant and positive trends except PHC per million populations and the fertility rate which are favorable to improve the health status. Among the 18 selected determinants, 15 determinants have significant and positive trends. Per capita income at current prices, public health expenditure, and provision of drinking water villages covered, have shown the highest growth rate; whereas female literacy rate, literacy rate, couple protection rate, sex ratio and number of hospitals have shown the lowest growth rate. The growth rate of other determinants was moderate during the study period in the state. The favorable and unfavorable monsoons during the study period resulted in fluctuations in food production and output. This was the reason for insignificant and negative trend in per capita food availability in the state. Secondly, PHC per million populations was statistically significant and its growth was marginally negative. Thirdly the fertility rate had also negative trend which exhibited the awareness of people in small family norms. Per capita income at current prices in the state had increased from Rs.7352 to Rs.18314 that is, a two fold increase during the study period.[5]

Determinants of Health Status: In this section, an attempt has been made to analyze the influence of the determinants on the health indicators, in the study area from 2002-03 to 2016-17, using secondary data collected for Tamil Nadu State. Four important health indicators are selected to evaluate the health status. They are (i) life expectancy at birth, (ii) birth rate, (iii) death rate and (iv) infant mortality rate. Secondary data were collected for the selected 18 health determinants. Several

combinations of determinants were tried, taking into consideration, the interrelation among the determinants and suitable models were arrived at. Hence out of 18 determinants, only 10 health determinants are used for the purpose of analysis.

To analyze the influence of first six determinants on health status namely life expectancy and birth rate in the study area, a multiple regression model of the following formula has been used.

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \beta_4 X_4 + \beta_5 X_5 + \beta_6 X_6 + U$$

It is estimated by the method of least squares separately for Tamil Nadu. The study period is about 15 years from 2002-03 to 2016-17. The computed results are in the Table 4 for life expectancy.

Table 5: Results of Multiple Regression Analysis for Tamil Nadu Life Expectancy at Birth

Variables	Parameter Estimates Tamil Nadu
Intercept	0.781
X_1	-2.941* (-3.110)
X_2	0.048 (0.101)
X_3	1.214 (1.018)
X_4	0.162 (0.311)
X_5	0.241 (1.041)
X_6	-5.271 (-0.816)
R_2	0.939
No. of observations	15

Source: Computed from secondary data.

From Table-5 it has been inferred that the number of PHCs and HSCs was significant and influencing the life expectancy at birth at state level. The number of PHCs and HSCs, the number of doctors and nurses, and per capita food availability were significant with marked influence on the life expectancy at birth at District level.

Conclusion

There is much that other states can learn from Tamil Nadu's public health system. Tamil Nadu's system is replicable in other states because its administrative foundations are similar to those of most other states.[6] As in other states, Tamil Nadu's health department is headed by an IAS officer and staffed at state and district levels by medical officers. While the general problems affecting a state bureaucracy do affect Tamil Nadu's health department, the very existence of a specialized cadre with a clear, focused mandate, means that it is much better placed to protect public health than a more generalized and many of the health targets are still remained unachieved.

An Analysis of Industrial Labourer in India with Special Reference to Tamil Nadu

S. Saravanan[1], S. Thangamayan[1], S.N. Sugumar[2], S. Chandrachud[3]

[1]Assistant Professor, [2]Professor and Head, [3]Associate Professor, Department of Economics, VELS Institute of Science, Technology and Advanced Studies, Pallavaram, Chennai

Abstract

Labour markets play a significant role in determining the success of the economic restructuring policies and their impact on the population. The social aspects of minimum wage and job security regulations are necessary to promote the welfare of the workers. Rapid growth of employment and real wages should be of primary interest to workers in any country. They are also justified in view of varying conditions of demand and supply and varied job requirements like skill, knowledge, aptitude, ability, experience etc. but the object of the government is to minimize income inequalities and inequalities in the distribution of wealth. Human Resource managers are expected to understand these varying approaches because they provide them theoretical underpinnings for much of the role of Human resource management. The three popular approaches to industrial relation are unitary approach, pluralistic approach, and Marxist approach. This reflects that no proper implementation of rules and monitoring authorities is apparently found with industries. The analysis Age-wise distribution of workers revealed that 32.22 per cent of workers belong to the age group of 21 to 30 years followed by 25.56 per cent of workers in the age group of 31 to 40 years. This indicates that 57.78 per cent of the workers fell in the age group of 21 to 40 years in all the three category of industries.

Keywords: *Industrial Labour, Employment, wages.*

Introduction

Labour markets play a significant role in determining the success of the economic restructuring policies and their impact on the population. The social aspects of minimum wage and job security regulations are necessary to promote the welfare of the workers. Rapid growth of employment and real wages should be of primary interest to workers in any country.[1] An international comparison involving countries South Asia, East Asia, Latin America and the developed world reveals that over the last 25 years or so. While employment and real earnings per employee in the manufacturing sector have risen only slowly in India, the performance of the East Asian countries has been most outstanding in this respect. The rapid growth of employment and real earnings per employee in East Asia is the combined result of labour policies along with a whole range of successfully implemented export orientated industrialization policies which yielded rapid GDP growth. Wages and employment are two variables which vitally affect the economic well-being of a substantial segment of population of any nation.[2] it is worthwhile to take a look at the place occupied by wages and employment in major schools of economic thought. If one takes a broad sweeping view of economic theory as it has evolved over time, one can discern at least five types of approaches to the issues of wages and employment determination. Wage differentials on the basis of occupations, units and areas (when real wages are taken into account) can be justified on the basis of equal pay for equal work among workers. They are also justified in view of varying conditions of demand and supply and varied job requirements like skill, knowledge, aptitude, ability, experience etc. but the object of the government is to minimize income inequalities and inequalities in the distribution of wealth.[3] Thus wage differentials are not desirable in a socialistic pattern of society. However, formulating uniform wage policy ignoring differences in individual Skills, knowledge etc., units ability to pay, varying living costs in different regions, varying demand and supply conditions, differences in occupations etc., is practically not possible. Hence, a compromise between uniform wage policy and wage differentials has to be

developed in view of the principle of socialistic pattern of society Inter-personal, inter-unit, inter occupational differentials are more predominant in unorganized sector of Indian economy. But even in organized sector and public sector units, wage differentials are quite common. But the tendency appears to be towards minimization and regularization of personal wage differentials and to narrow down the gap between maximum and minimum wage in a unit. [4]

Structure of Minimum Wages in Tamilnadu

Table 1: Comparative Minimum Wages Rates Across States in Tamilnadu (in Rs.)

Sl. No.	Industries	Rates as on 31.12.2004	Rates as on 15.11.2010
1.	Spinning, Printing, dyeing	57.40	170.72
2.	Power loom	59.25	81.91
3.	Finishing, bleaching	98.54	170.72

2. Department of Labour and Employment, Tamil Nadu, 15.11.2010

Industrial Labour Relations: Existence of conducive labour relations is critical for promoting economic development in general and industrial development in particular. A study of data on number of strikes and lockouts in India reveals a declining trend. It is a welcome feature on the industrial front. It augurs well for the Indian economy. The number of man-days lost because of lockouts has continuously been on the decline. In regard to the spatial dispersion of the incidences of strikes and lockouts, it is observed that Gujarat, Andhra Pradesh, kerala, and Rajasthan are the most affected states.[5] among sectors, financial intermediaries (excluding insurance & pension funds) recorded the maximum number of strikes and lockouts)

Table 2: Strikes and Lockouts (Man-Days Lost, in Millions)

Year	Strikers		Lockouts	
	Number	Man-days lost	Number	Man-days lost
2004	236	4.83	241	19.04
2005	227	10.81	229	18.86
2006	243	5.32	187	15.01
2007	210	15.06	179	12.11
2008	250	7.02	182	10.46
2009	91	2.05	31	0.84

Source: Labour Bureau, shimla

Approach to Industrial Relations: The scenario of industrial relations is perceived differently by different people, For some, industrial relations is related to class conflict, others perceive it in terms of mutual co-operation and still others understand it in terms of competing interests of various groups. Human Resource managers are expected to understand these varying approaches because they provide them theoretical underpinnings for much of the role of Human resource management. The three popular approaches to industrial relation are unitary approach, pluralistic approach, and Marxist approach.[6]

Trade Union Membership: As of today, there are more than 66,000 registered unions and most of them are affiliated to one of the other central trade union. Table 3 presents details about the Central Trade Unions, their affiliates, political affiliation, date of establishment and membership claimed.

Trade Union Membership

Table 3: Details of Trade Union Membership in India

Year	No. of Unions Registered	Membership ('000)
1990	52016	7019
1991	53535	6100
1992	55680	5746
1993	55784	3134
1994	56872	4094
1995	57952	6538
1996	58805	5613
1997	59968	7408
2008	66000	8207

Source: Various issues of Labour Year Book-2010.

As Table 3 shows, there has been a steady increase in the number of registered unions, but their membership fluctuated from year to year. The figure slipped to all time low in 1993, but increased in the years that followed.

Industrial Relations

Table 4: Trade Union Facility, Grievance Procedure and Labour Enforcing Authorities of Industrial Workers

Industrial Relations Facility	Number of workers			Total Number of Workers
	Cotton spinning	Cotton weaving and processing	Power Loom

Total	120 (100.00)	120 (100.00)	120 (100.00)	360 (100.00)

Source: Survey data. Note: Figures in parentheses are percentages to respective totals.

Of the 360 selected workers 33 workers have trade union membership and all of them are cotton spinning industries. About 327 workers are not the members of trade union. Since all other industries do not permit any involvement in trade union activity. In the cotton weaving and processing and power loom industries no one gets enrolled himself/herself as member of any trade union. Among the three sample industries out of 360 industrial workers, 41 in cotton spinning, 42 in cotton weaving and processing and 36 in power loom industries follow the prescribed grievance procedures for the redresses of workers Problem. 241 workers opined that no proper grievance procedure is available and practiced in the industries. However, grievances, if any, are settled through mutual discussion between the workers and the management. Table 4 also depicts that the visit of labour enforcement authorities availability among three industries. 147 workers consented that the facility is available, whereas 213 reported that no such labour enforcement authorities visited the industries. This reflects that no proper implementation of rules and monitoring authorities is apparently found with industries. The industrial workers belong to three categories of industries viz. cotton spinning, cotton weaving and processing and power loom industries in the study area. The analysis Age-wise distribution of workers revealed that 32.22 per cent of workers belong to the age group of 21 to 30 years followed by 25.56 per cent of workers in the age group of 31 to 40 years. This indicates that 57.78 per cent of the workers fell in the age group of 21 to 40 years in all the three category of industries. The gender-study of Industrial workers explores that 224 (62.22%) are male and 136 (37.78%) are female workers. It is also to pin point that out of 360 industrial workers 31 are male children workers and 14 are female children workers. This reflects employment of child labour is seen in the industries.

Suggestions

1. The practice of social security measures must be applied to the ground so as to elicit employee motivation and involvement and the consequent gratification. Nothing strokes employee motivation like assured social security measures.
2. Strategic planning and continuous strategy development need to be environment-friendly to be free from the risk of ‘set-up to-fail syndrome’.
3. Industrial workers clamoring for more wages and bonus payment produce the unpleasant effect of disturbing industrial peace and harmony. They must be brought to the mainstream through nurturing a shared vision where intellect and acumen reign supreme along with brawn power.
4. All industrial workers need to own themselves with full freedom to join trade unions to create

the competing values framework of collaboration creation competition and control. Employers and Employees should not prey upon one another.

Conclusion

Labour is the most dynamic agency in the process of production. The inestimable importance of labour in terms of its productivity has been emphasized with the appearance of the Robinsian Scarcity approach to theory of economics. The promotion of economic development through flexibility and swiftness of production hinging on this indispensable agency has therefore become conspicuous in itself.[7] Industrial establishments need to be aware of the imminent cleavages between the employers and employees resulting from preventable factors such as factious labours, dullness of morbidity of labourers resulting from lack of fluidity of market factors, unpleasant spread among the stages of production resulting in dehumanizing labour and rendering it more and more mechanical.

An Analysis of Tax Revenue and Non Tax Revenue in Tamil Nadu

S. Thangamayan[1], R. Premalatha[1], B. Chithirai Rajan[1], Telu Suvarna[1], S.N. Sugumar[2], S. Chandrachud[3]

[1]Assistant Professor, Department of Economics, VELS Institute of Science, Technology and Advanced Studies, (Deemed to be University) Chennai, [2]Professor & Head, Department of Economics, VELS Institute of Science, Technology and Advanced Studies, Chennai, [3]Professor, Department of Economics, VELS Institute of Science, Technology and Advanced Studies, Chennai

Abstract

The State Governments maintain law and order, administer justice, build up social and economic infrastructure and ensure a social safety net for the poor. Tamil Nadu has been subsidizing the provision of power, food, health services and nutrition and education with the overall welfare perspective in mind. The Consolidated Fund is the principal head in which resources flow and expenditures are incurred under the Revenue Account and Capital Account of the Fund. There was a turn round in the Revenue Account from deficit to surplus because Revenue Receipts exceeded the Revenue Expenditure during 2011-12. Non-Tax Revenue is comprised of State's Own Non-Tax Revenue and Grants-in-Aid from the Central Government. Grants-in-Aid accounted for 54 percent and State's Own Non-Tax Revenue 46 percent. There was a fall in non-tax revenue during 2009-10 because of the decline in the quantum of grants-in-aid from the Centre as well as the receipts from own non-tax revenue. Among these two components' the decline was more pronounced in grants-in-aid (22.7%) as compared to own non-tax revenue receipts (12%). In the subsequent years, non-tax revenue registered increases ranged between 0.6 percent in 2012-13 to 29.9 percent in 2013-14. The main problem of Tamil Nadu is that the growth rate of Tax Revenues is very slow growth. In the backdrop of sluggish economic growth that witnessed both at all India and in Tamil Nadu, the 12th Five Year Plan as well as Annual Plan had been formulated in the State. All India had an average growth rate of 8 percent during the same period.

Keywords: *Tax Revenue, Non-Tax Revenue, Economic Development.*

Introduction

In a growing economy the role and functions of the State Government have been expanding both in terms of more extensive coverage and in terms of intensity. The responsibility of delivering many resources intensive public services is vested with the State Governments which are also closer to the people. The State Governments maintain law and order, administer justice, build up social and economic infrastructure and ensure a social safety net for the poor. Tamil Nadu has also been subsidizing the provision of power, food, health services and nutrition and education with the overall welfare perspective in mind. The Consolidated Fund is the principal head in which resources flow and expenditures are incurred under the Revenue Account and Capital Account of the Fund. There was a turn round in the Revenue Account from deficit to surplus because Revenue Receipts exceeded the Revenue Expenditure during 2011-12.[1] It is the main source of fiscal imbalance with serious implications for public investment and growth of the economy. The revenue surplus in the subsequent period mirrors fiscal correction. It is a change for the better because fiscal situation had really bettered compared to earlier years. However, the slowdown in growth at the all India level has affected the revenue receipts in 2013-14, narrowing the revenue account surplus. The Capital Account deals with assets created in the form of capital expenditure and outstanding loans receivable by the Government. All through the years, it has exhibited a deficit which is desirable as it represents an excess of capital investment over capital receipts.[2] Non-Tax Revenue is comprised of State's Own Non-Tax Revenue and Grants-in-Aid from the Central Government. Grants-in-Aid accounted for 54 percent and State's Own Non-Tax Revenue 46 percent. There was a fall in non-tax revenue during 2009-10 because of the decline in the quantum of grants-in-aid from the Centre as well as the receipts

from own non-tax revenue. During 2009-10 and 2010-11 the receipts from State's own non-tax revenue had declined. The fall in 2009-10 was mainly on account of the decline in receipts originated in economic services and in 2010-11 it was mainly due to fall in interest receipts and dividends and profits. According to Dalton, "is concerned with the income and expenditure of public authorities and with the adjustment of one to the other, adjustment not necessarily to equality, but to whatever arithmetical relationship. A series of additional resources mobilization measures taken by the State has helped to sustain and improve its own tax revenue base.[3]

Source: Tamil Nadu Economic Appraisal, Various issues, 2011-12.

Growth of Income Taxes of Tamil Nadu: The income tax of Tamil Nadu was Rs.8067 Lakh in 1980-81. It increased and reached Rs.29950 lakhs in 1989-90. The average income tax is Rs.19659 lakh per year. The linear growth rate comes about 30.14 per cent. The index number increased from 100 to 371.26 in 1989-90. The highest annual growth rate registered is 44.38 per cent in the year 1989-90. During the second period 1990-91 to 1999-2000, the Income Tax was Rs.32680 lakhs in 1990-91 and it touched the highest Rs.962223 lakhs in 1998-99 and it decreased Rs.266700 in 1999-2000. Industry is 76416 lakhs per year. The linear growth rate works out to 79.56 per cent. The index number has increased to 816 in 1999-2000. The highest annual growth rate is 586.42 per cent in 1998-99. In 2000-01, the value as income tax is Rs.278375 lakhs and it touched the highest Rs.192865 lakhs in 2010-11. The average of Food Products is Rs.173554 lakhs per year. The linear growth rate comes about-3.41 per cent. The index number has come declined 69.28 in 2010.11. The highest annual growth rate registered is 35.47 per cent in 2004-05.

Growth of Land Revenue of Tamil Nadu: The land revenue of Tamil Nadu was Rs.434 lakhs in 1980-81. It increased with fluctuations and reached Rs.2591 lakhs in 1984-85 and touched the highest Rs.1382 lakhs in 1989-90. The average land revenue is Rs.1312 lakhs per year. The linear growth rate comes about 24.27 per cent. The index number increased from 100 to 318 in 1989-90. The highest annual growth rate registered is 308.67 per cent in the year 1984-85. During the second period 1990-91 to 1999-2000, the land revenue was Rs.1443 lakhs in 1990-91 and it touched the highest Rs.6031 lakhs in 1997-98 and it declined touched Rs.4723 lakhs in 1999-2000. The average was Rs.3558 lakhs per year. The linear growth rate works out to 25.25 per cent. The index number has increased to 882 in 1999-2000. The highest annual growth rate was percent in 1991-92. In 2000-01, the value as land revenue was Rs.5572 lakhs and it touched the highest Rs.20773 lakhs in 2008-09. The average of Food Products is Rs.14532 lakhs per

year. The linear growth rate comes about-3.03 per cent. The index number has come upto 322.11 in 2005-06. The highest annual growth rate registered is 311.44 per cent in 2004-05.

2013-14	7857.34	19.9	46.3	6.7	0.9

Source: Budget Documents, Government of Tamil Nadu.

Non-Tax Revenue: Non-Tax Revenue is comprised of State's Own Non-Tax Revenue and Grants-in-Aid from the Central Government. Grants-in-Aid accounted for 54 percent and State's Own Non-Tax Revenue 46 percent. There was a fall in non-tax revenue during 2009-10 because of the decline in the quantum of grants-in-aid from the Centre as well as the receipts from own non-tax revenue. Among these two components the decline was more pronounced in grants-in-aid (22.7%) as compared to own non-tax revenue receipts (12%). In the subsequent years, non-tax revenue registered increases ranged between 0.6 percent in 2012-13 to 29.9 percent in 2013-14. On an average during the five year period ending 2013-14 the revenue realization from this source registered a growth rate of 6.9 percent. In the State's total revenue receipts the share of non-tax revenue witnessed a steady decline. On an average during the five year period 2009-10 to 2013-14 its share in total revenue receipts worked out to 15.6 percent. It's ratio to GSDP more or less remained constant at 2.0 percent.[4]

Conclusion

It is concluded from the analysis that the Tax Revenues is mounting. The main problem of Tamil Nadu is that the growth rate of Tax Revenues is very slow growth. In the backdrop of sluggish economic growth

that witnessed both at all India and in Tamil Nadu, the 12th Five Year Plan as well as Annual Plan had been formulated in the State. All India had an average growth rate of 8 percent during the same period. The targeted growth rate in Tamil Nadu could not be achieved in all the sectors viz. agriculture, manufacturing and services and this could be attributed to fallout of global economic crisis, erratic and inadequate monsoon rains, rising oil prices, shortage of power and lack of demand in export-oriented industries.[5] Therefore, it is absolutely necessary to speed up the rate of growth of Tamil Nadu economy so as to make the increase the revenue service.

Abstract

This paper focus on Gender is a common term where as gender discrimination is meant only for women, because females are the only victims of gender discrimination. Eleventh plan witnessed economy strength in many dimensions and is well prepared to achieve faster, sustainable and inclusive growth. Twelfth five year plan aims at inclusive growth which should result in lower incidence of poverty, broad-based and significant improvement in health outcomes, universal access for children to school, increased access to higher education and improved standards of education, including skill development. The study of status of women is very much complicated. In a developing nation like India, women's lower status is reflected not only in their work being underpaid, un-recognized, but also in their limited access to productive resources and support services such as health and education. The focus of this paper is on issues concerning gender disparities in the context of India so as to examine the nature of prevalent discrimination and biases against women. It is clear from the above cited information is that our government is keen in feminine advancement. All these schemes have a positive impact on female advancement. Girl baby's birth rate which was considered as negative in many parts of India, government awareness programs had changed this negativity. Infant Mortality Rate (IMR) though has decreased considerably during 2007 to 2016.

Keywords: *Gender discrimination, Women Empowerment, Economic Independence.*

Introduction

Gender is a common term where as gender discrimination is meant only for women, because females are the only victims of gender discrimination. Gender discrimination is not biologically determined but it is determined by socially and the discrimination can be changed by the proper and perpetuate efforts. Denial of equality, rights and opportunity and suppresment in any form on the basis of gender is gender discrimination. India adopted five year planning strategy from Russia to accelerate economic growth. We are now in 12th five year plan (2012-17) its theme is "Faster, more inclusive and sustainable growth". According to the National Sample Survey Report (2011-12), the workforce participation rate of male is 54.4% and female is 21.9%. As per the India Country Report, 2015 by Ministry of Statistics and Program Implementation on the Millennium Development Goals, the percentage share of females in wage employment in the non-agricultural sector during 2011-12 increased to 19.3% which is higher than 18.6% reported during 2009-10 by National Sample Survey Organization. Office of the Registrar General and Census Commissioner and Ministry of Statistics and Program Implementation are involved in collection and dissemination of data covering wide range of issues that affect women's empowerment.[1] The report titled "Women and Men in India–2015" by Ministry of Statistics and Program Implementation, Government of India highlights the status of women covering health, education, work and decision making along with social obstacles in women's empowerment. Eleventh plan witnessed economy strength in many dimensions and is well prepared to achieve faster, sustainable and inclusive growth. Twelfth five year plan aims at inclusive growth which should result in lower incidence of poverty, broad-based and significant improvement in health outcomes, universal access for children to school, increased access to higher education and improved standards of education, including skill development. It should also be reflected in better opportunities for both wage employment and livelihood, and in improvement in provision of basic amenities like water, electricity,

roads, sanitation and housing. Women and children constitute 70% of the population and this twelfth plan aims to give special attention to them in terms of reach of relevant schemes in many sectors. I could say this five year plan took 360 degree measure to empower female gender in all aspects.[2]

Objectives of the Study

1. To understand and analyze gender inequality in India.
2. To suggest cures to reduce gender inequality in India.

Research Methodology: The status of poor women in India can be analyzed by identifying underlying themes that affect their socio-economic development. The study is based on secondary sources of data. The secondary sources like books, journals, magazines and articles have been examined for this study.

Statement of the Problem: Reflects the extent of socio-economic development. Over a period of time that achievements in India's developmental process have been significant. The goal of reducing gender inequality has held a prominent place in international organizations and in national strategy statements.[3]

Data Collection: For the present work, data for the study have been collected from the Statistical Abstract of India and other related documents published by Census of India, and from other world reports on India.

Area of the Study: The study of status of women is very much complicated. In a developing nation like India, women's lower status is reflected not only in their work being underpaid, un-recognized, but also in their limited access to productive resources and support services such as health and education. The focus of this paper is on issues concerning gender disparities in the context of India so as to examine the nature of prevalent discrimination and biases against women.[4]

Results Discussion

Constitution of India not only grants equality to women but also enforces continues measures of positive discrimination in favour of women. Our government always strives for women's advancement in different spheres. In that way 12th five year plan adopted and implemented numerous schemes which focuses on feminie gender equality and female empowerment.[5]

It is clear from the above cited information is that our government is keen in feminine advancement. All these schemes have a positive impact on female advancement. Girl baby's birth rate which was considered as negative in many parts of India, government awareness programs had changed this negativity. Infant Mortality Rate (IMR) though has decreased considerably during 2007 to 2016.

Table 1: Infant Mortality Rate

Year	Female	Male	Total
2012	44	41	42
2013	42	39	40
2014	40	37	39
2015	39	35	37
2016	36	33	34

Literacy rate of girls as also witnessed a remarkable growth in this 12th five year plan which is evident from the below data.

Table 2: Literacy and Education

Indicators	Gender	Ratio
Literacy 2011	Total	73.0%
	Female	64.6%
	Male	80.9%
Gross Enrolment Ratio at Primary level–2015-16	Total	99.2%
	Female	100.7%
	Male	97.9%
Gross Enrolment Ratio at Upper Primary–2015-16	Total	92.8%
	Female	97.6%
	Male	88.7%
Gross Enrolment Ratio at Secondary level–2015-16	Total	80.0%
	Female	81%
	Male	79.2%
Gross Enrolment Ratio atHigher Secondary Level–2015-16	Total	56.2%
	Female	56.4%
	Male	56%

Source: Ministry of Women and Child Development.

Women's mean age at marriage at all India level is 22.1 years and the same in rural and urban areas are 21.6 years and 23.0 years respectively. The women's mean age at marriage has shown an increasing trend in all the major States and at all India level it has increased from 21.2 to 22.1 years during 2011 to 2015. This gives an opportunity for the women to set up their career and be financially independent. For female growth to be inclusive government must create adequate

livelihood opportunities and add to decent employment commensurate. 12th five year plan as sited above has introduced various new schemes and enhanced existing schemes to encourage livelihood opportunities.[6]

In 2011, the Workforce Participation Rate at all India level was 25.51% for females and 53.26% for males. The current work force the number of female entrepreneurs has doubled over

Table 3: Workforce Participation

Participation in Economy		
Labour Force Participation Rate (LFPR) (15+ years) 2015-16	Total	52.40%
	Female	27.40%
	Male	75.50%
Unemployment Rate (15+ years) 2015-16	Total	3.70%
	Female	5.80%
	Male	3.00%
Worker Population Ratio (15+ years) 2015-16	Total	50.50%
	Female	25.80%
	Male	73.30%

Source: Ministry of Women and Child Development

The past ten years to about 10 million mostly due to the rise in enterprises. Their share rose in all sector and women now account large percent in total entrepreneurs.

Table 4: Women Enterprises

Year	Indicators	Registered Sector	Unregistered Sector	Economic Census-2005*	Total
2010-11	No of Women Enterprises (in lakh)	2.15 (13.72%)	-	6.40 (4.34%)	8.55 (18.06%)
2015-16	No of Women Enterprises (in lakh)	2.15 (13.72%)	18.06 (9.09%)	6.40 (4.34%)	26.61 (7.36%)

Source: Ministry of Women and Child Development

Female owned enterprise had experienced a drastic growth in this last five years. This increased female enterprise has positive impact on employment generation results in reduction of income inequalities. Twelfth Plan has to meet the aspirations of millions of young men and women.[7]

Gender Inequality in India: The Ministry of Women and Child Development is administering following schemes for gender equality socio-economic development of women. Swadhar and Short Stay Homes to provide relief and rehabilitation to destitute women and women in distress. Support to Training and Employment Program for Women (STEP) to ensure sustainable employment and income generation for marginalized and asset-less rural and urban poor women across the country. Rashtriya Mahila Kosh (RMK) to provide micro-finance services to bring about the socio-economicupliftment of poor women. National Mission for Empowerment of Women (NMEW) to strengthen the overall processes that promotes all-round Development of Women. Rajiv Gandhi National Creche Scheme for Children of Working Mothers (including single mother) to provide day care facilities for running a crèche of 25 children in the age group 0-6 years from families having monthly income of less than Rs 12,000. One Stop Centre to provide integrated support and assistance to women affected by violence. [8] Scheme for Universalisation of Women Helpline intended to provide 24 hours immediate and emergency response to women affected by violence. In order to strengthen the process of gender budgeting the Ministry of Women and Child Development has been undertaking various capacity building measures for the officials of the State Governments by organizing training programs workshops regularly. In order to improve employability a separate Ministry of Skill Development and Entrepreneurship has been created. Equal Remuneration Act, 1973 provides for payment of equal remuneration to men and women workers for the same work of similar nature without any discrimination.

In order to ensure social security to the workers including women in the unorganized sector, the Government has enacted the Unorganized Workers' Social Security Act 2008. The Maternity Benefit Act, 1961 regulates employment of women in certain establishments for a certain period (12 weeks) before and after childbirth and provides for maternity and other benefits. Indira Gandhi MatritvaSahyogYojana (IGMSY) Scheme is being implemented as Conditional Maternity Benefit for pregnant and lactating women to improve health and nutrition status to better enabling environment by providing cash incentives to pregnant and nursing mothers to partly compensate wage loss both prior to and after delivery. The Sexual Harassment of Women at Workplace (Prevention, Prohibition and Redressal) Act, 2013 has been enacted, which covers all women, irrespective of their age or employment status and protect them against sexual harassment at all workplaces both in public and private sector, whether organized or unorganized.[9]

Conclusion

In nutshell, various welfare programs are implemented by government to secure female gender and in favour of women empower. It is even apt to say that government took 360 degree measure to have positive discrimination for female. This five year plan witnessed remarkable growth in female gender but still there are lots more to overcome, government has to pay more heed to elevate females. Education is the most important way to erase gender inequality. So, steps must be taken in order to promote education among women. Women should be given free education up to post-graduate level. Every girl must get the opportunity to go to school. Sufficient number of seats must be reserved for the eligible women candidates for services in all autonomous institutions, semi-government and government institutions. More police protections should be given around cities and towns especially during nights so that the employed women can move on freely to complete their tasks. More political and decision making power must be given in the hands of women.

Abstract

Organ donation is a process where the organs are surgically removed from one person and being transplanted into other person for the medical purpose. However recent statistic shows that there is a shortfall of organ donation globally. Malaysia's organ donation rate is among the lowest. Malaysia is a country with a multiracial resident which are Malay, Chinese, Indian Buddhism, and Christian. This study analysed knowledge, awareness and attitudes regarding organ donation within each group. The present study was conducted at Shah Alam area in Selangor. A total 369 questionnaires were completed. 73.2% agree to donate organs to different races where Chinese were less willing to do so (19.8%) followed by Malay (23.6%) and Indian (29.8%). About 48.5% of the respondents had a good knowledge where Malay is the highest (18.2%) and Indian is the lowest (13.8%). Meanwhile the level of attitudes shows no significant difference among the races with p=0.271. Fortunately, 96.7% of the respondents are aware about the allowance of each religion in organ donation. Unwillingness to donate organ has been influenced by culture-religious perceptions and concrete beliefs towards medical system. So, identifying the barriers and education to the community are of utmost need to overcome the shortage.

Keywords: *Organ donation, Knowledge, Awareness, Attitude and Population etc.*

Introduction

Organ donation is an effective way to save life and it became the standard procedure to cure lives of the patients that have the chance to survive. Most organ and tissue donations occur after the donor has died with the consent of the next of kin, some organs can be donated while the donor is alive. Organ donation is usually the only option of treatment in many end organ diseases.

Nevertheless, the shortage of organs has become a worldwide concern since the demand exceeds the number of donors. Despite that, the highest organ donation rate in the world is in Spain, with 31.5 donors per one million people, other European countries have a mean of 15 donors per one million people.[1] Higher education, younger age and factors associated with political affiliation determined respondents' willingness to donate organs, and consent was given to donors' relatives.[2]

Materials and Method

Data Collection: Self-conducted questionnaires were distributed among 369 respondents to obtain data on respondents' knowledge, awareness and attitude. The ranges on level of knowledge and attitude were categorized using scoring scheme. For level of knowledge, (0-4= Poor, 5-8= Moderate and 9-13=

Good) meanwhile for level of attitude, (0-4=Poor, 5-8= Moderate and 9-12= Good).[3]

Data Analysis: Data obtained during the study was analyzed by using Statistical Package for Social Science (Version 23). The descriptive statistics,frequency and percentage had been used in presenting the result, which was used to analyze the knowledge, awareness and attitude. In order to check for association between socio-demographic variables, Chi-square test had been used. Later, the results were presented in words and depicted in tables & graph.

Results

In this study, 380 respondents were approached for participation but only 369 questionnaires were managed to be collected (98% response rate). The frequency analysis of each socio-demographic data has been tabulated in **Table 1.**

Table 1: Frequency Distribution Table of Demographic Data of Respondents

Variable	Answer	Frequency	
		n	%
Age	<40 years old	308	83.5
	>40 years old	61	16.5
Gender	Male	141	38.2
	Female	228	61.8
Level of education	Primary	4	1.1
	Secondary	65	17.6
	Diploma/equivalent	92	24.9
	Degree/equivalent	189	51.2
	Master/phd	14	3.8
	Informal education	5	1.4
Religion	Muslim	123	33.3
	Buddha	83	22.5
	Hindu	109	29.5
	Christian	54	14.6
Ethnicity	Malay	123	33.3
	Chinese	123	33.3
	Indian	123	33.3

As shown in table-1, the age group of less than 40 years was the highest at 83.5% compared to the age group of more than 40 years at 16.5%. The percentage of female respondents (61.8%) was higher than males (38.2%). The percentage of the degree holder is the highest at 51.2% followed by diploma at 24.9%, secondary schools at 17.6%, master at 3.8%, informal education at 1.4% and lastly primary school at 1.1%. In term of religion, Muslim respondents was the highest at 33.3% followed by Indian at 29.5%, Buddha at 22.5% and Christian at 14.6%. In this study, the prevalence of each ethnicity is same which is one hundred and twenty-three participants (33.3%).

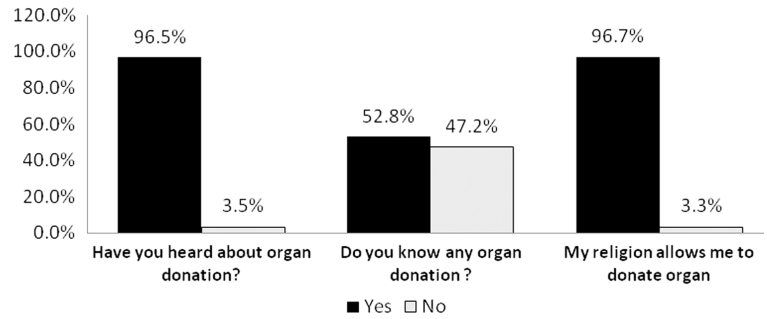

Figure 1. Awareness Component of Organ Donation

Level of Knowledge & attitude Regarding Organ Donation: With regards to level of knowledge, a score out of 13 has been categorized into levels where a score 0-4 indicates 'Poor knowledge', 5-8 indicates 'Moderate knowledge' and 9-13 indicates 'Good knowledge' about organ donation. Out of 369 respondents, 179 (48.5%) achieved good knowledge while 164 (44.4%) had moderate knowledge and 26 (7%) had poor knowledge. Malay is the highest at 54.5% had good knowledge followed by Chinese at 49.6% and Indian at 41.5%. This finding is different with the previous study where Malay showed the least percentage of being good in knowledge regarding organ donation (Table 2)

Chinese	61	16.5	48	13.0	14	3.8	
Indian	51	13.8	66	17.9	6	1.6	

In this study, level of education, religion and ethnicity were found out to have a significant association with level of knowledge regarding organ donation. (Education: p-value=0.036, Religion: p-value=0.043, Ethnicity: p-value=0.030) and there is no significant association between age and gender with the knowledge on organ donation. Besides in Figure 2, it could be seen that Muslims show the highest percentage at 34% followed by Hindus at 29%, Buddhist at 23% and Christian at 14%.

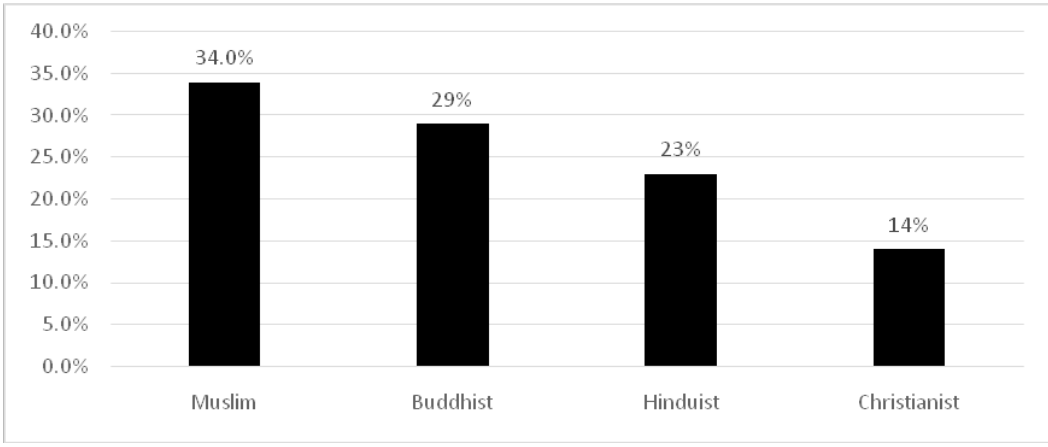

Figure 2. Allowance of Organ Donation Regarding Religion

With regards to level of attitude, a score out of 12 has been categorized into levels where a score 0-4 indicates 'Poor attitude', 5-8 indicates 'Moderate attitude' and 9-12 indicates 'Good attitude' about organ donation. Out of 369 respondents, 313 (84.8%) achieved good attitude while 54 (14.6%) had moderate attitude and 2 (0.5%) had poor attitude. Out of our ethnic groups Indians shows positive attitude at 111 (30.1%) followed by Chinese at 103 (27.9%) and Malay at 99 (41.5%. However in poor level, it stated that Chinese and Malay are at the highest percentage (0.3%) meanwhile Indians show no prevalence of poor knowledge. (Table 3).

Table 3: Socio-Demographic Data Associated with Attitude on Organ Donation

Independent Variables	Agree		Disagree		Neutral		p-value
	n	%	n	%	n	%

Christian	31	8.4	8	2.2	15	4.1	
Race							
Malay	69	18.7	22	6.0	32	8.7	0.001*
Chinese	60	16.3	38	10.3	25	6.8	
Indian	106	28.7	7	1.9	10	2.7	

In this study, none of the socio-demographic variables were found out to have a significant association with level of attitude regarding organ donation. Table 4 shows the proportion of respondents with good, moderate and poor knowledge in relation to the socio-demographic variables.

Relationship between Socio-demographic variables with the Willingness on Donating Organ: Based on the finding out of 369 respondents, 235 (63.7%) agreed to donate their organ meanwhile those who disagree and neutral towards the willingness are 67 (18.2%) respectively. It has been established that less than 40 years old respondents have high anticipation to donate organ at 55% compared to the elder group of age and in terms of gender, females show high anticipation 39.3% than males. In terms of education, degree holder respondents show the highest anticipation at 32.5%.

In this study, it can be seen that Hindus show the highest anticipation of willingness to donate organ at 26.3% compared to Chinese and Malay and this finding was similar with the previous study (Loch et al). In term of ethnicity, Indians were the highest in willingness to donate organ at 106 (28.7%) compared to Chinese at 38 (10.3%).

Table;4: Socio-demographic Variables Associated with the Willingness on Organ Donation

Independent Variables	Good		Moderate		Poor		p-value
	n	%	n	%	n	%	
Age							
<40 years old	263	71.3	43	11.7	2	0.5	0.594
>40 years old	50	13.6	11	3.0	0	0.0	
Gender							
Male	123	33.3	17	14.6	1	0.3	0.519
Female	190	51.5	37	10.0	1	0.3	
Level of Education							
Primary	4	1.1	0	0.0	0	0.0	
Secondary	56	15.2	9	2.4	0	0.0	
Diploma/equivalent	78	21.1	12	3.3	2	2.2	0.618
Degree/equivalent	158	42.8	31	8.4	0	0.0	
Master/Phd	13	3.5	1	0.3	0	0.0	
Informal education	4	1.1	1	0.3	0	0.0	
Religion							
Muslim	99	26.8	23	6.2	1	0.3	
Buddha	69	18.7	14	3.8	0	0.0	0.130
Hindu	101	27.4	8	2.2	0	0.0	
Christian	44	11.9	9	2.4	1	0.3	
Ethnicity							
Malay	99	26.8	23	6.2	1	0.3	
Chinese	103	27.9	19	5.1	1	0.3	0.271
Indian	111	30.1	12	3.3	0	0.0	

Based on Table 4, it can be found that socio-demographic variables of age, religion and ethnicity have a significant association with the willingness to donate organ where (Age: p value: 0.001, Religion: p value: 0.001, Ethnicity: p value: 0.001). In addition, the socio-demographic variables of gender and level of

education do not significantly affect the respondent's willingness to donate their organs.

Discussion

Level of Knowledge Regarding Organ Donation: Firstly, in regards with knowledge, we believe that it has an association with the willingness towards organ donation and other study have confirmed it.[4] In this study, most of the respondents have a good knowledge. The existed studies stated that awareness regarding organ donation has an association with the level of knowledge as seen inYiieHuern S, et al.[5]The health care providers were the right source of information to spread the importance of organ donation since they are informed about organ donation, similar toAgarwal S; 2015[6] There is a significant association between the socio-demographic variables of level of education (p=0.036), religion (p=0.043) and ethnicity (p=0.030) with knowledge on organ donation (Table 1).

Level of Attitude Regarding Organ Donation: The attitude towards organ donation has influenced on the rate of organ donation in the communityas observed inVijayalakshmi AP et al.[7]Based on Table 2, 313 of the respondents which more than half show a positive attitude regarding organ donation. In this study, none of the socio-demographic variables have significant association with attitude regarding organ donation, because there are no vast differences among each variables. In Malaysia, even though they have lived harmoniously for a longtime but it is clear from this study, that there is still a sense of separation that is maintained. Dissimilar in attitude towards organ donation have been noticed but those who were less likely to donate usually consist of the ethnic minorities based on western country studies byBilgel H et al.[8] In this study, 96.7% of the respondents aware that their religion allows the organ donation procedure and this is differ from the previous study that stated that most of the respondent misunderstanding and unclear about the allowance in their religion. In addition, it could be said that level of knowledge has an association with the attitude regarding organ donation. However previous study stated that different religions had a significant association with the attitude on organ donation where Hindus and Chinese were likely to have positive attitude[5].

Relationship between Socio-demographic Variables, Level of Knowledge and Level of Attitude with The Willingness on Donating Organ: With regards to the willingness, it has been established that 235 (63.8%) of the respondents are willing to involve in organ donation and organ transplant. Based on the finding results in Table 3, there is a significant association between socio-demographic data of age (p=0.00), religion (p=0.001) and ethnicity (p=0.001). Meanwhile gender and level of education have no significant association with the willingness regarding organ donation. However it has been stated in the previous study that the educational level was associated with the willingness to donate organ.[8] Compared to the older group, the younger shows high anticipation to donate organ and it is because of the thought that their organs are too old to be transplanted and they want to be buried with a complete body parts,similar study was noticed in Vijay Kumar M, et al.[9] In this study the Malays' knowledge are not corresponding to their willingness. This can be due to the dilemma that always being faced by Malays that they are not clear about the allowance,similar to Noordin N, et al.[10] Total knowledge of participants being high and higher willingness towards organ donation where 40% of respondents willing to donate had a good knowledge. [5]This finding also corresponds with the previous study that found out that who are young and with higher education had more positive attitudes towards donating organ.[7]

Conclusion

From this study, it can be concluded that this study's finding are various and different at certain points with the previous study. Most of the respondents are aware about the organ donation and the level of knowledge is good. However,opinion between ethnicity differ. In addition, attitude of the respondents also is good but it is also differing within the ethnicity. According to the relationship, there is a significant association between socio-demographic data of ethnicity, education and religion on total knowledge on organ donation. Meanwhile there is no significant association regarding attitude, where we failed to reject the null hypothesis. Besides, data has been analyzed to observe the relationship between the socio-demographic variables with the willingness in donating organ and there is an association with the age, religion and ethnicity. Most importantly, though a majority of the respondents were aware and supported organ donation, but in reality, most of them have not registered as organ donor**.**

Abstract

Obesity or excess body weight is considered a public health concern worldwide. Being obese significantly increases the risk of numerous clinical disorders like heart diseases, type II diabetes mellitus, hypertension, stroke and others. Obesity is now common in both gender. The aim of the study was to find out the relationship between the prevalence of related dominant diseases of obesity and each category of obesity according to WHO. This cross-sectional study was conducted at Seksyen 13, Shah Alam area in Selangor. A total of 260 questionnaires were distributed equally to 130 male and 130 female. The results showed that obesity have a higher prevalence in hypertension (p=0.001) with 69.24% (Class I=8.08%, Class II=38.08%, Class III=23.08%), followed by diabetes mellitus type II (p=0.039) 60.38% (Class I=21.15%, Class II=26.15%, Class III=13.08%), heart problem (p=0.001) 42.69% (Class I=10.00%, Class II=16.15%, Class III=16.54%) and stroke (p=0.004) 4.23% (Class I=0.38%, Class II=1.15%, Class III=2.69%). Results showed significant difference in all variables which is less than 0.05. Even though the causes of excess body weight are multi-factorial, Hence, lifestyle modification can significantly reduce the risk of morbidity and mortality.

Keywords: *Obesity, Body mass index, Hypertension, Stroke, Heart diseases, Diabetes.*

Introduction

Obesity is a major public health problem and becomes an important epidemic in both developed and developing countries and is associated with considerable reduction in life expectancy. Overweight and obesity have been evaluated by anthropometric measurement of weight-for-height. More recently, BMI has been used. The normal range is 19-24.9 kg/m2, overweight is 25-29.9 kg/m2, and obesity >/= 30 kg/m2. obesity is classified into three classes,

Class I has BMI of 30.00-34.99,

Class II has BMI of 35.00-39.99 and

Class III BMI is over or more than 39.99.[1]

Obesity among adolescent undeniably important as this will reflect on prevalence of other related diseases in future.[2] Therefore, obesity is a multi-factorial phenomenon.

According to Frank Q. Nuttall, MD, PhD.[3] Blood Glucose Control in People with Type 2 Diabetes).in one of his articles stated that the body mass index (BMI) is the metric currently used for defining anthropometric measurement of height/weight characteristics in adults and for classifying them into several groups. From previous research also stated that hypertension, ischemic heart disease, diabetes, and recurrent stroke were the most common risk factors for obese people. The prevalence of hyperlipidemia, ischemic heart disease, and diabetes was significantly different between the age

groups. Hyperlipidemia, diabetes, and ischemic heart disease were more common in age groups of 41-50, 41-60 and above 60, respectively.[4]Hence, the negative effects of obesity on the health are beyond dispute. The excessive body fat represents a strong risk factor for several medical diseases, the most important of which are type 2 diabetes, hypertension, cardiovascular diseases and osteoarthritis.[5]

Methodology

Questionnaire were distributed among resident in Seksyen 13, Shah Alam. A cross-sectional study is a research method that involve observation of all populationat one specific point of time. A cross-sectional study was conducted among 260 of general population in Seksyen 13, Shah Alam, Selangor.

Data obtained during the study was entered, sorted and analysed by using Statistical Package for Social Science (SPSS) IBM (Version 20). For descriptive statistics, we used frequency distribution table and percentage, mean,standard deviation and medianrange. For inferential statistics, we used Chi-square for nominal data to test the hypothesis. We used odds ratio and 95% confidence interval as the measure of association. Significance level was set at 0.05. P value less than 0.05 was considered significant

Results

Table 1: Socio-Demographic Studies of Respondents

Variable	Answer	Frequency	
		n	%
Gender	Male	130	50.0
	Female	130	50.0
Age	18-27	36	13.8
	28-37	65	25.0
	38-47	99	38.1
	>47	60	23.1
Race	Malay	120	46.2
	Chinese	37	14.2
	Indian	91	35.0
	Others	12	4.6

In this study, a total of 260 respondents participated. 130 each were male and females. The age of the respondents were divided into four groups 18-27,28-37,38-47, and >47 and the race was also divided into four which include Malay, Chinese, Indian and others. The participation of Malay respondents is 46%, 14.2% from Chinese,35.0% from Indian and 4.6% from others.

Table 2: Prevalence of Obesity among Gender associated with the category of Obesity

Obesity Classification	Male		Female		Total	
	Frequency	%	Frequency	%	Frequency	%
Class I	43	16.5	33	12.7	76	29.2
Class II	66	25.4	58	22.3	124	47.7
Class III	21	8.1	39	15.0	60	23.1

Table 2 showed that male have a higher prevalence of obesity in Class I which is 16.5% compare to female at 12.7% and also in Class II which is 25.4% compare to female at 22.3%.In Class III, the prevalence of obesity in female is higher than male with the difference of 6.9%. Class II has the highest prevalence in both gender which is 47.7% followed by Class I (29.2%) and Class III (23.1%). The result from this table showed that the p-value is 0.027. So, the null hypothesis for the first specific objective was rejected. Thus, there is significant relationship between the prevalence of obesity among gender associated with the category of obesity.

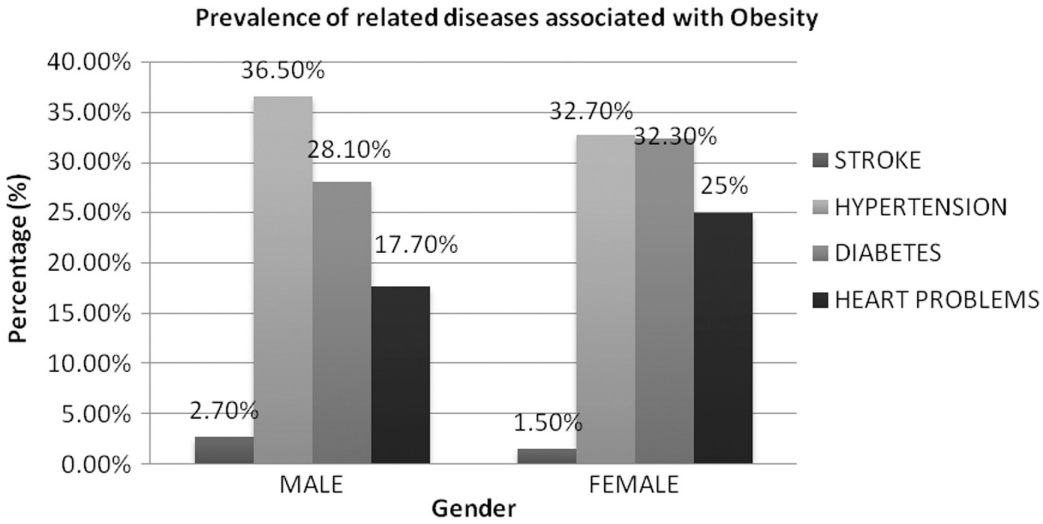

Figure 1: Percentage of related diseases associated with obesity

Table 3: Prevalence of Related Diseases Associated with Obesity

Disease	Male		Female	
	Frequency	%	Frequency	%
Stroke	7	2.7	4	1.5
Hypertension	95	36.5	85	32.7
Diabetes	73	28.1	84	32.3
Heart problems	46	17.7	65	25.0

Table 3 showed that between four major diseases that associated with obesity, hypertension is the most dominant disease that occurred in obese people with the percentage is 69.2% followed by diabetes (60.2%), heart problems (42.7%).Stroke is the least common disease compared to the others which occuredin 11 out of 260 respondents with the percentage is 4.2%.The p value is 0.001, Reject null hypothesis. Thus, there is significant relationship between the prevalence of related disease with the obesity population.

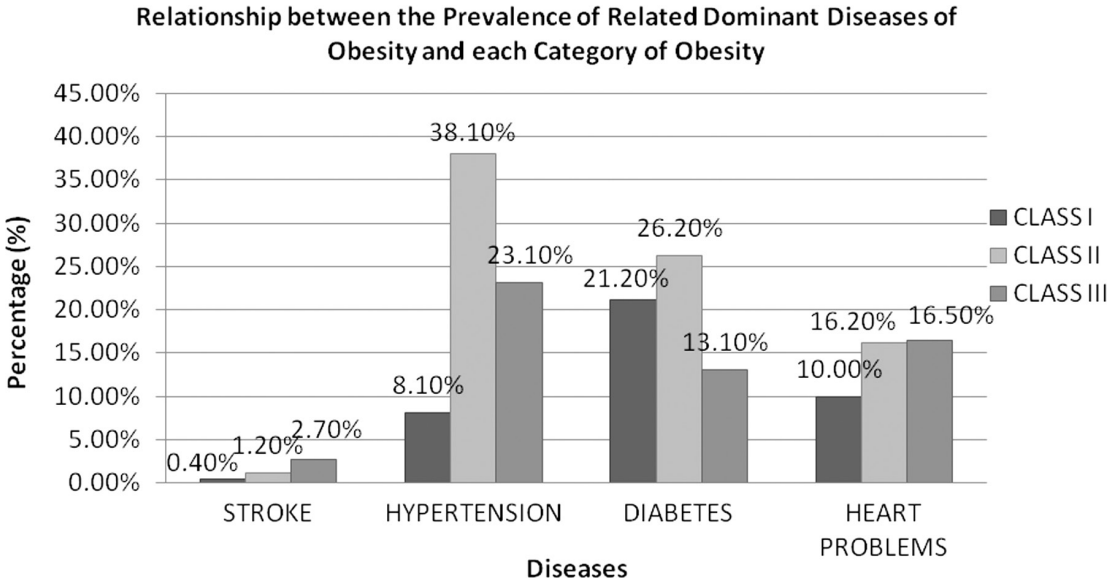

Figure 2: Percentage of related dominant diseases of obesity in each categoryof obesity

Table 4 : Relationship between The Prevalence of Related Dominant Diseases of Obesity and each Category of Obesity

Disease	Classification of Obesity					
	Class I		Class II		Class III	
	n	%	n	%	n	%
Stroke	1	0.4	3	1.2	7	2.7
Hypertension	21	8.1	99	38.1	60	23.1
Diabetes	55	21.2	68	26.2	34	13.1
Heart problems	26	10.0	42	16.2	43	16.5

Table 4 showed that diabetes is the dominant disease that occur in people in Class I obesity with the percentage is 21.2%. In Class II, the highest prevalence of disease that happen in the respondents is hypertension with 38.1%. Hypertension is also most dominant disease in Class III obesity with the result 23.1% followed by heart problem, diabetes and stroke. The results showed that obesity have a higher prevalence in hypertension (p=0.001) with 69.24% (Class I=8.08%, Class II=38.08%, Class III=23.08%), followed by diabetes (p=0.039) 60.38% (Class I=21.15%, Class II=26.15%, Class III=13.08%), heart problem (p=0.001) 42.69% (Class I=10.00%, Class II=16.15%, Class III=16.54%) and stroke (p=0.004) 4.23% (Class I=0.38%, Class II=1.15%, Class III=2.69%). Since all the p-value is less than 0.05, thus, there is a relationship between the prevalence of related dominant diseases of obesity and each category of obesity.

Discussion

Data from this study showed that socio-demographic studies of respondent had given a variation values. Firstly, gender of the respondents obtained that male and female had given the different values of the prevalence of obesity according to the types of obesity. Apart from that, the number of respondent was divided equally which is 130 from male and another 130 is female. The age was divided into four groups to find out whether obesity can develop diseases in different age groups. Generally, the old aged group with obesity showed more complications to their health status compared to middle aged. Gender-specific differences in the relationship between BMI and body fat were largely explained. Excess weight-for-height attributable to lean and bone tissue rather than body fat was observed as high prevalence of overweight men according to BMI criteria,similar to the study ofVan Den Beld AW, et al;[6] Thus, there is a likely underestimation of adiposity by BMI in elderly people for whom there is a loss of lean tissue, particularly skeletal muscle, and bone, as seen in Van Den Beld AW and Pasco JA, et al;[6,7] Race is also one of factorial phenomena that associated with obesity due to their religious beliefs and traditions based on MR B. in 2002.[8]

The results of the analysis confirmed the first hypothesis that there is association between the prevalence of obesity among gender associated with category of obesity. BMI of male respondents showed that male have a higher prevalence of obesity in Class I and Class II than female. Meanwhile, female have a higher prevalence in Class II obesity. Another factor affecting greater likelihood of obesity among women is weight gain related to hormonal transitions.

From this research study, The data analysis showed that between the four major diseases t associated with obesity, hypertension is the most dominant disease followed by diabetes, heart problems and stroke. In other research, obesity was obtained as a strong predictor for diabetes and related disease such as hypertension, cardiovascular disease, dyslipidaemia and albuminuria similar to the study of Ko G.[9]

The evaluation from this research also obtained that there was relationship between the prevalence of related dominant diseases of obesity and each category of obesity. It showed that diabetes was the most dominant diseases among Class I obesity. However, in Class II and Class III obesity, the highest prevalence of disease was hypertension.

Furthermore, from this research it had been proven that the cross-sectional study had linked obesity to hypertension, diabetes, heart problem and stroke. Firstly, the prevalence of elevated blood pressure dramatically increases with weight gain, particularly among individuals

< 55 years old,which is similar with the previous research by Must A, et al.[10]In hypertensive subjects, being overweight is associated with cardiovascular abnormalities such as increased progression of left ventricular hypertrophy similar to De Simone G, et al.[11]

Moreover, the link between obesity and diabetes is supported by evidence from research reported byMurtagh J. 2015.[12] The association of these two variables occurs as a result of peripheral insulinemia, from increased free fatty acids in the liver and inhibition of hepatic clearance

of insulin which could cause decreased peripheral insulin sensitivity as shown in previous study Daneshfard B, et al. and Mozaffarian D, et al.[4,13] However, this study and previous research have demonstrated a significant association between BMI and risk of stroke among men,similar to Jood K, et al; 2004.[14]

This study also obtained that obesity is the risk of heart disease is present due to the fact that obese persons have the tendency to produce high levels of free fatty acids,which leads to the hypertriglyceridaemia and an increase in production of low density lipoproteins (LDL), while high density lipoproteins (HDL) cholesterol is low. The ratio of LDL to HDL is high leading to greater atherogenic risk. A study from this research found that almost 42.7% of heart problem like coronary risk was attributable to a BMI >25 kg/m2 similar with a research by Nanchahal K, et al.[15]. For supporting this study, the American Heart Association (AHA) continues to recognize obesity as an independent cardiovascular disease risk factor,as seen by Ferreira-González I, 2014.[16] Evidence from this studies and recent studies supported the AHA's statement that obesity increases the risk of heart diseases events.[17,18]

However, since correlation study on the prevalence of related dominant disease of obesity and each category of obesity showed a significant relationship, it is easily understood that, the classification of obesity may indirectly change the prevalence of associated diseases with obesity in this country.

Conclusion

From this study, it can be concluded that classification of obesity had given a variation of result on the related diseases. The classification of obesity showed that all of the types gave a high risk to develop health problems (WHO, 2016). According to the findings, it showed that Class II obesity is the highest prevalence in both gender compared to Class I and Class III. The most dominant disease that usually occurred to the obese person is hypertension, second is diabetes, third is heart problem and the least common is stroke. Apart from that, the common disease in Class I is diabetes, the common disease in class II and Class III is hypertension, but class II and III have a higher possibility to get other diseases like heart problem, diabetes and stroke e. So, there is significant association between the prevalence of related dominant diseases of obesity and each category of obesity among resident in Seksyen 13, Shah Alam. Moreover, data been analyzed to observe the correlation between prevalence of obesity among gender associated with category of obesity, which showed that study had rejected null hypothesis. Thus, there is significant relationship between the prevalence of obesity among gender associated with the category of obesity. Similar finding also obtained for correlation between prevalence of related diseases associated with obesity. Hence, study had rejected null hypothesis and thus proving the significant association between the prevalence of related diseases with the obesity population. Based on the data of the relationship between the prevalence of related dominant diseases of obesity and each category of obesity, the correlation study between these two variables give the significant association observed between them, where study had to reject the null hypothesis.

Haematogenous Spread of Fluconazole Resistant Candida Tropicalis from Mycobiome of Respiratory Tract in COPD Patients

Pamela Banerjee[1], Satadal Das[2]

[1]Research Officer, International Institute of Innovation & Technology, New Town, [2]Consultant Microbiologist, Peerless Hospital & B. K. Roy Research Centre, Kolkata, West Bengal

Abstract

The association between candidaemia and particularly the drug resistant candidaemia with COPD is largely unknown, although COPD patients with drug resistant candidaemia show very high mortality rate. Thus in this study we aimed to find whether there is a significant association between COPD and drug resistant *Candida tropicalis* isolated from blood and sputum from such cases as this species is now commonly isolated from blood. After isolation of the *C. tropicalis* from blood fluconazole resistance was confirmed by broth dilution technique following CLSI guidelines and then association with COPD was statistically analyzed. Fluconazole resistant *C. tropicalis* in blood was 53.3% in patients with COPD, while it was only 12.5% in patients without COPD. Similarly in the sputum fluconazole resistant *C. tropicalis* was 100% in COPD cases while they were only 33.3% in non- COPD cases. Although recently there is development of many newer antifungal agents but the mortality due to candidaemia still remains very high particularly in COPD patients. Thus early initiation of the proper antifungal treatment is essential in such cases.

Keywords: *Cndida tropicalis, Fluconazole, COPD.*

Introduction

Invasive *Candida* infection commonly occurs in patients with compromised immune system and COPD is frequently found associated as a co-morbid factor in such infection. In Indian subcontinent, *Candida tropicalis* is the commonest *Candida* species isolated from blood [1] and COPD is an important co-morbidity in about 10.3% patients suffering from *Candida* infection in the blood. In patients suffering from COPD, the role of bacteria and fungi has not yet been clarified [2,3]. The European Academy of Allergy and Clinical Immunology recently indicated our poor knowledge regarding the association of fungal infection in COPD cases [4].

Mycobiome is a collective term of respiratory pathogens in patients suffering from COPD which includes *Candida* spp.[5,6] and *Candida* spp. isolated from COPD patients are quite different than those isolated from healthy persons[6]. In COPD patients frequent antibiotic treatment due to associated infections often leads to proliferation of *Candida* growth in the respiratory passages[7]. Thus the research on *Candida* spp. in COPD patients is extremely important, this is because the respiratory tract is the main point of entry of fungi, upon which they can exacerbate the COPD and invade the body.

Materials and Method

The patients: Patients who were admitted in ICCU were included in this study after permission taken from the Institutional Ethical Committee. Only those patients were considered where they showed *C. tropicalis* isolated from their blood. From the clinical history of the patient presence of COPD was confirmed. In this way a COPD group and a non-COPD group was separated. Other demographic data of the patients were also recorded.

Confirmation of the isolated fungal strains: Assimilation tests and other biochemical tests were

performed to confirm the diagnosis of the isolated fungus as *C. tropicalis*. A negative germ tube test was also observed.

Antifungal drug sensitivity test: The isolated *C. tropicalis* were then tested for the fluconazole resistance initially by disk diffusion method with Hi Media disk and then MIC values were determined by serial broth dilution method as recommended in CLSI guidelines. In this way fluconazole resistance was confirmed.

Analysis of the data: After collection of all data significance of the drug resistance *C. tropicalis* isolated from blood in COPD patients was determined by statistical analysis.

Results

Fluconazole resistant *C. tropicalis* in blood was 53.3% in patients with COPD, while it was only 12.5% in patients without COPD. Similarly in the sputum, fluconazole resistant *C. tropicalis* was 100% in COPD cases while they were only 33.3% in non- COPD cases. The details of the findings are given in Table 1 and Fig. 1. Statistical analysis between fluconazole resistant *C. tropicalis* isolated from blood in COPD and non-COPD cases showed a Chi-squared value of 7.396 with a p-value of 0.0065; similarly differences between fluconazole resistant *C. tropicalis* isolated from sputum in COPD cases and non-COPD cases was also highly significant with Chi-squared value of 5.893 and p-value of 0.0152.

Table 1: Showing increased drug resistant *C. tropicalis* in blood and sputum in COPD patients

	Fluconazole Sensitive Candida Tropicalis		Fluconazole Resistant Candida Tropicalis	
	Without COPD	With COPD	Without COPD	With COPD
Total number of cases	21	7	3(12.5%)	8(53.3%)
Sex	M 13 F8	M5 F2	M1 F2	M6 F2
Age in years range	17-52	20-64	27-53	24-48
Presence of Candida tropicalis in sputum	8(38.1%)	6(85.7%)	1(33.3%)	8(100%)

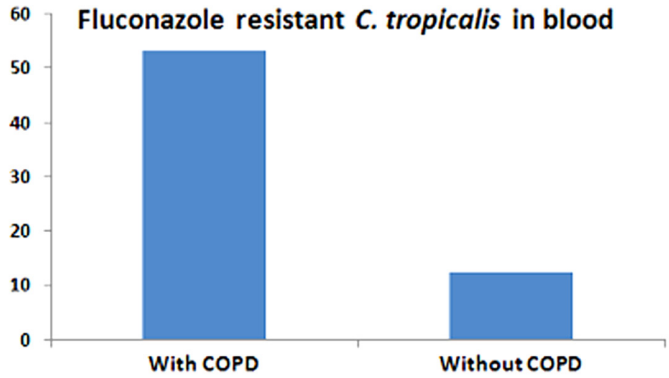

Fig. 1: Cadidaemia patients showing more fluconazole resistance in COPD patients

Discussion

It was Castellani who described "tea tasters cough" long ago, and after that there was an extensive study on the role of the yeasts on respiratory tract infections, but still it is not solved whether there is a definite relation between them or not.

The term candidiasis denotes a fungal infection caused by different species belonging to the Genus *Candida*, which are yeast like fungus. Although most *Candida* species including C. tropicalis are also found in animals but *C. albicans* is found only in human beings. In many persons this fungus may present normally in mouth, vagina, intestine etc. In immune-compromised patients this fungus can spread easily throughout the body. In patients with COPD also they can spread easily in comparison to an otherwise normal person. They can also spread through contaminated inanimate objects like air-conditioning vents, food, clothing etc and can cause infection. Before infection there is always increased colonization of them in the vulnerable areas of the body particularly in the lining of the respiratory tract. When normal microflora of the part is diminished as in antibiotic treatment they can spread without difficulty in different

parts of the body. Respiratory tract candidiasis is usually associated with sore throat, hoarseness, dyspnoea, fever, and cough[1-4]. Among different organisms isolated from blood, Candida species is the fourth most commonly isolated organism. Candida, Aspergillus and Mucorales are the three fungal groups which are commonly isolated from respiratory tract materials in patients admitted in ICU. It was found that 18-56% incubated patients harbor *Candida* species in ICU [3] and about 10% patients admitted in ICU are suffering of *Candida* infection. The presence of *Candida* in respiratory samples usually indicates multifocal colonization, in presence of COPD they easily invade the surrounding tissue and finally can cause candidaemia, in COPD cases isolated *Candida* species is usually drug resistant which causes a very high mortality rate in this group of patients. Ostrosky-Zeichner prediction rule and the *Candida* score are two important assessment method which should be used in such cases.

A novel proteinase – tropiase of *C. tropicalis* increases vascular permeability and haemorrhagic activity. Two other virulence factors of *C. tropicalis* namely phospholipase and biofilm formation are also key factors in the pathogenecity. The growth of *Candida* spp. is enhanced due to decreased mucociliary clearance thick mucus, and altered immune reaction [8]. These factors ultimately lead to colonization [9,10]. Many bioactive elements like collagenase, elastin, chitin, β glucan, trypsin, gliotoxins etc. are present in the *Candida* spp. which can degrade tissue matrix particularly in patients of COPD and can easily enter the blood [11-15]. This damaging action usually causes a Th-1 type response in healthy people but this can initiate Th-2 type response in COPD patients. The pathogen-associated molecular patterns (PAMP) of *Candida* triggers inflammation [16].

Conflict of Interest: The authors declare that there is no conflict of interest.

The authors declare that it is an original work and has not been sent to any other journal for publication.

Source of Funding: Funding for this study was provided by Peerless Hospital & B. K. Roy Research Centre, Kolkata.

The Purchase of Over the Counter Medicines (OTCM)

Shakeel-ul-Rehman[1], M. Selvaraj[2]

[1]*Assistant Professor, Department of Management Studies, Islamic University of Science & Technology, Awantipora,*
[2]*Professor and Joint Director, Sona School of Management, Sona College of Technology, Salem, Tamilnadu*

Abstract

Purchase of over the counter medicines (OTCM), commonly known as self-medication is a common practice visible among majority of people curing majority of minor ailments. The practice is common not only in developing countries but the pace is equally evident in developing nations. The trend of OTCM is getting more and more popular over time. In this busy world, people generally prefer OTCM in order to save money and time in the form of doctors' fee and long waiting line. In majority of the cases OTCM is supported by high end advertisements, personal promotion and word of mouth publicity. Moreover the virtual platform in the form of online marketing has made it more accessible, cost & time saving practice by getting home delivery. The results of the present study support the investigation done by the researcher that the proposed factors are significantly associated in making an overall perception towards purchasing OTCM.

Keywords: *Purchase Decision, Consumer Involvement, Information, Evaluation.*

Introduction

Conferring to Martins et al[1] the term self-medication can be defined as the use of non-prescription medicines under an individual's own initiative. It generally refers to use of non-prescription medicines, usually over-the-counter (OTC) drugs, to treat certain 'minor' ailments, by patients themselves without consulting a medical practitioner and without any medical supervision or consultation. Supported by Zafar et al[2], it comprises of acquiring medicines without a prescription, purchasing drugs by resubmitting/ reutilizing an old prescription, taking medicines on advice of relative or others, or consuming leftover medicines already available at home (Clavinjo[3]). The study of Gupta et al[4] determine that lack of sufficient money to go and consult to doctor may be another reason for self-medication. Supported by the World Health Organization[5] (WHO), that responsible self-medication can help prevent and treat ailments that do not require medical consultation and provides a cheaper alternative for treating common illnesses. However, it is also recognized that self-medication must be accompanied by appropriate health information supported by Kafle and Gartoulla[6]. Studies on self-medication are influenced by many factors, like education, family, society, law, availability of drugs and exposure to advertisements. A high level of education and professional status has been mentioned as predictive factors for self-medication (Hebeeb, and Gearhart[7]).

The most common medications used for self-medication are analgesics and antimicrobials (Shankar, Partha and Shenoy[8]). Self-medication may be seen as part of the greater drive towards self-care whereby individuals assume greater responsibility for their own health, and undertake activities to improve their health, prevent and limit disease and restore health after injury or illness (Hughes, Mcelnay and Fleming[9]; Bond and Bradley[10]; Nettleton[11;] Bessell et al[12]).

There has been a tendency for the public to perceive OTC medicines to be safer than prescription medicines (Bissell, Ward and Noyce[13]; Hughes, Whittlesea and Luscombe[14]), but it has been recognised that OTC medicines have the possibility for harm as well as advantage (Lessenger and Feinberg[15]). This may result in what has been variously referred to as the misuse or abuse of OTC medicines and their potential to cause

Corresponding Author:
Dr. Shakeel-ul-Rehman
Assistant Professor, Department of Management Studies, Islamic University of Science & Technology, Awantipora-192122
e-mail: rehman.shakeel@islamicuniversity.edu.in

addiction and dependency. Similarly Lessenger and Feinberg[15] suggested medicines such as stimulants, laxatives, sedatives and dissociative substances such as dextromethorphan as being liable to abuse. The latter are available for purchase in many countries and combine codeine or dihydrocodeine with either ibuprofen or paracetamol and have led to particular concerns about addiction and also gastric or hepatic damage, respectively (Reay[16] 2009; Frei et al[17]).

As identified by Bruden[18] that in a number of developing countries many drugs are dispensed over-the-counter without any medical supervision. Serious threat of self-medication is that it often gives temporary, superficial relief and thus guises symptoms possibly revealing of a more serious problem. Secondly some might actually be ineffective, e.g. taking antibiotics for viral illness. In developing countries like India easy availability of wide range of drugs coupled with inadequate health services result in increased proportion of self-medicated drugs compared to prescribed drugs (Phalke, Phalke and Durgawale[19]; Durgawale[20]). In several studies it has been found that inappropriate self-medication results in wastage of resources, increases resistance of pathogens and generally entails serious health hazards such as adverse drug reactions, prolonged suffering and drug dependence (Kiyingi and Lauwo[21]).

Background of the Study

As OTCM has been concerted in other disciplines, like medical sociology, pharmacy practice, public policy, environmental science, etc., but little focus has been towards consumer decision making process, the present research tries to fill the gap and is a step towards determining the parameters of consumer decision making process and the relationship of various factors in managerial perspective towards over-the-counter medication.

OTC medication offers advantages like easy access to medicines, self-management of minor ailments with the involvement of pharmacists, and utilization of available resources. However it is not always safe and has been associated with negative health consequences (Bertoldi et al[22]).

A study conducted by Nga et al[22] showed that frequent reported reason for buying antibiotic was cough in urban setting and fever in the rural setting. Then Hollis et al[24] comprises a combination of self-profiling to understand the mind of the consumer, and conjoint analysis to understand the choice of features and communications. Comparing a variety of marketing mix variables such as brand, price, and retailer reputation, Dawar and Parker[25] found brand to be the most important signal used by consumers to evaluate product quality.

For health care providers who recommend OTC drugs to patients, the study of Catlin, Pechmann and Brass[26] suggests the possibility that the instructions given should go beyond simply recommending the drug and assuming the label will provide all the rest of the information. Provision of more detailed information or instructions may be beneficial to patients in some cases. Cooper[27] concluded that, OTC medicine abuse is a recognised problem internationally but is currently incompletely understood. Research is needed to quantify scale of abuse, evaluate interventions and capture individual experiences, to inform policy, regulation and interventions.

Despite label instructions about storage and administration, Schaefer, Shehab, Cohen and Budnitz[28] found that both unsupervised over-the-counter cough and cold medication consumption by children two to five years of age and caretakers' inappropriate administration (e.g., giving a higher dosage than recommended) accounted for most visits to the hospital emergency department due to an adverse drug event. The prevalence of supplying antibiotics by community pharmacists without prescription is illegal and alarming. Pharmacists and patients' perception, knowledge and attitude are crucial in developing interventions to improve the current practices of dispensing medicine (Himmelstein, Miron-Shatz, Hanoch and Gummerum[29]; Nagaraj, Chakraborty and Srinivas[30]; Abdasaeed et al[31]). Likewise the report of Malvi, Papiya and Sonam[32] supported that pharmacist should be more attentive towards the people who take the medicine without the prescription. Helping the peoples to know about the drugs very clearly can reduce the incidence of any adverse effect in future due to indiscriminate and unnecessary self-medication.

Objectives: To examine and evaluate the role and influence of various factors like: Involvement, Information and Evaluation criteria on Purchase Decision towards Over the Counter Medication.

Methodology

The present research is a survey based study conducted at Islamic University of Science and Technology in Awantipora town of Pulwama District

of Jammu & Kashmir during March to June-2018. The structured questionnaire was distributed personally to the respondents on the basis of Convenience Sampling Technique. The validity of the overall scale has been tested by reliability analysis, showing that a valid/ reliable scale (with Cronbach's Alpha = 0.739) has been developed for the study. It has been accepted by Hair, Anderson, Tathan and Black[33], so further analysis is permitted. Descriptive statistics, Linear Regression Modeling, Mean Scores were used to test the variables in order to get inferences.

Results and Discussions

The results and discussions are presented under various headings as:

ANOVA Results: ANOVA test was conducted in order to know the feasibility of all the variables in the model and the results were significant with $P < .05$, F Value = 196.519, Friedman's Chi-Square value = 3433.394, & Kendall's coefficient of concordance W = .986 (it is used for measuring agreement among raters, W rages from *0*-no agreement to *1*-complete agreement).

Model Assimilation: Based on the researchers own impression of relating the variables. The results show that there is a significant & effective relationship between the variables. Each of the factors has been assigned its statistical values based on the performance in the test. In the Linear regression model each of the three factors (Demography= INV, Information=INF & Evaluation=EVAL) were entered as input factors/ predictor variables and two factors (Purchase Decision=PD & Frequency of Purchase=FoP) has been entered as output factors/target variables. Individually the input factors have significantly contributed towards the Purchase Decision in the study. The analysis presented in table 1 shows that the conceptual model developed for the study fits the test very well.

Table 1: Statistical Results

Variables	Av. M.	Adj.R2	Model M.	Model SD	F-Value
INV-FoP	1.89	.163*	55.44	4.18	6.666
INV-PD	1.89	.134*			
INF-PD	3.19	.597*			
EVAL-PD	3.64	.230*			
PD-FoP	1.73	.767			
INV, INF, EVAL-PD	55.44	.897*			196.519

*= P<0.05

Managerial Implications: The term 'misuse' is applied to the use of a drug for medical purposes but in an incorrect manner, for example, use over an extended period of time or at an increased dosage. By definition, all products available for self-medication can be misused. Patient deaths have occurred as a result of the abuse of non-prescription products. The likelihood of inappropriate use occurring is increased by the ease of access to many of these products from a range of outlets, advocated by (Hughes, Mcelnay and Hughes[34]; Barragry and Morris[35]). Further Hughes[36] analysed self-medication with non-prescription drugs is likely to expand due to continued deregulation of products and patients assuming greater responsibility for their own health. Pharmacists are in a prime position to oversee the safe and effective use of such products through advice and counselling, but this role will require support through technology to assist monitoring, and evidence-based guidance on what is the most appropriate product in the management of a particular condition.

Moreover Jafari, Khatony and Rahmani[37]; Ali, Ibrahim and Palaian[38] suggest the need for interventions that may include awareness programs for the university students, medicine refund policies and any other novel initiatives that could minimize the medicine storage and self-medication practices. The level of medical knowledge and the patient's awareness of the information are important factors for appropriate self-medication, if the patient is adequately informed and directed, many side effects can be prevented (Dimitrijevic et al[39]; Uday, Nagesh, Venkat[40]).

Conclusion

Health care and health protection is every person's right. Every individual has the right to get sufficient

information and counselling regarding advantages, drawbacks, risks and limitations in order to evaluate over-the-counter medicines. The present research is also supported by several previous studies in the field of over-the counter medication, like the study of Chawla, Agarwal and Arora[41] which emphasize the need for proper education and training regarding need for rational prescribing, physician should do judicious prescribing while there is also an urgent need for legal measures to restrict the over the counter purchase of drugs so that pharmacist can dispense drugs only on prescriptions. Studies which categorize the types of barriers or determinants which lie between patients and services in terms of geographical, social, economic, cultural and organizational factors should be carried out to bridge the gap between patient and health system (Nath et al[42]).

Effect of Internet Use in Adolescents: A Scoping Review

Justin Varghese[1], Nailu A.[2], Henry O.A.[2], Shalini Quadros[3]

[1]Former Student of Occupational Therapy, Currently working as an Occupational Therapist in Calicut Wellness one Rehabilitation Clinic, [2]Former student of Occupational Therapy, [3]Assistant Professor, Department of Occupational Therapy, SOAHS, MAHE, Manipal

Abstract

Introduction and Background: Internet has a wide variety of uses in our daily life, like sharing files and information, communication, education, work, entertainment, shopping etc. Internet use has been found to be more in adolescents. Many studies have identified both positive and negative correlates of internet use among adolescents The aim of this scoping review was to find the literature available on the positive and negative effects of internet use in health of adolescents and also to find its effects on the occupational functioning in adolescents.

Method: Scoping review was conducted by collecting the studies done on adolescents and internet use from major online databases available in Manipal Academy of Higher Education library. Full text studies related to positive and negative effects of internet in healthy adolescents that were published in English between 2000 and 2017 were included for review. Our literature searches initially gathered 136 studies. 40 full text studies were found to be relevant and were independently screened by three investigators.

Result: Out of the 40 studies identified, 12 studies positively and 26 studies negatively discussed about the effect of internet use on adolescents. 2 studies found that internet use had both positive and negative effects on adolescent health. The positive effects on health included improved self-awareness, improved peer interaction etc. and the negative effects included loneliness, decreased energy etc. There were 4 studies that discussed about the effect of internet use on occupational functioning of adolescents.

Conclusion: Internet use may have both positive and negative influence on health of adolescents and if it is used in the supervised environment can have beneficial effects on health and occupational functioning among adolescents.

Keywords: *Adolescents, Adolescents age group (12-20), Consequence, Effect, Health, Impact, Internet use, Mental health, Occupational functioning, Outcome, Physical health, Result, Social health, Socialmedia.*

Introduction

The Internet is a basic system of net worked computers that have an ability to share the data around the world[1]. It has a wide variety of uses in our daily life, like sharing files and information, communication, education, work, entertainment, shopping etc. According to one of the surveys, 54.4% of the world population use internet in December 2017[2].

In recent years, internet use has become a major part of the occupations that human beings engage in[3]. The use of internet has either replaced many existing occupations of many individuals (e.g.: Internet based games instead of outdoor games) or have eased many of the occupations that individuals engage in(e.g.:online shopping).

According to a survey conducted in Europe in 2016, internet use has been found to be more in adolescents. In a study by Tsitsika[4], the authors have stated that internet is a basic tool for information, communication, and

e-mail: shalini.quadros@manipal.edu

entertainment among adolescents. Internet use may have both positive and negative effects on adolescents[5].

Since, adolescence is a stage of swift physical, psychological, social and development changes[6] and time spent in internet use is more in adolescents[2], it is important to find the positive and negative influence of internet on health. Occupational therapists are always interested in understanding the effect of various occupations on functioning of individuals A literature base is necessary to help us in identifying the influence of internet use on the health and thus on the occupational functioning of adolescents. Hence, it is important to find how the internet usage can influence the occupational functioning in adolescents.

The research question for the current scoping review is: What is the current literature available on the effect of internet use in adolescents?

The aim of the current scoping review was to identify the current literature available on the effect or influence of internet usage in adolescents The objectives were to find the positive and negative effects of internet usage in health of adolescents and to understand how internet usage affects occupational functioning in adolescents.

Method

Articles were accessed through the single widow search from MAHE Library which includes databases such as Scopus, PubMed/MEDLNE, ProQuest, Springer Link, Up to Date, SCIFINDER, WEBOF SCIENCE, Journal Citation Reports, RESEARCH TO PUBLICATION, MU Digital Repository, SciVal, ACCESS Medicine, Adis Insight, Clinical Key, Dyna Med Plus and CINAHL Plus Full Text.

The keywords used were "Adolescents", "Adolescents age group (12-20)", "Consequence", "Effect", "Health", "Impact", "Internet use", "Mental health", "Occupational functioning", "Outcome", "Physical health", "Result", "Social health" and "Social media".

All literature focusing on effect of internet use on adolescents from January 2000 to December 2017 were considered for the current scoping review. Studies conducted in healthy adolescents, English articles on effect of Whats App, Facebook, Instagram, and twitter through phone and computer in adolescents were included in this review. Studies on effect of online video games in adolescents and with any one of the keywords in the title were considered for this review.

Studies on effect of television, offline phone games or video games and iPad games in adolescents were excluded from the current review.

Procedure: Our search yielded 136 studies with any one of the keywords in the title. A total of 109 studies remained after excluding the duplicates. Abstract screening of 109 studies was done based on inclusion and exclusion criteria. 78 studies were fully reviewed after excluding 31 studies that did not meet the inclusion and exclusion criteria. It was found that 38 studies did not discuss about the effect of internet use on health or occupational functioning of adolescents as they were conducted on adolescents with physical or mental illness and few were on parent's perspectives or collective write-ups on internet use in adolescents. Finally, 40 studies were found to be relevant for our research question and were reviewed by the three investigators independently and were charted.

Results and Discussion

The aim of our study was to identify the literature on the effects of internet use on adolescents in regard to health and occupational functioning.

Out of the 40 studies, 12 (30%) studies have found that internet use has positive effects on adolescent's health whereas 26 (65%) studies have found that internet use has negative effects on health of adolescents. 2 (5%) studies have concluded that internet use has both positive and negative effects on health of adolescents. Out of 40 studies, 4 studies (10%) have discussed the effect of internet use on occupational functioning in adolescents.

The geographical distribution of the study population in all the 40 studies included in the review is described in Table 1.

Table 1: Geographical distribution of the studies done on internet use by adolescents

Continent	Europe	Asia	North America	South America	Australia	Africa
Number of studies	16 (40%)	10 (25%)	7 (17.5%)	2 (5%)	4 (10%)	1 (2.5%)

Though the percentage of population using internet is very high in India[2] only 2 studies have been conducted on the effect of internet use on Indian adolescents.

All the studies included in this review comprised of qualitative and quantitative designs like cross-sectional studies, cohort studies randomized controlled trails etc. 16 (40%) of the studies on the effects of internet use on health of adolescents were cross-sectional, 10 (25%) of the studies were surveys, 7 (17.5%) studies were randomized controlled trails, 1 (2.5) of them was a pilot study, 1 (2.5%) was a longitudinal study, 1 (2.5%) was a cohort study and 4 (10%) studies were observational studies.

Positive effects of internet use on adolescents: One of the studies done to identify the effect of online fitness programs on health of adolescents have found that online fitness programs improved the quality of food intake and physical fitness in adolescents[7]. But it can be noted that these programs may not have caused direct impact on health of adolescents. Instead, they might have improved the knowledge of adolescents on maintaining a healthy lifestyle. Adolescents accessed online information for knowledge related to fitness and this has found to assist physical health promotion in adolescents[7,8]. Few studies have also identified that online based sexual education programs at school helped in improving the sexual health and awareness in adolescents[11,12,13].

Interaction with distant friends enabled expression of emotional needs among adolescents using online communication method such as Facebook, online video chatting etc.[9, 10] Online tasks and education classes on emotional balance strategies for adolescents by involving them in online mental health based classes have found to improve emotional regulation in adolescents. These online tasks and educational classes taught various problem solving techniques and coping strategies to the participants[14].

Occupational functioning of adolescents in terms of academic performance was studied and was found that internet use improved language skills [15] and information gathering skills about curricular subjects[9,10] through online dictionaries and blogs. Peer interaction was another component of occupational functioning which improved in adolescents by joining and seeking help from social media pages[14, 18]. Most of the studies have found that adolescents who used the internet under parental supervision showed better quality of life in terms of health & occupational functioning[36].

Negative effects of internet use in adolescents: Prolonged exposure to internet is found to have harmful effects on mental health of adolescents. It was found that internet use can cause depressive symptoms such as mutism, mood swings [16-21], loneliness and introversion[22], reduced self-esteem and loss of interest in pleasurable activities [23-27] in adolescents. Adolescents were found to. involve themselves in risk taking behaviors such as online interaction with strangers and revealing personal details to strangers online[22, 28]. Aggressive behaviors were found to be more in adolescents using internet for prolonged time[21,22,29,30,31].

Adolescents involved in internet use for longer time were also found to have increased Blood Pressure[32] and Body Mass Index [32]. Internet addiction led to lack of energy and sleep deprivation [33] in adolescents. Many studies have identified that prolonged internet use led to decreased social interaction with family and friends[17,18,23,30,33,34,35]. Internet addiction was also found to have negative influence over academic performance in adolescents [29]. Adolescents who accessed internet in unsupervised environment were likely to develop Internet Addiction, Problematic Internet Use (PIU) and Internet Use Disorder[36].

Implications, strengths and limitations: The findings of the current scoping review can be used in creating awareness on the effect of internet use on health in adolescents. The scope of using internet in rehabilitation can be explored. This preliminary scoping review to identify the research on the effects of internet use on adolescents may help in identifying research gaps and aid for further research. Future research may be conducted to identify the influence of internet on the areas of occupational functioning. The strengths of the current study are that the data collection was done from major online databases and all the steps involved from screening of abstract to full text analysis was done by three investigators independently. Titles of certain studies conducted on adolescent's internet use might not have been captured by the search strategy used in this review.

Conclusion

Internet use may have both positive and negative influence on health of adolescents. Internet, if used in the supervised environment can have beneficial effects on health and occupational functioning among adolescents. If internet is used in unsupervised environment can have

harmful effects on health as well as on occupational functioning among adolescents.

Stress Levels among Medical Students of Various Years INA Medical College, Thiruchirapalli, South India

Shankar S.[1], Elango S.[2], Rajkali R.[3], Priyatharsini T.[3], Raghavi A.[3], Rajiv K.[3]

[1]Assistant Professor, [2]Professor and HOD, [3]Interns, Department of Community Medicine, Trichy SRM Medical College Hospital and Research Centre, Thiruchirapalli

Abstract

Background: The medical education aims to create citizens who care for the nation's sick, promote public health. Medical schools that produces doctors seem to exert more stress which many students fail to cope up with making them a vulnerable group in the society. This could have a negative impact on patient care, patient safety and their professional career. This study helps us to identify the level of stress with different years of medical students and compare among males and females.

Methodology: A Cross sectional study was conducted among 200 medical students of all four years selected randomly of a private medical college and hospital at Trichy (Thiruchirapalli) for duration of 2 months from august to October, 2018. Data was collected using a pre-tested and semi-structured questionnaire [13].The questionnaire contains five indicators related to physical, sleep, behavioural, emotional and personal.

Result: From the study,Overall dangerous levels of stress is seen among 27% of the total students. Very high levels of stress is seen among 39% of the total population. According to physical indicators, dangerous levels of stress is seen among 4th year girls and among males, it is more common with 1st year. According to sleep indicators, 4th year male students tend to have dangerous levels of stress while it is more common with 1st year female. Behavioural indicators of stress show that there is dangerous level of stress with 2nd year females and 3rd year males. With personal indicators, dangerous levels of stress are seen with 4th year girls and among 1st year males. Dangerous levels of emotional stress is seen with the female students of 4th year and male students of 1st year.

Conclusion: The stress levels seem to vary between males and females of each year of study. Study shows there is high levels of stress among medical college students of Trichy.

Keywords: *Medical Students, Trichy, Stress Indicators, Depression, Academic Pressure, Pattern*

Introduction

The goal of medical education is to create a knowledgeable, competent, and professional physicians meant to care for the nation's sick, advance the science of medicine, and promote public health. Medical schools undertake an extensive selection process to identify intelligent and altruistic individuals with a strong commitment to these goals and they spend four years trying to prepare to achieve these goals.[1]The fact is that education itself is a stressful process to many students. Admission into medical school currently is achieved after years of hard work[2]

Stress is defined as "a highly subjective phenomenon and it is a nonspecific response of body to any demand for change. And now this factor has merged to become an inevitable part in a medico's life[3].

Medical school being recognized as a stressful place could exert a negative effect on the academic performance, physical health and emotional wellbeing

Corresponding Author:

e-mail id: drshankarcmchrc@gmail.com

of the students [4]. This stress has serious consequences which may lead to the development of depression and anxiety and may even have a negative impact on patient care, patient safety and professional career [5]. Studies on psychological problems such as stress, depression and anxiety among medical students have found that these disorders are under-diagnosed and under-treated [6] Failure to detect these disorders unfortunately leads to increase psychological morbidity with unwanted effects throughout their careers and lives [7].

Other factors including academic pressure, financial concerns, sleep deprivation [8]and a "hidden curriculum" of cynicism [9]have been hypothesized to contribute to this decline in students' mental health. Fear of failure, volume of subjects that are to be mastered and the high level of expectations from parents do also play its part. [10]Very few studies have been done among the south Indian medical students in this field. This study aims to bring out the amount of stress undergone by medical students of various terms of medical student.

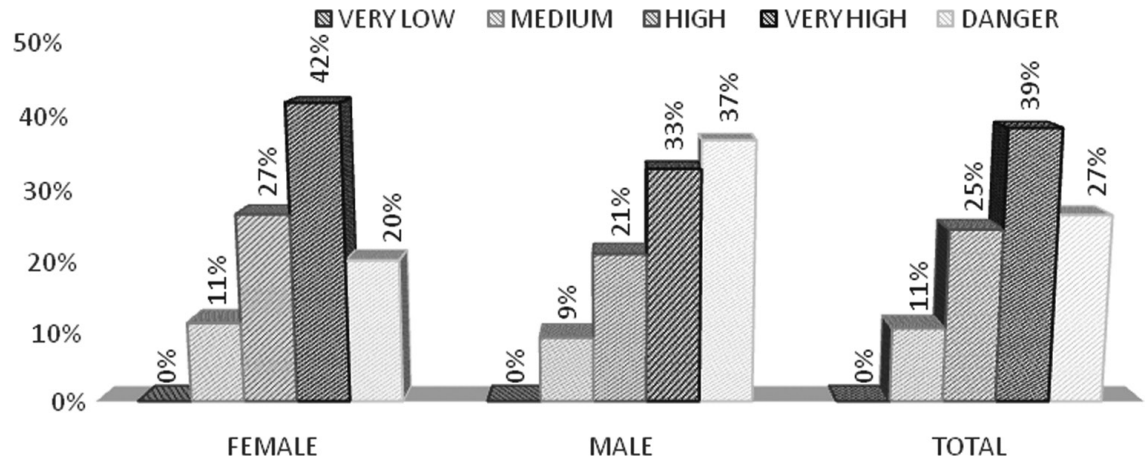
Objective: To determine the stress levels among medical students during various years of their study period.

Materials and Methodology

A Cross sectional study was conducted among 750 medical students of all four years, excluding interns, among which 200 students were selected randomly. Study was conducted at a private medical college and hospital at Tiruchirapalli for duration of 2 months from august to October, 2018. Datawas collected using a pre tested and semi structured validated questionnaire. The questionnaire consisted of socio demographic factor of students along with **Stress indicators questionnaire** developed by the counselling team international [11]. Questionnaire first explained to the students and then students were asked to fill the questionnaire. The questionnaire contained five indicators related physical, sleep, behavioural, emotional and personal. Each indicator had questions and its scores ranges from 1to 5. Sum of total scores for each indicator is categorised into five stress levels (very low, low, high, very high, danger), based on the scale stress levels among different year students, both gender were analysed. Data was entered into M S Excel and data was analysed with SPSS software 16 software. Chi-square test was used to find the difference between stress levels among different groups.

Results

Study was conducted among 750 medical students of all four years, among which 200 students were selected using systematic random sampling. Around 50 students from each year were taken, among which 1st year consisted of 28 female and 22 males, while 2nd year had 29 females and 21 males, 3rd year 31 females and 19 males and 4th year 36 females and 14 males.



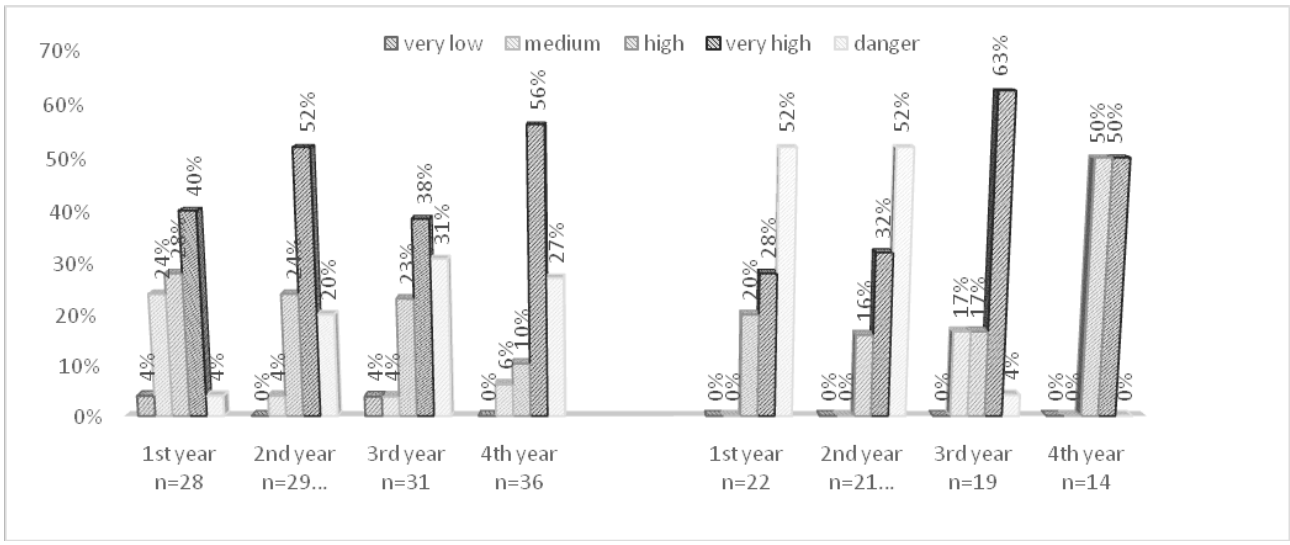


Figure 1: Gender Wise Distribution of Overall Stress among Students

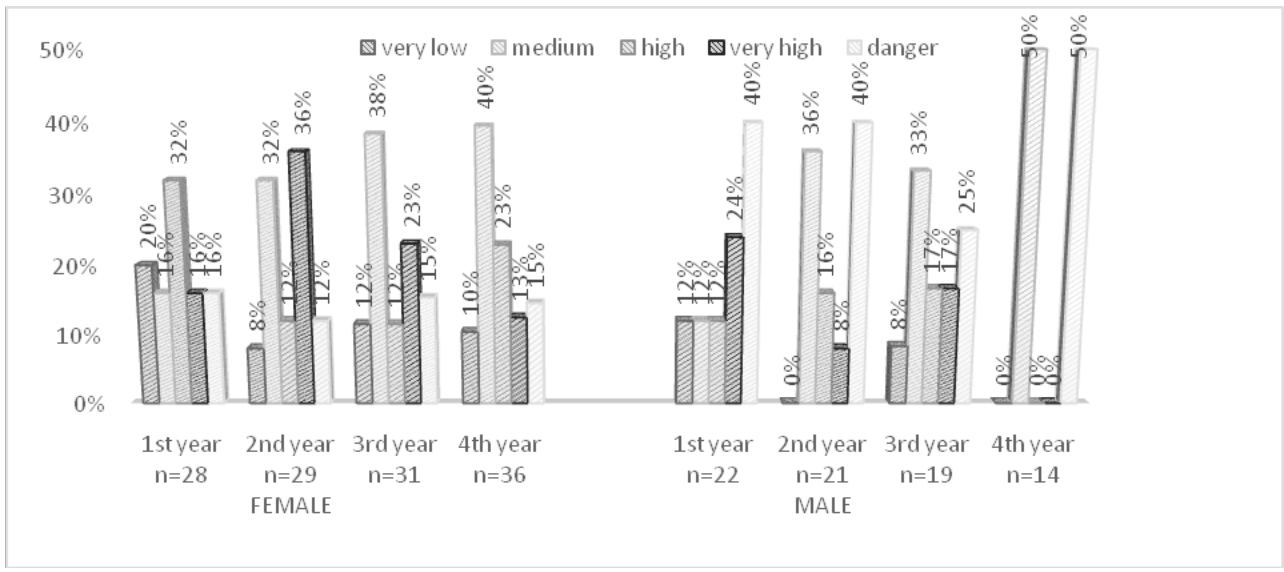
Overall dangerous levels of stress is seen among 27% of the total population. It is about 20% of the total female and 37% of the total males. very high levels of stres is seen among 39% of the total population of which 42% females and 33% among males. high levels are seen among 25% of total population of which 27% among females and 21% among males.

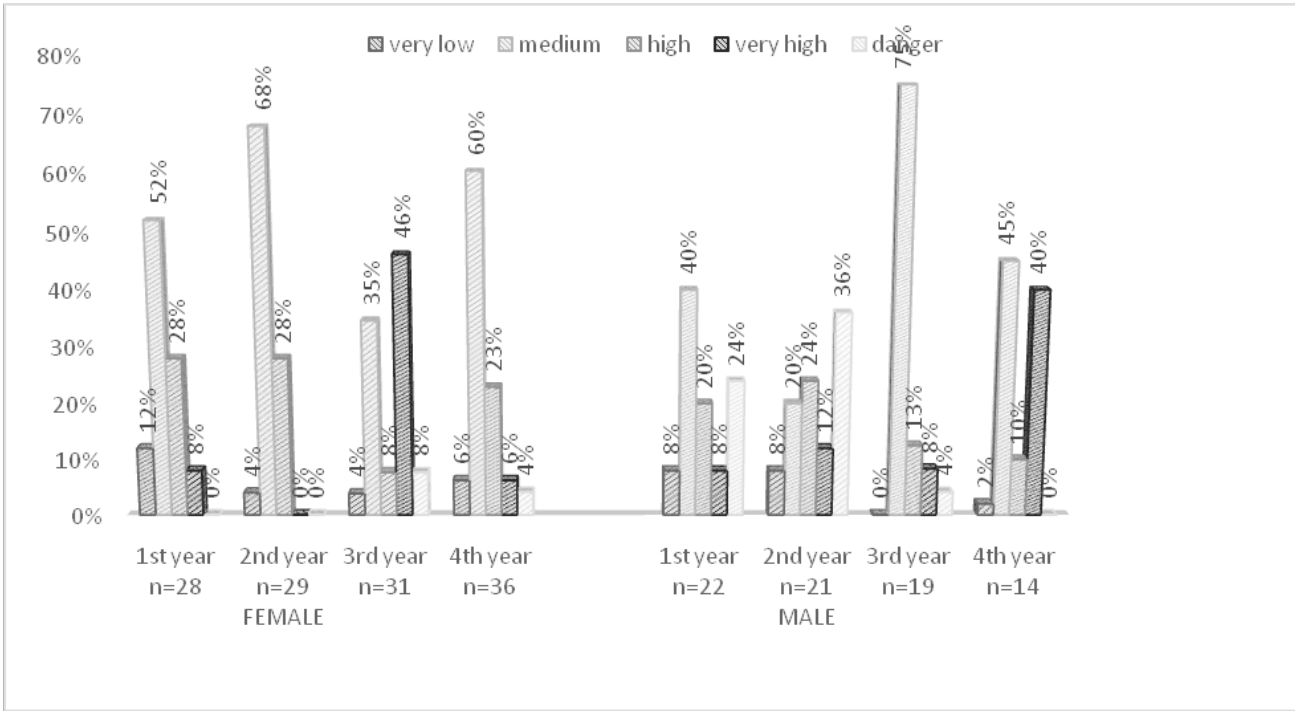


*According to chi square test p value for female is 0.046(significant): males is 0.003(significant)

Figure 2: Gender and Year Wise Distribution Stress Based on Physical Indicator

Very high level of Physical indicator of stress tends to be seen among 4th year students which is about 27% of the entire study population. Amongst girls, very high levels are seen among 4th year students which accounts for about 56%of the 4th year girls and nearly 27% seems to have dangerous levels of physical stress. But in case of boys very high levels are seen among 3rd year students, of about 63%. Interestingly, dangerous levels are seen among 1st year boys which is about 52% compared to 1st year girls where about 4% of students seem to have dangerous levels

Most common physical indicator of stress complained among students is generalized feeling of tense all over the body**.** Other common symptoms include decreased intake of diet and lack of vigorous exercises. The stress difference among females of different years was significant with p value of 0.046 while in males was highly significant with value of 0.003

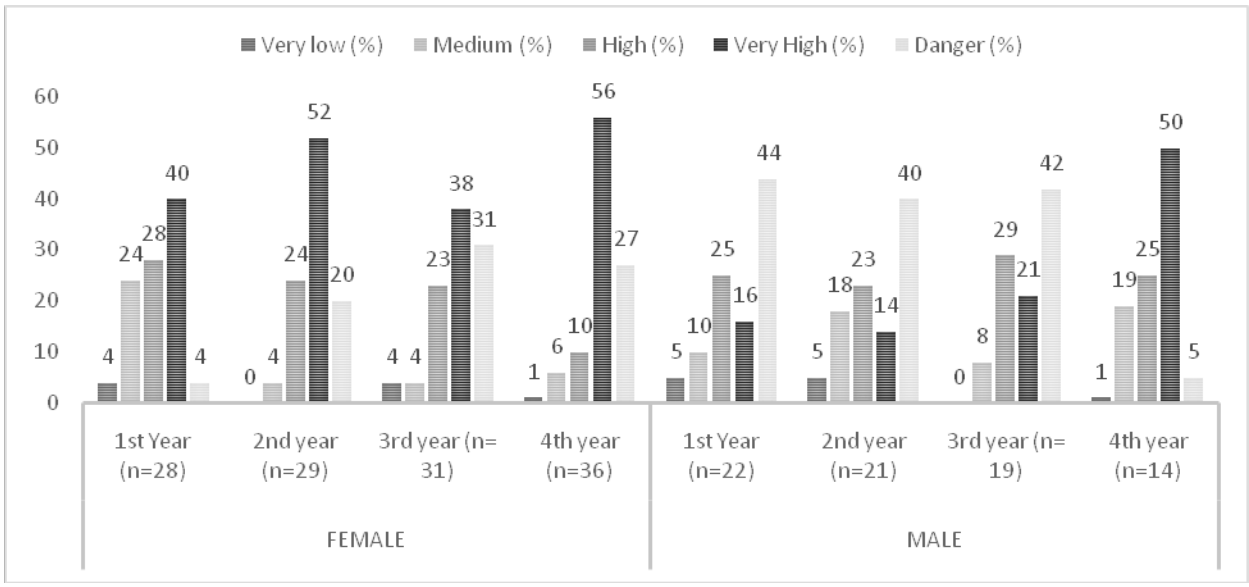


*According to chi square test p value for female is 0.992(not significant): males is 0.332(mot significant)

Figure 3: Gender And Year Wise Distribution Stress Based On Sleep Indicator

Sleep indicators reveal that stress would have a dangerous impact on the sleep of the final year male population. About 50% of 4th year male students tend to have dangerous levels of stress among 4thyear males students. Girls of 1st year seem to have dangerous level of stress affecting 16% sleep among whole 1st year girls. Study shows that very high levels of stress is seen among 2nd year female which is about 36% of the same year female, accounting for 4.5% of the entire people under study. Among boys very high levels of stress is present with the 1st year students which is about 24% of the class boys. 1st year girls have very low impact on sleep which is about 20% of the 1st year girls and among boys very low levels is seen with 1st year male students which is 12%.

Among Sleep indicators most common symptom seems to be tiredness during awake despite adequate hours of sleep. Other common indicators include insomnia and nightmares. The stress difference among females of different years was not significant with p value of 0.992 while in males was significant with value of 0.332.

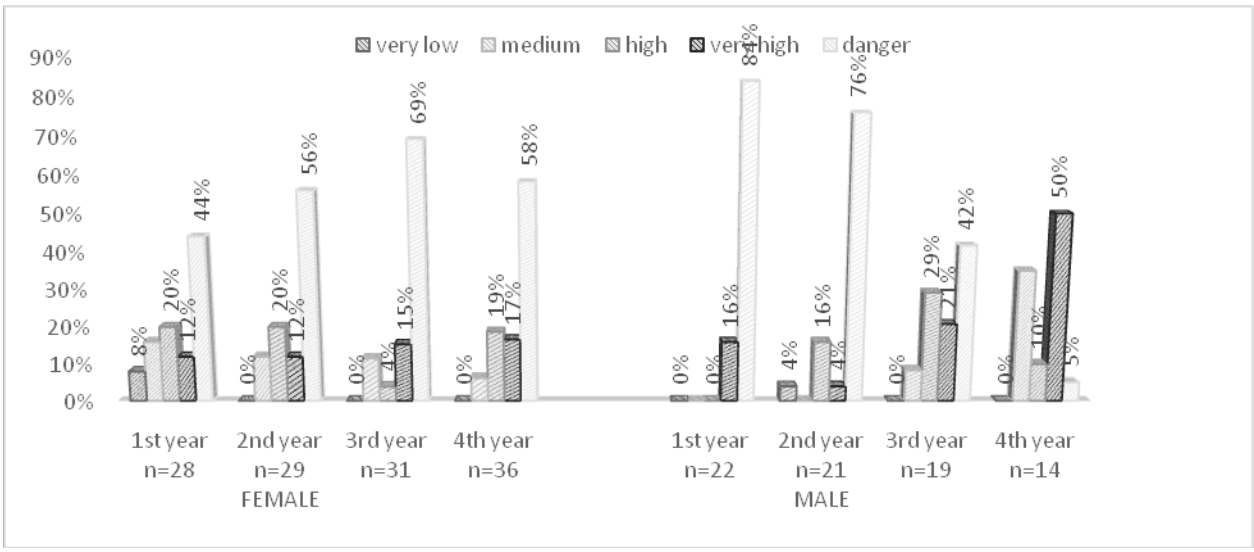


*According to chi square test p value for female is 0.001(significant): males is 0.043 (significant).

Figure 4: Gender And Year Wise Distribution Stress Based On Behavioural Indicator

Behavioral indicators of stress show that there is dangerous level of stress of about 36% among 2nd year male students which accounts for about 4.5% of totalpopulation understudy. Among females dangerous levels are seen with 3rd year which is about 8% of all females.

Very low levels of stress are seen among 1st year female students about 12% of the total female of the same year. Among males low stress levels is seen among 1st and 2nd year students which is about 8% of the respective year population. Within study group, most common indicator of being stressed appears to be studying despite of being sick, thus taking very less self-care. Other common indicators includes taking more time to study than usual and stuttering while speech. The stress difference among females of different years was highly significant with p value of 0.001 while in males was significant with value of 0.043.



*According to chi square test p value for female is 0.922(not significant): males is 0.332(not significant)

Figure 5: Gender And Year Wise Distribution Stress Based On Personal Indicator

Among personal indicators of stress, dangerous levels is seen with 4th year female which is about 39.3% of all 3rd year female and about 4.8% of the entire study group conversely dangerous levels of stress is seen among 1st year boys with 44% among the group of first year and shows a gradual decline in personnel indicators with 5% among 4th year boys. Among girls very high levels is constantly seen among all years. Very low levels of personnel stress are common in3th year boys.

Among personnel indicators of stress, decrease in hours of television watching seems to be the most common indicator of stress with a mean of 2.90. Other common indicators include difficulty in proper planning of work and decreased interest over hobbies. The stress difference among females of different years was not significant with p value of 0.922 and males also were not significant with value of 0.332.

*According to chi square test p value for female is 0.272(not significant): males is 0.001 (significant)

Figure 6: Gender And Year Wise Distribution Stress Based On Emotional Indicator

Emotional indicators of stress among medical undergraduate students show that dangerous levels of emotional stress is seen among the female students of 4th year which is about 14% of the entire population and accounts for 58% among the 4th students seem to show dangerous levels of stress. Among male students dangerous levels of emotional stress is seen among 1st year students with 10.5% among the entire sample size and 84%among the 1st year male students. Among female students, there is an increasing trend of very high levels of emotional stress with 1stand 2nd years showing 12% in each year, 3rd years with 15.4% and final years with maximum of 17%.Among male students very high levels of emotional stress is seen among the 4st year students with 50% of the male students of the same year.

Very low levels of stress is seen among the 1st year female students with 8% of this entire 1st year female population. Among boys very low levels is seen among the 2nd year with 4% of the same year boys. Trying to hide their emotions from their family members seems to be the most common emotional indicator causing stress among the medical students. With a mean of 2.84. temper outburst also seems to be an important behaviour among students which is more common among the 4th year students (mean 2.39).The stress difference among females of different years was not significant with p value of 0272 while in males was highly significant with value of 0.001.

Discussion

According to physical indicators, dangerous levels of stress is seen among 4th year girls of about 6.5%of the total population and Interestingly among males,it is more common with 1st year boys which are about 7%.Generalized feeling of tense all over the body seems to be the most common symptom.

According to sleep indicators, 1% of 4th year male students tend to have dangerous levels of stress. Conversely, among girls of 1st year 2% seem to have dangerous level of stress affecting sleep. Most common symptom seems to be tiredness during awake despite adequate hours of sleep.

Behavioural indicators of stress show that there is dangerous level of stress of about 4.5% among 2nd year femalesand 4% with 3rd year males. Most common behavioural indicator of stress is lack of self-care.

According to personal indicators, dangerous levels of stress are seen with 4th year girls which are about 8.5% of the total population. Inversely, dangerous levels of stress are seen among 1st year boys about 10%. Decrease in hours of relaxation like television watching seems to be the most common indicator of stress

Dangerous levels of emotional stress is seen with the female students of 4th year(14%) and male students of 1st year (10.5%)trying to hide the emotions from their parents seem to be the most common cause of stress among the medial students.

According to the results there is variation in different parameters of stress between male and female students of south india when compared to other developed countries[12].among the early college years women seem to be more stressed when compared to males[5]. In first year students high levels of stress is seen with47% of students which is low when compare to medical students of Andhra Pradesh(78%)[3]. About 65% of the total students under study seem to show high levels of stress which is higher when compared to developed countries like Malaysia (56%),Saudi Arabia (57%)[13], Thailand (61.4%) [14].

Conclusion

Based on the study it is inferred that there is high levels of stress is seenamong medical college students of Trichy when compared to other countries. But among first year students stress seem to be much lower than the neighbouring states of south India.Male students tend to show higher levels of stress during their early years and gradually tend to get accustomed.Study load does not seem to have a great impact on their stress level during 4th year of study. Among females high stress is seen among 4th year compared to 1st year indicating that study load seems to have a greater impact on their stress levels. Orientation programmes, counselling and tutorship might help the first and final year students to reduce their stress. Friendly relationship with their parents could help students to cope up with stress.

Isolated and Combined Effect of Continuous Run Alternate Pace Run on Selected Motor Fitness Physiological Haematological Variables among Male Athletes

T. Arunprasanna[1], M. Sundar[2], K.M.M. Jaskar[3]

[1]Scholar, [2]Prinicipal, [3]Asst. Professor, Alagappa University College of Physical Education, Karaikudi, Tamil Nadu

Abstract

The study aims to determine the isolated and combined effect of continuous run, alternate pace run and combined training on the selected motor fitness variable (Muscular Endurance), physiological variable (Breath Holding Time), and hematological variable (Red blood corpuscles) among the male athletes of Alagappa University affiliated colleges. The research involved a random subject selection of forty athletes with age ranging from 17-25 years and had four equally divided groups namely experimental groups A, B, C and control group D with 10 athletes each. The groups endured the training activities for twelve weeks with a schedule of thrice a week whereas the control group remained with no activities. The data procured in prior and after the training programme was examined with the application of Analysis of Covariance and the fixation of level of significance at 0.05. Scheffe's test was applied at the significance of 'F' ratio in order to evaluate the differences that occur significantly between the paired means. The study revealed that the selected variables of the combined group with the two endurance trainings outperformed the other groups.

Keywords: *Continuous Run, Alternate Pace Run, Muscular Endurance, Breath Holding Time, Red Blood Corpuscles.*

Introduction

A mission for perfection is often confronted with numerous difficulties. To improve the sports performance the athlete needs to take part in systematic training by the way of scientific method of training. Therefore athletes or players need proper systematic training to improve their performance through different kinds of training .[1]Significant improvement in VO2 max may not be possible when the runner reaches a plateau. It is, therefore, suggested that more emphasis should be given to improve the anaerobic threshold level of athletes.[2] Actual effect of training depends upon several factors such as training loads, means of recovery, assessment of load and performance capacity, sports equipment, nutrition, psychological characteristics and method adopted for imparting theoretical instruction. [3] The tendency of the systems of heart and blood vessels, lungs, body temperature regulators, body constituents, and the function of muscles and skeleton upon the capacity of an athlete leads to the enhancement of sports performance.[4]

Continuous running: Continuous running boosts the heart rate to the vicinity of 130 and 160 thumps for a given period of time at a relentless pace or power. The average time span of such running will be more than 30 minutes for a youthful competitor and from 60-120 minutes for an adult. Continuous training structures the reason for all other preparing techniques both anaerobic and aerobic.[5] Ernst Van Aaken, German physician and coach, is credited with introducing and popularizing this system of training. Ernst Van Aaken's work in this area started in 1920's but received widespread support at the later. Continuous training differs from maximum force constant action of slow time span to minimum-force action of a broadened span, long-slow distance, or "LSD" method. The long distance sprinter keeps up a pace that is simply beneath his dashing pace, despite the fact that this will rely upon the overall distance and the distance of preparation runs.

Alternative pace run: Running for long time at a speed with a variation in progressive stretches in accordance with a plan is Alternative pace run. In

general, for a person at slow pace for 1.0 km, the heart rate ranges from 130 to 150 beats per minute while considering fast pace for 0.5 km, the heart rate ranges from 170 to 180 beats per minute. The maximal oxygen intake at a subsequent distance of 1.0 km is stirred up. The alternative pace run supports the consumption of oxygen and the ability of varying speed.

Muscular endurance: Muscular endurance is very important for the football game. A long duration sport is to improve the muscular endurance. Enhancing muscular endurance gives an assortment of wellbeing and fitness, benefits, decreases fatigue, injury, back pain and develop the good posture.[6]

Breath holding time: Breath holding time is the period when one can hold the breath without inspiration and expiration.[7]It is characterized as a person's capacity to hold the breath, an intended maximal inward breath without exhalation during the period of holding the breath. Breath holding time is the times consumed to keep or without taking the breathing action as much as possible.

Red blood corpuscles: RBCs the non nucleated in the blood are the carriers of oxygen to every part of the body. Their haemoglobin content acts as carrier to all the body tissues. It enhances the rate of action between CO2 and water 250 times and thus facilitates CO2 carriage. RBCs are produced in bone marrows and the life span ranges between 90-140 days.[8]

Statement of the problem: The purpose of the study was to find out the Effect of Continuous Running, Alternate Pace Run, on selected motor fitness, physiological and hematological variable of male athletes.

Methodology

The research was designed to discover isolated and combined effect of continuous run, alternative pace run on the selected motor fitness variable (Muscular Endurance), physiological variable (Breath Holding Time), and hematological variable (Red blood corpuscles) among the Alagappa university college's athletes. For this purpose, forty athletes from the college were chosen randomly as subjects for the study and their age ranged between seventeen and twenty five years.

Test administration of the selected variables

i. Sit-ups (Bent knees) to evaluate the muscular endurance of the abdomen.

ii. Breath Holding Time to estimate the capability of the subjects in holding the breath for an extended period of time.

iii. Red blood corpuscles count to find out the number of red blood cells in the blood.

Training programme: The experimental groups I, II, III and IV were subjected to twelve week of continuous run (Group I), alternative pace run (Group II), combined training (Group III) and control (Group IV) on three alternative days a week. Each of the training programmes extended from 60 to 90 minutes with a schedule in the morning from 6.00 am to 8.00 am. The control group underwent usual exercises and was devoid of any specific training. The subjects underwent their respective programme under strict supervision prior to and during every session. They experienced a 10 minutes warm up and cool-down exercises which included jogging, stretching, striding and push-ups. A regular self-analysis of the stature of the subject was done during the whole training session and none reported of injuries whereas muscle soreness that occurred in the earlier weeks lowered down in the later period.

Statistical techniques: The design of the experiment and the random group involved forty as subjects who were divided into four groups containing ten each. This study was based on the chosen criterion variables such as motor fitness, physiological, hematological variables namely muscular endurance, breath holding time, red blood corpuscles. The four selected group underwent continuous run, alternative pace run, combined method and controlled training respectively. The study mainly aimed at finding out the effects of different endurance trainings among the subjects on selected criterion variables. The data was obtained from the four experimental groups and the control group at the beginning and after the conduct of the test. The procured data was statistically examined for significant difference using the method of analysis of covariance i.e., ANCOVA. Due to the involvement of the four various groups and at the significance of the F ratio for the adjusted post mean, the post hoc test utilized the Scheffe's test to measure the difference of the paired means.

Results and Discussions

Table I: ANCOVA for the data extracted from the pre and post tests of the training groups of Continuous, Alternate Pace Run, Combined and Control method on Muscular endurance (Sit-ups means count in No of attempt per minute)

Test	CNG	APG	CMG	CTG	Source of Variation	Variation in Sum of Squares	Df	Squared Mean	'F' Ratio observed
Pre test Mean	26.4	26.6	26.1	26.7	Between	2.28	4	.570	.074
SD	2.22	3.37	2.60	3.16	Within	345.9	45	7.687

Adjusted post test mean	28.82	29.52	31.81	25.82	Between	215.26	4	53.817	19.331*
					Within	122.49	44	2.784	

*Required table value with significant level at 0.05, degree freedom 4 and 45 and 4 and 44 are 3.20 and 3.21 respectively. B.M., W.G, B.S, W.S are Between Means, Within Groups, Between Sets, Within Sets respectively.(Sit-ups means count in No of attempt per minute)

The data analysis done statistically from the Table I indicates that the mean values of pre-test of the training groups of continuous, alternative pace running, combined and control method are 26.4,26.6,26.1 and 26.7 respectively. The F ratio .074 obtained for pre-test observed to be lesser than 3.20 of table value for the degree of freedom 4 and 45 necessary for significance level at 0.05. The means of post-test of the training groups of continuous, alternative pace running, combined and control method were found 28.8,29.7,31.5 and 26.1 respectively. The F ratio 4.345 obtained for post-test was greater than 3.21 of table value for degree of 4 and 45 necessary for significant level specified at 0.05. And the resultant means of the adjusted post test scores of the training of continuous, alternative pace running, combined and control method were 28.82,29.52,31.81 and 25.82 respectively. The ratio of F for the adjusted post-test 19.331 was also greater than 3.21 table value for the degrees of freedom 4 and 45 necessary for 0.05 specified as level of significance. The analysis mentioned above shows that the result has a significance of difference of the means of adjusted post-test of all the groups. For post hoc test Scheffe's test as was used in order to identify which specific group had the significant difference and to evaluate which paired means showed significance of difference and also the conclusions are given in Table II.

*Required table value with significant level at 0.05, degree freedom 4 and 45 and 4 and 44 are 3.20 and 3.21 respectively. B.M., W.G, B.S, W.S are Between Means, Within Groups, Between Sets, Within Sets respectively.(Breath Holding Time means count per minute).

The analysis of the data done statistically shown in the Table III indicates that the mean of training groups of continuous, alternative pace running,combined and control method are 37.3,37.5,37.8 and 37.6 respectively. The F ratio .025 for the pre-test was lesser compared to the table value 3.20 for degree of freedom 4 and 45 necessary with a significant level at a specification of 005. The means of post-test of the training groups of continuous, alternative pace, combined, control method were 43.5,43.9,45.6 and 37.1 respectively. The F ratio 7.701 obtained for post-test was greater than 3.21 of table value for degree of 4 and 45 necessary for significance level specified at 0.05. The means of adjusted posttest scores of the training groups of continuous, alternative pace running, combined and control method were 43.69,43.917, 45.356 and 37.03 respectively. The ratio of F 33.97 for post test scores was greater than 3.21 of table value for degree of 4 and 45 necessary for significance level at 0.05. The analysis mentioned above shows that the means of adjusted posttest measures of the all the groups differed significantly. For post hoc test Scheffe's test as was used in order to identify which specific group had the significant difference and to find out which paired means showed significance of difference and the derived results are given in Table IV.

Post test Mean	6.03	6.09	6.29	5.64	Between	2.264	45	.566	4.685*
SD	.346	.347	.144	.529	Within	5.437	45	.121	
Adjusted post test mean	6.12	6.01	6.23	5.61	Between	2.491	4	.623	9.407*
					Within	2.912	44	.066	

*Required table value with significant level at 0.05, degree freedom 4 and 45 and 4 and 44 are 3.20 and 3.21 respectively. B.M., W.G, B.S, W.S are Between Means, Within Groups, Between Sets, Within Sets respectively.(RBC count means count by millions).

The Table V indicates that the mean values of the pretest belonging to the training groups of continuous, alternative pace running, combined and control method are 5.517, 5.83, 5.80 and 5.75 respectively. The derived F ratio 1.191 for the pretest was lesser compared to 3.20 of table value for degree of freedom 4 and 45 necessary for a level significance specified at 0.05. And the means derived from the scores of posttest of the training groups of continuous, alternative pace, combined, control method were 6.03,6.09,6.29 and 5.64 respectively. The F ratio 4.685 obtained for post-test was greater than 3.21 of table value for degree of 4 and 45 necessary for a significant level at a value of 0.05. The means of adjusted post-test of the group of continuous, alternative pace running, combined and control method were 6.124,6.011,6.233 and 5.609 respectively. The F ratio 9.407 obtained for post-test was greater than 3.21 of table value for degree of 4 and 45 necessary for significance level at 0.05.The analysis mentioned above shows that the result has a significant difference of the means of the adjusted post-test of the all the groups. For post hoc test Scheffe's test was used in order to identify which specific group had the significant difference and to evaluate which particular paired means showed significance of difference and the conclusions are shown in Table VI.

Discussion on Findings

The current study clearly reveals the significant improvement of the combined training group on the chosen variables such as muscular endurance, breath holding time and red blood corpuscles when compared with the groups of continuous, alternative pace run group, combined training and control trainings.

Discussion on Findings: The hypothesis of the study is that the combined training would have significant improvement from base line to post treatment on motor fitness physiological and hematological variables of inter collegiate men athletes. The result of the study indicates that all the motor fitness, physiological and hematological variables improved significantly after the 12 weeks of treatment. Hence the investigator's first hypothesis was accepted at 95% of confidence level.

Conclusions

The combined training group showed significant improvement with the influence of motor fitness, physiological and hematological variables in comparison with the groups of continuous training, alternative pace run and control training.

An Evidence-Based Approach for Decision Making in Dental Implants

V. Ramya[1], Sajid Hussain[1], Bhuvaneshwarri[1], Preethe Padmanabhan[1]

[1]Reader, Sree Balaji Dental College And Hospital And Hospital Biher University

Abstract

The purpose of this article is to discuss clinical decision-making and treatment strategies in the management of periodontal patients. Both benefits and risks or treating periodontally compromised teeth/dentitions in combination or not with implant placement are accounted for. Also the benefits and risks of using implants to cost-effectively improve the prognosis for the mobile natural tooth or tooth-supported fixed partial dentures are presented.

Keywords: *Dental implants, fixed prosthesis, desicionanalysis, ridge augmentation, markov model.*

Introduction

The evidence-based approach, a process for reviewing large volumes of clinical and scientific data, emerged in medicine and dentistry during the 1990s. This approach was implemented in therapeutic decision-making with the aim of maximizing the potential for successful patient care outcomes. Information derived from clinical trials is considered more reliable than information based on intuition, authority, or custom. There is a hierarchy when considering the levels of evidence. Systematic reviews of randomized controlled trials are considered to be at the highest level, whereas expert opinion is considered the lowest level of evidence.

Advanced periodontal breakdown will call for extensive cause-related treatment of the disease to achieve and maintain periodontal health. It may also require comprehensive prosthetic reconstruction to restore function and aesthetics to the patient[1]. During the last decades careful scientific documentation has provided a solid base for implant therapy as a reliable treatment modality to replace the lost teeth. Today we know that treatments including implant-supported single crowns or fixed partial dentures as comprehensive therapy will generally have a good prognosis when performed on the correct indications and followed by proper oral hygiene measures and supportive care.[2]

Dental implants or dentures?: According to Smith & Pell, 'the effectiveness of an intervention has to be judged relative to nonintervention. Observational studies evaluating patients before and after treatment with dental implants have demonstrated great advantages with regard to function, esthetics and psycho-social factors[2,3].

Old vs. New implant techniques and components: Essentially, the same type of implants and strict protocols were used during the first 30 years of osseointegration, which means that these factors were well controlled in clinical studies. The influence of other factors such as jaw, age, bone quality and health, could be evaluated and risk factors have been identified in retrospective analyses of the literature. Based on this information, patient selection and surgical techniques could be improved without altering the components[4] Implant surface modification is a well-documented fact that a slight increase of surface roughness results in more and earlier bone-implant contacts as well as a higher resistance to removal torque forces. The few randomized controlled trials comparing implant surfaces have used two-stage procedures in patients with good bone conditions. When evaluating the literature on implant treatment in more challenging situations, such as soft bone, immediate loading and bone grafting, it seems moderately rough implants perform better. However,

Corresponding Author:

Reader, Sree Balaji Dental College And Hospital, Biher University
e-mail: dr.ramya@yahoo.co.in
Contact No.: 9894383459

randomized controlled trials are needed to prove this point scientifically.[5] At present, the third generation of implant surfaces is already a clinical and commercial reality, often based on nanotechnology. However, the new surfaces on well-documented implant designs are probably not hazardous for the patients and may result in a faster integration, which theoretically would allow for shorter healing periods prior to loading[6].

The decision-making model: The decision-making model describes two major components, the normative and the descriptive, which are involved in decision making. The normative aspect of decision making relies on quantitative information derived from systematic reviews and predictive models on the probabilities and uncertainties of treatment outcomes. Clinical outcomes, such as survival or success of a tooth or a restoration, are assessed based on the utility they offer to the patient and then cost. Normative analyses allow quantitative comparisons of alternative therapies and can identify optimal treatments for multiple attributes. The descriptive aspect in decision making involves cognitive processes and biases of both providers and patients that translate the normative information into clinical action. Although implant-supported prostheses have become the treatment of choice in an increasing number of patients, it remains controversial under which conditions retaining a tooth may be futile and replacing in tooth with an implant-supported prosthesis may be considered over-treatment. Owing to the complexity and variability in designs of revocable dental prostheses, the discussion will be limited to fixed dental prostheses[7].

Overall scheme of dental decision making (Adapted from Chapman &Sonnenberg, 2000)[8].The normative components of decision making are marked in blue and the descriptive components are marked in redThomas et al., in his systematic review did not show enough evidence to demonstrate superiority of and particular type of implant or implant system, or between a one-stage vs. a two-stage implant placement..

Smoking has been identified as a significant risk factor for implant failure. In patients with periodontitis-associated tooth loss compared with patients who lost their teeth largely unrelated to periodontitis, the risk for developing peri-implantities was significantly increased over a 10-year follow-up period (risk ratio of 9, 95% confidence interval: 3.94-20.57%). Despite the higher incidence of biological complications in patients with periodontitis-associated tooth loss, survival rates of implants were not significantly different from those found in patients with periodontitis-associated tooth loss. The 5- and 10- year survival rates were reported to be greater than 90% in both groups of patients.[9,10]

Impact of implant-supported dental prostheses on oral health-related to quality of life: Conclusive evidence has indicated that patients with implant-supported overdentures in the mandible report improved satisfaction with chewing compared to patients with conventional complete removable dental prosthesesAlthough patients rated the Implant-supported complete denture higher than the conventional complete denture for chewing ability and function, the overall rating was not significantly different between the two types of prostheses. The available information is insufficient regarding the economics of different treatment modalities, perception of esthetics, therapies avoiding active treatment (e.g. adoption of a shortened dental arch compared with the prosthetic provision) and quality of life outcomes with respect to fixed conventional prostheses compared with implant-supported or removable prostheses.[13]

Outcomes of oral implants placed in augmented bone: Cumulative survival rates for implants in bone that has been regenerated by barrier membranes ranged from 79.4% to 100% after 5 years of function. The survival rates of implants in augmented bone were found to be similar to those generally reported for implants placed in nonaugmented sites[14]. The method of bone augmentation does not seem to affect the outcomes of implant therapy because implant survival rates were comparable following guided bone regeneration and distraction osteogenesis (95.8% and 96.5-97%, respectively).[14]

The use of autogenous bone alone or as a component of a composite graft does not seem to affect implant survival. Implant survival rates were higher when a membrane was placed over the lateral window (93.6%) compared to when no membrane was used (88.7%). Similar results were found by other authors who reported an overall survival rate of 91.5% when implants were placed in grafted sinuses. The implant survival rate in grafted maxillary sinuses was found to be 87.7% with autogeneous bone grafts, 94.9% when autogenous bone was combined with various bone substitutes, and 96.0% following the use of bone substitutes along[15].

Decision analysis: Another approach to decision-

making, which so far has not been applied to implant dentistry, is decision analysis. Decision analysis provides a methodology for comparing alternative treatment strategies by calculating expected values of the resulting outcomes. Quantitatively describing the possible events and their likelihood enables an assessment of the effect of variations in basic assumptions on the optimal therapy. It provides a mechanism to evaluate the same clinical decision along multiple outcome dimensions, such as survival, utility and costs.

Markov Model: The Markov model is more convenient for using to model the prognosis of clinical problems with ongoing risk and will be applied to decision making in implant dentistry. Basic assumptions of the Markov model include a tooth or prosthesis, is always in one of a finite number of health states, referred to as Markov states, and that there is no memory in the process. If appropriate data are available, each state can be assigned to a utility and a cost. All events are modelled as transitions from one state to another, using transition probabilities. The time horizon of the analysis is divided into equal increments of time that are called Markov cycles[16].

The state-transition diagram for a tooth undergoing periodontal therapy is described. Arrows emanating from and returning to the same state indicate that the tooth has a certain chance of remaining in the same state during subsequent cycles. Tooth loss is the absorbing state as there can be no further transition to another state from this point. For the purpose of this analysis, the cycle length was set to 1 year as most available data present transitions from one health state to another in the form of annual rates. Annual transition rates *r*retrieved from the literature were transformed into transition probabilities *P[t]* using the following formula: $P_t = -e^{-rt}$, Constant transition probabilities were used in accordance with the assumption of the Markov chain because there is little information indicating that transition rates change over the modelled time frame.

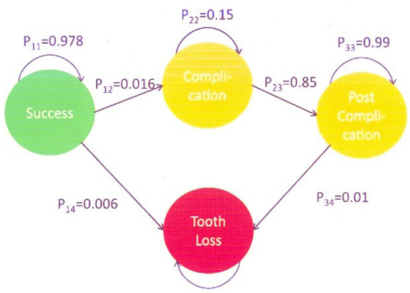

Fig A – Periodontal therapy aimed at tooth retention

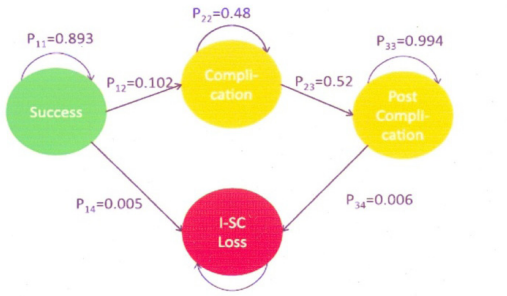

Fig B. tooth extraction and replacement using an implant-supported *single crown*

Markov models adapted for the treatment of decision of a single tooth presenting with periodontitis is used. Three Markov processes were developed for alternative therapies, including (i) periodontal therapy aimed at tooth retention (Fig. A), (ii) tooth extraction and replacement using an implant-supported single crown (Fig. B), or (iii) tooth extraction and replacement using a tooth-supported fixed dental prosthesis (Fig. C). Transition probabilities for implant-supported single crowns and tooth-supported fixed dental prostheses were derived from the literature

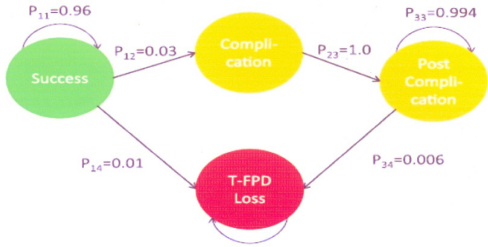

Fig C. Tooth extraction and replacement using a tooth-supported fixed dental prosthesis.

Conclusion

Decision analysis holds great promise for aiding providers and patients in shared decision-making regarding the retention or replacent of diseased teeth with implant-supported dental prostheses. By quantifying outcomes for alternative treatments it may help to identify the most appropriate care for individual patients based on utility and costs and thereby mitigate under-treatment and over-treatment. With the increasing availability of electronic health records and progress in health informatics, robust decision-support tools may become available that can be integrated into the clinical workflow.

Emerging Trends of Pharma Industry Policies for Ensuring Women Retention "New-Fangled Women Friendly Policies Which Foster Gender Neutral Workplace"

A. Nafeesa Begum[1], G. Brindha[2]

[1]Research Scholar, Department of Management Studies, Bharath University, [2]Professor& Head, Faculty of Management Studies, Dr. MGR Educational and Research Institute, Chennai

Abstract

Today, behaviour of women employees has changed the environment of the private organization. Young women employees always ready to switch over whenever she dissatisfy with any reason in the job. Retention strategy is a powerful recruitment tool. Private organizational issues matters as lost knowledge and training time. HR managers should identify the needs of the women employee and then devises the retention strategies. As different individuals have different priorities does not fit one strategy. HR professionals face the vital challenge to retain talented women employees. Retention strategies are fall into four categories- job enrichment, salary, working conditions and education, addressing these issues this article demands a specialized approach that emerge new fangled women friendly policies which foster gender neutral workplace in developing retention strategies.

Keywords: *Retention strategies for female employees, scope, trends and policies.*

Introduction

The fast developing knowledge economy coupled with the information technology during the last two decades has totally changed the complexion of our business and employment relations. The globalized economy and the labour market have further added new dimensions to this phenomenon. India has taken advantage of this growing trend entering the Pharmaceutical sector of economy and industry[1]. Though the Indian is fast responding and taking the challenge head on and competing effectively in the new Pharmaceutical dominated global market the industrialist-employer in the Pharmaceutical industry are facing another challenge, namely, finding suitable people to recruit to the jobs being generated by them. When and where they are able to find people who can meet their expectations, they are facing the new challenge that this is coming their way in the form of retaining the people working with them. In fact, recruitment and retention are two sides of the same coin. Economically and financially employee retention, of late has acquired greater significance.[2] It is much more costly and time consuming to find the right replacements. Resultantly the employee retention has turned out to be a critical challenge to the employers. They have become very sensitive to the problem of employee retention. Researchers also are seized of the situation and getting involved in this challenge.

Researchers have found that workplace culture and women's personal character traits play major roles in retention. So what are the things that make a difference? Women prefer workplaces that are collaborative rather than hierarchical, explains Heather Metcalf, director of research and analysis at the Association for Women in Science[3]. And they are more apt to stay in work environments that allow for creativity and flexibility, she says. Conversely, women are fleeing companies that encourage employees to practically live at work, she says. While 71 percent of women with young children work outside the home, according to the Pew Research Center, women still shoulder more responsibility for child care and elder care than men. So living at the office to show they are committed to their jobs is not an option."Creating workplaces that have a lot of flexibility, that allow for people to work in a way that fits best with them, boosts creativity and job satisfaction," Metcalf says, and these are the settings where women stay and thrive. No matter what type of organization women work for, large or small, public or private, their

relationships with their immediate bosses are critical to whether they feel engaged and content[4]. The ideal supervisor is committed to his or her subordinates' advancement and development, assigns stretch projects, and provides necessary support and feedback to help them be successful, Bilimoria says[5]. And workplaces that employ women in higher levels are more apt to retain women at the lower levels.

Objectives of the Study

1. To identify the emerging trends and policies for retaining women employees in Pharmaceutical industry
2. To identify the scope of ensuring women retention in Pharmaceutical industry
3. To suggest new policies that are women friendly and that will foster gender neutral work place

Scope of the Study: Keeping in view the critical problem the organizations in the Pharmaceutical industry have been facing ever since the Pharmaceutical industry came into existence in India to retain their performing employees at different levels, this study seeks to understand the different strategies of different organizations for retaining their employees and examine whether those strategies have any universal base and comparison with the experiences of high-tech organizations or organizations depending on the knowledge workers or professional employees and if so what are these common employee retention strategies being in practice in different organizations in the Pharmaceutical industry in Chennai.

The scope of this study is confined to Pharmaceutical industry in Chennai. The study throws light through valuable suggestion to increase the female employees' retention in the organization. This study can help the management to find the weaker parts of the female employee feels towards the existing organization retention strategies and also helps in converting those weaker part in to stronger by providing the optimum suggestions or solutions. This study is a clear guide for the solution seeker about the factors which induced women employees to stay back in the same organization. Special attention has been shown in this research about their empowerment in the society economically as well as professionally. Career development is an existing trend to be stay in their organization and how these factors induced them; all those answers will be make this research unique and an find an enhanced approach towards balancing gender at workplace.

Emerging Trends for Retaining Wowen Employees

More Women Leaders: The first thing that gives a woman confidence at her workplace is having women leaders to look up to[6]. This also indicates that the company offers them an environment conducive to scale the corporate ladder. It would be more beneficial if women leaders took on the role of mentors in mentorship programmes that are already at work in certain companies.

Sexism-Free Work Culture: Every workplace must offer a safe and secure environment for employees that help them grow personally and professionally. But it is a sad reality that this is not always true in India. Some of the biggest companies here lack sexual harassment cells and policies against discrimination at the workplace. Create a culture that does away with sexism at work by educating your employees about 'unconscious biases' and 'benevolent sexism'.

Pay men and women equally: When you hire talented women, understand that they put in the same amount of hard work and time as the men and acknowledge that with equal pay. Offer them equal opportunities and trust them with responsibilities similar to what their male counterparts are given to foster increased confidence and professional growth.

Transparent Performance Evaluation Policy: Make it clear to all employees how they are going to be evaluated and about the requirements to be met to make career advancements. It is commonly seen that most organisations promote men on potential and women only on measurable and proven performance. Check your talent management systems and do away with such biases.

Flexible Work Schedules: Many Indian companies already offer flexible schedules to their employees, but most often they turn out to be only the freedom to choose their shifts. True flexibility means allowing your employees to adjust their work schedules to maintain a healthy work-life balance without being penalised. [7]As long as they turn in their work on time and are producing results, their physical absence from office shouldn't be a concern. Having flexible schedules end up in happier, more satisfied and extremely productiveemployees. Good intentions, alone, are not enough to make women

employees want to work for your company. Treat them well, provide them opportunities for professional development and create a culture that values their talents and respects them as individuals.

Paternity Leave: Reputation being known as a company that promotes gender equality will go a long way in attracting top female talent. And offering a generous paternity leave policy is one of the most effective ways to demonstrate a commitment to women and working families. While paternity leave is designed for men, it ultimately benefits working mothers and children. Furthermore, since most states don't require it by law, implementing paternity leave shows that an employer is willing to go above and beyond to promote equality and inclusion.

Empower Female Employees to Shape Company Culture: Startup land has become famous for offering a fraternity-like atmosphere: free beer, video games, and personalized goodiesf[8]. While it's not fair to say women don't like these perks, tech companies should include women on the teams that are shaping company culture. Expanding the activities beyond those evoking college dorm rooms will help attract talented women who don't feel connected to those traditions.

Finally, it should go without saying that the best way to attract female talent is to offer competitive wages and excellent benefits that will support them in their life choices regardless of if they decide to have children or not. While the grand gesture of Face book and Apple will surely help their recruitment efforts, our corporate culture as a whole needs to focus on making small, but important, everyday changes and sticking with them

Career Development Program: Every individual is worried about her career. You can provide them conditional assistance for certain courses which are beneficial from your business point of view. Conditional assistance means the company will bear the expenses only if she gets an aggregate of certain percentage of marks. And entrance to that course should be on the basis of a Test and the number of seats to be limited. For getting admitted to such program, you can propose them to sign a bond with the company, like they cannot leave the company for 2 years or something after the successful completion of the course.

Timely increments: Timely Increments in salary makes talented employees to stick to the organisation for long time. Many researchers have found that the salary and increments were the core reasons behind leaving of employees to other organisations and competitor organisations attracts talent by showing sole monetary benefits, indeed most of the talent is getting attracted for this reason. It is universal fact and one has to accept that the monetary benefit is the core reason for an employee decision-making on retention in the organization

Conclusion

In a competitive business climate, retaining key employees is vital for the health of the company. But when these key employees are women, many corporations and industries continue to be befuddled as to how to retain this valuable cohort. Indeed, it's surprising how many supposedly modern institutions are caught in a time-warp. Unfair compensation, gender imbalance in senior management positions, inflexible schedules and even active discouragement of female employees continue to plague companies large and small. The good news is, above few simple strategies can vastly improve conditions for female employees. Women who are trained to develop an executive-type persona in terms of gravitas that is, confidence, poise under pressure and decisiveness – as well as communication and appearance become more confident and are better able to command a room, thereby clearing a path to high-stakes and high-visibility positions. By utilizing some or all of these ideas, companies can benefit from a healthier and more balanced work environment. It just makes sense.

To Assess the Marketing Practices on Social Media in Selected Tertiary Care Hospitals in Bangalore

Viniya C.[1], Khyathi G.V.[2], Sarala K.S.[3]

[1]Postgraduate Student, Department of Hospital Administration, M S Ramaiah University of Applied Sciences,
[2]Assistant Professor, Department of Hospital Administration, M S Ramaiah University of Applied Sciences,
[3]Assisstant Hospital Administrator. Ramaiah Medical College Hospital, Bangalore 560 054

Abstract

Social Media is becoming more utilized by hospitals and health care professionals and patients; from 2002 traditional media advertising has been replaced by digital media. Social media marketing is the use of social media platforms and websites to promote a product or service. Social media marketing is becoming more popular for both practitioners and researchers. Firms can allow customers and Internet users to post user-generated content that is online comments, product reviews, also known as "earned media," rather than use marketer-prepared advertising copy. This study focused on review of literature for measuring the effect of social media on hospital industry, barriers of social media marketing, uses of social media in hospital for patients and health care providers. It was a retrospective study. This Study attempted to check the strategies which can be implemented on social media in health care industry and a comparative Study was conducted on three corporate hospitals marketing practices on their official page of social media such as Facebook, twitter, and LinkedIn. From the comparative study the industrial gaps were found and analysed. The corporate hospital-Ashowed an average post of 4.2, Hospital B showed average post of 1.1 and Hospital C showed average post is 0.1 on daily basis on their official page. From the comparative study it was found that Hospital A was extremely active on their official page where they had posted theme based posts, videos and health education compared to Hospital-C. Hospital -B was moderately active on their official page compared to Hospital-C. Based on the gaps recommendations was given to Hospital-C were timely post, engaging with followers, targeting audience, responding to quarries,theme based post, health care tips post.

Introduction

Social media marketing is a form of internet marketing strategy that utilizes complete social media networks/websites as a marketing tool. The gaol of socialmedia is to produce contents that users will share with their social network to help an organization to reach and to exposure to the customer. Sites: Example-Facebook, Twitter, LinkedIn, Google+, Wikipedia, YouTube, etc.

One of the key components of social media marketing is social media optimization. Likesearch engine optimization, is a strategy for drawing new and unique visitors to a website.

Social media marketing helps a company get direct feedback from customers (and potential customers) while making the company seem more personable. The interactive parts of social media give customers the opportunity to ask questions or voice complaints and feel they are being heard. This aspect of SMM is called social customer relationship management. Social media marketing became more common with the increased popularity of websites such as Twitter, Facebook, Myspace, LinkedIn, and YouTube.[1]

Advantages of Social Media Marketing in Health Care Industry: When using social media for marketing products, social media could be easily utilized to create cost effective strategies and campaigns that can create viral results. Social media has the power to drive traffic to your website, blog, articles, etc. Social media is able to bring people together, especially when promoting global products or cause-related campaigns and ideas since it

allows people from the different geographical location to meet at a single point and express their views. Social media could be the spark you are looking for to attract attention to your site, product or service. It could also be used to further build loyalty and long-term relations with your audience. Social media marketing could always be a fun and creative method of doing business.[2]

Disadvantages: The wrong online brand strategy could put organizations at a viral social disadvantage and may even damage organization reputation, that is, when you make a mistake offline, a few will know but when you make a mistake in front of hundreds or thousands of you online audience, most of them will know Using social media for marketing and advertising could be more time consuming than companies expect. In order to get social media's full effect, organizations need to understand how it works, when and how to use it and which channels to focus on depending on organization end goal of using social media. And also Social media can have a negative influence on worker productivity. Employees may waste valuable time using social media channels such as Facebook and Twitter. They can also use social media to attack the company's reputation.[2]

Literature Review: The study indicated about the social media importance in present situation for business marketing and what is the importance of communication via social media to the brand awareness, conducted survey at Malaysia university two hundred questions asked and 75 percent of response rate they have got. In the study two propositions and two hypotheses were developed & tested using mean & regression analysis. After hypothesis test result showed in the study online marketing communications & online advertising are very effective in brand promoting & product purchase through organizations website & SM platforms. The study results shows social media marketing creates more purchasing intension of brand in this generation people are relaying on Social media to know information about organization's & services.[3] A study on usage barriers & measurement of social media marketing an exploratory investigation of small & medium Brand to Brands. Study has been conducted in order to identify the difference between users & non-users of based on organization's innovations T-test has been conducted. The results indicate significant differences in terms of organizations, &Reliability acceptances was a=.83. SNS users & M=2.46, SD=0.71 & non-users M=3.1 SD=1.34 t (88) =2.94 pb.005 found result through t-test.[4] Study purpose is to determine the impact of SM as a health communication and to understand the evolving impact of SM effectiveness and consumers preference's for health care. It involves both survey and interviews the survey questionaries' carries website content analysis of two hospitals. This shows significant results when consumers select a hospital Results shows trusted sources are word of mouth and traditional channels are more effective in n100 most of them are believed in traditional channels and social media, results have showed people are believing traditional channels unless special events example patients experience on the Facebook page,and marketing communication is more effective of sending messages to target population/audiences.[5] The study objectives are to discuss various interventions used in SMM for Health promotion and education and to discuss various interventions used in Social media marketing for promotion of public health. The Social media marketing sites like Facebook, blogs, YouTube and various organizations Social media tools. Results are the clinic which was chosen shows blog mainly used for video and audio featuring. Researchers provide context for their medical news and experiences and at the same time clinic provides Facebook and YouTube support system for patients when they required information. And clinic podcast blog where you can hear watch and download news on stories and conditions physicians updated blogs to read hear about innovations has been analyzed in the study how blogs are useful to patients and on what basis they provide information to the patients.[6]

Aim: Is to analyze the various marketing strategies practiced by selected tertiary care hospitals in Bangalore

Objectives

1. To study implementation strategies of social media marketing practices in health care
2. To conduct comparative analysis of the social media practices of hospitals
3. To analyse the gaps of social media marketing practices in Tertiary Care hospital
4. To recommend marketing strategies via social media

Methodology

A retrospective study was conducted from March to June 2018 at a tertiary care hospital in Bangalore. The study was conducted on social media marketing practices of three different corporate Hospitals.

The study focused on Implementation strategies of various social media practices from different websites. The data was collected for a period of four months where the content of social media official page such as Facebook, twitter, and LinkedIn wascompared among three different hospitals. From the above comparative study gaps were identified and analyzed and recommendations were given as per the results.

Results and Analysis

Implementation strategies: Various marketing strategies were taken from different websites. Through analysis it was seen that, advertising, ensuring patients queries, updating about hospital achievements, giving health tips responding to the all kind of comments in blog ensuring content with inspiring and educating your audience were the various marketing strategies adopted by hospital industry.

Comparative Study: Comparative analysis of different hospital practices the data was collected from the official page of three different corporate hospitals and was analyzed.

Table 1: Face bookdata

Facebook data	Hospital A	Hospital B	Hospital C
Number of Posts	513	135	22
Likes	21,288	15,712	7,697
Share	990	249	101
Comments	416	37	129
Number of Videos	20	6	2
Likes	2,617	1,834	3,204
Views	5,605	12,142	12,008
Share	39	62	6
Comments	14	8	1

Table 2: Facebook photos post data

Facebook data	Hospital A	Hospital B	Hospital C
Health education photos	79	61	1
Likes	4,836	1,187	10
Share	75	15	0
Comments	28	5	0
Time line photos	298	104	37
Likes	16,580	13,220	2,933
Share	264	181	85
Comments	144	22	147

The above table represents the marketing practices of three corporate hospitals. It is a comparative statistics of three hospitals Facebook data. The data was collected from hospitals Facebook official page for the duration of four months. Hospital A posts are theme base which changed on weekly basis and their post mainly focuses on health education, achievement of hospital, promotion of the services which creates brand image with attention seeking slogan, which creates awareness about the hospital services. Hospital B posts are mind test posts, creating awareness about services of hospital, and discounts of services provided by hospital prompting brand by introducing the hospital new doctors,services,videos,health education posts. Hospital C post and videos are very less compare to Hospital A and Posts are not theme basis it's all about events of hospital and some posts are achievement of doctors and a very less health education post. When the Hospital-A and B posts regarding success rate of the surgeries by the hospital, offers on hospital services, and health educational tips are mostly liked, shared, and commented by the customers, the hospitals responds to the quarries of the customers.

Table 3: Linked in data

LinkedIn data	Hospital B	Hospital C
Number of Post	95	19
Likes	137	50
comments	2	0
Videos	3	1
Likes	3	1
Comments	0	0

The above Tables represent the marketing practices of two corporate hospitals. It is a comparative statistics of two hospitals Facebook data. The data was collected from hospitals LinkedIn official page for the duration of four months. Hospital B posts are brand promoting, creating awareness about services of hospital, and events of hospital prompting new services by introducing the hospital new doctors,services,videos,and hospital technology. Hospital C post and videos are very less compare to Hospital A and Posts are not on daily basis it's all about events of hospital and some posts are achievement of doctors and a very less videos.

Table 4: Tweets data

Tweets data	Hospital A	Hospital B	Hospital 3
No of tweets	519	100	20
Likes	1,025	139	42
Direct message	30	8	0
Re tweets	186	27	25
Reply	139	6	0
Number of Videos	7	3	0
Likes	26	45	0
Direct message	2	1	0
Retweets	1	0	0
Reply	1	0	0
Views	69	21	0

The above Tables represent the marketing practices of three corporate hospitals. It is a comparative statistics of three hospitals tweets data. The data was collected from hospitals twitter official page for the duration of 4 months. Hospital A posts are theme base which changed on weekly basis and their post mainly focuses on health education, and videos contains content about health educational and informative about particular diseases and achievement of hospital, promotion of the services which creates brand image with attention seeking slogan, which creates awareness about the hospital services. Hospital B posts are mind test posts, creating awareness about services of hospital, and discounts of services provided by hospital prompting brand by introducing the hospital new doctors,services,videos,health education posts responding the queries of audience. Hospital C post and videos are very less compare to Hospital A and Posts are not theme basis it's all about events of hospital and some posts are achievement of doctors and a very less and activity is very less compare to Hospital A and Hospital B.

Analysis of gaps

Table 5: Average Number of posts

Average	Facebook	Tweets	LinkedIn
Hospital A	4.20	4.25	Not present
Hospital B	1.10	0.81	0.77
Hospital C	0.18	0.16	0.15

The above Tablerepresents marketing practices of three different corporate hospitals Comparative study was done. The study shows Hospital A was found to be extremely active on Facebook and twitter the data shows they average post on Facebook was 4.20/day and in twitter 4.25 tweets/day. Hospital B was found to be moderately doing good data shows average post in Face book 1.10 /day and in twitter 0.81 per day and in LinkedIn 0.77/day. From the comparative study industrial gaps were found in hospital C the average post in Facebook was 0.18/day and in twitter 0.16 per day and in LinkedIn 0.15/day and doesn't have live chat in Facebook page, average post and videos are very less, not theme base post, health education photos are very less on all three official page.

Discussion

The study showed examination of only two hospitals[5] but the research was done on three different corporate hospitals determining their marketing tools. organizations should carefully choose from social media options coming up every day. Side by side Organizations have to update to the latest additions on the social media circuit and which one of them is current favourite for optimum results. From the study it showed that Facebook, linkedin. twitter were the most favourite or optimum used social web page.[6] From the study only literature reviews were condisered for the study but the reseach used observational an inevestigating the content on social media.[7]

Recommendations: Identify Topics & Trends on Daily basis: The healthcare industry is completely changing rapidly, and social media plays an important role in understanding how individuals are talking about their communities, their preferences and even a particular organization. If organization notice a trend in conversations, seize the moment send a social post on social media site. It can help to understand what exactly organization followers want based on their like and comment and interest also it helps to create brand awareness.

Organization can ask them to leave their reviews and feedback as comments or direct readers to your review page. If happy reviewers leave their opinions, they provide valuable information for those who have not yet decided whether or not they wish to use your service and you should respond to their feedback immediately.

Incorporate images in organization posts: One of the most powerful tools organization can use to help to increase social media engagement is to incorporate visual content. Instagram, and Snap chat have thrived the power of visual storytelling and Facebook. Brand has a wide variety of choices to increase social media

engagement through visual content. Organization can also shareimages of new services that are inculcated within the organization to reach the people.

Step-1: Document who is your ideal customer

Step-2: Create a social media matrices statement

Step-3: Research Your Social Competitive Landscape

Step-4: Identify key success matrices

Step-5: Create creative content and video to engage

Step-6: Engage with customers/followers don't ignore

Conclusion

Social media is a one of the best and trending practice at current situation, followers are increasing daily on all kind of social media sites example Facebook, Twitter, YouTube, Google+, and LinkedIn. By studying current practices of three hospitals and by comparing the hospitals practices in Facebook, Twitter, and LinkedIn data it was identified average posts on daily basis that showed Hospital A is doing extremely well and Hospital B is moderate when compared to Hospital C, Hospital C posts are less in all the sites and posts are not theme base but other two hospitals are active on sites their posts and are theme based and hospitals also getting many likes, shares, comments, follower's views interaction on their official page. Study identified gaps of Hospital C practices were analysed and recommended for the best practices on social media to engage with patients, create awareness, to market the services to respond feedbacks and to monitor the success rate and sustain with competitors.

Employees' Perspective of Knowledge Management in Health Care Industry on their Performance

C. Kathiravan[1], E. Chandramouli[2]

[1]Associate Professor, Department of Business Administration, Annamalai University, [2]Lecturer in Physiotherapy, Division of Physical Medicine and Rehabilitation, Annamalai University, Doctorial Research Scholar Department of Business Administration

Abstract

Knowledge Management embraces a variety of practices employed by healthcare industry to identify, represent, create, and allocate knowledge for awareness, reuse and learning. The importance of the research was to identify the employees' perspective of knowledge management in health care industry on their performance. The research was conducted in Chennai. The sample frame of the study is Chennai district alone. Convenience sampling technique was adopted. The analysis found that there is influence of employees' perspective of knowledge management on employees' performance in healthcare industry. It is also found that there is influence of employees' performance on performance of health care industry. The analysis also found that there is positive relationship between knowledge creation and knowledge sharing. Hence it is concluded that highly encouraging incentive system must be incorporated within the healthcare industry, especially to technical and nontechnical employees so that their aspirations and happiness level can be duly met. This will surely enable the young talents to go a long way in enriching employees' performance in healthcare industry.

Keywords: *Knowledge creation, knowledge sharing, employees' performance, healthcare industry.*

Introduction

Knowledge Management embraces a variety of practices employed by healthcare industry to identify, represent, create, and allocate knowledge for awareness, reuse and learning.

KM is a situate of integrative procedure of synchronizing infrastructures and technical & managerial tools, storing, designed towards creating, sharing, diffusing, capturing, and efficiently using knowledge by groups and individuals, in search of healthcare industry goals by providing time, space, tools and encouragement. It is a administration discipline (i.e. handle, govern, direct, control, plan, coordinate, organize, enable, facilitate and empower) that look for to improve healthcare knowledge processing**,** with the reason of contributing to the formation and maintenance of an organic, producing, unified whole system, enhancing, maintaining, acquiring, and transmitting the health care's knowledge base.

Healthcare deliverance relies greatly on evidence and knowledge based medicine; in addition, deliverance of care replies on collaboration of several buddies that require exchanging their knowledge in order to offer quality of healthcare. This is predominantly true in healthcare setup, but also in public healthcare where the conclusion making is mostly based on data and confirmation collected by knowledge. In healthcare, knowledge management is organism developed mostly in the field of electronic healthcare documentation management and healthcare organization management; in this context, earlier researches in the business field have been tailored and functional to the Healthcare KM. But Healthcare knowledge management raises various issues and challenges due to the own personality its Knowledge.

While KM systems use Information Technologies to administer the storage, creation, sharing and reuse/use of knowledge; healthcare presents particular challenges to the use of KM such as impact of medical errors, system complexity and substantial growth of knowledge in the medical field. We will indication each of these dimensions in the following paragraphs; then we will look at the function that knowledge management can play in healthcare, its challenges and advantages; lastly we will position at perspectives of healthcare KM.

Healthcare deliverance involves healthcare professionals such as family physicians, nurses, specialists, counselors, technology technicians, social workers, radiologic lab technicians, psychologists, etc. It also engages third parties such as hospital and clinic administrators, human resources, managers in finance, drug companies, health care ministry, activists groups, health care insurance companies, research communities, education organizations, etc. Besides; partners in healthcare delivery are discrete around a lot of geographical areas while they are drama on the same patient.

Review of Literature

Jawad Karamat, et al. (2019) found that performance-based drivers and healthcare related drivers have considerable positive relationship with KM implementation. The research concluded that government involvement to encourage KM implementation is essential particularly in upward nations[6].

Manivannan, et al. (2019) found that there is significant difference towards information technology and knowledge utilization and knowledge motivation and do not differ towards knowledge storage, knowledge sharing enablers and knowledge creation with respect to gender groups. It is noted that independent sample t test result that moderately perceived towards knowledge management with respect to gender group of the bank employees. Hence it is concluded that the current team building efforts in bank management should be sustained to promote the integrated strategy in knowledge management.

Manivannan M. and Kathiravan (2016) concluded that there is a positive relationship and betweenknowledge management and employee's performance among the bank employees[9].

YadollahHamidi, et al. (2016) recommended that training programs should be detained in organize to learn how to use obtainable technologies such as email, discussion groups, intranet, blogs, office automation and to use KM processes[12].

Manivannan M. and Kathiravan (2016) found that there is influence of information technology, knowledge, top management support, organization and innovation on knowledge management among bank employees in Chennai City[8].

Edward T. Chen (2014) suggested that that KM will also promote the healthcare industry if KM execution is correctly designed and implemented. KM will modify the method in which hospitals, patients and doctors interact. KM can be pertained to gather the requirements for healthcare that is rising with the raise of population and the slow leaving of baby boomers[3].

Zaeem, et al. (2013) identified that there was a positive correlation between KM process and healthcare performance. In additional words, whatever activities of KM procedure were enhanced, organizational performance will be enhanced to the same quantity.

Shabani, et al. (2012) stated that all factors of the model namely find, learn, apply, share, create, evaluate, maintain and eliminate knowledge effected on the implementation of KM and all factors were in good position excepting learning and eliminating knowledge[5,10].

Ehsan Borousan, et al. (2012) studied that the entitled on implementing knowledge Management system in healthcare. Sample size of the research was 235 from medical centre users. The research paper identified that the there is impact of perceived usefulness, incentives for KMS users, perceived ease of use, organizational support and concerns of data security and confidentiality on affecting the implementation of a KM system[4].

Acharyulu (2011) identified that Web technology allows healthcare industries to build web and knowledge portals that can grip considerable amount of data and finished it reachable to customers anywhere anytime[1].

Christo El Morr and Julien Subercaze (2010) stated that in the near future, they will see a joining between semantic web technologies and health 2.0 the developed by HCLSIG. The ensuing functions might moderately develop computerized knowledge management associated to healthcare[2].

HosseinZadeh, et al. (2010) found that part of knowledge storage was minimum than the normal among the analyzed components. Hence, it is necessary to expand the significance of knowledge storage among the libraries employees and use knowledge storage systems [5,13].

Materials and Method

Research Design: Descriptive research design was adopted. The research design includes organization of the collected data, tools to get the relevant data, monitorial availability to perform the research, varied skills and the abilities of the researcher and the guide and time frame for each steps of research within the allotted spell of time (Srivastava, 2008)[11]. Based on these balanced steps are structured to perform this investigation.

Framework

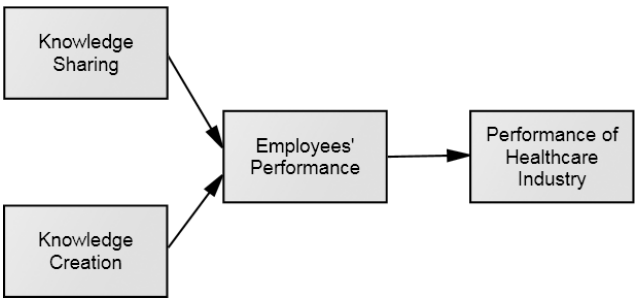

Figure 1: Conceptual framework of the study

Altogether this study includes four different variables. Knowledge sharing and knowledge creation were the independent variables; employees' performance was dependent variable; performance of healthcare industry was the outcome variable.

Objectives of the Study:

- To study the influence of employees' perspective of knowledge management on employees' performance in healthcare industry.
- To know the influence of employees' performance on performance of health care industry.

Hypotheses of the Study:

- There is no influence of employees' perspective of knowledge management on employees' performance in healthcare industry.
- There is no influence of employees' performance on performance of health care industry.

Tool for Data Collection: A well-designed questionnaire was used to gather the data for this research. The questionnaire contains four sections are presented. The section-I was constructed to obtain the demographic outline of the employees of healthcare industries; The section – II scale was used to know the Knowledge sharing and knowledge creation; the Section – III was used to know the employees' performance and the section-IV was used to analyze the performance of healthcare industry.

Reliability Analysis: Reliability analysis was also applied to test the reliability of the factors presented in above table. The reliability range from 0.78 to 0.94, which satisfies the Cronbach's alpha, should be at least 0.70 to be considered as acceptable.

S.No.	Variable	Reliability
1	Knowledge Creation	0.80
2	Knowledge Sharing	0.78
3	Employees' Performance	0.90
4	Performance of Healthcare Industry	0.94

Sample Design of the Study: The sample frame of the study is Chennai district alone. The respondents of the study are healthcare industries employees only. Though the healthcare industry included all the constructions under the technical and non technical alone is considered in this study.

Sample Size: Totally 145 questionnaires were distributed. 130 questionnaires were received. 15 questionnaires were not received. Out of 130 received questionnaires 125 were eligible and the remaining 5 were with flaws. Hence, the sample strength was 125.

Sampling Technique: Convenience sampling technique was adopted even though several researchers do not consider it as a better method (Srivastava, 2008)[11]. Data thus collected were verified for the eligibility for the adoption of the further processes. Care was taken to pair responses of the two schedules correctly.

Tool for Data Analysis: Path analysis was adopted for primary data analysis.Knowledge sharing and knowledge creation were the independent variables; employees' performance was dependent variable; performance of healthcare industry was the outcome variable.

Analysis and Interpretation:

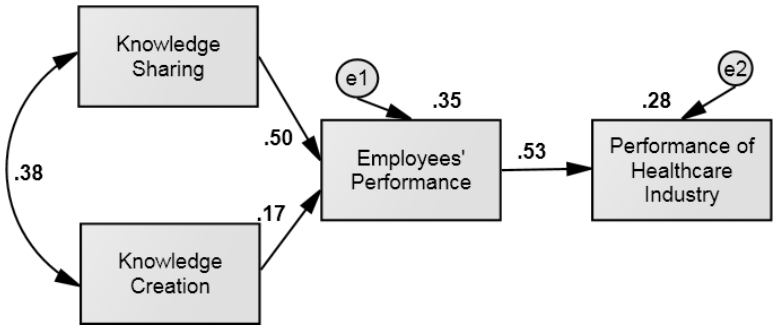

Figure 2: path analysis of employees' perspective of knowledge management in health care industry on their performance

Table 1: Model Fit Indication

Indicators	Observed Value	Recommended Value (Premapriya, et al. 2016)
Chi-Square	2.164	---
P	0.236	Greater than 0.050
GFI	0.998	Greater than 0.090
AGFI	0.965	Greater than 0.090
CFI	0.998	Greater than 0.090
NFI	0.996	Greater than 0.090
RMS	0.012	Less than 0.080
RMSEA	0.001	Less than 0.080

Source: primary data

The results shown in above table outline of the model fit, which contains the RMSEA score was 0.001 and RMS was 0.012 are well nearby the recommended limit of less than eight percent. All the goodness of fit indicators falls

into best level of fit. The chi-square value was 2.164 and probability value was 0.236 as against the recommended level and suggested by Saminathan, et al. (2019). In this model, the research has obtained GFI, AGFI, NFI and

Compared Fit Index were greater than 90 percent as against the recommended level.

Table 2: Regression Weights

DV		IV	Estimate	S.E.	C.R.	P	p
Employees' Performance	<---	Knowledge Sharing	0.374	0.027	13.968	0.504	0.001
Employees' Performance	<---	Knowledge Creation	0.161	0.035	4.609	0.166	0.001
Performance of Healthcare Industry	<---	Employees' Performance	0.963	0.063	15.263	0.533	0.001

Source: primary data

H_0: Knowledge sharing has significant influence on employees' performance.

Influence of knowledge sharing on employees' performance computed CR value was 13.968 and the probability value was 0.001. Hence, the hypothesis was rejected. The computed standard regression weight was 0.504. It shows that the one unit increase of knowledge sharing leads to increase of 50.4 percent on employees' performance. Hence, it is finished that there is influence of knowledge sharing on employees' performance in healthcare industry in Chennai. This finding is supports the study of Manivannan and Kathiravan (2016) found that there is a positive relationship and betweenknowledge management and employee's performance among the bank employees.

H_0: Knowledge creation has significant influence on employees' performance.

Influence of knowledge creation on employees' performance computed CR value was 4.609 and the probability value was 0.001. Hence, the hypothesis was

rejected. The computed standard regression weight was 0.166. It shows that the one unit increase of knowledge creation leads to increase of 16.6 percent on employees' performance. Hence, it is finished that there is influence of knowledge creation on employees' performance in healthcare industry in Chennai.

H_0: Employees' performance has significant influence on performance of healthcare industry.

Influence of employees' performance on performance of healthcare industry computed CR value was 15.263 and the probability value was 0.001. Hence, the hypothesis was rejected. The computed standard regression weight was 0.533. It shows that the one unit increase of employees' performance leads to increase of 53.3 percent on performance of healthcare industry. Hence, it is finished that there is influence of employees' performance on performance of healthcare industry in healthcare industry in Chennai.

Table 3: Covariance

IV		IV	Estimate	S.E.	C.R.	R	p
Knowledge Creation	<-->	Knowledge Sharing	8.673	1.015	8.546	0.377	0.001

Source: primary data

H_0: Knowledge sharing has significant relationship with knowledge creation.

Influence of knowledge sharing on knowledge creation computed CR value was 8.546 and the probability value was 0.001. Hence, the hypothesis was rejected. The computed standard covariance value was 0.377. It shows that the one unit increase of knowledge sharing leads to increase of 377 percent on knowledge creation. Hence, it is finished that there is positive relationship between knowledge sharing and knowledge creation in healthcare industry in Chennai.

Findings

- The analysis found that there is influence of employees' perspective of knowledge management on employees' performance in healthcare industry. This finding is supports the study of Manivannan and Kathiravan (2016) found that there is a positive relationship and betweenknowledge management and employee's performance among the bank employees.
- It is also found that there is influence of employees' performance on performance of health care industry. This finding is supports the study of JelenaRasula, et al. (2012) result showed that knowledge management practices positively influence organizational performance[7].
- The analysis also found that there is positive relationship between knowledge creation and knowledge sharing.

Recommendations

- Knowledge sharing as positively influences on employees' performance. Hence, it is recommended that the healthcare management involves a broad integration of knowledge sharing mechanisms which effort to promote innovation, such as the allotment of a budget for providing sufficient training for knowledge transfer, the linking of employees-turnover to the making of new ideas, or the formation of teams systematically dedicated to new initiatives generation.
- The result indicated thatKnowledge creation as positively influences on employees' performance. Healthcare management should require enlarging the number of social meetings between employees and individual and patients outside of work to increase the inter-organizational knowledge flow. Training programs should be provided to the employees on timely basis. Whenever new system is being introduced adequate training should be given to the employees to bring in knowledge creation.
- It is recommended that highly encouraging incentive system must be incorporated within the healthcare industry, especially to technical and non technical employees so that their aspirations and happiness level can be duly met. This will surely enable the young talents to go a long way in enriching performance of healthcare industry.

Conclusion

Knowledge Management embraces a variety of practices employed by healthcare industry to identify, represent, create, and allocate knowledge for awareness, reuse and learning. The importance of the research was to identify the employees' perspective of knowledge management in health care industry on their performance. The research was conducted in Chennai. The sample frame of the study is Chennai district alone. Convenience sampling technique was adopted. The analysis found that there is influence of employees' perspective of knowledge management on employees' performance in healthcare industry. It is also found that there is influence of employees' performance on performance of health care industry. The analysis also found that there is positive relationship between knowledge creation and knowledge sharing. Hence it is concluded that highly encouraging incentive system must be incorporated within the healthcare industry, especially to technical and non technical employees so that their aspirations and happiness level can be duly met. This will surely enable the young talents to go a long way in enriching employees' performance in healthcare industry.

Conflicts of Interest: None of the authors have any conflicts of interest relevant to what is written. This includes employment, consultancies, stock ownership, honoraria, paid expert testimony, patent applications and travel grants.

Funding Source: No Fund was provided for: data collection, analysis, and interpretation; trial design; patient recruitment.

No public funding was received.

Sterilization and Disinfection in Orthodontics: A Literature Review

Abhik Sinha

Former Post-Graduate Trainee, Department of Orthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Microorganisms are ubiquitous in nature and are responsible for causing infection, contamination and decay. The practicing dentists in general and orthodontists specifically, along with their personnel are routinely at risk of being exposed to patients with blood borne diseases like HIV/ AIDS, Hepatitis B and C and air borne diseases like Tuberculosis. These infections can directly be transmitted by oral fluids, blood, contaminated instruments and surfaces and through the respiratory system. Thus, preventing the spread of infection and cross-contamination in this field is absolutely important. The older strains of microorganisms rapidly develop resistance, whereas the newer strains evolve equally fast, thus, providing a constant challenge to orthodontists. Sterilization is defined as "the process by which an article, surface or a medium is freed of all the living organisms either in vegetative or spore form. This article reviews the various sterilization techniques pertinent to the orthodontic armamentarium and set-up for an effective orthodontic practice.

Keywords: *Orthodontists, respiratory system, sterilization, spores, AIDS, Tuberculosis.*

Introduction

Infectious microorganisms are ubiquitous and pose a big challenge to Orthodontists. Starnbachstated that "Orthodontists have the 2nd highest incidence of Hepatitis B among dental workers". Saliva remains the most common mode of transmission. Other factors include skin lesions, puncture wounds, Dental aerosols and instrument contamination.Both patients as well as practitioners remain at risk for spread of infection such as Hepatitis B, AIDS, Tuberculosis because of the diverse bacterial flora in the oral environment. Thus, accomplishing proper infection control through sterilization and disinfection becomes essential to prevent cross-contamination.[1]Sterilization is defined as "A process by which an article, surface or medium is freed of all the living microorganisms either in vegetative or spore state". Disinfection, on the other hand, is "the destruction of all pathogenic microorganisms capable of giving rise to infection". The various sterilization protocols pertaining to orthodontics have been discussed in this review.[2]

History:

1. **AntonieVan Leeuwenhoek (1632 – 1723):** Studied debris surrounding teeth and observed bacteria using a crudely built microscope.
2. **Sammelweis in Vienna and Holmer in USA:** Stated that hand washing is necessary to prevent the spread of disease-causing agents.
3. **Louis Pasteur and John Tyndall:** Advocated the destruction of vegetative bacteria and spores using heat.
4. **Joseph Lister (1827–1912):** Emphasized on washing hands, surgical linens with phenols and boiling the instruments before surgery to reduce complication.

Sterilization techniques

A. **Physical agents:**

   1. **Sunlight:** Sunlight possess germicidal effect due to a combination of ultraviolet rays and heat.
   2. **Dry heat:** This method of sterilization causes – denaturation and coagulation of proteins, along with loss of functional integrity of membrane molecules. This also significantly changes the loading and unloading properties of nickel-titanium wires with an increase in its stiffness.[3]

      i. **Hot air oven:** Thistechnique is widely used for dry heat sterilization. Different

materials can be sterilized using different method as follows –

- **160°C for 1 hour –** for glassware, scalpels, scissors, forceps, glass syringes, swabs, dusting powder, liquid paraffin, grease and fats.
- **190°C for 6 – 12 minutes –** for orthodontic pliers, mirrors, burs.[4]

ii. **Flaming:** Tip of the instruments like loop of wires, searing spatulas and point of forceps are held in a Bunsen flame till redness. Scalpels, needles, mouth of culture tubes, cover slips and glass slides are made to pass without making them red hot.[5]

iii. **Glass bead sterilizer:** This method uses a metal cup and glass beads of diameter between 1.2 – 1.5 mm at a temperature of 218°C – 240°C for 3 – 5 seconds. This method is useful for sterilizing orthodontic bands. A single molar band requires 220°C for 45 seconds to have a sporicidal effect.[6]

3. **Moist heat:**

i. **Pasteurization:** This is done at 63°C for 30 minutes to reduce the bacterial population of a liquid like milk. Spores are not affected by this method.

ii. **Boiling:** Vegetative bacteria are killed immediately at 100°C. Spores may require prolonged periods of boiling.

iii. **Autoclaving:** This method is considered the gold standard of sterilization and is the most popular. It is based on the principle "when pressure inside a closed chamber increases, the temperature at which water boils also increases, liberating 518 calories of heat". This method is useful for – Heat resistant plastics, dental instruments, dental handpieces, cotton rolls, gauze, aesthetic syringes, towel packs, glass slab.

Vandrell et al reported that orthodontic ligature cutting pliers sterilized either with steam autoclave or dry heat did not show any significant difference in mean wear.[7]

The recommended cycles for various articles are as follows:

i. Settings for general wrapped items:

Temp. - 121°C, Pressure - 20 PSI

Time - 30 min Setting

ii. Settings for bottled solutions:

Temp. - 121°C, Pressure - 20 PSI

Time -- 30 min Setting

iii. Setting for "Flashing" an unwrapped instrument:

Temp. – 132°C, Pressure - 30 PSI

Time - 4-7 Min Setting

This method can be used for a broad variety of items such as instruments, clothing, glassware, cotton.

4. **Filtration:** This method is effective in removing microbes from heat-labile liquids like serum and other blood products, drugs, vaccines, IV fluids, enzymes and culture media. They can be of the following types:

- **Candle filters:** Unglazed ceramic filters, Diatomaceous earth filters
- **Asbestos filters:** Seitz filter, Sterimat filters
- **Sintered glass filters:** Finely powdered glass particles
- **Membrane filters:** Cellulose Esters

5. **Radiation:** This can further be classified as follows -

A. Non-ionising radiation:

- **Infrared radiation:** Rapid mass sterilization of prepacked items like syringes, catheters
- **Ultraviolet radiation:** For disinfecting operation theatres and laboratories

B. Ionising radiation:X-rays, gamma rays and cosmic rays

6. **Vibrations:** These consist of Ultrasonic and sonic vibrations using high frequency of sound waves. The sensitivity of this technique among microoranisms are variable though.

B. Chemical agents:

1. Ethylene oxide sterilization: Ethylene oxide is a gas above 10.8°C, having excellent penetrating

ability and sporicidal action. The procedure involves releasing the gas into a tightly sealed chamber where it circulates for upto 4 hours and then mixed with CO_2 and nitrogen to reduce its concentration. Once the sterilization is done, flushing should be done for 8 – 12 hours to remove all the ethylene oxide and hence prevent "chemical burns".

This method is used for sterilizing leather, paper, metal, wood, rubber etc. The Conventional orthodontic marking pencils, hence, can effectively be sterilized by this method.[8]

2. **Chemical immersion/Cold sterilization:** This technique of sterilization is effective only for heat sensitive nonsurgical instruments and impressions using alginate.

    - 2% glutaraldehyde, which is a colourless liquid and having pungent odour, is a popular disinfectant used in dentistry for inactivation of bacterial spores. Metallic instruments, heat sensitive plastic rubbers, face masks and fiber optics can safely be immersed in this solution and kept for 6 – 10 hours at room temperature without corrosion. Long immersion time, odour, irritation to the eyes and mucous membrane are relative disadvantages.

This method is useful for sterilizing elastics such as elastomeric modules. Plastic items and cheek retractors can also be effectively sterilized. They may bring about a pitting corrosion of orthodontic instruments compared with surface corrosion by other method.[9]

- Alcohols such as Ethyl and isopropyl alcoholare effective as a disinfectant for instruments and a skin antiseptic. Isopropyl alcohol is a better fat solvent, less volatile and more bactericidal than Ethyl alcohol at a concentration of 50% - 70% and hence is preferred for denaturation of proteins and lipids along with disintegration of cell membrane. It is also useful in sterilizing the skin before cutaneous injections as it is a dehydrating agent.

Isopropyl alcohol, however, lacks sporicidal activity in the presence of blood and saliva and also causes corrosion of metallic instruments. This method can be used for sterilization of orthodontic archwires and elastic moduli.

- Aniline dyes such as Brilliant Green, Malachite Green and Crystal violet and Acridine dyes like Proflavine, Acriflavine, euflavine and aminacrine are effective against gram positive microorganisms.
- Halogens such as Iodine and Chlorine have markedly bactericidal and moderately sporicidal activity. Hence they are used as skin disinfectatnts and antiseptics.
- Phenols such as Lysol and Cresol, which are obtained by distillation of coal tar between temperatures of 170°C and 270°C, causes damage to the cell membrane.
- Metallic salts such as Salts of silver, copper and mercury are effective disinfectants with mild antiseptics. Copper salts, in addition, are fungicidal.
- Surface active agents alter the energy relationships at interfaces, thus, producing a reduction of surface tension. They possess both hydrophilic and hydrophobic properties and are widely used as wetting agents.[10]

(3) Laser (Light amplification for stimulated emission of radiation): Various lasers such as CO_2, Argon, and Neodymium-doped yittrium aluminium garnet (Nd:YAG) lasers are also useful in sterilizing instruments, operating rooms and surface of wounds. They are very expensive and this limits their use.[11]

Sterilization and disinfection of orthodontic instruments and materials:

(1) Sterilization of orthodontic pliers: Corrosion is the most common consequence, which should be prevented by drying the instruments with pressured air before sterilization. Otherwise, ions' react to create a loose layer of rust. Autoclaving, too, blunts and corrodes the sharp cutting edges of orthodontic instruments and is also more time consuming. 1% sodium nitrate can be thought of as an alternative. Glass bead sterilization at 218°C for 15 seconds can also be used effectively. For larger instruments, however, an ultrasonic bath using Sekusept 5% is recommended.[12]

(2) Disinfection of orthodontic brackets: 0.01% Chlorhexidine is the disinfectant of choice for both metal and ceramic brackets. Although this do not affect the adhesion ability of metallic brackets, the ceramic brackets do show a sub-clinical level reduction in the attachment ability.[13]

(3) Decontamination of orthodontic bands: The stainless-steel bands of various sizes frequently need to be tried on patients' mouth during fixed orthodontic treatment. The tried but unused band should be kept separately without mixing them up

with the new ones and processed through a pre-sterilization cleaning procedure and stored them separately. Later, they should be decontaminated from saliva and blood and autoclaved before further use.

(4) Sterilization of orthodontic archwires: Pernier et al (2005) conducted studies on 6 different archwires by autoclaving them at 134°C for 18 minutes and their surfaces were analysed. No significant changes were observed on the surface of the archwires that would restrict their use.[14]

(5) Disinfection of elastomeric ligatures: Polyurethane polymers which are frequently used as ligature and chains are sterilized through cold sterilization. Repeatedly disinfecting the same elastic destroys the cross-links in the molecules of polyurethane polyesters.[15]

(6) Bacterial contamination and disinfection of removable acrylic appliances: Use of removable appliances results in the formation of a biofilm layer on the areas beneath hooks and springs and the smooth acrylic surfaces of the appliance. This biofilm mostly contains Lactobacillus and Streptococcus mutans. Toothbrushes are not efficient enough to remove these microorganisms. Soaking the appliance in a chemical solution such as Chlorhexidinegluconate and Cetylpyridinium chloride was found to effectively eliminate *Streptococcus mutans*.[16]

(7) Sterilization of elastomeric ligatures and chains: Chemical sterilization is not done for elastomeric materials since they destabilize their physical properties. Elastomeric modules, however, can be cut into smaller sections, covered with a clear tubing and then cold sterilized.[17]

(8) Sterilization of Alginate impression: 2% glutaraldehyde and 1% sodium hypochlorite are commonly used disinfectants for alginate impressions. The alginate impression, however, should not be immersed in the disinfectant solution for more than 10 minutes to protect their surface characteristics. Nowadays, self-disinfecting alginates are also commercially available.[18-20.]

Table 1
TECHNIQUES OF STERILIZATION

- Physical
  - Sunlight
  - Heat
    - Dry heat
      - Red heat
      - Flaming
      - Incineration

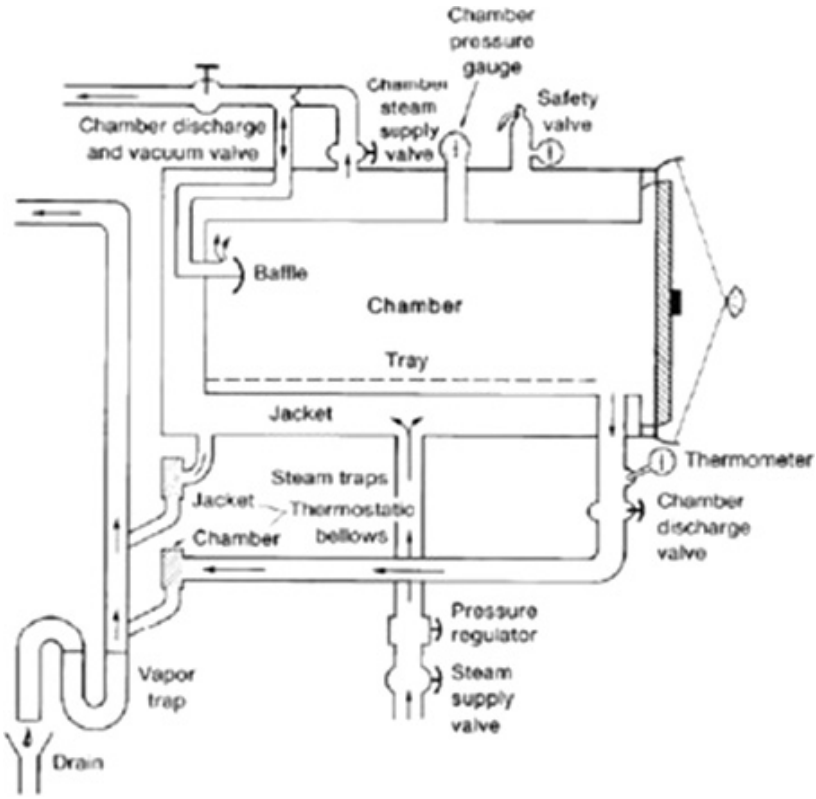

Figure 3 Components of an autoclave

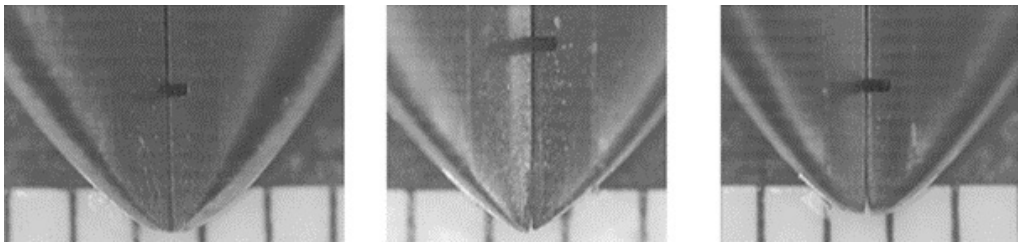

Figure 4: Orthodontic pliers and cutters should be sterilized properly before their use

Conclusion

As the saying goes – "cleanliness is next to Godliness", it is important for orthodontists to run their practice setup in a way that would restrict the spread of infection. Transmissible diseases such as AIDS, Hepatitis B and C make it essential for the practitioners to protect their clinic staff and patients using proper sterilization techniques. A thorough understanding and application of the sterilization techniques will help achieve the safety that our profession demands from us.

Triphala: A Wonder Therapy in Dentistry

Rinkee Mohanty[1], Aishwarya Bal[2], Rashmita Nayak[3], Abhaya Chandra Das[4], Saurav Panda[4], Gatha Mohanty[5]

[1]Professor & Head, [2]Post Graduate Trainee, [3]Professor, 4 Reader, [5]Senior Lecturer, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan, (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

From the medieval terminologies of the Sanskrit language, the word "Ayurveda" came into existence. It essentially beholds the meaning "essence of life" and symbolizes longevity. It emphasized on the plant derived and animal product-based treatment to cure ailments pertaining to physical existence and mental health. Triphala is one such plant that acts as a Rasayana and enriches oneself with vitality and boosts his/her immune system through its adaptogenic, immuno-modulatory anti-oxidant and detoxifying properties. These effects implore us to discover its usefulness in the field of dentistry in contrary to preferring systemic antibiotics. Systemic antimicrobial therapy causing resistance and superinfection is rechanneling us to come across newer effective solutions for dental diseases.

Keywords: *Ayurveda, Triphala, Myrobalans, Longevity, Periodontic therapy, endodontic therapy.*

Introduction

For centuries, drugs have been an essential part of the therapeutic and preventive armamentarium. Drugs can be naturally derived, synthetically manufactured, or biologically extracted. The collective effort in the amalgamation of chemistry and biology opened doorways for pharmaceuticals and allopathic medicine. However, new drug discovery is on the verge of experiencing massive setbacks due to the evolution of pathogens into multi-drug resistant strains and causing major side effects further discomforting the patients. Unchecked use of anti-microbial medicine is failing to serve their purpose and their increased usage is causing toxicity leading to systemic failure.[1]

This is compelling us to go back to the traditional sciences of the Indian alchemy i.e. Ayurveda, Unani, homeopathy which is still considered as age old valuable resources. Ayurveda has immense potential in the treatment of various ailments if used in safe and rational formulation. It can be an inspiration to path breaking discovery maneuvering us towards integrative medicine.[1]

Triphala is one such traditionally formulated drug that has taken a life of its own. It is the drug of choice in various metabolic disorders, systemic conditions and in the treatment of carcinoma. It empowers inherent immunity and delays the natural degenerative processes taking place within our human body. It is extremely beneficial to mankind as it is natural and bereft of any toxicity. It is easily affordable and widely available. Triphala has various pharmacological applications in the field of medicine and dentistry, and further research is necessary to strengthen and promote its importance and usage.[1]

History of Triphala

Triphala has been used in folk medicine for 1000 years. Charaka one of the greatest physicians mentioned Triphala in his compilations Charaka Samhita. Charaka believed that Triphala along with ghee and honey can increase the life span of a human being upto a hundred years.[1] Sushruta is known as the Father of surgery and the author of Sushruta Samhita has also written about this drug in his book. Sushruta considered Triphala effective in the management of wounds and ulcers. Sushruta called "Periodontium" as "Dantamula" and Periodontal

Corresponding Author:
Dr. Rinkee Mohanty
Professor & Head, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: rinkeemohanty@soa.ac.in

diseases as "Dantamulagatarogas" in Sushruta Samhita and associated the use of Triphala in Dantamulagata rogas.[2]

In the Ayurvedic texts, Nighantu has classified Triphala into three types. They are

1. Swalpa Triphala-composed of Draksha, Parushaka, Kharjura[3]
2. Sugandhi Triphala-composed of Kasmarya, Kharjura, Draksha[3]
3. Madhura Triphala-composed of Ela, Jatiphalam, Lavangam[3]

Ingredients and Formulations

As the name suggests "tri" means "three" and phala means"fruit". Myrobalans are fruit bearing plant species. Triphala constitutes of the myrobalans namely *Terminalia chebula, Terminalia Terminaliabellerica, and Emblicaofficinalis.* The pericarps of each fruit after removing its seeds are powdered and then formulated in equal proportions.

Amalaki

Botanical name-*Emblica officinalis:* It has excellent healing ability due to the treatment of various systemic diseases such as diabetes, cardiac ailments, anemia and carcinoma due to its immune-stimulatory actions and anti-oxidant actions. It acts as an efficient anti-microbial substance against various micro-organisms such as *K. pneumoniae, P. mirabilis, E. coli, S. paratyphi* A and B. The best aspect about amalaki is that even after its diverse usage for various diseases it does not cause any side effect on long term use. This is only possible due to cytoprotective and anti-ulcerogenic nature.

Hiritaki

Botanical name-*Terminalia chebula:* The most important constituent of this fruit is tannin, which chiefly contains acids such as chebulic, gallic, chebulagic along with corilagin. Due to its broad anti-microbial spectrum it acts as an anti-viral, anti-fungal and anti-bacterial effective against numerous gram stained biofilms. Its radical scavenging and effective wound healing capacity make it effective for usage in diabetes and vitreoretinopathy. It also used to increase gastrointestinal motility due to its anti-spasmodic action. It also acts as a hypolipidemic or anti-hyperlipidemic reducing cholesterol levels.

Bibhitaki

Botanical name-*Terminalia belerica:* It is widely used as folk medicine and contains various essential acids, polyphenols and lignans. It is also made up of triterpenoids, beta-sitosterol, and cardiac and saponin glycosides. Its cardio-protective aspect allows us to use it in hypercholesterolemia and cardiac disorders. Due to its gastroprotective and hepatoprotective aspect it is widely used in the treatment of gastro-intestinal disorders such as colic, indigestion and diarrhea. It is useful in treating chronic lung conditions as it acts as a bronchodilator. It is also used in systemic diseases due to its hypoglycemic and hypotensive effect.

Other Active Ingredients Present in Triphala are:

1. **Vitamin C:** It has anti-oxidant properties and is an essential nutrient necessary for tissue repair.It also contains several enzymes which are important for the immune system. It also plays a crucial role in the wound healing and formation of collagen.*Emblica officinalis* contains Vitamin C.[4]
2. **Tannins:** These are polyphenolic compounds which contain the property of astringency and are water soluble. They also prevent cellular oxidative damage. They are potent antimicrobials. Due to their anti-oxidant property they also act as anti-carcinogens and anti-mutagens. They also inhibit protein glycation. *Terminalia chebula*contains tannins.[4]
3. **Flavones:** They belong to a class of Flavonoids comprising of non-saturated 3 carbon chain. They have been extensively explored due to their neuroprotective property. They also have anti-amyloidogenic and anti-inflammatory properties.[4]
4. **Gallic Acid:** It is a trihydroxybenzoic acid. It is used as an intestinal astringent and also as an anti-diarrheal. It also contains epigallocatechingallate. *Terminalia belerica*contains gallic acid.[4]
5. **Quinones:** Quinones belong to a class of cyclic organic compounds. Vitamin K is a napthoquinone and is widely used due to its anti-hemorrhagic properties. *Terminalia chebula*contains anthraquinones.[4]

Ethnopharmacology of Triphala

1. **As an Anti-Neoplastic Agent:** It has immunostimulatory effect. It causes apoptosis of the carcinogenic and mutagenic cells. It also

facilitates the cytotoxic T-cells and NK cells. All these properties make it a potent chemopreventive and chemoprotective agent.

2. **As an Anti-Inflammatory Agent:** It is used as an analgesic, anti-pyretic, anti-microbial without any potential ulceration and damage to gastric epithelial lining. When these properties of Triphala at a concentration of 500 / 1000 mg/kg body wt and indomethacin at a concentration of 10 mg/kg body wt was compared Triphala showed excellent potency.[5] All these activities make it an effective anti-inflammatory agent

3. **As an Anti-Oxidant:** It acts on the molecular level and increases Vitamin C and Glutathione.Its enzymatic effects show enhancement in the level of glutathione (peroxidase, reductase, transferase) and reduction of myeloperoxidase and xanthine oxidase levels. Inhibition of lipid peroxidation is also observed. Triphala when administered 1g/kg/body wt for 48 days inhibited gamma-radiation induced activity and scavenges superoxides.Thus the polyphenols in Triphala act as potent anti-oxidants.[5]

4. **Use in Wound Healing:** It is effectively used in the management of burns and wounds seen in diabetic patients.It enhance nourishment to the tissues and decreases the effect wound healing delaying factors such as infection and collagenolytic activity. It shows significant approximation of wounds when used as an ointment. It also facilitates regenerative capacity and enhances wound healing when used with collagen sponges.[5]

5. **Use in the Treatment of Diabetes:** Triphala is known to have hypoglycemic property. It acts as an anti-diabetic by downregulating the digestive enzymes and glycation enzymes reducing glucose absorption. It also inhibits alpha-glucosidase and alpha –amylase. These convert polysaccharides into smaller glucose molecules.

6. **Anti-Microbial Spectrum of Triphala:** It exerts broad antimicrobial activity. It inhibits 37.96% of fungal species especially Aspergillus *in vitro*. It effectively inhibits *E. coli, S.aureus, P.vulgaris, S. typhi* and *P.aeruginosa.*[1].

7. **Triphala as a Stress-Reducer:** Humans experienced increased stress due to modernization of life style. Stress is simply described as a state of disharmony. It effectively reduces stress induced due to cold and noise. 1g/kg/body wt for 48 days could effectively control 100dB noise for 4hr/day for 15days. It reduces cortisone levels along with lipid peroxidases and efficiently reduces cold-induced stress.[5]

8. **Other Uses:**

(a) It acts as a colon purifier and cleanses the gastrointestinal tract

(b) It is also used in arthritis management

(c) It acts as an anti-obesogenic[1]

(d) It is also a neuroprotective agent and used in parkinsonism and alzheimers disease.

(e) It is used in chronic eye infections such as retinopathy.

Triphala in Dental Management

Since ancient times Triphala has been used for various medicinal and dental purposes due to its wide range of effectiveness and low side effects. It is also proven that Triphala is at par with many chemical drugs used in the treatment of various field of dentistry. In future Triphala might be used as an adjunct to various dental therapy in the effective management of dental problems.

Triphala in Conservative and Endodontic Therapy

1. **Anti-carious property:** Triphala extract inhibits the two mechanisms by which the micro-organisms colonize on the enamel surface. It prevents the attachment and accumulation induced by sucrose and glucose breakdown products. It also acts as a bacteriostatic and restricts the growth of *S.mutans*along with the reduction in the bacterial glycosyltransferases thereby reducing the incidence of pit and fissure caries by about 40%.[4]Thus by inhibiting the salivary pellicle formation and accumulation of acids causing demineralization of enamel, it prevents the carious activity. Triphala when used twice daily reduced the streptococci count by 17% and 44% at 48hr and 7days respectively in comparison to CHX which showed only 16% and 45% reduction.[6] Potent anti-cariogenic activity is seen when 0.6% of Triphala is used as a mouthwash without any extrinsic or intrinsic staining.[4]

2. **As An Endodontic Irrigant:** Various tissue dissolving agents, antibacterial agents and chelating agents are used for chemical debridement of the

complex root canal morphology i.e. inaccessible to instrumentation. But these irrigants are toxic and distasteful. Some of them are also inefficient in removing the smear layer. This led to the use Triphala and other unani medicine as root canal irrigants. It has notable antimicrobial action against the three and six weeks old opportunistic micro-organisms infecting the root canal. Hence, it acts as an alternative to other chemical irrigants such as sodium hypochlorite(NaOCl). Its action is superior to NaOCl when the concentration of NaOCl is 0.5% and 1%. Triphala in conjunction with 10% dimethyl sulfoxide actively eliminates *E.faecalis.*[1]

Triphala in Periodontal Therapy

1. **As an Anti-plaque agent:** Triphala in 50 µg/ml concentration inhibits the growth of *S.mutans*.[4] Hence it decreases the formation of plaque by inhibiting the adherence of the bacteria. It also adsorbs to the cell surface of the micro-organism leaching out its cellular constituents and denaturing its enveloping proteins leading to bacterial cell death. This occurs due to the presence of tannic acid. 10% Triphala mouthwash when used in teenagers showed effective anti-plaque activity in randomized clinical trials.[1]

2. **As an Anti-collagenase agent:** Most of the periodontal destruction occurs due to the presence of the key biomarker i.e. matrix metalloproteinases. These are a group of enzymes that activate cascade mechanism are gradually led to the production of collagenases especially MMP8 and MMP13. and gelatinases MMP2 and MMP9.The most potent inhibitor of these MMPs is Doxycycline. However, its prolonged use leads to a wide range of side effects and systemic toxicity which is not observed in the usage of Triphala extract. 1500 µg/ml of Triphala efficiently inhibits the production of MMP9 which is within its therapeutic dosage range.[4]

3. **Use in Gingival Inflammation:** The cardinal signs of inflammation are calor, rubor, tumor, dolor and loss of function. Due to the presence of Vitamin C and tannins there is reduction in the bleeding of gingiva on probing and enhanced healing of the gingival tissues after non-surgical and surgical therapy. Triphala mouthwash when combined with non-surgical periodontal therapy showed effective reduction in the values of various gingival indices such as bleeding indices, oral hygiene indices and plaque indices.

4. **Use in Periodontal Therapy:** Significant improvement in the clinical parameters and reduction in the signs of periodontal destruction such as clinical attachment loss, mobility, pocket probing depth and sensitivity when Triphala was used as a mouthwash along with powdered formulation for 1 month. There was noticeable amount of reduction seen in the clinical indices' values.

Conclusion

Triphala is a promising herbal drug that acts on myriad of diseases and has multidimensional applications. It is having notable therapeutic usage for maintaining the physiological equilibrium which finally results in preventing and inhibiting the progression of diseases. This review summarizes several evidence-based results obtained by scientific studies which describe various pharmacological uses of Triphala. However current data is insufficient and additional research work and clinical survey is necessary to embolden its use in dentistry.

Diet Counseling: Prevention for Early Childhood Caries

Saswati Dhal

Intern (BDS), Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Diet counseling plays a very important role for adopting a healthy lifestyle.Researchers suggested that diet counseling is neglected all over the world day by day. So that dentists are facing a lot of diseases in the oral cavity.Therefore, diet counseling is mandatory for all. This is more beneficial when this process begins earlier. The goal of the diet counseling is to get rid of harmful eating habits,to continue the balance diet and the avoidance of the diseases.The future eating habits can be shaped in a healthy manner by providing children nutrition education..though the parents are not well familiar with the harmful food and the harmful eating habits of their children,the duty of the dentist is to make the parents well educated about what to prefer for the children to have on their diet and what not to have. It is very prodigious to know what is harmful and what is useful for their child.

Keywords: *Diet Counseling, Preschool Habits, Nutrition Education.*

Introduction

Nutrition is defined as the total of series that worried in the process of increase in size, preserving a condition or situation or the state of being preserved and restore the living body as entire or its parts of whole.Nutrition is a science food and its state of being connected to health.[1] Balanced diet is one which contain something fit to be eaten in such quantities and proportion the need for energy, aminoacids, vitamins, fats, carbohydrates and other nutrition is consecutively met for maintaing health, vitality and general well being and also makes provision for a short duration of leanness.[1] Up to five year of a child life is a period of rapid physical, mental and emotional development. They communicate up to extreme level during this year.The preschool is the perfect time to help children to change the attitude towards healthy food and to teach them goodeating habits. The poor quality and inaccurate nutrition badly impacts the physical and mental development and learning ability of the child during the preschool period. For the normal growth and development of a child and to prevent a number of nutrient related diseases.It is necessary to consumption of healthy diets.[2, 3]

Coressponding Author:

Diet counseling: Before counseling a child and mother, dentist should know what the child is eating.The purpose of diet counseling should explain to the patient in the first appointment.[1]

- To correct the imbalance diet which could affect the general health of the patient and sometimes it is also reflected in his oral health.
- That we are looking for possible dietary causes of the caries problem of patient, so that we can reduce the risk offuture caries by dietary means.[2]
- What beneficial outcome could be available for him in better oral health and appearance and possibly improved health in general.

This program is based on a step by step progression through:

- The diet diary of a child should introduce with a brief discussion for the intention of diet counseling.
- To get an idea of food that the child is consuming a 24-hour diet record should prepared.[1]
- A weakly diet chart is advised to prepared by the patient.

- Reducing the sugar factors.
- Educating the patient about the decay process of sugar.
- To consumption of more acceptable food rather than more cariogenic food.[1]

Guidelines for counseling: For the successful diet counseling the accurate and truthful statement is that the patient, not the counselor bears the responsibility for making changes in food selection and eating habits.[4] The guidelines are:

- Gathering information about the patient.
- Evaluate and interpret information.
- Development and implement a plan of action.
- Cooperation of the patient's family in all aspects of dietary changes.

For the normal growth and development of a child and to prevent a number of nutrient related diseases it is necessary to consumption of healthy diets.

Diet Charting for Preschooler: Preschooler between the age of 2-3 years are able to eat a variety of healthy foods.

Daily caloric and protein requirement for the preschooler is

- Caloric – 1500
- Protein – 2g

Sample menu for a preschooler: During the preschool years child should be eating the same food as the rest of the family.This included fresh vegetables and fruits, non fat or low fat diary product[milk, yogurt, cheeses], lean meats[chicken, turkey, fish, lean hamburger] and whole grain cereals and bread and the same time eliminate the junk foods.

Sample 24-hour menu for preschooler[5, 6]

- **Breakfast:** ½ cup non-fat milk, ½ cup cereal, 4-6 oz or ½ cup cantaloupe or banana.
- **Snacks:** ½ cup non fat milk, ½ cup fruits such as banana or berries, ½ cup yogurt.
- **Lunch:** ½ bowl rice, or 2 slice whole wheat bread with 1-2 oz of meat, veggies, ¼ cup green vegetables
- **Snacks:** 1 teaspoon peanut butter with 1 slice whole wheat bread or some fruits.
- **Dinner:** ½ cup nonfat milk, 2 ounces meat, fish or chicken, ½ cup pasta or rice, ¼ cup vegetable

How much to eat from the food you offer it is child should decide. Nobody should force the child to eat or restrict the amount of food allow them to eat. Day by day child's appetite can change. They might eat more some days and some days they might eat less. So, it is necessary to plan adiet chart according to day and weak (Table 1-6)[7].

Table 1. 24-hour sample diet chart for prescho

Meals	Food
Breakfast [6:30 AM -7:00AM]	2 sandwich, 2cup milk or 2 bread omelet
Mild morning [11:00AM]	1 Stuffed paratha paneer and one fruit
Lunch [1:00PM]	1 small plate rice, 1/2 cup dal or curd, 1/2 cup mixed vegetable
Eveningsnacks [5:00AM]	1 cup milk, 4-6 biscuits
Dinner [8:00PM]	2 pieces chapati, 1/2 cup dal, 1/2 cup vegetable
Night [11:00PM]	1 cup fruit custard

Table 2. 7 days sample diet chart for preschooler[9]

Day	Monday	Tuesday	Wednesday	Thursday	Friday	Saturday	Sunday
Breakfast	1 egg omelette, 1 cup of mik	1 bowl of ceregrow with 6-10 chopped almonds, 1 cup of mik	1-2 idlis and vegetable samber, 1 cup of milk	1 bowl of ceregrow, 1 cup of milk	1 slice of whole grain toast and avocado, topped with tomato slices, 1 cup of milk	2-6 inches whole wheat pancakes topped with peanut butter and berries, 1cup of milk	1bowl of ceregrow topped with raisins, dried cranberries
Morning snacks	1 bowl papaya cubes	1 cup fruit salad	Fruit smoothie with spinach	½ chopped apple with 1 spoon peanut butter	1 banana, 2-3 walnut	1 Banana with 1 spoon peanut butter	Single slice tomato cheese sandwich

Day	Monday	Tuesday	Wednesday	Thursday	Friday	Saturday	Sunday
Lunch	Small bowl of rice with dal, gourd curry	Mixed veg curry, 2-3 chapatis	Small bowl of rice, egg curry	Small bowl of rice, sambar, green bean curry	2 chapatis, egg bhurji with vegetable	Small bowl rice, curd, tomato raita	2 chapatis, dal, mixed vegetable
Early evening snacks	1 bowl of cerebrow with walnut and dried cranberries	1cucumber, tomato and cheese sandwich [1-2 slice of bread]	1bowl of ceregrow with chopped cashews and raisins	½ cup oat meal topped with ½ cup chopped berries, 1 cup of milk	1 bowl of ceregrow topped with nuts and dry fruits	1 bowl of ceregrow	2-3 whole grain, 1 cup of milk
Dinner	2 chapatis, green beans, 1 cup of milk	Rice, rajma curry, 1/3 cup of yogurt	1chapati, vegetables, 1/3cup of yogurt	Mixed vegetable pulao, cucumber and tomato raita	Bowl of dal palak khichidi	2 chapatis, paneer bhurji with capsicum	Curd rice, drumstick sambar

Diatary Goals

- Sugar should reduce about 48% in the food.
- Reduce overall fat consumption approximately 40%-30%.
- Reduce saturated fat consumption.
- Reduce cholesterol consumption to about 300mg/ day.
- Sodium intake reduce about 5g/day.

Table 3: Food Group Score[10]

Food	Rda	No. of Servings
Milk	3	X8
Meat	2	X12
Fruit and vegetable	1	X6
Vitamin C	1	X6
Others	2	X6
Bread and cereals	4	X6

Table 4: Nutrient Score[10]

Protein and niacin	cheese, dried peas, dried beans, eggs, fish, meat, milk, vitamin A.
Iron	beef, eggs, liver, green leafy vegetables.
Folic acid	cereals, spinach, yeasts
Riboflavin	broccoli, chicken breasts, eggs, milk, mushrooms
Vitamin C	grapefruits, green peppers, oranges, strawberries, tomatoes, calcium and phosphorus cheese, eggs green leafy vegetables, milk

Table 5: Sweet Score

Liquid	[X5] soft drinks, fruit drinks, cocoa, sugar and honey in beverages, ice cream, flavoured yogurt, pudding, custard
Solid and sticky	[X10] cake, doughnuts, sweet rolls, pastry, canned fruit in syrup, bananas, cookies, chocolate candy, caramel, chewing gum, dried fruit, jelly, jam.
Slowly Dissolving	[X15] hard candies, breath mints, antacid tablets, cough drops

Table 6: Assessment of Dental Health Diet Score

Score	Result	Interpretation
72 – 96	Excellent	Counseling not required
64 – 72	Adequate	Educate the patient
56 – 72	Barely adequate	Counseling required
56 or less	Not required	Counseling with diet modification

Conclusion

Preschool is the most vital period of a child in which the child develops most of his personality which is remain shaped for rest of the life. It has a huge impact on the adulthood of the particular child. A good nutritional habit will leads to a healthy living with a healthy oral cavity. So it is the rights of every child to have a disease free life and a disease free oral cavity. Good nutrition and healthy eating habit build a healthy foundation of life.

Incidentally Significant Finding in an Asymptomatic Patient

Satya Ranjan Misra

Professor & Head, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The oral physicians have been playing a significant role in diagnosing systemic diseases from their oral manifestations. Not only from the clinical findings in the orofacial region but also from dental radiographs valuable diagnostic information regarding the diseases affecting the body can be detected. Dental panoramic radiographs have been used as screening radiographs for the diagnosis of oral and dental diseases. In addition to this they have been employed as valuable tools for age determination, prediction of osteoporosis and even for diagnosing calcified atherosclerotic plaques in common carotid arteries in asymptomatic patients. A dental panoramic radiograph of a 54-year-old man was taken for checking the alveolar bone height to treat periodontitis and plan prosthesis. Incidentally it was seen that both carotids had calcified masses and warranted further investigation. Ultrasonography revealed the presence of stenosis of the common carotid artery on the left side and outflow obstruction, thereby preventing a possible cerebrovascular incident in an otherwise healthy patient. The case is shared to increase awareness regarding the role of the dentist in prevention of stroke in unsuspecting individuals.

Keywords: *Atheromatous Plaque, Calcifications, Common Carotid Artery, Panoramic Radiograph.*

Introduction

Atherosclerosis is a frequently encountered disease caused by cholesterol deposits on the arterial walls and they form adherent plaques, which may later calcify and cause obstruction in the flow of blood. [1]As these atheromatous plaques increase in size, they reduce the lumen of the blood vessels and hence the blood supply is compromised, and depending on the size of these plaques, the quantity of oxygen supplied to vital organs is determined. The less the oxygen supply the more effect on the functionality of the organs and it can eventually endanger the life of the individual.[2] It takes time for the changes to be clinically visible and felt by the patient and by the time it is diagnosed already a considerable damage is done. Hence it is imperative that the disease is detected early so that interventions can be promptly executed.[1,2] There is a need to find a cost-effective, early diagnostic tool for diagnosing this life-threatening condition. The dental panoramic radiograph which is a common screening radiographic procedure employed in dental patients for oral and dental diseases as well to obtain an overview of the orofacial structures, also could be used to visualize the cervical vertebrae area in which calcifications of atheromas in the carotid artery can be visualized, thereby providing early diagnostic information.[3,4]

On digital panoramic radiographs, Lande and Friedlander, detected the common carotid artery calcifications first in a study published in 1981.[5] Thereafter in Baker and Friedlander in 1994 showed that panoramic radiographs can be used to detect the risk of cerebrovascular accidents in asymptomatic patients. [6]The appearance of these carotid artery calcifications appears as radiopaque masses which are irregular or sometimes circular in shape, heterogenous, may appear as concentric rings and seen either unilaterally or bilaterally. As the size increases, they may appear rectangular or linear. [7-9] The location of these structures is posterior to the angle of the mandible and a little above it and at the level of the third and fourth cervical vertebrae, adjacent to the hyoid bone. [2,10]

Case Report: A 54-year-old male patient reported to the dental hospital for treatment of periodontal disease and evaluation for placing dental implants. He was advised for a dental panoramic radiograph. On the panoramic radiograph, besides his dental and alveolar bones status evaluation, it was incidentally detected

that multiple concentric irregular spherical calcified masses, largest one having about 0.6cm in greatest diameter, were seen in between the third and fourth cervical vertebrae bilaterally, hinting at calcifications of the common carotid artery. Since the patient was a chronic hypertensive patient, he was advised to undergo an ultrasonographic evaluation of the neck region based on findings of the dental panoramic radiograph. Ultrasonogram of the patient revealed 42% stenosis in the left common carotid artery and decreased blood outflow in both the common carotid arteries, but significantly obstructed on the left side. The patient was referred to the cardiologist for management.

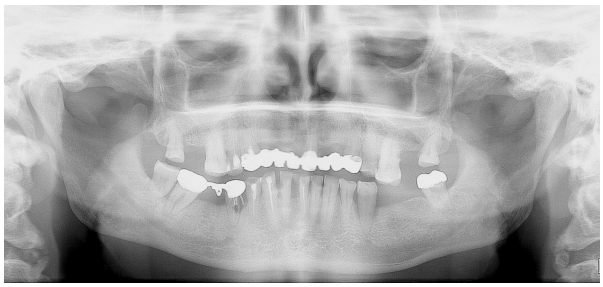

Figure 1. Panoramic radiograph showingmultiple sub-centimetric concentric irregular spherical calcified masses, largest one having about 0.6cm in greatest diameter, were seen in between the third and fourth cervical vertebrae bilaterally, possibly calcifications of the common carotid artery.

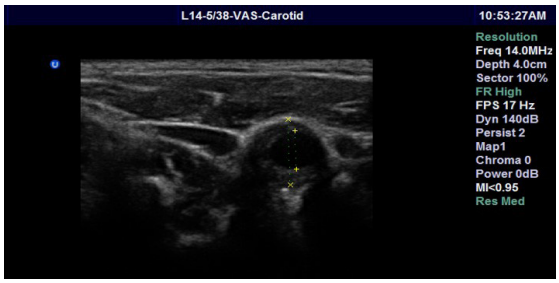

Figure 2. Ultrasonogram showing 42% stenosis in the left common carotid artery.

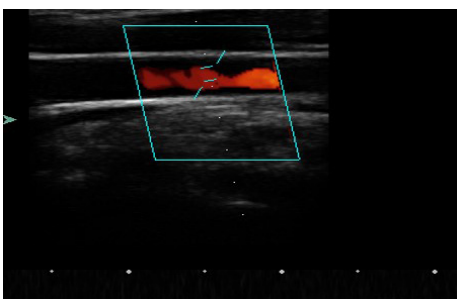

Figure 3. Colour doppler ultrasonogram of the left common artery showing severely decreased blood outflow suggestive of stenosis.

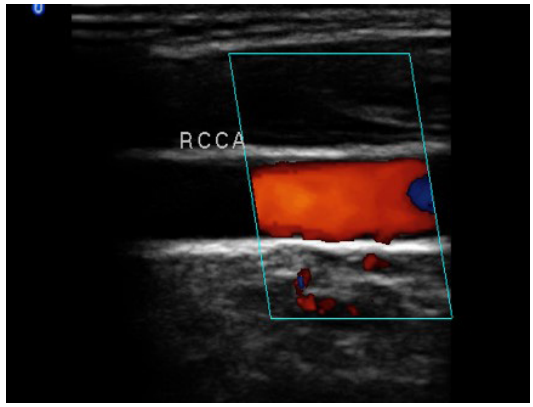

Figure 4. Colour doppler ultrasonogram revealed decreased blood outflow in the right common carotid artery.

Discussion

The carotids are the principal arteries supplying blood to the brain and traverse through the neck diving into the two terminal branches at the level of the superior thyroid cartilage.[4] Since the carotid atheromas can significantly reduce blood flow to the brain their early detection of paramount importance. The atheromas occur with severe coronary heart disease and can cause stroke in elderly individuals above fifty.[2]

It was reported by Cohen and Friedlander [11] that carotid atheromas detected by dental panoramic radiographs in about a fourth of elderly patients had a history of adverse vascular events like stroke, angina, myocardial infarction, etc. Even in a study reported by Griniatsos et al [12]it wasfound patients who have carotid calcifications on panoramic radiographs had suffered from cardiac disease. However, Sisman and Ertas[13] associated these panoramic radiographic findings with chronic smoking while others liked them to diabetes mellitus [14,15], hyperlipidaemia [16], hypertension.[17] and increasing age. [18-20]Not only that women were more frequently affected and the presentation was usually unilateral. [21,22]

It must be noted that common carotid artery calcifications have to be differentiated from other physiologic and pathologic structures which could be visualized on the same region like the thyroid cartilages, styloid process, calcified stylohyoid ligament, sialoliths, lympholiths, tonsilloliths and phleboliths.[23,24] Hence adequate knowledge of the radiographic landmarks of the different anatomic structures present in the cervical region is essential to correctly diagnose carotid calcifications on dental panoramic radiograph.

Conclusion

The literature emphasizes the presence of calcifications of the common carotid arteries on a dental panoramic radiograph is common in an elderly and susceptible population. The incidence of such findings in a general population is about one-fifth to that found in individuals with systemic diseases. It may be emphasized that panoramic radiography plays a vital role in the early detection of calcified atheromas in the common carotid arteries in asymptomatic individuals and referral to the cardiologist can help save lives.

Oral Manifestation of Viral Disease in Children

Digma Digdarshni

Intern (BDS), Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Viruses are integral to infection and a basic insight into the characteristics of commonly encountered micro-organisms is inertial for good infection control practice. Oral manifestation of viral infection will lead to specific discomfort and irritation in children. Neonates and natals are more prone to infection due to on developing immune system. Site and source of exposure of the infections dependant to the sign and symptoms. Disease such as Herpetic gingivostmatities, secondary harpies, herpes labials caused by 'Varicella zoster virus'. Other virus diseases like measles, Rubella, AIDS seen in the children, are highly contagious in nature. disease can be diagnosed clinically and by laboratory diagnosis by immmunofluorosence & culture. Antiviral medications are given to the children who are suffering from viral diseases. Antiviral therapy typically involves a delicate interplay between host cellular functions & viral target of action.

Keywords: *Viral Infections; Oral manifestations; Antiviral therapy.*

Introduction

Oral manifestation of various viral infection & ulcerative lesion are very subjective to the identity for the early diagnosis. Early diagnosis is important for the early up taking of medications and management of infections. Parents are not well familiar with the infections lesions seen in the children's oral cavity. A dentist should aware about the lesions on the child's mouth during the dental practices. These viral infections demands discomfort and irritation of the child, which distract the child's from its daily routinary life, some of viral infections in the children are:[1-4]

Human Herpesvirus: Herpes simplex virus infections are common vesicular and ulcerative lesion of skin and mucosa found mostly in the children, transmitted through saliva or body fluids. Usually occurs in early childhood and pre-school period. Which period is more prone caught infection, due to frequent exchange of saliva. [5-8] They are classified as Primary herpetic gingivostmatities & Secondary or recurrent herpetic lesion.

Primary herpetic gingivortomatitis: This called as acute herpetic gingivostmatities. Most of the cases are subclinicall and known as primary lesion. Occurs in early childhood & Pre-school period. The incubation period is 5 to 7 days. Site of occurrence is hard palate, attached gingiva, dorsume of the tongue, brccalmucoca, lips. It appears in the form of mulitiple inflammatory small vesicle with thin walled covering, which arereptured frequently. Samll, shallow, oval shaped discrete ulcer covered with greyish white oryellow plaque. Serosanguinous fribrin like exudates from lips, there is difficulties in speech,and mastication becomes extremely painfull. The disease is self limiting in nature. Lesion begins to heal in between 7 days to 14 days and leaves no scar.[1, 5-8]

Recurrent oral HSV infections: Secondary herpies is the result of re-activation of the virus present before. Occurs due to re-infection in sero-positive persons. There is 40% chance of secondary herpes when the antibody is already present inside. In 10% individuals in which it is asymptomatic. HSV transmitted through saliva. Occurs widely in certain interval in some patients it is once a month or in some patient it is once a year. Prodominal Symptoms are Tingling & burning sensation and feeling tautness in the site of infection. Presence of oedema at the site of lesion, formation of clusters of small vesicle can be seen. Mainlyoccurs in vermillion border of lip, surrounding with skin. Greyish white vescile present which ruptured very quickly leaving red ulcerations having a size of 1-3 mm to 1-2 cm. The lesion heals gradually within 5-10 days and leaves no scars. CNS complications and vagiinal fungal infection may occur.[5-8]

Vericella Zoster: Also called as "varicella". It is an acute disease occurs in the children mostly in the seoson of winter and springs. Incubation period is 2 weeks and mode of contamination is by air borne droplets or direct contact with infected persons. Small blister like lesion present involving the oral mucosa, tongue, gingiva, palates and also in the mucosa of pharynx, which rupturs forming minor acute ulcerations. Appearancace is slightly raised vesicle surrounded by erythema. Ruptures very soon after formation, and forms a small eroded ulcer with red margins. Patient should be rehydrate to control pruritirs warm baths with soap or baking soda, application of calamine lotion is recommended. Anti-viral drug Acyclovir 800mg five times/day for 5 days. Valacylovir 100mg TDS or fumicyclovir 500mg TDS for 7 days. [5,8,9]

Coxrackie Virus: Another virus commonly cause hand, foot-mouth lesions. Oral manifestation in children shows herpangina & acute lymphonodular pharyngitis. Transmitted through oro-fecal route and nasopharyngeal droplets. Highly contagious disease seen in kids below the age 5 years in seasons of summer & spring. Site of infection is buccal mucosa, tongue, soft palate. Appearance is vsicular or papular lesion surrounded by zones of erythematous halos. Management is mainly be Maintenance of hydration. [5-8] **Measles**. Measles is also called "Rubella" or "Morbilli". It is an acute viral dermatotropicinfection,which is contagious & priority affecting the children. Transmitted through the droplet infection or by direct contact by person to person. [5] Incubation period is 8 to10 daysProdomal symptoms are Onut of fever, molaics cough & coryza. Oral leision proceed 2-3 days before continuous rash. Site of infection is Buccal muccosa

Koplik & Sporls: They are bluish white specks surrounding with a bright red erythematous covering. Marginsare Small irregularly shaped blocks, subjected as "grains of salt" on red background. Swelling and focal ulceration of gingiva, palate & throat.

Diagnosis: Mainly by Clinical diagnosis: kplik's sports. Lab diagnosis; Antibody titters. Antibody appears in 3 days.

Management: Vaccine MMR: One injection of life, attended measles virus given subcutaneously in children, over one year and second dose of vaccine is given in 12-15 months.

Passive immunization: Human immunoglobulin given in dose 250 mg for children under 1 year & 500 mg for over age of 1 year.

Rubella: Known as germen measles cause by Jogovirus. Transmitted through droplets, injection, if may be congenital results in birth defect. Baby with rubella called congenital rubella syndrome. Incubation period is 14-21 days.

Foreselhemei's right: In the soft palate there is presence of small, discrete and dark redpapules.

Petechiae: Petechiae can be seen for the palate.

Management: Human rubella immunoglobulin given after exposure.1, 5-8

Human immune deficiency syndrome: HIV infection transmitted to the child from the mother during the pregnancy or during the birth. Other route of spreading is the transfusion of blood and its products, from a infected person.when breast milk are also consider to be a source of infection. Oral candidiasis may be seen in child with HIV infection. Oral candidiasis may leads to esophagial candidiasis. Gingivitis may be seen. Parotid swelling is most common in children than elder individuals.[6-10]

Conclusion

Viruses are like hijackers. Thy invade into living normal cells & use those cells to multiply and produce other infections cells like themselves. This can kill damage or change the cell & can make a person sick. Antiviral medication, they work by interfering with the production of viral DNA/RNA. Antiviral medications are more effective when they are taken earlier. The most challenging thing in viral lesion is the differential diagnosis of infection in children because, most of them will show the similar clinical picture misleading the diagnosis. The dentist plays a very vital & major role in diagnosis, treatment & prevention of contamination of such contagious infection. 6,9,10

Oral Focal Mucinosis: A Rare Clinical Entity

Shubhangi Pareek[1], Swagatika Panda[2], Sayantanee Chaudhury[3], Abhay Chandra Das[4], Alkananda Sahoo[5], Neeta Mohanty[6]

[1]Post Graduate Trainee, [2]Professor, [3]Post Graduate Trainee, [4]Reader, Department of Periodontics and Implantology, Institute of Dental Sciences, [5]Senior Lecturer, [6]Professor and Head, Department of Oral and Maxillofacial Pathology and Microbiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Oral focal mucinosis (OFM) is a very uncommon clinical entity whose exact cause remains unknown. It is a soft tissue lesion which presents clinically mainly on gingiva, usually not associated with pain. It may appear as a sessile or pedunculated mass having the same colour as that of the surrounding oral mucosa. The histopathological picture of oral focal mucinosis is that of myxoid degeneration of the surrounding connective tissue stroma in a focal pattern. It mainly occurs in adults during the 4^{th}–5^{th} decades but rare cases affecting the children and young adults have also been reported. The final diagnosis depends totally on the histopathological picture in such cases and complete surgical removal is regarded as the treatment protocol with no recurrence reported so far. We present here a case of oral focal mucinosis which is rare and requires proper clinical and histopathological screening so as to avoid wrong diagnosis and also to rule out all the other myxoid lesions which may be indicated in its differential diagnosis.

Keywords: *Mucinosis, Myxoid degeneration, Gingiva, Soft tissue lesion.*

Introduction

OFM is a rare clinical entity most commonly affecting the gingiva. It usually presents as an ingenious, symptomless and sessile swelling or with a pedunculated base with a higher predilection in females. It is considered to be the correspondent oral lesion of cutaneous focal mucinosis (CFM).[1] Though its exact etiology remains unidentified, an excessive production of hyaluronic acid by the fibroblasts may be related to its occurrence.[2] Histopathologically, areas of myxomatous connective tissue with collection of mucins like material in a fibro-collagenous connective tissue stroma are evident with foamy and fibroblast like cells in well localized areas in the myxoid matrix. Oral focal mucinosis quite difficult to diagnose based upon its clinical presentation and it is often misdiagnosed as fibroma or granuloma.[3] Thus, a proper biopsy followed by histopathological examination becomes necessary for its proper diagnosis followed by the appropriate treatment measures to avoid any recurrence.

We present here a case of oral focal mucinosis in a 22-year-old young female which was clinically diagnosed as fibroma but its histopathology revealed an entirely different diagnosis.

Case Report: A 22-year-old female presented with gingival swelling in relation to the right mandibular posterior tooth region since the past 1 year. On examination, a painless, pedunculated gingival swelling was present in the lingual aspect of 48 measuring about 1cmx1cm in greatest dimension. Based upon these findings a provisional diagnosis of fibroma and fibroepithelial polyp was given. It was excised completely and sent for histopathological examination

Histopathological findings: The Hematoxylin and eosin stained sectionshowed a keratinized stratified squamous epithelium beneath which loose myxomatous

Corresponding Author:

e-mail: swagatikapanda@soa.ac.in

connective tissue stroma was noticed. Sparsely distributed stellate shaped fibroblasts were also evident in the lesioned tissue. The underlying connective tissue stroma was minimally inflamed and moderately vascular.

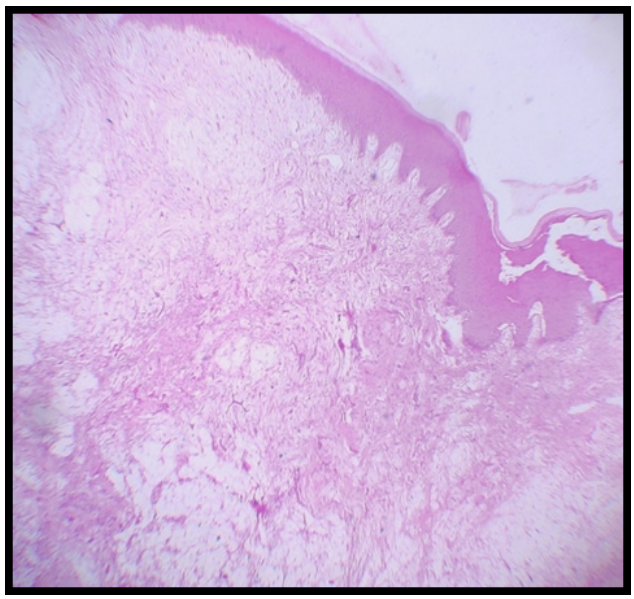

Figure 1 (4x view): The photomicrograph of hematoxylin and eosin stained section showing keratinized stratified squamous epithelium with underlying myxomatous connective tissue stroma.

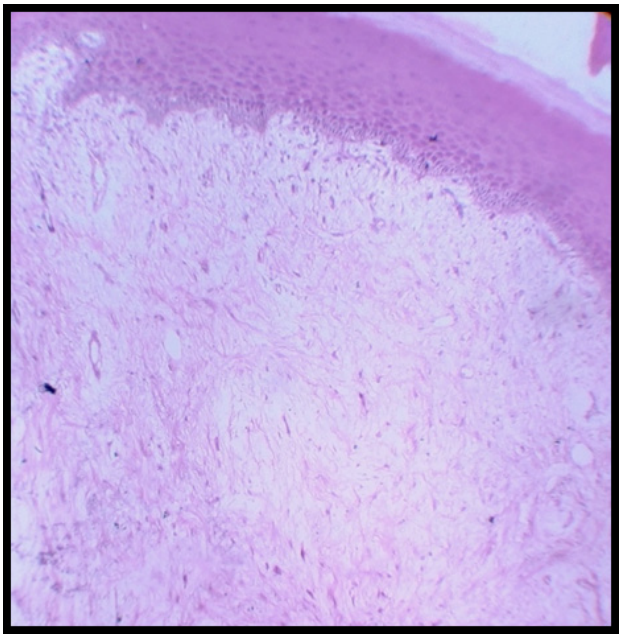

Figure 2 (10x view): The photomicrograph of hematoxylin and eosin stained section showing stellate shaped fibroblasts in a minimally inflamed myxoid stroma.

Based upon these findings a final diagnosis of Oral focal Mucinosis was rendered.

Discussion

Being an uncommon lesion, oral focal mucinosis is often misdiagnosed thus a proper and thorough understanding of its histopathology becomes mandatory. It is the oral correspondent of cutaneous focal mucinosis also known as cutaneous myxoid cyst.[1,4] Majority of the cases involve the gingiva or the hard palate as a painless, sessile swelling without any colour changes.[5] OFM does not show any distinct clinical features and hence there is no case reported in the literature that was diagnosed correctly based upon its clinical presentation.[3,6] However, the histopathological features are distinct and final diagnosis is always based upon the microscopic evaluation. It is characterized by a focal collection of loosely arranged myxoid connective tissue stroma with mucinous material. Fibroblasts and foamy cells are often present in this myxomatous stroma. Sometimes the overlying stratified squamous epithelium may show loss of rete ridges if the lesion is not deep enough. Connective tissue stroma is mostly moderately vascular and shows minimal inflammation.

Pyogenic granuloma, fibroma and minor salivary gland tumor are some of the lesions to be considered in its differential diagnosis.[3] The treatment of Oral focal mucinosis is complete surgical excision and there is no recurrence if it is done properly. It should be asserted that such lesions are impossible to diagnose clinically due to their extremely rare occurrence. OFM must always be ruled out in the soft tissue lesions affecting the adults and for this purpose the role of histopathological examination is inevitable.

Conclusion

The case presented in this paper highlights the role of an oral pathologist in the final diagnosis of such myxoid lesions involving the oral cavity and to rule out the differential diagnosis although the exact cause of oral mucinosis still remains unexplored.

Endoscopic Approach to Maxillofacial Trauma

Arkaja Sahoo[1], Sthita Prajana Lenka[2], Karishma Rathor[3], Suchismita Ghadai[4], Madhumita Sahoo[5]

[1]Intern, Institute of Dental Sciences, [2]Professor, Department of Oral and maxillofacial Surgery, Institute of Dental Sciences, [3]Tutor, Institute of Dental Sciences, [4]Intern, Institute of Dental Sciences, [5]Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The article reviews the manner in which the endoscope assisted techniques is applied for "the treatment of maxillofacial trauma" and enlightening some aspects of these techniques and mentioning the experience of ours. Over the past few decades, "diagnostical imaging, surgical techniques and development of surgical instruments put forwarded tremendous progress in the facial fracture management. Having a bird's eye view over some authors, "endoscopic interventions" to "maxillofacial trauma" has become a usual method for the reduction of "zygomatic arch, orbital blow out, medial orbital wall, frontal sinus, and last but not least the sub condylar mandibular fractures" in the recent years. Substituting the open reduction with that of the reduction of "facial fractures" combining with that of an endoscope has boost the management of the patients with less complications beyond desire and more painless procedures. On the other hand, endoscopic approach enables to decrease per surgical morbidity helping the surgeons to achieve results somewhat true to expectations. Inkling to "endoscopic reduction" is represented by "dimension, extension and sites of the fracture and so the surgeon's perspicacity".

The rate of morbidity along with the extra time of hospitalization can be shortened with the introduction of this instrument called endoscope in the field of maxillofacial surgery depicting the true scenario of modern health care along with the advanced section of biomedical engineering and research.

Keywords: *Endoscopic approach, maxillofacial trauma.*

Introduction

The first endoscope was developed in 1806 by Philipp Bozzini in Mainz with his introduction of a "Lichtleiter" (light conductor) "for the examinations of the canals and cavities of the human body. The first to use an endoscope in a successful operation was Antonin Jean Desormeaux whose invention was the state of the art before the invention of electricity. The use of electric light was a major step in the improvement of endoscopy. Endoscopes are minimally invasive and can be inserted into small incisions and openings of the body. Endoscope was first used by Tagaki in 1918 to examine and describe the knee joint in the early twentieth century. In the last few decades the endoscopic technique has undergone tremendous progression and changes in terms of complexity and capability with the introduction of the endoscopic approaches in the diagnostic procedures. [1] At the present scenario it has become finest necessity of the modern health care simultaneously with the advanced section of biomedical engineering research. The surgeons can treat the facial fractures innovatively with the help of endoscope. Oral and maxillofacial surgery involves exquisite and tiny anatomical structures and leads to limited access to the to the operative field for performing intraoral procedures which gave rise to the need of increment of magnification and illumination of the operative area. [2]

"Hence the endoscopic approach in maxillofacial trauma has been reported in treatment of zygomatic arch, orbital fractures, frontal sinus fracture, and sub condylar mandibular fractures with acceptable results. "[3]The management of oral and maxillofacial region has undergone dynamic changes in the last 2 decades. To start with the digital radiographyuntil the introduction of ultrasonography and endoscopy in the diagnosis as well

Dr. Sthita Prajana Lenka
e-mail: sthitaprajanalenka@gmail.com

as treatment planning. These devices have increased the accuracy and capability of the diagnostic procedures. Endoscopy has become promising tools to accomplish these objectives. Endoscopic surgery, or minimal invasive surgery, has found wide acceptance in many surgical specialtiesendoes and in many cases has become the standard of care. Endoscopy in health sciences in short refer to look into a hollow cavity or organ for medical problems with the help of an endoscope. The instance that looking into a hollow cavity which is not practically possible to naked eyes comes dated back 2500years. Hippocrates reports the use of a speculum to examine a rectum forth century BC. Abulkasim was reported to use a mirror to examine the cervix in 10 century AD. In 1805 Bozzini introduced **"The Lichtlriter" an illumination device. Desoman** was first to develop an effective endoscope in 1843. The digital video camera was used in 1982. [4] In the 21st century endoscope has been used by clinicians to examine the cavity that don't have an external opening. Thus, in the field of maxillofacial region the application of endoscopic surgery includes "fractures of the floor and medial wall of the orbit, sub condylar fractures of the mandible & last but not least fractures of the zygomatic arch. "

Medial wall and orbital floor fracture: The term Facial trauma commonly grips the orbital region mostly causing esthetic deformities and functional problems.

Indications of surgery after the orbital trauma: Intraocular and intra orbital pain, Diplopia, enophthalmos (posterior displacement of the eyeball within the orbit), The eyeball displacement, Local edema, Local hematoma, Restricted ocular mobility, Epistaxis. These complications need some surgical techniques to be treated which involve various surgical approaches and use of various reconstruction materials. The surgical approaches in orbital trauma is broadly divided into trans antral approach involving trans nasal and trans maxillary technique and transcutaneous approach involving subciliary, transconjunctival, midtarsal and infraorbital coronal techniques. On the other hand, reconstruction materials include autologous bone grafts usually the iliac crest bone, high density porous polyethylene and titanium plates/meshes.

With the intervention of new endoscopic instruments, the older techniques that have been used for the repair of orbital floor fractures have been renewed with time. Through a definitive Caldwell-Luc incision can be easily carried out. Thus risk here the risk of eye deformity is alleviated, and there is an improvement in the visualization of the fracture. As a setback it cannot be used in certain cases though, where the repair of the orbital rim and floor, both are undertaken. As noted, paranesthesia of the infraorbital nerve might still be a case of risk with a transient occurrence.

Regardless these techniques being considered as esthetic surgeries sometimes complicate the predicament. The decision of whether to operate or not to depends upon the type fractures and thus in turn the incisions involved. Thus, the endoscopic approach in orbital trauma came into process in case of less complicated orbital fractures such as diplopia caused by the entrapment of the periorbital tissue and for those kinds of fractures that require open access involving high esthetic considerations. Eyelid retraction, scleral show or ectropion are some of the major drawbacks which go hand to hand with that of the correction of the fractures through surgical method. As for the same, "The Trans antral approach associated with the reduction and fixation of fractures through the endoscope have been proposed by some of the authors". [5] Thus undoubtedly the involvement of"endoscopic technique" provided us with better illumination and assessment in term leadingto fewer complications. The process is highly technique sensitive. Thus the endoscopic approaches enables the repair of orbital floor fractures with no facial scars and risk of ectropion

Fractures of the zygomatic arch: The well-grounded and dependable form of the zygomatic arch fabricates it as one of the most delicate structure in the maxillofacial trauma. Hence the traditional coronal approach put forwards with many complications as well as drawbacks which include "scar alopecia, scalp dysesthesia, significant blood loss and injuries to the frontal branch of the facial nerve". Thus the endoscopic assisted surgical approach in zygomatic arch repair helps in minimizing the complications related to surgery along with reduces the post- surgical scar succoring the extensive access incision. "An optical cavity between the superficial and deep temporal fascia" is made by maneuvering of a periosteal elevator. As a result the facial nerve is preserved from getting injured. Thusthe superior orbital rim marks the end of the dissection, which ensures the incision of the periosteum of the arch followed by arch reconstruction. "Goal of zygomatic arch repair includes restoration of its preinjury shape and stability. Endoscopic assistance is indicated in complex zygoma-fractures, Lefort III level injuries, isolated arch

fractures of patients with prominent contralateral arch contours as discussed by LEE". [5]

Mandibular sub-condylar fractures: Represent an absolute indication to reduce through open access" the dislocation in the middle cranial fossa and in the external ear canal, the dislocation of the joint, the inability to obtain an adequate occlusion and the presence of an open wound of the joint, with presence of foreign body and/or infection".[6] Two of the techniques which are used consists of use of intraoral incision and a dissection along the mandibular ramus which boasts the placement of the endoscope and the second one consisted of performing a cutaneous incision close to the mandibular angle's inferior border as a "mini-Risdon approach". The first technique is best known to avoid scar formation as compared to the first one. The intervention of endoscope to repair the sub condylar fractures of mandible as a whole helps to reduce the risk of "facial nerve injury, lower morbidity, faster postoperative recovery, reduced rate of ischemic avascular necrosis of the condyle, and most importantly on the esthetic point of view no scars". On the stumbling block point of view it takes prolonged surgery times with high costs of equipment and more technique sensitive. "The development and testing of a new osteosynthesis device to stabilize the fixation of a sub condylar fracture, as discussed by Meyer, may represent a further stimulus to the use of endoscopy in the reduction of such fractures."[5]

Patients: "According to the report of the cases of 8 patients endoscopically treated with sub-condylar displaced fracture of the mandible, there were 5males and 3 females, aged between 34 and 61 years old. At a 46, . 4 years. In 6 of the 8 patients, the fracture was unilateral, in 2 patients the fracture was bilateral. In the patients with bilateral fracture, both condyles were displaced medially out of the respectively Glenoid fossae, and clinically could be observed a pre-contact of the posterior with anterior open bite. In the 6 patients with unilateral fracture were clinically evident malocclusion, facial asymmetry and a cross bite and a limitation in mouth opening. All patients in the test group were carried out CT Scans before and after surgery, 2 days later and a year later".[5]

Conclusion

The man-oeuvre of endoscope in maxillofacial surgery depicts one of the vital scenario of modern healthcare stitched together with the advanced sectors of "biomedical engineering and research". The requisition of endoscope in the field of maxillofacial trauma has become one of the most eye-catching field to study upon as it uses laser surgical approaches than those of the classical surgical method for surgery. It in terms reduces the time of hospitalization and the morbidity rate in the field of maxillofacial surgery. As our field basically covers a very small area thus we believe that the endoscopic intervention is going to put forward good outcomes in surgical cases in lieu of aesthetics primarily.

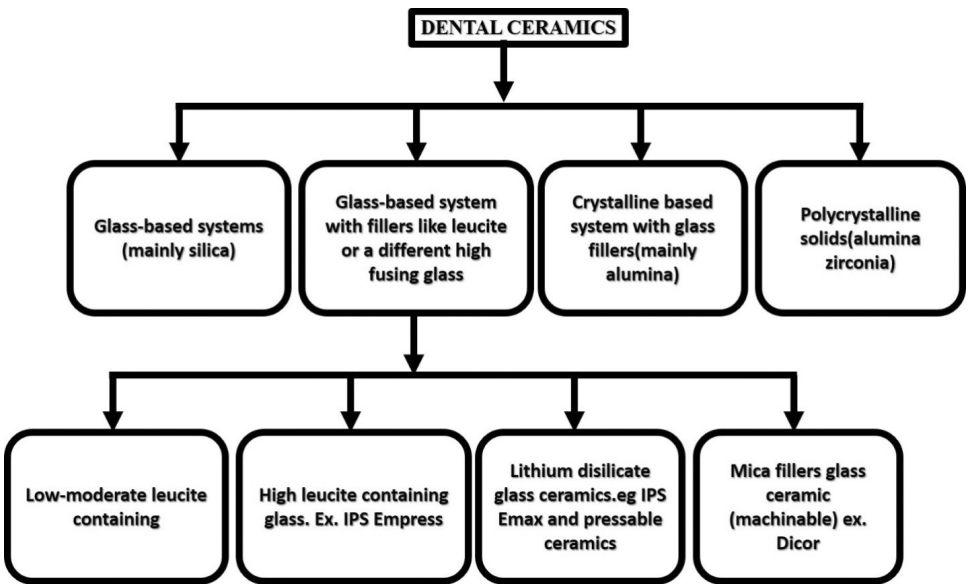
Recent All Ceramic Systems in Dentistry: A Systemic Review

Kajal Kiran Sahoo[1], Sudipta Sahu[2], Sashikant Sethy[2], Nikita Sahu[2]

[1]Tutor, Department of Prosthodontics, [2]Tutor, Department of Public Health Dentistry, Institute of Dental Sciences Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract



This article encompasses the variety of all ceramic materials available now a days and their clinical applications. It will help the clinicians understand the advantages and disadvantages of different types of ceramic materials available based on their microstructure, processing method and usage area. Although PFM or Porcelain fused to metal crowns had rampant use because of their long-term clinical success rate, the quench for more esthetic, more biocompatible materials led the way for the usage of new all-ceramic crowns-a new age dentistry destination.

Keywords: *Ceramics; Dentistry; Biocompatible; Clinical applications.*

Introduction

The word "CERAMICS" comes from a Greek word meaning "of pottery" Or "for pottery". Ceramics is defined as an inorganic, non-metallic crystalline solid prepared by the action of heating and subsequent cooling. The use of ceramics in dentistry is encouraged by their bioavailability, esthetics and durability. Dentalceramics, since introduction have undergone numerous modifications in terms of chemistry, aiming at the need for dental usage. Although PFM or Porcelain fused to metal crowns had rampant use because of their long-term clinical success rate, the quench for more esthetic, more biocompatible materials led the way for the usage of new all-ceramic crowns-a new age dentistry destination.[1]

Classifications of Dental Ceramics: The variety of ceramic compositions and different types of manufacturing techniques led the clinicians to make wise choices for the usage of all ceramics (Figure 1).

Corresponding Author:
Dr. Kajal Kiran Sahoo
e-mail: drkajal2@gmail.com

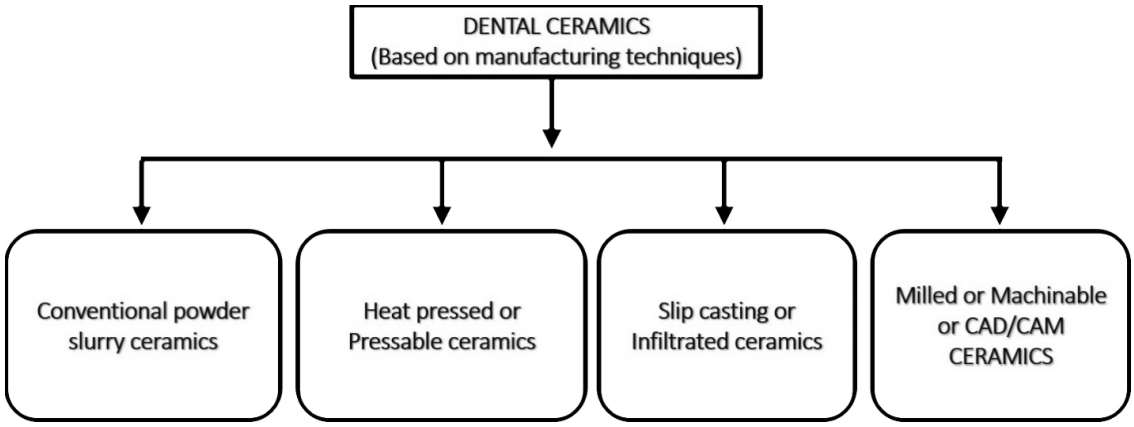


Figure 1. Classification of ceramics

Conventional Powder Slurry Ceramics: It involves ceramic powder available in various shades and translucencies and deionized water to produce a slurry. It's applied over refractory die with a brush and vibrated and compacted to remove excess moisture. It is then fired under vacuum to improve density and esthetics.[2]

Use: It is typically applied as veneer layer on all ceramic frameworks as it has good translucency.

Heat Pressed/Pressable Ceramics: They are available in monochromatic ingots made of crystalline particles distributed throughout a glassy material.The lost-wax method is used with heat pressed technique. The final restoration is subsequently stained and glazed to achieve the final esthetic result.

Use: It is used for making inlays, onlays, veneers, crowns, anterior fixed partial prosthesis, 3/4th crown, and also for coping on which conventional powder porcelain is built to achieve final shape and shade.[3]

Example: IPS Empress, Ivoclar Vivadent/IPS Emax Press

Slip Casting: This technique consists of preparing stable suspensions, the slip and fabricating structures by building a solid layer on the surface of a porous mould that absorbs the liquid phase by means of capillary forces. The slip is the homogeneous mixture of ceramic particles suspended in afluid, usually water, which is applied over gypsum die. It uses crystalline i.e., Alumina based ceramics infiltrated with glass fillers.

Fine grain alumina particles are sintered to form a porous substructure, which is infiltrated with molten glass, which flows into the pores by capillary action. The final core is fully sintered before final application of veneering porcelain. This procedure gives the final restoration of outstanding properties. The double sintering procedure gives the final restoration excellent fit and high strength. The only disadvantage of this procedure is it includes many complicated steps.

Use: It is used for making onlays, veneers, crowns, anterior fixed partial prosthesis and posterior fixed partial prosthesis.[4]

Example: Inceram Alumina (by VITA Zahnfabrik)

Milled (Machinable Ceramics): This machinable ceramic blocks for CAD/CAM restorationsare available in

1. Feldspathic Porcelain based ceramic
2. Leucite Reinforced glass ceramic
3. Lithium Disilicate glass ceramic
4. Glass infiltrated ceramic
5. Polycrystalline Alumina
6. Polycrystalline Zirconia

Computer aided designing and machining can involve any of the two procedure:

I. Hard Machining-where fully sintered ceramic block is milled resulting in significant tool wear and residual flaws.

II. Soft Machining/green Machining-where the partially sintered ceramic blocks is milled and then subsequently fully sintered to eliminate porosity.

Here the individual blocks are bar coded with actual density of each block for shrinkage calculation and the milling machine automatically changes its tools according to need.[5]

Example:

1. Vitablocks (VITA Zahnfabrik)
2. Inceram Spinell (VITA Zahnfabrik) alumina fillers
3. Procera (Nobel Biocare)
4. Lava (3M ESPE)
5. Cercon (Densply)

} Zirconia fillers

The flexural strength of alumina is about 350-450Mpa while that of zirconia is 650Mpa.

1. Polycrystalline ceramics are more difficult to process than glassy ceramics. These higher strength ceramics tend to be relatively opaque compared to glassy ceramics. So, they are usually used as substructure material upon which glassy ceramics are veneered.
2. Polycrystalline Alumina: The first fully dense polycrystalline material used for dental application is developed in 1983 with PROCERA Alumina system by Nobel Biocare. It has the highest strength among alumina-based materials though its strength is much lower than zirconia.
3. Polycrystalline Zirconia: In its pure form zirconia oxide is a polymorphic material that occurs in three crystalline forms that are temperature dependent

a. Monoclinic (room temp-1170 degree Celsius)

b. Tetragonal (1170-2370 degree Celsius)

c. Cubic (2370-melting point)

This reversible tetragonal-monoclinic (t-m) phase transformation is accompanied by increase in volume upon cooling. This transformation can be prevented by stabilizing tetragonal zirconia by adding 3mol% yttria. Stabilized tetragonal zirconia exhibit excellent mechanical properties. It is well established fact that grinding or sandblasting leads to phase transformation to monoclinic and associated development of compressivestress. So chairside polishing to a mirror finish successfully eliminates the thin layer of monoclinic phase and compressive stress but may not fully remove deep defects due to grain pullout. It is also well-established fact that glazed zirconia is more abrasive than polished zirconia. But when monolithic zirconia is used rougher surface leads to increased wear of antagonist enamel. Thus, in case of monolithic zirconia it should be carefully done if any grinding adjustment needed. Zirconia processed by microwave sintering can have smaller grain sizes and increased translucency compared with those of conventional firing. [6, 7]

Conclusion

The evolution of dental ceramics over past few years is most interesting from glass ceramics to zirconia. Remarkable progress has been made in ceramics processing and development and further breakthrough will occur in near future with emerging interpenetrating phase composites. However successful application of these materials will depend upon clinician's ability to select the appropriate material, manufacturing technique, bonding procedures and esthetic and functional requirements.

Post Operative Care: A Review

Sushil Kumar Sahoo[1], Santosh Kumar Subudhi[2], Sthitaprajna Lenka[3], Sanchari Sinha Roy[4], Harsh Mohan Pathak[5]

[1]Post Graduate Trainee, Department of Oral and Maxillofacial Surgery, [2]Professor, Department of Oral and Maxillofacial Surgery, [3]Professor, Department of Oral and Maxillofacial Surgery, [4]Post Graduate Trainee, Department of Oral and Maxillofacial Surgery, [5]Reader, Department of Oral and Maxillofacial Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Optimal post-operative care has a multidisciplinary group of healthcare professionals and a patient oriented approach in order to avoid any post-operative complications & enables a rapid return to normal health. In the last 10 years, there has been an enhanced recovery after surgery, various implementation of programsover the world to reduce any complications and length of stay challenging the models of intra operative care. Various aspects of intra operative care have consensus guidelines without any controversy, while others like perioperative fluid management therapy remains contentious.

Keywords: *Post-Operative Care; Diet; Nutrition.*

Introduction

Post-operative care deals in managing the patient after surgery. This includes care which is given during the immediate post-operative period both in the operating room and the post anesthesia care unit/ICU as well as during the stay in the hospital.[1] Goal is to prevent any complications such as infection, to promote healing of the surgical wound and to return the patient to the state of normal health.

Phases of Post Operative Care:

(a) Immediate post-operative care

(b) Surgical ward care

(c) Rehabilitation and convalescence.

Post-Operative Observation:[1]

(1) Care for first 24 hours

(2) Care after 24 hours.

Care for first 24 hours: Vital signs, respiratory status, status of pain, the incision and any drainage tubes should be monitored for every 1-2 hours or at least for 8 hours. Body temperature must be monitored, as the patients are hypothermic after surgery & may need warm blanket or warm intravenous fluid.

Care after 24 hours: After the first 24 hours, if patient is stable, vital signs to be monitored every 4-8 hours. Surgical wound to be monitored for amount of drainage and any sign of infections. Dressing should be done using sterile technique.[1]

Airway obstructions and Management[2]

Obstruction by tongue: Muscle tone loss can cause the fall back of tongue against the posterior pharyngeal wall which may be aggravated by masseter spasm during emergence from unconsciousness.

Obstruction by foreign bodies: Dentures must be removed before any operations.

Laryngeal spasm: Can occur at light level of unconsciousness and is an aggravated by stimulation.

Laryngeal edema: May occur in small children after traumatic attempts of intubation or during epiglottitis.

Bronchospasm / Bronchial obstruction: Mechanical ventilation via a cuffed endotracheal tube may still be needed if an adequate PaO_2 or $PaCO_2$ cannot be maintained [9]. The American Society of Anesthesiologists[9] (ASA) defined a difficult airway as

Corresponding Author:
Dr. Santosh Kumar Subudhi
e-mail: santosh.subudhi1976@yahoo.com

the clinical situation in which a conventionally trained anesthesiologist may experience difficulty with either mask ventilation or tracheal intubation or both. of all, cricothyroidotomy is the life-saving procedure, and is the final 'cannot ventilate, cannot intubate' option.

Techniques for Performing Cricothyroidotomy[9]:

(1) Conventional preparation technique.

(2) Rapid four step technique[16]

Conventional surgical Tracheostomyis the most preferred method of Airway Management. This has remained the gold standard, having been used in elective and emergency cases. Surgical approachis identifying the isthmus of thyroid which can be retracted upwards or downwards to expose the tracheal ring.[1, 11, 12]

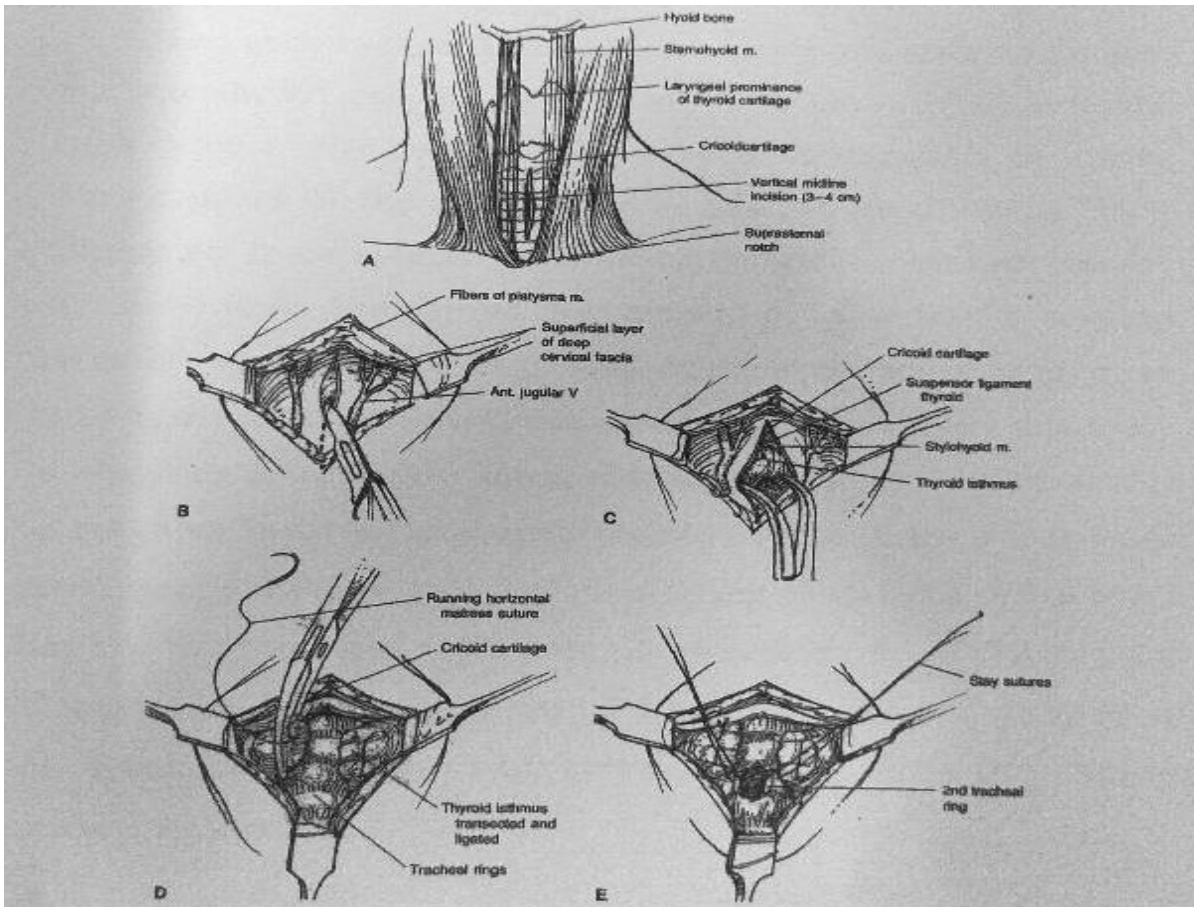

Figure 1. Surgical Tracheostomy

Loose suturing should be done as tight suturing may lead to mediastinal emphysema.

Fluid Imbalances:

(1) **Respiratory alkalosis:** Common in early post-operative occurs with hyperventilation.

(2) **Respiratory Acidosis:** Occurs with hypoventilation.

(3) **Metabolic Acidosis:** Management is resuscitated and ensure good reperfusion. Replacementof bicarbonate is required in severe acidosis.

(4) **Metabolic alkalosis:** Relatively uncommon, depletion of acid or loss of hydrogen ion results in this condition.

Input and Output of Fluids[13]: Normal individual takes an average of 2000 to 2500ml of water in a day and normal output is around 1500ml. Minimum urinary output is 500ml & insensible loss (skin 75% and lungs 25%).

Fluid and Electrolyte Balance[5]: An adult requires 70gm of protein in 24 hours. Protein requirement may be ignored in first 48 hours as there is no hypoproteinemia. The need of potassium should be remembered as its

deficiency is not seen in 1st 2-3 days, so potassium chloride of 0.2% should be added to glucose saline.

Measurement of Blood Loss is done using weighing gauze, measuring suctioned blood and adjusting the volume of irrigation during operation.[8]

Reasons for Replacement to hypovolemia, hemorrhage and third space loss i.e from intestines and insensible loss i.e burns.[6]

Types of Fluid Replacement:[3] Red blood cells, colloid, crystalloid.

Shock: Defined asa condition in which circulation fails to meet the nutritional needs of the cells and at the same time fails to remove the metabolic waste products.[13]

Types of Shock: 1) Haematogenic/ Hypovolemicshock 2) Traumatic shock. 3) Neurogenic shock. 4) vasovagal shock. 5) psychogenic shock. 7) septic shock. 8) Cardiogenic shockusually caused due to injury to heart, cardiac arrhythmias or congestive cardiac failure.[13, 15]

The compensatory mechanisms which includes i adrenergic discharge. ii)hyperventilation iii) release of vasoactive hormones. iv)resorption of fluid from interstitial tissue v) resorption of fluid from the intercellular to extracellular space. Vi)renal conservation of body water and electrolytes.

Management of Hypovolemic shock: 1) resuscitation. 2) immediate control of bleeding. 3) extra cellular fluid replacement. 4) drugs like sedatives, chronotropic agents[13] (used for patients in bradycardia) 5) inotrophic agents (improve strength of cardiac muscle contraction) 6) Vasoconstrictors (used in neurogenic shock) 7) Beta blockers (cardiogenic shock with stiff myocardium and rapid heart rate) 8) Diuretics (reduced vascular volume).

Management of Postoperative Nausea:

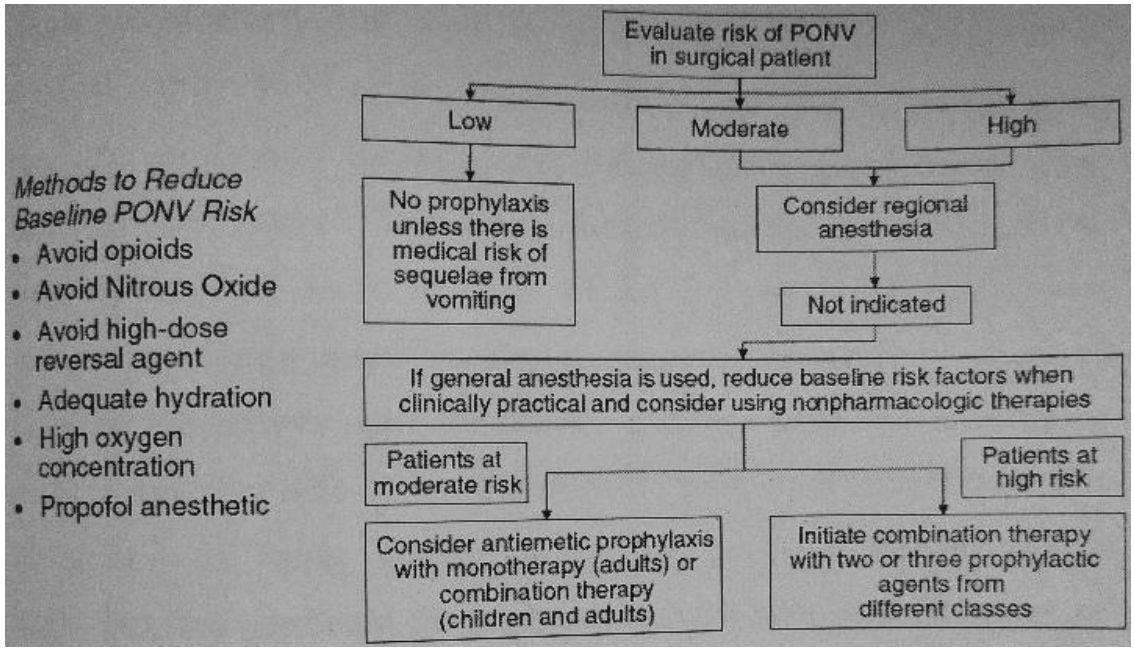

Figure 2. Flowchart showing postoperative nausea (PONV)

Fever: It happens when pyogenic stimulation might activate thermal control centers.

Post Operative Fever Management[4]: Medications like opioids, sedatives and NSAIDS possess immune modulator effects. It may be a normal inflammatory response induced by surgical stress & not by infection. Interleukin-6 concentration seems to be a good predictor of post-operative fever and it acts as a pyrogen in post-surgical patients.

Post Operative Pain Management[2]: A combination of local anesthetic blocks, neuraxial blockade, parental medications like narcotics and non-steroidalanti-inflammatory drugs are used to relieve from pain. Sometimes constant monitoring is required which is carried out in high dependency unit (HDU).

Respiratory Complications And Management[2]: Post-operative respiratory complications include atelectasis, aspiration pneumonia and other pneumonias. Preoperative treatment with incentive spirometry and chest physical therapy is useful. Sometimes pulmonary infection such as bronchitis or pneumonia should always be treated and operation delayed if possible, with the use of anesthetics has the potential for causing a severe pneumonia after operation. Use of bronchodilator aerosol or ultrasonic mist aerosol, incentive spirometry and oxygen therapy are useful.

Deep Venous Thrombosis Management[2]: It includes a low-dose subcutaneous heparin (5000 units 8 or12 hourly), graded compression support (thromboembolism deterrent) or TED stockings. Thrombosis confined to calf vein carries a low risk of pulmonary embolism so that the patient is given TED stockings and mobilized. INR measured daily until ratio stabilizes.

Traumatic Pneumothorax[13]: Air in pleural cavity is known as pneumothorax and when it is due to trauma is known as traumatic pneumothorax. 3 types: closed, open and tension pneumothorax. Patient may show signs of dyspnea, pain, shock and cyanosis. Hyper-resonance on percussion note and absence of breath sounds on auscultation are seen.

Cardiac Complications[2]: Cardiovascular complications include dysarrthmias, myocardial infarction, ventricular failure and hypertension which is managed by careful volume management and use of diuretics, digoxin afterload reduction therapy and oxygen therapy.

Acute Chest Pain[15]: Commonly encountered are angina pectoris, hyperventilation and myocardial infarction.

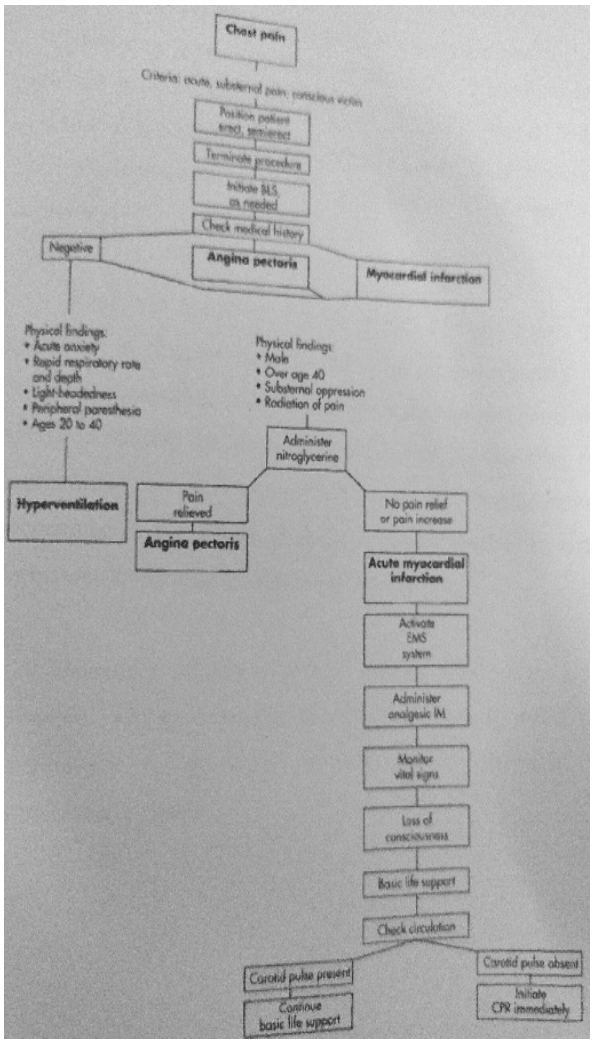

Figure 3. Algorithm showing management of acute chest pain[15]

Post Operative Bleeding Assessment and Management[17]: Reactive bleeding occurs within 24-36 hours of operation. Secondary bleeding usually occurs 7-10 days after operation as deep-seated infection. Reoperation is generally needed after correction of hypovolemic shock.

Hiccups[14]: Caused by spasmodic contraction of diaphragm. Hiccups requires insertion of nasogastric tube and aspiration through such tube. Inj. Pethidine may be required.

Nasogastric Tube[20]: It is inserted before, during or after surgery. Purpose is to decompress the stomach and prevent nausea and vomiting and aspiration. It is removed when bowel sounds are present, flatus or stools have passes and total amount of aspirate is less than 200-300ml in 24 hours.

Diet and Nutrition: For first 6 hours after operation the patient takes liquid diet. Normal diet may be given after post anesthetic nausea has passed off. Routinely intravenous injection of 100ml of 25% glucose in the morning as well in the afternoon. Oral intake should be commenced as soon as possible after surgery.

Suture Removal: Normally after 7 days suture is removed. After suture removal, Steri-Strips are applied over Mastisol liquid adhesive, the area is prevented from getting wet, so that the strips remain for 5-7 days. Most cutaneous infections are treated with cephalexin (Keflex) 500mg twice per day for 7-10 days. Patients allergic to penicillin are placed on clindamycin (cleocin) 150mg QID for 7-10 days.

Conclusion

Careful postoperative care is as important as preoperative preparation for a successful outcome of surgery. Management of post-operative complications by awell-trained critical care unit can better eliminate the morbidity and mortality on a high-risk patient, who underwent surgery.Many complications can be prevented by thorough pre-operativeevaluation, yet the patient who is predisposed to many diseases will be susceptible to complications after surgery. Post-operative care remains an important part of a maxillofacial surgeon's responsibility. Meticulous post-operative care, can decrease the incidence of complications and can enhance the patient's overall recovery. Advances in medical knowledge and technology have bought about a steady decrease in post-operative complications.

Platelet Rich Fibrin: A Promising Innovation in Periodontics

Srishti Songaya Chatterjee[1], Abhaya Chandra Das[2], Sourav Panda[2]

[1] Intern, [2] Reader, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The periodontal diseases are usually complex and multifactorial, and causes a loss of connective tissue attachment. Thus, regenerating the lost periodontal tissues becomes an important part of the therapy. Procedures such as bone grafts, Guided tissue regeneration (GTR), root biomodifications are routinely used to achieve regeneration but their success rates are limited. Platelets have an important role in regenerating the lost periodontal structures since they release growth factors when they come in contact with damaged tissues. Platelet rich plasma (PRP) and Platelet rich Fibrin (PRF) are platelet concentrates which can be obtained from patient's own blood. Choukroun's PRF is a natural biomaterial which is fibrin based and prepared without any addition of anticoagulant. The slow polymerization speed used during centrifugation renders it to be a better healing material. This article reviews the preparation of PRF and the efficacy of using it in regeneration of various periodontal structures.

Keywords: *Centrifugation, healing, platelets, platelet rich fibrin, regeneration.*

Introduction

Periodontics is defined as "the scientific study of periodontium in health and disease".[1] These diseases are usually complex and multifactorial causing a connective tissue detachment with the resultant breakdown in periodontal tissues. Thus, therapy is aimed at preventing progression of the disease and regenerating the lost tissues which is possible due to biological events like cell adhesion, migration, proliferation and differentiation.[1] Several procedures such as bone grafts, GTR, root biomodification, which are routinely used to achieve this regeneration[2] achieve only a fraction of the total volume of tissues.[3]

Blood, whose main function is to supply oxygen and nutrients to different parts of the body and in turn also carries the metabolic wastes from them, consists of 4 components – RBCs, WBCs, platelets and plasma. Platelets are important in the initiation of wound healing by releasing growth factors, which causes cellular organization, remodelling, migration and proliferation at the site of injury.[4] These properties led to the consideration of platelet concentrates for the purpose of therapy.

Historical background: Regenerative potential of platelets had been considered for use in wound healing since the 1970s and by 1980s their clinical applications had begun with the following timeline:

- 1970- Fibrin Glue by Matras
- 1997- Platelet Rich Plasma by Whitman et al
- 1999- Plasma Rich In Growth Factor (PRGF) by Anitua et al
- 2006- Platelet Rich Fibrin by Choukroun et al
- 2006- Concentrated Growth Factor (CGF) by Sacci

In the initial years, the use of fibrin adhesives clinically was limited due to the complex preparation procedure and the cross-infection risks that it carries. PRP is prepared by collecting patient's own blood in a test tube in which anticoagulants are added. After the first spin, three different layers are formed:

Corresponding Author:

e-mail: drabhaya2011@gmail.com

i. Superficial layer is rich in platelets and some WBC.

ii. Intermediate layer, which is very thin, is rich in WBC.

iii. Deeper layer separates the RBCs.

- For production of Pure – PRP (P-PRP), the upper layer, which is rich in plasma along with superficial buffy coat is collected for 2nd spin.
- For production of Leukocyte rich PRP (L-PRP), the entire buffy coat and a few RBCs are collected for 2nd spin.
- After 2nd spin, the platelet pellets are collected and homogenised by mixing it with lower 1/3rd of plasma and upper 2/3rd is discarded.

However, PRP has some drawbacks[5]:

i. The quality of PRP depends on the numberof platelets and leukocytes, type of anticoagulant used and time of placingthe fibrin scaffold after clotting.

ii. The bovine thrombin which is used as an anticoagulant for production of PRP can develop antibodies against clotting factors such as V, XI and thrombin, which can in turn affect the process of coagulation.

iii. In PRP, the fibrin network is immature and consists mainly of fibrillae with small diameter due to simple fibre polymerisation. This fibrin network supports platelet application during surgery but dissolves quickly.

These limitations led to the development of 2nd generation of platelet concentrates by Choukroun known as Platelet rich fibrin.

Platelets and Platelet Rich Fibrin: Platelets are tiny, irregularly-shaped cells,devoid of nucleus which are derived from larger cells called megakaryocytes. They have a life span of 7 – 10 days. During any injury, when the platelets come in contact with an exposed endothelium, they release certain growth factors to facilitate wound healing.[6] (Table 1)

Table 1: Various growth factors and their functions

Growth factors	Functions
Platelet-derived growth factors (PDGFs)	Cell proliferation, cellular migration, collagen production to repair wound.
Transforming growth factor (TGF)	Angiogenesis, Re-epithelialisation, Regeneration of Connective tissues.
Vascular endothelial growth factor (VEGF)	Angiogenesis, Tissue Remodelling.
Endothelial growth factor	Proliferation and multiplication of endothelial and mesenchymal cells leading to epithelialisation

The platelet concentrates can be classified depending on their leukocyte content and fibrin architecture as follows[10]:

First Generation:

(1) Platelet Rich Plasma (PRP)

(2) Pure Platelet Rich Plasma (P-PRP) / Anitua's Plasma Rich Growth Factor (PRGF)

(3) Leucocyte Platelet Rich Plasma (L-PRP) / L-PRP Gel

Second Generation:

(1) Platelet Rich Fibrin (PRF)

(2) Pure Platelet Rich Fibrin (P-PRF)

(3) Leucocyte Platelet Rich Fibrin (L-PRF)

(4) Concentrated Growth Factor (CGF) (Solid fibrin material with leucocyte)

(5) Advanced Platelet Rich Fibrin (A-PRF)

(6) Injectable Platelet Rich Fibrin (I-PRF): (used to prepare sticky bone)

(7) Titanium Platelet Rich Fibrin (T-PRF)

Preparation of PRF: Choukroun's PRF preparation protocol, given in Nice, France[8] requires a blood collection armamentarium, 10 ml dry glass test tube without the anticoagulant, and table centrifuge.

Once the subject's blood is collected and placed in a test tube, it is centrifuged for 12 minutes at 2700 rpm.[9] This results in the blood samples settling to various layers and a coagulation cascade sets off immediately in the absence of an anticoagulant. Thus, the following layers are formed (figure 2):

i. Superficial layer – Straw coloured acellular plasma

ii. Intermediate layer – Fibrin clot

iii. Deeper layer – RBCs

The superficial layer consisting of the acellular plasma is removed. The intermediate layer consisting of the fibrin clot is separated from the deeper layer consisting of RBCs.[10] After removing the clot, it is kept

between two gauge pieces and squeezed to produce the fibrin membrane.[11] The exudates from serum containing proteins Vitronectin and fibronectin hydrates graft materials, rinses surgical site, and storesthe graft. The clot is then placed inside a PRF box and covered to squeeze out the fluids (figure 3). In this way a PRF membrane with a constant thickness that remains hydrated for several hours is obtained.

Clinical implications of PRF[12,13]:

(1) In sinus floor elevation procedures, PRF can be combined with bone grafts to accelerate healing.

(2) In ridge augmentation procedures – to stabilize and protect graft materials.

(3) To preserve the sockets following extraction.

(4) In root coverage procedures for single and multiple tooth recession.

(5) In 3 – walled osseous defects for regeneration.

(6) Treatment of furcation defects.

(7) For cystic cavity filling.

(8) In Implantology, PRF is used for a better osseointegration on the surface of implant.

(9) In the Guided tissue regeneration of periodontal ligament, alveolar bone and cementum.

Advantages of using PRF over PRP[14]:

(1) The preparation technique is simple and cost effective with a single step centrifugation.

(2) It is obtained from an autologous blood sample that requires minimal manipulation.

(3) An external addition of Bovine thrombin is not required, thus averting immunological reactions.

(4) It allows a favourable healing due to a low and completely natural polymerization process.

(5) It can be used solely or in combination with bone grafts to accelerate the healing of the grafted bone.

(6) In case a fibrin membrane is used, a surgery at the donor site becomes unnecessary, thus reducing patient discomfort.

Disadvantages[15]:

- Since an autologous blood is used, the final amount obtained is low.
- It is highly technique sensitive and the PRF protocol has to be strictly followed.
- The clot polymerization necessitates use of a glass-coated tube.
- An experienced clinician is required for PRF manipulation.

Future directions[16,17,18]: A very limited literature is available on the result of using PRF for periodontal surgery and its mechanism of action. There is a need to quantify the release of growth factors over time. Various factors are responsible such as presence or absence of leukocytes and its amount, type of activation, number of platelets, composition of cell and the type of preservation during collection, transportation and centrifugation. The parameters related to centrifuge such as its size, duration, and vibration is also important. Other factors that are essential are cost, ergonomics and amount of the final product formed. Further application of platelet concentrates in clinical practice should be done to acquire more knowledge on PRF.

Conclusion

Choukroun's PRF technique is a simple and inexpensive that brings about a successful regeneration of periodontal tissues. The use of an autologous platelet rich fibrin enhances healing while reducing the disease transmission through blood. However, further clinical trials involving a large number of subjects is required for the long run.

Minerals and Oral Health

Somesh Singh

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Human body requires abundant amount of minerals, essential elements for proper working and their nonappearance or abundance may bring about serious breaking down of the body and even demise in outrageous cases. Urbanization have influenced the human eating regimen with slanted inclination towards refined eating routine but healthfully denied low quality nourishment and mineral intake reduces immunity and often lead to different oral and systemic diseases. Minerals even in small amount plays a crucial role in growth and development and maintainance of craniofacial and oral structure.

Keywords: *Mineral, Oral Health, Risk factors.*

Introduction

Appropriate support of all metabolically cells and tissues is essential to the overall well-being of the human body. Follow components are compound micronutrients which are required rather in moment amount yet assume a fundamental job in keeping up the uprightness of different physiological and metabolic procedures happening inside living tissues. Anyway there had been constrained knowledge, importance given by oral physicians with respect significance of trace elements.

Classification of Minerals[1]

(A) Major Minerals: Calcium, phosphorous, sodium, potassium, magnesium.

(B) Traceelements: Iron, iodine, fluorine, zinc, copper, cobalt, chromium, manganese, molybdenum, selenium, nickel, tin, silicon, vanadium.

(C) Trace Contaminants With Known Function: Lead, mercury, barium, boron, aluminium

Role of Major Minerals

(A) Calcium: The best natural sources are milk and milk products, eggs and fish.

Its function are:

- Formation of bones and teeth.
- Coagulation of blood.
- Contraction of muscles.
- milk creation.
- keeping the cell membranes undamaged.
- Metabolism of enzymes and hormones.

A day by day admission of 400 to 500 mg is required for adults. No obvious disease because of insufficiency has been observed.

Sources: Milk, yogurt, cheese, beans, and kale.

(B) Phosphorous: It is widely distributed in food stuff. It is essential for the formation of bones and teeth although specific requirements have not been recommended, some researchers have recommended that its admission ought to be atleast equivalent to calcium consumption.

(C) Magnesium: Magnesium constructs strong enamel for your teeth and counteracts the development of cavities.

Sources: Spinach, kale, dark chocolate.

(D) Potassium: Needed for nerve function and muscle contraction.

Sources: Vegetables, legumes, fruits, milk, cheese, variousmeats, whole grains.

Role of Trace Elements and Contaminants

1. **Copper:** Copper is the third most rich follow component with just 75-100mg. Copper is available in pretty much every tissue of the body and is put away mainly in the liver alongside the heart and kidney[2]. Copper is transferred to the liver in the gut and discharged into bile.

Biological Functions: A noteworthy number of metabolic enzymes work appropriately because of copper.

- Plays a vital role in aerobic respiration energy production.
- production of hemoglobin.
- Melanin production.
- Thyroid hormone thyroxine production[3].
- Copper can be an antioxidant as well as a prooxidant.

Role in Oral Health and Diseases

- Long-term dietary deficiency of Cu, particularly during active growth stages causes deficient keratinisation and anemia[4].
- Infections: decreased immunity may lead to different oral cavity infections due to accompanied neutropenia[5].
- Bone defects and pain: bone deficiency modifications include loss of cortex thinning trabecular formation. Osteoporosis and formation of occipital horns may occur owing to copper-requiring enzyme functional deficiency.
- Oral lesions: India's average intake of copper is 2.1–3.9 mg / day, whereas it is more than 5 mg / day owing to intake of areca nut.It cause OSMF and leukoplakia.
- Cu is also believed to possess caries promoting property.

2. **Zinc:** There are 2–4 grams of Zn spread all over the human body. Zinc is stored in the prostate, eye, brain, muscle, bone, kidney, and liver parts. It is the second most abundant transition metal after iron in humans[6].

   Biological Functions: Zinc can be split into three primary classifications: catalytic, regulatory, and structural. The catalytic activity requires a big amount of enzymes[7]. It plays a major role in the function of immune, wound healing, protein synthesis, DNA synthesis and cell division. For proper sense of taste and smell zinc is required.

Role in Oral Health and Diseases

- Zinc naturally occurs in the oral cavity in plaque, saliva and enamel. Zinc is converted into oral health products to regulate plaque, decrease malodor and delay calculus formation.
- Taste disorders: the role of zinc in taste functions can be valued at various organizational levels, such as taste buds, sensory nerve transmission, and brain[10].
- Zinc-deficient diet may lead to normal orthokeratinized oral mucosa parakeratosis. Zinc deficiency may therefore be a potential risk factor for oral and periodontal diseases.
- As transferrin carries iron and zinc, zinc levels increase as iron levels decrease in patients with iron deficiency.. Thus, OSMF patients with iron deficiency anemia also show higher serum zinc levels.

3. **Iron:** Iron is the human body's most abundant essential trace element. The total iron content in the body is approximately 3–5 g, most of it in the blood, and the rest in the liver, bone marrow, and hememuscles[11].

   Biological Functions: Heme is the major ferrous or ferric iron-containing substance found in hemoglobin, myoglobin, and cytochrome. Heme forms covalent bonds to create hemoglobin, the main oxygen carrying pigment, in mammalian RBCs with the globin protein[8].

Role in Oral Health and Diseases:

- Iron deficiency anemia is the most frequent expression of low serum concentrations of this significant trace element.
- Oral premalignant lesions and conditions: OSMF patients encountered important decreases in serum iron levels with elevated complete iron binding ability.

4. **Cobalt:** Cobalt is an important trace element that can happen for the human body in both organic and inorganic forms. It is an essential component of organically formed vitamin B12 and plays an important role in the creation of amino acids and neurotransmitters. The human body is poisonous through inorganic cobalt forms.

Biological Functions:

- Cobalt is needed to efficiently form amino acids and various proteins for myelin sheath manufacturing. Cobalt also plays a crucial role in producing the neurotransmitters that an organism needs to operate properly[9].

Role in Oral Health:

- In relation to erythropoiesis, vitamin B12 also plays a significant role in nerve repair and regeneration.
- Cr, Co, Ni and amalgam alloys released from metal alloys frequently used in oral cavity dentistry were connected with lichen planus and oral lichenoid responses.

5. **Chromium:** Chromium exists in the oxidation states of both insoluble and soluble forms.The total body content of chromium is relatively low and is about 0.006 g in an average healthy human adult. Trivalent Cr is an essential trace element and, by serving as a cofactor for insulin action.

   Chromium exposure was correlated by occupation through inhalation with multiple lung, GIT, and central nervous system cancers. Chromium is primarily excreted in urine and faeces and tiny quantities in hair, sweat and bile[10].

   Biological Functions: Chromium helps in controlling blood sugar and lipid levels. It improves the efficiency of insulin and stimulates glucose absorption from muscles and other tissues.

   Role in Oral Health and Diseases: Hyperglycemic status of undiagnosed chromium-deficient patients may lead in a broad spectrum of oral manifestations observed in diabetes such as delayed wound healing, suppurative periodontitis, multiple oral fungal infections, premature periodontal illnesses, and hyposalivation[11].

6. **Selenium:** Selenium is a essential trace element in antioxidant enzymes such as glutathione peroxides and reductase of thioredoxin. Too much is detrimental to the human body.

   Biological Functions: Selenium has anti-proliferative and immunomodulatory properties.

   Role in Oral Health and Diseases: Trace components such as selenium is an significant rationale for the treatment of pre-malignant tumors such as leukoplakia, situations such as OSMF, and oral cancer patients to decrease oxidative pressure in the body.

7. **Molybdenum:** In 1778 Carl Wilhelm Scheele discovered the element and in 1781 Peter Jacob Hjelm first isolated it.

   Biological Functions: Also influenced is protein synthesis and body growth. High levels of molybdenum can decrease copper absorption and lead to copper deficiency[12].

Role in Oral Health and Diseases

Molybdenum have a cariostatic effect.

8. **Fluorine:** Fluorine makes the body mass negligible and enters the system through food and water.

   Biological Functions: In bone and teeth, fluorine appears in the form of fluorapatite crystals. Fluoride is also believed to stimulate osteoblastic activity in combination with calcium[10].

   Role in Oral Health and Diseases: Dental caries was correlated with low concentrations of fluoride in water. Excessive levels of fluoride may lead in a sort of enamel hypoplasia during the calcification phase of the teeth.

9. **Iodine:** Iodine is required in all periods of life during the formative years. Maintaining the daily functions of the body is essential and due to deficiency or excess there may be effects on the body.

Biological Functions

Iodine plays an important role in thyroid hormones.

It helps in

- Metabolism
- Development of brain.
- Immune function.

Role in Oral Health and Diseases: The most frequently reported symptoms of iodine deficiency are extreme fatigue, irritability, mental disorders, weight gain. Iodine deficiency in children causes cretinism.

Adult hyperthyroidism can result in Addison's disease.

Conclusion

Deficient consumption of an important trace element may reduce important biological functions within tissues, and restoring the physiological concentrations of that element may facilitate or deter impairment.Preventive medicine has gained more oral attention nowadays and general health can not be considered separately and as a matter of reality the oral cavity can efficiently mirror systemic health the combination of different micronutrients and trace components has been used as a therapy for oral illnesses such as oral leukoplakia, oral submucous fibrosis. And so on, as their collective result

is more useful than being applied alone. Consequently, for both general and oral physicians, understanding of clinical aspects of trace elements is becoming essential.

Ozone-Boon in Dentistry

Susant Mohanty[1], Antarmayee Panigrahi[2]

[1]Professor & Head, [2]Reader, Department of Pedodontics and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University). Bhubaneshwar, Odisha, India

Abstract

Since the knowledge of extensive array of actions of **ozone,** it has been proposed to be used in dentistry owing to its antimicrobial, antiseptic, healing property and considerable **biocompatibility**. There have been scattered reports of cases and trials but still lacks enough data to compile recommendations. This review presents with its chemical and biological actions of ozone and its different uses in dentistry in every field.

Keywords: *Ozone, Bactericidal, Dentistry.*

Introduction

Ozone is derived from Greek word "OZEIN" meaning odor. It was first mentioned by Martin Van Marun in 1785 but in 1840 Christian Friedrich Schoenlein, Professor in University of Basel explained the different properties of oxygen and ozone. Since 19th century ozone has been used for various therapeutic purposes. [1] Ozone molecules comprises of three oxygen atoms and present in small amounts in upper layer of atmosphere abundantly. It is known to have protective effects against ultraviolet rays and self-cleansing property as well.[2]

With proven bactericidal, fungicidal and disinfectant activity ozone has been widely used in medical fields surgery, cosmetics as well as in dental infections. Most commonly concentration in medical and dental field ranges from 1-100gm/ml which is 0.05-5%. There are basically three forms of availability: gaseous form, ozonated water and oil form. [3]

Mode of Action

Antimicrobial Effect: As per the available scientific literature, ozone has been effective in killing wide range of gram positive and gram-negative bacteria including those which are antibiotic-resistant. It acts mainly by chemically damaging the bonds in cytoplasmic membrane and altering intracellular contents which occurs due to secondary oxidants effects. However, these actions are non-specific but selective to microbial cells and cause no damage to human cells which carries inherent antioxidant ability. Thanomsub et al also proved enhanced antimicrobial activity in aqueous environment with acidic pH.[4-5] In 2003, Babior BM made a striking discovery that ozone can be produced in vivo within neutrophil which are activated physiologically and pathologically. This discovery also emphasized its bactericidal activity which is also a part of amplifying processes in inflammation and activating associated genes.[6]

Action on Immune system: ozone affects cellular as well humoral immune system. Also, it enhances proliferation of cells in immune system and immunoglobulins. It increases sensitivity and activity of macrophages intensifying phagocytosis process.[7] Viebahn- Hansler R reported that use of ozone-based therapy resulted in increased interferon production, tumor necrosis factor and interleukin-2 which subsequently lead to torrent of immunological based reactions. Thus, indirectly hinting towards its efficient use in patient with compromised immune systems.[8]

Action against inflammation and Pain: various available literature has well proven the fact that ozone has both analgesic as well as anti-inflammatory effect. It acts in various ways on different targets by decreasing the production of inflammatory mediators, inactivating the metabolic products of pain pathway by oxidation and also by enhancing the vascular supply which in turn improves oxygen availability to tissues and thereby eliminating toxic products. Ozone being negatively

Corresponding Author:
Dr. Antarmayee Panigrahi
e-mail: antarmayee.pani@gmail.com

charged ion neutralizes the acidic environment of infection.[9-10]

Uses of Ozone in Dentistry: Multifaceted antibacterial action of ozone makes it a potential therapeutic and preventive agent to be used in different fields of dentistry in different forms.

Dental Caries: Being a microbial associated disease process ozone have been suggested as alternative to arrest or reverse the carious lesions justifying era of minimal intervention dentistry. It has been proven to eliminate and thus reduce the bacterial load.[11] Baysan proved in his study that bacterial load is considerably reduced in carious root lesion and progression of dental caries clinically ceases.[12]

Liquid and gaseous forms of ozone have shown remarkable antimicrobial activity against *E. fecalis* and *S. mutans* in vitro as well as in ex-vivo conditions thus can be recommended to be used in medical management of dental caries. These forms can be easily accessible and suitably used with toothbrush and other chairside procedures.[13]

Documented trials have also been done to assess the effect of ozone treatment in crown lesions as well as on root lesions and it significantly proved that intervention using ozone stops or regress the dental caries process. Combination of ozone with photodynamic treatment have shown little effect on microbial colonies in plaque biofim.[14]

However still there remains need for further exploration withmore robust research design to provide with suitable and viable alternative form with more documented evidence for clinical use widely.

Dental Plaque: Dental caries and periodontal diseases are mainly plaque derived diseases.

Ozone being bactericidal has been proposed to control microorganisms constituting dental plaque. Oil form has been used for treatment of acute necrotizing ulcerative gingivitis. Because of its bactericidal property and enhanced oxidizing activity it has been effectively used as subgingival irrigant. Aqueous form of ozone has shown similar antimicrobial and antifibroblastic activity as 2.5% sodium hypochlorite. It is a potent antiseptic with less cytotoxicity and demonstrate supreme biocompatibility for use in oral cavity. This can be used as an adjunct to conventional restorative and periodontal therapy owing to its multivariate antimicrobial actions.[15]

Oro-mucosal Conditions

Apthous Ulcer: certain reports have suggested its topical use for recurrent aphthous ulceration in tongue and lip, however it needs further investigation for validation. It has also been tried in aphthous stomatitis in cases of patient with compromised immune system and other available options failed to give desirable results.[16]

Mucositis: Scattered reports in literature indicated use of ozone gas and oil form to be advantageous in use for treatment of chemotherapy and radiotherapy induced mucositis. Currently various research is going on to derive treatment protocol using ozone as preventive agent in these cases.

Temporomandibular Joint Disorders: Daif conducted a randomized controlled study to evaluate effect of administration of intra-articular ozonated water in cases of internal derangement of temporomandibular joint and disc displacement and proved its efficacy in 87% of patients. However additional scientific evidence is required to provide more considerable results.[17]

Endodontic uses: With the change in concept from mechanical to chemical preparation of root canal system morefocus is given on disinfection of root canal system reducing bacterial load thereby assuring increase in success rate. Ozone water had been proposed and investigated to be used as root canal irrigant. This has been found to be efficacious in reducing endodontic pathogens mainly *E. fecalis, Candidaalbicans*, *Pseudomonas aeruginosa.*[18]

Oil form of ozone has been used successfully with equal efficacy as sodium hypochlorite and sodium peroxide combination. This also eliminated the odor caused due to anaerobic activity in teeth with chronic infection.[19]

Bleaching: Use of ozone for 3-4min on inner aspect of root canals of discolored and non-vital teeth provided significantly superior results and esthetic outcome.[20]

This was first attempted by Tessier et al in growing rats experimental model in reducing the stains on incisors by tetracycline. further studies are required for its potential use clinically.[21]

Root Sensitivity: Use of ozone spray for 60 seconds on exposed dentin followed by wash with mineral water in cyclic manner resulted in quick relief. This effect of desensitization lasted longer as ozone could

successfully remove the smear layer on root surface, opening of dentinal tubules and efficaciously plugging thereby reducing exchange of fluids and thereby sensitivity. Thus, it is a quick and long-lasting method for desensitization. Various combinationshave been tried by different researchers in assessing its effect in molar incisor hypomineralisation and showed effective and prolonged reduction in sensitivity with CPP-ACP paste.[22]

Wound Healing: ozonated water and oil has been used in cases of aphthous ulcers, herpes labialis, ANUG, alveolitis, gingival infections, etc. as it enhances physiological healing as well as controls opportunistic infections. It has shown significant reduction in time post extraction as it forms a pseudomembrane and thereby protecting from any further trauma. It has noteworthy impact in healing of jaw bones which has compromised vascular supply due to radiotherapy, thus used as adjunct in therapeutic bone healing postoperative. [23-24]

Prosthodontics & Implants: Plaque accumulation on denture comprises of several microorganisms mainly C.Albicans which leads to denture stomatitis causing immense discomfort to the old patients. Thishave been proficiently controlled by topical application of ozonated oil over the mucosal surface as well as acrylic surface ensuring complete disinfection. Also using ozonated water(2-4 mg/l) as mouth rinse for 1min by the patient wearing dentures have proven to be effectively reduce incidence of stomatitis and reducing growth of candida albicans.[25]In field of implantology ozone works as miracle as it aids in regeneration of periodontium similar to natural teeth. When used along with cyclosporine, ozone oil has demonstrated increased bone density and quality of osseointegration of dental implants.

Pediatric Dentistry: Ozone has been a boon to pediatric dentistry especially in children with phobias. It has been used in managing carious lesions by exposing the lesion to ozone for 60 seconds as it results in sterilization of the lesion and in turn promoting remineralization. Though till now there is not enough data to substantiate its use as solo agent for the treatment of dental caries but can be used in combination with conventional restorative techniques.[26-27]

Conclusion

With ever changing concepts and innovations in dentistry the concept of treatment has changed from surgical to medical management of lesions. Ozone being a wide spectrum antiseptic available in various forms and having considerable biocompatibility proves to be a viable alternative to treat wide range of problems in dentistry. It can be either used solo or as adjunct or in combination with other traditional and conventional treatment regimen. However, this calls for further research and more compiled data to derive the protocol and design recommendation for usage of ozone in dentistry.

Abstract

Laryngopharyngeal reflux (LPR) refers to laryngopharyngeal involvement of gastroesophageal reflux disease. Finding of LPR is carried out by surveying the clinical indications, videolaryngoscopic assessment of the larynx and by double probe pH monitoring. Hoarseness of voice is an important symptom for diagnosis of LPR in children and frequently the only presenting symptom. Double probe pH monitoring which includes esophageal and pharyngeal is both specific and sensitive for finding of LPR. Early diagnosis and treatment often results in improvement of hoarseness and prevent complications. Endoscopic examination of larynx and hypopharynx is vital for patient choice as preferred findings are associated with diagnosis, treatment & outcome. Treatment incorporates the way of life adjustments & medications.Here we are presenting vocal process granuloma, unusual presentations of prolonged laryngopharyngeal reflux in a 12 year old boy.

Keywords: *Laryngopharyngeal reflux, hoarseness of voice, pediatric age, granuloma.*

Introduction

Laryngopharyngeal reflux is a typical clinical substance characterized as the retrograde progression of gastric substance to the larynx and pharynx.[1] It happens when the upper and lower esophageal sphincters don't function effectively and permit the gastric contents & acid dribble into larynx which cause edema and inflammation. LPR gives several indications and ranging from foreign body sensation throat to subglottic edema. The various clinical presentations of LPR in children are usually non-specific. The clinical presentations are postnasal drip, globus sensation in throat, throat clearing,cough, chocking sensation in throat. The endoscopic picture of larynx may cause posterior commissure hypertrophy, ventricular obliteration,vocal fold edema, subglottic edema, presence of granuloma, diffuse laryngeal edemaand thick endolaryngeal mucous.[2] Here, we present a case of LPR in young boy with giant granuloma at posterior larynx.

Case Report: A male child of age 12 year presenting with irritating dry cough ever since five months and dysphonia since 3 months. He was obese child with habit of taking frequent carbonated drinks and exposed to passive smoking from family members. He had a breathy voice, with inability for completing sentence. He has also complain of sensation of fullness in throat, repetitive throat clearing habit since last 2 months. The hoarseness of voice was gradually becoming worse and accompanied by occasional throat pain. He had no past history of prolonged intubation or any traumatic intubation. On examination with flexible nasopharyngolaryngoscopy, there were swollen, reddish mass at both vocal process (Figure 1). Bilateral vocal folds were mobile and congestions seen in posterior part. Sputum sent for acid fast bacilli and found out negative. Chest X-ray appears normal. Routine blood tests were within normal limit. The patient was sent to gastroenterologists for further

Corresponding Author:
Dr. Priyanka Debta
e-mail: dr.priyankadebta@gmail.com

evaluation and to rule out gastroesophageal reflux disease and after 24 hour pharyngeal pH monitoring appears to be laryngopharyngeal reflux. This confirmed acid reflux induced granuloma at the posterior commissure. Patient was planned for micro-laryngeal excision of the both granulomatous lesions of the larynx at vocal process. The both side vocal process granulations were excised and sent for histopathological examinations. The histopathological report revealed non-specific inflammations. The child was beginning on hostile anti-reflux treatment by omeprazole 20 mg orally day by day with steam inhalation for 2 months. He had also undertaken speech therapy after surgery. The parents of the child were counselled and advised for avoiding passive smoking, carbonated drinks, coffee chocolates and reduction of weight of the child. After two months of treatment, there was complete resolution of all the symptoms. Examination of the larynx (Figure 2) by fibreoptic nasopharyngolaryngoscopy revealed normal appearance after 3 months of follow up.

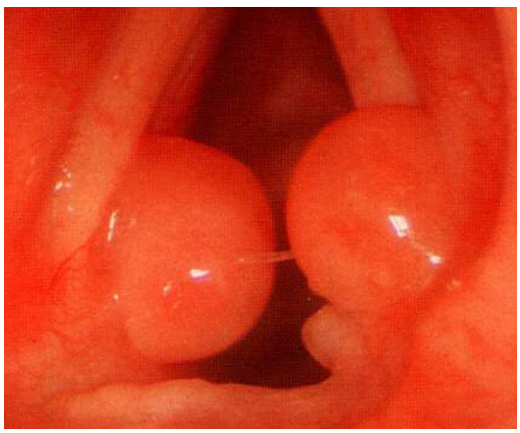

Figure 1. Fibreoptic Laryngoscopic picture of giant granuloma at bilateral vocal process

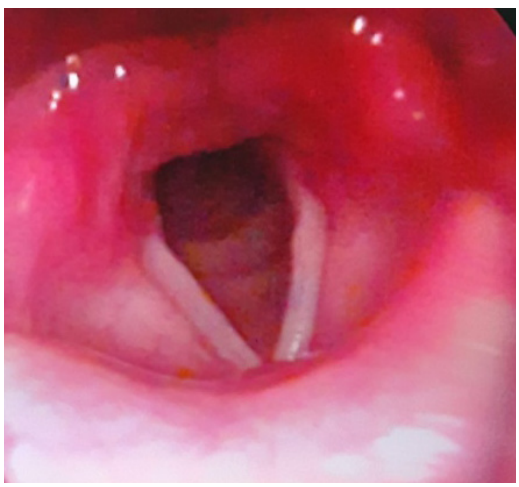

Figure 2. Post-operative view of Larynx after 3 months of treatment.

Discussion

Laryngopharyngeal reflux (LPR) is an inflammatory disease due to back flow of the gastric acid into the larynx and pharynx, where it contacts to the tissues of the upper aerodigestive tract. [3]The physiological hindrances for counteracting LPR are lower esophageal sphincter, esophageal freedom affected by esophageal peristalsis, gravity, saliva and upper esophageal sphincter. At the point when these physiological obstructions fall flat, stomach substance come/corrosive in contact with the laryngopharyngeal tissues, prompting harm of epithelium, ciliary brokenness, adjusted affectability and aggravation. The quality of voice is affected in 6-23% of school going children.[4] LPR is a well-established etiology for hoarseness of voice in children.[5]The most frequent medical symptoms are persistent cough, clearingof throat,globus pharyngeus and roughness of voicein LPR protuberance or foreign body in throat and non-agonizing in nature.[6,7] Heartburn is a common symptom in gastroesophageal reflux disease (GERD) and seen above than 75% cases whereas found less than 40 percents patients with LPR present indigestion/ heartburn.[8]

There are a few hazard factors for creating back laryngeal granulations like delayed intubation, awful intubation, improper endotracheal cylinder site, high sleeve weight and strange laryngeal life structures.[9] However there was no such factor identified in this case. The pathogenesis of vocal process granuloma and association with LPR is still unclear, however it is likely identified with an interference of typical mending process after damage or constant chemical injury of arytenoids or vocal process of the larynx. The critical role of LPR in causing laryngeal granuloma of the vocal process has been exhibited via the reality that the greater part of vocal progression of granuloma determine by clinical treatment of an acid reflux.[10]

Laryngoscopic examination is done by using flexible trans-nasal or rigid trans-oral laryngoscope. The laryngeal findings are vocal fold edema, redness and edema localized to posterior larynx,arytenoid and inter-arytenoid area. Sometimes patients present with having subglottic edema, contact ulcers,granuloma & also pseudosulcus. These phenomena are also frequent pronouncements seen during laryngeal examinations for assessing dysphonic patients. Accurate Laryngoscopic assessment in LPR patient is often difficult,so it isn't informed to cause determination

with respect to LPR exclusively dependent based on Laryngoscopic discoveries.[11] Diagnosis of LPR might be built up by posing inquiries of the manifestations, videolaryngoscopic assessment of the larynx or twofold test pH checking. Mobile 24-hourtwofold test (esophageal and pharyngeal) pH observing is exceptionally delicate and explicit for conclusion of LPR.[12]There is no ideal diagnostic method for LPR in pediatric age. There are different method available for diagnosis of LPR and these are pH monitoring, intra-luminal impedance, barium studies, scintigraphy, ultrasound, fluoroscopy and esophageal biopsy. The present highest quality level test for LPR is the double test 24 hour pH checking. In any case, it is an obtrusive test with false negative outcomes coming to as high as half.[13] Some extra examinations like radiography, esophageal manometry, spectrophotometric estimation of bile reflux and biopsy from mucosa.

Most of the post-intubation injuries on posterior larynx resolves spontaneously whereaswhile nearness of indigestion has been related with delayed danger of damage at the back larynx.The symptomatic improvement is improved by altering the dietary routines. Patients be supposed to eat food untimely i.e. at least 2 hours before bedtime.They are additionally educated against ingestion with respect to extreme espresso or carbonated beverages which influence sharpness and lead to reflux.[14] Highly spiced foods,high fat foods,chocolate and high calorie diet aggravates acid reflux, so should be avoided by patients.[15]LPR patients are advised to stop or avoid smoking.Weight reduction is an important criterion for patient experiencing LPR because of predominance of the manifestations in corpulent patients.Patients are advised for regular exercises of atleast 30minutes each day as less active children are more prone for developing of LPR.[16] In case of giant granulomatous lesions at vocal process affecting laryngeal function, need micro-laryngeal surgery and biopsy as done in this case.

Conclusion

Laryngopharyngeal reflux (LPR)suspected from the patient history and endoscopic findings. Granuloma at posterior larynx is a long term and severe complications of LPR. Multichannel intra-luminal impedence and pH monitoring studies are useful for confirmation of LPR. There are no specific tests for diagnosing LPR. Empirical treatment with PPIs has been broadly acknowledged as an analytic tests & treatment alternatives of LPR. Other treatment are dietary adjustments and life style modification like avoid passive and active smoking and drinking alcohol, weight loss and avoid caffeine.

Oral & Perioral Piercing: Fashion or Vandalization from Dentists' Perspective

Arpita Datta[1], Antarmayee Panigrahi[2], Susant Mohanty[3]

[1]Postgraduate Student, [2]Reader, [3]Professor & Head, Department of Paediatrics and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneshwar, Odisha, India

Abstract

Oral & perioral piercing has been an age-old tradition among people throughout the world including India. Until most recently seen among the youth primely, apart from various tribal communities- as signs of traditional norms, maturity in adolescents, trend setting or various cultural & religious faith. Being an extremely painful process, it possesses various complications that are deleterious & can be overcome to a larger extent with proper counseling and post-operative care. The aim of this review article is to throw light upon cons of this body adornments & character played by dentists in overcoming such complications.

Keywords: *Oral & Perioral Piercing, Adolescents, Dentists, Complications.*

Introduction

Oral piercing is a form of beautifying procedure in which a needle is inserted, generally without anesthesia into the oral cavity or perioral structures followed by different forms of jewelry that can be made of metals or acrylics[1]. Various reasons associated with these customs are religious beliefs, style statements, symbol of bravery, adding to glamour, mark of puberty in some boys & girls, after nuptuals, identity of various tribal communities, self-distinctiveness for adolescents[2,3].

History: The foremost depiction of piercing was in the frame of a dog fabricated by 1500 BC, in Egypt, regarded as a symbol of grandeur and was revived by 1970s in the West. Body discerning is also evident in the Bible. Oral piercing specially started among the ancient forest ethnic groups residing in Indonesia, Africa and South America. American races like Haida, Mayans, Tlingit & Aztecs began piercing tongue as a grand custom- believed to please deities. Even Asian & Middle Eastern Sufis & Fakirs daunt pierced tongue. Eskimos show labret pressed into lower lip as a representation of transition to manhood in boys and as an act of sanctification in girls. Males & females from Ethiopia have also been seen to use diverse visage piercings, with a belief that the lip lamella in females help to acquire prestige and demand an upgraded matrimonial price. African tribal ladies don lip lamellae known as "Pelele" adorned over upper lip for venereal reasons. Two tribal groups The Nubas & The Dogon punch their lips, specifically with a ring, a tradition discrete of Africa. The Mayans & The Aztecs pierced their lips with labrets while the Makololo tribes adorned lip plates. In Hindu and Chinese cultures, the lips, cheek or tongue are punched as an age-old custom. In Indian places like West Bengal, Karnataka, etc an old practice of perforating the tongue or cheek using an iron bar, only taken out as the person performs a round of the village collecting alms, held each year as a ceremony. The punk movement put piercing back into fashion in developed countries along with a broader "body painting", i.e., the discretionary moderation of bodily aspects by tattoos, searing, scars or punching. Scully and Chen in 1992, first reported piercing of tongue in medical records[4-9].

Prevalence of Oral Piercing According to Age and Gender: A recent study revealed that oral and/or peri-oral piercings can be found in almost 5.2% of youths found 4-fold greater in females in comparison to males, and higher in athletes compared to their counterparts. The most prevalent ages are 18- 30 years[10]. Firoozmand

LM et al stated that students, 14 to18 years had 3.6% oral piercing[11]. Adolescents exhibited 4% and 24% tattooing and piercing respectively by Bosello R et al[12]. Average age of a person having pierced tongue is 19 years[13]. 5 New York high schools had 49 adolescents who had oral piercing[14]. A study in England showed prevalence of lip piercings about 0.5% & 0.7% in males and females respectively while tongue piercings around 1% & 1.9% respectively in men and women[15].

Materials used for Oral piercings: Less allergenic and nontoxic materials should be used for jewellery insertion or perforation. Generally, Titanium, 14 or 18K gold, acrylic, stainless steel, stone, wood, bone or ivory are used[16].

Sites of Oral & Perioral Piercings:

1. **Tongue:** Vertical piercing along middle of tongue, anterior to lingual frenum, most common piercing site Dorsoventral. It can also be pierced several times, laterally along the whole width-dorsolateral. These sites increase risk of nerve injury or excessive post-operative bleeding. A more explicit form of piercing of tongue involves separation of anterior region into two different halves, thus giving rise to bifid tongue cut either with a scalpel or by passing a nylon thread within the piercing site and then braiding it for weeks, until his thread moves fully along anterior region of tongue. Tongue piercings usually require initial long barbell, to allow for postoperative healing to occur. Once the wound starts healing (i.e within 2-4 weeks), a smaller jewelry must be put in through to avoid further complications[17].
2. **Lip:** The lip is next most commonly pierced site in oral cavity or midline, also known as Monroe piercing, might also be pierced a bit off the mark at times. Captive-bead rings are mostly preferred over labrets for postoperative swelling and are easily cleaned than labrets. Once the swelling has subsided, ring may be replaced with a labret. The lower lip usually pierced through mucosal tissue just below the vermillion and the size of jewelry depends upon tissue thickness pierced[18].
3. **Frenum:** Mandibular lingual frenum and Maxillary labial frenum are most commonly pierced. Buccal frena are rarely pierced. Piercing done through fold of mucosa present under the tongue for the lingual frenum and under lining mucosa of upper lip between central incisors for labial frenum. These piercings are relatively simple and quickly healing but postoperative care for lingual frenum piercings are complicated as food contaminates the area each and every time. Both ring and barbell can be worn in these punchings[18,19].
4. **Uvula:** Uvula is least commonly pierced site due to its critical anatomy, chance of jewelry aspiration and difficulty in normal functional activities like swallowing. Captive bead ring is mosly used jewelry[18].
5. **Cheek:** Cheek piercing is generally seen near dimples. It involves perforation of cheek from external tissue towards oral cavity. The usual placement of jewelry is symmetrical on either side of the face. jewels like barbells or labrets are commonly used[19].
6. **Tooth:** This has been, tried earlier but could not be succeeded due to functional difficulties of piercing the teeth through and through for donning rings, until most recently the trend setter is dental gems or jewelries being cemented to the labial surface of maxillary and mandibular incisors or cuspids after drilling the tooth slightly[18,].

Dental inlays and crown: The use of dental inlays and crown for beautification, is a form of mere tooth disfigurement encountered within present day people in the outskirts of tropics, carried out to mark prosperity or any memorable noble incident of their lives. In India too, the teeth of Hindu kings were restored using inlays of glass or pearls. The ancient Roman civilization also provides many such evidence of gold- dental restoration. In Muslims, the presence of a gold crown on an anterior tooth symbolizes his/her visit to the holy pilgrimage of Mecca[20].

Short term & Long-term complications of oral and perioral piercing

1. **Pain:** Mainly due to the fact that these piercings are done by un-trained professionals, without local anaesthesia, using unsterilized armamentarium, thus are quite painful to the wearer because of inflammation as an immediate response to the wound[21].
2. **Hemorrhage:** Due to punching of tissues, the blood vessels and vascular nerves might be harmed and mutilated, which is of major concern in case of medically compromised patients and in case of tongue piercing as tongue being a majorly

vascularized tissue. Some cases have also witnessed hypotensive syncope. Lip piercing can also depict profuse bleeding in case of tear or trauma though bleeding can be controlled in most of the cases[22,23,24].

3. **Swelling & Inflammation:** Ulceration followed by inflammation is quite painful and is evident in 9% of recipients. Swelling is evident within 6- 8 years of piercing and reaches its maximum potential by 3rd day, which can compromise deglutition speech and even breathing[25-30].

4. **Nerve damage & paraesthesia:** It is to be kept in mind during tongue piercing so that lingual frenum id not damaged, which can give rise to serious complications[25].

5. **Anaphylactic reactions:** Allergic contact dermatitis can be seen due to the material used in different forms of jewellery the Europian union has strictly advised to reform the nickel content of jewelries to be not more than 0.05%, and gold used to be of 14-18 K[22,25,26].

6. **Localized Infections:** As the dental or oral jewelry bearers are not always provided with adequate infection control measures, so the instruments that invade the subcutaneous tissues are the prime cause of localized infections in these folks. Moreover, the aggregation of plaque and calculus worsens the condition of infection[31-33].

7. **Tissue Alterations or hyperplasia:** This is mainly a long term complication giving rise to hyperplastic scarring or hyperplastic overgrowth of the tissue over the jewelry itself, making it extremely painful and mandating surgical removal followed by a sterile labret insertion, which is found to recurr[34-36].

8. **Dental Trauma:** A complicated late presentation of tongue or lip piercings are mainly tooth attrition, fracture, dental decay, erosion, faulty oral habits of playing with the jewelry etc. which is deleterious for both oral and dental health[37-38].

9. **Increased salivary flow and speech impediment:** In case of any foreign material insertion within the oral cavity tends to increase the salivary secretion. Moreover, the tongue piercings cause transient disphonia, which normalizes within a week or two[39].

10. **Bacterial plaque accumulation, Gingival Recession, Clinical attachment loss & Bone Changes:** These are all these long-term results of faulty or specifically oversized oral jewellery, that acts as the major irritating factor thus giving rise to fenestrations[40].

11. **Aspiration or Ingestion:** A real time emergency in case the bar ball type of oral piercing has got loose threads and thus slips down the throat to reach the lungs or even during its removal slacks suddenly[41].

12. **Ludwig's Angina:** It is a life-threatening health condition that demands immediate professional care, mainly arises due to increased tongue swelling, respiratory tract obstruction & rapid transmission of infection to all three spaces, from either tongue, lip or cheek piercings[41].

13. **Communicable diseases:** Blood borne diseases namely bacterial endocarditis, HSV, Epstein Barr Virus, HIV and many such are caused mainly due to faulty infection control and improper hygiene of the piercing parlours[42,43].

14. **Radiographic alterations:** These create radio opacities thus giving rise to artifacts during panoramic radiographies, which must be avoided during radiographic exposure[41].

Post-Operative Oral care[40]

- Cold and liquid diet for 24 hours followed by soft food.
- Cold pack application both externally for half an hour with intra oral ice compression for 45 minutes on an average for at least 5 days post injury.
- Using alcohol free mouthwash containing 0.02% Chlorhexidine for at least 2 weeks.
- Avoid consumption of caffiene, alcohol, cigarettes, tobacco during the healing period that interferes with re-epithelialization.
- Talking less, mostly preferable for comfort and easy oral tissue recovery.
- Exchange a long sized jewellery with a shorter one after healing, as it is advisable for both dental hard tissue safety & oral hygiene maintenance.
- Try to maintain thorough oral prophylaxis so that the wound healing along the piercing is proper. Use a soft bristle brush to avoid any irritation.
- Check for any fulminating infection both peripherally as well as under the piercing site, in case it persists consult oral physician as soon as possible.
- In case of threaded piercings, check for proper fit

every second or third day a week, to avoid any mishap.

Conclusion

Thus oral & perioral piercings which is a trend, most commonly seen in the youths of both developing and developed countries along with several tribals, pose an extremely dangerous threat to not only oral health but systemic health as well. According to the AAPD guidelines, these practices should be abandoned. But in case of any such practices, young children should obtain proper approval of their parents. Moreover, the persons practicing these as occupation should also abide by all the universal infection control measures, to avoid any infections following piercing. Dentists being the prime and first professionals to face these consequences should try to impart a powerful message regarding the ill effects of such behavioral executions to specially the youth, which is falling prey to these malpractices most easily.

Patient Centered Care: A Paradigm Shift in the Delivery of Oral Health Care

Aishwarya Bal[1], Rinkee Mohanty[2], Anurag Satpathy[3], Rashmita Nayak[4], Abhaya Chandra Das[5], Saurav Panda[6], Manoj Kumar[7]

[1]Postgraduate Trainee, [2]Professor, [3]Professor, [4]Professor, [5]Reader, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Patient centered care is a nonlinear and archetypal approach towards treatment planning of patients which acknowledges the patient as an individual with his/her own tale to tell. It enhances trust and rapport, provides clarity and characterizes the patient's symptoms and concerns. After generating and testing many hypotheses patient-oriented care lays the robust foundation for an ongoing treatment. The two pillars of patient centered care are oral health literacy which helps in non-judgmental articulation of where the patient and the oral health care provider's level "is at" and oral health coaching which primarily focuses on the intentional behavioral change and evolving towards positive attitude towards any treatment. Yet the backbone of this approach is the dental team performance because outcomes of any dental treatment are deeply interlinked with team performance. Through effective communication low level of health literacy can be identified and patients can be empowered, encouraged and motivated to take responsibility of their self-care. Thus, this review article provides a holistic approach using a rich history of social and psychological science citing major perspectives and insights from behavioral sciences, clinical practice management and public health, coupling it with patient empowerment and comprehensive care.

Keywords: *Patient centered care, oral health care, oral health literacy, oral health coaching, health behavior, motivational interviewing.*

Introduction

Any dental treatment however precise and accurate is rendered unsuccessful without patient compliance. In the 18th century, Voltaire quoted that "Doctors are men and women who prescribe medicines of which they know little, to cure diseases of which they know less, in human beings of whom they know nothing". In today's fast paced digital era of dentistry majority of the dentist's time is dedicated directly on providing oral health care with relatively less time spent on patient interaction and evaluation. Patient centered care is one such gateway which allows the health care providers to have a better understanding of their patients even before looking into their signs and symptoms. It is prototypically individualistic with an emphasis on the unique aspects of self, personal attributes and personal goals[1]. In patient-centered care, a patient's specific health needs and desired health outcomes are the driving force behind all health care decisions. This oral health care approach has paved its way to the center stage wherever quality of dental treatment and effective delivery of oral health care is being prioritized[2]. This approach has become the need of the hour and is worthy of our attention because 54% of the patients symptoms are missed and 45% of patient's concerns are not disclosed by the patient[3]. Dental institutions, clinical practitioners, congressional representatives are now including this phrase in their lexicons but the complete understanding of patient centered care in the dental setting is still largely in its infancy. To understand the ideology of patient centered care one has to have a clear picture of the commonality

Corresponding Author:
Prof. Rinkee Mohanty
Professor & Head, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: rinkeemmohanty@soa.ac.in

and cohesiveness of this methodology of care with oral health literacy, dental team execution, oral health coaching and above all the power of communication in transforming lives. The prime objective is to be more of a human and then clinician in the process of oral health care delivery.

Values of Patient Centered Care:

1. Shift from being an authoritarian to being a coach
2. Prioritizing patient preferences and expectations
3. Providing optimum comfort and support emotionally and physically
4. Transparency in informing and educating patients about their clinical status, associated risk factors, progress and prognosis of the treatment
5. Increasing the role of family and friends in decision making and patent experience.
6. Continuity of maintenance of oral health care
7. Active collaboration between patients, families and providers.
8. Ease of access to care[4].

Milestones of Patient Centered Care

1. Oral health literacy
2. Dental team performance
3. Oral health coaching

Oral Health Literacy: Oral health is an essential constitutive of overall health and well-being. Oral health literacy is the ability of the individuals to comprehend, attain and plan out an appropriate approach to taking oral health care decisions. It is one of the most crucial factors in determining and executing an efficient treatment plan as it as a strong predictor of individual health status, and their level of general and oral health risk factors

Roadblocks to Oral Health Literacy:

1. Age
2. Social stigma
3. Socio-economic status[5]
4. Fear of the unknown
5. Communicational and linguistic barriers
6. Cultural barriers
7. Health care provider himself can also act as a barrier

Consequences of Poor Oral Health Literacy

1. Lack of understanding of pre and post-operative instructions
2. Lack of patient involvement in the treatment planning
3. Haphazard communication between patient and dentist
4. Inability to achieve the desired result and outcome of the treatment
5. Poor continued maintenance of the oral health after treatment
6. Decreased follow up and poor prognosis of the treatment due to lack of internal motivation

Instruments of Measurement of Oral Health Literacy: Studies on Oral health literacy have been extensively carried out to find tools of assessment for measuring oral health literacy. Some of them are:-

1. Rapid Estimate of Adult Literacy in Dentistry-30 (REALD-30)[6].
2. Rapid Estimate of Adult Literacy in Dentistry-99 (REALD-99)[7].
3. Rapid Estimate of Adult Literacy in Medicine and Dentistry (REALM-D)[8].
4. Test of Functional Health Literacy in Dentistry (TOFLiD)[9].
5. Test of Functional Health Literacy in Adults (TOFHLA)[10].
6. Oral Health Literacy Assessment (OHLI)[11].
7. Health Literacy Management Scale(HeLMS)[12].

Dental Team Performance: Dental teams are at a unique position to provide brief interventions and prevent health risk behaviors to benefit the patient, beyond the remit of solely improving their dental condition. When one decides to enter into the noble profession of health care, he/she has great duty and even greater moral responsibility towards society and the needful people who require medical and dental attention due to plethora of reasons. But the evolution from an amateur to being connoisseurs of care leads to increased perplexity, complexity, steering the physician towards entanglement in cobweb of competition, technology, advancements in the medical and dental field. Hence it becomes even more imperative to go “Back to Basics”. Similarly, in a

dental setup the dentists should have a common goal and work as a team to provide best possible treatment.

Traits of a Dental Team:

1. Be in a constant state of self-reflection
2. Hone and polish their soft skills
3. Be a collaborator rather than a competitor
4. Have a competent diagnostic acumen and skill set
5. Should be amiable and approachable
6. Should exhilarate interdependency and synergy
7. Have the ability of critical thinking and evidence-based decision making
8. Able to effectively cater to needs and expectations of the patient
9. Ability to distinguish between active and quiescent disease and interlink them with risk factors
10. Show compassion, civility and dignity towards the patients, their family and friends
11. Maintain a conducive and professional dental ambience.

Oral Health Coaching: Oral health coaching though neglected and poorly understood is a vital part of patient centered care. It is a dynamic process in which an inquisitive, empathetic broad-minded oral health physician conducts a multidisciplinary step wise assessment to identify certain health risk behaviors and educate the patients to promote their health using a tailored style of communication. Bringing intentional change in the behavior of the patient is dynamic and full of uncertainties.The journey from paternalism to partnership is cumbersome but necessary. In an era where dentistry aims at delivering care-based treatment on the causes of oral diseases instead of their consequences in depth study and various models of health behavior are being proposed.

Conceptual Models of Modifying Health Behavior[13].

1. The Health Belief Model developed by social psychologists at the U.S. Public Health Service in the 1950s
2. Social Cognitive Theory started as the social learning theory in the 1960s by Albert Bandura[14]
3. The Precaution Adoption Process Model was first discussed in 1988 by Weinstein[15]
4. The Theory of Reasoned Action and The Theory of Planned Behavior was formulated by Ajzen and Fishbein[16]
5. The Integrated Behavioral Model was integrated by Fishbein[17]
6. Health Locus of Control Theory is the framework of Rotter's social-learning theory of personality (1954)[18]
7. The Transtheoretical Model of Behavior Change also called as Stages of Change Model was developed by Prochaska and Di Clemente in the late 1970s[19]

Key theories that have unified and evolved out of previously proposed theories are:

- Information, motivation, behavior skills
- Motivational interviewing

Information, Motivation, Behavior Skills: This theory allows for the close inspection of minutiae in behavior. Behavior is the way in which one conducts oneself especially towards others. Behavior arises from one's level of consciousness and most of the unacceptable behavior comes out of insecurity.

The triple aim framework of this theory is

1. Knowledge and information about the behavior
2. Motivation in the individual to perform the behavior
3. Necessary skills to perform the behavior[20]

We as dental physicians have the sapience to inter-relate the risk determinants to the signs presented by the patient and advise the most efficacious treatment to the patient. But we can take a step ahead to educate and guide the patients in the dental set up by informing them about what led to their deteriorated dental and general health conditions and why are they experiencing discomfort in the first place. We should also put forward all the possible treatment options available along with their outcomes, advantages and disadvantages. Then comes the responsibility of motivating the patient towards choosing their individualized treatment option (after thoroughly studying patient behavior, compliance, socio-economic status etc.). Lastly we have to make the patient believe that they are fully capable of holding the reigns of their health in their own hands and the prognosis of the entire process is majorly dependent on their response, attitude and readiness to the treatment.

Motivational Interviewing: Direct persuasion and confrontation are least likely to be effective and successful in modifying any patient's attitude regarding dental treatment rather it can lead to increased resistance towards the health care delivery. It is important to observe patient's verbal and non verbal signs and signals so that we can accurately gauge his readiness towards the treatment as well as behavior change. Motivational interviewing is driven by the ideology that intrinsic motivation resides within the individual and can come to limelight by eliciting certain desirable response from the patient. It is effective in dental practice as it changes the role of the clinician from "telling the patient what to do" to "guiding and supporting them in their decision propelling them towards an achievable goal. Motivational interviewing has been a successful approach for alcohol dependent patients[21] and regular smokers[22].

Coherent Communication: George Bernard Shaw very rightly said that "The single biggest problem in communication is the illusion that it has taken place." The "Lack of Knack of Coherent Communication" is the doom of the dentists. Very often our impaired judgment tends to become a significant limitation in the flow of information from patient to physician during history taking and from physician to patient while giving health care instructions. The similitude in all the three concepts i.e. oral health literacy, dental team performance, and oral health coaching is the need for plain sailing communication. Effective communication is the pre-requisite to appropriate history taking which in the fullness of time facilitates correct diagnosis.

From Conundrum to Communication:

1. Use of open–ended questions to facilitate communications between patient and the dentist
2. Reflective deep active listening to enhance clinical reasoning
3. Being attentive and vigilant and noting the miniscule details
4. Improving linguistic skills as patients are most comfortable in conversing in their native language
5. Being deprived of any pre formed notion and look into each patients with a "fresh set of eyes"

Conclusions

Terry Canale said *"The patient will never care how much you know, until they know how much you care."* As practicing dentists, we should have this clarity that we are not just dental care providers. Dentists now are being redefined as Doctors Engineers and Artists. As doctors they are trained tomanage oral ailments; as engineers they utilize scientific knowledge and principles to analyze and contrive a successful health care delivery framework; as artists they sculpt the dentofacial structures in the most esthetic manner. Consequentially, it is a matter of paramount importance that we start redesigning the care processes and making them more dynamic and personalized by delineating the stereotypical guidelines and introducing new gold standards. This exemplary approach not only diagnoses, restores, preserves, aligns, reconstructs, transforms the oral and maxillofacial structures of the patients but also their lives.

Microbial Host Interaction in Periodontal Diseases

Ayushi Priya

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Various studies were performed to understand the molecular basis of the host microbial interaction. It is the interaction of the microorganisms with the host which determines the course and extent of the periodontal disease. Entry of bacteria itself or bacterial products into the tissues may be important in the disease process and to evade the host defence mechanism. Periodontal diseases such as gingivitis and periodontist are common inflammatory disorders caused by microbiota inhabiting the plaque. This paper highlights the various interaction courses which leads to progression of periodontal disease. It can be stated as a multifactorial disease as collective interactions of etiological agents and host responses along with environmental factors play an important role in the onset and progression of the disease.

Keywords: *Periodontal disease, Bacteria, Host defence.*

Introduction

Periodontal disease is the manifestation of direct or indirect interaction of bacteria or bacterial substances with the host tissue which eventually leads to tissue degradation and expression of the disease. As the disease progresses various serial events takes place in different levels including the bacterial plaque, in the gingival sulcus in epithelium in bone and connective tissues due to imbalance in the tissue homeostasis. The microbial flora triggers the various immune response innate, inflammatory, and of adaptive nature which stimulate periodontal breakdown and collagen destruction and determine the susceptibility of the host to develop the destructive or progressive periodontitis under influence of factors like behavioural, genetic and environmental.[1-3]

The virulence properties of the microbes can be studied as

(a) Factors that favour bacterial species colonisation and invasion of host cells.

(b) Factors responsible for causing direct or indirect tissues degradation.

The defence mechanism of the host comprises of two distinct sets of responses

(a) Innate immunity

(b) Acquired immunity

These responses against the pathogenic bacteria are activated sequentially during the disease progression. Innate immunity can be seen acting immediately and is responsible for recognising the specific bacterial pathogen based on the cell surface receptors. Whereas for acquired immunity it takes a week to develop significant response on the cellular and humoral level.[4]Thus, it can be stated that both host immune and bacterial factors play a dependent role in advances of the diseased state and for bringing various notable changes in the microbial flora present in the oral cavity and to the affected cells.

Evidence acquisition: Computerised searches consisting of published articles received from Google, PubMed, PMC free article, Google Scholar, Science direct, Medline, EMBASS

Different keyword including periodontal disease, bacterial plaque, pathogenesis, virulence, host defence, adherence, coaggregation, invasion, evasion, tissue destruction was used in the literature search. Moreover, the reference of all paper was again searched for further relevant studies.[5]

Discussion

In order for simple understanding of the interaction of the microbes and hostit has been described step by step as

(A) Adherence of bacterial species for colonisation and survival: For survival of any bacterial colony it is necessary for the bacteria to attach itself to any available surface as of primary importance to avoid displacement by the flow of fluids in the oral cavity. Hence adherence can be interpreted as first step of interaction of bacterial species with the host. This is mainly achieved by large molecules called as adhesins present on the bacterial surface. They are categorised as

(a) Fimbrialadhesins

(b) Non- fimbrialadhesins

- Fimbrialadhesins are further classified into five major categories as 1) Chaperone- usher pili 2) curli 3) typeIV pili 4) type III secretion pili 4) type IV secretion pili.
- Non- fimbrialadhesins are 1) auto transporter adhesins2) outer membrane adhesin 3) secreted adhesins 4) biofilm formation associated adhesins.

The attachment can be seen to the pellicle or the saliva coated tooth surface. This adherence as studied on *Actinomyces viscosus* and *Porphyromonas gingivalis* shows attachment of fimbriae on the bacteria surface to the proline rich proteins on the saliva coated tooth surfaces.

Other form of adherence is of *P. gingivalis* to the epithelial cells and fibroblasts, fibronectins through fimbriae.

Studies on plaque present in oral cavity have revealed adherence between different bacterial strains, referred to as coaggregation. The bridges formed by these associations among the initial colonisers help numerous later colonisers to associate with the microbial community. A relevant example is of *A. viscosus* attachment of surface fimbriae to the polysaccharide receptors of *Streptococcus sanguius.*[5]

Few examples of adhesins and target substrates are:

- *A. viscosus*

Attachment surface – tooth or the tissues or *S. sanguis*

Substrate- saliva coated mineralised surface or the epithelial cells.

Bacterial adhesin – fimbriae

Receptors- salivary hydroxyapatite or galactosyl residue

- *P. gingivalis*

Attachment surface- tissue

Substrate- connective tissue

Bacterial adhesion- membrane protein

Substrate receptors- fibrinogen, fibronectin

- *F. nucleatum*

Attachment surface- Pre-existing plaque

Substrate- *P. gingivalis*

Bacterial adhesion- heat and protease sensitive protein

Substrate receptors- galactosyl residues

(B) Host tissue invasion: The bacterial presence in the host tissues have been recognised for years, based on various histological studies it has been seen that there are two method through which bacterial invasion takes places in the host cell. One by causing ulcerations in the epithelium of the gingival sulcus or of the adjacent pockets and have been traced in the intercellular spaces of the gingival tissues. Another mean of tissue invasion may be seen as direct penetration of bacteria into the host epithelium or the connective tissue cell. This have been demonstrated in *A. actinomycetemcomitans, P. gingivalis, F.nucleatum* and *Treponema denticola* during the laboratory investigations.[1,2]

This ability of invasion has been proposed as a key factor to distinguish between the pathogenic and non-pathogenic forms of bacterial species. Localization of bacterial species affect the organism, the host cell by forming an environment which constantly delivers toxic molecules and enzymes to the host tissues. Some studies and investigators suggest that the "bursts of disease activity" observed in periodontitis is related to phases of bacterial invasion in the host tissues. It has also been seen that recolonization of bacterial species may be due to persistent presence of these species in the periodontal pocket acting as a reservoir.

As for the host, it recognises different bacteria and antigens with help of different receptors present in periodontium. Junctional epithelium through its special

structural framework and form along with epithelial and non-epithelial components perform antimicrobial mechanism.[3]It acts as a barrier in terms of physical and chemical dynamics against the pathogenic properties of the microbial film. This is achieved by giving a favourable environment for local immune recognition process. The leukocyte infiltration and antigen diffusion from the gingival crevice into gingival laminators propria is facilitated by smaller connections between the no of desmosomes and gap junction epithelium and by the wide intercellular spaces of junctional epithelium. The gingival epithelial cells, fibroblasts and inflammatory cells respond to the microbes by increasing cytokine expressions and release of growth factors and metalloproteinases. Thus, the chemotactic factors play an important role in maintaining protective response against pathogen of the plaque biofilm.[6,7]

(C) Bacterial evasion of host defence mechanism: For the survival of the bacterial species following neutralisation processes are carried by the species and the host in response. As production of extra cellular capsule-studies have revealed isolation of encapsulated *P. gingivalis* strains from the host tissues and a hypothesis suggests that capsular bacterial strain is protected from the host immune system. Other mechanisms seen are opsonisation in which immune cells known as phagocytes target bacteria and bacterial products and destroy them. To counteract this defence mechanism. Specific bacterial species produce immunoglobulin degrading proteases to destroy phagocytes. They also suppress activity of lymphocytes of polymorphonuclear leukocytes involved in host defence system. As studied in *A. actinomycetemcomitans*, they release two toxins leukotoxin and cytolethal distending toxin that enhances the pathogenicity of the microorganisms in aggressive periodontitis and in chronic state of the disease.[8]

Observations have released that *P. gingivalis* is capable of inhibiting production of interleukin-8, a pro inflammatory chemokine released during the pathogenic entry of the bacteria in the epithelial cells. It can thus be seen that various molecular changes in the bacteria and its effect on the host cell gives it an advantage to evade PMN- mediated destruction.[9-11]

(D) Host tissue damage by the microbes: There are various factors involved in a disease process which gradually cause tissue destruction while progression of the disease. According to studies, it has been seen that in *P. gingivalis*, three compounds of enzymes collectively called fungi pains are responsible for the 85% of total protein degradation activity. There are cysteine protease and are multifunctional protein that helps in tissue degradation, host defence evasion and have role in adhesion process. Bacteria also cause tissue destruction by mechanism of induction, indirectly induces host tissue proteinase such as elastase and matrix metalloproteinases which also cause tissue damage. Hence various interactions and processes interplay which gradually leads to disease formation and severity. It has also been noted that metabolic by product's like ammonia, fatty acids, indoles, volatile sulphur compounds produced by bacteria alter and inhibit the growth of host tissue cells and disturb the metabolic balance of the cell.[12]

Conclusion

Thus, by understanding the molecular basis of periodontal disease by studying the process of interaction between the bacteria and host we can gain opportunities for therapeutic manipulation of the disease and discover various agents and techniques to minimise or to find the cure of the disease. It can also be concluded that *P. gingivalis, A. actinomycetemcomitans* and *T. forsythia* are pathogens when present in sufficient number cause disease state or are main cause for aggressive condition of the disease. The gram-negative bacteria which are the major constituent of the plaque release endotoxins which leads to induction of cytokines production by the host cells. These products result in inflammatory changes like the vascular permeability increase, the blood vessel engorging. Thus, the active host responses are both protective and destructive. The inflammatory chemical mediators released by affected cells such as interleukins, metalloproteins and prostaglandins cause actual destruction of tissue and bone. Hence various articles reviews and researches carried for better understanding of these chemical changes will help researchers to recognise and evaluate disease and formulate method of prevention and cure. As doxycycline, matrix metalloproteinase (MMP) inhibitors.[12] are already being used to treat periodontal conditions. Similarly, cytokines inhibitors, antagonists or destructive cytokines interleukin-1 and tumor necrosis factor which interrupts cell signalling pathways are seen as competent local agents for future use in treating disease and in-patient care.

Effects of Tobacco in Females all Over the World

Arunima Chakraborty

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Tobacco addiction is one of the greatest public health challenges and a major health issue in both developing and developed nations. It is considered as an epidemic all over the globe and every year over 4.9million deaths are caused due to tobacco use. The World Health Organization (WHO) estimated it to rise up to 10 million annually. In India 40% of the total population including males and females have either smoked or chewed tobacco in some or the other forms. On an average 10.3% of women are smokers in India. Tobacco smoking and chewing is linked with some serious health issues including cancers of any form, cardiopulmonary diseases, low birth weight and other illnesses. All these issues are seen to be increasing in women all over the world. Smoking was found to be a significant risk for various negative health outcomes including oral health problems in women of reproductive age groups. Most of the consequences of tobacco can hamper the normal bodily functions including delayed wound healing to complicated issues like birth defects and even premature death of the baby and the mother. The aim of this review is to highlight the effects of tobacco products on females all over the world and the remedies that can be thought to prevent the population from its abuse.

Keywords: *Tobacco; Smoking; Oral health; Cancer.*

Introduction

Chewable tobacco is more prevalent towards the poor, less educated and socially backward class. When exposed to tobacco the saliva alters its behavior and loses the antioxidant quality which leads to increased number of harmful bacteria, killing the good microbial flora. The epidemic of tobacco use is one of the greatest threats to global health today, and India is the fourth largest consumer and third largest producer of tobacco after China and Brazil. According to the most recent study by the WHO, in June, 2019 there were 8 million deaths globally due to this and 30% of them were women. More than 7million of these deaths are directly linked to tobacco addiction while 1.2 million are the result of second hand smoke. There are various ways to use tobacco, it can be sniffed sucked or smoked. The leading cause of mortality and morbidity in India is because of tobacco and its byproducts and studies have shown that India had the highest number of deaths because of oral cancer.[1-9]

Smoking in women is directly linked to 80% of the COPD deaths each year, which is greater than stroke. The risk of dying of lung cancer is 20times more in female smokers than nonsmokers.[4] Tobacco smoke contains thousands of noxious chemicals including the gaseous and solid particulate phase.[10] The gaseous phase contains carbon monoxide, ammonia, formaldehyde, hydrogen cyanide and many other deadly irritants including 60other carcinogenic compounds. While the solid phase is also called the 'tar' which itself is made out of toxic chemicals like benzene. So passive smoking also known as "second hand smoke" is also as dangerous and cause of lung cancer with heart ailments for the women who have never smoked. Women using tobacco have an increased risk of periodontal and gingival diseases, dental caries and halitosis.[4, 10]

On the aesthetic point of view women who smoke age faster, which is a growing concern in the population. Smoking tobacco of any kind causes facial wrinkles and graying of hair prematurely. It has many adverse reproductive and early childhood effects including increased risk of infertility, premature delivery, stillbirth, low birth weight and sudden infant death syndrome (SIDS). Women users have observed to be showing early menopausal symptoms 3-4 years prior to the actual age with a lot of complications. And women who smoke post-menopausal have low bone density which later leads to osteoporosis and even risk of hip fracture.[4]

The Surgeons general report also suggested that women smokers are more likely to suffer from depression and anxiety disorders than the later. Tobacco usage also have harmful effects on clinical outcomes including surgical and non-surgical therapies among women, as it affects the healing process. On the oral cavity, Tobacco not only causes discoloration of teeth, periodontitis, dental caries, gingivitis,ANUG,but also pre-cancerous lesions like erythroplakia, leukoplakia, oral sub mucous fibrosis.[1]

Nicotine: Nicotine is the main component in tobacco products that makes tobacco users addicted to it. It is a stimulant with properties similar to cocaine and other amphetamines [(1)]. Nicotine is one thousand times more addictive than alcohol, 10-100 times more than barbiturates and 5-10 times morethan cocaineor morphine. The addictive effect of nicotine is due to its capacity to release the happy hormone or dopamine- a chemical in the brain that is associated with feelings of pleasure.[(1)] Hence with time this effect wears off and smokers and chewers need greater amounts of nicotine in any form to achieve the same level of satisfaction. Therefore, the Tobacco users self-medicate themselves by continuing the use of different products. The Oral changes due to tobacco are 1) irritation of the oral mucosa 2) mucosal drying 3) higher intraoral pH 4) alterations of immune response.[1] Tobacco can be used in the form of chewable and smoke, these include beedi,cigarettes, hookah,paan, zarda etc.[1]All these items also contain arsenic and recently in a study, it was revealed that the concentration of arsenic in the scalp hair and blood samples of tobacco chewing patients is more prevalent than non-chewers.[8] Arsenic is one of the most dangerous and life threatening elements to be found in a human body causing several bodily dysfunctioning.[8]

Health Effects of Tobacco: Globally smoking accounts for 1 in 20 deaths among females.[10] Smoking both actively and passively is injurious to health.[10] Approximately half of these users die early before the age of 45-50years. Below are some harmful health effects of tobacco that are important for women to be aware of:

Reproductive Issues:

Women smokers are likely to develop

- More painful and irregular periods
- Low estrogen levels leading to mood swings, fatigue and vaginal dryness
- Early onset of menopause
- Issues for pregnancy

Respiratory Isuues:

There is no cure for COPD which occurs commonly among tobacco smokers. Every year more women die of COPD than men in an alarming amount.[5]

Cardiovascular Issues:

- Tobacco users have increased risk of heart diseases than non-users.[5]
- Women who smoke while using oral contraceptives and are above the age of 35years have a greater risk of heart diseases.[5]
- Women users are more prone to die from an abdominal aortic aneurysm, which is weakening of the blood vessels that carry blood from the heart to the body.[5]

Cancer:

- Tobacco users are facing increased risk of several kinds of cancer including cervical,lung, kidney, ora l,pancreatic,breast,colorectal cancers,etc.
- As already mentioned earlier the carcinogenic property of nicotine that is present in tobacco is the main culprit behind the cause of several kinds of cancer.[5]
- When female smokers become smoke free the mind and body begin to heal by itself and helps the patient to fight the cancer.[5]

Pregnancy and Tobacco:

- There are several effects of tobacco over the pregnant woman and her child. It hampers the normal brain function and development before birth and during early childhood.[5]
- The risk of developmental anomalies in these cases is higher causing syndromes like cleft lip and cleft palate.[5]
- Above that it also affects the fertility of the individual with increased frequency of pelvic inflammatory diseases, which is also a huge factor in ectopic pregnancy.[5]

And last but not the least

Weight Gain:

- Smoking which is one of the most common media of tobacco is directly linked with the sensitive subject of weight gain in females.

- Women are particularly sensitive with weight gain issues at all stages of smoking.
- Compared to their non-obese peers, obese women are more likely to develop nicotineaddiction. And among women who are trying to quit smoking are held back by the fear of gaining weight again.
- And hence it should be made clearer and more aware that in the process of quitting this habit of smoking a significant amount of weight is gained but this decision can avoid other life-threatening effects of smoking.
- Moreover, post cessation weight can always be reduced easily by healthy food choices and exercise.[6]

Conclusion

For some unknown reason some of the effects due to the usage of tobacco vary from male to female and is seen to be more deleterious in females.[6] Hence it is said that if we educate the women, we educate the society, for that interventions among both men and women are required. These awareness programs and discussions should not only be limited to the well to do families but also reach the population with lower socioeconomic status who require the most of these programs.[9]

This can be achieved by two ways:

1. By the government in form of camps, acts, street plays and in general motivating the population to visit the nearest hospital to the dentists and hygienists
2. By the dentists, with the help of public health dentists: They can play an immense role by acting as a role model and a mentor to the affected population and show them the correct path.

Tobacco cessation centers (TCC) should be set up to counsel the patient for a healthier lifestyle and to motivate them for the greater good. This can be achieved with the help of 5As approach that is Ask,Advice,Assess,Assist and Arrange and the 5Rs approach at the chair side which is Relevance,Risk,Reward,Roadblock,Repeat. These procedures should be discussed and interacted with the patient at her every visit. Prevention is always the economical option and hence the government with the help of dentists should find out the high-risk group and divide the users into high, medium and low risk groups and act accordingly. These groups should be at first identified properly and then approached in an individual or community level.

Urban and rural health centers might also help with more visual aids like pamphlets,posters,ads etc. of the effects of tobacco in both oral and general health of the patients. All these efforts must surely motivate the females of all generations to choose a healthier lifestyle and quit tobacco for the better future

Ethnomedicinal Plants of Odisha: An Alternative Therapeutic Choice Against Multidrug Resistant Bacteria

Subhashree Satapathy[1], Debasmita Dubey[2], Shakti Rath[3]

[1]Project Trainee (Microbiology), Central Research Laboratory, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [2]Post-Doctoral Fellow, Department of Biotechnology and Bioinformatics, Sambalpur University, Burla, Odisha, India, [3]Assistant Professor (Research), Faculty of Dental Sciences and Nursing, Central Research Laboratory, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

From the time of second world war, the field of medical microbiology has witnessed emergence of multidrug resistant (MDR) strains of bacterial pathogens, due to many obvious factors. Moreover, empiric therapy also adds 'fuel to the fire' the MDR problem. Unfortunately, there are genetic recombination method, transformation, conjugation and transduction operative in nature facilitating the upgrade of genetic makeup of pathogens from drug sensitivity to resistance. Commensals, *Staphylococcus aureus* and *Escherichia coli* have epitomized the upgrade of genetic makeup deeply, in causing utmost clinical consternations, as *S. aureus/* MRSA is the superbug in the health domain. Notorious MDR *Pseudomonas aeruginosa* is a great killer, by UTI infection. Today, the torrent of MDR pathogens has been recorded to get circulated in communities and escalate to hospitals, causing damnedest shenanigans of 'infection dynamics. Down the ages, plants have been an unwitting source of natural products for human health. World Health Organization is widely holding medicinal plants, nowadays, as the best source of drugs. Approximately 80% population of the developed nationsstill use phytomedicines; therefore, phytomedicines or phytodrugs should be investigated more in order to understand their chemical properties and efficacy as medicines

Keywords: *Ethnomedicinal Plants; MDR bacteria; Therapeutics; Odisha; Antibiotic resistance.*

Introduction

In present day, 70% of population in developing nations are still dependent on customary prescription of plants for their essential medicinal use. Natural medications are as of now are the most sought-after source and their prominence is expanding step by step.[1] Around 1000 plants with therapeutic uses are referenced in ancient vedas and around 800 plants have been utilized in customary medicinal medications. The different indigenous frameworks, for example, Siddha, Ayurveda, Unani and Allopathic utilize a few plant animal varieties to treat distinctive aliments.[2,3] The utilization of home-grown medications getting to be mainstream because of poisonous quality and reactions of allopathic drugs. This prompted unexpected increment in the quantity of home-grown medication makes.[4] Home grown medications as the real cure in customary arrangement of drug have been utilized in medicinal practices since centuries. The practices proceed with today on account of its therapeutic properties just as spot in social convictions in numerous pieces of world and have made a huge commitment towards keeping up human wellbeing. Plants are essential components of medications and one-fourth of pharmaceutical remedy in the US contain no less than one plant-inferred fixing. In the last century, approximately 121 pharmaceutical items were planned dependent on the customary learning acquired from different sources.[5]

Treatment using plants is an ancient process, practiced from beginning of human origin. The relationship between mankind and their search for drugs is recorded and documented in all civilization, across the world. Knowledge of plants with medicinal properties and their usage is an outcome of years of research and trials by various ancient health care workers to modern day doctors and researchers.[6] Modern day science has approved and accepted the phototherapy and plant-based medicine, known by traditional and ethnomedicinal literatures are being explored now. The information of the growth of concepts linked to the usage of herbal therapeutics with cognizance has improved the capability of healthcare workers and doctors to reply to the queries that have arose with the dispersion of professional services in easing of human's lifecycle.[7] Despite documentation and examinations of numerous phytocompounds and plant-extracts having therapeutic efficacy by researchers no drug/compound has yet been articulated with technical precision for controlling a specific disease.[7] There is a gap between research outcomes and herbal drugs trade till now, since the main stream therapeutic system remains resistive to herbal drugs irrespective of frequent failures of synthetic medicines.[8] In future for more specific needs herbal drugs would serve properly, if those could be used as therapeutic agents, without any dyslogistic prejudgment. Another system, integrative medicine spearhead now-a-days, wherein the regular chemical synthetic drugs are mixed up with herbal medicines for treating critical ailments including cancer.[9]

Emergence and Spread of multidrug resistant bacteria: In last 30 years and more, resistance of pathogenic bacteria to antibiotics and drugs created problems in the control of infectious diseases. Particularly, millions of people of all age groups die each year from infectious diseases such as tuberculosis, respiratory, wound and enteric infections, worldwide.[10] Particularly, due to bacterial diarrhea, 3 million people die each year. The situation becomes leg-shivering due unhygienic and sanitation facilities in developing countries. Virulent enteric bacteria, *Klebsiella*, *Enterobacter, Salmonella, E. coli, Shigella* and a few more are still active in the non-hygienic rural India and these are the causative organisms of high infant mortality and outbreak of epidemics in several tribal pockets, and need due attention, with a proven fact that these pathogens are also multidrug resistant.[11] The emergence and spread of MDR bacteria both in hospital and community settings has been well established by several surveillance reports WHO and other from associated organizations. In fact, it has become the most important challenge for the authorities to control these superbugs. Specifically, enteropathogenic bacteria, *Escherichia coli, Enterobacter aerogenes, Salmonella typhi*, *Salmonella paratyphi, Shigella sonnei, Shigella dysenteriae*, *Klebsiella oxytoca*, *Vibrio cholerae*, and *Enterococcus faecalis* etc. createlife-threatening situations, where more than one kind of infection is diagnosed in patient.[12] Since, the field of medical science depends a lot on the empiric therapy, these bacteria get heavily exposed to antibiotics without any reason, and slowly develop the resistance mechanisms. Particularly the part of our body like oral cavity, gut, skin where we have the maximum population of bacteria, the horizontal transfer of the resistance genes becomes easier and rapid.[13] Antibiotic resistant strains of *Enterobacter* species and other bacteria belonging to Enterobacteriaceae family are the major causative agents of gastrointestinal infections and they spread rapidly in both hospital and community settings. MDR *Klebsiella oxytoca* strains isolated from patients of our hospital are now resistant to almost all antibiotics un the market and it's a leading cause of urinary tract infections.[14] Unscrupulous and unprescribed use of antibiotic is major reason behind the development antibiotic resistance and its spread. As a result, several infectious diseases are becoming increasingly difficult to treat. Moreover, not many new antibiotics are coming to the market which solve this problem of antibiotic resistance and certain bacteria are resistant to the current generation of antibiotics too. If this process of development of antibiotic resistance is not halted, the human and animal society is looking toward a dreadful medical disaster in near future. The medical and scientific fraternity must think of an alternative to antibiotics for the treatment of infectious diseases. Medicinal plants are one of the major alternatives that can be sought after.[15-17]

Ethnomedicinal plants of Odisha: Odisha has typically deciduous rain forests. The Eastern Ghats runs in the western side of state including the Kandhamal district. Eventually, there an undulating terrain in Kandhamal district that leads to ridges which becomes dried up in summer & in furrows the green belt, continues throughout the year. But the vegetation in the mountain top (ridges) gets affected during the hot summer. Secondly, practice of shifting cultivation as well as collection of flowers from *Mahua* plant, forest

fire lit by local inhabitants. This entails obliteration of rare flora (& fauna) from the forest base.[18] From time immemorial the inhabitants belonging the schedule cast and schedule tribe people depends on the forest for their house construction purpose, food, cultural practices as well as health care system. Plants required for house construction purposes are certain timber yielding plants including *bamboo*. The cultivated food species include the upland rice, ragi and corns. Cash crops like turmeric and ginger are produced by them. To grow these crops, they clear the forests which yields them firewood plant and timber plants. This leads to disturbances in natural phytodiversity.[19] For their health care system, they collect wild plants parts & totally depend on them so much that, they do not get from modern medicinal system (Government hospitals). Prima facie, plant-extracts shall be used for control of all pathogenic MDR bacteria, *in vitro,* asslowly, uses of phyto-drugs are deeply held today for their obvious holistic action on the health domain. In other words, a phyto-drug used against one ailment has ameliorating effect on another.[20] Moreover, the ethnic information on plants is a boon to scientific workers, during work on drug targeting. This work should help apothecary in locating phyto-drugs in complementary /supplementary drugs to treat these MDR bacteria. During the last several decades, many phytocompounds have been identified and are used against infections/other ailments.[21] Considering the vast potentiality of plant-drugs as antibacterial and antifungal agents, a systematic investigation would be useful to locate newer ones, which would serve as alternative/ supplementary control agents against MDR pathogens, including against the MDR tubercle bacillus.[22]

Conclusion

To put in sotto voce, a cavalier rather an intransigent attitude for an in-depth study of plants, for health care needs in this present state of rapid emergence of MDR pathogens, would be a pharmacological infraction, not least because chemical drugs cannot be explored, but phytochemicals as antimicrobials too have other health-ameliorating effects.

Oral Health Related Quality of Life Following Third Molar Surgery & its Complication

Barsa Ray[1], Sthitaprajna Lenka[2], Suchismita Ghadai[1], Smrutirekha Marandi[1], Reshmin Begum[1]

[1]Intern, [2]Professor, Department of Oral & Maxillofacial Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Third molar surgery is the most common oral and maxillofacial surgery performed worldwide. Complication of third molar surgery includes pain, dry socket, swelling, bleeding & infection which is most common. Factors affecting third molar surgery include age, sex, medical history, poor oral hygiene, smoking, type of impaction, time taken, surgical technique, use of antibiotics, use of antiseptic subjects & use of intra-socket medicines. In this article, after third molar surgery, we review oral health related quality of life & its complication.

Keywords: *Oral health; Quality of life; third molar surgery.*

Introduction

One of the most common oral and maxillofacial procedures is the surgical removal of the impacted third molar. Many third molar surgeries are done without complication. This may lead to severe patient problem, such as hemorrhage, pain and swelling, infection and dry socket, paresthesia. Major complication of third molar tooth extraction include post-operative neurosensory deficits. In third molar removal, complication rates increased due to accidental injury during the procedure and other factors such asage, health condition,smoking, contraceptive medication intake, deficient oral hygiene and surgical treatment. Complication rates shows that female patients are most commonly affected than male patients. The resulting risk is directly associated with impaction complexity and the patient's age.[1]

Factors Affecting Third Molar Surgery

Bleeding: Hemorrhage is one of the major complications of the surgery but happens rarely if appropriate measures are taken during the procedure. It can be primary or secondary bleeding; it can be reduced by using proper surgical technique and preventing flap tearing or unnecessary soft tissue overlapping.

Edema: The most complication after third molar operation is post operative edema. It may be caused by tissue reaction to pressure or trauma during surgery, swelling persists after surgery for 48 hours. Use ice packs on the face to make the person feel more comfortable and sweat reduction. Medications used for edema control are corticoids, analgesics, hyaluronic acid.

Trismus: Trismus is a normal & expected outcome of third-party molar surgery. Jaw rigidity typically peaks on the second day & reduces by the end of the second week upon removal of the impacted third molar, postoperative pain to reduce the opening. Treatment for trismus are heat therapy, Analgesics, A soft diet & muscle relaxants.[2]

Pain: The most common affective post-operative condition expected after third molar operation is pain. The post-operative pain starts when the regional anesthesia effects have faded away. Analgesic such as metamizole, paracetamol & other nonsteroidal anti-inflammatory analgesics are used to reduce the pain. Before surgery, the use of non-steroidal analgesic can contributeto the role of helping in post operative pain control. Men may be less sensitive than women to post operative pain, so they need more pain relief.[3]

Corresponding Author:
Dr. Sthitaprajna Lenka
Professor, Department of Oral & Maxillofacial Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: sthitaprajna@gmail.com

Infection: An abnormal postoperative can differ with the removal in infection of the affected third molars. Infection after third molars surgery is not so common complication. Antibiotics, oral prophylaxis reduces the risk of infection. But it also leads to an increased risk of moderate, negative effects. Few post operative infections are significant enough for surgery, antibiotics & hospitalization. Use of clindamycin as an alternative drug for aerobic & anaerobic treatment.

Management: Postoperative infection involves the systemic administration of an antibiotics & surgical drainage. Penicillin appears to be a safe first choice antibiotic given to the patient after infection or streptococcal disease, although there has been documented increased resistance to penicillin.

Dry socket: After extraction, the sequence of normal healing does not always occur. In some cases,premature necrosis of the clot causes early formation of the clot in the socket, accompanied by pain & halitosis. Dry socket is characterized by painful tooth socket containing bare bone & broken-down blood clot. Infection of socket may occur either before, during, or after the extraction. Vasoconstrictor in local an aesthetic solution may lead to 'dry socket' by with the blood supply of the bone. People who use contraceptive drugs are more likely to develop dry socket. Dry socket occurs more frequently in wounds which has poor fillings with blood clot in immediate postoperative period. Dry socket is most likely found to be higher in smoking patients. Dry socket incidence can be minimized by different techniques. Most of the technique used to reducing the bacterial infection of the surgical site such as insertion into the socket of either antibiotics or steroids at the time of extraction. When dry socket occurs, it can be treated the relief of pain & the speeding of recovery. The socket should be irrigated with warm saline & all degenerating blood clot removed. A loose dressing, composed of Zinc oxide on cotton wool is placing into the socket. For several days, the dressing may need to be changed on a daily basis some topical antibiotics such as metronidazole are used for healing the dry socket.[4]

Management: In reference to dry socket prevention in literature,it is possible to differentiate into two groups such as-Non pharmacological & pharmacological preventive measures. Pharmacological measures are anti bacterial agents, antiseptic agents, steroids anti inflammatory agents, clot supporting agents & anti fibrinolytic agents. Non pharmacological preventive measures include the use of high quality current preoperative radiographs, proper preparation of procedure, use of good surgical theory, extraction should be carried out with minimum amount of pain & maximum amount of care & finally verify the presence of blood clot after extraction.

Nerve Disturbances: One of the most complication of third molar surgery is lingual and inferior alveolar nerve neurological damage. Neurosensory may also present as anesthesia, hypoesthesia, hyperesthesia, dysesthesia in distribution of lingual nerve & inferior alveolar nerve. The lingual nerve is weakened during examination of soft tissue flap,whereas the inferior alveolar nerve is injured when the roots of the teeth are pushed out the socket, the lower alveolar nerve is damaged. There are many types of neurosensory can be used assess impartially the severity of nerve injury & observe recovery of the sensation. Risk factor of the inferior alveolar nerve are depth of impaction & dental accessibility to alveolar canal. The treatment available after third molar surgery for lingual nerve or lower alveolar nerve injury tends to have impulsive clinical outcomes and rarely lead to full recovery. Surgical treatment of neurosensory deficits are external neurolysis, direct suturing, autogenous vein graft bridging nerve defect, bridging nerve defect deficits after third molar surgery. vitamin B, laser therapy, corticosteroids & acupuncture are not surgically handled for neurosensory deficiencies.[5]

Temporomandibular Disorders: TMJ disorders affects the jaw joint & the jaw-controlled muscles. Due to how complex the joint is, they may be difficult to diagnose and treat. TMJ disorder is a disease that directly affects the TMJ. According to the study woman are affected more than men to experiencing severe pain & restricted jaw movement. There are so many causes of Temporomandibular disorders such as Physical injury, grinding the tooth during sleep, autoimmune diseases, dental surgery & infections. Genetic, hormonal or environmental may be other triggers. As a precipitating activity for temporomandibular joint dysfunction, third molar removal was involved. Treatment of temporomandibular disorders may require anterior splints, casual splints, occlusal adjustment & removable therapeutic partial prosthesis & also physiotherapy may be need to cure temporomandibular disorders.

Management: There are two types of management occurring in the temporomandibular disorders such as conservative treatment modality & surgical

management. Conservative treatment modalityismoist heat, ice application,soft diet,sleep on one side. Surgical management are arthroscopy, arthrotomy & TMJ implants.

Maxillary tuberosity fracture: Maxillary tuberosity fracture is a possible sequel to maxillary posterior teeth removal. Often a small fragment of the bone can be dissected carefully from its periosteum & delivered with the tooth. One of the major complication of maxillary third molar removal is the fracturing of maxillary tuberosity. Excessive force can cause fracture of maxillary tuberosity. Proper support & controlled force can prevent the complications of maxillary tuberosity fracture. There is various type of technique should be taken to prevent the causes such as proper analysis of the radiographs of tooth & surrounding structures, correct technique of extraction with careful force application & lastly support to the alveolus during extraction of maxillary third molar.

Management: It is a removal of comminuted bone and teeth loss fracture and soft tissues repair. Delay in teeth removal in case of 6-8 weeks maxillary tuberosity. Fractured tuberosity tooth splinting into other standing teeth for 1 month.[6]

Mandibular fracture: Mandibularfracture isinfrequent but acute complication of third molar excision. During & after third molar removal, mandibular fracture is rare. Complication during surgery usually occurs within the first 4 weeks of post surgery. Factors include age, gender, angulation, severity & degree of impaction, tooth volume in the jaw, infection, associated bone lesions that lead to the risk factors. Fractures may occur in the patients who are older than 30 years. In some cases,women are more affected than men due to lower biting force rates compared to men. Patients with full denture are able to produce higher levels of biting forces, which are transferred during mastication to the soft mandible. Postoperative mandibular fracture as a result of extraction is difficult to establish. Post operative fractures were more common than intraoperative fractures. Intraoperative fractures were more common among the females. Anterior to the mandibular angle was found pathological mandibular fractures.To prevent the surgeons command of applied force by the mandibular fracture, the patient should be on the right side relative to the left side.

Hemorrhage: It is defined as loss of blood escaping from the circulatory system. There are various types of hemorrhage includes capillary, venous, secondary, internal,secondary,intermediate,primary,external, arterial. Hemorrhage causes multiple trauma, hypertension,bleeding disorders, any surgical emergency. Emergency treatment is required for cerebral hemorrhage. It is usually involving medication & close monitoring in an intensive care unit. In rare cases, surgery may be required to relieve pressure around brain.

Method: This was aretrospective clinical study for postponement of teeth removal in case of 6-8 weeks of maxillary tuberosity fracture. All mandibular third molar surgeries performed in the maxillofacial oral surgery unit. Surgery in clinical practice was conducted after dental school by staff physicians,oral and maxillofacial surgeons, or residents with at least 1 year of experience in dentoalveolar surgery. Neither patient nor surgeons were rewarded for taking part in the study.Criteria for Inclusion & exclusion has shown that patients are stable between 14-40 years of age and free from severe periodontal disease and have no history of psychiatric illness. Womencannotbe pregnant or lactating.A typical surgical arrangement between medical centers includes procedures common in united states operations such as intravenous anesthesia asses to the third molar from buccal aspects and bone extraction with rotating directions for the lower third molars. After surgery, both patients were evaluated 1 poor for access to wound healing status, and the existence of neuro-operation deficits apply to the third molar tooth.[7]

Indications for Removal of Impacted Third Molar

Pericoronitis: Soft tissue infection which usually occurs around a partially damaged tooth's crown. Transient declines can lead to a bacterial infection leading to mild to severe pain or trismus. Infection may be spread to adjacent spaces in the head & neck.

Periodontal diseases: Retention of an impacted third molar can damage the second molar's bone and may results in periodontal defects. It can cause recession & periodontal gaps, which can contribute to root caries & mobility.

Caries: The later part of the third molars raises a hygiene problem for majority of patients. Over increasing age, dental caries and pulpal necrosis lead to a growing number of third molar removal.

Root resorption: Root resorption is normal in the 21-30 age group associated with an impacted third molar. Middle third of the distal surface of the adjacent second molar is the most common root resorption site.

Pathology: Several forms of tumors & cysts are associated with impacted teeth follicles. If the affected teeth have a specific pathology, they should be removed and the pathological cyst or tumor should be sent for histopathological examination.[8]

Management of facial pain: Due to proximity of the temporomandibular joint and the associated muscles, third molars may cause pain.

Prevention of pathologic mandible fracture: When the tooth is lodged in the mandible, it takes up space that would otherwise contribute to its strength. This situation can predispose a person in the field of impaction to fracture of the mandible.

Contraindication for Removal of Third Impacted Third Molar

Damage to adjacent structures: Many critical structures cover third molars and these areas are affected by excessive degrees of risk. During surgery to remove these teeth, careful clinical & radiographic analysis is required.

Patient's age: Third molar can be removed at any age, but when done in patients in their late teens or early 20's, surgery is simpler and associated with less morbidity. Older patients tend to respond less favorably to the removal of teeth, particularly affected third molars, due to bone stiffness.

Medical compromise: It is important to check the medical history of the patient and advise the patient before beginning the operation. Consider delaying surgery in cases of cardiac or respiratory disorders, immune damage, or severe coagulopathy.

Factors affecting risk: Factors that increase the risk of complications after divisions are presence or absence of underlying systemic disease that can interfere with normal healing such as diabetic mellitus, chronickidney disease, hepatic disease, etc. Aging is not seen in patients as a significant risk factor. With an increase in age, local third molar removal complication molar become more frequent & severe. Certain considerations such as anatomical location of the tooth, root morphology, adjacent tooth status, certain conditions contributing to restricted oral cavity access, patient cooperation or complaints,bulk of supporting bone in the maxilla or mandible, ankylosis of the tooth, presence or absence of acute or chronic infection, presence or absence of related diseases or pathologies, occurrence or absence of other regional bone or soft tissue disease, occurrence of maxilla or mandible fracture associated with it, history of temporomandibular joint disease & disorder.[7,8]

Treatment after third molar surgery: These are three types of treatment should be taken after third molar surgery such as pain management and relaxation below the molar removing the tooth flap or removing the tooth. To managing the pain dental surgeons may use local anesthesia to help with the pain during the process. If there is swelling or pain present antibiotics like penicillin or erythromycin should be prescribed. After the extraction oral surgeons may also recommended home treatments like over the counter pain relievers, warm salt water rinses, oral water irrigators, good oral hygiene including brushing & flossing & to avoid using hot compresses near the extraction areas.[8,9]

Conclusion

Although there is a good understanding of clinical condition associated with retained third molars, little is known about the effect of these conditions on the quality of life of patients affected. There is that recognition that an important outcome is the effect of oral conditions on quality of life that can be quite useful in making treatment decisions. This study allowed assessment ofthe incidence of post-operative complications associated with removal of impacted third mandibular molars. The success of the operation depends on the experience of both doctors and on the health status of patients.

Mucocele on Lower Lip Excision Through Laser: A Case Report

Faizan Qamar[1], Susant Mohanty[2]

[1]Post Graduate Trainee, [2]Head, Department of Pediatric and Preventive Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Mucocele are a common benign lesion of oral mucosa involving salivary glands and their ducts. They develop following traumatic severance of a salivary duct, causing extravasation or retention of mucous material from salivary glands in subepithelial tissue. More predilectionsareseen towards children and young adults with trauma being the number one etiology. The motive of this report is to narrate a clinical case of a male patient aged 13 years visiting the Paediatric and Preventive Dentistry department, having a complain of swelling in the lower lip for1 month. On intra oral examination a well circumscribed swelling was present in the lower lip mucosa adjacent to the lower right canine tooth in the line of occlusion. Treatment plan was to excise it through laser under topical anesthetic spray. Surgery was quick, bloodless, and well received by patient. Post-surgery problems, discomfort, pain and scar were minimal on follow-up post 7 day.

Keywords: *Mucocele, Extravasation, Traumatic, Laser, Paediatric.*

Introduction

Mucous extravasation phenomenon, mucous escape reaction or mucocele is a common lesion of the oral mucosa involving salivary glands and their ducts. They result from traumatic injury of a salivary duct, due to biting of the lip or cheek, crowding of teeth, pinching of lip by extraction forceps or any kind of accidental trauma leading to spillage of mucin into the subepithelial tissues. Mucocele are not true cysts as they lack an epithelial lining.[1] The causative factors include calculi, faulty restorations, chronic cheek and lip biting and sharp bone spicules and rough irregular borders of the appliances. The lower lip is the region where the occurrence of mucocele is the highest. Mucocele is apainless swelling which can measure from a few millimeters to a centimeter. Appearance of a blue colour lesion post injury is indicative of mucocele. Often a peripheral lesion is traumatic causing it to collapse, butchances of recurrence are high under these conditions.[2]

Mucocele is the most routine salivary glandlesion in the oral cavity seen in more than 60% of cases. There are two types of mucocele, extravasation type and retention type. In child and young patients, extra vasation type of mucocele is more and the later type of mucocele is very rare. These extra vasation mucoceles under go metamorphical changes. In the first stage, mucus spills and diffuses from the excretory duct into then eighboring tissues. In the next resorption stage, due to foreign body reaction, formation of granuloma takes place. In the last stage, pseudo capsule (no epithelial lining)circling the mucosa is formed.[3]

Clinically it can be seen as a bulge or bubble; inelastic on palpation, asymptomatic, of different sizes and having a smooth surface. The colour of the lesion can be blue or similar to that of the surrounding mucosa, depending on the extensionof the lesion into the tissue. The patient oftenreports a bubble that has burst and fills up again, discharging a liquid having salty taste.[4] Treatment planning can include surgical excision, cryosurgery, laser excision ormarsupialization.

Case Report: The motive of this report is to narrate a clinical case of a male patient aged 13 years visiting

the Paediatric and Preventive Dentistry department, Institute of Dental Sciences (IDS), Bhubaneswar, Odisha presenting a chief complain of swelling in thelower lip for 1 month. Patient had a history of trauma and habit of lip biting. On intraoral examination the patient had lower anterior crowding. The swelling was raised, domed shapedvesicle,well circumscribedpresent in lower lip mucosa adjacent to the lower right canine tooth in line of occlusion. The margin between the swelling and normal tissue were relatively clear and well defined. It appeared normal in colour as compared to the adjacent mucosa. Its size was 0.5 x 0.5 cm, smooth surface and firm in consistency. The child was having no problem in oration or mastication. No other abnormal oral findings were detected. Based on the above history and clinical features a provisional diagnosis of mucocele with respect to 31,32 and 33 wasgiven.Treatment plan was to excise it through laser and patient was made aware about the benefits of using laser for excision and all the required informed consents were taken prior to the laser surgery. Routine blood investigations were conducted and results were found to be under normal limits.

Phase I: Oral prophylaxis was done and then the area around the lesion was made sterile by applying betadine solution using a tweezer and gauge. Surfaceanesthetic spraycontaining Lignocaine U.S.P (15% w/v) was sprayed over the lesion. The patient, chair side assistant and the clinician wore the laser protective eye glasses. The laser tip was activated using a cork prior to surgery.

Phase II: The lip was then pushed upwards with finger pressure to increase the lesion's prominence. First the excision of the base of the lesion was started using a 940 nm diode laser [ilASE^{TM} diode laser from BIOLASE Inc.] in continuous contact mode at 1.8 Watt of power around the margin of the swelling and simultaneously continuous suction was done. The margin of the lesion was excised using an in and out brushing motion, and later it was made deep to completely separate the lesion and its remaining tissue tags. The tip of laser was regularly cleaned with gauge dipped in saline to remove charred tissue remnants. Tissue forcep was used to simultaneously pull the tissue during laser excision. Once the lesion was excised the surgical area was cleaned with a sterile gauze using (0.9% W/V) normal saline.Post-op instructions recommended 0.2% chlorhexidine mouthwash rinses thrice daily for one week and the patient was advocatedorthodontic treatment for the correction of lower anterior crowding to avoid recurrence of the lesion.Surgery was quick, bloodless, and well received by the patient. Post-surgery problems, discomfort, pain and scar were minimal on follow-up post 7 day.

Histopathology: Microscopic examination of the completely excised biopsy sample showed mucin filled cyst like cavity below the mucosal surface. Minor salivary glands and granulation tissues were present below and lateral to the spilled mucin. The histopathological examination was suggestive of Mucocele.

Discussion

A mucocele lesion in a 13-year old male patient was treated with laser excision in the Paediatric and Preventive Dentistry department,Institute of Dental Sciences, Bhubaneswar, Odisha. Clinically, the mucocele presents as an asymptomatic vesicle with blue or pinkish color. The size can vary from 1 mm to few centimeters. The lesion is routinely due to injury to the minorsalivary glands and having a prevalence of 0.2 casesper 1,000 persons.[5]

The term mucocele is derived from the Latin word "Mouco" meaning mucus and "Coele" meaning cavity. They are basically "mucus filled cavities" usually present in the oral cavity, lacrimal sac, and paranasal sinuses. Mucocele are the most frequently occurring lesion of the minor salivary glands. It is second only to irritation fibromas in being the most common benign soft tissue tumor of the mouth.The prevalence of mucocele is 0.4%to 0.8% with very minor differences between males and females. The most affected site is the lower lip (40% to 80% of all cases), similar to this case, followed by mucosa of cheekand floor of the mouth.[6-8]

In the present case, the patient gave a history of trauma and lip biting habit in the 32, 33 areas, which ultimately lead to mucocele formation at the site due to the repeated trauma. The primary objective in the treatment of mucocele is the complete resection of the lesion in order to prevent its recurrence. We have to completely remove the affected and surrounding glands along with the main lesion to avoid recurrence.[9,10]Several conventional techniques are used for excision of mucocele, but in our case laser excision was well tolerated by the paediatric patient with excellent hemostasis and faster and clean surgery. Postoperative problems, discomfort, and scarring were minimal on follow-up.[11-15]

Conclusion

Mucocele is a very common salivary gland lesion and is seen more in cases of paediatric patients. Paediatric patients are very often fearful and un cooperative towards injection and surgery. Laser excision is a very good alternative to conventional surgery and can also be performed under topical surface anesthetic spray leading to better compliance in children. Laser provides a clean, painless, bloodless surgery. The post-operative complication rare and suturing is not done. The chances of scar formation are minimal. The patient imbibes a positive attitude towards dentistry.

Awareness of Patients towards Different Prosthetic Rehabilitation Like Fixed Partial Denture, Removable Partial Denture, Implants at Institute of Dental Sciences, Bhubaneswar

Abhilash Mohapatra[1], Gopal Choudhury[2], Abhijeeta Mohapatra[3], Upasana Dhar[4]

[1]Professor, [2]Professor and Head, [3]Professor, Department of Prosthodontics, [4]Post Graduate Trainee, Department of Public Heath Dentisty, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Objective: Assessment of the patient attitude and knowledge towards various tooth replacement option at a tertiary care dental hospital.

Study Design: A cross sectional descriptive study.

Materials and method: A survey was conducted on 150 partially edentulous male and female patients above the age of 20 years, using a self-explanatory questionnaire. Complete edentulous and dentulous patients were excluded in study. Age, gender and attitude of the patients towards each type of prosthetic replacement was noted. Data were analyzed using SPSS 25. Frequencies of age, knowledge and source about each replacement procedure and limiting factors were calculated.

Results: Ninety five percent of patients were aware of various prosthetic rehabilitation procedure. Dentists were the main sources of information regarding the prosthetic option followed by friends and relatives. Ninety percentage had awareness about removable fixed partial, 85% about fixed partial dentures and 65% about dental implants. A majority of patients (52%) had objection on the cost of fixed partial. Major disadvantage and deterrent for implant therapy were cost and surgery and for fixed partial denture were sacrifice of healthy natural teeth.

Conclusion: The study showed that most of the patients were aware of different prosthetic rehabilitation options. The awareness about this were created by dentist and electronic media. But it was found that cost was a major deterrent for implants and fixed partial denture.

Keywords: *Prosthetics rehabilitation, missing teeth, awareness, implants, oral health.*

Introduction

For general wellness of an individual we seldom give much importance to teeth, but loss of teeth not only affects the body physiology, it also affects the psychological aspect of an individual. So, in prosthodontics we not only aim in restoring function and esthetics of edentulous patients but also the psychological health of that individual.[1] Removable partial dentures are a very popular and cost-effective prosthetic rehabilitation option for partially edentulous patients. The major advantage of this is that it is a reversible procedure and can be given in wide range of age group. However, it also has its own set of demerits like pain, discomfort, soreness and loss of attached gingiva in abutment teeth.[2] Fixed partial dentures are a gold standard in treatment option for patient wanting a fixed prosthetic

rehabilitation. These have a good esthetic, functional and psychological compliance by the patient. However, they have the disadvantage of loss of tooth structure of abutment tooth, Postoperative sensitivity, caries and fracture of abutment tooth[3]. So overall prognosis is good for the rehabilitation procedure.

After the advent of implants the treatment option available to prosthodontics has been broadened[4]. Partially edentulous and complete edentulous patients can be given different treatment options like fixed, semi fixed or hybrid dentures and removable partial dentures. Dental implants are now an accepted treatment of choice for replacing single missing tooth[3]. Implant supported prosthesis provide increased masticatory efficiency, improved esthetics & phonetics and above all reduce the bone resorption of the alveolar ridge.[5]Since the prosthetic treatment planning has to be devised according to patients concern and needs, understanding patient's knowledge, attitude towards prosthetic replacement prior to receiving treatment is the necessity.[6,7]

Yusuf and Fakiha had evaluated the awareness and attitudes of patients towards prosthetic rehabilitation of missing teeth at the university dental Hospital, Riyadh, Kingdom of Saudi Arab. They concluded that 53.1% of the population surveyed did not get their teeth replaced. They have emphasized on the need of motivation and education of patients leading them to make the decision favourably.[8] Shigli K, have surveyed the attitude towards replacement of teeth among patient at Institutes of Dental sciences, Belgaum, India and concluded that majority of study subjects were only aware of mastication function performed by teeth.[9].The present survey is aimed towards assessment of attitude and knowledge of patient about prosthetic rehabilitation options. And utilization of dental services by patients who reported to Institute of Dental Sciences, Bhubaneswar located in east India in state of Odisha.

Materials and Method

This descriptive cross-sectional study was done over a period of 6 months during Jan 2019 – June 2019 for assessment of the knowledge and attitude of patients towards prosthetic rehabilitation options. Non probability consecutive sampling technique was used. Two hundred partially edentulous patients of age 20 years and above, having history of no systemic disease attending department of prosthodontics and implantology of Institute of Dental Sciences Bhubaneswar were included in the study. Completely dentate and completely edentulous patients were not part of the study. A self- designed questionnaire containing total 14 questions, out of which 8 were knowledge based and remaining 6 were attitude-based questions were used for data collection. After taking informed consent from the patients, a questionnaire was filled in by the principal investigator containing questions about age, gender, income, education, occupation, level and sources of information regarding different prosthetic treatment options and awareness and knowledge of each treatment. Data were analysedusing SPSS25 Mean ±S.D was calculated for quantitative variables like age. For qualitative variables like gender and knowledge, frequency and percentage were calculated.

Results

Evaluation of data sheet of the selected sample for the study (n=200), the result showed that the mean age of the patient was 45.04 ± 8.5. Sixty-fivepercentage of the patient were of the age 30-50 years and patients above 50 years were 30%. 123 patients (62%) were male patients while 77 patients (39%) were female as is shown in Table 1.The awareness level in patients about the different prosthodontic rehabilitation options like removable partial denture, fixed partial denture and dental implants were assessed. Ninety percentage had awareness about removable partial dentures, 85% about fixed partial dentures and 65% about dental implants.

Table 1. Demographic data of the patients

S.No.		No	Percentage (%)
Age			
1	Under 30 years	10	5
2	30-50 years	130	65
3	Above 50 years	60	30
Gender			
1	Male	123	62
2	Female	77	39
Income per month			
1	Below Rs 20,000/-	70	35
2	Rs 20,000/- 40,000/-	90	45
3	Rs 40,000 and above	40	20

4	Housewife	40	20

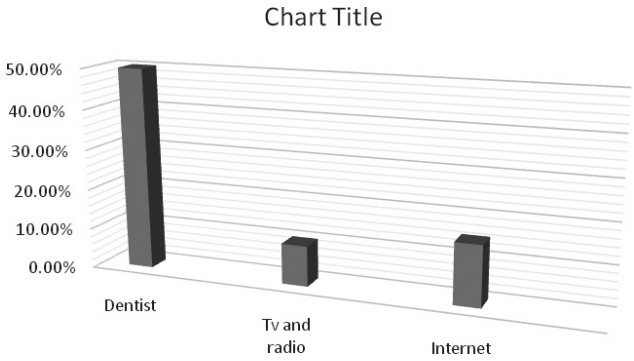

Figure 1. Awareness of different prosthodontic options in patients

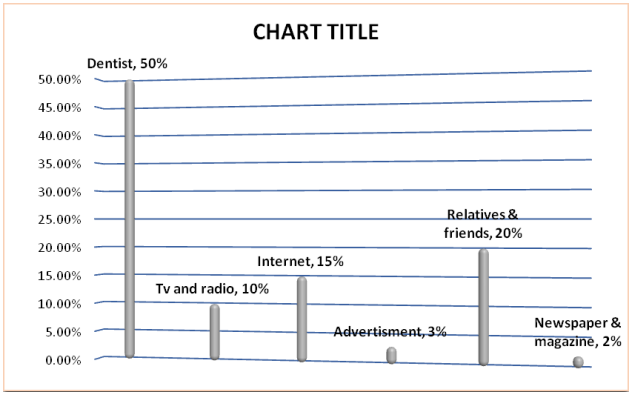

Figure 2. Major source of information for the patients about the prosthodontic rehabilitation option

Discussion

Internet and social media have made information available to a vast majority of persons who were previously unaware of prosthodontic rehabilitation procedures. So, loss of teeth which was previously thought to be an accepted norm of ageing is now being challenged by procedures like implant and fixed partial dentures. Implant has been a tried and tested procedure with overall success rate of 94%.[10]Most of the geriatric patients as found in the present study showed disinterest in dental rehabilitation due to lack of information or financial concern. And the patients with greater financial opportunity, higher education were more aware of prosthodontic rehabilitation options. Most of the patients were satisfied with removable partial denture, and patients wearing fixed partial denture were significantly happier with it. No significance difference was found in awareness between male and female patients, but female patients were more concern about aesthetics in comparison to males.

With the advent of implants,it has become a viable treatment option for restoration of edentulous sites due to its excellent biocompatibility, strength and long-term success. Even thorough 65% of the patients knew about implant restoration but were not keen for it as it had a high cost, and involved a surgical procedure. Tapper et al reported in their study that patients believe the durability of implant is more than 10-20 years, it needed less care[11]. But they also found patients are not opting for implant was it high cost.[11] In the present survey it was found that 50% patients were aware of the treatment options mostly from the dentist followed by other medias like Tv, radio and internet. But in a study in Japan by Akagawa et al it was found that only 20% of patients received their information from the family dentist.

So, in India a lot of educational program and advertisement has to be done to educate the patients about the various prosthetic rehabilitation option. The implant as a treatment option has to be propagated and measures should be taken in India to reduce it cost. And there is a need for dental insurance to cover the maximum population in India to reduce the cost of dental treatment and make the option of various rehabilitation procedure available to common man.

Conclusion

Within limitations of this study, as it was done in a mostly urban population, it was found that the patients were aware of different treatment options. The main source of information was from the Dentist, followed by relatives and internet. And the cost was the most prohibitory factors for the various treatment options.

Conventional Techniques and Newer Advances of Painless Local Anaesthesia Delivery in Paediatric Dentistry: A Review

Arpita Datta[1], Antarmayee Panigrahi[2], Susant Mohanty[3]

[1]Postgraduate Student, [2]Reader, [3]Professor & Head, Department of Paediatrics and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneshwar, India

Abstract

Behavior shaping of children during local anesthesia delivery has been one of the most important and determining step in pediatric dentistry. Along with several conventional, the more comfortable and non-invasive method are wand, cclads, vibraject, accupal, dental vibe, syrijet mark li system and many more. The advantages of theses recent advances are that the operator can control the amount of local anesthesia being administered while making the patient's injection experience as painless as possible. Therefore, a constant research is opening up many such prospects that can make the life of both a pedodontist and a child way more smoother and hassle free.

Keywords: *Local anesthesia, newer method, painless dental anaesthesia.*

Introduction

Administering a completely painless local anesthesia in pediatric dentistry is not only the most challenging task for a pedodontist but also a myth. We can rather transform their experience into a more comfortable one.[1] As pain during any dental procedures can make a child unco-operative for following visits to a dental operatory thus imparting a negative perspective to child's mindset.[2] Thus to counter-act this fear related to needle prick in patients, a lot of researchers have been working to find out and substantiate the regular local anesthetic delivery systems.[3] So, the aim of this review is to highlight various conventional as well as new & improved devices featuring different techniques that can make the patient's local anesthetic experience as painless as possible.

Conventional Method

The various techniques that has been used to decrease the pain perception of a patient are:

Corresponding Author:
Dr. Antarmayee Panigrahi
Reader, Department of Paediatrics and Preventive Dentistry. Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneshwar, India
e-mail: antarmayee.pani@gmail.com

1. Buffered anesthesia: Sodium bicarbonate is added to common anesthetic solutions like lidocaine or articane, before administration to neutralize the acid. Moreover carbon dioxide formed as a by product has a topical effect in the form of CO_2 microbubble and has a diffusion trapping effect i.e. the basic anesthetic solution is converted to acidic by CO_2, providing prolonged anesthetic effect because the changed molecules need time to be converted back to basic form by the body, to cross the nerve membrane. Additional benefits are short time of onset, reduced pain perception and burning sensation during injection. However, research shows that some patient factors like stress levels, fatigue and uncontrolled diabetes can lower the buffering capacity to some extent.[4] Though many of the study results have shown that there are no significant results with buffered solutions, [5,6,7] in contrast to a single study by Kashyap et al[8].
2. Warming anesthetic solutions- Higher temperatures like 42°C, body temperatures (21°C) etc. imparts less pain during truncal anesthesia or infiltrations than compared to room temperature.[9] Studies have also shown varying results in terms of degradation of drug and vaso-constrictors which is inconsistent with electronic databases.[10,11]
3. Cooling-Cooling the site before anesthetic administration using various method like ice

popsicles under pressure, applying cotton soaked in dichlorodifluoromethane spray prior to palatal injections work by the gate control theory thereby increasing the pain threshold and decreasing post anesthetic discomfort to children.[12]

4. Camouflaged Needles help to distract the child while reducing dental treatment anxiety and at the same time maximize patient co-operation.[13]

5. Needle size & length - Short needles (10,20 or 30mm) of 27 or 30 gauge specially help in administering the local anesthetic in a difficult -to -manage child, during maxillary or inferior mandibular nerve blocks, thus reducing the pain and fear both[14].

6. Topical anesthetic - EMLA (eutectic mixture containing lidocaine & prilocaine local anesthetic) - 5%, benzocaine - 20%, lidocaine cream - 5% and spray - 10% can act as topical anesthetics by reducing the pain of needle pricks and takes around 2-3 minutes to act, thus making the whole experience subtle[14].

Newer Advances

Electrical Based:

1. Computer controlled local anesthetic delivery system: CCLAD was first used in the mid-1990s which uses computerized flow rate & pressure using needle for local anesthetic delivery. Advantageous due to lesser pain sensation from fluid pressure over syringe a continuously monitored flow rate.[15]

2. Comfort control syringe- It is a device that comprises of five pre-designed speeds for different injection techniques used in oral cavity. Administration of anesthetic solution goes on very slowly for beginning 10 seconds then at the pre-set speed for rest of the solution, which gives a better tactile sensation to operator.[16] Though marked differences in terms of advantages over conventional syringes have not been reported so far.[17]

3. The WAND- It has three parts namely a central unit, foot bar & throwaway handpiece that holds the anesthetic cartridge through which the solution passes within the needle to intended tissue. The foot bar keeps a check over flow rate and on aspiration prevents unintended vascular infiltration. It also features three formulated speed settings-moderate (0.005 ml/s), quick (0.03 ml/s) and jet (0.06 ml/s).[18] Studies substantiate its better acceptability among pediatric population.[19]

Vibration Based

1. **Vibraject:** Vibration incorporated anesthetic delivery system first used in U.S, 1995, that works upon the gate control theory to reduce pain(blocked by vibrations in the dorsal grey horn of spinal cord)[20] during, both needle insertion within tissues and solution deposition with an additional soothing effect due to the humming sound produced.[21] Studies have shown positive results in most of the subjects within some exception as well.[22,23]

2. **Dental vibe:** It is a processor -driven- motor-operated device consisting of an u-shaped probe that vibrates concurrently and provides with an oscillating vibration to the site of injection. It makes the patient experience as much painless as possible while injecting the local anesthetic, intra-orally at any site. [24]

3. **Accupal:** This wireless motor operated device uses both pressure as well as vibration, to administer anesthetic solution to palatal and alveolar regions just adjacent to the site of injection. Its head comprises of a hollow slot bearing needle connected to the motor that works by blocking the painful stimulus, thus using the gate control theory. [25]

Needle Less Injection System

1. **Jet injector:** Uses a high-pressure jet of solution to pass through a small pore into the hypodermic region without a needle under heavy mechanical force. Can be used for rubber dam clamp placement, provide a slit during abscessed tooth, space maintainer fabrication etc.Syrijet MarkII and MED-JET are most commonly marketed jet injectors.[26]

2. **Injex:** This needle less system uses a spray of anesthetic that spreads subcutaneously under the syringe pressure in a horizontal layered fashion. Most feasible for giving supra-periosteal injections but not for blocks. Though studies have shown variable patient acceptance.

3. **Comfort-in™:** It is a spring-loaded injection system without needle for the subcutaneous administration of any liquid medication. A compact power device that delivers up to 0.5 ml/50 units of any given solution, through a micro-orifice (0.15 mm) by means of a narrow, high velocity jet injection, which penetrates the skin in less than one-third of a second. Nozzles are disposable and intended for one time use only. Depth of penetration ranges from 2.1 mm to 6.1mm, subcutaneously in a cone like fashion.

On Horizon

Buzzy system: It is a very new and innovative device that comprises of a bee- shaped gadget producing vibrations & cooling through freezable wings. The purpose of the cold and vibration is to delay or diminish the transmission of pain stimuli to the central nervous system. Baxter et al. (2009)stated that Buzzy involved three nonpharmacological mechanisms of pain relief. These were gate control theory, descending noxious inhibitory control, and distraction. even to this day a lot of studies are going on regarding its efficacy in using during intra-oral injections, whereas it has been successfully used in other phlebotomy & intra dermal injections of injections.

Conclusion

Thus, to conclude it is to be understood that pain and anxiety, which is one of the prime causes for stress among children is the environment of the dental operatory, dentists and above all the fear of the anesthetic syringes. This might even lead to drop-outs from further appointments. Thus, the most prime call of the hour is to tame the mind of the child before taming the child himself or herself. In this whole procedure the most important step towards inculcating a positive behavior among the psychology of a very young child is to alleviate this very fear of the unknown from young minds. The various conventional and newer method of painless local anesthetic delivery is already showed improved results over the following years and we are also hopeful that these procedures are also going to inculcate a very bright future in the history of pediatric dentistry in the years to come the most recent advances of needle- less injectors and also the buzzy system is actually going to create a buzz in the coming times.

Oral Manifestations of Dermatologic Diseases

Satya Ranjan Misra

Professor & Head, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Diseases of all organ systems of the body have the potential to create an impact on the oral cavity. These oral mucosal changes may be either the first, the only or the most severe form of that disease, the primary target of the therapeutic protocol and the most significant reason for morbidity or lowering the quality of life in individuals. The skin is sometimes considered the largest organ of the body helping in preventing many diseases by serving as a physical barrier. However, there are numerous dermatologic diseases which may be infectious, auto-immune or as a result of a hypersensitivity reaction. Since the diseases and their manifestations are many, the important ones are described briefly in this overview to increase awareness regarding the diseases of the skin and their effects in the mouth.

Keywords: *Dermatologic disease, diagnosis, immune-mediated, underlying disease.*

Introduction

Many of the dermatological diseases produce oral manifestations which are characteristic. The reason why skin diseases affect the mucosa is that the mucosa and skin have same embryological derivation. Mucosa and skin merge one another and they have similar histological structures. The commonly encountered diseases with their characteristic oral lesions are presented here in this paper.

Measles: Young children, will develop suddenly, a rise of temperature and in oral mucosa, an erythematous area, white small dots or elevations will be seen and these are called "Koplik's Spots" the presence of Koplik's spots is a diagnostic sign that the patient is suffering from measles.[1]

Ectodermal dysplasia: Some patients may present with no teeth at all in the mouth. On taking history the patient will reveal that the teeth have not erupted and on radiographic examination, if no teeth were found in the jaw, this is congenital absence of teeth called as "Total anodontia".Total anodontia is a clinical sign to diagnose "Ectodermal Dysplasia".[2]

In Ectodermal Dysplasia, there is a defect in ectoderm and all structures developing from ectoderm are defective. The patient will have thin, scanty, lustreless hair, depressed nose, absence of eyelashes and eyebrows and the patient will be very sensitive to hot as his skin has no sweat glands and the skin is very dry, susceptible to infections as there is no sebaceous gland. The nails are dystrophic in appearance. Thus, total anodontia in mouth helps to diagnose Ectodermal Dysplasia.

Ellis–Van Creveld Syndrome: The patient has few missing teeth and few erupted teeth are malformed. The important observation in these patients is that the labial mucosa is fused with alveolar mucosa. This characteristic oral sign is a diagnostic point to diagnose Ellis – Van Creveld syndrome or Chondroectodermal Dysplasia. It is a hereditary condition in which ectoderm and mesoderm are affected. As a result, structures developed from ectoderm are affected and the mesodermal structure, cartilage is also affected.[3]

The patient will have stunted growth with short, long bones due to chondrodysplasia associated with features of ectodermal dysplasia. The patient will have polydactyly or syndactyly and cardiac malformations.

Epidermolysis Bullosa Dystropica: The patient develops oral bullae frequently, and ruptures to form ulceration. When the ulcers appear in the mucosa, it produces pain and difficulty in oral cavity. The lesion heals and produces scar and again bulla develops, ruptures, ulcerates and heals. This oral manifestation suggests that the patient is suffering from Epidermolysis Bullosa Dystropica.[4]

Erythema Multiforme: The patient has acute

inflammatory erythematous patches which develop following vesicle formation and rupture of the vesicle. The ulcers are painful and reddish and covered with encrustations, excess salivation, inability to take food and drinks. This clinical sign of oral cavity suggest that the patient is having Erythema multiforme.

Erythema multiforme is an acute inflammatory disease of skin and mucosa characterized by erythema and oedema. Numerous vesicles develop bilaterally and symmetrically, rupture and form ulceration in the skin. The erythematous ulcer is painful and heals from center to periphery giving a target of iris or Bull's eye appearance.[5]

Steven–Johnson's Syndrome: The patient will have vesicles or bullae which ruptures and leave surface covered with a thick white or yellow exudate, ulcerations of the lip and bloody crusting with erosion of pharynx also occur. If these oral signs occur along with eye lesions, skin and genital lesions it is suggestive of "Steven Johnson's Syndrome" which is a very severe bullous form of erythema multiforme.[5,6]

Bechet's Syndrome: Sometimes the patient will complain of painful ulcers which occur in crops at any intra oral site with erythematous border and covered by grayish or yellowish exudates. These oral manifestations, occurs along with genital and ocular lesions, it is indicative that the patient is affected by "Behcet's Syndrome".

The oral epithelium or some cross-reacting microorganisms act as antigen to stimulate normal antibody and cell mediated immune response which causes the pathological lesion. The immunologic competence and cytotoxic potential might cause epithelial damage resulting in ulceration.[7]

Ehlers–Danlos Syndrome: In some patients, the oral mucosa becomes excessively fragile, and easily bruised with delayed would healing, gingival bleeding, periodontal diseases and severe bleeding following tooth extraction. Enamel hypoplasia, recurrent subluxation of temporomandibular joint with radiographic findings such as stunted and deformed roots, large pulp stones in pulp chamber with high cusp, deep occlusal fissures in premolars and molars are present. These oral findings associated with hyper elastic, fragile skin, fragile blood vessels with immediate injury following minor trauma and positive Gorlin sign which denotes the ability to touch the nose with tongue are characteristic features of Ehlers–Danlos–syndrome, which is a generalized defect of connective tissue essentially of collagen. [8]

Reiter's Syndrome: If the patient presents with painless, red, slightly elevated, granular or vesicular areas with white circinate borders on the lips, buccal mucosa and gingiva along with palatal lesions appearing as bright red spots, which darken and coalesce, and if these oral changes occurs along with urethritis, arthritis and conjunctivitis, it is suggestive that the patient it suffering Reiter's syndrome. [9]

Pemphigus: The patient has multiple erythematous ulcers with severe burning sensation and pain. These ulcers develop after vesicle formation and rupture of that vesicle. The ulcer remains in the mouth for a long time and cause disturbances in mastication. The oral mucosa peels leaving erythematous area on pressure. This clinical sign is suggestive of pemphigus vulgaris.[10] Pemphigus is a serious chronic skin disease with oral manifestations characterized by the appearance of vesicle and bulla which rupture and form ulcer.

Pemphigoid: In some individuals large sized hemorrhagic bullae on oral mucosa which ruptures to leave a fibrin covered superficial ulceration which heals by scar formation are present with diffuse gingival involvement leading to chronic desquamative gingivitis. Chronic blistering diseases of mucous membrane of skin mouth, eye, nose, larynx, pharynx, esophagus and penis resulting in permanent scarring of the affected areas, are suggestive features of pemphigoid, which is an autoimmune disease.[11]

Lupus Erthematosus: The patient has got an oral lesion in the lip in the form of erythematous patch with white dots. This patch is elevated and central portion is depressed. The elevated margin is slightly indurated, surrounded by whitish border. The ulceration in the superficial area is covered with crusting and margins of the lesion have little keratinisation associated with white striae. This clinical sign suggests that the patient is having lupus erythematosus.[12]Lupus erythematosus is a rather common disease, and it is an autoimmune disease. Lupus erythematosus may be discoid lupus erythematiosus or systemic lupus erythematosus.

Scleroderma: Sometimes the lips of the patient may become rigid and the oral aperture narrows considerably, skin folds are lost around the mouth giving a mask – like appearance to the face. The tongue also becomes hard and rigid, causing difficulty in speaking.

Involvement of esophagus causes dysphagia. Restricted movements of the mandible are seen causing pseudo ankylosis.[13] The radiographs may reveal uniform thickening of periodontal membrane especially around the posterior teeth and calcinosis of soft tissues around the jaws. The presence of these manifestations suggests that the patient is suffering from scleroderma.

Lichen Planus: In some cases, the buccal mucosa, tongue gingival may exhibt interlacing white lines forming lattice network, annular arrangement, plaque papular, bullous or atropic ulcerative lesion. On the surface of these lesions, the line of intersection of these radiating violaceous lines delicate grayish white streaks named as wickham's striae is present. Chronic desquamative gingivitis and symptom of burning sensation on taking spicy foods are characteristic findings of oral lichen planus which are more common in individuals under stress. This manifestation is suggestive of lichen planus and skin lesions may also be there. On the skin, flat polygonal papules of violaceous colour present on the flexor aspect of fore arm, wrist, neck trunk and genitalia are present associated with pruritis. If the patient is suffering from diabetes mellitus, hypertension associated with Lichen planus, the features are suggestive of Grinspan syndrome.[14]

Psoriasis: Some patients exhibit variety of oral mucosal changes such as yellowish white round or oral lesions which can be scrapped off leaving a bleeding surface, geographic tongue with marked fissuring and diffuse erythema, associated with angular cheilitis, which are oral findings characteristic of psoriasis. These patients have extensive sterile pustules with shedding of nails, dry scaling silvery white patches on skin which on scrapping leaves raw bleeding points called Auspitz sign are present. Psoriaris is a chronic genetically determined, inflammatory disease of skin characterized by rapid cell turnover with increase mitotic activity.[15]

Leprosy: While examining the teeth, if we find a pink colour tooth without mobility, it may be pink spot or non-vital tooth, but on taking radiograph, if there is no destruction of dentin within root canal and if periapical infection is absent, tooth may not be a pink spot or non-vital tooth, but the pink colour may support it may be a leproma, a granulation tissue found in the pulp of the tooth in leprosy patients. If we search for systemic change, patient may have depressed nose, mobility of anterior teeth, maxillary and palatal destruction, cutaneous nodules and loss of skin sensation. Thus pink tooth in mouth is a diagnostic feature to diagnose systemic disease leprosy.[16]

Conclusion

Oral mucosal lesions may pose a diagnostic challenge for the oral physicians and dentists as many different dermatologic diseases look similar owing to the overlapping clinico-pathologic presentation of these diseases irrespective of the aetiopathogenesis. The diseases may be infectious, autoimmune, allergic or idiopathic but affect the oral mucosa with a myriad of abnormal changes.

Knowledge and Attitude Regarding Local Anesthesia among Dental Professionals and Awareness in General Population

Supriya Das[1], Shashirekha Govind[2], Amit Jena[3]

[1]Post Graduate Trainee, [2]Professor & Head, [3]Professor, Department of Conservative Dentistry and Endodontics, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Background: Local anesthetics (LA) are stereotype drugs in dentistry. Though these drugs are used routinely, most of the dentists are unaware of the dose calculations, effective dose or complications and another vital knowledge about the drug. The objective of the survey was to evaluate the knowledge, attitude of dental professionals regarding local anesthesia and its implementation in their daily practice. Awareness of local anesthesia among general population and their expectations from the clinicians was also evaluated.

Method: A survey was conducted on 1080 patients and 540 dental professionals of Odisha through google form survey and hand forms. Questionnaire were made in English and Odia language. Data were analyzed using SPSS statistics 24.0.

Result: Out of 504 dental professional 31% were general dentist, 32.5% were specialist and 36.5 % were undergoing post graduate training. 73.3% of the clinicians didn't knew the equivalent weight of adrenalin in 2% local anesthesia with 1:200000 concentration. 76.2% were wrong regarding dosage of lignocaine. 84% of the clinicians lacked in knowledge about LA allergy testing and 91.8% were unaware about Articaine. MDS especially more than 15 years of experience (100%) were found to be more knowledgeous and have a positive attitude towards local anesthesia when compared with PGs and BDS but when it comes to practice MDS (51.1%) with <5years (40.4%) experience implement better. Out of 1080 general population, 50% have fear for injections. 75.6% are unaware about the different complications of local anesthesia. 83% are unaware about different techniques of nerve block. 84.1% of the patients expect their clinicians to explain the techniques to them.

Conclusion: Desired level of knowledge regarding local anesthesia is lacking among dental professionals, and a deliberate effort must be made to improve it. Lack of awareness of local anesthesia was found among general population.

Keywords: *Local anesthesia, Knowledge, Practice, Awareness, Public.*

Introduction

Field of anesthesia has evolved leaps and bounds over the past few decades. It targets for inhibition of nerve conduction during various dental procedures.[1] The success of local anesthesia administration depends on various factors like site of administration, injection techniques, dosage and allergic complications.[2] The practice of local anesthesia in dentistry has unfortunately spawned carelessness regarding an appreciation of the amount of anesthetic that can be administered to the patient and such attitude continue to predominate even in many respected and well established institute[1]. A 2% LA implies 2 gram of the drug dissolved in 100ml of solution i.e. 20mg/ml. Though these dose calculations appear simpler, most of the dentists are not confident

e-mail id: amitjena@yahoo.com

in doing it.[3] Misdirected needle placement may lead to facial paralysis, inferior alveolar and lingual nerve paresthesia and muscle trismus among others. Use of more concentrated solutions may also be less safe or toxic effect in patients. LAs, if delivered in excessive dose or injected directly into the bloodstream, they may cause major systemic toxicity.[4]

We have developed great skills in maintaining safety to patients who are subjected to anesthesia but we do not take effort to convey our skills to the lay persons. On the other hand, patient's awareness has increased and they are very much concerned about the operative aspect of their treatment. Thus, the objective of the study was to evaluate the awareness of local anesthesia among general population and their expectations from the clinicians. Knowledge, attitude of dental professionals regarding local anesthesia and its implementation in their daily practice was also evaluated.

Materials and Method

This study was approved by the Institutional Review Board of SOA University, Bhubaneswar. The cross-section questionnaire was designed for both groups in Department of Conservative Dentistry and Endodontics, Institute of Dental Sciences, Bhubaneswar.

A total of 1080 patients and 540 dental professionals including both males and females were included in this study. Two sets of questionnaires were prepared in two language (English and Odia) for general population and dental professionals based on KAP. Validation of the questionnaire was done and were circulated among the dentists and general populations of Odisha and distant population were approached through online google survey forms forwarded through mails and other social media. Questionnaires for clinicians comprised of 35 questions. Questionnaires for general population comprise of 17 questions.

The inclusion criteria are:

- Dentists of India having BDS or MDS degree
- Practicing interns of different hospitals or institutes who have completed their four years of BDS course with passed status.
- Patients who came to the OPD of Institute of Dental Sciences and Hospital, Bhubaneswar for any treatment.
- Patients above the age of 18 years and below 70 years.

The Exclusion criteria were:

- Students continuing their BDS course.
- Patients below the age of 18 and above 70 years.
- Psychologically unstable patient.

Results

The survey data was subjected to statistical analysis by SPSS statistics 24.0, SPSS South Asia Pvt Ltd., www.spss.co.in using ANOVA, post-hoc test and the mean difference is significant at the 0.05 level. 504 dental professionals and 1080 patients participated in the study. Out of 504 dental professional 31% were general dentist, 32.5% were specialist and 36.5 % were undergoing post graduate training. Table 1 showed the response of the clinicians towards different questions regarding local anesthesia. 73.3% of the clinicians didn't knew the equivalent weight of adrenalin in 2% local anesthesia with 1:200000 concentration. 76.2% were wrong regarding the safety dosage of lignocaine with adrenalin. 84% of the clinicians lacked in knowledge about LA allergy testing and 91.8% were unaware about Articaine. Table 2 showed the response of the patients towards different questions regarding local anesthesia. 50% patients still have fear for injections. 75.6% are unaware about the different complications of local anesthesia. 83% patients are unaware about different techniques of nerve block. 84.1% of the patients expect their clinicians to explain the techniques to them. Table 3 revealed the KAP analysis based on qualification and experience. It was observed that MDS (100%) especially with more than 15 years of experience (100%) were more knowledgeful and have a positive attitude towards local anesthesia when compared with PGs and BDS but when it comes to practice MDS (51.1%) with <5years (40.4%) experience. Responses of BDS, MDS and PG students were significantly different ($p<0.05$) in all the question asked.

Table 1: Clinician's Questionnaire

Knowledge Based Question	Correct Answer	Wrong Answer
Most commonly used local anesthetic agent in India	100%	0%
Onset of action of lignocaine as nerve block anesthesia is	65.1%	34.9%
Preservative in local anesthetic agent	82%	28%
Concentration of lignocaine used for topical application (gel form)	21.8%	78.2%
Equivalent weight of adrenalin in 2% LA with 1:200000 concentration is	26.7%	73.3%

Knowledge Based Question	Correct Answer	Wrong Answer
Systemic complication of LA	62.4%	37.6%
Safety dosage of lignocaine with adrenalin is	23.8%	76.2%
To obtain a nerve block, local anesthetic agent should be injected	84%	16%
Aspiration is recommended to avoid	39.5%	60.5%
Most common immediate complication of LA	48.8%	51.2%
Hypersensitivity reaction are most common in	50.4%	49.6%
Which symptom(s) reminds you of anaphylaxis	83.1%	16.9%
Which drug should be used as first choice in management of anaphylaxis	59.7%	40.3%
Alternative anesthetic to those who are allergic to lignocaine	43.7%	56.3%
Are you aware about pressurized syringe technique	56.8%	43.2%
Are you aware about pulpal anesthesia	90.4%	9.6%
What is the recommended dose for injecting LA for testing LA allergy	29.3%	70.7%
For LA allergy test, needle should be inserted into	16%	84%
Which is the preferred route for epinephrine in local anesthetic injection in case of allergy	43.1%	56.9%
Concentration of Articaine with 1:100000epinephrine that can be used as a primary buccal infiltration of the mandibular 1st molar	29.3%	70.7%
Equivalent weight of Articaine with 1:100000epinephrine that would be effective for primary buccal infiltration of mandibular 1st molar is	8.2%	91.8%
Attitude Based Question	**Yes / Correct Answer**	**No / Wrong Answer**
Do you test for LA allergy before injecting LA to the patient	85.5%	14.5%
Do you use any topical anesthesia before injecting LA	82.8%	17.2%
Do you prescribe any premedication before injecting LA	12.1%	87.9%
What length of needle do you use most often during infiltration	61%	39%
What length of needle do you use most often during block	63.9%	36.1%
What gauge of needle do you use most often during infiltration	62.1%	37.9%
What gauge of needle do you use most often during block	62.1%	37.9%
Do you regularly ask your patients if they have any LA allergy before the treatment	86.3%	13.7%

Knowledge Based Question	Correct Answer	Wrong Answer
Practice Based Question	**Yes / Correct Answer**	**No / Wrong Answer**
Have you ever tried any alternative therapies other than LA for anesthesia	15.4%	84.6%
What emergency drug do you keep in your clinic?	62%	38%
How much time do you take to inject a 1.8ml cartridge	29%	71%

Table 2: Patient's Questionnaire

Questions	Yes	No
Do you feel nervous in hospital environment?	58.4%	41.6%
Do you have fear of oral injection?	50%	50%
Are you aware about LA?	63.6%	36.4%
Have you ever been injected orally?	67.8%	32.2%
Have you ever been prescribed any medication prior to LA?	80.5%	19.5%
Are you aware of any complication related to LA?	24.4%	75.6%
Did you ever have any allergy due to LA?	95.1%	4.9%
If the previous answer is yes, was your clinician successful in managing it?	86.8%	13.1%
Do you mention your medical complications prior to any treatment?	65.5%	34.5%
Are you aware about different techniques of LA?	17%	83%
Do you expect your clinicians to explain the techniques to you?	84.1%	15.9%

Table 3: KAP analysis (ANOVA & Post HOC Test)

Knowledge	Qualification	**BDS**	**Good**	**Average**
			0 %	100 %
		PG student	20.7 %	79.3 %
		MDS	41.3 %	58.7 %
	Experience	<5 years	0 %	100 %

Discussion

Failures to analyze the dose of LA that can be safely administered to patients is seen to be a very common issue among the dentists irrespective of whether they are general practitioner or specialists. Only 23.8% of the dental practitioner responded correctly the questions related to safety dosage of lignocaine with vasoconstrictors and correct response to equivalent weight of adrenalin in 2% local anesthesia with 1:200000 concentration was only 26.7%. The obtained results confirm that most of the dentists use local anesthetic routinely to perform various dental procedures without having proper knowledge of doses to be used. Various complications arise due to incorrect administration of LA injections, few of the complications are permanent and can harm patients or can also be life threatening.[3, 5-7]. Remaining 76.2% of the dentists are still confused regarding the dosage of lignocaine with or without vasoconstrictor. Such confusions are problematic, especially when anesthetics are administered to medically compromised patients.[8-10]

Aspiration prior to injecting LAs prevent accidental intravascular injection. Few authors recommend to perform at least two negative aspirations prior to injecting local anesthetics but dentists often fail to appreciate this importance of applying such procedures to all injection events.[11,12] 39.5% of dentists know the importance of aspiration when injecting local anesthetics, while is similar to another study in which 38-43% of practitioner perform aspiration. 60.5% are still not aware about the toxicity can occur due to positive aspiration.[1,13] This is upsetting since high levels of toxicity occurs due to accidental intravascular injection of the local anesthesia.

Hematoma is commonly encountered by the dentists in their clinics (48.8%) followed by syncope (37.6%) followed by failure to achieve anesthesia (16%). The unintentional nicking of the blood vessels (artery or vein) with needle during the injection of local anesthesia might result in effusion of blood into extravascular space with subsequent hematoma formation. Although anaphylaxis is not common in their routine practice dentists should be aware of the signs & symptoms of it, and treat the severe reactions in the light of recent advance.[14] Similar to a study by Moore PA et al,[15] the present study shows that the most of the dental professional are aware of this fact. In contrast to Eskandari et al[16], 59.7% of the dental professionals use epinephrine as their first choice of drug in the management of anaphylaxis. Additional agents include aminophylline and corticosteroids for managing asthma, allergic, or anaphylactic reactions[17] According to Eskandari et al[16], most dentists who encounter patients with anaphylaxis in their clinics do not seem to be aware of the urgency of this conditions, this increased in this field in the last few years.[18] These results are similar to the present study, as only 12% of the dental professionals are aware of the use of corticosteroids after the administration of epinephrine. To treat severe systemic reactions, systemic corticosteroids and antihistamine may also be used, but it is not preferred choice of drug prior to or as a substitute for epinephrine for the treatment of anaphylaxis.[19] From practice-based questions, it was observed that, dentists are practicing with their outdated knowledge and are not getting updated with the recent advancements and keeping their choices to few possibilities.

Among the respondents of general population, 67.8% have experienced oral injections and 63.6% were aware about local anesthesia. It was disappointing to know that only 24.4% of the patients were aware about the complications of local anesthesia. The fact that 74% of the patients considers local anesthesia as a painful procedure, is a huge disappointment. For this, improper injection technique could be the possible reason. From the feedbacks, it was also seen that patient expects a detailed explanation of the treatment to be done. Busy hospital schedule not giving doctors enough time to explain the risk factors could be the reason.

Conclusion

Desired level of awareness regarding local anesthesia is lacking among dental professionals, and a deliberate effort must be made to improve it. Upgradation of the academic knowledge and reflecting them into practice is the most essential step that every practitioner must follow. Undergraduate students to be encouraged to acquire and reflect the theoretical knowledge before each clinical activity. Effective doctor–patient communication (verbal and nonverbal) influences variables like patient satisfaction, patient compliance and medical outcome,

assessments of communication skills should be an integral part of the academic training.

Enlightenment of patients and their relatives about the procedure, will improve the quality of work remarkably. These few considerations will help patients to experience a complete painless dentistry

Medication Impact on Dental Prosthesis

Sweta Surabhi

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneshwar, India

Abstract

Dental implants are a type of artificial prosthesis, which is used, in treating patients with partial or complete edentulism. Implants have been is use in dentistry as a very reliable prosthesis since the past 30 years. Dental implants mainly attribute their success on the process of Osseointegration. Osseointegration includes in itself the processes of bone remodeling and healing. Systemic medication can interfere with these processes. The sole objective of the followingreview article is to acknowledge the association between systemic medications consumption and the subsequent effect it has on bone metabolism and their impact on dental implant failure.

Keywords: *Implant; Osteoporosis; Osseointegration; Bone Remodeling; Medication.*

Introduction

An implant is any object or material such as an alloplastic substance or other tissue that is partially or completely inserted or grafted into the body for therapeutic, prosthetic or experimental purpose. Dental implant is defining as a substance that is placed into the jaw to support a crown or fixed or removable denture. The success of implants in dental practice is dependent on the process of Osseointegration. Osseointegration – is the apparent direct attachment or connection of osseous tissue to an inert, alloplastic material without intervening connective tissue. This review article emphasizes on the impact of systemic medications on implant prosthesis.[1-3]

Bisphosphonates: Bisphosphonates (BSPs) are the category of drugs used in the prevention and treatment of bone related disorders likemultiple myeloma, osteoporosis or any other cancer metastasis that spreads secondarily to the bone.[4]

Commomly used BSPs are Alendronate, Risedronate, Ibandronate and Etidronate.

BSPs cause selective deposition of bone by:

(a) Promoting osteoclast apoptosis [programmed call death]

(b) Impairing osseous blood supply

(c) Showing higher attraction for hydroxyapatite crystals [which constitute the bone]

The adverse effects of prolonged use of BSPs leads to the occurrence of Bisphosphonate-related Osteonecrosis of Jaw [BRONJ]

This could be a possible risk factor for dental implant therapy. Despite this BSPs aren't an absolute contraindication for success of dental implants and patients under BSP therapy can safely undergo implant procedures. The possible reasons for this maybe:

- Sterile operating conditions
- Frequent bone irrigation
- Efficient use of antimicrobials
- Regular check up, recalls and prompt management of wounds

Proton pump inhibitors: Proton Pump Inhibitors (PPIs) are the category of drugs that are used in the reduction of gastric acid production and hence used for the treatment of Gastric Esophageal Reflux Disease {GERD} and gastric ulcers. Commonly used drugs are Rabeprazole, Pantoprazole, Omeprazole, Esomeprazole and Lansoprazole. Long-term use of PPIs can cause osteoporosis due to its effect on calcium metabolism. This can in turn lead to increased bone loss and fractures.[6-8] The ways in which the calcium metabolism is altered can be:

(a) Reduced calcium absorption from stomach and intestine as an acidic environment is needed to facilitate calcium absorption.

(b) It can affect bone resorption by inhibiting osteoclastic proton transport system.

(c) It decreases urine calcium excretion.

Non-steroidalanti-inflammatory drugs: Non-Steroidal Anti-Inflammatory Drugs {NSAIDs} are the category of anti pyretic, analgesic and anti-inflammatory drugs used very commonly for management of dental pain and in systemic conditions such as arthritis, cold, headache and joint injuries. Commonly used drugs are Aspirin, Paracetamol, Ibuprofen, Aceclofenac, Diclofenac and Ketorolac. 8NSAIDs inhibit COX-2 enzyme and the production of Prostaglandin that has a pro-inflammatory role and even facilitates normal bone healing, bone formation, osteoclastic activity and angiogenesis.[9,10]

So, use of NSAIDS can cause:

(a) Perio-implant bone loss

(b) Delayed bone healing

(c) Decreased bone to implant contact

(d) Decreased bone area and bone density

So, it is recommended to keep the patients off of NSAIDs for control of pain and oedema prior to and post implant placement and opt for alternative medications for the management of pain and oedema.[11]

Selective serotonin reuptake inhibitors: Selective Serotonin Reuptake Inhibitors (SSRIs) are the most common group of drugs used for treatment of depression and anxiety disorders. Commonly used drugs are Fluoxetine, Sertraline, Paroxetine and Escitalopram. These drugs increase the concentration of serotonin by inhibiting serotonin reuptake from synaptic clefts. SSRIs show their action on Serotonin receptors and transporters which are present in osteocytes, osteoblasts and osteoclast found in bone and thus alter the function of these cells all of which are involved in bone remodeling.[12]

This results in defective bone metabolism by

(a) Increasing osteoclast differentiation.

(b) Anti-anabolic skeletal effects causing degrading impact on mineral quantity in bone and the trabecular pattern of bone architecture.

(c) Decreased differentiation and mineralization of osteogenic cells.

(d) Reduction of osteoblast marker genes including alkaline phosphatase, osterix and osteocalcin.

(e) Problems encountered with mechanical loading.

This in turn results in bone loss, defective Osseointegration and hence implant failure.So careful surgical treatment planning is recommeneded in such patients.[13]

Anti-hypertensives: Anti- hypertensives are a group of drugs that reduce blood pressure by different mechanisms.

Commonly used drugs are:

1. Beta-Blockers like Atenolol, Bisoprolol, Propranolol and Metoprolol.
2. Thiazides diuretics like Chlorthalidone, Hydrochlorothiazide and Metolazone.
3. Angiotensin-Converting Enzyme {ACE} Inhibitors like like Captopril, Enalapril, Lisinopril and Perindopril.

These drugs indeed have a beneficial effect on implant therapy. This is achieved by,

1. Blocking their beta 2 adrenergic receptors [also known as Beta Blockers]
2. Increasing calcium absorption [Thiazide Diuretics]
3. Shifting balance towards bone deposition by inhibiting Renin-Angiotensin System [ACE Inhibitors]

So, these Anti-hypertensives can be given to patients planned for implant therapy without them causing any hindrance in the treatment.[14]

Cyclosporine: Cyclosporine belongs to the category of immunosuppressive drug used to stop the occurrence of transplant rejection and for the treatment ofvarious immune-mediated diseases. Cyclosporine have been reportedly causing osteoporosis by,

(a) Anti-anabolic effects on osteoblast.

(b) Suppressing T-Lymphocytes required for bone modeling.

(c) Creating a loss of balance between bone resorption and deposition that may result in osteopenia and enhanced bone loss.

(d) Increasing incidence of bone fractures.

(e) This in turn will have a negative impact on implant supported prosthesis and will affect its prognosis.

Chemotherapeutic agents: Chemotherapeutic agents are also known as Antineoplastic agents. These drugs are used directly or indirectly to deteriorate the proliferation of rapidly growing cells especially malignant cells. Commonly used drugs are Methotrexate, Capacitabine, 5-Fluorouracil and Cisplatin. They lack the selectivity between fast growing cancer cells and normal cells, which have accelerated cell cycle like the cells of bone marrow cells, hair follicle, etc. This in turn has detrimental effects on the process of bone healing. They also affect patient's nutritional status, which in turn impairs the process of osseointegration and healing. So due consideration should be given to such patients at the time of implant treatment planning.[15-17]

Glucocorticoids: Glucocorticoids are a group of drugs that are indicated in the treatment of various inflammatory and chronic conditions such as rheumatoid arthritis, bronchial asthma, Idiopathic Thrombocytopenic Purpura, Inflammatory Bowel Disorders and many other autoimmune diseases. Commonly used drugs are Beclomethasone, Budesonide, Betamethasone, Cortisone, Dexamethasone, Hydrocortisone and Prednisolone. One of the most common side effects of glucocorticoids is bone loss, which in turn negatively affects implant Osseointegration. Glucocorticoids promote apoptosis of osteoblast and also favour differentiation of bone marrow cells into adipocytes. They directly stimulate PTH production.

These have also been shown to be associated with decreased bone formation and enhanced bone resorption by increasing osteoclastic activity and impairing maturation of osteoprogenitor cells into osteoblasts. They decrease Vitamin-D dependent intestinal calcium absorption and increase renal excretion of calcium and phosphate ions. However various clinical studies conducted in this regard have concluded that glucocorticoids have less effect on Osseointegration in mandible and significant effects in skeletal bone. So, these drugs aren't much of a contrainidication in placement of dental implants.[18-24]

Conclusion

Various systemic medications alter the success of implant therapy by mainly regulating the process of bone remodeling which directly affects the Osseointegration process that forms the backbone of implant therapy.Hence very careful consideration by the dentist is essential before performing implant placement procedures.

Laser Excision of Fibrous Epulis in a 11-Year-Old Boy: A Case Report

Sourav Bhattacharjee[1], Susant Mohanty[2]

[1]Postgraduate Student, [2]Proferssor & Head, Department of Pedodontics and Preventive Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneshwar, India

Abstract

Fibrous epulis is a commonly occurring benign localised growth of the gingiva that exhibits slow growth and is painless. It has a multifactorial etiology, most commonly being irritation due to calculus deposition because of poor oral hygiene, periodontal diseases and hormonal changes. A 11-year-old boy reported to the Department of Paediatric and Preventive dentistry with a complaint of a slow growing painless gingival mass in the mandibular anterior region since the last 6 months causing difficulty in mastication. After proper clinical, radiographic and blood investigations a decision to excise the lesion with a Diode laser under local anaesthesia was taken. Laser provides for a more rapid, more precise, sterile and bloodless field of surgery and is better accepted by paediatric patients. Intra-operative co-operation of the patient was good and a 7-day post-operative follow up showed satisfactory uneventful wound healing.

Keywords: *Epulis, Excision, Diode Laser, Paediatric.*

Introduction

The epulis can be categorized as one of the most frequent lesions of the mouth, benign in nature.[1] The term epulis can be traced from old Greek and is a non-specific generic clinical term that denotes it as tumour like lesion "of the gingiva".[2] Epulis fall under the category of reactive lesions, and not a true neoplasia. They usually have a fluctuant growth rate while remaining asymptomatic]. The dental literature summarizes 3 main subtypes of epulis based on histology -fibrous, granulomatous (pyogenic granuloma), and giant cells epulis (myeloid).[3,4]. Etiological factors that precipitate epulis growth and recurrence are yet to be known. Several factors however could beaccounted for including history of traumatic injury, status of nutrition, level of oral hygiene being maintained, addiction habits to nicotine and alcohol, medications being taken and body hormonal configuration, pregnancy.[5] Some studies show a female predilection for such soft tissue tumours.[6] The gingiva of the anterior teeth region is most frequently affected. Fibrous epulis commonly presents as pinkish to dark red in colour; round, oval or lobular; pedunculated or sessile;may also sometimes be ulcerated. Epulis are highly vascular that causes them to bleed.[7,8] Surgical excision under local anaesthesia is usually the treatment of choice. In paediatric patients where patient co-operation is an important aspect, use of laser is preferable as it minimizes the chances of bleeding.[9]

Case Report: A 11-year-old male child patient reported to the Department of Paediatric and Preventive Dentistry at Institute of Dental Sciences, Bhubaneswar with a chief complaint of a mass growing in his lower front teeth and gum region resulting in a difficulty to chew food, since the last 6 months. The mass had a history of slow growth with no associated pain and had created a space between the two mandibular permanent central incisors. Clinically the patient elicited good general health. Intraoral examination revealed a pale pink, circular, isolated, firm and non-fluctuant swelling of about 2 x 2 centimetre in size with a sessile base extending lingually interdentally with respect to teeth number 31 and 41 (Figure-1). The gingival and periodontal status of other teeth was below satisfactory.

Imaging with periapical radiograph did not reveal any abnormalities. Results of routine blood investigations were found to be normal. The patient was made aware of the advantages of surgery using laser in paediatric patients and a decision to surgically excise the lesion using diode laser.

Oral prophylaxis was performed prior to the planned surgery. The area around the lesion was anesthetized with 2% lidocaine with epinephrine (1:2,00,000) without infiltrating directly into the body of the lesion. Protective eyewear was put on by the clinician, the patient and the chairside assistant before the commencement of the procedure. Resection of the lesion was started base first using a 940nm diode laser (iLASE^{TM} diode laser from BIOLASE Inc.) in continuous contact mode at 1.8 W of power rating in the presence of a high-volume evacuation. The laser tip was wiped frequently during resection to clear off the attached charred tissue. The margins of the lesion were resected using a brushing motion, that were later made deep to completely separate the lesion along with any remaining tissue tags. Post-operative haemostasis was achieved satisfactorily. The whole procedure was completed in under 10 minutes and was well tolerated by the patient (Figure-2). The patient was prescribed the use of topical anaesthetic gel and was educated on proper oral hygiene practices. A 7-day follow-up of the patient showed satisfactory and uneventful post-operative healing (Figure- 4).

Histopathology: After complete excision tissue sample was transferred to the Department of Oral and Maxillofacial Pathology for histopathological examination in 10% formalin-buffered solution (Figure-3). The haematoxylin and eosin stained section showed parakeratinised hyperplastic stratified squamous epithelium proliferating into the underlying densely collagenous stroma. Minimal chronic inflammatory cells were seen with few engorged blood vessels in the stroma. The histopathological examination was suggestive of fibro epithelial hyperplasia.

Figure 1: Pre-operative clinical view of epulis in relation to mandibular anterior gingiva and tooth number 31 and 41.

Figure 2. Immediate post-operative view

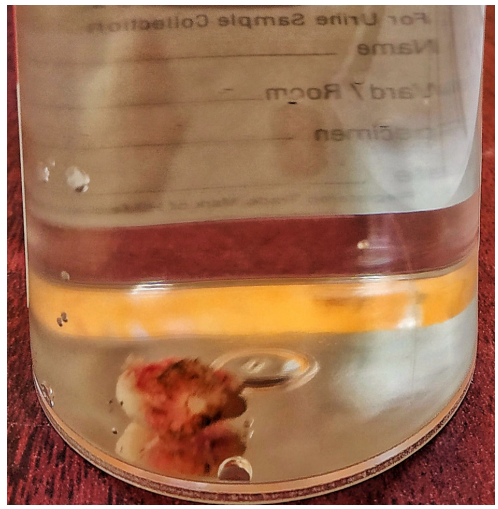

Figure 3: Excised tissue stored in 10% formalin

Figure 4: 7 days post-operative view showing satisfactory healing

Discussion

Virchoff in 1864 was the first to describe the term epulis [10]. Fibrous epulis is usually characterized by a well-demarcated mass of tissue, with a smooth surface and broad base, firm and non-fluctuant in consistency, mostly occurring in maxillary anterior gingiva and teeth region.[3, 11-12] These features seem to be consistent with our case. Epulis may be caused, among other factors due to long standing irritation from decayed teeth, poor quality restorations and calculus deposition.[13-14] This seems to be in line with the findings of our case as the child presented to our department with significant

amount of calculus deposition. The lesion is usually common in the 4th to 6th decade of life and has a male to female ratio of almost 1:2, which makes the occurrence of the lesion in our case in an 11-year-oldmale child quite rare.[15] Our case is also in accordance with most reports in the dental literature that show the most common site for growth of fibrous epulis is the anterior region of the oral cavity, which can be due to the fact that the anterior region is most likely to be affected by calculus deposition compared to the posterior part of the oral cavity, along with other factors like crowding of anterior teeth that makes oral hygiene maintenance difficult.The treatment of choice in such cases is surgical excision of the lesion followed by correction of the local cause of irritation, which reduces the chances of the lesion occurring again in the future.[16] In our case, diode laser was chosen to be the machinery for excision as it Is ideal for paediatric patients as it is better accepted by patients and parents alike while also enhancing treatment outcome.[17, 18] Laser also provides a plethora of other benefits such as a highly sterile surgical bed, eliminating the need for post-operative antibiotics; faster rate of healing and increased precision while performing the surgery.[19]

Conclusion

Due to its multifactorial nature the diagnosis and treatment of epulis often proves quite challenging even for the seasoned clinician. Although usually painless and asymptomatic, they can grow to large enough sizes to hamper with occlusion and mastication. Complete excision of the lesion is considered the best possible management protocol in such cases. Lasers provide an excellent alternative to the traditional scalpel for surgery in paediatric patients, that promises enhanced patient co-operation intra-operatively and patient satisfaction post-operatively.

Cavernous Hemangioma of the Tongue: A Rare Case Report

Neeta Mohanty[1], Shubhangi Pareek[2]

[1]Professor and Head, [2]Post-Graduate Trainee, Department of Oral and Maxillofacial Pathology and Microbiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Over 50% of hemangiomas are found in the head and neck region with the most common sites of involvement being the lips, buccal mucosa, tongue and the palate. These are basically considered to be developmental vascular malformations or hamartomas instead of true neoplasms. We present here a case of cavernous hemangioma on lateral body of tongue in a 63-year-old male who was diagnosed clinically simply as hemangioma. Histopathology plays a vital role in the final diagnosis of such lesions. Other important factors like the age of the patient, the size and site of the lesion and its association to some vital structures play a major role in treatment of the lesion and its surgical approach.

Keywords: *Cavernous hemangioma; head and neck cancer; Histopathology.*

Introduction

The vascular developmental deformities having a divisional growing stage followed by a gradual retrogradation are broadly characterized as hemangiomas with 60-70% of them occurring in the head and neck region.[1] The tumor originating from vascular tissue is mainly divided into two types: Hemangioma and a simple vascular malformation. Hemangioma can be again subdivided into capillary and cavernous types based upon its histopathological presentation.[2] Upon histopathological examination, capillary hemangioma displays a picture of single layer of endothelial cells lining many small capillaries in a moderate to densely inflamed connective tissue stroma whereas in case of cavernous hemangioma, epithelial cells lining large and thin walled vessels and sinusoids are seen which are usually separated by connective tissue septa.[3]

These tumors are described having a benign nature by 3 stages: division of endothelial cells, an accelerating growing stage, and lastly an impromptu regression. Pathogenesis of hemangiomas is associated with genetic as well as cellular elements, mostly the monocytes as they are regarded as the precursors of the endothelial cells present in hemangioma. A lack of balance in angiogenesis leading to the rampant growth of endothelial cells in combination with vascular endothelial growth factor, basic fibroblast growth factor and indole-amine 2,3-dioxygenase (IDO) are considered to initiate its development.[4]

Case Report: A 63-year-old male patient presented with a painless growth in tongue from past 2 years. On intraoral examination, a painless and symptomless reddish growth was present in the lateral border of tongue which was oval in shape and approximately 2cm in size. It was soft in consistency, reducible and compressible. Based upon these clinical findings a provisional diagnosis of Hemangioma was given and the tissue was incised and sent for histopathological examination.

e-mail: pareek.shubhi@gmail.com

Histopathological Findings

The hematoxylin and eosin stained section of the specimen revealed a parakeratinized stratified squamous epithelium with blunt rete ridges. Large cavernous spaces lined by endothelial cells and enclosing abundant amount of red blood cells were seen in the minimally inflamed connective tissue stroma. Occasional lymph spaces containing lymphatic fluid were also evident.

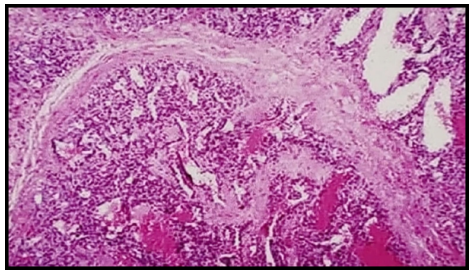

Figure 2 (10x view). The photomicrograph of H & E stained section showing large cavernous spaces lined by endothelial cells separated by scanty connective tissue septa.

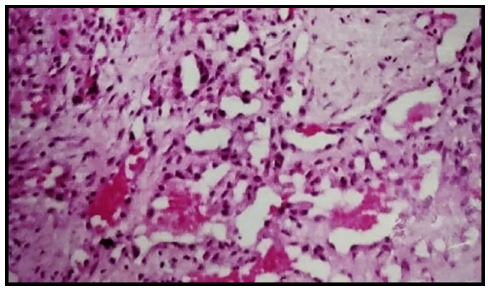

Figure 3 (40x view).The photomicrograph of H & E stained section showing abundant amount of red blood cells within the cavernous spaces.

Based upon these histopathological findings a final diagnosis of Cavernous Hemangioma was given.

Discussion

Hemangiomas mostly occur in the head and neck region with the face, oral cavity, and lips being affected the most with a higher predilection in females.[5] The word cavernous hemangioma basically indicates large vascular channels present in the lesion.[4] These large vascular channels made up of thin walled endothelial vessels or sinusoids and separated from each other by connective tissue septae are some of the characteristic features of cavernous hemangioma.[6]

As reported in the literature around 80% of these lesions are solitary and involve the head and neck region when number and location are considered.[4]

Clinically they present as a sessile or pedunculated soft and smooth mass which may vary in size from a few millimeters to centimeters. Color may also vary from pink to reddish purple and blanching of the lesion is usually present. A spontaneous hemorrhage may also occur as a result of some minor trauma.[6] In spite of maximum head and neck involvement, intraoral hemangiomas are very rare to be diagnosed by clinicians. Radiographic imaging becomes inevitable when is large lesions may compressupon the underlying vital anatomical components, like the facial nerve or orbit. Computed tomography (CT) and magnetic resonance imaging (MRI) are also employed in the volumetric analysis of hemangiomas and vascular deformities. These techniques also hold great importance from the diagnostic point of view as well as size, extension and location can also be easily analyzed.[5] Differential diagnosis like capillary hemangioma, pyogenic granuloma and angiosarcoma must be considered and ruled out clinically as well as histopathologically in the cases of cavernous hemangioma.

Rare sites such as tongue when affected by hemangioma brings along a variety of problems and discomfort to the patient like aesthetics, speech difficulties, inability to eat and swallow and may also show recurrent hemorrhages. Depending upon the size, stage, site of the lesion and the age of the patient, the treatment is decided. Radiotherapy and chemotherapy of tongue lesions are rarely indicated because of their side effects. Carbon dioxide laser when used as a treatment modality causes difficulty in speech, chewing and deglutination.[1,7]Surgical treatment is mostly advised in cases of unresponsive systemic treatments or when aesthetics is concerned. A complete surgical excision is performed. Conservative method of treatment are indicated in more aggressive lesions of the tongue however recurrence may sometimes occur with such procedures where as a loss in function may result after an aggressive surgical procedure.[5,6] Greater success rates have been achieved after treating such cases with cryotherapy.

Conclusion

Cavernous hemangiomas occur as a result of uncontrolled division of the endothelial cells and are basically considered as developmental aberrancies rather than an actual neoplasm. Though most commonly involving the head and neck region, they are very rare intraorally. When congenital, they usually regress

without any treatment but surgery becomes a treatment of choice in cases of such solitary tongue lesions.

Abstract

Background: Dry socket is most common post-operative complication seen after extraction of third molar or surgical tooth. Patient come to next day of surgery complains of severe pain in the extraction socket and foul smell from mouth. The main objective to treat the dry socket is relief in severe pain by local dressing materials.

Aim: The main objective of the study was to evaluate two dressings material in pain relief of dry socket.

Materials and Method: 30 patients were selected after taken the informed consent those were underwent extraction. The patient selected for the study was those who have severe pain after one day of extraction and proper examination the diagnosis was dry socket are equally and randomly to control and test groups (Zinc oxide Eugenol) and Group B (Alvogyl).

Results: At 7-day Alvogyl (2.90+.738) showed the highly statistically significant difference in relieving pain as compare to Zinc oxide eugenol (4.10+.316) dressings.

Conclusion: Alvogyl better than the ZOE dressing for providing pain relief in dry socket.

Keywords: *Dry socket; Post extraction complication; Alvogyl; Zinc Oxide; Eugenol.*

Introduction

After extraction dry socket is most common complication occurred in the dental practices it is due to interferes with the healing process that takes place after a tooth extraction. Blum (2002) defined alveolar osteitis as post- operative pain around the extraction socket which increases after few hours of the extraction accompanied by a partial or total disintegrated blood clot within the alveolar socket with or without halitosis".[1]

"Dry socket" was first described by Crawford in 1896.[2] The name dry socket is used because the socket has a dry appearance after the blood clot is lost and debris washed away. It will occurs due dislodgement of blood clot in 1-2 hr after the tooth extraction due this dislodgment the bone surface exposed in the oral environment which cause bone infection and more bacterial growth on the bone surface, cause severe pain in next 5-6 hour of extraction, it is commonly seen in the third molar extraction case because more bone cutting is required and not maintaining the irrigation protocol during the surgery.[3,4]

"Many literature reviews suggest that the aetiology for dry socket was due dislodgment clot from the extraction socket. Several contributing factors have been reported in literature to be associated with increased risk of dry socket.[5] They include traumatic extraction, preoperative infection, smoking, gender, nutritional deficiency, site of extraction,use of oral contraceptives, use of local anaesthetic with vasoconstrictor, inadequate

postoperative irrigation and low level of operator experience.[6] Increased age and systemic conditions, such as diabetes and immune-suppression have also been associated with a greater risk for dry socket. Several modalities have been advocated to reduce the incidence of dry socket in patients. They include the use of antiseptic mouth washes, antifibrinolytic agents, antibiotics, steroids, clot supporting agents and intra-alveolar dressings.[7] As a specific etiology has not yet been determined, it is necessary to follow preventive measures in the daily practice of tooth extraction starting with the patient's medical history."

"The most common management usually used by every dentist of dry socket include irrigation of socket toughly with normal saline, removes the tooth and bone fragments, necrotic tissues and food debris and inter alveolar medicament with potent antibiotic and NSAIDS. Placement of intra-alveolar paste is controversial in literature because it causes other complications.[9] Surgical intervention in the form of administering anaesthesia, curettage and irrigation of the socket to cleanse it of necrotic bone, tooth fragments, induce bleeding and primary closure by advancement flap, to protect the clot and enhance healing by primary intention.[10] The aim of the study was to elevate the pain Alvogyl and Zinc oxide eugenol dressings placed intra alveolar for the management of dry socket."

Materials and Method

30 patients were selected for the study that underwent extraction of teeth and complains of severe pain after 1 day. Prior to start with the procedure approval was taken from research and ethical committee. The selection criteria were pain around the extraction socket after 1-day, foul smell, total or partial loss of clot were selected for the study and randomly divided into test and control group. Visual Analogue Scale (VAS) for pain intensity reading were recorded at baseline and 7 day.[13] Pain was assessed on a 10 cm scale continuous interval scale with two ends-points representing the left endpoint marked ''no pain'' and the right endpoint marked "worst pain."

Treatment Protocol

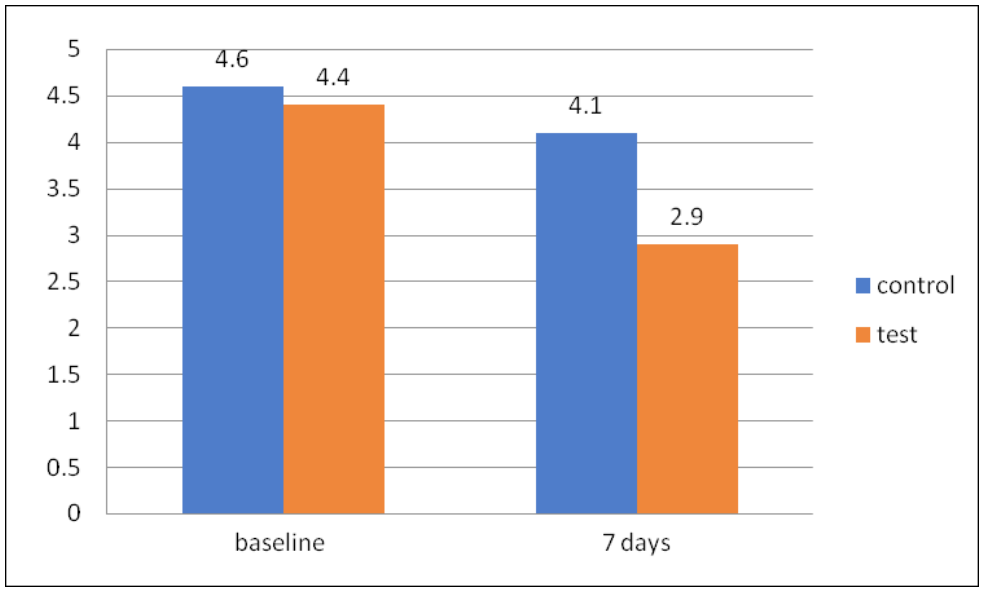
Control group: The local anaesthesia was applied by giving the block the socket is cleaned by the saline irrigation. Curettage is avoided to prevent the surrounding tissue after the clean the socket the ZOE paste is mixed in the clean glass slab mix with fibber of gauze pieces and make thick stick mix place in the area of interest.

Test Group: After doing the same procedure instead of ZOE Alvogyl dressing was given. The gauze was removed after 5 min. The pain level was assessed by visual analogue scale after baseline and 7 days after placement of the medicament.

Statistical analysis: Statistical analysis was carried out in the computer-based software using (SPSS Inc., Chicago, IL, version 16.0 for windows). Test for qualitative variables, mean and standard deviation were calculated. To test the significance of difference of mean rank of VAS between two groups was test by **unpaired t-test**.

Results

Intragroup comparison: On intra group comparison, the mean VAS scores reduced significantly at 7 days from baseline ($p<0.001$) in both the groups. (Table 1). The post hoc comparison of the scores also showed that the mean VAS scores had reduced significantly from baseline to 7 Days



Intergroup comparison: The mean VAS score at baseline in control and test groups were 4.60 ±.699 and 4.40 ±.699 respectively. At 3 months the mean VAS score was found to be 4.10±.316 and 2.90 ±.738 in the control and test group respectively. (Table 1, Graph 1).

The **unpaired t test** was used to compare the mean VAS scores between the two groups was statistically significant ($p>0.05$) at all the time intervals viz. baseline and 7 days.

Table 1. Comparison of visual analogue pain scale test and control groups

VAS	Groups	Mean (mm)	Std. Deviation	t-test value	P-value	Mean Difference
Baseline	Control	4.60	.699	.435	-.781	.200
	Test	4.40	.699			
At 7 Days	Control	4.10	.316	.001*	-3.430	1.200
	Test	2.90	.738			

Unpaired t-test; *significant difference (p-value<0.05).

Graph 1. Show the vas with time in different groups incorporated in the study

Discussion

Dry socket is the most common complication following extraction of teeth by general dentists and specialists. It is difficult to know the extract aetiology of dry socket and commonly seen in daily practice. The main goal after dry socket formation is to minimise the level of pain by using local dressing and pain killer. The main ingredient of local dressing is eugenol which potent pain killer and reduce the bacterial load in the socket. Alvogyl also contains butamben (anesthetic) and iodoform (antimicrobial). Blum, [2] Ahmad and Bloomer suggested using Zinc oxide eugenol in the management of dry socket.[7, 8] Bloomer and Alexander recommend Alvogyl in managing dry socket.[8, 9] Retardation of healing and inflammation were reported by Syrjanen and Syrjanen when using Alvogyl.[10]In our study, the statistically significant difference was obtained in the pain scores among patients treated with zinc oxide eugenol and Alvogyl. In our study we found that the Alvogyl showed the statistically significant difference in relieving pain than Zinc oxide eugenol dressings. Alvogyl required a smaller number of dressings when compared to zinc oxide eugenol.

Conclusion

Alvogyl dressing is a better alternative for Zinc oxide eugenol dressing for the treatment of dry socket.

Dental Radiography in Pediatric Dentistry: A Review

Susant Mohanty[1], Antarmayee Panigrahi[2]

[1]Professor & Head, [2]Reader & PhD Scholar, Department of Pedodontics and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneshwar, Odisha, India

Abstract

Diagnosis and proper treatment planning in dentistry relies on dental radiography especially in cases of extent of caries, periodontal diseases, developmental disorders and oral pathologies. In pediatric dentistry management of child while taking radiograph can sometimes become challenging as it can affect the whole treatment plan and psychology of the child towards dental treatment. Thus, it becomes imperative to be aware of modifications needed in techniques of obtaining radiographs. This review emphasizes on all the possible alteration in techniques that can be used in infants, children through adolescence including those with special health care needs,along with recent advances.

Keywords: *Dental radiography, Children, Lollipop radiograph.*

Introduction

A thorough examination of oral cavity of the child is best supplemented by dental radiology aiding in precise diagnosis and treatment planning. Most commonly radiographs in pediatric dentistry are indicated for detection of caries, assessing status of dental injury, evaluating tooth development and eruption status, diagnosing any pathological conditions etc. However, in cases of infant, children, adolescents and children with special needs is challenging and needs special attention and precision so that radiography can be used with minimal but should be able to provide reliable information required for diagnosis and treatment planning.[1,2]

Projection Method: After obtaining detailed medical and dental history dental radiographs are needed for completing the clinical examinations. In pediatric dentistry there needs some modifications while taking radiographs depending on patients age, cooperation, and medical conditions. For example, while taking radiographs for very young patient xray film can be held by the parent or the guardian. In some cases, using biteblock or holding the film with the hemostat also helps. Also, the film can be held in occlusion by the patient eliminating the dependency on holding it stably by anyone.[1,3]

For infants (<3 Years): usually size 0 intra-oral radiograph is used for recording. This is most challenging because of very young age of the child and placement of radiograph in molar region is difficult. In maxilla placement leads to gagging and coughing and in case of mandibular it irritates the sublingual tissues and reflex tongue movement makes it further difficult.[4]Yet another problem encountered while dealing with them is stabilizing the head during taking the radiograph to avoid distortion. In these cases, parental / guardian help is needed to hold the film and controlling head movement of the child. Also, both the child and guardian are asked to face the same direction limiting the movements.[1]

Special Children: In cases of special children with limited ability to comprehend mentally and physically, the intraoral film with bitewing tabs are used to hold them in place. In some cases, an 18-inch floss is tied through the tab for retrieval and as a safety factor. Safety measures like lead apron, thyroid shield should be strictly used in these cases and also for the accompanying parent/guardian.[5]Cases where intraoral radiography is impossible to obtain, in such patient extra-oral radiographs like panoramic, lateral jaw or 45

e-mail: antarmayee.pani@gmail.com

degrees projections can be used. Various modified intra-oral holders have been proposed though but its use still remains impractical.[6, 7]

Children with gag reflex: Apprehensions increases the tendency to gag in children. It is mostly interpreted as effort by the child to protect himself as reflex defense mechanism against invasion. This is the main reason using tell show do and use of euphemisms are needed to make the child aware of the procedure before taking them for the radiograph. Most common method to reduce the gagging is distraction. This is done by asking them to raise one leg or hand, taking long breath or counting numbers. Also, it is advisable to take the radiograph in the morning hours than afternoon or evening. Also, to be noted is that when the child is empty stomach or half–filled the tendency to gag is more.[8]

Various sedative and topical anesthetic have been proposed to be used for managing gagging like phenothiazine derivatives, barbiturates, antihistamine and nitrous oxide. Temporary relief can be obtained by use of topical application or rinsing with xylocaine. Precise placement of radiographic film and manner needs to be modified in children to accommodate with gags in children. Especially in children with smaller jaws, shallow lingual vestibule or nasal obstruction commonly presents with this difficulty.[8]

Modifications in intra-oral periapical films: To reduce the anxiety or gagging and to minimize discomfort film packets can be modified as per the requirement of patient. These modifications include using the occlusal film and bending it while placement, using a smaller size or wetting and bending the corners of the film to decrease the irritation to sublingual tissues. Use of cotton rolls and tapping of x-ray films have also been suggested by few authors.7, 9

"Reverse bitewing" has been used as one of the alternative techniques in which the film is positioned in buccal vestibule and the x-ray beam is directed from the opposite side of the patient's head through the jaws.10

Management of child's behavior: Managing child behavior in dental office in itself is a difficult task which becomes even more challenging when it needs intervention with different equipment. Various techniques have been used, rather combination of behavior management techniques is advocated to deal with children.In children aged less than 3 years, desensitization technique is employed. Tell show do technique is the most commonly used method combined with use of euphemisms naming x-ray tube as a 'camera' to take photo of the teeth. This not only helps in reducing the anxiety of the patient but also comforting the child. In the first dental visit it is recommended either to not take radiographs or use the least difficult one without causing any discomfort to the child.Though use of small radiograph and bending of radiograph is advocated but it results in distorted image."Lollipop radiography" is another term used which mainly is practical application of concept of desensitization. In this child is asked to lick a sugarless lollipop, and after few licks x-ray film is placed and child is asked to hold it like the lollipop. Once the child is stabilized, radiograph is taken.[11]

Advanced Imaging Techniques

Computed tomography (CT): In conventional radiography the representation of athree-dimensional object in a two-dimensional manner leads to image distortion, overlapping of structures, and low contrast masses. CT is a more advanced digital and mathematical imaging technique which creates sections where tomographic slices is not distorted by adjacent structures. It validates differentiation and is most commonly used non-invasive procedures. This is a quick and patient friendly method.However, this being more expensive than routine radiography, these are indicated in cases of intracranial diseases, facial fractures, tumors, temporomandibular joints, neonatal teeth, supernumerary teethor extent of developmental disorders.[12]

Xeroradiograhy: It is an electrostatic imaging technique that uses xerographic based copying technique to record images. This was invented in 1937. Most commonly used in imaging of skull, respiratory tract, TMJ, mandible, and dental structures. This is mainly advantageous owing to its accuracy in recording of tissues with different thickness in single film. No special skill is needed for copying and maintaining these. For periapical imaging the plate used is comparatively smaller than conventional x-ray film. These features make it more advantageous in cases of children.[13]

Cone Beam CT (CBCT): Also known as dental volumetric radiography or dental CT. The prime feature of CBCT is acquisition of multiple planar projection with rational scan producing volumetric data set and inter-relational images. 2D digital array combined with 3D x-ray beam with circular columniation results in

production of cone and hence the name "cone-beam". In pediatric dentistry this is used in cases of skeletal malocclusion, evaluation of tumor or cyst, cleft lip and palate, craniofacial anomalies, localization of supernumerary teeth or impacted teeth. Precise details help in appropriate treatment planning and predictable prognosis.[14]

Magnetic Resonance Imaging (MRI): It is non-ionizingradiation-based method associated with radio frequency band of electromagnetic spectrum of wavelength 109-1011nm. This is non-invasive imaging technique which uses magnetic field to produce image. This is mainly advantageous in detection of diseases, assessing the healing and soft tissue lesions, intracranial hemorrhages, extent and rupture of vessels etc. MRI has also been used in diagnosis and assessing the outcome of medical management of carious lesion being able to differentiate with accuracy the diseased and healthy enamel or dentin. This can be used in special children and syndromic patients being a non-invasive technique thus well accepted by the children as well as parents.[15]

Conclusion

With knowledge of proper behavior management techniques and radiographicrecommendations added with improved innovative radiographic techniques dental radiography can be obtained with minimum discomfort and maximum accuracy. A pediatric dentist should not only be compassionate but must be aware of modifications of the techniques to be employed in patients as and when required.

Tooth Supported–Conventional Overdentures: Two Case Reports

Debashish Sahoo[1], Sitansu Sekhar Das[2], Sangram Panda[3], Sreeprada Dash[1]

[1]Post-Graduate Trainee, [2]Professor, [3]Reader, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Rehabilitating the completely edentulous patients poses many challenges in the prosthetic dentistry. Providing them with the conventional denture prosthesis is the standard treatment protocol. But the major drawback of this treatment protocol is that the patients generally face difficulty in adapting to the denture prosthesis such as difficulty while mastication, looseness of the denture prosthesis, unstable while speech. To overcome this, tooth supported conventional denture prosthesis has evolved as treatment plan which showed acceptable clinical results and the patient satisfaction was better than as compared to the conventional complete denture prosthesis. Due to the tooth supported denture prosthesis there was reduction in the bone resorption process, stable prosthesis, the esthetics and occlusal functions such as mastication and speech. In this case we shall be discussing two case reports one with mandibular tooth supported over denture prosthesis other one with maxillary tooth supported overdenture prosthesis.

Keyword: *Tooth supported, overdenture, Retention, Stability.*

Introduction

As long as the tooth is present, the volume of bone is maintained in the arch. Along with the tooth loss, there is loss of the periodontal ligament which paves the way for the resorption of the alveolar bone which is very fast initially after the extraction, later the resorption rate is reduced. Because of this reason, the residual alveolar ridges gradually become compromised and are unable to provide adequate retention, stability and support to the final denture prosthesis. So, in order to prevent the loss of the alveolar bone and the resorption process of the ridges, tooth supported denture prosthesis can be provided as a treatment modality to the partially edentulous patients. These Tooth supported over dentures provide retention of the definitive prosthesis, preserve the alveolar bone and maintains the proprioception there by enhancing the treatment quality and level of patient satisfaction.

Rationale for over denture concept[1]

- Extraction of all teeth and replacing it with complete denture prosthesis should not be considered as the best treatment option
- Preventive prosthodontics focuses on the procedures which can eliminate further prosthodontic problems to the patient. The over denture is a method in preventive prosthodontics which helps to maintain the periodontal ligament support to the ridge and prevent the bone loss process.

Indication:

1. Partially edentulous patient (fewer no. teeth). Mostly in the younger population
2. Patents with mutilated dentition
3. Cleft palate cases
4. For congenital diseasessuch asmicrodontia, in certain cases of partial anodontia.[2]
5. Amelogenesis imperfecta and dentinogenesis imperfecta
6. Rehabilitation of patients with maxillofacial trauma

Contraindication:

1. Uncooperative and under motivated patients

2. Patients with poor oral hygiene
3. Tooth with lack of periodontal support
4. Inability of the patient to afford the treatment procedure.

General considerations to be kept in mind during treatment plan formulation:

Periodontal consideration: Presence of any Periodontal inflammation, periodontal or gingival pocket with the abutment teeth, horizontal or vertical bone defects and poor zone of attached gingiva should be addressed before the commencement of the treatment procedure.[3,4]

Endodontic consideration: Prior to the treatment, the abutment teeth should be treated endodontically as :

1. This helps to alter the crown root ratio
2. Clinical crown reduction creates interocclusal clearance, which furthers helps in teeth arrangement for the denture prosthesis
3. Provides channel for connecting the attachments.

Treatment procedure

1. This comprises of Endodontic therapy of the abutment teeth, management of dental caries if present, location and distribution of abutmentteeth, gingival and periodontal contemplation.
2. Management of the carious abutment teeth: restoration of those teeth followed by frequent recall check-ups and periodic fluoride application on to those abutment teeth.[1]

Location of abutment teeth: In an ideal tooth supported overdentures, there should be presence of two abutment teeth on each side of the quadrant that provides equal distribution of forces on to these abutments and also helps to retain the definitive prosthesis.[5]

1. Canines, second premolars or second molars in eachquadrant
2. Mandibular canines being the last teeth to be lost, they are more frequently used for the overdenture prosthesis
3. Mandibular incisors are sometimes preferred as abutment teeth if the mandibular arch form is intact.

Clinical procedure: (For tooth supported over denture)

1. Extraction of teeth with poor prognosis
2. Periodontal therapy
3. Restoration and Endodontic therapy of abutment teeth
4. Tooth preparation of the abutment teeth for the overdenture coping
5. Application of fluoride over the prepared abutment, placement of the metal copings over theabutment teeth.
6. Primary and secondary impressions procedures and subsequent steps of recording the jaw relation, try in of the denture in fabrication of a conventional complete denture
7. On the intaglio surface of the final denture prosthesis, the areas near to gingival margin should be relieved to prevent the impingement of the denture on to the soft tissue area. If necessary, resilient liner can also be used for the patients.

Case-1: A 55-year-oldmale patient reported to the Department of Prosthodontics, Institute of Dental Sciences, Bhubaneswar with the chief complaint of difficulty in chewing food due to loss of teeth. Clinical examination showed loss of vertical dimension (figure no.1) and upon intraoral examination, revealed a completely edentulous maxillary arch and partially edentulous mandibular arch with presence of 32,35,41,42,44(figure no.9). Radiographic and clinical examination revealed that 41 and 32had poor periodontal support and there was large amount of bone loss around these teeth leading to the grade -III mobility with poor prognosis whereas there was minimal bone loss with respect to 35,44,42 and these teeth had better prognosis as compared to 41 and 32. Patient was explained regarding the treatment plan of extracting the tooth with poor prognosis and using the remaining teeth as abutment for a tooth supported overdenture prosthesis. Atraumatic extraction of 41 and 32 were done followed by endodontic therapy (root canal treatment) of the remaining abutmentteeth (35,44,42) (figure no.2 & 3). After the healing of the extraction socket and competition of the endodontic procedures, the tooth preparation was commenced providing a chamfer finish line and dome shaped structure to the abutment teeth with only 2 mm of clinicalcrownremaining (figure no.4). Impressionwas made with alginate and cast was poured with type-1Vdie stonematerial. Metal coping (0.3mm thickness) was fabricated on the obtained casts.These Metal copings were then checked in the patients mouth and cemented using type-1 Glass ionomer cement (figure no.5). After

1 hour, a preliminary impression of the maxilla and mandible was made using alginate in a stock tray which was later poured using type-II dental plaster. Primary casts were obtained over which the custom trays were fabricated for both maxillary and mandibular arch with a 2mm thick spacer wax and 4 tissue stops of 2*2mm dimensions. Border molding was done and secondary impression were made using light body in relation to mandibular arch and zinc oxide eugenol in relation to maxillary arch. Facebow record was made to determine the orientation of the maxilla and mount the maxillary cast in a semi-adjustable Corident CSA-600 articulator (figure no.6). Over the obtained casts, the denture bases and occlusal rims were fabricated which is later used to record the tentative jaw relation and helps in mounting the lower cast on to the articulator. Teeth arrangement was done followed by wax try-in (figure no.7). After the final consent of the patient, the dentures were processed using heat cure acrylic resin which was then trimmed, finished and polished. Laboratory remounting and occlusal correction was also done. Extensions of the denture was checked inside the patient's mouth on the day of denture insertion (figure no.8).Final Denture insertion was done, the retention and stability of the prosthesis was checked (figure no. 10). Follow up of the patient was done in 24 hours, after one month and after 3 months. The patient was highly satisfied with the rehabilitation process.

Figure 1. Preoperative facial profile

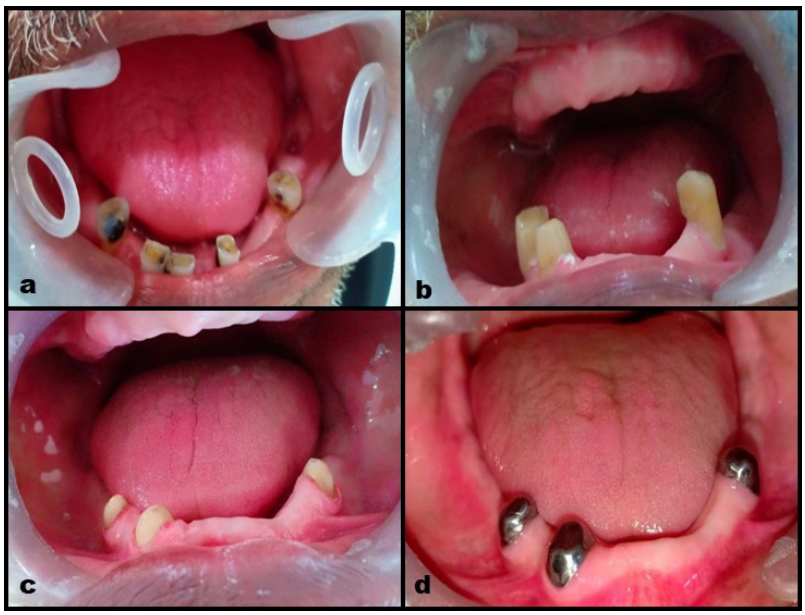

Figure 2a. Pre extraction photograph; 2b. post extraction intra oral of mandibular arch photograph of maxilla & mandible; 2c. Abutment tooth preparation; 2d. Cementation of metal copings

Figure 3a. Facebow Record taken; 3b. Wax Try-In; 3c Denture inserion; 3d. Post -operative photograph

Case-2: A 55 year old female patient reported to the Department of Prosthodontics, Institute of Dental Sciences, Bhubaneshwar with the chief complaint of difficulty while chewing food and also was quite unhappy with the appearance of her teeth ((figure no.11). Clinical examination showed loss of vertical dimension and upon intraoral examination, revealed a completely edentulous mandibular arch and partially edentulous maxillary arch with presence of 13, 15, 23, 24, 25(figure no.12 & 13). Upon radiographic assessment revealed that there is very minimal amount of bone loss around these abutment teeth in the maxillary arch. Thus, the patient was proposed with tooth supported overdenture prosthesis with respect to the axillary arch and implant supported over denture with respect to mandibular arch. But due to the financial constraint of the patient agreed for the Tooth supported maxillary overdenture and conventional mandibular complete denture prosthesis. Endodontic treatment was done for the abutment teeth in the maxillary arch after which the tooth preparation was done to provide a chamfer finish line with only 2 mm of crown structure remaining beyond mucosa and thereby giving these crowns a dome shaped structure (figure no.14). Metal copings of 0.3mm thickness were fabricated from the casts obtained from the primary impression and were cemented after checking intraorally using type -1 glass ionomer cement (figure no.15). Primary impression of the maxilla was made using alginate and the mandibular impression was made using impressioncompound after the fabrication of the custom trays, the Border molding was done using low fusing compound and secondary impression was made using light body poly vinyl siloxane impression material in relation to maxillary arch and zinc oxide eugenol impression material in relation to mandibular arch. Then the subsequent steps in fabrication of a conventional complete denture prosthesis was followed i.e. Jaw relation was done followed by try-in (figure no. 16). Final Denture processing was done followed by trimming, finishing and polishing of the denture and was inserted later on the same day (figure no. 17). The patient washighly satisfied with the esthetics of the denture, phonetics and mastication efficiency. She was followed up after 24 hours, 7 days, 15 days and 1 month, 3 months.

Discussion

Preserving the residual alveolar ridge is very cardinal for the success of the final denture prosthesis. As long as tooth are intact, the alveolar bone is conserved. Tooth supported overdenture are inclinically practice since many decades and is proven with increased retention and stability and patients' satisfaction. Retaining natural teeth as abutments for dentures can considerably reduce the progress of residual ridge resorption. Multiple abutments can be used. The stress concentration can be shared between the denture bearing areas and the abutments. The over denture has numerous advantages andits applicationsare more as compared with conventional completedenture prosthesis.

Advantages of conventional over denture:

1. Adequate Proprioception
2. Increased Retention
3. Prevents shrinkage of surrounding alveolar bone
4. No significant pressure on to the alveolar ridges.
5. Positive psychological Motivation to the patients through the presence of teeth.

But along with its advantages the overdenture also poses certain limitations such as:

1. In order to prevent periodontal diseases, the patient should maintain adequate oral hygiene
2. Overdenture prosthesis are slightly bulkier
3. Frequent maintenance of the prosthesis and periodic recall of the patients are necessary
4. Slightly more expensive than conventional complete denture prosthesis.[6]

Conclusion

A tooth retained overdenture is generally advised when the patient has few teethremaining with good support or the patient doesn't want to undergo extraction of the natural dentition. This procedure actsas an alternative to rehabilitation with dental implants or even total edentulism. The success of overdenture prosthesis depends upon adequate case selection with critically analysing each step in the fabrication of the denture prosthesis. The tooth-supported overdenture is a best treatment option since the proprioception is maintained and there is improvement in the stability and retention of final prosthesis. It is necessary to have patient awareness about good oral hygiene to maintain the abutment teeth, so that rehabilitation process remains satisfactory for a long time.

Eating Disorders: A Comprehensive Review

Smita R. Priyadarshini[1], Suvranita Jena[2], Rajat Panigrahi[1], Abhishek Ranjan Pati[1], Basant Choudhury[3]

[1]Associate Professor, [2]Post Graduate Trainee, [3]Assistant Professor, Department of Oral Medicine and Maxillofacial Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Eating disorders are regarded as "psychiatric syndromes"characterized by irregular eating habits and severe distress about body image. A multidisciplinary approach of a dentist, a psychiatrist and a physician are important and mandatory for correctly diagnosing and proper management of the patient with these disorders. The oral manifestations should be treated at the earliest, failure to which it may lead to more severe systemic complications. This review elaborates the current data regarding the aetiology of each, investigative features, risk factors involved, associated complications and treatment modalities that will be efficacious for the clinician in management of such disorders.

Keyword: *Anorexia Nervosa, Bulimia Nervosa, Binge Eating Disorder, Oral Manifestations.*

Introduction

Psychological issues manifest by disorders in body structure, weight regulation and dieting patterns are referred to as eating disorders. The specific types of eating disorders are:

- Anorexia Nervosa
- Bulimia Nervosa
- Binge Eating Disorders

These are considered as group of psycho-pathological disorders affecting the patient's relationship with food and his/her own body. These disorders generally are seen in young females. Anorexia nervosa involves anoutline of "self-starvation, but also include binge eating and purging". A pattern of binging and purging are involved in bulimia. Binge eating disorders are generally characterised by episodes of uncontrolled eating without the purging behaviour.

Anorexia Nervosa

Anorexia was 1st described as "a nervous loss of appetite" in the medical literature in nineteenth century. It is considered as psychiatric disorders which is characterised by irregular eating behaviours, severe self-induced weight loss and psychiatric co morbidities. In 1970, Early criteria emphasised anorexia nervosa as a "behavioural disturbances (self-starvation, loss of body weight), endocrine disturbances (loss of menstrual cycle, loss of sex derive) and psychopathological disorder (fear of fatness)".

Incidence and Prevalence: As per several researches AN is more dominant in females than compared to men by almost 10%. 0.3% has been recorded in as an average prevalence rate for females who are young as per several epidemiologic studies. Each year in out of 10000 population there is an incidence of AN of about 8 cases. It has been noted that the in industrial western societies there is a predominance where there is an idealisation of thin body types.

Theories of Aetiology

There are primarily 3 theories of aetiology:[2]

1. Cognitive – behavioural
2. Biological
3. Psychodynamic theories

In Cognitive behavioural theory it focuses on the role of severe fear of gaining weight and disturbance in the body image which in turn is motivation of the anorexic individual to be subjected to certain behaviour such as "restrictive eating, excessive exercise" to maintain the weight reduction or accomplish loss in weight.

A combination of numerous variables like "personality characteristics, interpersonal stress, pressure to be thin, body image disturbances and social modelling (media representation of extreme thinning as beauty)" often interrelate to motive the onset and maintenances of eating disorders.

Biological perspective takes into interpretation the title role of genetics and pre morbid temperament or personality characteristics that might play a role in the development and care of the illness.

Psychodynamic theory hypothesizes that individual's grief from AN find a sense of self and identity in the existing disorder. Here it states that the individual possesses a dangerous terror of maturation including "weight gain, puberty and sexuality" and finds a sense of safety with a disorder that avoids the feared events.

Signs and symptoms[8]

Physical signs	Behavioural signs
• Excessive Weight loss • Dry skin • Brittle nails • Low blood pressure • Abnormal heart rhythms • Scanty menstrual periods • Alopecia Xerosis • Bloated stomach	• Refusing to eat • Distorted self perception • Obsessive compulsive disorders • Depression

Causes:

- During puberty or pre pubertal period, having positive history of severe trauma or any emotional stress
- Irregularities in brain chemistry- "serotonin" may play a part which is involved in depression
- Due to high cultural value for lean body
- Aninclination towards perfectionism
- Positive familial history

Risk factors

Includes:

- Weight gain
- Dieting
- Suffering from OCD
- Participation in any events that prize a lean body
- Pessimism attitude
- History of any traumatic events in life
- Experience of any big life change eg- moving to new places or new school

Diagnosis

This includes a questionnaire, some laboratory examinations and most important – the clinical examination.

"**SCOFF** questionnaire"[6] developed in Great Britain is generally used by the doctor for diagnosis.

"S = do you feel sick because you feel full?"

"C= do you lose control over how much you eat?"

"O = have you lost more than 13 pounds recently?"

"F= do you believe that you are fat when others say that you are thin?"

"F= does food and thoughts of food dominate your life?"

Some important laboratory investigations routinely done for AN –

- Blood investigations to look for anaemia, electrolyte imbalance, cholesterol levels, liver and kidney functions.
- Electrocardiogram
- Bone density test for osteoporosis

Treatment

Nutritional rehabilitation and **psychotherapy** are considered corner stones of treatment.[6]

Nutritional rehabilitation helps the individual to reach a healthy weight, normalise eating patterns and their perceptions towards hunger and fullness.

Goals of weight gain are:

"2 – 3 lbs (0.9-1.4 kg / week) for hospitalized person.

0.5 – 1 lbs (0.2 – 0.4 kg/ week) for outpatient".

Enteral and parenteral nutrition: Individual requires tube feeding or intravenous feeding nutrition. Parenteral nutrition is through veins. Intravenous feedings must be administered slowly and very carefully to avoid refeeding syndrome. This can cause hazardous hormonal and metabolic variations that disturbs electrolyte equilibriums. This may result in heart failures. The "MAUDSLEY APPROACH" [8] is used for adolescent and other young people in the early stages of AN. This approach for refeeding may be effective. The family being the central player in person's nutritional recovery family therapy is advised.Parents take charge of planning and supervising all of their child's meals and snacks.

Psychotherapy and medications[2]: Considered as main therapeutic approach. This should be given in an individual, group or family setting.

Anti-depressants: Studies suggests that individuals suffering from OCD could be useful from this anti-depressantmedication.

Nutritional suppressants: Vitamins such as – "vitamin B 12, C. D and minerals, calcium, iron, zinc and magnesium supplements" may be recommended.

Bulimia Nervosa: In 1979, it was 1st recognized as a "psychiatric syndrome" where overeating is followed by vomiting and considered as an aberrant pattern of behaviour.Characterised by excessive concern towards body size, binge eating and inappropriate compensatory behaviours.[7]

Demographic features: Women are more bulimic than man. Teenage girls and young women are commonly affected.

Signs and symptoms: With bulimia nervosa, this also happen several times ina day for plentiful months which often lead which prevents weight gain due to purging.

Purging may include

- Forced vomiting
- Extremeworkout
- Use of laxatives, enemas or diuretics

Symptoms

- Investing a lot of time in workout
- Suddenly consumption large amounts of food or purchasinghefty amounts of food that disappear right away.
- Repeatedly going washroom after meals
- Eliminating away packages of laxatives, diet pills etc

Causes

- The exact cause isnot known.
- Individual is aware of his/her abnormal eating pattern.
- Fear with binge purge disorder may be present
- Genetic, psychological, family, society factors may play a pivotal role.

Types[8]

1. **Purging type** – people who binge and purge using vomiting, laxatives, diuretics oe enema.
2. **Non purging type** – those who exclusively use fasting and workout as compensatory behaviour.

Diagnosis

A physical examination will be done for these patients showing-

- Ruptured blood vessels and eyes (from strain of vomiting)
- Dryness of the mouth
- Pouch like appearance for cheeks
- Flushes and reactions present
- Evident minute cuts on top of finger joints

Blood investigations may show imbalance in electrolyte level or dehydration.

A detailed dental inspection may show dental caries and marginal gingival inflammation.

Wearing away of enamel or pitting are present due to prolonged exposure to acid during vomiting.

Treatment

- Amalgamation of nutritional, counselling, psychotherapy and medication.

"Nutritional counselling with cognitive behavioural therapy" is ideal psychotherapeutic approach.

- Anti-depressants

"Selective serotonin re uptake inhibitors" (SSRIs) used such as:

1. Fluoxetine
2. Sertraline

During initial days of treatment above medications increase the risk for suicidal so adolescent and young adults should be cautiouslywatched.

Psychotherapy[8]

1. **Cognitive behavioural therapy:**

   This may include: During the initial sessions consistent eating schedules of 3 meals /day and schedule snacks are built up. Dairy will be maintained for eating patterns. Exercises will be assigned by the therapists that will further help in changing the behavioural responses to unhelpful thought pattern.

2. **Interpersonal therapy:** Here the therapists do not deal with weight, food or body image. The goals are to:

- Feelings Should Be Expressed
- Tolerance of Uncertainty and Change Should Be Discovered
- Development of a strong sense of individuality and independence should be done.

3. **Motivational enhancement therapy:** Therapy is reinforced in an individual or group setting and manages to give an empathetic approach to help people have a better understanding and change their attitude concerning food.
4. **Focal psychodynamic therapy:** Focuses on how unresolved early childhood experiences may a role in later development of eating disorders. Therapists helps to gain insight into how certain stresses and conflicts in early years may have created emotional patterns and negative way of thinking.
5. **Diaelectrical behavioural therapy:** This incorporates mindfulness, acceptance skills and emotional regulations.
6. **Family therapy:** This therapy helps to grow a better understanding between all the family members and their complex nature of eating disorder with improving their communication skills with one another and train on coping up with stress and adverse feelings.

Binge Eating Disorder

Characterised by "presence of binge eating and three or more behaviour indicators related to over consumption of food". This must happen two days per week for six or more than six-month duration in minimum, and vomiting as inappropriate compensatory behaviour is not associated with this disorder.

Theories of aetiology:

- Depression is often associated and lowtemperament often implicated in aetiology
- Neurotransmitter and hormones have been hypothesised in onset of this disorder including "cholecystokinin, somatostatin, endogenous opiates and serotonin". [5]

Clinical Features Characterised by:

- Due to lack of self-control, individual consumes huge amount of food which is larger than normal amount within two hours period.
- Individual should have at least three of these additional findings- person consumes more amount of food than normal required, continue to eat until feels uncomfortable, even when not hungry consumes large quantity of food.
- Intake of food in secrecy.

Treatment: FDA approved "**lisdexamfetamine dimesylate (Vyvanse)"** as the first ever medication for the treatment for bingeveating disorders in the year 2015. It is a CNS stimulant which was previously approved to treat "attention – deficit – hyperactivity disorders". [5] Other psychotherapy treatment are similar to bulimia nervosa.

Complications of Eating Disorders[8]

Gastrointestinal complications

- Frequent use of laxative causes bloating, dehydration, electrolyte imbalances.
- Frequent forced vomiting causes irritation of gut lining resulting complications include gastro oesophageal reflux disease, gastritis and oesophagitis.

Heart complications

- Bradycardia is a common finding in such patients.

Hormonal complications

- Hormonal changesoccur due to prolonged starvation which further worsens the health consequences. Hormones commonly affected are – "growth hormones, stress hormones and thyroid hormones".
- This leads to irregular menstruation. Infertility, pregnancy complications, thinning bones (osteoporosis).

Bone complications

- Patients with A.N experiences osteopenia and osteoporosis. It leads to bone density loss.

Blood complications

- Anaemia is common result of malnutrition and starvation.

Skin complications

- Dry, flaky skin are commonly encountered implications associated with brittle nails and hairs.

Neurological complications

- Seizures, numbness in hands and feet (peripheral neuropathy), disordered thinking are encountered among patients.

Emotional complications

- Anxiety disturbances along with depression are frequently seen. These individuals have higher risk for substance abuse including smoking, alcohol and drug abuse.

Oral Manifestations[1]

Eating disorders share similar oral manifestations. These are some most common encountered manifestations

1. Dental erosion

- "Hell, storm and Hurst" et al initially reportedthe impact of eating disorders.
- Secondary to frequent vomiting, gastric reflux, Perimyolysis is a specific type of enamel erosion seen. This usually cause increased tooth sensitivity to touch, hot and cold temperature.

2. Dental caries

- Prevalence of caries remains unclear among normal populations and eating disorder patients.

3. Periodontal diseases

- Generally poor oral hygiene leads to inflammation of the gingiva and which further predispose to periodontitis. Vitamin C deficiencies may also affect marginal periodontitisleading to gingivitis.

4. Mucosal lesions

- Angular cheilitis, candidiasis, glossitis and mucosal ulcerations are common findings encountered in these individual.
- Soft palate is generally injured by objects used to induce vomiting.
- Due to offending action of acid during vomiting to the epithelial surfaces, erosions are commonly encountered.

5. Salivary findings

- Enlarged parotid glands due to "sialadenosis" which is a non-inflammatory expansion of the salivary glands.
- Xerostomia as sideeffect of many anti-depressant medications.
- Necrotizing sialometaplasia and association with bulimia has been reported.

6. Miscellaneous-

- Includes stomatopyrosis and dysgeusia.
- Accelerated alveolar bone loss due to osteoporosis is common.

Dental management

- While taking history, questions related to eating disorders should be included.
- Custom trays and 1.1% neutral fluoride gel are recommended by the researcher.
- Due to increased chances of tooth wear, individual should avoid brushing during initial hours after vomiting.
- Intake of acidic drinks, low calories beverages should be reduced.
- Composite restorations reducesensitivity.
- Full mouth reconstruction and occlusal rehabilitations should be done by porcelain veneers.
- Regular dental check-ups should be encouraged.

Conclusion

Eating disorders being considered as psychiatric

disorder require specialized diagnostic and treatment approaches. These diseases are markedly different from obesity where the latter is often considered as a "chronic medical disorder". Therefore, the clinician should be able to correctly diagnose and distinguish between the eating disorder and obesity. A multidisciplinary approach of a dentist, a psychiatrist and a physician are important and mandatory for correctly diagnosing and proper management of the patient with these disorders.[1] The oral manifestations should be treated at the earliest, failure to which it may lead to more severe systemic complications.

Pigmented Lesion of Oral Cavity

Namrata Mishra

Post Graduate Trainee, Department of Oral Medicine and Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

In the oral fissure most commonly pigmented lesion is seen.Lesion depicts a large diversityof clinical entities,from anatomical to systemic illness manifestation. Systemic history,dental history,drug history,extra oral and intraoral study is needed for the evaluation of patient.some cases laboratory exploration and biopsy are being done.

Keywords: *Diagnosis, Exogenous Pigmentation, Drug Induced Pigmentation, Endogenous Pigmentation.*

Introduction

In the oral fissure most commonly pigmented lesion isseen. Lesion depicts a large diversity of clinical entities from anatomical to systemic illness manifestation. Pigmentation designate as process of deposition of pigments in tissues. Different pestilence will escort to variety of tinge in the mucosa. Pigmented lesion of oral fissure is due to escalation of melanin pigments,expanded number of melanocytes, drumming out of accidentally introduced exogenous materials. Oral pigmentation may be anatomical or inveterate. Morbid pigmentation can be sorted into exogenous and endogenous based upon the germ.[1,2]

Exogenous pigmentation is actuated by drugs, tobacco, smoking, amalgam tattoo, or heavy metals instigated.

Endogenous pigmentation can be analogous with endocrine disorganization, syndromes, infections, chronic irritation, reactive or neoplastic.[2]

Classification

Burket's classification:

Endogenous: Focal melanocytic pigmentation: Freckle/ephelis, Labial melanotic macule, Oral melanoacanthoma, Melanocytic nevus, Malignant melanoma

Multifocal or diffuse pigmentation: Physiologic pigmentation; Drug induced melanosis; Smokers melanosis; Inflammatory hyperpigmentation; Melasma

Melanosis associated with systemic or genetic disease: Addison'sdisease; Cushing's disease; Graves' disease; Primary biliary cirrhosis;Vitamin b12 deficiency; Peutzjeghers syndrome; HIV/AIDS associated melanosis; Café au lait pigmentation;

Idiopathic pigmentation: Laugier- hunziker pigmentation;

Depigmentation: Vitiligo

Haemoglobin and iron associated pigmentation: Ecchymosis; Purpura; Hemochromatosis;

Endogenous pigmentation: Amalgam tattoo; Graphite tattoo; Ornamental tattoo; Heavy metal pigmentation; Hairy tongue; Drug induced pigmentation; Medicinal- metal induced pigmentation.[3]

Based on Hue: Red- Blue-Purple Pigmentation

Blanching: Haemangioma; Varix

Non-blanching: Thrombus; Hematoma

Brown pigmentation: Melanotic macule; Pigmented nevus; Melanoma; Melanoacanthoma

Blue–grey pigmentation: Amalgam tattoo; Other foreign body tattoos; Blue nevus

Drug-induced pigmentation: Anti-malarial drugs; Bleomycin; Clofazimine; Tetracycline; Oral contraceptives; Doxorubicin; Ketoconazole; Minocycline; Zidovudine

Differential verification of oral pigmented lesion: Appraisal of the patient depicting with a pigmented lesion should add on a full systemic and dental history, drug history, extra oral study, intra oral study with some laboratory exploration.

- Onset and duration of contusion should be included in the history such as,
- Presence of congenital signs and symptoms.
- Associated skin hyperpigmentation presence.
- Use of non-prescription and prescription drugs.
- Smoking history
- Pigmented contusion on lips, perioral skin, face should be distinguished.
- Evaluation of number, distribution, size, shape, and hue of lesion.
- Non neoplastic lesions depictregularborders, tiny, symmetric and uniform in tinge, whereas irregular borders, hue variation and surface ulceration show neoplasm.
- Diascopy is also as a tool for verification.

Melanotic macule: It is most commonly seen in oral mucosa which is of melanocytic origin. In adult females' patients tiny, isolated, well defined, uniform pigmented lesions are visualised. Lower rim, gingiva and palate are most common site. Factors affecting melanotic macule is localised trauma, functional hyperactivity, differential confirmation is amalgam tattoo, melanoma, melanocytic nevus, focal ecchymosis.[4]

Melanoplakia: When there is a benign variation without any aggressive changes of melanin pigment is "melanoplakia". Depth of tissue and amount of melanin presence determines the clinical presentation of melanoplakia. Incase of women when one consumes oral contraceptives temporary light brown pigmentation is seen. Pregnancy and increased level of estrogen and progesterone causes the same.[5]

Lentigo: The persistent changes seen on face and perioral region which are related to prolonged solar damage. They are tan to dark brown tint and size ranges from 2mm to 2cm. Hyperplasia of basal melanocytes and elongation of rete pegs is seen in histologically.

Leopard syndrome: Autosomal, dominant disorder with characteristic features that include multiple lentigines café au lait spots electrocardiographic condition, ocular hypotelorism, obstructive cardiomyopathy, pulmonary stenosis, abnormal genitalia, retardness of growth and deafness.

Laugier–hunziker syndrome: Acquired benign macular hyper pigmentation. Occurs due to alteration in the function of melanocytes which causes increase in synthesis of melanosomes subsequent transport to basal cell layer.

Drug Induced Pigmentation

Antimalarial drug: Prolonged use of antimalarial drug depicts slate –grey in color,which resembles silver asplenamine.

Minocycline: Tongue, gingiva, mucous membrane, hard palate is predominant site for deposition which is brown in colour.

Malignant melanoma: Melanocytic origin malignant neoplasm also known as melanoma or melanocarcinoma. Lacks pigmentation clinically but presence of melanin histopatthologically which is composed of non-pigmented melanocytes.

Etiology: Xeroderma pigmentosum, increased number of melanocytic nevi, ultraviolet exposure, genes affecting are RB1, CDKN2A, Melanocortin-1receptor gene.

Types: Nodular melanoma, Amelanotic melanoma, Acral lentiginous melanoma, Mucosal lentiginous melanoma.

Seen in palate, maxillary alveolar ridge which is a deeply pigmented disorder.

Most deadly primary skin carcinoma. Cutaneous melanoma is mostly observed in white crowd. Male predilection is common of mostly over the age of 45 incidence is increasing which is a suggestive study of epidemiology. ABCDE CRITERIA is best explained in cutaneous melanoma; asymmetry, irregularborders, variegation of colour, diameter greater than 6mm, andevolution or surface elevation. Looks of nodular lesions,which implies invasion into the deeper connective tissue which gives a sign of good prognosis. Poor prognosis is associated with the level of tumour involvement in the dermis [**Clarks level of invasion**], neurotropism, surface ulceration, lymphatic or vascular invasion, thickness of tumour [**Breslow tumor thickness**].

Differential diagnosis: Haemangioma,Traumatic haematoma, Blue nevus, Traumatized nevus.

Treatment planning: Mode of treatment planning in malignant melanoma is wide local excision in early stage.Wide local excision along with regional lymph node dissection is doneif there is involvement of lymph and also bone removal is also indicated if there is involvement of jaw in case of more advanced stage. In case of metastatic lesion chemotherapy and radiation therapy is being done.[6]

Addison's disease: 1 in 100,000 people are affected by this rare endocrinal disorder termed as Addison's disease. Female and male predilection is same and it is observed in all age groups. Thomas has first elaborated this disease in 1855 in the book entitled [On the constitutional and local effects of the disease of suprarenal capsule].Manifestation of this disease is weight degradation, prolonged worsening fatigue, overall weakness, appetite loss, hypotension.{bronzing} narrates the hyper pigmentation which is generalized and mainly seen on sun exposed skin and over pressurized area just like elbow and knee, which are induced by escalated levels of beta lipotropin. Hyperkalaemia and hyponatremia are associated gastrointestinal distress like anorexia, nausea, vomiting. Palate, tongue, buccal mucosa, vermillion border of lip area is the first evidence of intra oral pigmentation.[7]

Cushing's disease: ACTH dependent [80%]and ACTH independent [20%]is responsible for chronic glucocorticoid excess. Later are mainly due to benign [60%] or malignant[40%] adrenaltumours.

Classification

ACTH dependent: bilateral adrenal hyperplasia, adrenal adenoma, adrenal carcinoma,ectopic ACTH secretion,Cushing's diseaseor ACTHsecreting pituitary adenoma.

ACTH independent: Iatrogenic Cushing's syndrome.

Pseudo Cushing's syndrome: Obesity, alcoholism, depression.

Clinical manifestation is buffalo hump, circular face, obesity, fragile bone[osteoporosis], hypertension, menstrual abnormality, hirsutism, anxiety, purple to red and wide abdominal cutaneous striation, insomnia, retardation of growth, euphoric ruddy face.

Diagnosis: When there is establishment of diagnosis of Cushing's syndrome segregates into disorders of excessive ACTH and ACTH independent primary adrenal over production of cortisol disorders [bilateral micronodular/macronodular hyperplasia, carcinoma, adenoma] in which plasma ACTH significance are less or unnoticeable. To determine the cause ACTH is measured. The patients with low/unnoticeable values should next encounter adrenal gland imaging along with computed tomography or magnetic resonance imaging to recognize unilateral masses with bilateral disease or adjacent contralateral atrophy. Those with normal or upraised ACTH values should undergo additional testing, usually with pituitary MRI, 8mg dexamethasone suppression, corticotropin releasing hormone, inferior petrosal sinus sampling. Spotting and successive resection of abnormal ACTH or cortisol-producingtissue/ tumour, involvement is there in the optimal treatment of Cushing's syndrome. First line of treatment of Cushing disease is transsphenoidal surgery.[8]

Medical treatment-to minimise ACTH production proopiomelanocortin transcription factors evaluation is being done. These add on the somatostatin analoguepasireotide and dopamine analogue cabergoline for the proper functioning. [9]

Peutz–Jjeghers syndrome: It is a pigmented mucocutaneous lesion, an inherited, autosomal dominant disorder differentiated byhamarmatous polyps in the gastrointestinal tract. From 1in 8300to 1in 280000 individuals are estimated in this disease. It is also associated with remarkable morbidity, variety of clinical course, mostly seen in small bowel

History: Description was given by CONNOR in 1895 and illustration by HUTCHINSON in 1896 described in a pair of identical twins first with melanotic macule. Peutz in 1921 of Dutch family had given the primary description of Peutz Jegherssyndrome which was published. Nasal polyposiswas described by PEUTZ and JEGHERS enumerated a description in 10 cases from various families in his work in 1949, and defined the relation between pigmented lesion, gastro intestinal polyposis and elevated risk of neoplasm, approximately half of his patients has encountered gastrointestinal neoplasm.

Gene responsible for this disease is only the remarkable mutation inducing PJS affect the STK11 [serine/threonine protein kinasealias LKB1] which is located on chromosome19P13.3. STK11 is the

official nomination for LKB1by the human genome organization. This gene was named in 1998. It encrypts versatile serine threonine kinase, which is dominant in second messenger signal transduction. The serine threonine kinase harmonizes cellular multiplication, regulates cell polarity, and noticed to have a predominant role in responding to low cellular energy levels. The STK11 protein is responsible for inhibition AMPK activated protein kinase and signals downstream to stop rapamycin mammalian aim.

Clinical features of PJS are in intestinal mucosa, anal area, palms, soles of the feet, and sparely on the fingers, on the buccal mucosa, orbits, nostrils, and perioral region, and in rim mucocutaneous macules are seen as hyper pigmented lesion. 95%of the patients shows the characteristics pigmentation and are induced by pigment laden macrophages in the derma. They appear particularlyflat, blue-grey to brown spots 1-5mm in dimension. Neoplastic degeneration of these lesion is extremely seldom. These macules can be differentiated from common freckles as they never seen in the oral cavity. Hyperpigmentation may fade during the period of adolescence.

Treatment planning: Intra operativeenteroscopy [IOE] and double balloon enteroscopy [DBE] is the two-prime mode of diagnosis and treatment of tiny bowel hamartomas. In intra operative enteroscopy is a mixture of laparotomy [or laparoscopy] withendoscopy. It allows arrangement to confirm the small bowel is appreciated and nearly all polyps are eradicated in an endoscopic or surgical manner. Double balloon enteroscopy technology that permits the inspection and remedy ofjejunum and ileum mostly in everypatient. The system comprises of a 200 cm enteroscopy and a 145 cm over tube which is having a latex balloon at their ends. By implementing these balloons to hold the intestinal wall, the endoscope can be pierced further without making expendable loops of intestine. [10]

Café au lait pigmentation: Café au lait macule [CALM] are termed after their typical coffee and milk tinge and a color only slightly darker shade than the surrounding dermis. CALM is mainly of two varieties they are coast of California and coast of maine. Coast of California is the most common which is having a fairly regular border, clearly and distinct margins. They may range in dimension from few mm to several cm and may be appeared as multiple or solitary spots. Coast of maine is second and less frequent type of CALM that is having irregular border and usually appears bigger and solitary. CALM is mostly seen in neurofibromatosis-1 [NF1] having an autosomal dominant condition differentiated in presence of numerous neurofibromas. [11]

Graves' disease pigmentation: Cutaneous manifestation is clinically associated with thyrotoxicosis which is having features of telangiectasia, erythema, hyper pigmentation hyper hydrosis, heat intolerance, warm dermis and the dermis illustrates direct role of thyroid hormone on dermal tissue. Direct thyroid hormone role in dermis is arbitrated through the thyroid hormone receptor. Thyroid hormone receptors were discovered in epidermal keratinocytes, vascular endothelial cells, Schwann cells, sebaceous gland cells, smooth muscle cells, skin fibroblasts, hair erector pillu muscle cells, and number of variety of cells that builds the hair follicle. Responsive genes of several thyroid hormones have been discovered in dermis. Thyroid hormone plays a vital controller of epidermal homeostasis. Thyrotoxic epidermis is seems to be slender but not atrophic. Clinical inspection has been complexing by the data that mostly thyrotoxicosis may add autoimmune mediated glycosaminoglycans accumulation with thickened dermis outcomes. The hair in thyrotoxicosis is often soft and fine. Plummer nails which is having a concave contour escorted by distal onycholysis. A diffuse, non-scarring baldness isalso remarked. In thyrotoxic patients, hair growth is enhanced which is a suggestive invitro studies. [12]

Amalgam tattoo: The pigmented lesion depicts unaccompanied, numerous or diffuse pigmentation. The introverted pigmented lesion which picturises dark hue are ephelis[freckles], tattoos and the mouth melanotic macule. Dental amalgam tattoo which is a most common solitary pigmented lesion. It occurs in almost 0. 4% to 0. 9% of the US and 8% of Swedish population among adults. It happens as an outcome of colouring of the tissue by foreign pigmented which was injected within or subepidermal either accidentally or intentionally. Amalgam fillings and metal molecules from prosthetic restoration which are soaked up accidentally is mostly used for dying of oral mucosa. Region of marginal gingiva or buccal mucosa is the clinical site where mostly oral mucosa tattoos is being observed. By the method of clinical examination or an x-ray, the metal fragments –the dust from amalgams or other metals inside the tattoo may be distinguished. During various dentistry arbitration the metal particles may accidentally approach the site of the oral mucosa. Hence it is feasible

that while doing the systematic preparation of the cavity, the gingival sulcus is hampered and the amalgam particles may invade into the epithelium. While doing the placement of restoration. While removing old amalgam restoration or removal of old fixed prosthetic fillings, the gingiva may be destroyed, and creates an entry point for the metal flecks. The tattoo is known asa modification in the hue of the oral fissure which is clearly appreciated in its setting without crushing, it remains static, polished and of dark grey to blue tint which is seen clinically. Surgical arbitration and excisional biopsy are the most common treatment modality. [13]

Graphite tattoo: Likely to occur on the palate and appeared traumatic implantation from a lead pencil. The lesions depict unusually macular, grey or black also focal appearance. Graphite bear a resemblance to amalgam in tissue although special stains can separate the two microscopically.[14]

Haemangioma: Most common tumour of infants which is distinguished by an initial proliferation during infancy followed by spontaneous involution over the next 5 to 10 years, evacuating a fibro fatty residuum. Tumour of microvasculature is considered to infantile hemangioma.4-10% of infants is affected in infantile haemangioma with a predisposition for female, Caucasian, less birth weight and premature infants.[14]

Lingual varix: Caviar tongue is also regarded as lingual varicosities and sublingual varices, which is thought as a physiological change, involved with advancing age, usually developed due to superannuated elastolyticdetoriation of sublingual veins. It is predominantly observed at the under surface of the tongue along the sublingual glands where the mucosal surface is slender and translucent which enables visualization of submucosal vascular construction. On dermoscopy test, dark blue lacunae propose absence of it. Less number of lacunae contained haem which was characteristically deposited in the lowest part of the lacuna shows an appearance [HYPOPYON]of the eye a new dermatologic symbolic term is used to elaborate significant character as half and half lacuna.[15]

Black hairy tongue: It is an acquired, benign state characterized by the looks of abnormally hypertrophied and filiform papillation elongation of dimension more than 3m on the dorsal surface of tongue.It is also regarded as hyperkeratosis of tongue, lingua villosanigra, keratomycosis linguae.Male predilection is more, elderly group, person who consume excessive black tea or coffee, alcohol and does smoking, and having poor oral hygiene, patients having antibiotics such as penicillin, neomycin, doxycycline and xerostomic agents, and antipsychotics drugs are mainly suffers from this disease. Patient should maintain good oral hygiene, gentle debridement with a soft toothbrush or tongue scrapper to encourage desquamation of hyperkeratotic papillae. Rinsing with diluted hydrogen peroxide or baking soda topical application is done to upgrade desquamation of keratinized filiform papillae.[16]

Conclusion

Pigmentation is known as the process of accumulation of pigments in tissues. Numerousdiseasesinduce varieties of hue in the mucosa. It can be emerged from intrinsic and extrinsic factors which can be anatomical or pathological. Dentist should be aware of proper diagnosis and treatment modalities.

Biomaterials in Oral and Maxillofacial Surgery

Madhumita Sahoo[1], Sthitaprajna Lenka[2], Karishma Rathor[3], Arkaja Sahoo[1], Suchismita Ghadai[1]

[1]Intern, [2]Professor, [3]Tutor, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Aim: This review aims in giving a brief idea on evaluation of the pros and cons of different hard tissues biomaterials and how the implementation of these biomaterials has aided in restoring the function of traumatized connective tissues.

Introduction: Over the years, there has been a significant difference in the use of biomaterials. The biomaterials however having an animal origin on synthetic origin have been used, yet there are many that need to be reported with passing years. Some researchers have revealed that implementation of the synthetic biomaterials show a lower rate risk in the transmission of disease. The use of the biomaterials in medicine and dentistry provides us with a thorough understanding of the scientific basis of these applications. The biomaterials had their discrete use for the hard tissue traumas and for the soft tissue traumas as well, according to the specifications and requirements the biomaterials that would best replicate the physiologic body part and would restore its normal function were used. The advances made in last decade have made the utility and applications in the clinical conditions possible.

Discussion: The hard tissue biomaterials with passing time went through proper research, a lot of implementation with few failures and improper cognizance of biomechanics finally paved a way to its successful contrivances in the treatment of traumatized hard tissues. The steady long-term improvement that has been seen successfully in case of the joint replacements for the TMJ serves a testament to this. The hard tissue biomaterials also play a major role craniofacial surgery with the skeletal fixation.

Conclusion: Consequently, it has to be noticeable from these frames of references that the applications of biomaterials currently being used, demand structural functions even in those organs and systems having no such structural importance in their nature or very effortless chemical or electrical functions.

Keywords: *Bone grafts, Implants, Plates, Screws, and Ceramics.*

Introduction

Biomaterials were not put into practice until the approach of on a sterile surgical procedure was introduced by Dr. J. Lister in the 1860s. With due course of time various biomaterials came into play, some proved to be successful and some exacerbated the infections. Biomaterials are the kind of materials that are used in the replacement of the part of the body in a much efficient, safe, steadfast, lucrative and biocompatible manner. It helps in restoring the normal functioning of the part that has been replaced. They come in both natural and synthetic forms. They have been further classified as Alloplasts, Allografts, Autografts, and Xenografts. The basis on which the materials can be considered as compatible materials for replacement are that it should be steady enough to be easily sized in an operating room, should be biocompatible, non-allergic, non-carcinogenic, and non-toxic with chemically inert nature. It should be dependable much to physically replicate those of the tissues that has to be replaced. The materials should be able to retain its new form with memory. They should

Corresponding Author:

e-mail: sthitaprajna@gmail.com

entitle the fixation to the host bone by the screws, sutures and wires. The materials should be synergistic enough not to enhance the growth of microorganisms nor foster the resorption of underlying bone or distortion of the adjacent tissues; it should be radio-opaque in order to permit the radiographic evaluation. It is the responsibility and outlook of the clinician to have a thorough appraisal of the diversity of the materials available and hence use them for the appropriate clinical procedures.[1,2]

The long-drawn biocompatibility of a material is reliant on the active relationship between host and implant and is dominated by many factors.[1] Calnar reported, the alloplastic implants may initiate 6 different biological responsesi.e.[1], Immediate inflammation with early rejection, Delayed rejection, Fibrous encapsulation·Incomplete encapsulation with progressive cellular response, Slow resorption and Incorporation. The successfulness of the biomaterials that is incorporated in the body not only depends on its physical and mechanical properties but also depends upon the surgical technique used by the surgeon along with the patient's activities and health condition, how the body is reacting to the materials also plays a major role. There can be certain failure due to deplorable effect of the materials on the body's immune system; for example, Implant might have effects like toxicity, induce allergic reactions, carcinogenic. So, taking the adversities into account the implants should be biocompatible enough not to provoke or irritate the surrounding tissue structures and should be accepted by the tissues along with whole of the body.[3]

Materials Used

Metallic biomaterials: Metals are used as biomaterials due to their outstanding mechanical properties with admirable thermal and electrical conductivity with some having anti-corrosion properties. Some metals aid as a passive substitute for hard tissue replacement such as temporomandibular joint, whole hip and the knee joints. These are even used fracture healing aids such as bone plates and screws, dental implants and for the spinal fixation devices. There are certain metal alloys that have been magnificent and actively used in devices like, vascular stents, catheter guide wires and orthodontic wires. Vanadium steel has been known to be the first metal alloy developed specifically for human use. It helped in the manufacture of bone fracture plates and screws. The metals such as, Iron (Fe), chromium (Cr), cobalt (Co), nickel (Ni), titanium (Ti), tantalum (Ta), niobium (Nb), molybdenum (Mo) and tungsten (W) were used in for the manufacture of implants as these can be pretty well tolerated by the body in minute amount.[4]

Stainless Steels: In order to overcome the minor disadvantages offered by the vanadium steel, stainlesssteel 18-8 type (type 302 in modern classification), came into practice for the first time for implant fabrication as it was stronger and corrosion resistant than the vanadium steel. Due to the corroding nature of vanadium steel in vivo, its being no longer used. With time 18-8sMo stainless steel came into play containing a small percentage of molybdenum to overcome its corroding property which came to be known as 316L stainless steel. Later in 1950s the carbon content of 316 stainless steel was reduced to have a better anti-corrosion effect.

CoCr Alloys: Substantially there are two types of cobalt-chromium alloys; Catastable CoCr alloy and CoNiCrMo alloy. The castable CoCrMo alloy has been used in dentistry and reasonably used in constructing artificial joints. The wrought CoNiCr alloy is relatively new and is mostly used in the stems of prostheses for joints like knee and hip. The molybdenum helps in making the grains finer leading to better strength after casting and the chromium enhances the anti-corrosion property. In vitro studies have suggested that particulate Co is toxic to human osteoblasts cell lines and restrain the synthesis of type-I collagen, osteocalcin and alkaline phosphatase in the culture medium. Howbeit, the particulate Cr and CoCr alloys are well tolerated by the cell lines with no visible toxicity.[5]

The Clemson university Advisory Board for biomaterials has been formally defined as to be "a systemically and pharmacologically inert substance designed for implantation within or incorporation with living systems."[1]Black defined biomaterials in as "a non-viable material used in a medical device, intended to interact with biological systems".[1]

Hard Tissue Biomaterials

Bone Repair and Joint Implants: With the advancement of the biomaterials and its various types through meticulous clinical researches have paved new pathways in the treatment of traumatized hard tissues, degenerated connective tissues. These researches have further lead to an escalation in the design quality, with a higher performance rate in vivo of the biomaterials. With due course of time the surgeons and researchers

have done advancement in the treatment of the joints, including Temporo mandibular joint (TMJ) by using fixation devices and artificial TMJ.There are various devices used in the treatment of hard tissues and are as follows.

Screws: Screws are the devices that have gained a wide acceptance over a period of time for the affixation of shredded bone particles. Basically bone screws are categorized into two types:

Cortical bone screws, these have compactthreads, and Cancellous screws, these have wide threads for getting more thread-to-bone contact. The threads might have a 'V' or a buttress shape. The cortical screws can be further classified on the basis of the following criteria, Penetrating power, Self-tapping and Non-self tapping. The self-tapping screws are known to have cut flutes which helps to thread the pilot drill-hole while positioning. On contrary, the non-self-tapping screws require a tapped pilot drill for the positioning. The grasping capacity of screws depends on the size of the hole of the pilot drill, depth of screw engrossed, the outer diameter of the screw and the quality of the bone. So, the designation of the screws ought to be based on the analysis of the calibre of the bone at time of insertion. Mainly the implementation of bone screws is done in the following case;As inter-fragmentary fixation device to "lag" bone fragments together, Attach a metallic plate to bone. The screws are used for the affixation of mandible fractures, fractures involving cancellous bone, oblique fractures in cortical bone and in bone plate fixation.[6]

Plates: Plates help in the fixation of fragments of the bone. They can be categorized as, firm or very rigid which is used to gain primary bone healing. And the other one is relatively flexible which helps in the physiological loading of bone. They come in a wide range of varieties. The cross-sectional shape decides the strength and rigidity of the plate.

Stainless steel plates: These aim in increasing the healing rate of the fracture, lessen the loss of bone in the site safe-guarded by the plate. Thereby it also helps in decreasing the occurrence of re-fractures that is usually seen in plate removal. As the bone and plate make a complex structure, they need a proper interlinkage. The interfragmentary compression causes friction atsurface, resulting in increased resistance to torsional loads. Contrastingly exceeding compression results in micro fractures and necrosis of the bones in contact as a result of the vesicular canals getting collapsed. The compaction between the fracture fragments can be acquired with a precise type of plate known as a dynamic compression plate. The most common mode of failure seen in bone plate-screw installationis loosening of screw and falling through of the plate.[7]

Osseous grafting materials: The successful outcome of the bone defects is totally determined by the growth of the new bone at the affected site. A global range of materials has been noticed to be suitable for the treatment of osteal defects. The materials used in the treatment of osseous defects has the properties that are expedient enough such as biocompatibility, osteoconductivity, osteoinductivity, availability, mechanical strength, restorability and ease of application. The materials used for the reconstruction of defects in the periodontium are categorized as Bone graft, Ceramics, or Synthetic polymers.

Bone Graft: Autograft- Bone graft that is achieved from the patient is known as autograft. It proves to be advantageous over other material, as osteogenic factors and progenitor cells serve as the wholesome source of them. It has been noticed that a large number of autografts have been obtained from the iliac crest. Nevertheless, the assemblage of graft demands a second surgical procedure and thereby leads to certain complications as in, creates donor-site morbidity and prospective fracture risk. The restricted accessibility of autograft can be outmaneuvered by using a relatively small volume of graft to elevate a synthetic bone graft as a substitute.[8]

Allograft: Osteal defects have been treated accompanied by a donor bone. It serves as a fallback mode to autograft. The allograft needs to go through a series of filters to take the edge off the risk disease transmission. Moreover, allograft is not readily available. The clinical studies utilizing allograft bone in reconstruction of bone defects showed a good result of new bone formation. The periodontal defects when treated with demineralized, freezed dried bone allograft (DMB) allowed a good sign of new bone growth with periodontal attachment.

Xenograft: It has been seen that; huge amount of the graft material has been attained from bovine-extracted anorganic bone. Xenograft has shown a visible change in new bone growth at the affectedsite, with limitation in the periodontal rejuvenation.

Ceramics: Hydroxyapatite: These can be derived naturally from corals or can be synthetically attained. It has been seen that the calcium phosphate compounds having chemical formulas similar to that of the anorganic bone are known to be defect fill materials. These materials have the potential to embody alveolar bone in patients having deformity in the periosteum. Although a recent clinical study suggested that the hydroxyapatite materials do not show a visible rejuvenation in the periodontium.

Bioactive Glass: These materials serve as a replacement for the synthetic graft materials aiming to aid in new bone formation. Precisely these materials intend to revitalize new bone formation at the site of implant-bone interface. Although this material has its set back, yet it has proved to be better in the reconstruction of periodontium as compared to the hydroxyapatite materials.[6-8]

Conclusion

Hence, while considering the biomaterials to be used all the pros and cons that have been discussed needs to be taken into consideration. Despite a huge number of materials available to surgeons, the applicability must be given utmost importance. If an implant is subjected to stress or local recurrent trauma, an inflammatory response and an eventual extrusion of the implant can occur, in order to overcome these there must be adequate recipient tissue available to cover the implant and shield it. With every passing day new breakthrough in the surgical method and instruments have allowed these materials to be used in ways that were less frequent.

Intracanal Irrigants Used in Pediatric Endodontic Treatment: A Review

Ankita Sinha[1], Susant Mohanty[2]

[1]Postgraduate Trainee, [2]Professor & Head Department of Pediatric and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Root canal therapy success in deciduous teethis achieved by meticulous removal of debris and necrotic tissue.Anatomy and root resorption increasethe complexity of the primary root canal system during instrumentation. Also, the formation of smear layer during instrumentation of root canal hinders the cleaning and shaping of root canal system. These are the major hindrance in complete eradication of bacteria while performing *cleaning* & *shaping* of root canal systems. The use of irrigants in root canalalong with mechanical instrumentation is very effective during procedure of cleaning and shaping in endodontic treatment. The irrigants that are most routinely used include saline, sodium hypochlorite, EDTA, chlorhexidine and MTAD. None of the irrigants alone fulfill the ideal requirements for optimal activity. Various studies have shown that anirrigating solution when used in a particular sequence is better in attaining optimal irrigation. The purpose of this article is to study the effectiveness & correlation among various available root canal irrigants used in pediatric dentistry.

Keywords: *Root canal irrigants, Primary teeth, Smear layer, Intracanal medicaments, Sodiumhypochlorite.*

Introduction

Maintenance of primary teeth areas essential as permanent teeth for the balanced development of occlusion, arch length maintenance, speech and mastication for healthy oral environment.[1] Advancing carious primary teeth generally required endodontic therapy as caries progression occurs at fast rate in primary teeth.[2] Successful endodontic treatment *relies* on the *combination*of *biomechanical preparation, irrigation* & *obturation*. Anatomy and resorption of root increases the complexity of the primary root canal system during instrumentation. Also, the formation of smear layer during instrumentation and presence of accessory canals, ramifications of root canals hinders the cleaning and shaping of root canal system. Intracanalirrigation at present is the best method of working for lubrication, microbial destruction, removal of dentin debris, and tissue residues duringbiomechanical preparation of root canal system.Intracanal irrigants facilitates mechanical debridement by emptying out necrotic loose wastes, disintegrating tissue residues & also helps in disinfecting the root canals. Studies haveshown that microorganisms recovered from asymptomatic teeth are different from those present within a clinically symptomatic tooth. The most frequent bacterial species in infected primary root canals were *Treponema denticola, Enterococcus faecalis and Porphyromonas gingivalis* reported by Cogulu et al in 2008.[3]

Ideal requirements of irrigants used in pediatric dentistry are[4]

a. It should have broad antimicrobial spectrum activity.
b. It should have high efficacy *against* anaerobic microorganisms & facultative microbial colonies organized in the bio film.
c. It should be *able* to disintegrate remnants of necrotic tissue of pulp.
d. It should *inactivate* endotoxin.

e-mail: drankita132@gmail.com

e. It should either suppress the formation of a smear layer during instrumentation in endodontic procedure / disintegrate the latter once it has formed.

f. It *should b*e nontoxic systemically when they come in contact with the *vital tissues* & should be *not caustic* to *periodontal* tissues with very slight possibility to result in anaphylactic reaction.

Normal Saline: It is isotonic to the body fluids and the most common used irrigating solution in endodontic treatment. It has been recommended to use in combination with other root canal irrigants or should be used in between intracanal irrigations with other solutions.[5] It is safe even if it is pushed into periapical tissues.[6]

Sodium Hypochlorite [NaOCl]: 0.5 % Sodium Hypochlorite was used initially for irrigation of infected wounds by Henry Drysdale Dakin and Alexis Carrel.[7]Sodium Hypochlorite is weakly *alkaline* which acts on the protein *albumin*, denatures & turn them soluble in water.[8] Hypochlorous acid and hypochlorite ions are present in NaOCl solution which when unite with organic tissues of root canals act as solvent & releases chlorine and this chlorine combines with the protein amino group to form chloramines. This ultimatelyled to degradation of amino acid and its hydrolysisand thus, they interfere with cellular metabolism. *Chlorine*is *a strong oxidant* possesses *antimicrobial action*, which impedes bacterial enzymes actions through irreversible oxidation of theirsulphydryl group. NaOCl is used in concentrations ranging from *0.5% to 5.25%;* it is a potent antimicrobial agent which effectively *dissolves pulpal remnants* and organic components of *dentin*. It is usedin concentrations of 0.5– 5.25% solution at pH 11 and 0.5% solution (Dakin's solution) at pH 9. NaOCl is well recognized for its antibacterial activity. *25°C* increase in temperature,increases the *effectiveness* of sodium hypochlorite by a *factor of 100* but it gets decrease when diluted.[9] NaOCl has been commonly used but it has unpleasant taste and odor; inability to completely remove smear layerand relatively toxic to periradicular tissues and damages permanent tooth follicles, damages oral mucosa and peripheral tissue.[10]

Hydrogen peroxide: It is popularly used for disinfection and sterilization in dentistry in concentration ranging from 1% to 30%[11]. It works by creating effervescence which removes debris and also acts as an oxidizing agent which efficiently denatures bacterial proteins and DNA. *Studies* have shown that in *higher concentration*, it is not tolerated by patients and also has the possibility of inducing cervical resorption.[1]

Chlorhexidine gluconate: Chlorhexidine *[CHX]* gluconate is used in dentistry because of *antimicrobial* properties. It has a wide antimicrobial spectrum & is effective against both gram *(++)* andgram *(--)* bacteria as well as yeasts.2% CHX is used in *endodontic procedure*. It acts by adsorbing onto the cell wall of the microbes & results in leakage of the *intracellular* constituents. Studies have shown that at *low concentrations*, small molecular weight substancesespecially phosphorus & potassium leak out showing bacteriostatic effect of CHX. It also shows bactericidal effect caused by the precipitation or coagulation of the cellular cytoplasm,which is attributable to cross-linking proteins at high concentration[12]. *Studies have* depicted that CHX in liquid form eliminate bacteria more quickly than the CHX gel. 2.5% NaOCl in combination with 0.2 % CHX showed greater antimicrobial effect than that of either irrigant used separately. But their combination result in carcinogenic product which can possibly leak into surrounding tissues. Its use as final irrigant in endodontic treatment is contraindicated by khademi et al because of its limited effect on gram negative bacteria when compared to its effect on gram positive bacteria[13]. CHX gluconate, in concentrations *0.2%-2%,* offers a *very good alternative* for root canal irrigation with because of *antimicrobial activity*. Many *studies* have shown that it has optimal biocompatibility in clinically used concentrations. It is foundthat in bactericidal concentrations, it isinjurious to canine embryonic fibroblasts & aid continuance to bacterial lifecycle at low concentrations.[14]

Ethylenediamine Tetraacetic Acid (EDTA): *EDTA* is a *chelating agent*routinely used for the removal of *thei*norganic portion ofsmearlayer in endodontic procedure.The very frequently used method to remove the smear layer is using 17% concentration of EDTA for one minute followed by a final rinse with NaOCl. The prolonged exposures cause*excessive removal* of both peritubular & *intratubular* dentin[15]. *EDTA* (17% percent) does not possess antibacterial activity. EDTA acts by reacting with the calcium ions in dentin which results into soluble calcium chelates.[16] The continuous rinse with 5ml of EDTA (17%)as a final rinse for 3 minutes; efficiently removes the smear layer from root canals[17]. Studies conducted shownthat when EDTA used as an irrigant in primary teeth, it deleteriously affected the dentinal tubules which may be the cause for primary tooth erosion later.[18]

Citric acid: Citric acid also used as airrigant for removal of smear layer. Generally, it is used in range of 1%-50% concentrations[19]. Studies showed that 10% citric acid when used as a final irrigant results in good removal of smear layer from apical root-end reported by Gutmann*et al*[20]. Also found that 25% concentration of citric acid was not much effective in *eradication* of biofilm of *E. faecalis* after 1, 5,10-minute interval of exposures.[21, 22]. Studies have shown 6% citric acid for 15 to 30 seconds is quite effective in removing the smear layer of the primary teeth but at higher concentrations peritubular dentin destruction was observed.[23,15]

MTAD: Torabinejad et al developed a MTAD irrigant which is combination of chelating and antibacterial properties. *MTAD* is a combo of *tetracycline isomer*(i.e. 3 % doxycycline), *4.25% citric acid*, and *detergent* (tween-80).[24] Acid removes the smear layer & doxycycline shows *antibacterial* effect. It is advised to use MTAD clinically for *20 minutes* as initial irrigant then irrigated by 1.3% NaOCl which is followed by final rinsing with *MTAD* for 5 minutes.[25] The results depicted that MTAD is effective for the removal of the smear layer but does not cause change in the structure of the dentinal tubules. Nara et al conducted a study to compare the antimicrobial efficacy of *3% NaOCl,* MTAD & *propolis* against E. faecalis and found that MTAD was more effective than 3% NaOCl and propolis against*E. Faecalis.*[26] *Venkataram et al* conducted study to differentiate the *effectiveness* of *chamomile, MTAD* and 2.5 percent of *sodium hypochlorite* on removal of smear layer from the root canal system of deciduous teeth and found MTAD is most effective among all.[27] Studies have shown that MTAD irrigant is less cytotoxic when compared with other irrigants like 3% hydrogen peroxide, EDTA. But there is chance of discoloring the young permanent buds present below the primary teeth. Thus,MTAD use is limited in primary teeth.[26]

Maleic acid: Maleic acid is anirrigant which is actually a mild organic acid. *Ballal et al* in 2009 reported that 1 min *final* irrigation with 7 percentconcentration of maleic acid was more efficient than using 17% concentration of EDTA in removal of *smear layer* from the apical 1/3rdof the root canal.[28]

Tetraclean: Tetraclean is a combination of doxycycline hyclate, an acid, and a detergent. Tetraclean is similar to *MTAD* with a reduced amount *of doxycycline* [50mg/5ml in place of 150mg/5ml for *MTAD*], polypropylene glycolas surfactant, cetrimide, *citricacid*. It is suggested to use, it as a 5-minute final irrigant rinse to remove microbial population & smear layer of the infected root canals.Studies have shown that *Tetraclean*induced a high degree of biofilm disintegration in following time intervals i.e. 5, 30, 60 minutes at *20°Cwhen* compared *withMTAD.*[29]

Smear Clear: Studies have shown that Smear Clear is a chelating agent consisting of (17%) EDTA solution along with cetrimide & extra proprietary surfactants when used for 1 minute. These contents help in removal ofthe residual inorganic matter from the canal during endodontic procedure. Smear Clear consists of cetrimide (quaternary ammonium*compound*) & a *cationic detergent* which is *effectiveagainst* gram++ and gram– microbes.[30]

Herbal Irrigants

Triphala: Indian medicinal herbal formulations *Triphala* consistof dried & powdered fruits of 3 medicinal plants. They are named as Terminalia Bellerica, Terminalia Chebula & Emblica Officinalis. Studies reported that Triphalaobtained 100 percent destruction of E. faecalisat *6* minutes. *It contains fruits* that *are rich in citric acid* removes thesmear layer.[31]

Morinda Citrifolia

Morinda Citrifolia commercially known by Indian Mulberry or Noni is considered indigenous to tropical countries. Its juice is broadly used for the sanative effects such as *antibacterial, antihelmenthic, analgesic, hypotensive antiviral, antitumor & anti-inflammatory.* Various invitro studies were conducted which reported that the *Morinda Citrifolia* was effective to remove smear layer in primary teeth[32].

German Chamomile and Tea tree oil

Anothermedicinal plant namelyGerman Chamomile (*Marticariarecutitia L.*) used mostly for its analgesic, anti-microbial, anti-inflammatory, sedative and antispasmicproperty. *Tea tree* oil (*Melaleuca alternifolia*) isan Australian plantwhich has antiseptic, an antifungal & a mild solvent property. Tea tree oil's important active constituent is terpineol (usually 30- 40%), which possess *antibacterial* & *antifungal* properties. An SEM study was conducted using *german chamomile* extract & *tea tree oil*as aroot canal irrigants. Also, found that the effectiveness of chamomileinremoval of smear *layer* was predominant to *NaOCl* effectivenessbut *less than*the combination of sodium hypochlorite & EDTA.[33]

Conclusion

Through the time of biomechanical preparation smear layer is produced which consists of organic and inorganic components which interferes with the mechanical debridement of root canals. Thus, use of intracanal irrigants supplements the chemicomechanical debridement of root canal system.Irrigation plays important role in success of endodontic procedure of primary teeth. Further researches required for finding a suitable single irrigant which possess all the ideal requirements in pediatric endodontic treatment.

Methodological Errors in Research: A Review

Dharmashree Satyarup[1], Manish Kumar[2], Radha Prasanna Dalai[3], Sashikant Sethy[4], Karishma Rathor[4]

[1]Professor, [2]Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, [3]Professor & Head, Department of Public Health Dentistry, GITAM Dental College and Hospital, Visakhpatanam, Andhra Pradesh, [4]Tutor, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Errors occur in research either from ignorance or neglect. These when present undermine the generalizability of the study and compromise its authenticity. The list of errors in research is exhaustive but an attempt is made to list the most common methodological errors and the ways to prevent them.

Keywords: *Error, bias, research, methodology, study design.*

Introduction

Designing and conducting a research takes time, skill and knowledge. If the researcher does not go through the process diligently with a clear goal and method, it is very likely that the results obtained will be skewed or depict an inaccurate picture. Because research studies are carried out on people and are liable to practical and ethical constraints, they are almost invariably subject to bias or errors in research. Errors should not be interpreted as 'Mistakes' – rather errors are sources of uncertainty, both in estimates in the data and the inferences about the results.

Errors in research can occur due to various causes and reasons, but can be broadly classified into methodologic or non-methodologic errors. Methodological errors in research are of various types: random or chance variation, measurement bias, selection bias, reverse causation and confounding. Non-methodological errors in research include problems with execution of the study, reporting of results and issues influencing blinding, quality and completeness of data. The list in each category of error above is exhaustive as there are many potential sources of errors in any research. The aim of this review is to comprehensively address methodological errors, its types and points to be kept in mind to reduce them while conducting research.

Methodological errors:

1. **Random variation:** It is also called random error and caused by factors which vary from one measurement to another. They are caused due to natural variability or 'noise in the system'. It is a chance occurrence and hence idiosyncratic, might not occur in repeat studies.[1] It leads to false association between cause and effect. Parameters resulting from laboratory analyses can vary each time, over time. E.g. Reading on the weighing scale changes each time stance or position changes. Asking multiple questions and multiple analyses done on same set of data can also lead to increase in source of random error.

   Chance of errors tend to average out in studies with larger number of samples, repeating the measurements and better study design. Hence, predicting the effect of these errors and establishing a threshold which limits errors but permits execution of an efficient study in terms of expenditure and time are highly preferred. Also establishing the outcomes to be assessed and measured before the start of the study and use of single appropriate statistical analyses will reduce the possibilities of chance errors.

2. **Systematic Error:** Systematic error is defined as 'an error having a non-zero mean, so that its effect is not reduced when observations are averaged.'[2] Systematic errors are also known as BIAS. Bias is due to error either in study design, analysis or interpretation of results. Bias affects the validity (internal and external) of research. Systematic errors unlike random errors, stay even after multiple repetitions of the study as they are integral to study design and hence cannot be controlled by increasing the sample size. Systematic errors creep into research generally through a worn-out instrument, incorrectly calibrated instrument or a person consistently recording an incorrect measurement.[2,3] Systematic errors are caused due to selection bias, measurement bias and reverse causation.

2.1. Selection Bias: Including patients or subjects in a non-random way leads to selection bias. This causes the sample selected to be not representative of the population to be studied. Hence the findings of the study cannot be generalized. The following are different types of selection bias.

2.1.1. Sampling bias: Results from non-random selection of subjects, where certain subjects are selected over others, resulting in a biased sample.[4]The subjects are hence not balanced out and objectively represented. The external validity of the study is compromised due to sampling bias, whereas selection bias in contrast affects internal validity. Examples include exclusion of subjects due to dropouts, screening for participants before the trial etc.

2.1.2 Time Interval: Terminating a trial as soon as the preferred results are reached/ obtained leads to bias.

2.1.3. Exposure: The different types of exposure bias are:

- **Clinical susceptibility bias:** Occurs when one disease influences the occurrence of another disease.[5] E.g. Diabetics are predisposed to delayed extraction healing. Hence follow up of different impaction techniques among diabetics would actually give an untrue picture of which approach has lesser complications.
- **Protopathic bias:** Occurs when there is a lag time between the emergence of the first symptom of the disease and the start of treatment, both done before the diagnosis of the disease.[5,6,7]E.g. Prescription of painkillers for pain from an undiagnosed tumor may lead to the faulty conclusion that, the painkiller caused the tumor. This can be overcome by introducing a time-lag and excluding all exposures before the start of study.
- **Indication bias:** Occurs when there is a confusion about the timeline regarding cause and effect, especially when treatment influences exposure[7]. E.g. When a population is at high risk of developing a disease, a treatment initiated in them might lead to afaulty conclusion that the given treatment initiated the disease.

2.1.4. Data: Post hoc alteration of data to obtain results in bias. This can be either done by

- Cherry picking:When data is manipulated to give the desired results, while the real data is ignored in fear of obtaining hard to explain results.[8]
- Rejecting bad data on post hoc basis instead of predetermined criteria and excluding outliers (data that is significantly different from the others). This causes loss of information that could have been derived from these wayward observations.

2.1.5. Studies:

- Conducting multiple experiments and reporting only the expected and desirable outcomes.
- Including only the most desirable studies while doing a meta-analysis.
- Data dredging to present the most acceptable and significant results.

2.1.6. Attrition: It is similar to survivorship bias or failure bias. It occurs due to dropouts or withdrawal or nonresponse or protocol deviators. It excludes the subjects who

don't reach the end of the study. Hence, it can give results that are biased in relation to exposure and outcome.[9] For example, in a clinical trial for use of nicotine gum as an aid for quitting smoking, the researcher can obtain biased results if he excludes the dropouts as they dropped out because the gum was not effective.

2.1.7. Publication Bias: The results that don't conform with the beliefs, interests and prejudices of the publishing house or sponsor don't tend to be accepted for publication. Hence, most commonly the most acceptable ideas tend to be published than negative results, even though they might provide fresh view.[10]

2.1.8. Confirmation Bias: Occurs from the tendency to alter experiment design or results to conform with confirmatory evidence rather than trying to disprove hypothesis.[11]

2.2 Measurement Bias: The variability in data measurement, availability or quality that is not occurring by chance leads to bias in measurement.[12]It is also known as "detection bias".

For Example: A scale measures 1 kg as 1.1 kg due to some error. When used to measure weights of all respondents in research:1 kg = 1.1 kg; 10 kg = 11 kg; 100 kg = 110 kg

There are different types of measurement bias:

2.2.1 Recall Bias: This is usually seen when data is collected about an occurrence in the past. Some events are generally more remembered than the others, while others are remembered incorrectly and someothers, completely forgotten.[13] It depends on the way the events of the past are recollected by the participant. It is also referred to as response or reporting bias.Recall bias is most common in case-control and retrospective cohort studies where the researcher depends on self-reporting. For Example: Cancer patients may remember more exposure in their life that they consider 'toxic', but forget many other life experiences (visit to a nuclear thermal plant) that could have contributed to their diagnosis. Improper blinding of the researchers can lead to overzealous questioning expecting a specific answer from casesrather than controls. Hence, it can be prevented by stringent blinding and collection of data prospectively.

2.2.2 Observer/ Researcher/ Experimenter Bias: This occurs when the research is prejudiced to see what it intends to see. It results in systematic differences in the real scenario due to bias in the process of observation.[14]Observer bias is frequently possible as all medical tests interpretation is most commonly open to varied interpretations. Observer bias can be minimized by ensuring that the observers/ investigators are well trained and calibrated;screening priorly for potential prejudices; and have clear rules and criteria in place.

2.2.3 Attention Bias: This occurs when the study subjects alter their behavior because they are aware of being studied/ observed. This isalso popularly known as Hawthorne effect.[15,16]In this bias, the expected change is usually observed initially when the subjects are aware of being studied/ observed and then gradually reverts back to the original after the novelty of being observed wears off. It is more commonly seen in behavioral studies. In clinical trials, attention bias can be avoided by having a control group which ensures that the Hawthorne effect is present in both the groups equally. It can further be controlled by blinding of the participants. In observational studies, attention bias can be reduced to a great extent by discarding the first set of observations and permitting the subjects to get accustomed to being observed and hence safeguard against the effect of this bias.

2.2.4 Expectation Bias: This occurs when the researcher expects the subjects under the trial group to do better than those in placebo.[16] That is, the researcher errs in measuring the data in order to obtain the expected outcome. This can be overcome by blinding of the observer or those who are recording the outcome.

2.2.5 Verification Bias / Detection Bias / Work-up Bias / Referral Bias: This occurs due to improper use of gold standard test in the study. When the gold standard

is used selectively that is, it is used on some while others are excluded it results in increase of sensitivity (True positive results) and decrease in specificity (True negative results) of the diagnostic test.[17] This is especially seen when the gold standard is deemed expensive, invasive or risky limiting its widespread use and hence different gold standards are used in different patients.

Example: In emergency room, people with ankle swelling are more likely to get x – rays for fractures than those without swelling. People with ankle fractures without swelling are left out. This increases the sensitivity of the diagnostic test (Over estimation) and decreases the specificity(Under estimation).

2.2.6 Insensitive Measurement Bias: This occurs when the tool that is to measure the outcome lacks accuracy. The outcome measures selected are incapable of detecting clinically significant changes or difference thereby leading to Type II or β error. To reduce Type II or β error, power of the study has to be increased 16. Power of the study can be increased by increasing the sample size. Hence, to reduce insensitive measurement bias, a larger sample size has to be chosen for detecting a practical difference when one might not exist.

2.2.7 Lead time Bias: This is seen in scenarios of screening for diseases where the disease would have been left undiagnosed but for the screening test. Hence, the diagnosis of the undetected condition gives a false picture of longer survival.[18]

Example: Squamous cell carcinoma patient with metastasis dies at age 70 years. Cancer was diagnosed 1 year back at age 69 years (Survival rate of 1 year). But, if cancer is detected in routine screening at 65 years, and subject died at 70 years, then survival rate would be misinterpreted to be 5 years (Lead Time). This gives a false impression that screening of a disease increases the survival rate of a subject from the specific disease.

2.2.8 Response Bias / Volunteer Bias / Self-Selection Bias: It occurs when patients enrol themselves in a trial, which results in a non–representative sample. When patients self-enrol for a trial, representation of the sample is compromised.[19,20.] Also, the people who respond to a survey tend to be different from the those who choose to ignore it. It is the way a respondent answers a question to erroneously mislead because of an expectation to impress the investigator. E.g. No one really admits to a question on drunken driving even when they might have done so on some occasion.

2.3 Reverse Causation / Reverse Casualty: In cases where disease is determined by multiple factors and complex pathophysiology, the direction of causation is questionable. Usually the factor that appears first is deemed causal while the other factor appearing later is assumed to be outcome but in retrospective studies where establishing a timeline is difficult, the potential for reverse causal error arises.[3] E.g. In studying the relationship between smoking and depression,there is likelihood the causal relationship can be either ways. Observational studies in general are not clear in pointing out the direction of causality, and hence they need to be supported by interventional studies when feasible.

2.4. Confounding Bias: Confounding factor is a third variable, that distorts the observed relationship between the exposure and outcome. It causes error in characterization of relationship between two factors. Confounding involves a third factor as opposed to reverse causality where two factors are erroneously associated.[3] The presence of this undetected or unknown third factor causes flawed association between the two factors. The two factors appear to demonstrate a statistically significant relationship, which may not be supported by a biological relationship but by the presence of the third factor, which is commonly known as the confounding factor. These factors are independent risk factors for the study outcome and associated with both outcome and exposure. If confounding bias is not controlled, then it may cause an over-estimate the true association (Positive confounding) or under-estimate the association (Negative Association).

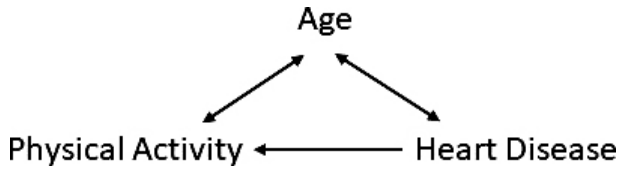

Figure 1. Age is a confounder as it is associated with both physical activity (Exposure) and Heart disease (Outcome)

In the above example, age is a confounder as it is associated with both physical activity (Exposure) and Heart disease (Outcome) (Figure 1). The effect of confounding can be overcome during the study design by restriction (Restricting the selection of variables with respect to confounder), matching and randomization. The effect of confounding can be overcome during the analysis by stratified analysis and regression analysis.

Conclusion

There is plethora of errors in research and can occur during the planning, data collection, analysis and publication phase. Understanding various types of errors in research allows an investigator to critically and independently review the scientific literature and avoid potentially harmful or suboptimal treatments for the patients. Evidence based dentistry practice demands a thorough understanding of errors in research and how it affects the study results and its outcomes. This review explores only methodological errors comprehensively without exploring non-methodological errors. Hence further reviews exploring non-methodological errors are much appreciated in future.

Role of Colours in Paediatric Dental Clinic Setup

Madhumita Barik

Intern (BDS), Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Dentistry decoration is very important in children. Anxiety and fear of dental treatment in children is seen in many countries**.** An attractive and comfortable environment should be designed for both children and parents. If the dental environment colour can have a beneficial effect on the baby, these colours may contribute to the child's comfort, thereby decreasing dental anxiety. The uses of child friendly colours like yellow, blue in the dental work place enhance a positive dental attitude in the child. It is important for the dentist to establish a friendly relationship with children to combat fears and deliver effective and efficient treatment.

Keywords: *Colours, Paediatric Dental Clinic Setup, Dental anxiety,friendly relationship.*

Introduction

Dental anxiety affects children as a prevalent issue. It has been of concern for many years and it is still a barrier to dental care.[1] Dental anxiety in childhood is stressful for both the kid and the parents. Friendly atmosphere in dental clinic can reduce dental anxiety of children. Colour plays an imperative role in child's life.[2] Colouris one of the best ways of transferring messages and meaning. Colour stimulates and works synergistically with all of the senses, symbolizes abstract concepts and thoughts,expresses fantasy or wish fulfilment or produces emotional responses.Colour can be viewed biologically, mentally and could therefore provide psychological answers.[1] The colour of the dental setup can have a beneficial effect on the behaviour of the baby, decreasing dental anxiety.[2] By adding bright colours to the dental system and colourful equipment, the kid would feel great and be comfortable in the dental clinic. If environment colours can have positive influences,then those colours will make more comfortable, reducing their stress.[3] Some kids respond positively in a paediatric dental practice, while others are anxious.[1] Using child-friendly colours in the dental office could generate a favourable atmosphere for them all.

Role of Colour: Colour is an important characteristic in the lives of a child. Colour is an essential component of today's life and is seen in all we perceive. It has been commonly recognized that colours play a crucial role in our emotions and expression. Colour preferences in particular are related to whether a colour conveys favourable or negative feelings.[2] A child's environment including his/her clothes, toys and accessories convey many psychological messages through colours.[1] A child sometimes express his/her emotions through colours. The colour of paediatric dental clinic should be such that, the child gets more attracted and comfortable. If the child sees his/her preferred colour they get more surprised and happier, which gives a positive response to the dentist.[4] If the colours chosen are found not to be preferred by the child, they express a negative emotion. Specific colours generally elicit specific feelings, but for each person, the specific feelings engaged are by no means the same. The emotion caused by a colour relies on nationality, past experiences and private preferences at times.[1]In our exercise, the use of colours helps both the kid and the employees feel more comfortable while in a dental setup. Terwogt and Hoeksma conducted a survey with comparable purpose in which fundamental emotions such as anger, happiness, sadness, fear, surprise and disgust were represented by the colours red, blue, yellow, green, black and white.[2] The associations of some mood tones with specific colours have been discovered to be more evident and accurate than others.[5] Happiness, cheerfulness and a favourable emotional state are connected with the colour yellow. Secure, calm, comforting is associated with the colour blue. Red with anger, aggression, excitement, and black with depression or anxiety.[1] Neutralcolours such as beige or light shades of green and blue for the wall decor promote a tranquil feeling. Children require free, empty spaces to move around. They usually don't seat in one place. So, as soon as they enter a dental clinic there must be a space provision or play room area.[6-8] The walls

of the play room area should be painted with bright colours such as yellow, blue. In accordance with bright colours the walls can also be painted with cartoons and animals so that the child gets more attracted. So, with such attractive walls it's better to engage the children in some interesting activity to relieve their anxiety before their turn comes for dental check-up or treatment. Selectedtoys, building blocks and wall attached activity centres have proved to be the main attraction for the children of all ages.[9,10] So, this should also need to be considered according to their preferablecolours. Often clinics have roof to floor tiles for easy maintenance and cleanliness, andcolours projecting office ambience. Children imagine and accept bold, bright fresh colours such as yellow,blue,orange,pink,green and may dislike grey, black and white, brown etc. Undoubtedly, the use of happy colours is very important for designing the children's waiting room. You can also use a colourful background for the waiting and treatment room. The degree of darkness and brightness of colour should only be considered for these two rooms. It is better to use the same colour for both the waiting room and treatment room.[4] In this situation, patient who got familiar with the waiting room before will also get familiar with the new environment without any stress. The accessories used in paediatric dental clinic should also be made up of attractive colours. The colour of dental chair should not be dull rather it should be bright and attractive. The dentist can also incorporate use of colourful gloves with mint smell which will make the child feel good and comfortable. The drapes used should also be of bright colours with pictures on it.[11,12] It will make the patient happier. Pope DJ et.al. studied girls preferring pink colour, while most boys preferred blue to be positive. This may be due to cultural imparity as most parents in their toys, clothes and room accessories bring up girl children in a pink setting and boys in a blue environment.[2] So this should also be a topic of concern for the dentist in preferring colour scheme for dental clinic setup. A pleasant and colourful environment relieves the anxiety of children and also projects the office ambience. By defining the child-friendly colours, we can integrate such radiant colours into the clinical configuration that will assist decrease children's anxiety and thus decrease the time consuming and stress-free dental procedure.[2]

Conclusion

The colour relationship and its emotional impacts are based on colour perception and environment perception. The dental clinic's colour and atmosphere have an important effect on the behaviour and reaction of a child to therapy. Thus, by adding appealing colours to the dental setting and integrating colourful equipment, a favourable attitude could be enhanced and the kid could be at ease.

Aesthetic Clinical Crown Lengthening: an Answer to an Aesthetic Smile

Abhaya Chandra Das[1], Sourav Panda[1], SaumyaKanta Mohanty[2], Nitai Debnath[3], Sital Panda[4]

[1]Reader, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, [2]Reader, Department of Conservative and Endodontic, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, [3]Reader, Department of Prosthetic Dentistry, RIMS, Imphal, [4]MPH Student, Department of Public Health, RMRC, Bhubaneswar, Odisha, India

Abstract

To achieve an ideal smile, anterior maxillary labial gingival margin position plays a vital role. The gingival margin position is sometimes disturbed during or after the orthodontic treatment, which is mainly due to difficulty in plaque control, resulting in gingival enlargement. Anterior surgical crown lengthening may be undertaken to treat the gingival enlargement. A 23-year-old girl came to Department of Periodontics, with a chief complaint of anunaesthetic smile resulting from orthodontictreatment. Under local anesthesia, gingivectomy and frenectomy were carried out in the anterior maxillary arch (13 to 23) and periodontal dressing was given and followed up to 6 months. She was very satisfied with the aesthetic result.

Keywords: *Crown lengthening, frenectomy, gingival enlargement, gingivectomy, orthodontic treatment.*

Introduction

Aesthetic smiling depends upon the management of dental malocclusion and gingival zenith in varying degrees for many years.[1] Recently, patient awareness along with expectations have reached to a point, that is not less than ideal aesthetics result. But only orthodontic treatment may not provide an acceptable outcome (Morley, 1999).[1] Specially, in the maxillary anterior region, the gingival labial margin position acts as a vital parameter to achieve an ideal smile. Anterior surgical crown lengthening may be accepted to treat the complication such as gingival enlargement resulted from orthodontic therapy.[2,3] The putting of fixed orthodontic appliances is a favorable condition for plaque deposition, which is mainly due to the difficulty in the regions between labial gingival marginand brackets. Without plaque removal regularly, can give rise to several diseases like gingivitis, gingival enlargement, and clinical attachment loss (in severe cases).[4]The present case reportdiscusses crown-lengthening procedures of maxillary anterior teeth associated with plaque induced gingival enlargement and ismainly focused to obtain an aesthetic outcome.

Case report: A 23-year-old girl came to our Department of Periodontics, with a chief complaint of an unaesthetic smile resulting from orthodontic treatment (figure 1,6).

Figure 1: Preoperative view showing enlarged gingiva of maxillary teeth

Corresponding Author:
Dr. Abhaya Chandra Das
Reader, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: drabhaya2011@gmail.com

The patient was free from any systemic diseases, and without tobacco chewing habits. Conventional orthodontic treatment had been carried out over a period of 2 years. There was favorable tooth alignment after orthodontic treatment, but however there was enlarged gingivain the anterior maxillary arch due to poor plaque control, which was ultimately compromised the aesthetic outcome on smiling.

Treatment: Oral prophylaxis was carried out. After 1 month, under local anesthesia (2% lignocaine hydrochloride with 1:80,000 epinephrine), surgical crown lengtheningor gingivectomy[5,6] was carried out in the anterior maxillary arch (13 to 23)after marking for external bevel incision (this is based on repeated ratio) (figure 2). To provide ideal smile, Chiche and Pinault (1994)[7] has given the following repeated ratio formula:

Width of tooth = 0.75 to 0.80 (ideal ratio)

Length of the tooth: Frenectomy was also performed in order to reduce the relapse of midline diastema (figure 3).[8,9] A significantly increased clinical crown in maxilla anterior region was obtained. Then periodontal dressing (Coe-Pak, GC America INC, USA) was given to minimizes the postoperative infection and hemorrhage (figure 4).[10] It also assists healing by preventing surface trauma during mastication, and protects against pain,which is induced during mastication, as a result of the wound contact with food or the tongue.[10-13]

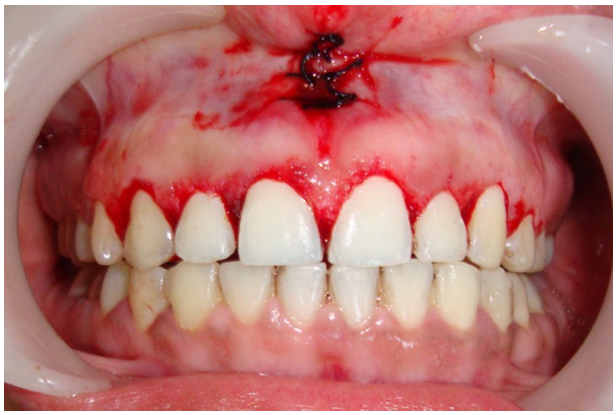

Figure 2: Marking for external bevel incision

Figure 3: Postoperative view on the same day.

Figure 4: Coe-Pak placed on the surgical site

Figure 5: 2 week postoperatively

Results

The present case was weekly follow-up visits forthe first month (figure 5).The reason was to have meticulous plaque control and had an optimum healing. Later on, recall visits were done monthly during the next 6 month (figure 7) and onwards. These recall visits revealed that the patient maintained oral hygiene perfectly, and was very satisfied with the aesthetic outcome.

Figure 6: Preoperative view

Figure 7: 6 month postoperatively

Conclusion

Aesthetic clinical crown lengthening or simply gingivectomy can be carried out in anunaesthetic gingival margin following conventional orthodontictreatment to provide an aesthetic pleasant smile.

Advances in Bracket System: The Newer and Aesthetic Approach: A Review Article

Lipika Mali[1], Sumita Mishra[2], Subhrajeet N Sahoo[3], Smruti B. Nanda[3]

[1]Post-graduate Trainee, [2]Associate Professor, [3]Lecturer, [4]Assistant Professor, Department of Orthodontics & Dentofacial Orthopaedics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneshwar, India

Abstract

Aesthetic brackets gained admiration due to growing requirement for improved aesthetics throughout fixed mechanotherapy. The bracket systems have modernized from pin and tube to lingual, self-ligating and invisible aligner system. The new advances in Orthodontic brackets have contributed in making the treatment a pleasant experience for the patient by boosting their confidence and have also reduced the chair side time for the clinician. This article discusses the recent advances in the Orthodontic bracket systems.

Keywords: *Aesthetic brackets, Advances in brackets, Lingual, Self-ligating, Ceramic, Invisalign.*

Introduction

Orthodontic patients, these days demand for aesthetics during fixed mechanotherapy which has led to an enormous amount of research & development in introducing bracket systems that are aesthetically pleasing without compromising the desirable performance of the required appliance. Several developments have been made in the field while each approach is unique and desirable in its own way; each has its own drawbacks as well. Such as, developments of smaller stainless-steel brackets provide the same performance but the metal display inevitable. Lingual brackets are more aesthetic or almost equal to invisible, but increase the technical difficulty for the clinician, thereby increasing the chair side time. Recently, a new addition to the Orthodontist's armamentarium is the invisible aligners or the clear aligner system, which incorporates a transparent plastic aligner for correction of minor malocclusions, especially in adult cases. But the biggest hurdle with this system is the treatment cost.

Corresponding Author:
Dr. Sumita Mishra
Associate Professor, Department of Orthodontics & Dentofacial Orthopaedics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneshwar, India
e-mail: sumita.mitali@gmail.com

Rise of these various aesthetic bracket systems has occurred at a faster rate due to the rising need of the patients. The purpose of this review article is to discuss the recent advances in orthodontic bracket system and how it benefits the Orthodontist to deliver better treatment aesthetically.

Recent advances include:

1. Plastic brackets
2. Ceramic brackets
3. Self-ligating brackets
4. Lingual brackets
5. Invisible aligners

Plastic brackets: Newmann was the first person to introduce these brackets that came into the market in the early 1970's. Originally it was made from acrylic, but due to various drawbacks later was manufactured from polycarbonate. [1] These brackets could not be adopted worldwide by the Orthodontists because of its numerous drawbacks. Few of setbacks of these bracket system included staining and odour, mainly its low strength and low stiffnessraised problemsat the time of bonding such as - tie wing fractures and permanent deformation. Due to lack of strength and rigidity, "high-grade medical polyurethane brackets and polycarbonate brackets reinforced with ceramic or fibreglass fillers and/or metal slots have been recently introduced and are becoming increasingly popular".[2]

Figure 1. Plastic brackets

Figure 2. Ceramic bracket

Ceramic bracket: Since their introduction in the 1980s, in comparison to traditional appliances, ceramic brackets have proved to be more advantageous.[3]

They excel in terms of strength, wear resistance, stress deformation, color stability and more importantly aesthetics during the treatment phase which is a primary consideration for most patients opting for orthodontic treatment.

The basic material is aluminium oxide, which based on the method of fabrication can be monocrystalline or polycrystalline.[4]

Monocrystalline alumina: This is pure crystalline form of alumina that does not contain any binder.

Polycrystalline alumina: This material contains a binder along with alumina to make it mouldable into a desired shape from which brackets are easily cut out.

Polycrystalline Zirconia: Available in three crystalline forms namely cubic, tetragonal and monoclinic, zirconium was also used for bracket fabrication.[4, 5]

Inspire of rigorous research in development in the field of ceramics, only alumina ceramics have shown consistent improvement in the field, making it the most favourable material for bracket fabrication for clinical use.

Ceramic brackets will all the advantages also have their drawbacks such as: bonding and bond strength, frictional resistance, bracket breakage and low fracture resistance, iatrogenic enamel damage and problems while removal of the bracket. Various studies have measured and compared the bond strength of ceramic brackets with different retention mechanisms and it has been found brackets that have been retained with mechanical measures, tend to have sufficient bond strength and seem to result lesser damage to the enamel during debonding as compared to the chemically retained bracket.[5] Modification of bond strength can also be done by selection of correct adhesive, various types of enamel conditioner and varying the etching time.

Self-ligating Bracket: As the name suggests, this is a ligature free system with a locking clip to keep the arch wire in place. Depending on the interaction of the bracket and wire, it may be an active or passive bracket. The absence of ligature wire results in lesser soft tissue trauma to the labial and buccal mucosa. Leading points of self-ligating brackets are full arch wire engagement; low friction between bracket and arch wire; less chair side assistance; faster arch wire removal and ligation, thus lesser chair side time.[6]

The evolution of self-ligating brackets is shown in the figure below:

Figure 3 The evolution of self-ligating brackets

*Recent advancements in orthodontic brackets - A review. A Kakadiya et al.

Indian Journal of Orthodontics and Dentofacial Research, July-September 2017;3(3):129-135

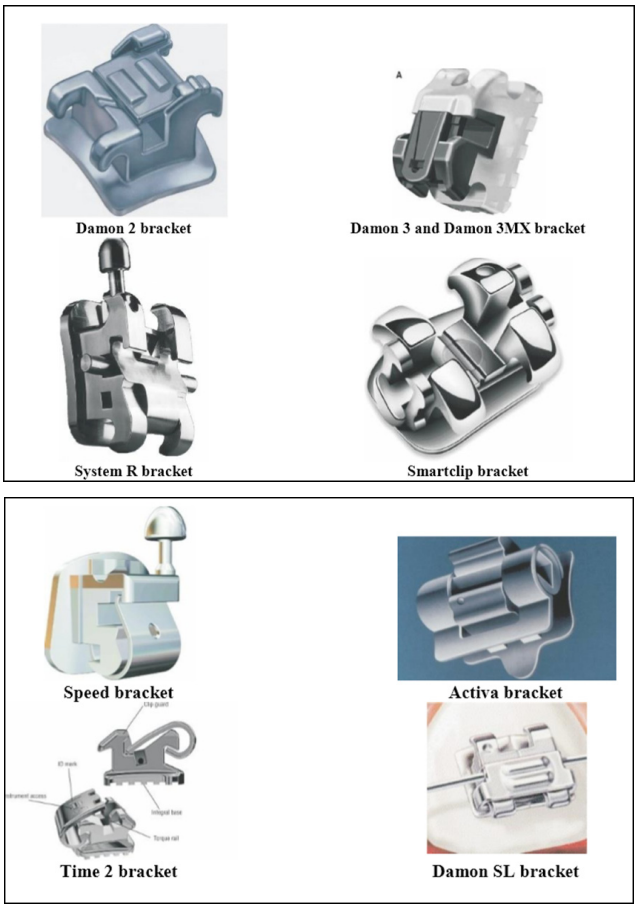

Figure4. Self ligating brackets

Recent developments of self-ligating brackets are the tooth coloured or aesthetic self-ligating brackets.

Self-ligating brackets have gained popularity because of the robustness offered along with the easy usability saving precious time of both the clinician and the patient. [7]

A study of treatment efficiency by Harradine concluded the following:

1. Less chair side time due to non-usage of ligature wire
2. Reduction of treatment duration by approximately 4 to 6 months
3. An overall reduction of the number of patient appointments needed for active therapy to 12 months from 16 months
4. Same PAR score reduction in matched cases[6]

Similar findings were also reported by Dr. Robert Fry at the annual AAO session in Toronto in 2001.[8]

Currently available self-ligating bracket systems, today, exhibit extremely low friction in addition to secure engagement of the full bracket which, in addition to reduced duration of treatment, fulfils anchorage requirements especially involving tooth movement of a larger magnitude with ease and predictability.

Lingual Brackets: The technique begun in 1970 and Dr.Kinya Fujita introduced the mushroom shaped arch wire in 1979.[9] The system enables successful treatment of patients with certain specific social and professional requirements with high aesthetic requirement that does notallow them to get orthodontic treatment done using the conventional method, where the brackets and the arch wire are visible. Since its introduction in 1970, the lingual system has been extremely popular and has undergone extensive evolution to have gained success and acceptability.[10, 11]

Figure 5 Lingual brackets

The most significant change in design is the size of the bracket. The new lingual brackets are smaller and more closely adapted to the lingual vestibule. The shape of the bracket has also been dramatically changed. There are three small wings (two occlusal and one gingival) and a 0.018" x 0.025" slot for the arch wire.[12] The absence of a hook and bite plane further reduce the overall dimensions of the bracket leading to greater patient comfort.

Invisible Aligners: Clear aligners are the most recent development in the field of orthodontics and have gained immense popularity since their introduction as they have the highest esthetic quotient. With an increase in the number of adult patients demanding orthodontic tooth correction, most of them being working individuals, clear aligners become an important option for both the clinician and the patient in spite of smaller appliances and even ceramic brackets as they are much more noticeable. The tooth movement occurring in clear aligners is mostly uncontrolled tipping with the center of rotation being located between the center of resistance of the tooth and the root apex. Some studies suggest limitations of this appliance in form of anchorage control. To counter the limitations of the system, aggressive research and development is continuously pouring into the technique that, over a period of time, has eventually led to more efficient and successful treatments.[13, 14]There are several companies that are manufacturing these aligners, such as Clear correct, 3M Clarity aligners, K line etc.The drawbacks of the system make case selection a tedious task as they add onto other criteria that need to be addressed while treatment planning such as age, bone quality and tooth morphometrics.[15]

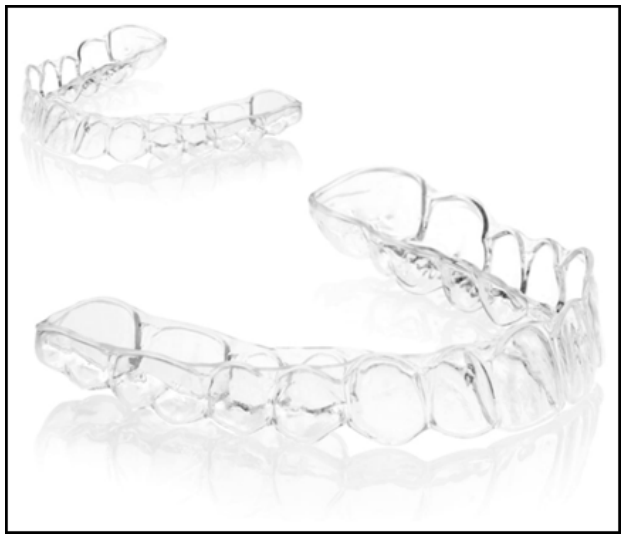

Figure 6 Clear aligner

Conclusion

The article summarizes the recent advancements in Orthodontic brackets along with a brief description of the plastic brackets, ceramic brackets, self-ligating bracket, lingual bracket, and the new clear aligner system. As technology advances soon these brackets will also be obsolete and newer ones would take their place. Keeping up with the technological advancement is a tough job. The rise in quality also comes with a rise in its cost. The Orthodontist should wisely choose which bracket system would be best for the selected case and also fulfil the aesthetics requirements of the patient.

Preventing Dental Caries through Microbiome Manipulation

Silvie Sital Jena

Intern, Institute of Dental Sciences, Siksha'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Oral microbiome is natural and has a harmonious relationship with the host by delivering important benefits. But sometimes this dynamic balance gets interrupted either by high sugar intake or low saliva flowwhich decreases the pH level in biofilm. This increases the risk of caries or what we call dysbiosis. Several studies and new insights are put forth to promote symbiosis and prevent dysbiosis. This article focuses on the various method that can achieve our motto i.e. maintenance of equilibrium. Numerous proposed ecologicalapproaches been brought into clinical practice for this purpose. Probiotics, prebiotics,quorum-sensing targets, sugar polyols, antimicrobial peptides, replacement therapy with designer bacteria are some of the discussed approaches in the review some of which have undergone successful clinical tests setting milestones in the field of dentistry.

Keywords: *Oral microbiome, Dental caries, Biofilm, pH, Prevention.*

Introduction

Dental caries concept has evolved through years and now considered to be a "multifactorial" disease with no single causation pathway. Previously the main goal was elimination of dental plaque but later several studies have highlighted the beneficial aspects of oral microbiome such as acting as a barrier for opportunistic pathogens, carrying out metabolic processes beneficial for the host,preventing erosive enamel lesions and hypersensitivity. Thus, "shotgun" suppression of microbiome may not have a long-termsuccess, but targeting the cariogenic bacteria or virulence factor has provedto have an effective outcome.[1-3]

Ecological Approaches

Antimicrobial Peptides: Antimicrobial peptides (AMPs) are heterogeneous group of molecules that has antifungal, antibacterial and antiviral property which is mediated by selectively interacting with the membrane's phospholipids leading to disruption of membrane and cell death. Besides naturally AMPs in saliva, some are synthetically produced in labs like STAMP (Specifically Targeted Anti-Microbial Peptide) which targets *Streptococcusmutans* withoutharming beneficial bacteria. Other synthetic AMPs include KSL-W, L-K6, GH12,1018. But despite of its remarkable outcomes;questions still remain whether it will be able to work against excess acid production in high caries risk individuals.[4-6]

Probiotics: Probiotics are harmless effector strains which are introduced into host microflora. It can have both systemic and local effects. Local effects include competitive inhibition with caries producing bacteria,bacteriocin-producing probiotics targeting *Streptococcus mutans*. But again, the probiotics have their darker part too. Some strains like *Lactobacillus* and *Bifidobacterium* are themselves acidogenic and aciduricand contribute to caries progression. But very recently two oral commensal species, *Streptococcus dentisani*and *Streptococcus A12* have been introduced where they inhibit the growth of *streptococcus mutans* as well as lower the plaque pH through arginolytic action. But still these are on trials for whether they inhibit dental cariesor not.[3, 7]

Prebiotics and Arginine Metabolism: Prebiotics involve nutritional stimulation of beneficial species to maintain balance and promote oral health. Arginine, arginine-rich peptides and urea are commonly used in prebiotics which have alkalizing effects which counteract the acidic environment created by caries-inducing bacteria. Many commensal bacteria use arginine or urea to produce ammonia which in turn play a great role in pH balance and alter the remineralisation-demineralization equilibriumbeneficially. Further a systematic review and meta-analysis on anticaries effects of arginine formulated in dentifriceshas revealed that when arginine is combined with fluorides it produces synergistic effects against caries as compared to fluorides alone. Thus,this

has proved to be a promising strategy for caries control.[8-12]

Sugar polyols: Sucrose being one of the main reasons behind caries progression;sugar substitutes have grabbed a lot of attention. These are believed to have anticaries action through number of mechanisms. Xylitol; a non-nutritive sugar substitute has been under researchsince years and have potential cariostatic effects. It inhibits *mutans* growth by disruption of the energy processes leading to futile energy cycle and cell death. The common vehicle for xylitol delivery isdentifrices,gums,candies, lozenges and mouth rinses. Erythritol anticaries effects can stay up to 3 years.[13-15]

Quorum-sensing (QS) targets: Another approach for a healthy plaque ecology can be brought about by interfering with the fundamental cell-cell communication in the biofilm. This process is called QS which is mediated through pheromones and their specific receptors. As QS is not directly related to the bacterial growth;so,emphasizing in this would allow less harmful bacteria to grow andabsence of selective pressure which can lead to antibiotic resistant strains.[6, 16,17]

Replacement therapy with "Designer"bacteria: Modification of the dental plaque can be brought about by introduction of avirulentcounterparts of *S.mutans* in the biofilm in place of the cariogenic strains. Several "designer" bacteria have been studied under bacteriotherapy against cariogenic biofilms including glucansynthesis-defective mutant of *S.mutans,*variants of *S.salivarius*(TOVE-R) and a recombinant alkali-generating ureolytic strain of *S.mutans.*Most genetically modified strain used is a wild type *S.mutans* which naturally produces mutacin 1140; an antibiotic which can kill cariogenic stains of *S.mutans*.[17]

Natural Products: Includes secondary metabolites and phytochemicals derived naturally i.e. from plants, herbs,shrubs,fruits, etc. Potential cariostatic properties include:

- Inhibition of bacterial growth
- Inhibition of acid production
- Inhibition of glucan synthesis
- Inhibition of bacterial adhesion

Polyphenols from propolis and cranberry proanthocyanidins have been into much consideration are potent inhibitor of water-soluble glucan and decrease the acid production. Propolis consist of apigenin and tt-farnesol which when combined with fluorides suppress dental caries substantially.Likewise, cranberry proanthocyanidinscan lower acidogenicity and glucan synthesis. Bioactive molecules likexanthorrhizol(from*curcumaxanthorrhiza*)or macelignan(from*Myristicafragrans*)can be almost compared to chlorhexidine. Another phytochemical named '*Gallachinesis*'can beneficially regulate demineralization-remineralizationof the dental film.Natural products still remain unexplored source of potent anti-cariogenic and non-toxic antibiofilm moleculesthat can be combined with fluorides and conventional microbicides like chlorhexidine and triclosan.[18,19]

Other Approaches: Calcium phosphate-osteopontin(inhibit biofilm formation), Nano particles Graphene oxide, Ceramic water.[20]

Conclusion

Fluorides no doubt will remain the most economical,conventional and sought-after prevention protocol for dental caries but however fluoride alone cannot offer complete protection against this multifactorial disease. Hence the search for cariostatic agents goes on every year around which can be combined with fluorides and synergistically improve the cariostatic property.Introducing these ecological method into clinical practice can definitelybring a new era in dentistry where prevention with lead to long term disease control. Present scenario and culture make it difficult to achieve and sustain behavioral dietary changes;Thus, these approaches can help clinicians and practitioner to shift the way of management of a disease more biologically.

Pediatric Implants

Biswabandita Mohanty[1], SusantMohanty[2], Antarmayee Panigrahi[3]

[1]Postgraduate Student, [2]Professor & Head, [3]Reader, Department of Pedodontics and Preventive Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneshwar, India

Abstract

Absence of teeth in children and young adolescence has long term effects the normal function, alveolar growth, speech, aesthetics as well as negative impact on the psychosocial development of these growing children. Partial or complete anodontia could be either genetic or induced by trauma or dental caries. Owing to growing phase and transitory changes the takes place in and around dentoalveolar structures poses a greater challenge for clinician to devise a treatment place suiting all needs of the children without hampering the growth aspects. Various options for replacement of teeth ranges from removable partial dentures, semi-fixed dentures and most recently pediatric implants have been introduces. This paper encompasses all the aspects of pediatric implants along with the clinical consideration.

Keywords: *Implants, Children, Anodontia.*

Introduction

Teeth loss may cause function lease which can lead to various problems of alveolar origin and can also hinder the psychological development of the child due to displeasing aesthetic.[1] Congenital partial anodontia and traumatic tooth loss are frequently encountered in pediatric patients.[2]. Missing maxillary and mandibular anterior can hamper the child's living quality.[3] As these children are in their growing phase several changes occur in their skeletal framework including jaws and treatment option will thus be limited. A There are a number of removable and even if few there are some fixed options for children[4]. Many authors suggest the use of implants for those children but this option again comes with its own pros and cons.Hence, it is important to measure benefits of implants placement in growing patients against the concerns regarding their premature placement.[5] A careful diagnosis, treatment planning and a coordinated health care practice can help us to confer ultimate treatment results.[6]

Implant Interrelationships

Implant Growth Interrelationships:

Effect of Transverse growth of Maxilla on Implant Placement: After 10 years of age there will only be a little amount of change in the intercanine distance which is 10mm (0.9mm). So, during this phase if an implant body is placed in the position of central incisor then there are chances that midline diastema can occur in between the implant placed and the adjacent natural tooth which can further shift the midline towards implant side. Around the age of 15years the midpalatal suture usually closes.[7]

Effect of Saggital growth of Maxilla on Implant placement: Due to the maxillary growth in downward and forward direction, the implant can lose its labial bone. If the implant is placed in the anteriors then it might fail to follow the natural teeth and may become relatively more palatal and if the implant is placed in the lateral region then it could not stop its mesial drift which can result in asymmetric arch form.[7]

Effect of Vertical growth of Maxilla on Implant Placement: Cronin and Oesterle introduced the vertical dimension of the maxillary growth as the most disturbing implant-positioning factor.39 Ranly calculated that an implant inserted in the anterior part of maxilla at the age of 7, will 9 years later be located 10mm more apically than the neighboring teeth.[8]

Effect of Transverse growth of Mandible on Implant placement: The relative lateral movement of the bone in the premolar region by bone apposition on buccal side and bone resorption on lingual side, is the cause of eventual lingual positioning of an implant if in case it is placed before growth completion.[7]

Effect of Sagittal growth of Mandible on Implant placement: The condylar growth causesa lengthening of a mandible, but this has no direct impact on implants. The height of the mandible increases mainly through bone apposition at the dentoalveolar complex, especially during the tooth eruption phase and the growth at the condyle. The latter makes the mandible undergo a limited rotation. Superposition was performed based on the small implants placed in the corpus mandibulae.[7]

Effect of Vertical growth of Mandible on Implant placement: The mandibular rotational growth of the significantly affects the anteroposterior and vertical eruption patterns, which are thus intimately connected. This rotation is important for implant insertion because the variation in compensatory amount and direction of incisor eruption could affect the relationship of an implant to an adjacent tooth.[7]

Interrelationship of Implant placement with type of Anodontia[9, 10]: Sharma and Vargervik's classification, which can provide basic indications and timing of implant placement in adolescent.

Group I

Children congenitally missing a single tooth and having adjacent permanent teeth: For those patients the development of dentoalveolar complex adjacent to the edentulous space is of prime concern. As the patient grows there is increase in height of maxillary and mandibular alveolus. Hence forth if the implant is placed before the growth completion then there are chances that it can get submerged as compared to the adjacent natural tooth.

Group II

More than a few teeth missing but adjacent to the edentulous lite there is presence of permanent teeth.

They are the most complex patients to be dealt with. There is need of orthodontic optimization and consolidation of edentulous space. So, in those cases it is always better to wait till growth completion which can be ascertained when there will be no change in two lateral cephalograms taken 1 year apart.

Group III

Complete Edentulous Arch: Usually the patients of ectodermal dysplasia come under this category. As there is no teeth so, the dentoalveolar growth will not be a major concern. The only problem that can be caused can be due to downward and forward growth of mandible whose sequel can be jaw size discrepancy. But this will not adversely affect the implant positioning.[11]

Implant placement in patients with Cleft lip and palate: Treatment of the cleft lip and palate patient involves a multidisciplinary team that encompasses multiple specialists is necessary to achieve the desired result. Alveoloplasty represents an essential procedure to assure a bone foundation that permits an adequate orthodontic treatment and a final dental rehabilitation. Between 10% and 50% of patients undergoing alveoloplasty do not achieve an adequate orthodontic treatment closure of the dental spaces.[12]

Closure the dental space by means of a dental implant is a relatively recent modality of treatment. In fact, it was first published by Verdi et al.[13] One of the success criteria of alveoloplasty is the volume of bone that remains in the cleft alveolar region. If there is not an adequate volume of bone it is not possible to insert the implant; a common situation due to the lapse of time between alveoloplasty and implant insertion.

According to literature the secondary alveolar bone grafting should be done between 8 and 11 years and implants should be placed between 6months of bone grafting to avoid resorption. Longer implants said to have longer duration of survival than shorter implants. Other implant factors as if diameter, surface texture etc. does not have much effect on longevity of implant.[14]

Mechanism of Integration of Endosteal Implant: Two concepts of endosteal implant–tissue reaction have been proposed [15]. They are:

- Dr. Per Ingvar Branemark - osseointegration
- Weiss - Fibro – osseous integration

Osseointegration: Osseointegration is defined as "1) Osseous integration (1993) the apparent direct attachment or connection of osseous tissue to an inert alloplastic material without intervening connective

tissue. 2) The process and resultant apparent direct connection of the endogenous material surface and the host bone tissues without intervening connective tissues. 3) The interface between alloplastic material and bone."– Glossary of Prosthodontic Terms.

Factors affecting osseous integration – Load on the occlusal table, design and surface texture of the implant, material biocompatibility and infection control.

Fibro-Osseous Integration: According to Weiss in-between the bone and implant surface there is presence of collagen fibers which leads to formation of a fibro-osseous ligament which is similar to that of a periodontal ligament. He supports the concept of early implant loading.

Osseointegration Vs Biointegration: Putter, in 1985, proposed 2 different ways of implant retention which can either be mechanical or biomechanical. Where the implant body is of metal there, we get a mechanical retention by help of vents, slots, dimples, threads etc. In those cases, retention solely depends on surface area as there is no chemical bonding.

In cases where bioactive retention needed to be achieved there the implants are coated with hydroxyapatite. Those bioactive material help in forming a physicochemical bond by simulating bone formation.

Controversies on Age of Implant Insertion: In the consensus meeting held in 1995, there came a decision that in partially edentulous cases implant placement should be delayed till the craniofacial and skeletal growth completion. In girls the growth spurts are expected to occur at 12 years and for boys it will be at 14years of age. Individual variation of about 6 years needed to be considered i.e. 9-15 years for girls and 11-17 years in boys. Thus, the chronological age is not reliable factor for assessment of growth cessation. Other diagnostics such as seriel cephalometric radiographs taken 6 months apart for at least 2 years, change in dental positioning by eruption of 2nd molar and evaluation of skeletal age are considered to more reliable indicators of growth cessation. A combination of more than 1 method isalso preferable.

Even if superimposing tracing of serial cephalometric radiographs for over a 1 year is considered to be more reliable method but this consumes a lot of time and radiation exposure to patient which indeed causes delay in implant placement.[7]

Recommendations for Implant Placement[7,10]

Anterior Maxilla:

- This area is very unpredictable regarding growth. So, considered as the riskiest site.
- In this area there is prominent vertical growth.
- If the implant placement is too early then that can lead to requirement of transgingival and transmucosal lengthening of implant which can result in poor implant prosthesis ratio.
- When the implant is placed prematurely the maxillary transverse growth also gets adversely affected as the mid-palatal suture remains open till puberty.
- The adjacent natural teeth also can get adversely affected.
- So, it's better to place an implant in this area after skeletal growth completion

Posterior Maxilla: If an implant is placed too early in this area then it can become occlusally submerged as the vertical growth of maxilla occurs by apposition of bone on the alveolar aspect resorption in nasal or maxillary sinus area.

It can have a poor long-term prognosis both on implant and the adjacent tooth due to implant infra-occlusion. Therefore, implants need to be placed after growth cessation

Anterior Mandible: The transverse and sagittal growth in this area is completed relatively earlier as the mandibular symphysis gets closed in early childhood. So, this area has a better potential to support implant prosthesis in children.

Posterior Mandible:

- Premature insertion of implants in these areas can lead to infraocclusion of implant and can adversely affect the natural adjacent teeth as the mandible still undergoes rotational growth which causes a significant change in alveolus and mandibular boarder and those changes are mostly influenced by various facial growth types.
- So better to insert an implant after skeletal growth completion.

Guidelines for Implant Placement: Guidelines for implant placement in younger patients by Misch et al (2005)

These are as follows:

- **Chronological age of patient:** Placement of implants in anterior mandible should be delayed for females upto age of 15years and for males the age consideration is 18 years. This is to be taken into consideration that mostly the patient's chronological age is sometimes lesser than the patient's biological age.
- **Endocrine changes:** This factor is somewhat relative. The female patient should have their menstrual cycle started and there should be at least voice change and body hair presence in case of male patients, and most often need to shave.
- **No growth during last 6 months:** Growth and development of jaws are considered to be nearly completed if no sutural growth had occurred during last 6 months.

Present Scenario

Mini Implants: Mini-implants have been used extensively in a wide variety of situations, such as: it stabilizes the dental arch against the forces directed occlusally while the main fixture heals; it can give anchorage to removable prosthesis; an orthodontic anchor; it can help in preserving teeth affected with; a temporary anchor for transplanted teeth; and a support for a single prosthetic rehabilitation.[16]

Biomimetic Implants: There can be improvement in integration of endosseous implant by bio modifying its surface. Bio modification is the process in which biologically active proteins such as extra cellular matrix protein, RGD peptide sequence are inserted into the titanium surfaces. In early stage of implant insertion, it simulates the osteogenic cells and hence accelerates osteogenesis around implant surface. There are draw backs such as reduced availability of materials, possible immunogenicity, unpredictability in enzymatic degradation and comparatively higher cost. Therefore, to attain a favorable tissue response, RGD or non-RGD sequences, which contains synthetic small peptides those make close contact to integrins, are considered to be effective alternatives. Currently peptidomimetics is playing a pivotal role in biomimetic approaches to dental implantology. [17]

Conclusion

Dental implant insertion can be a possible mode of rehabilitation in children and adolescents. Yet long-term clinical studies are necessary for sound conclusions. Published reports on the use of dental implants in young patients are as yet very limited; Even if many case reports but yet the success rate had not been much satisfactory as there had always been a need of further modifications either by surgery of the maxilla or mandible or by modification of the prosthesis till the child had grown into an adult. This again consumes lot of time of operator as well as the of patient and his/her parents and its always a troublesome issue to expose the child to various repeated surgeries which ends up in making the child and mostly their parents more apprehensive. Another most striking issue in implant placement cases is the cost factor. The parents of an anodontia or oligodontia patient not always belong to an upper-class society so, even if they want the treatment of their child to be done but the cost factor pulls them back. Specially in case of growing children there is a need of cost-effective implant.

So, there is need for further research in this field to known the type of implant specification in case of growing children, to understand proper arch morphology and bone density for a proper treatment planning and if possible, to make a cost-effective dental implant for those patients who suffer silently.

Palatogingival Groove and the Perio-Endo Lesion: Management through Endo–Perio Regenerative (IPRF) Approach: A Case Report

Anurag Satpathy[1], Gatha Mohanty[2], Pratiti Datta[3], Rinkee Mohanty[4], Rashmita Nayak[1], Sourav Panda[5]

[1]Professor, [2]Senior Lecturer, [3]Post Graduate Trainee, [4]Professor & Head, [5]Reader, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Khandagiri Square, Bhubaneswar, Odisha, India

Abstract

Palatogingival groove is an anatomic malformation commonly occurring in maxillary lateral incisors. It frequently goes undetected andis often associated with complex Periodontic-endodontic lesions. Palatogingival groove harbour microbial plaque and cause pathological changes thereby resulting in lesions involving the periodonto-pulpal complex. This case report presents a complex perio-endo lesion associated with a palatogingival groove in maxillary lateral incisor which was successfully managed with both endodontic and regenerative periodontal therapy with the use of injectable platelet rich fibrin (iPRF).

Keywords: *Palatogingival groove, periodontal regeneration, perio-endo lesion, iPRF.*

Introduction

Palatogingival groove (PGG) is adevelopmental anatomic malformation present on the lingual surface of the teeth. It is most commonly found in maxillary lateral incisor[1]. PGG originates when the central fossa on the palatal aspect and crosses the cingulum,extending to varying distances apically. There have been several reported classification of PGG based on location of groove[2], degree of invagination of the groove towards the pulp cavity and degree of severity based on microcomputed tomography studies[3]. However, the most clinically relevant classification among them is mild, moderate, and complex types based on their depth and complexity[4].Several etiologies have been put forth for PGG from being a mild form of dens invaginatus[5], to incomplete attempt of a tooth to form another root[6]. Also, proposed area genetic mechanism[7]and racial link[8].

This innocuously present anomaly may often go unnoticed and result in a pathology which may lead to loss of tooth[9]. Simultaneous involvement of periodontal disease and dental pulp may complicate diagnosis and treatment planning.While an endo-perio lesion with initiation of the pathology from infection of dental pulp is common, periodontal lesions are less commonly seen to be involving the pulpo-dental system. Such cases need a multidisciplinary approach for best prognosis[10]. We present a complex perio-endo lesion associated with a palatogingival groove in maxillary lateral incisor which was successfully managed with both endodontic and regenerative periodontal therapy with the use of injectable platelet rich fibrin (iPRF).

Case report: A 22 year male patient reported to the Department of Periodontics and oral Implantology of Institute of Dental Sciences, with a chief complaint ofpain and occasional gum swelling in relation to upper front toothregion which was associated with loosening of tooth and discharge from gums. He was apparently alright when he noticed gum swelling 6 months back. Pain was dull aching and intermittent which subsided after taking analgesic. The patient was worried about losing his upper front tooth which would hamper his looks.

On clinical examination a deep periodontal pocket of greater than8 mm depth was found onthe mesial aspect of left upper lateral incisor(22). A palatogingival groove (PGG) was found which extended into the gingival sulcus (Fig 1). Tooth was grade I mobile with mild tenderness on percussion. The crown was intact with no evidence of dental caries or fracture.A draining sinus was seen on the facial aspect in relation to tooth # 22 (Fig 2). Radiological examination revealed a peri-apical radiolucency in relation to toot # 22.A gutta-percha cone tracing into the sinus tract and periodontal pocket revealed a communication with the periapical area. No response was recorded in an electric pulp testing.

Fig 1: Pre-operative view - Palatal aspect; Deep periodontal pocket

Fig 2: Pre-operative view - facial aspect; Draining Sinus

Based on the clinical and radiological findings a diagnosis of primary periodontal and secondary endodontic lesion secondary to deep palato-gingival groove was arrived. A treatment plan of Endodontic treatment and regenerative periodontal surgery was planned.First phase of treatment included endodontic treatment for 22. Endodontic treatment was completed in a single appointment using a crown-down technique. The pulp chamber was accessed from the palatal aspect of the crown. After determination of working length, biomechanical preparation was done using rotary endodontic files (ProTaperNiTi files, Dentsply; Tulsa, Oklahoma). 3 % Sodium hypochlorite (Parcan, Septodont, Saint-Maur, France) and 17% ethylene diamine tetraacetic acid a.k.aEDTA (Prime Dental Products Pvt. Ltd, India) were used during the cleaning and shaping of the root canal. After thorough saline irrigation, the canal was finally irrigated with 2% chlorhexidine solution (R4, Septodont, Saint-Maur, France) and dried with paper points.Dry canal was obturated and sealed with thermoplastized gutta-percha along with a resin-based sealer (AH Plus,De Trey, Dentsply, Konstanz, Germany).

Second phase of treatment included regenerative periodontal therapy. After administration of local anesthesia, on the facialside (Fig 3), a mucoperiosteal flap was reflected after placing the sulcular and two vertical releasing incisions. On the palatal side, a mucoperiosteal flap was reflected after placement of sulcular incision only (Fig 4). Reflection of the flap on the facial side revealed a window like defect involving the root of the tooth. On the palatal side, reflection of the flap exposed the PGG completely. The PGG was seen to be extending from the crown to almost the entire length of the root portion.

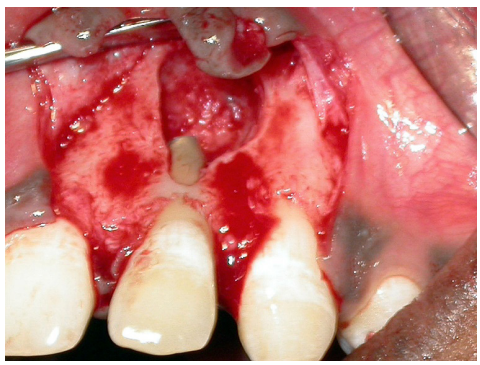

Fig 3: Osseous defect facial side

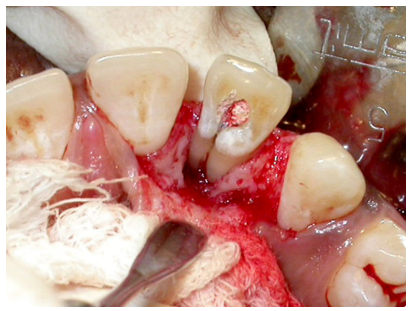

Fig 4: Deep palatogingival groove on the palatal aspect

On the palatal side, the root was cleaned and planed using periodontal curettes (Gracey Curettes # 1-2, Hu-Friedy, USA). Bleeding was arrested and PGG was

obliterated with glass ionomer cement (GC FUJI IX GP, GC Corporation, Tokyo, Japan).

On the facial side, the defect was debrided to remove all granulation tissue and the cystic epithelial lining if present. Apisectomy was done by bevelling the root end and restored with glass ionomer cement (GC FUJI IX GP, GC Corporation, Tokyo, Japan). The defect was then filled with injectable platelet rich fibrin (iPRF)[11] (Fig 5). Flap was sutured back using interrupted sutures. Post-operative instructions were given. Suitable antimicrobials and analgesics were prescribed.

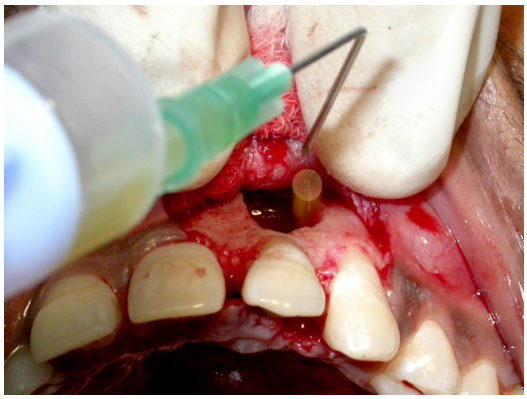

Fig 5: iPRF application into the osseous defect

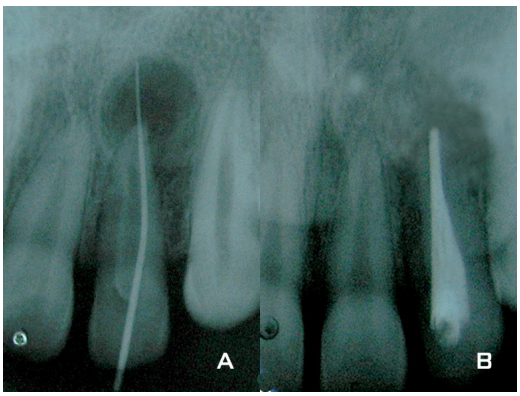

Fig 6: (A) Pre-operative Radiograph (B) Post-operative Radiograph

Patient was asymptomatic with minimal discomfort postoperatively. Sutures were removed after 10 days. The patient was placed on review for periodic monitoring. After 9 months there was a minimal residual pocket of 4 mm on the palatal side, no mobility and radiographic evidence of defect fill (Fig 6).

Discussion

An un-detetectedpalatogingival groove often is associated with a deep-seated severe pathology. Therefore, it is important to carefully undertake a clinical examination. Although in our case there was a draining sinus in the facial aspect, sometimes it is difficult to find a probe a very narrow pocket. In these cases, gutta percha tracing has been of much benefit. PGG is most likely seen in the maxillary lateral incisor and less frequently in the maxillary central incisor.

Obliteration of PGG is essential to convert the groove into a maintainable area which can be kept plaque free. GIC has been often used as a material of choice for this purpose. The same was also used as a root end sealing material after bevelling the root apex. Glass Ionomer cement has been a choice material for obliteration owing to its favourableproperties for both the tooth surface and periodontal tissues. GIC is resistant to degradation by water and has good sealing ability through chemical bonding[1].

A regenerative surgery was done owing to severe bone loss around the root. A good result was obtained after nine months with significant bone fill. This may be due to the fact that unlike bone loss associated with a deep periodontal pocket which has a communication to the oral cavity, periapical bony cavity is a contained one.Combining regenerative procedures with platelet-rich fibrin (PRF) has been extensively investigated and shown effective results[12]. In this case injectable PRF[11]has been used and the results were satisfactory. PRF has and its types such as iPRF, L-PRF[13], A-PRF[14] and PRGF[15] have been extensively utilised in regenerative therapy. This is based on the fact that after activation of the platelets entrapped within fibrin matrix, growth factors are released and it stimulates the mitogenic response during normal wound healing[16].

The success of treatment of palato-gingival groove depends on the ability to remove the irritants that are inflammatory, and followed by sealing the groove.

Conclusion

A combination of endodontic and periodontal treatment along with regenerative therapy including autologus platelet concentrates could give a satisfactory result in the management of complex perio-endo lesion associated with a palatogingival groove.

Plasma Cell Gingivitis: A Rare Finding

Smita R. Priyadarshini[1], Rohini Gaba[2], Pradyumna Kumar Sahoo[3]

[1]Reader, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, [2]Associate Professor, Department of Periodontics. Maharaja Ganga Singh Dental College & Research Centre, Sriganganagar Rajasthan, [3]Reader, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Plasma Cell Gingivitis is anunusual type of gingival enlargement that has distinctive features of infiltration of plasma cells into the sub-epithelial tissues of the gingiva. It is considered to be a hypersensitivity reaction to allergens. Allergens found mostly in consumables like tooth pastes, Khat leaves, chewing gums, etc.Here we have reported an unusual case of an 18 year of girl with gingival involvement in both maxillary and mandibular arches. There was resolution of symptoms after discontinuation of irritant.

Keywords: *Plasmacytosis of gingiva, Allergens, Marginal Gingiva.*

Introduction

Plasma Cell gingivitis is otherwise also known as Atypical gingivitis, plasma cell gingivostomatitis, Allergic gingivitis, plasmacytosis of the gingiva and idiopathic gingivostomatitis. Although the aetiology is not well defined. It is an immunological or allergic response to the irritants present in food items or other consumables. The primary irritant is cinnamon aldehyde widely used as a flavouring agent. These agents are commonly used in dentifrices, gums etc. Literature review classifies these lesions into 3 types allergic, neoplastic or of unknown origin.[1]

Case report: A 18yrs old female patient reported with a complaint of pain in the lower front teeth in the past 2 months. Pain was dull & vague which aggravated on having food with no relieving factors. The patient also gave history of bleeding gums on slight provocation while cleaning teeth 2 years back for which she had got her oral Prophylaxis a year ago. She also gave history of ulcerations on lips and nose which healed by self in 7 days. It was associated with mild fever in 2 times since a period of last 6 months. She gave a history of Cleaning her teeth using babul twigs once daily along with an herbal tooth paste

Figure 1. Red marginal and attached gingiva

On extraoral examination there was a healed crusted lesion at the ala of nose. Intraoral examination revealed

gingival enlargement at the free & attached gingiva with distinct mucogingival junction, With a brightred colour of the free & attached Gingiva. It was soft & oedematous withLoss of stippling'spositioned coronal to CEJ with bleeding on probing & presence of generalised pseudo pockets (Figure 1). For this a provisional diagnosis of Chronic inflammatory gingivalenlargement, Recurrent herpes labials & Dentinal caries – 37,38 was given. The blood investigations revealed normal values of Hb%- 12 gm %, CT- 4 min 20 sec, BT- 2 min 45 sec, RBC – 4.1 ml/mm cube, Platelets: 2,10,000 /mm cube, TLC: 9,000/ mm.

Figure 2. Panoramic Radiograph with mild bone loss

Panoramic Radiograph revealed interdental bone loss (Figure 2). Excisional biopsy of the gingival tissue was done and Histopathological examination revealed oral epithelium spongiosis with infiltration of inflammatory cells a damage to the lower spinous & basal layers with dense infiltration of plasma cells extending in to oral epithelium & dissecting type of injury. Thus, a final diagnosis of Plasma Cell Gingivitis & Dentinal Caries irt 37,38. Follow up after 15 days on discontinuation of babool twigs and the herbal toothpaste revealed marked decrease in the lesion (Figure 3).

Figure 3. Follow up after 15days

Discussion

Plasma Cell Gingivitis is an unusual type of gingival enlargement that has a distinct feature of infiltration of gingival sub epithelial by plasma cells. The localized lesions are plasma cell granuloma where as in plasma cell gingivitis there is mild marginal gingiva enlargement extending to the attached gingiva.[2] These lesions are considered asan allergic reaction to antigens present in consumables and food products. These allergens can be identified as cinnamon, aldehyde or anyflavouring agents present in chewing gums and dentifrices. These could be due to use of herbal toothpaste as in this case.[3] Siteis oral aspect of attached gingiva and primarilyoccurs at the anterior gingiva with maxilla more commonly involved than the mandible. They involve themarginal gingiva but not the entire width of attached gingiva. Gingiva appears red, friable, granular that bleeds easily on slight provocation and doesn't induce a loss of attachment. It could be classified into 3 types caused by an allergen, Neoplastic nature and of unknown origin.[4]Traditionally treatmentinvolves conventional therapies like plaque control and maintain a complete dietary history to find out the possible allergen & eliminate that. If no such agent is identified, then detailed allergic antigen testing is done including the patch test.[5]

Treatment consists of both medical and surgical procedures. Corticosteroids (topical, intralesional, and systemic) antibioticsis given. LASERS could be used for destruction of the tissues. Gingival excision of the tissueis done if no underlying cause is identified and an Immunofluorescence test could be followed. This would help in identification of polyclonal plasma cells. In some cases, although all the evaluations and therapeutic interventions are carried still some patients do not respond to the treatment and no cause for the disease is identified.[6,7]

Conclusion

Importance of detailed history-taking, examination, and conduction of appropriate diagnostic tests, to arrive at a definitive diagnosis, is emphasized. An early diagnosis would direct the clinician toward an appropriate treatment plan, especially for unusual conditions masquerading as common lesions, which are refractory to conventional therapy.

Differences in Distance between Maxillary Posterior Root Apices and the Sinus Floor According to Malocclusion: A Review Article on Various Radiographic Images

Lipika Mali[1], Sumita Mishra[2], Subhrajeet N. Sahoo[3], Smruti B. Nanda[4]

[1]Post-Graduate Trainee, [2]Associate Professor, [3]Senior Lecturer, [4]Professor, Department of Orthodontics & Dentofacial Orthopaedics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneshwar, India

Abstract

The paranasal sinuses are bony cavities at the beginning of upper airway has a pyramidal shape and situated on both sides of the maxilla. They are first to develop and reach their maximum at which all the permanent teeth except the third molars have erupted. The floor of maxillary sinus extends upto the alveolar process of maxillary arch and the hard palate thus, sharing a close anatomic and functional relationship with posterior teeth. In Orthodontic procedures the close relationship of the inferior border of the sinus and maxillary posterior root apices of teeth makes it an absolute prerequisite for clinicians to have an in-depth knowledge of the aspect. This relationship makes it an indispensable diagnostic criterion in determining an orthodontic treatment which involves mesialisation or distalization of the molars, intrusion of the maxillary posteriors or micro-implant anchorage. A sound knowledge of the anatomic extensions of the maxillary sinus, especially the floor of the sinus, is fundamental tool to prevent damage to nearby vital structures.

Keywords: *Maxilla, Paranasal sinus, Maxillary sinus.*

Introduction

Paranasal air sinuses are hollow spaces filled with air, surrounded within the bones of the nasal cavity.[1] There are 4 paired sinuses in humans lined with pseudo stratified columnar epithelium. According to the location, each sinus is named.

1. **Maxillary sinus:** Amongst all the sinuses, it is the largest. Located under the eyes in the maxillary bone.
2. **Ethmoid sinus:** It is situated beneath the bone of the inner corner of each eye and resembles a honeycomb like formation of 6-12 small sinuses.
3. **Frontal sinus:** Located bilaterally, confined by the bone of the forehead and is located above the eye level and nasal bridge.
4. **Sphenoid:** One sinus is located on each side, behind the ethmoid sinuses and inside the sphenoid bone.

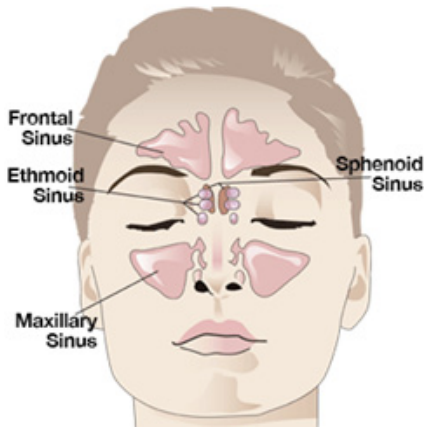

Fig. 1 Paranasal Air Sinuses

The maxillary sinuses are pyramidal in shape and lies in the body of the maxilla. They are the ones which develop at first during the second month of intrauterine

life.[1] These sinuses serve multiple purposes such as: moisturizes the air, equalizes variations in air pressure, maintains resonance expanding the olfactory mucosa area, reduces cranium weight, as well as plays a chief role in development of facial structures.[2,3] Reaches their maximum size by,with the eruption of permanent teeth.[4, 5, 6]

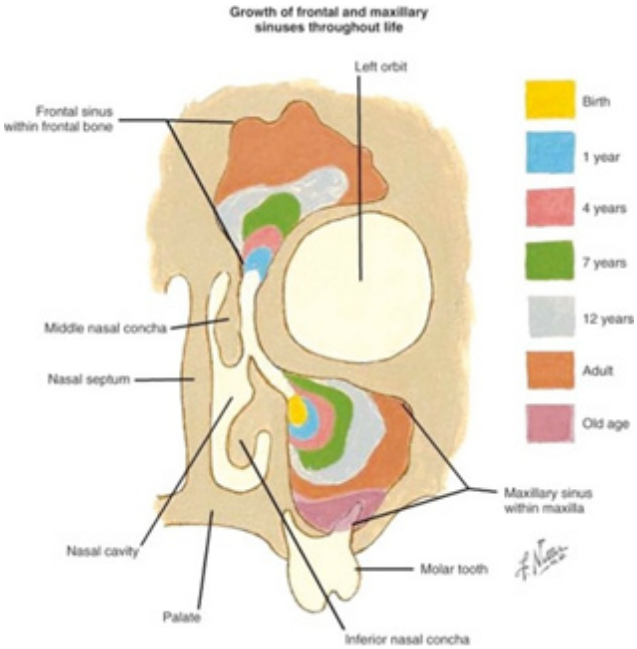

Fig. 2: Growth of maxillary sinus with age

Maxillary sinus floor is formed by thealveolar process of maxilla, sharing a close anatomic and functional relationship with posterior maxillary teeth.

Fig. 3 Maxillary sinus border

In a few cases the floor might overlap the root apices of the maxillary second premolars.[7, 8]And cases where the first molars are absent, for a longer duration of time, the sinus might occupy the alveolar process space of missing site thus invading more inferiorly, and hindering Orthodontic tooth movement (intrusion or protraction) as a result of the approximation of the maxillary sinus floor with tooth roots.[9]It is an indispensable diagnostic criterion to determine the relation of the maxillary sinus and the posterior teeth before Orthodontic treatment which involvesmesialisation of the second molar (in case the first molar is missing) or intrusion of the maxillary posteriors.[10]Proper assessment of the maxillary sinus is required to determine and treat dentofacial structures approximating or perforating the maxillary sinus. The evaluation also plays a chief role in movement of teeth those areapproximating the sinuses, placement of Temporary Anchorage Devices (TAD), and in some surgeries where the maxillary sinus contour is involved during Orthognathic surgery to prevent complications such as perforation of sinus and trauma to maxillary posterior teeth root apices.[11, 12,]

Clinical Consideration: The adult sinus has variable extensions. Its floor may extend towards the crestal bone between adjacent teeth or in the inter-radicular area of multi rooted teeth, and creates elevations (also referred as hillocks).[13]

14-28% of cases the root extensions overlapped by the sinus exhibit a cortical lining running along the root apex. The close relationship of the apex of the maxillary posteriors to the sinus, especially in second molar and first molar region, has various implications during treatment planning, such as:

1. **Extraction complication:** Displacement of root into the sinus cavity or Oro-antral fistulaeafter extraction of the first and second molars is a frequent complication. Hence the clinician must study the radiograph in detail and be cautious while handling the apical portion of the roots in close proximity to the maxillary sinus floor.
2. **Implants:** Wehrbein and Diedrich wrote about relation between the root length projection on the maxillary sinus and amount of sinus pneumatization post-extraction in panoramic radiograph and found that sinus expansion after extraction can greatly decrease the bone height available for placement of the implant.
3. **Endo antral syndrome:** Pulpallyinfected teeth near the maxillary sinus sometimes might spread into the sinus and lead to serious complications.
4. **Orthodontic:** Intrusion or bodily movements of the teeth across the sinus floor by Orthodontic tooth movement, cause greater amount of tipping and mild

to moderate apical root resorption sincesinusfloor is highly corticated.

5. **Periodontalor** periapical pathology in maxillary premolars and molars may spread beyond the boundaries of the supporting dental tissue into the maxillary sinus, which might lead to inflammation of the sinus or sinusitis.

Thus, knowing the anatomical relationship is necessary for diagnosing and planning a proper dental procedure.

Orthodontic Research Consideration: Accurate evaluation of the maxillary sinus is of utmost importance considering anatomical variations, close relation to the maxillary posteriors, and the implications that pneumatization of the maxillary sinus may possess. Supra eruption of maxillary posterior teeth, as is seen commonly in cases of missing opposing mandibular teeth, can also cause the floor of maxillary sinus to droop down leading to sinus pneumatization, in these cases requirement of intrusion with temporary anchorage devices (TADs) might be planned. Tooth movement across the sinus floor, particularly, is associated with a risk for root resorption and/or a higher degree of tipping. Orthodontic tooth movement despite the above-mentioned anatomical limitations is possible.

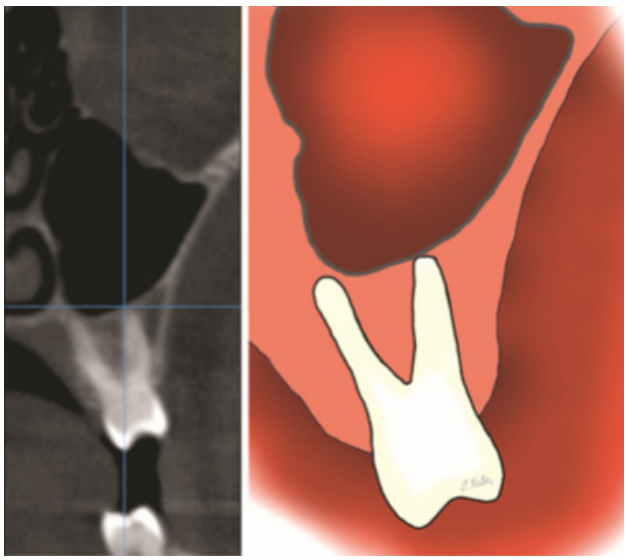

Fig. 4: Tangential view of left second molar tooth.

Movement of tooth through sinuses could be achieved in both antero- posterior and vertical directions by application of light and continuous forces.Cacciafesta et al., Re et al., Oh et al., Park et al. and Kuroda et al. found that the overall translation involves initial tipping followed by up righting.[14] MS Yao et al. said that for the intrusion of molars slight distal tipping is required.[15] Various studies have found, maxillary second and first molar in intimate relationship to sinus with the disto-buccal root of the maxillary second, being closest to the maxillary sinus followed by the mesiobuccal root of second molar. Maxillary first premolar is considered to be farthest away from the sinus followed by the second premolar. For Orthodontic tooth movement the thickness of lower border of maxillary sinus and its relationship with the posterior teeth is important. Evaluation of this relationship gives us a basis for appropriate force application during Orthodontic tooth movement. Thus, understanding anatomy and relationship or approximation to the apices of maxillary posterior teeth is of utmost importance before planning the treatment in relation to this specific area, especially the first and second molars. In cases where the maxillary posterior teeth are missing orare extracted, Orthodontists desire translation of adjacent posteriors for closing the spaces. Light-continuous force is advisable to reduce iatrogenic effects during Orthodontic treatment through the sinusfloor.

A study was conducted using Computed Tomography for measuring the average distances between the root of maxillary posterior teeth and the sinus floor. Scans from those 12 subjects, revealed that the apex of the mesiobuccal root of maxillary second molar was found to be closest to the sinus floor and farthest from the buccal bony surface whereas the apex of the buccal root of the maxillary first premolar was found to be closest to the adjacent lateral bony surface and farthest from the sinus floor. A study performed by Eberhardt et al. concluded that mean distance between the apex of the maxillary posterior teeth and the sinus floor was approximately 1.97 mm. 40% cases showed intimate relationship between the sinus floor and the root apices of the maxillary first and second molars. In 20% of cases the palatal roots are in close proximity to the sinus floor than to the palate. Before attempting Orthodontic tooth movement, the maxillary sinus floor and the posterior teeth in proximity must be studied properly and evaluated thoroughly via two-dimensional and three-dimensional radiography to ensure an improved prognosis of the finalised treatment plan.[15]

Conclusion

Maxillary sinus growth and development greatly affects the dentofacial structures. Regarding the approximation of the floor of the maxillary sinus and

the root apices,one must be careful whilecarrying out proceduresinvolving the maxillary posterior teeth. The application of light to moderate forces (by Temporary Anchorage Devices, segment and multibrackets) to for gradualmovement of the teeth through maxillary sinus in adults appears to be practical and secure. Translation of the teeth can be achieved, but the teeth tend to tip easily initially, resulting in root resorption. In a few cases, unpredicted complications such as root resorption, pulp ischemia, alveolar bone loss, and perforation of the sinus membrane were found to occur while moving the teeth through the maxillary sinus.Thus, all the above-mentioned elements should be surveyed prior to planning the treatment in patients requiring Orthodontic treatment.

Natural Tooth Pontic: Instant Esthetic Yet Temporary Functional Solution to Solitary Missing Tooth: A Case Series

Anurag Satpathy[1], Rajdeep Beura[2], Sheetal Acharya[2], Pratiti Datta[2], Akshyata Panda[2]

[1]Professor, [2]Post Graduate Trainee, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Khandagiri Square, Bhubaneswar Odisha, India

Abstract

Loss of a tooth in the anterior esthetic region hampers patient' esthetics and function along with jeopardizing the social life. Among the available options to replace the missing tooth, utilizing the patient's own natural tooth as a pontic comes as an instant esthetic yet temporary functional solution. A case series of two cases is presented in which the natural tooth was successfully used as a pontic for the management of single missing tooth in the maxillary and mandibular arches.

Keywords: *Natural Tooth Pontic, Anterior Esthetic Region, Resin-Reinforced Fibre Splint, Single Missing Tooth.*

Introduction

Loss of a tooth in the anterior esthetic zone is quite unpleasant for the patients of all ages, both gender and having any level of education[1,2]. It severely affects their looks, speech, confidence, morale and eventually their quality of life[3]. Almost all of them desire for not losing the tooth and if inevitably so, an immediate replacement to avoid adverse impact on their social life[4].

An immediate esthetic replacement of the tooth can be of a temporary nature, semi-permanent or permanent treatment. Patients mostly opt for a secure, fixed tooth replacement. Regular options for replacement of a single missing tooth include treatment partial dentures, Marylandbridges, fixed partial denture (Metal, Ceramic or Metal-Ceramic) and dental implant. The best suited option would consider esthetics, functions and economic concerns of the patient all considered simultaneously.

Utilizing the patient's own tooth to replace the failing or missing tooth as a natural tooth pontic (NTP) gives an additional option and is beneficial in several ways such as perfectly matching shade, shape and size[5]. Additionally, it provides a positive psychological support at minimal cost and chair-side time. It also almost requires very little laboratory procedure, all that can be done in a single visit[6].

We present a case-series of two cases in which the natural tooth was successfullyused as a pontic for the management of single missing tooth in the maxillary and mandibular arches.

Case Report

Case 1: A 58-year-old male patient reported to our outpatient department with a recently exfoliated lower anterior tooth. He was concerned about his looks and wanted to get the missing tooth replaced. He was apparently alright two years back when he noticed loosening of one lower anterior incisor. The loosening increased progressively leading to exfoliation of the tooth 5 days back. On examination the mandibular right central incisor (Tooth # 31) was missing (Fig 1). The overall oral hygiene was poor with moderate stains and calculus. There was no mobility in the adjacent teeth or any other tooth. This was patient's first dental visit. His family history and medical history was non contributory. Patient revealed that he was carrying the exfoliated tooth which he had carefully stored in a bottle immersed in tap water in a hope that the same could be re-fixed.

All options for replacement of a single missing tooth were explained to the patient. However, taking

into account of his concern for esthetics and immediate need, a treatment plan for a Natural Tooth Pontic was made. Patient was made educated and motivated for maintenance of oral hygiene. He was also explained about procedure, advantages, disadvantages and the temporary nature of the NTP. He intended to go for asingle tooth implant prosthesis after 2 months and deferred it owing to his financial constraints. A written consent was obtained before commencement of any treatment.

Full mouth supragingival and subgingival scaling was done in the same appointment.Scaling and polishing was done on the extracted tooth to remove all stains and deposits on them. The crown portion of the natural tooth was then sectioned from the root using a tapered diamond bur (Mani, Japan) at a distance from the cemento-enamel junction so that the apical end of the root was just short of the underlying mucosa and thus making a sanitary ridge-lap surface (Fig 2 (2)). The position of tooth was repeatedly checked before bonding to ensure perfect alignment in the edentulous space. The pulp chamber of the tooth was then cleaned and sealed with composite resin (Filtek™ Z350, 3M ESPE). A floss template was used to determine the length of resin-reinforced splinting strips (SPLINT –IT, Pentron Clinical Technologies, USA). The entire mesio-distal length of one adjacent tooth on either side was considered to be included in the bonding area. Abutment teeth (32 & 41) and the natural tooth pontic (31) were then etched on the lingual sided with 37% phosphoric acid (Total-Etch; IvoclarVivadent AG, Liechtenstein) for 25 seconds, thoroughly washed, and dried. Following this, a bonding agent (Adper Single Bond, 3M ESPE) was applied to the etched surface of enamel and cured for 20 seconds. A layer of flowable composite (Filtek Z350xt ™, 3M ESPE) was placed across the tooth # 41 and # 32 and the natural tooth pontic. The previously cutresin-reinforced splint was moderately wetted with the bonding agent (Adper Single Bond, 3M ESPE) and placed over the composite. The natural tooth pontic and the split werestabilized in the desired position cured. An additional layer of composite (Filtek™ Z350, 3M ESPE) was applied over the splint, carved and shaped before curing to ensureall part of the splint was covered by the composite. Allundesiredrestorative material was removed using diamond burs (Mani, Japan). Occlusal interferences in protrusion movement and lateral excursions were checked and removed. Finishing and polishing procedures was done using composite finishing kit (Super-Snap, SHOFU INC, Kyoto,Japan) (Fig 2 (3)).

The patient was happy with the final outcome of the procedure (Fig 2.(4) & Fig, 2(5)). Detailed post-operative instructions were explained to the patient. He was trained to use an interdental brush for maintenance of the natural tooth pontic area and was put on a maintenance recall schedule.

Case 2: A 41-year-old healthy male patient reported to our outpatient department with the chief complaint of mobility and extrusion of anterior teeth. He was concerned about his appearance and was apprehensive that his tooth might fall-off and wanted to get it treated. He was apparently alright one year back when he noticed loosening of one upper anterior incisor. The mobility of the tooth increased progressively with slight extrusion to reach its present state. There was no pain or swelling associated. On examination upper left central incisor (Tooth #12) was grade III mobile with extrusion(Fig 3). Patient revealed that this was his first dental visit. He was hypertensive and was on medication for the same since six months.

The tooth had a hopeless prognosis and was indicated for extraction. However, the patient needed an immediate replacement as he was concerned about his looks, thus a natural tooth pontic was planned with immediate extraction. After detailed explanation, a written consent was obtained before commencement of any treatment.

An atraumatic extraction of #12 was performed under local anesthesia (Fig4 (1)). The natural tooth was used as a pontic in a similar manner, as has been discussed above(Fig 4. (2) & Fig 2 (3)). Detailed post-operative instructions were given. Patient was happy and appreciative of the outcome (Fig 4 (4)) and intended to return for a fixed partial denture as a replacement after two months.

Discussion

Patients with loss of teeth in the anterior region require an immediate attention owing to their social and psychological concerns[7]. Among the various options available for rehabilitation, utilization of patient's own tooth as a pontic offers an immediate rescue to the patient's malady.

Natural tooth pontic were designed on similar principle of a Maryland bridge, replacing the acrylic tooth with the natural one[8]. NTP is highly appreciated by patients since it can be done in the same visit. Not only does it save them embarrassment, it works as a temporary arrangement prior to a more definitive treatment.

NTP relies on adhesive dentistry for its success, with the availability of periodontally stable adjacent teeth which act as abutments. It is technique sensitive and requires a sufficient level of clinical skill to achieve satisfactory result. Several adhesive composite resins have been used to bond the natural tooth. The tooth is splinted with an additional reinforcement using wires, nylon, fibre splints, resin-reinforced etc[9].

Clinical failures often stem from the inability of these materials to be chemically incorporated in the composite resin when the loading stresses are applied to NTP. Also, low fracture strength of the composite resin may lead to de-bonding leading to unpleasant social scenarios.

We used good quality composite resin in our cases. Resin-reinforced splinting strips as used by us are quite translucent. It is pretreated with resin, adaptable and thus saves time.Strassler et al [10] however, suggested against the use of composites owing to its varying esthetics, susceptibility to wear and nidus for plaque accumulation. Chafaie et al[11] and Pankratz et al[12] reported an improved clinical performance of fibre-reinforced composite bonded prosthesis over five years.

In both the cases, a sanitary pontic was adopted which has no contact with the underlying mucosa which is beneficial in maintaining a plaque free area and allowing uneventful healing of the extraction socket. Prevention of formation of microbial plaque is essential for long term stability of periodontal health[13, 14]. Preservation of a part of root in the pontic gives an illusion of tooth emerging like a natural tooth [15, 16].

Natural tooth pontic comes along with its share of limitations such as technique sensitivity, reliance on patient's motivation for oral hygiene maintenance, irritation from tongue, minimal functional efficiency and above-all possibility of de-bonding. Notwithstanding these short-comings, successful natural tooth pontics have been reported[17-19] with Nakamura et al reporting a case treated with natural tooth pontic stable after eleven year [20].

Conclusions

Both the patients were satisfied with the outcomes of our treatment modality. This endorsesit's utility as a regular viable option wherever indicated. However, patient selection, plaque control and skill of the operator are crucial for its success.

Halitosis-Bad Breath: Etiology, Diagnosis, Treatment

S.S.R. Raghu Ram

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Bad breath is also known as Halitosis, it is the most common amongst the general population. Halitosis has been the 3rd highest reason for opting dental care, which follows tooth caries and periodontal issues. Technology and communications have witnessed enormous growth in this field recently, particularly because growing in for halitosis remedies on television ads, internet promotions and in weekly magazines. The level of guidance and misinformation on bad breath among the people, person to person, as a resultant thing. None of the human life can have complete resistance against the halitosis in their life time. Halitosis may be a sign of major or minor issues with your digestive processes, gingival diseases, allergic point of any infections, an acid system of the bod, low immune or most common cause than anything else – bad oral maintenance or contaminating bacterial growth. Unawareness of the proper maintenance and preventive measure to keep themselves hygienic for a better life in a quality manner and so as the oral health. The negative interference of bad breath needs to be taken into consideration as the relationships in today's society, as that in one of the pillars for having a quality life and proper life concept. This short review provides a comprehensive idea of the etiological factors of breath breath/ foul oral smell/halitosis, the prevalence, the diagnostic procedure and treatment aids for such conditions.

Keywords: *Oral malodor; Volatile Sulphur compounds; Breath malodor; Chlorhexidine mouthwashes.*

Introduction

Bad breath or oral malodor or halitosis is most common of us elementally have some transient unpleasant oral odor in our whole day to day life. When it becomes severe or chronic, that might cause the decrease in self-confidence and interactions socially. Halitosis have been a concern of millions of people, as it receives most of the attention in public, humorous literature than by the scientific, one of the examples phrases such as "Never settle or breathe until or before you reach the desert." The phenomenon which gets often oversimplified by the commercial industry of dental sciences, misconception in the normal society and not much understood by any scientific communities. of late,the awareness about halitosis and oral health problem is increasing enormously and need to be recognized and addressed to Dentist or dental profession,Many adults suffer from halitosis, on regular basis and causes the mind to set and may lead towards the social disagreement and personal discomfort.[1] There on, some authors estimated approx. 50 percent of the middle-aged and the elder individuals produces unaccepted social breath, upon raise in the morning they attribute from physiological causes.[2] The authorized incidence ratio is almost the same in male patients and female patients with oral halitosis or bad breath; In regard to prevalence and severity of bad breath there are no differences based on gender. However, more often women seek preventive or curative procedures than in men. Thus, this could be the sign of women are generally more concerned about the self-appearance and status of health in themselves.[3,4.] No matter whether the odorous substance emit from oral or non-oral places. 'Bad breath' is the term generally used to mentioned or indicated for any foul odour in air expired. Other names used are halitosis, fetor ex ore, bad or foul smell, breath malodour, fetor oris, and oral cavity malodour is foul or offensive odor exhaled through the person's mouth.[5] There only few patients who regularly visit dental clinics seeking for treatments, despite the reports of high prevalence in breath malodorous."Bad breath paradox", the term is given to this fact, due to the complete unawareness of this fact by people suffering from halitosis or bad odours. Whereas, few others may remain convinced by the fact that they are suffering oral malodorous, although few cases, no basic objective can be seen (pseudohalitosis or halitophobia)[6]

History: Odours play an important role in giving the evidence in creation and social bond conservation, as they are loaded high octane values for culture. This problem of bad breath has been reporting for ages and ages. Reference from the Papyrus manuscripts of date Back to 1550BC.[7] Sulphur is the devil's supreme malignant odour smelled. During Christianity, and more or less foul smell that was produced by sins. In Islamic literature a treaty in year during 850 mentioned about dentists and dental procedures for treating patients suffering from fetid breath and suggested them to use the siwak whenever the smell orally had changed or at anywhere while getting up from bed. Mouth is considered as the body's opening door, in Hindu culture and therefore need to be kept clean and mainly before offering prayers in the morning or while waking up. This practice is not only limited to brushing the teeth alone but also scraping the tongue by using an instrument specifically designed for cleaning tongues and use of mouth washes. Before the initial prayers are offered the teeth brushing and tongue scraping is practiced in Japan by Buddhist Monks.[8]

Etiological factors: Oral bad breath immediately after awakening is most common and it is not considered as the bad breath or halitosis. Chronic and persistent oral malodorous is mostly caused by oral or at times nasopharyngeal diseases. Generally, the decomposition of food and beverages or particles, body cells, blood smear and few chemical components of saliva results in Halitosis.[9] Hence almost 90 percent of causes of halitosis are seen orally in the mouth itself. The gram-negative bacteria of the oral microbes are most commonly cause the bad breath or halitosis, which includes *Prevotella melaninogenica (Bacteroides), Tannerella forsythensis (Bacteroides forsythus), Fusobacterium nucleatum nucleatum, Porphyromonas endodontalis, Enterobacteriaceae, Eikenella corrodens, Fusobacterium nucleatum vincentii, Treponema denticola, Porphyromonas gingivalis, Prevotella intermedia, Centipeda periodontii, Fusobacterium periodonticum, Bacteroides loescheii* and *Fusobacterium nucleatum polymorphum.*[10]

Primarily the volatile sulfur compounds cause the Halitosis or bad breath, particularly, hydrogen sulfide and methyl mercaptan, these are the proteins containing sulfur amino acids results in halitosis by bacterial putrefaction.[11] The products or by products mentioned would be involved in the transition from healthy gums to gingivitis followed by periodontitis or any other periodontal diseases. Local causes of bad breath are mainly the Tongue and Sulcus of the gingiva and includes remnants of odoriferous particles of food and beverages on and interdentally, between the two teeth, necrotizing ulcerative gingivitis (NUG) coated tongue, Smoker's Breath, artificial dentures,healing surgical wounds or extraction wounds, dehydration conditions and caries. Easy identifying factor of NUG is the fetid Odour as that is one of the confined characteristic features of NUG. [12,13] The increase in rate of Saliva putrefaction, accumulation of any debris in the pockets of chronic periodontitis conditions cause the unpleasant or foul odour from the mouth.

Diagnosis: Earlier the diagnosis for measuring halitosis were decided through human's judgement, by sensing the own smell and asks the patients to blow air from mouth to sense the odour of patient's saliva or breath, this procedure was followed for years and centuries. For detecting the Halitosis by which particular compound, they create a hypo additive, nonlinear bonding between the number of oral malodorous substances available.[9] As the human sensory system also have the limited places to judge and isolate the ability processing orally. By comparing the two odours (organoleptic assessment) of exhaled sir of the oral cavity and exhaled air of the nasal cavity, generally the clinical assessment of bad breath or any oral malodorous is subjective for individuals.[10] In Organoleptic measurements, based on perception of examiner on a patient's oral malodorous the subjective test score is measured. Earlier there are different quantitative and semi- quantitative scales had been used, however, at the most recently organized International Workshop on Oral Halitosis year 1999, there was a consensus for using the scaling ranges from 0 to 5, measurements of breath odours is objective in rare situations when talked about clinical practices, as it is costlier and consumes time.In case of volatile sulphur substances, a pitta le sulphide monitor can be used for measuring, but this provides an inaccurate assessment by sources and intensities of oral malodorous, as oral malodours comprises of agents other than volatile sulphur compounds.[14] Though it is not used in clinical practices or clinic works, the potential method for determining oral malodorous and its components are by Gas Chromatography of Oral Breath.Same way, there are many other assessments to determine or detect the oral breath and its components are by Detection of bacterial activities in trypsin, Benzoylargin-Naphthylamide test,dark field microscopy and Real time Polymerase

Chain Reactiondetection for causative oral microbes. As mentioned, all these falls outside the routine practice for obvious reasons.[15] Other tests are: Saliva odour test, Flossing odour test, Spoon test.

Treatment: Identifying the cause of malodour is important, before rendering any treatment. Through which the proper treatment could be given to the corresponding source can be employed.[16] Any systemic sources causing malodour, must be specially treated by the physician or appropriate specialists. Primary treatment is to bring the awareness in the patient which can be directed them to prevention to the source and lessening the bacterial accumulation orally, time to time. Proper and regular teeth cleansing, which includes teeth brushing and use of dental floss interdentally, can significantly bring down the oral halitosis, patients with poor oral health and its related gingivitis or periodontal diseases are more prone to use on regular basis. In cases where the oral health condition is already good, or improved and yet the oral halitosis persists, the tongue might be the causing factor of oral halitosis and thereby cleaning or tongue, should be followed every time after the teeth brushed. It is observed that there can be only transient reduction in oral malodour by using the chewing gum. The suggestible range of mouthwashes for treating the oral halitosis act by reducing either by the bacterial loading or by the odoriferous compounds associated to Triclosan, have direct action opposing or resisting the sulphur compounds and an antibacterial effect. Used in toothpaste, mouthwashes, fluoride applicants, it may reduce the oral halitosis or bad breath. However the action of triclosan On oral halitosis against the compounds of sulphur seems to have dependence on the solubilizing agent with which it gets delivered.[14] Chlorhexidine Gluconate gives the down fall in Bactria which produced volatile compounds of sulphur and mouthwashes or spray which can be effective at reducing oral halitosis or bad breath, for several hours to keep the oral hygiene intact and to reduce the bacterial growth than by improving oral health. Chlorhexidine/ Cetylpyridinium Chloride and zinc lactic acid can also reduce the oral halitosis, these are supplied and available in mouthwashes. The major disadvantage of chlorhexidine usage of long term is that it has an unpleasant taste, causes stains over the tooth surface, if used frequently it may give burning sensation of mucosa and tongue orally, hence the patients have high reluctance to use the chlorhexidine mouthwashes.[15, 16]

Conclusion

Social aspects and oral malodorous has the major relation which always been a source of concern among the society which, in an attempt of hiding them, usage of different components and different method to reduce the oral malodor. Oral halitosis has been an obstacle for experiencing full conjugal life every time. To have the breath smelling mint-fresh, one has to remember the routine rinsing of mouth after each meal, either with mouthwashes or normal water, habit of practicing teeth brushing followed by tongue cleaning daily, and incorporating more of digestive herbs and spices in their daily intake of food. And one should remember it's not wise to ignore bad oral smells, and shrug it off by annoying, embarrassment, or simple insignificantly. Educating about the oral health and general body health should be accomplished with views to a dynamic balance, these can be done by involving humans - physically and psychological aspects, as well as to have their social interactions, so that the individual person do not become puzzled of any sick parts in them.

Newer Advances in Non-Surgical Periodontal Therapy: An Update

Sarmishtha Das[1], Rinkee Mohanty[2], Anurag Satpathy[3], Rashmita Nayak[3], Saurav Panda[4]

[1]Postgraduate Trainee, [2]Professor & Head, [3]Professor, [4]Reader, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Periodontal disease is an inflammatory condition which involves the interaction between periodontal pathogen, acquired and environmental factors and the host. Along with the gold standard of scaling and root planning the recent technologies play a crucial role in recognizing the disease in early stage, eradicating the periodontal pathogens and causative factors which were previously inaccessible, delivering medication without systemic complications and improved home care techniques. The present review is focused on prevailing treatment modalities of periodontitis patient, chemico-mechanical approaches of treating patients and the use of home care treatment installations to reduce the needless dental visits. The review also attempts to throw lights on the current trends and future developments in some of these treatment choices.

Keywords: *Nonsurgical periodontal therapy, scaling and root planning, laser, probiotics, local drug delivery.*

Introduction

Periodontitis is a multifactorial disease that involves the association between the pathogenic microorganisms and the host which acts as a most common cause of tooth mobility and tooth loss.[1] The current etiopathogenesis suggests that the site specific pathogens accumulate in the periodontal pockets which causes interaction between the microbes and host leading to the generation of inflammatory mediators and ultimately destruction of the periodontium.[2, 3]

The overall aim of NSPT is to elicit an oral hygiene status that is compatible with the healing of periodontal tissues. The success of NSPT solely depends on compliance of the patient, daily home care and effective plaque control.[4] Formerly the treatment of periodontitis was focused mainly on eliminating the biofilm and environmental factors.[5] The current treatment modalities are giving importance to the host mediated immune responses which are responsible for periodontal destruction.

Corresponding Author:
Prof. Anurag Satpathy
Professor, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: drasatpathy@gmail.com

Rationale

- To promote tissue healing and to evaluate tissue
- Arrest the progression of periodontal disease
- Induce positive change in the sub-gingival bacterial flora
- To evaluate the patient's attitude towards periodontal treatment
- Long term success of periodontal treatment depends predominantly on maintaining the results achieved with phase I therapy

Advantages: NSPT in spite of it being the mandatory phase 1 therapy is beneficial in patients with systemic conditions in which surgical periodontal treatment is contraindicated. Also, gingivitis and mild chronic periodontitis may be controlled with NSPT alone.

Laser therapy: Dental LASERS can be used as an adjunct to the scaling and root planning procedures. FDA has approved the Er: YAG laser for using it

in debridement. The application of LASER along with conventional SRP also provides a new locus for attachment of connective tissue after the removal of microbiota.[6] According to Choi et al the process of fibroblastic activity begins after 24-48 hours of the laser treatment and increases after 72 hours.[7] The fibroblastic activity alleviates in restoring the periodontium after destruction by inflammatory diseases and also improves the clinical attachment level. There is also a significant decrease in the spirochete like *Treponema denticola* and other motile rods and an increase in the number of coccoid cells.[8]

Nevertheless, mechanical debridement still functions as the gold standard for scaling and root planing procedures but the compilation of laser with SRP shows more effective decontamination of the pocket and a slow re-colonization rate of the treated site.

Perioscan scaler: It is an ultrasonic dental scaler that notifies the clinician the location of calculus optically via an acoustic signal during the treatment. The perioscan the software has the ability to detect the type of surfaces (whether it is bone, cementum or calculus) with which the ultrasonic scaler tip is making contact using a different oscillation pattern for different surfaces. The acoustic signal shows a green light when there is cleaned root surfaces and blue light when there are chunks of calculus left. Painless periodontal therapy can be achieved to a great extent by using Perioscan and lessens the chance of hypersensitivity and recession due to over instrumentation.[9]

Photodynamic therapy [PDT]: The principle of PDT is that at a certain wavelength (red light of 630-700nm) and in the composure of oxygen a photoactive substance (tricyclic dyes, tetrapyrroles) attach to the bacterial cells and highly excited oxygen molecules are created which eventually destroys the cellular structure of microorganisms. PDT is minimally invasive and has a broad spectrum of action against microbes. Study showed that photodynamic therapy along with SRP reduces the gingival inflammation.[10]

Perioprotect: They are patented customised trays which deliver medication in the deep periodontal pocket, furcation areas and other inaccessible areas of mouth. These are clear, mouth-guard like devices which allow the medication to reach below the gingival margin. The tray prevents the medication from seeping into the saliva by sitting close to the gingival margin.

The Perioprotect carry peroxide and an antioxidant to the patient mouth. A study done by Mark S. Putt in 2012,showed that the of use of 1.7% hydrogen peroxide gel delivered by Perioprotect (customized trays) after SRP in periodontitis patients results in decreasing the pocket depth.[11]

Local drug delivery systems: Local drug delivery system helps to slowly release the drug over a certain time period which helps the overall oral health and systemic status by increasing the drug concentration on the desired location and also by reducing the side effects of systemic antibiotic therapy. The list of local drug delivery systems currently available in the market.[12]

Table 1. Commercially available products for Local Drug delivery

Product	Antimicrobial agent	Dosage form	Manufacturer
Arestin	Minocycline	Biodegradable powder in syringe	Oropharma corp Warminster
Atridox	Doxycycline	Biodegradable mix in syringe	Attic labs,Ft, Collins,co.
Elyzol	Metronidazole	Biodegradable mix in syringe	Dumex corp. Co Denmark
Periochip	Chlorhexidine	Biodegradable device	Dexcel Pharma Inc. Jerusalem
Elyzol	Minocycline	Gel	Dumex pharma
Actinide	Tetracycline	Non-resorbable fibre	Alzacorp

Also, FDA has approved doxycycline hyclate carried in an absorbable polymer gel which is used after SRP to reduce the probing depth of the pocket. The drug delivery system is evolving into Micro particular and Nano particular, biodegradable technology. The Microparticular systems (size 1-1000 μm) and nanoparticle (size less ≤ 100 nm)which allows sustained release of drug, improve bioavailability and reduces any unpleasant taste of the drug. This ultimately results in a superior treatment method.[13]

Probiotics: The use of probiotics in the maintenance and improvement of periodontal health has been markedly increased over the decade. These signs of inflammation can be diminished by either decreasing the periodontal pathogens or by host modulation.

The bacteria evolve into multi resistant strains and due to the frequent use of antibiotics, the patient also

develops antibiotic resistance with time. Here comes the role of probiotics. It helps to facilitate the activity of certain bacteria which are beneficial for periodontal health and act as a selective inhibitor to harmful pathogens. They mainly act by three mechanisms.[14] Immune system modulation, production of antimicrobial substances and competitive exclusion.

The probiotic bacteria are lactobacillus and bifidobacterium, a non-pathogenic strain of *E. coli*, *clostridium butyricum, S. salivarius* etc. They can be delivered in the form of lozenges, tablets and toothpaste for example Periobalance chewing gum (containing strains of *L. reutari*) and Periobiotic toothpaste (contains *lactobacilli paracasei* strain).

Any serious complications regarding probiotics have not been cited yet but there are chances of systemic interactions. Hence probiotics must be used with caution in persons having major risk factors like immunosuppression or minor risk factors like dysfunction of barrier membrane of the intestinal epithelium, valvular diseases etc.[15]

Periodontal vaccine: Periodontal vaccine deals with specific bacterial strains which causes *periodontitis like P. gingivalis, T. denticola, T. forsythia* and *A. comitans*. The vaccinations can be achieved by active immunization (heat shock protein, hemagglutinin, synthetic peptides) passive immunization or by using DNA vaccines. With the help of gene therapy, we are gaining a future perspective in the development of the periodontal vaccine. DNA encoding of *P. gingivalis* gene produces a specific salivary IgA, IgG and serum IgG antibodies to neutralize *P. gingivalis.* The development of a multispecies vaccine that could target all four bacterial species is still in progress.

Nanotechnology: Recently nanoparticle systems have been introduced and because of their nano size so that they can reach all the inaccessible areas of the mouth. The nanoparticles were produced by the process of micellar polymerization which in turn results in a white powder like material of particle size 50-180 NM. Biocompatible nanoparticles are mostly made up of 2-hydroxyethyl methacrylate (HEMA) and polyethylene glycol dimethacrylate (PEGDMA). Triclosan and tetracycline are usually incorporated in this nanoparticle. These help in distributing the drug uniformly over a controlled period of time. Nano-diagnostics which uses nanotechnological advancements (Quantum dots, Nanoscale cantilever, Gold particles etc.) for detection of periodontal and other diseases at early stages.

This system can be easily incorporated in any other chemical plaque control devices like dentifrices, mouthwash, chewing gum etc. Henceforth the nanoparticles have the property of slow release and biodegradability and it has shown significantly good results after the scaling and root planning therapy. They are also inexpensive and easily available. Recent developments are giving us promising insight into the application of nanomaterials in periodontal diseases.

Host modulation therapy (HMT): Long term management of periodontitis requires a treatment strategy that would address both periodontal pathogen and host response. Chemotherapeutic treatment targets MMPs, cytokines and other mediators in the pathogenesis of the periodontal disease. HMT is an emerging treatment concept in the field of periodontics. Anti-proteinase, anti-inflammatory drugs and bisphosphonates are frequently used as host modulation agents. Sub antimicrobial-dose of doxycycline is used in adjunct to SRP in chronic periodontitis patients. NSAIDs are also used as they inhibit the formation of prostaglandins. Chemically modified tetracycline is used to reduce inflammation by inhibiting IL-12 and TNF alpha in chronic periodontitis patients.[16] Future HMT agents include nitric oxide synthase inhibitors, recombinant human interleukin 11 etc. Intensive periodontal therapy alongside HMT may have a profound positive effect on the overall health status of patients.

Ozone therapy: Ozone is unstable and produce nascent oxygen which results in destroying periodontal pathogens. It has an antimicrobial effect and is very effective against antibiotic resistant bacterial strains. It possesses immunostimulatory effects and stimulates the synthesis of immunoglobulins and enhances the sensitivity of microbes towards phagocytosis.[17] It has shown antihypoxic effects too as it increases the oxygen concentration in the blood which results in activation of aerobic processes like glycolysis, Krebs cycle etc. Currently, HealOzone by KaVo and Prozone by Wand H are some of the ozone producing appliances available in the market.[18] Ozone therapy is contraindicated in cases of pregnancy, severe anaemia, haemorrhage, a recent history myocardial infarction, hyperthyroidism.[19]

Home Care Techniques

Ara toothbrush: It is the first artificial intelligence toothbrush. Manufactured by Kolibre, a technological firm which specialises in dental products marketed this toothbrush in the year 2017. The brush uses Bluetooth to

connect to an app, which records and displays brushing data including frequency, duration and areas which are brushed thoroughly. It uses the property of sonic vibration for plaque removal. The weight is 70 GM's and has a two-week battery life. It is also able to see weekly emails presenting a review of brushing data and analysis over a seven days period.

Water irrigation system: An oral irrigator or water irrigating device is a dental home care product. It uses a stream of pulsating water (pulsation ranges from 1200-1400/min) to remove food debris and plaque. There is also a soft, site-specific, subgingival tip used for subgingival irrigation.

Other solutions that can be used in place of water-Chlorhexidine diluted, Povidone iodine (1:9), Stannous fluoride (1:1) solutions. It is just a point and shoot device which doesn't require high amount of dexterity. It helps patients to clean around braces, crown and bridges, implant surfaces and deep sub gingival pockets. Study cited that waterpik along with manual toothbrushes removes 29%-39% more plaque than regular waxed string floss.[20] Waterpik system is more effective in reducing bleeding and gingival inflammation than other water irritation device.[21]

Oil pulling: Oil pulling is an ancient, Indian practice which is believed to improve the oral health as well as systemic health. This involves swishing the oil inside the mouth for around 15-20 mins. The concept of oil pulling is simple – when we swish oil inside the mouth the bacteria gets dissolved in the oil. It can be done with various types of oil (coconut oil, olive oil, sesame oil) but most frequently used oil is coconut oil because of its pleasant taste. It contains fatty acids and high amounts of lauric acid, which harbour antimicrobial properties. Coconut Oil pulling has shown to reduce the amount of *Streptococcus mutans*.[22]

A study done by Kaliamoorthy et al on 60 adult patients with oil pulling for 10 minutes showed a significant decrease in the number of *S. mutans* in saliva within a span of two weeks. It is proven as an effective routine oral hygiene measure to reduce gingivitis. [23]

Conclusion

The treatment modalities in the field of non surgical periodontal therapy is radically changing and expanding horizons for a better understanding and treatment of periodontal diseases. Newer treatment method are increasing our inquisitiveness to venture deeper into the potentialities of the future of non-surgical periodontal therapy.

Musculoskeletal Disorders in Dentists

Anand Nayak[1], Swati Patnaik[2]

[1]Intern, Department of Periodontics and Oral Implantology, [2]Assistant Professor,Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Injuries or pain in the human musculoskeletal system, ligaments, muscles and nerves are called musculoskeletal disorders or MSDs. With the ever-increasing sophistication involved in treatment and the need of affluent precision in the field of dentistry, both patient expectations and simultaneously the time involved in procedures are increasing. This leads to prolonged muscle imbalances in the dental professionals due to awkward postures, repetitive motions, stresses, forceful exertions and various psychological factors also, resulting in stressed shortened muscle becoming ischemic and painful. This proliferative and infiltrative process can affect the tissue badly. Reviews and articles around the world have given us a vast spectrum of ideas about how MSDs effect dental practitioners. The objective of this study is to determine the prevalence, causes and simultaneously the prevention of Musculoskeletal disorders in dentistry.

Keywords: *Musculoskeletal disorders (MSDs), Prolonged Static Postures (PSPs), prevalence of MSDs, prevention of MSDs, Conclusion.*

Introduction

Dental profession prevents, diagnosis and treats diseases of oral cavity and related structures. Dentistry is a visually dependant occupation, where to better their visual demands, they are required and bound to work in affix posture for extended periods of time. This exposes them to many harmful factors. The awkward postures cause discomfort and disorders of the musculoskeletal systems and the peripheral nervous systems.[1]

Nearly a million people each year report taking time away from work to recover from loss of function due to overexertion in the lower back or upper extremities. Thus, making it a significant and costly workplace problem. MSDs can be defined as discomfort or chronic pain in the muscles, tendons and joints caused by repeated movements and uncomfortable body postures. Dentists come under high risk of MSDs as dentistry is one of the most demanding and stressful occupation in the world. Most dental workers provide care in a relatively small dental workplace while treating patients. During the whole treatment the dentists must stretch, reach, twist their bodies in order to reach for an equipment, dental materials or paperwork.[2]

Musculoskeletal system or MSS is composed of bones, muscles, tendons, ligaments, cartilage, nerves and blood vessels. This well organised system distributes loads and supports the body the action of skeletal muscles and joints produce obvious movements such as walking and running. In addition to movement, muscle contraction also fulfils some other important functions as joint stability and heat production. Hence this article sheds a light on what are the causes of growing number of musculoskeletal disorders in dentists and how we can prevent this by following easy yet crucial steps.[3,4]

Mechanisms of MSDs: According to WHO (2007), MSD can be defined as a disorder of the muscles, tendons, peripheral nerves not directly resulting from an instant event. These disorders are mostly created by work related environments. According to Centres for Disease control and prevention (2016), "work related musculoskeletal disorders are conditions in which the

Corresponding Author:
Dr. Swati Patnaik
Assistant Professor, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: swatiptnk88@gmail.com

work environment and performance of work contribute significantly to the condition and/or the condition is made worse due to work conditions."As per international statistical classification (ICD-10), in occupational health MSDs classified as:

- Diseases caused by mechanical vibration, affecting the hands and arms
- Neuropathies: Carpal tunnel syndrome, Other lesions of median nerve, Lesion of ulnar nerve, Lesion of radial nerve
- Diseases of musculoskeletal system and connective tissue: Synovitis and tenosynovitis Oral enteropathies.[5]

Musculoskeletal pain especially back pain is often the main occupation related hazard among dentists and dental students. Many of them ignore the early signs of symptoms of MSDs which then lead to chronic back pain, muscle ischemia etc. The early symptoms are excessive pain in arms, shoulders, burning sensation in neck and arms. So only if we know the causes that lead to early symptoms; then we can easily prevent MSDs.[6] When dentists are working in the same postures for hours then it initiates pain or injury to the muscle. In some major instances it may cause an end of their career.[7]

PSPs: PSPs stands for Prolonged Static postures. When a human body undergoes PSPs again and again; then it causes muscles Ischemia/ necrosis and imbalances. Dentists always find themselves in awkward and uncomfortable positions during treating patients. This position causes stress in muscles which can become very painful. These positions exert asymmetrical focus that can cause misalignment of the spiral column. PSPs also cause hypermobile Joints. During PSPs, due to muscle contraction the joints are restricted and the production of synovial fluid is restricted which causes the hyper mobility of joints. Neck MSDs are also caused by repetition movements of neck. Low back discomfort is associated with dentists in various researches.[8]

Prevalence of MSDs in dentists: According to International Journal of Applied Dental Sciences, the prevalence of MSDs among dentists is about 49-92%. Women reports higher frequency of pain and discomfort than men. Among the body parts neck was the most affected in 26% to 83.8%. Back pain was reported in 22.2% to 91% of dentists, in which upper back is 20% to 61.8% and lower back is 34% to 69.8%.[9]

Risk factors: The work in dentistry can be characterised bysome body postures with different degrees of distortion. There are many types of factors responsible for MSDs; occupational factors, medical factors and lifestyle factors. Usually two or more factors trigger MSD. A study of the working postures of dentists found that they spent 86% of their working time with neck flexion of at least 30% and 53% of their worktime with a trunk flexion of at least 30%.[10]

Prevention: By taking some steps in our day to day dental practice, we can prevent the risk of MSDs. Among many preventive measures the notable and important measures are as follows:

- We have to focus on adequate machinery, tool designs, modification of equipment and process, correct operations and maintenance of process.
- By creating a low-stress work atmosphere, by maintaining a good routine work practice we can also prevent MSDs.
- As primary measures we need to teach dentists and undergraduates about the risk factors and proper working postures.
- Secondly, proper diagnosis of the affected dentists with early signs and symptoms of MSDs and work forward to change their working setting and work environment.
- Thirdly, we need to help the people suffering from chronic MSDs by redesigning their work station as per their convenience.

Specific stretching and exercises for neck and shoulders to improve their health of the spiral column, maintains good working postures, optimises the function of the arms and neck. There are many stress relieving techniques which decreases stress related muscular pain. They include breathing techniques, progressive relaxation, visualisations, massage and aerobics.[10] Aerobics exercise when performed 3-4 times a week for at least 20 minutes, it increases blood flow to all of the tissues in the body and improves their ability to use oxygen.[11, 12]

Conclusion

Preventing pain and discomfort caused by MSDs is going to be a bigger task than assumptions in general. It is going to need tremendous change in the dental undergraduate's curriculum to teach and educate the

dental students about proper work postures and regular exercise to counter musculoskeletal disorders. Dentistry is a highly demanding field of occupation both physically and mentally, therefore we need to take care of our body so that we can treat and work for the betterment of society.

Early Orthodontic Treatment of Class II Malocclusion with Functional Appliances

Payada Patnaik

Post-Graduate Trainee, Department of Orthodontics & Dentofacial Orthopedics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The aim of this article is to figure out the studies that explain how the functional appliances affect the dentofacial structures in Class II malocclusions treated cases. Previous literature question about the proper timing &importance of initial stage orthopedic treatment. In the treatment of class II malocclusion, orthopedic appliances are effective,however such treatment have been questioned by Randomized clinical trials suggesting failure of treatment that were brought about in the initial stage of treatment reducing long-term benefits. Despite these questions modern orthodontics still revolve around the concept of growth modification.

Keywords: *Functional appliance, Growth modification, class II malocclusion.*

Introduction

"A functional appliance harnesses natural forces which it transmits to the teeth and alveolar bone in a pre-determined direction".They are fabricated to modify the patient pattern of function, the jaw relationships, and reprogram the neuromusculature, thus altering the functional matrix of the face. A famous design for treatment of skeletal class II malocclusion is early phase of functional therapy for growth modification proceeding with final fixed appliance treatment. The early phase deals with skeletal correction and the final phase with dental corrections. Occasionally early phase combines with the final phase. But ideally the final phase is simpler which primarily corrects dental malocclusion without extraction. The early phase may be associated with dental and dentoalveolar effectsalong with growth modification effects.

Numerous randomized clinical trials of initial class II treatment claim that initial treatment had fewer effects on the treatment sequel which includes skeletal modification, alignment of teeth, duration of treatment.[1] The main aim of this reviewis to focus on the early phase functional therapy in consideration with their treatment outcomes. However, obstacles are encountered while analyzing results from existing literature as successful outcomes are not steady for which it becomes problematic to correlate.

Outcomes of orthopedics appliances: Possible primary factors for the transformation of Class II malocclusion into Class I malocclusion are patient compliance, stimulatory effect on mandibular growth, restraining effect on maxillary skeletal base, mesial movement of tooth in the mandible, distal movement of tooth in the maxilla. The major goal of orthodontic treatment is to correct the esthetic appearance of the dentition and thus improving the psychology of patients.[2]

Pancherz[3] expressed that treating the patients ofclass II malocclusion with Herbst appliancefor around 6-8 months resulted in Class I dental arch relationships. Improvement was found in sagittal direction which includes molar and incisor relationships along with few skeletal and dental changes. Molar correction comprisesaugmenting the mandibular length, distalizing the maxillary molars, moving the mandibular molarsmesially. Correction of the overjet was seen due toadvancement in the length of the mandible

with mesial movement of mandibular incisors.[4] The authors concluded that maximum improvement in the malocclusion was seen because of dentoalveolar change with minimal skeletal change that was statistically significant.[5]

According to Woodside,[6] confinement of the growth of midface, stimulation of mandibular growth beyond its normal growth potential, posterior displacement of the condylar growth, transformation of ramal form, change in the direction of the growth of mandible more towards anterior/horizontal direction, remodeling of bone tempted by neuromuscular changes, and adaptive changes in glenoid fossa to a more anterior-superior position includes the orthopedic effects of dentoalveolar and skeletal changes.

Pancherz and Hagg,[7] observed when the functional appliance treatment was advised during the period of the peak height velocity usually between 10.5 and 14 years in girls, and 12.5 and 16 years in boys there was an increased condylar growth response. Andresen and Haupl, promoted concept of activator, found that with the new closing pattern of the mandiblenewer musculoskeletal adaptation was encouraged allowing the redirection of the orofacial musculature. When themuscles try to return the mandible to its original position, a bio-mechanical force is generated by the advancement of the mandible through the appliance.[11] According to few Studies, once the mandibular genetic growth potential has reached its maximum limit or the calculated termination of craniofacial skeleton growth has occurred most of the changes result from dentoalveolar correction[8] rather than from the continuous force to the condylar cartilage due to protraction of mandible. Ruf and Pancherz[9] stated Herbst appliance treatment in adults can be used in place of orthognathic surgery and also the resultant occlusal correction from Herbst treatment was observed due to dental movements. Keeling and coworkers,[9] have mentionedmaxillary forward growth can be inhibited byactivators and headgears, but activators are mostly less efficientin comparison to headgears. Keeling et al, Wheeler TT et al,[9,10] also mentioned mandibular re-positioning can correct class II malocclusion with the help of headgears or functional appliances. Tulloch and Ghafarifound that there is a higherlimiting effect on forward growth of maxilla with the headgears and functional appliances show a higher effect on anterior positioning of mandible.[11,12]

Wheeler and coworkers[11] have reported, the achievement of early therapy is dependent on complexity of malocclusion. Kevin O'Brien did a study and concluded that early orthodontic treatment in cases of Class II Division I malocclusion with Twin-block appliance increased the patient's self confidence level with a few negative social experiences. Even though marked changes were seen in these studies, there were prominent changes in the growth pattern of individuals, irrespective of the timing of the treatment, with favorable growth also it was possible in untreated control populations.[10,11] Tulloch and coworkers in their phase 2 trials of their study cited no characteristic differences were seen in patients with early treatment and patients without early treatment, relative to anterior-posterior or vertical skeletal or dental measures, PAR scores, length of fixed appliance treatment, or need for extractions or orthognathic surgery. The advantages of early treatment were no more visible. The study suggested that one-phase treatment was more clinically effective which was started during the early permanent dentition than in two-phase treatment started during mixed dentition. Clinical trials when compared with children of various dental ages for Class II correction with headgear and Frankel appliance suggested time period for eruption of second premolars or molars have no influence, suggesting that the initial treatment timing corresponds to late childhood just close to loss of the primary maxillary second molars, so as to prevent mesial movement of the permanent molar which mayassist in correction of the distocclusion.[12]

Kevin O'Brien et al in his study concluded, complete span of treatment with Herbst and Twin block appliance is same but Phase I treatment with the Herbst appliance is faster. Patient cooperation with the Herbst appliance is better than that with the Twin-block. Also no alteration in skeletal and dental effects of treatment with both the appliances, however a marked difference was found in different sex where girls reciprocate to therapy better than boys.[14] In UK a multicenter set up found substantial reduction in the overjet during early orthodontic therapy with the Twin-block appliance in Class II malocclusion children which was primarily because of dentoalveolar correction, with a slight amount of skeletal correction. The degree of the patient's original discrepancy was linked to the end result of treatment.[15] Ashok Kumar Jena, Ritu Duggal, and Hari Prakash summarized that correction of molar relationship and reduction of overjet in class II Division malocclusion cases were effective with both bionator and twin block appliances, wherein twin block was more effective than bionator in the therapy.[16]

Elements that affect the functional appliance treatment outcome

A. The Vertical Relationship: According to a study by Charron[17] for patient with class II skeletal malocclusion upward and forward pattern of growth may be supportive in. Pancherz[18] and Tulley[19] corelated maxillary-mandibular planes angle (MMPA) to treatment outcome which showed treatment of cases with activator for class II Division I malocclusion associated with open bite was unsuccessful. They found the direction of growth was more downward than forward, which further showed worsening of the open bite rather than a reduction in the overjet.

B. The Sagittal Relationship: In previous literature[20], data related to sagittal relationship changes with functional therapy suggested changes in SNB values in cases groups as well as in control groups supporting the point that sagittal skeletal relationship can be improved automatically with normal mandibular growth in most cases and which ones will be those, it is not possible to anticipate.

C. Timing of treatment: Functional appliances should be coordinated with period of active growth. Many studies previously agreed to initiate the treatment during middle to late mixed dentition. This isfrequently seen between ages 12.5 to 16 years in boys and 10.5 to 14 years in girls. Bjork, found the efficacy of functional appliances diminished as patients got older.

D. Patient Compliance: Patient compliance is generally not confined with the orthodontist with any treatment strategy. Bishara,[21] emphasized that benefits of functional appliance are absolutelyrely on patient's cooperation. Ahlgren,[22] reported for failure of treatment one of the major reasons was poor cooperation.

Possible mechanisms for the correction:

A. Maxillary growth in the mesial and vertical direction can be retarded or redirected.

B. The anterior dislocation of the mandible from the articular fossa and growth of the mandible (including growth of condyle) act as a secondary response.

C. Medially and vertically directed maxillary dentoalveolar growth can be retarded.

D. Combination of maxillary and mandibular orthopedic effect with maxillary incisor lingual tipping and mandibular incisor labial tipping overjet correction can be done.

Constraints of functional appliances:

A. Maxillary and mandibular molar extrusion are associated with functional therapy. However, this is advantageousto overcome the deep overbite but at the same time it can increase the lower anterior facial height.Therefore, in backward rotated mandible with decreased overbite cases, functional appliances are not advisable.

B. To attain bodily and rotational tooth movements with maximum functional occlusion a final phase of fixed appliance therapy is advised as individual tooth movements are challenging with functional appliances.

C. The treatment results are completely dependent on patient cooperation.

D. In nongrowing patients' functional appliances are rarely used in sagittal correction.

Conclusions

Generally,in growing and cooperative patients the functional appliances can be used to treat Class II malocclusions successfully. However,controversy still exists regarding the use of functional appliances. The ideal types of cases for treatment with functional appliances are non-extraction Class II, Division 1 malocclusions, with proclined maxillary incisors, lingually tipped mandibular incisors, deep overbite, flat to average mandibular plane inclination, and mandibular skeletal retrusion.The outcome of functional therapy entirely dependsupon the cooperation of the patient and treatment durationat the time ofgrowth. A second stage of treatment with a fixed appliance is required for achieving complete alignment and proper interdigitation of the dentition.

Vesiculobullous Lesions: A Comprehensive Overview

Saswati Priyadarshini[1], Sanat Kumar Bhuyan[2], Rajat Panigrahy[3], Pinali Das[4], Dr.Shayari Niyogi[5]

[1]Post-Graduate Trainee, [2]Professor [3]Reader, [4]Post-Graduate Trainee, [5]Post-Graduate Trainee, Department of Oral Medicine and Radiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Vesiculobullous lesions are defined as a form of muco-cutaneous diseases in which both vescicles and bullae are evident. 'Vesiculobullous' sometimes termed as 'Immunobullous'as decreased immune system of the body causes these diseases. These are either result of range of infections, decreased immunity, drug-induced, hereditary or caused by mechanical injury. In all cases ulcerations occur due to rupture of lesions which will further make the diagnosis of lesions difficult to make. This overview will provide a knowledge about the vesiculobullous lesions along with the characteristic's features affecting the mouth, complete etiopathogenesis, site of occurrence of lesions along with their recent advances in the identification of these lesions. This will also aid in differentially diagnosing the lesions which exhibit similar sign asvesiculobullous lesions but the histopathological examination and immunofluorescence lead to the definitive diagnosis of the lesions.

Keywords: *Steven-Johnsons Syndrome, Toxic Epidermal Necrolysis, Oral Lichen Planus, Erythema Multiforme, Mucous Membrane Pemphigoid, Pemphigus Vulgaris.*

Introduction

As put forward by William Osler, "Oral mucosa acts as a mirror which reflects the general health of a patient". Oral mucosa can be defined as a specialized stratified squamous epithelium which comprises of the keratinized and the non- keratinized components. Out of which keratinized part include attached gingiva, hardpalate, vermillion border of lip (masticatory mucosa), and the non-keratinized include junctional and sulcular epithelium, lining mucosa such as lips, alveolar mucosa, floor of mouth and soft palate, GI tract and specialized mucosa such as dorsum of tongue and taste buds.[1]

Layers of oral mucosa: Subdivided into Epithelium, Lamina propria and Submucosa. Epithelium is again divided into Stratum basale, Stratum spinosum, Stratum granulosum, Stratum lucidum and Stratum corneum.[1]

Desmosomes are proteins having adhesion quality which allow solidarity of epidermis and link the intermediate filaments within cells to the plasma membrane and adjacent cells acting both as adhesive complex and as a cell surface attachment site.[2]

Desmosomal proteins, namely desmoglein-3 is at higher level than desmoglein-1because it is necessary for the manifestations of disease and detection of antibodies for the diagnosis of diseases. When there is a deregulation or any disturbance of these proteins there is manifestations of various vesiculobullous diseases. The disease shows the signs of bullae/ vesicles owing to the layer of mucosa which affected and amount of deregulation of harmful proteins.[2] These vesicles and bullae are filled with fluid which can be identified from other by size, i.e. vesicles measuring less than 0.5 -10 mm and bullae measuring greater than 1.0 mm.[3]

Lichen Planus: Prevelant mucocutaneous disorder of oral mucosa that affects the oral and genital mucous membranes,skin, nails and scalp of idiopathic etiology. Mainly affects the middle-aged women and shows definite white striations at the periphery of the lesion. Sometimes papules, plaques, erythema, blisters can also be seen.[3] Primary cause isstress or any immune change but sometimes can be associated with dental materials or may be medication induced. Different forms of lichen planus are reticular, atrophic, erosive,hypertrophic and bullous amongst which reticular form is most common and bullous form is the rarest one.[4] Occurs mainly in buccal mucosa with highest percentage followed by gingiva, tongue and soft palate with a less common

frequency.[4] Histologically lichen planus is seen as saw tooth or civette patterns of epithelium .In severe cases direct immunofluorescence can be done to exclude other diseases like pemphigus and pemphigoid.[3] Treatment of OLP includes abolition of factors which are linked with lichenoid reactions, elimination of local irritants and the effective use of therapeutic agents.[3] Nikolsky's sign is positive in patients with OLP.[5] OLP can have malignant transformation into oral squamous cell carcinomas if it is retained for longer duration than skin lesions although rare as 0.13%.[6] Specific management therapies includes corticosteroids (topical, intralesional or systemic), retinoids, cyclosporine, psoralen plus ultraviolet A light, griseofulvin, and dapsone.[7]

Figure 1. Forms of lichen planus on tongue and buccal mucosa

Pemphigus Vulgaris: "Group of autoimmune mucocutaneous blistering diseases defined histologically by blisters in skin immunologically by circulating antibodies directed against the cell surface of keratinocytes". Pemphigus imitative of greek word 'pemphix' meaning bubble/blister.[3] Different types of pemphigus include PV,Pemphigus Foliaceous, para-neoplastic pemphigus, amongst which most commonly occurring variant is PV.[3] PV is associated with antigens such(human leukocyte antigens) A10, A26, Bw28 and DR4.[4] Usually expresses between the fourth and fifth decades of life, and affects both males and females. There is production of IgG and IgM antibodies in between the cells, embattled against desmosomal cell adhesion molecules such as desmoglein 3 and (in 50% of all cases) desmoglein-1.[8] Approximately, 10% of patients have upper tract obstruction by PV and results in supraglottic laryngeal edema.[9] In classical diseases of PV, Nikolsky's sign is evident.[5] "When the tangential pressure is applied on apparently normal skin/mucosa, with the thumb or finger pad result is a shearing force that dislodges the upper layers of epidermis from the lower epidermis resulting in formation of blisters", a phenomenon is known as Nikolsky's sign. Acantholysis is distinctive histological feature in which there is cell to cell contact loss in epithelial cell layers. There is fluid collection in between cells,dissolution of intercellular bridges along with increase in width of intercellular spaces leading to separation between cells and formation of blisters just above the basal layer there by leading to formation of suprabasilar split and resultant tombstone pattern of cells.[3] Tzanck cells are representative of pemphigus consisting of freely suspended, circular acantholytic epithelial cells within the vesicle. Discrete pattern of IgG2 & C3, are observed within the intercellular spaces of the epithelium by using direct immunofluorescence.[4] Moderate to high potency topical corticosteroids is suggested for non-progressing oral lesions, for e.g fluocinolone acetonide 0.05%, clobesatol propionate 0.05% applied 2-3 times daily. At a dose of 1-3 mg/kg/day, corticosteroids are the drug of choice in severe oral and skin lesions.[8]

Figure 2. Pemphigus showing positive Nikolsky's sign

Erythema Multiforme: Can be defined as a hypersensitivity reaction with either both skin or any other mucosal (stratum corneum) involvement. According to the amount of involvement of mucosa and the nature and pattern of distribution in skin it can be classified into major and minor types.[3] EM can have many contributing factors, amongst which the best documented is the infections and medications. Other factors are malignancy,vaccination, autoimmune disease and radiotherapy. Infections mainly the HSV 1 & 2, Tuberculosis, histoplasmosis etc. Drugs precipitating EM are Barbiturates, Sulfonamides, Carbamazepine, Antibiotics (fluoroquinolones).[3]

Described as a self-limited eruption that commonly carry mild or no prodromal symptoms. At the site of the eruption of lesion the person might feel burning and itching sensation. Primarily discrete lesions beginas a number of sharply delineated red or pink macules. Gradually Papules enlarges into plaques which are several centimeters in diameter.[10] Papules become darker red in the center which are defined as characteristic "target" or "iris" lesions. Cutaneous lesions in this case appear symmetrically on the distal part of extremities (Palmer &

Plantar surfaces) and progress proximally.[10] Treatment involves identifying the etiological factors as soon as possible. For symptomatic relief oral antihistamines and topical application of steroids are necessary.[10]

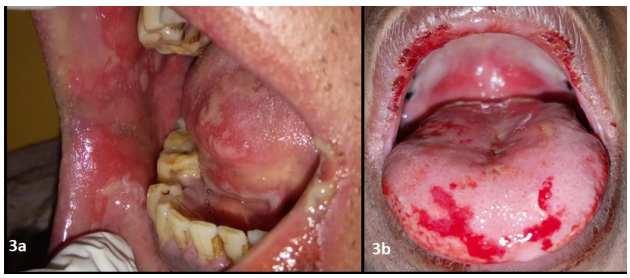

Figure 3. Erythema Multiforme

Steven Johnsons Syndrome & Toxic Epidermal Necrolysis: Stevens-Johnson syndrome is a "severe, episodic mucocutaneous intolerance reaction put forward by Hebra in 1866 and 'Albert Mason Stevens and Frank Chambliss Johnson in 1922".[15] Severe adverse drug reactions in which skin and mucous membranes are primarily affected are SJS and TEN.[3] SJS is said to occur when less than 10% of body surface area is involved.[16] TEN described as widely spread necrosed epidermis mostly caused due to drugs and their metabolites in which greater than 30% of body surface area involved.[17] Primary lesions in TEN can be seen as purpuric macules on the face and upper limbs as the disease gradually progresses into vesicles or fluid blisters these macules gradually increase in size and coalesce. In case of TEN is that airways are compromised due to disruption of mucosal surfaces[17] Suddenly during the prodromalphase, the mucocutaneous lesions tends to develop, and these new lesions continue to erupt for about 4 weeks after which they again re-epithelialize.

TEN/SJS are caused due to the following: "Allopurinol, Trimethoprim-sulfamethoxazole and other sulfonamide-antibiotics, aminopenicillins, cephalosporins, quinolones, carbamazepine, phenytoin, phenobarbital" etc.[3] As SJS and TEN are both life –threatening diseases, treatment of which includes systemic corticosteroids, intravenous immunoglobulin, cyclosporine, TNF-alpha antagonists, G-CSF which can prolong the lifespan of the patient.[17,16]

Mucous Membrane Pemphigoid: Also known as cicatricial pemphigoid, benign MMP. Chronic blistering diseases which less commonly affects skin but more commonly affects oral and ocular counterpart.[2] Laminin 5 and BP 180 are the basement membrane proteins responsible for the autoimmunereaction.[2] Characteristic of MMP is deposition of immunoglobulins and complement components along the basement zone.

Inside the oral cavity MMP can be seen in 2 forms: Bullous lesions are most common form occurring in the conjunctiva,nose, larynx, pharynx, esophagus, genitals and anus in which there is ulceration involving mostly the non-keratinized and less commonly the keratinized mucosa. Without scarring lesions befalling in the oral cavity usually heal, but ocular lesions are suggested for an ophthalmological consultation. In least cases nasal and genital involvement occurs. Nasal involvement seen as bleeding or crusting whereas genital involvement as painful ulcerations and erosions. Hoarseness of voice and dysphagia may be seen.[2] The second variant is desquamative gingivitis and involves only gingiva encircling the tooth which are highly erythematous and hyperemic.[2] In histopathogicalslide, subepithelial bullae along with absence of acantholytic cells are found. Immunofluorescence and biopsy are two positive method for diagnosis of disease.[2]

Initially topical corticosteroids are adequate for controlling of oral lesions. If lesions extend toextraoral sites,systemic corticosteroids are needed. Lesions occurring in extraoral regions are in the sequence following oral mucosa are the conjunctiva, skin, larynx.[12] Sometimes immunosuppressants such as dapsone,azathioprine may be used to reduce the toxic effects of systemic corticosteroids.(2)

Herpes simplex: Commonly manifests in young children as oral vescicles by either direct contact or contact with affected saliva. The lesions took almost 1-week time to occur after exposure and frequently identified in junctional epithelium in the corner of mouth followed by gingiva,tongue and hard palate.[11] Herpes infections are common vesicles like outbreaks of the skin and mucosa. Systemic or primary are the 2 common forms in which they manifest.[3]

Approximately 30% of young adults experience recurrent herpes infections due to the predisposing factors like sunlight,mechanical trauma, traumatic dental treatment (contact with chemical composition of materialused) which are followed by symptoms of pain, paresthesia, burning or tingling sensation.[11] The prevention of recurrence is treated by acyclovir. For treating acyclovir-resistant herpes simplex virusin immunosuppressed individual foscarnet is the drug of choice.[11]

Varicella-Zoster Virus: Chickenpox is the primary disease that results from Varicella ZosterVirus is usuallya mild disease of childhood, developing mainly on the face and trunk and less commonly intraorally as small vesicles,which appear initially clear and later on white as neutrophils try to accumulate.[11] Spreads by droplets of respiratory secretion.[11] Throughout the disease the Varicella-Zostervirus may headway along sensory nerves to reach dorsal sensory ganglia, where it can stay in dormant, unnoticeable position.[3] Details along the course of facial nerve,skin lesions appear as vescicles that become pustules which later on ulcerates further healing with a scar. Lesions are painful and results in itchiness and dryness of skin, eyes and odontalgia.

Investigations include viral culture, cytology and biopsy. Acyclovir is the drug of choice,800 mg orally five times daily for 7 days or 500 mg orally famciclovir, three times daily for 7 days. Post herpetic neuralgia is the ultimate suffering of the disease which lasts for several weeks to months to resolve.[11]

Paraneoplastic Pemphigus: Called as neoplasia induced by pemphigus[3]. Type of vesiculobullous disease described in 1990, with a distinctive profile of autoantibodies. Stomatitis that involving the vermilion border, lichenoid or bullous dermatosis along with ocular involvement develops.[11] Most prominent cutaneouslesions in skin are seen in upper chest andback. The mucocutaneous lesions shows similar characteristics with OLP, bullous pemphigoid, or EM in which Nikolsky's sign along with target lesions may occur. [11]

Hand Foot and Mouth Disease: Type A 16, Type A 5, type A 9 are most commonly involved enterovirus as the causative agent for HFM disease.[3] Children are mainly affected having an incubation period of 1 week before manifesting. Feco-oral contact and respiratory droplets are the two ways for transmission of disease.[3] Patient exhibits with prodromal symptoms of mild fever, sore throat, malaise along with multiple erythematous macules in oral cavity which progresses to form 1-3 mm vescicles.[13] Skin lesions appears late than mucosal lesions. Painful oral lesions are most commonly present on tongue, hard palate,buccal mucosa. Lesion can be diagnosed on the basis of past medical history, through examination of lesion, viral culture of lesion, detection of circulating antibodies.[11] Polymerase chain reaction is considered as the gold standard for enterovirus infection.[3] Treatment is supportive, no specific antiviral therapy is needed.[3]

Linear IgA Disease: Described by Bowen in 1901.[4] Mucous membranes, including gingivais generally affected by longstanding autoimmune disease of the skin.[11] In diseases occurring in adults and children such as linear IgA disease, cicatricial pemphigoid, presence of Ig Adeposition is seen at the basement membrane with the help of direct immunofluorescence.[4]

Infiltration of PMNL is manifested in adults which appear as a subepithelialbullae smaller in size. Lesions in oral and conjunctiva are more common. Lesions in nasal and genital areas are less common.[4] Pattern of distribution of lesion is termed as "cluster of jewels" as the peripheral old lesions are surrounded by tense vesicles.[14] Desquamative gingivitis is the only clinical symptom visible orally.[4]

Epidermolysis Bullosa: Group of hereditary diseases spread as dominant or recessive traits, and defined as presence of bullae mainly at places of trauma. Different forms include simplex, junctional, and dystrophic.[11] Epidermolysis acquisita, can be defined as the form which is non-hereditary autoimmune form generally precipitated by drugs.[3] When skin fragility decreases due to minor mechanical trauma which is further followed by formation of blisters and erosions and in some cases leading to formation of milia (small papules resembling cysts), and scar formation, then it is described as hallmark for EB.[18]

Prime aim is at cure of cutaneous lesions with various ointments which increases epithelization. Surgerymay be needed to treat difficultesophageal strictures and care should be taken about the protein and calorie intake of patient which should be double as that of normal individual.[18]

Measles: Measles also called as rubeola is a viral infection caused by paramyxovirus. Individuals are affected 2 days prior to the development of symptoms.[11] Patient usually have prodromal symptoms like fever, malaise, coryza, cough, conjunctivitis after an incubation period of 10-12 days. Exanthematous rash occurs in the body at first involving the face which lasts for 4-7 days. Clinical features includemaculopapular rashes on trunk, keratoconjunctivitis in both eyes followed by cervical and submandibular lymphadenopathy.[19] Disease typically affects the children and present intraorally as definite spots called as "koplik spots" which are white vesicles on buccal mucosa.[11] Inflamed marginal gingiva along with microabcess formation and pericoronitisare present in some cases.[19]

Artificial Intelligence: A Cognitive Advancement towards Future Dentistry

Sukanya Mishra[1], Anurag Satpathy[2], Rinkee Mohanty[3], Rashmita Nayak[2], Manoj Nayak[4], Abhaya Chandra Das[4]

[1]Postgraduate Trainee, [2]Professor, [3]Professor & Head, [4]Reader, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

With technological hindrances decreasing and research turning to development, we are on the threshold of a range of Deep-Learning enabled smart tools for dentistry called Artificial Intelligence. Artificial Intelligence is machine intelligence demonstrated in contrary to the intelligence of humans/animals. Starting from smart teeth scan while brushing, to smart scheduling, to smart patient communication, it can be used in data computation, as well as cloud computing through which an algorithm can be created which will help in diagnosis and will provide probable treatment options. It will have the major role in every branch of dentistry. Therefore, getting an in-depth knowledge of the various concepts, techniques and technologies involved will help with having a clear advantage in the future when it is time to adapt to the change with redefined roles for a rewarding practice.

Keywords: *Artificial intelligence, deep neural network, smart systems, adaptive learning dentistry.*

Introduction

What is smart? It is the presentation of quick-witted intelligence. At present, every part and field of the world is striving to become smart. We are trying to develop technologies that will decrease the manpower required to carry out day to day work and dentistry is one amongst them. Imagine a day when we would switch on our smart toothbrush and the minute, we put it inside our mouth it would scan the entire oral cavity, detect caries or fractured tooth or stains, measure halitosis, detect a mucosal lesion,analyses it and uploads onto a cloud server. This information can then be communicated to the dentist and an appointment can be automatically texted to our cell phones. This is one of the several examples of how artificial intelligence can get participate in the oral health care.

What is Artificial Intelligence?: Artificial Intelligence (AI), also known as Computational Intelligence or Machine Learning is a system's ability to correctly interpret external data, to learn from such data, and to use those learning to achieve specific goals and tasks through flexible adaptation[1]. John McCarthy, Alan Turing, Marvin Minsky, Allen Newell, and Herbert A. Simon are regarded as the founders of Artificial Intelligence. The term Artificial Intelligence was coined by McCarthy in 1955 [2].

Artificial Intelligence technologies have increased manifold in areas like expert systems, game development, theorem-proving, natural language interpretation, recognition of images and robotics in various fields like tele-communication and aerospace. The metamorphosis of technology to AI has begun in medical and dental field in the last decade[3].

Deep Neural Network: AI uses Deep Neural Network which are a complex web of interconnected computer processors influenced from human brain neural

nodes[4]. Deep learning has emerged simultaneously with the digital era, bringing an enormous quantity of data from every region of the world. However, this enormous data is unarranged and it could take decades for humans to contain it together and unravel required information from it. This data is collected from sources like social media, internet search engines, e-commerce platforms, and online cinemas, among others which can be easily acquired, analysed and shared through cloud computing. This network uses deep learning and has the ability to learn and evolve by repeated adjustments known as Back propagation Learning and from newer information[5]. It also works by projecting into Augmented Reality and Virtual Reality.

Augmented Reality (AR): It is a mechanism that augments a computer-generated virtual image on a real image for the patient to refer and have an idea about the prosthesis or restoration[6]. The patient can perform required customization before he/she actually tries it.A company named KAPANU has developed software, implementing AR in dentistry[7].

Virtual Reality (VR): It is a computer spawned mimicking of an existent surrounding or situation by using artificial intelligence[8]. It creates a real-life experience for the audience.

Significance of Artificial Intelligence in Dentistry: Presently, AI is mostly used as a Virtual Assistant with a Voice Controlled Software. In future it may perform numerous tasks more meticulously, effortlessly and with least errors, which may include: Working for 24hrs at a stretch without a break; Faster in work than human counterpart; Unbiased because they depend on the data provided and are not emotional[3]

It may be beneficial in:

- Booking, Scheduling and coordinating regular dental appointments according to the convenience of the patient as well as the dentist.
- Alerting the patients and dentists about detecting any genetic or lifestyle change in the patient and alerting them e.g. Periodontal tissue scan for diabetic patients and oral cancer screening for those who have the habit of smoking and/or tobacco chewing.
- Devising a virtual database of patients with detailed particulars and past medical as well as dental histories.
- Aiding in the differential diagnosis and treatment planning
- Regularly reminding and counselling patients with smoking or tobacco chewing habits etc.
- Rendering tele-assistance in cases of dental crisis, eliminating the immediate requirement of a dental professional on that spot.

Recent Dental Applications of Artificial Intelligence

Dental Education: AI uses augmentedreality andvirtual reality to simulate a clinical dental situation on which trainees can practice. Also, there can be an amalgamation of artificial intelligence in computer tutoring systems like in the Unified Medical Language System (UMLS)[9, 10].There is a huge improvement in student's quality of work due to feedback that the pre-clinical virtual patient/phantoms provides the students, without requiring intervention from a human teacher allowing students to be self- competent developing skill at a faster rate than with the traditional simulator units[3, 11].

DEXvoice: Hands Free Software. Itis a modified version of DEXIS imaging software[12] allowing dentists to use Amazon Alexa enabled voice activation to their dental workflow. The dentist uses its voice while operating to capture, show, compare, take and display images. No degloving, no typing, no touching is required; dentist simply speaks -Alexa, ask My Helper to show the OPG of the patient, suddenly the images of OPG appe**Digital Impressions**[13, 14]: It uses a laser optical focal scanning by voice commands to replicate each surface in different angulations projecting a 3-D image which is then sent to a dental lab. This provides an accurate fitting restoration unlike conventional impressions, decreasing chair side time as well as patient gag and discomfort. The virtual image produced can be accessed as and when needed.

Smart Toothbrush: Recent advancements in toothbrushes include Bluetooth enabled toothbrush that collect data about the individual's brushing habits, the brushing technique used, duration of brushing, areas covered etc[15, 16]. It is then connected to an app aiding in self-assessment. It can store history to keep a track on the oral hygiene routines. Examples are Ara Toothbrush by Kolibree and Oral-B Smart Series Electric Toothbrush White 6000[17].

Dental Robots: A Miami based company, Neocis, declared a FDA cleared implant robot assistant named

Yomi[18]. It relies on CT scan to analyse the bone thickness, width height, orientation of the implant plans the treatment procedure. It helps by guiding the dentist to where the implant should be placed and if the dentist goes wrong, he/she can feel the resistance[19]. It is therefore minimally invasive and can be used as an alternative to surgical guides minimizing the obstruction of operating field. A team of engineers, dentists, and biologists from the University of Pennsylvania have developed miniature robots that can work surfaces and may destroy biofilms.[20]

Dx Vision: A new innovation by Dentem, under construction, that would soon analyzeproblems within images detecting dental caries, suggesting treatment plans, and even prevents the dormant problems from occurring.

Dental Tele Assistance: Tele assistance is a persistent field in this 4G era employed by video conferencing to obscure areas where the dentist cannot be available immediately and nurses, pharmacists etc will deliver the emergency treatment[21]. Incorporation of AI with tele dentistry will help with quality diagnosis, suggesting treatments, can help elderly/handicapped who cannot visit the dentists[22]. For example, a periodontist can make use of a teleprobe that can be connected to the computer, to assess the pocket depths while videoconferencing. It may act as an antidote to physician burnout[23].

Nanorobots: Tiny robots can be impregnated into human body and will work in cellular/molecular level. It can be utilised for precise local drug delivery. A colloidal suspension of analgesic infused petite robots can be used to produce anaesthesia. It can recognise bacteria, viruses and DNA helping with the diagnosis of oral cancer and diabetes mellitus, can be programmed to penetrate neoplastic lesions, spot mutated cells and demolish them, can seal tooth with exposed dentinal tubes with desensitizing agents[24].

Smart Dental Chairs: In future the AI machines will have their own voice to communicate; present example is Alexa, Siri. The moment a patient sits, the AI transformed dental chair will scan and be able analyse data, genetic information, body functions and will provide the best treatment options.

Bio printing: Using machine learning 3D printer's technology can be advanced to a level where it can generate living tissues to assist in the surgical procedures in healthcare. For this to be successful the exact algorithm has to be found out. Here machine uses cells as ink, which are stacked, as layers between soft polymers like the hydrogels, till the tissue is constructed. Biomaterials used includes collagen, alginate, human adipose stem cells, hyaluronic acid etc[25]. Bio printing has advanced bone tissue engineering and can be used as a scaffold in periodontal regenerative procedure[26, 27]. Along with this it can be used in Root Canal Procedures to regenerate the neurovascular plexus of the pulp rather than removing the pulp.

Image Guided Implant navigation systems: GI system, Image Navigation Ltd., USA is an Imaging Automation based navigation technology. Here the operator performs implant surgery in 4-5 models to create a Learning Curve according to the surgical site. This articulates surgical gizmos of dental implants with computer generated pictures as well as assimilates optical tracking devices, which spots the required markers for implant placement, with pre procedural planning software. With the guidance of this augmented reality technology, the user drills into the target position as navigated by the pre surgical planning software. This promotes meticulous implant placement and impedes damage to the vital structures present in and around the implant placement area [28].

Limitations[29]

AI too has certain limitations:

- Data utilization: It is one of the major limitations. Companies assume that they haven't acquired enough data for deep machine learning as the required data is enormous. Secondly to be imparted in different government and private organizations, the data should have the right parameters.
- Cultural Limitation: People are resistant to innovations and change. They do not like to give up control. For example, patients trust doctors to do the treatments but if doctors are replaced by robots(non-living), the anxiety of the patient is obvious.
- Data bias: Since information to AI is through data, take into instance if the data is biased and is uncovered, AI will execute the same.
- Expensive: Research and development for AI devices needs lot of funding and currently the newer technology is expensive making it beyond the affordability of all health care units.

Conclusions and Future Directions: There is nothing much artificial in this super advanced machine intelligence. It is made by the humans for the amelioration of the human society and is absolutely humanly. AI is a continuously advancing process, creating sophisticated technologies. In the future decades we will find that these machines will perceive, learn, think and improvise through the method of cognition doing the works of a human in better ways. But at the same time, we do not want these deep learning machines should superimpose humans, and hence, it has to follow some ethical laws given by Isaac Asimov in 1950[30].

Artificial intelligence would be the ultimate version of Google. The ultimate search engine that would understand everything on the web. It would understand exactly what you wanted, and it would give you the right thing. We're nowhere near doing that now. However, we can get incrementally closer to that, and that is basically what we work on.

Impact of Sports Drink on Oral Health

Marlin Jena[1], Dharmashree Satyarup[2], Ramesh Nagarajappa[3], Upasana Dhar[1], Radha Prasanna Dalai[4]

[1]Post Graduate Trainee, [2]Professor, [3]Professor & Head, [4]Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Due to change in lifestyle, sports drink has grown rapidly in few years. Energy drinks intensify physical stamina, stimulate metabolism, prevent exsiccation and exchange electrolytes during activity attempts. In spite of its vogue, these energy drinks have a low pH and are acidulous in nature,it can cause erosion of dentin and enamel surfaces, lead to permanent loss of tooth bulk and rise in sensitivity of dentin. In addition to this all kind of sports drinks also cause massive destruction of tooth structure as well as restorative materials used. These energy drinks restrain unnatural colours which is likely to cause discoloration composite materials and glass ionomer cements. Acidic nature of the energy drinks could lead to a deprivation, increase in wear and roughen the surface of restorative materials. Many unfavourable outcomes of sport and energy drinks can be related due to consumption among age below 18. They should be guided to have a control diet, and consumption less amount of soft and energy drinks, keep away from negative oral health end results. Over-consumption of soft drinks which contains sweetener and have the lowest pH are probable source of preventable oral health issues.

Keywords: *Soft drink, Energy drink, Oral health, Dental caries, Dental erosion.*

Introduction

Oral health is an essential part of our general health: Preventiveness of oral diseases is bare necessity in case of health and well-being of athletes. In 2012 London Summer Olympic sports compose 30% cases were of dental consultation of all medical visits (second only to musculoskeletal),[1] highlighting the overburden of oral healthcare facilities during large-scale competitions. Trend is bigger in different sports facilities in recent years. Considering age of the participants, oral health was a real concern. Amongst which dental caries, periodontal disease, dental erosion, pericoronitis and impacted third molars were most widely complaint detected. 15–75% of athletes were affected by dental caries,15% were affected by moderate-to-severe periodontitis, 36-85% affected by dental erosion, 5-39% were affected with pericoronitis and dental trauma was conveyed in 14-57% of athletes at-risk.

The negative oral health pattern seen after trauma in 33-66% and deferred quality of life in cases of 28-40% of athletes and 5-18% face difficulty in performance. A very few proportions of athletes show positive effect on their well-being, achievements those who regularly attend dental care services, others show absence of sensitivity.

Athletes do have compromised oral health: Oral health is one of the determining factors to lead a quality life. Effects of oral health, would be astonishing if physical activity is not pretentious in athletes with compromised oral health. Pain of oral diseases arise due to animpact on performance,[2] which increased systemic inflammation[3] and weekend conviction and socialisation.

Nutrition and oral health: Physical activity and performance are rein-force by carbohydrate-containing energy drinks and gels,[4] are taken routinely through activities.[6] consuming carbohydrate containing beverages or food lead to dental caries.[5] Acidic food and soft drinks causative factor for dental erosion.[2]

Correspondence Author:
Prof (Dr). Ramesh Nagarajappa
Professor & Head, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: rameshpcd@yahoo.co.in

pro-inflammatory effects of a high carbohydrate consumption might also have possibility risk for disease of periodontium.[7]

Sugar supplements consumption: During exercise to maintain energy, workout supplements, soft or energy Drinks, and carbohydrate gels are frequently used by athletes. Sugar present in beverages stick to the tooth surface rather than saliva and elevate acid production for the oral microbes. Thus, it may advance risk for decay.

Acidic concentration: Energy drinks and workout supplements contain citric acid and malic acid with a pH between 2.4-4.5,Where the enamel of teeth is weak and cracked down by acids of pH lower than 5.5.

Dehydration due to low salivary production: Drying of the mouth in case of dehydration during sports action by dropping salivary flow amount thus decrease the defensive mechanism of saliva might intensify the effect of carbohydrates on caries and acidic drinks on erosion.[8] Antimicrobial action protect against periodontal diseases and re-mineralising effects of saliva.[9]

Promoting oral healthandpreventing of oral diseases while mitigating of risk: Steps those have influence on oral health and diseases use of fluoride containing toothpastes or mouth-rinses, other topical fluoride ingredients, behavioural change related to diet and oral hygiene maintenance and dental plaque removal. If recurrence, identification of pericoronitis and extraction of third molars is necessary. To avoid risk of trauma athletes should use mouthguards during sports. Modification of energy drink have been reported.[10] Even so, modification of sports drink has been created over time to increase the power boost by increasing sugar and caffeine content, these are known as energy drinks.

Table 1. Types of prevention and risk intervention for various following conditions:

Condition	Interference
All situations	Health promotion, education and behavioural change: Multilevel approach including individual athlete, medical, dental and performance team and national and international level sport organisations.
Carious tooth	Dietary habit: If reasonable, carbohydrate consumption decreases in quantity. Re-mineralizing agent: Xylitol is related with a remarkable reduction in caries occurrence and increased tooth remineralization. Fluoride: No less than 1400 ppm fluoride present in toothpaste or preferably 5000 ppm.
Periodontal effects	Oral hygiene: Efficacious elimination of dental plaque by brushing and cleansing interdental area assessed by early detection and treatment. Lessening risk factor: By ceasing use of tobacco.
Tooth erosion	Dietary habit: Abbreviate rate of consuming acidic food or beverage. Re-mineralizing agent: CPP-ACP has aptness to withstand action of acids in case of erosion. Energy drinks: Where reasonable, alleviate rate, evading extended retention in oral cavity, use of straw to drink.
Pericoronitis	Oral health status: Cautious elimination of plaque around impacted third molar. After twice pericoronitis occurs, extraction of impacted third molar is needed.

Impact of sports and energy drinks on discoloration of restorative materials: Resin material causes internal discoloration. It is probable to consume water-soluble stain like soft drinks[11]. Composites staining occurs due to habit of tobacco chewing, drinking alcohol and also using of different food dyes[12]. Higher possibility of staining in tooth because of energy drinks. Hydrophilic properties of glass ionomers may cause water sorption. Ceramics having higher predisposition to stain than composites due to hydrophobic nature.

Hypersensitivity of tooth: Balancing acidic and alkaline drinks in equal quantity can help neutralize the acidity of these drinks and it can help to keep teeth healthy, example, use of desensitizing tooth paste. These tooth-paste may include an ingredient called stannous fluoride, later it is for protecting teeth against awful sensitivity. Use of a softer tooth-brush, extra-silky and gentle floss to preserve teeth and gums strong. Drinking much higher acidic drink able to damage the tooth enamel and weaken your gum line, which expose the inner layer of teeth, it will cause painful tooth sensitivity. Particularly when you drink something very cold, symptoms of sharp pain arise in the sensitive teeth.

Summary

Oral health has consistently compromise in athletes with needful treatment. Main oral health issues affecting athletes are caries, periodontal diseases, erosion. Dental trauma in 'at-risk' games is also acknowledge. In the short-term consequences, compromised oral health can lead to discomfort and anguish, problems during eating and sleeping period, compressed value of life and outcome in activities. The long-term consequences higher risk of tooth loss, improved necessity for treatment and ensuing functional and psychological damages. These problems convey dietary habits from recurrent carbohydrate consumption and soft drinks, enhancement of host responses due to desiccation, dryness of oral cavity, rigorous training, oral health instruction and absence of adequate health raise or precautionary backing.

Differentways to promote oral health:

- Use of re-mineralizing materials can reinforce and preserve the surface of tooth. stuffs like mouth rinse, lozenges, sugarless gum, and other specific dental stuffs are useful for healthy tooth.
- Having milk, yogurt, and cheese which contains calcium and phosphate can benefit in re-mineralization of the tooth area.
- Softdrinks and lollies should be avoided. Drinking water can be used to allocate acceptable hydration. Having carbohydrate containing foods like bananas and whole grains.
- Visit dentist about pre-emptive care for oral health and invent a healthy diet schedule for exercises.
- Select to consume acidic or sugary brews then drink out of a straw, it is better to be less interaction with oral cavity.
- Take concentrating acidic and soppy drinks with water to lessen side effects.
- Right after consuming soft drink don't brush your teeth immediately. It will take about to 30 to 45 minutes of salivary interaction to initiate reparation of the teeth.
- Soppy or energy drinks should be avoided earlier to sleep.
- Before you consume any kind of drinks read the ingredient labels. If you already have teeth problems, avoid high amounts of acid and sugar.

Conclusion

Compromised oral health has an impact on performance of athletes. Aim to hike attention of the issue of oral health in sports and recommended approaches for avoidance and health advancement for best performance. Dentists should give instruction to the patients on their intake of food and drinks which can cause harmful effects to oral cavity. Drinks that are probably harm tooth and restorative materials are sports and energy drinks which comprise of sugar to feed oral microbes, and drinks having a low pH that can cause erosion of tooth and rise in sensitivity. Agonize poor oral health because of ingesting soft and power drinks should be conscious about the probable sources of oral health issues. Sports starts from school life from very young age. PT teachers should guide children to improve their oral health. So awareness about sports drinks is necessary.

Influence of Tobacco Marketing in Adolescents

Abhisek Jagdish

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Vulnerable adolescents are captivated by the sale-oriented advertisements into tobacco consumption. Prone to mislead and misguide they are under the deceptive marketing strategies and advertisements made by the tobacco industry. This has been reviewed for prevention of tobacco use and its eradication from the society. Electronic database was searched for the aforementioned literature using Medline, PubMed, EBSCO, Google Scholar. The aim of the study is to analyze the effects of deceptive marketing and advertisements on adolescents. Out of the 19 articles searched, 10 fulfilled the criteria and were included for research and review. In spite of the claim made by tobacco industry, the study shows it targets non-smoking youths especially teens. Proper check on deceptive indirect advertising should be taken into consideration. Banning of billboard, outlet advertisements of tobacco. Sponsorships by tobacco industry must be limited. Counter advertisements would prove to be beneficiary for the cause. Enforcement of presiding laws and policies checking on the liberty of tobacco industry is required.

Keywords: *Adolescents; Electronic Database; Tobacco Industry; Marketing; Laws & Policies.*

Introduction

Adolescent tobacco use is the most prominent cause of death and is a serious health concern. Use of tobacco is increasing day by day especially in adults & teenagers. Millions of lives are burnt in tobacco. If we see the context or tobacco use there are various such reasons why a person or an individual start using tobacco and gets addicted. Two basic types of tobacco are smoke tobacco & smokeless tobacco. If we see there is a dynamic role of marketing in increasing the use of tobacco among adolescent. Various marketing strategies such as Advertisement are used to create a positive attitude of adults towards tobacco. Promotions by celebrities & other public personalities are used as a trap to attract adults to invest in tobacco consumption. Advertisements play an important role in increasing the sale of tobacco. Advertisement with better & eye-catching visuals and with the face of top models influence folks in tobacco marketing. To create a diplomatic marketing regime in adults the campaigns use to convey the independency healthfulness & adventure along with social recognition. Tobacco company use the electronic media the more to promote their products through special ads and videos. Tobacco company sponsor various live events such as college functions, public program, cultural fest etc. to add on their marketing strategies.[1-4]

We see the advertisement in the newspaper, intermission of movies & through various TV programs. The most important place is the stores where they sell tobacco. In the place of advertisement with heavy investment, they use LCD screens & short videos & characters explaining different flavors. They also sponsor movies where actors & actress could be seen using it. Basically, an adult change behaviorally by the advertisement and start using tobacco. This advertisement increases likelihood to buy tobacco and use it among youth. Some use to start for the sake of experiment, while few uses it through peer pressure leading to addiction. Various researches show that 25-30% of the population are attracted due to advertisement. If we talk in the context of Indian market, the advertisement plays vital role in increase of tobacco market. If we see in the rural areas of India, it is basically because the youth follows elder peers and they adopt the wrong behaviour which they see around them since childhood. Beautiful designs in the tobacco packets and different colours

e-mail: abhisekjagdish1@gmail.com

are the eye-catching traps to attract people towards it. Curiosity towards the use of tobacco among adults result in experimentation & further results in addiction. Studies depict that youth are well aware of tobacco ads in stores and such impose influences youth perception regarding ease to access cigarettes' smoking.It has been seen in various case studies that a gender specific study shows that although the male/men take tobacco more but female/women have an emotional attraction for tobacco.[5-9]

In India market condition, it can be seen greatly that the market and advertisement acts as a booster for tobacco use. A simple example can be such that the shops which sale Tea & Coffee are seen to be selling cigarettes. Many posters showing cigarettes ads have been pasted in shops. Use of smokeless tobacco such as Pan is generally a practice in various rural areas and is a part of their culture & custom. Aim of this study is to know what are the prime factors involved in the increase of tobacco consumption among youths.[10-12]

Method

Various terms & inclusion criteria were taken into consideration to review the articles, inclusion criteria, attitude towards tobacco use, published studies, indian studies, conclusion, studies related to health effects, harmful effects of tobacco, search strategy, Electronics database were used to write the article using Medline, PubMed, EBSCO, google scholar, study book SobenPeter. The articles were searched in the relation to Marketise advertisement on tobacco. Total 19 were taken into consideration, out of which only 10 were included.[13]

Results

There are two tables where table 1 shows the inclusion criteria, table 2 shows relationship between tobacco ads & progression towards tobacco use among adolescents.

Table 1. Inclusion criteria

Authors name and year	Study type	Tobacco form	Results
Bansal *et al*., 2005[1]	Cross-sectional	Both	Cigarette companies have developed sophisticated campaigns targeting different socioeconomic groups. Marketing strategies have utilized the loopholes in Indian tobacco control legislation
Arora *et al*., 2012[22]	Longitudinal	Both	High receptivity toward tobacco advertising which may lead to future progression to tobacco among boys. Study reveals a strong relationship between tobacco marketing and adolescents tobacco usage
Patel *et al*., 2012[23]	Cross-sectional	Both	Study reveals advertising around the school and low economic status were strongly associated with tobacco initiation among adolescents advertisements on billboards, posters, and the receipt of a free tobacco sample around the school campus have been a significant factors in tobacco usage among adolescents
Sardana *et al*., 2015[24]	Cross-sectional	Both	Study reveals usage of smokeless and smoke form of tobacco is promoted through the promotional activities mainly through cinemas and providing free samples of tobacco product were most influential means of initiating consumption of tobacco products among youth
Arora *et al*., 2008[25]	Cross-sectional	Both	Exposure to tobacco advertisements and receptivity to tobacco marketing were significantly related to increased tobacco use among students
Stigler *et al*., 2006[26]	Cross-sectional	Both	Almost all psychosocial factors were significantly related to tobacco use, for students in both grades. Some of the strongest correlates included social susceptibility to and social norms about use. Exposure to tobacco advertising was a strong correlate of tobacco use for 6th graders, but not for 8th graders. Sixth graders scored lower than 8th graders on almost all factors, indicating a higher risk
Kotwal *et al*., 2005[27]	Cross-sectional	Both	Almost 42% of tobacco users started before the age of 12 years. Peer pressure, general stress, and media were important influencers
Imtiaz *et al*., 2015[28]	Cross-sectional	Both	Most of the subject interviewed were aware of the hazardous effects of tobacco and were also aware of statutory warning, but still dealt with tobacco usage
Basagoudar *et al*., 2017[29]			The study reveals that most of the adolescents have initiated tobacco smoking due their peer group motivation. Mean age for starting smoking was 14 years. Having smoker in the family and a student residing away from parents were strongly associated with ever smoking
Rani *et al*., 2003[30]	Cross-sectional	Both	Tobacco consumption in 15 years or older is significantly higher in less educated in with low socioeconomic status. The prevalence of tobacco usage smoking and chewing is strongly associated with individual's socio-cultural characteristics

Table 2. Relationship between tobacco ads & progression towards tobacco use among adolescents.

Studies and authors	Alluring advertising leading to tobacco initiation
Arora *et al*., 2008	Provided strong evidence that tobacco advertising and promotion are associated with tobacco use among adolescents. Advertisements and promotion develop likelihood among adolescents to experiment tobacco product
Bansal *et al*., 2005	Reveals unique strategies by tobacco manufacturers being used to draw attention of consumers and nonconsumers. Tobacco companies promote tobacco products through movies
Arora *et al*., 2012	Confirms 2.6 times higher risk of progression towards tobacco use among adolescents
Sardana *et al*., 2015	Reveals huge amount of investment of tobacco industries in advertisements thus luring the youth for tobacco intake. Free samples or coupons for promotion can be considered as incentive for early smokers to stick to specific brands or try a new brand
Patel *et al*., 2012	Reveals free availability in tobacco product promotion and advertisements trap adolescents for experimentation which may lead to addiction
Kothwal *et al*., 2005	Study shows that smoking in media is a potential problem which generate the desire of experimentation among adolescents
Strigler *et al*., 2006	Advertising and promotional activities leads to initiations of tobacco among adolescents

Table courtesy: Yashasvini, Patthi B, et al J Indian Assoc Public Health Dent 2018;16:188-92[14]

Discussion

This review shows that despite of Cigarettes & other tobacco product Act(COTPA).There is a drastic influence of the tobacco marketing in imitations & experimentation of tobacco. Tobacco companies have ruled out the rules & policies of COTPA which has certain rules & regulations for advertisement & marketing.There must be a strong enforcement to control the ads & promotion. Studies show that 2.6 times higher risk of progression towards tobacco among adolescents due to promotional activities.GYTS (2009) shows that three quarter of students are into tobacco addiction by billboards. As the female consumers are less, the tobacco companies are trying their best to attract female towards its use. It includes the female from higher economy group who can spend lot of money.[15, 16]

A large amount of capital is invested by the tobacco company in advertisement. Basically, major capital is invested in Indian market because there is a degradation in the use of tobacco in western countries & so all the tobacco companies are mainly focussing in Indian Market & its youth. Huge amount of money are invested by the company on hiring top models & celebrities for the advertisement & to promote the company's brand. Tobacco company creates a blind belief among youth & adults towards the use of tobacco. Say for example VIMAL Pan Masala has hired Ajay Devgan, the megastar of Bollywood to promote its tobacco brand. This ad comes in most of the newspapers, in movie hall during intermission & it has got proper media coverage though.Cigarette smoking by actors in cinemas & short films attracts the youth towards the experimental use of it.[17-19]

Conclusions

Tobacco usage is widely acceptable among adolescents. It's association with advertising, marketing policies, and ease of availability has flourished it's sale. Advertising strategies develop the positive aura for tobacco by sponsoring the sports events and sponsoring other social events. Marketing policies are generated to develop the normalcy toward tobacco. Cultural ethics have been broken down through effective advertising. Although youth is aware of health hazards, tobacco initiation is adopted due to curiosity generated through advertising and other promotional activities. Tobacco intake is prevalent among adolescents due to the positive impression created by the media promoters. Such promotional activities develop curiosity which leads to addiction of tobacco. Youth is aware of health hazards, but they require strong motivation to quit. Strong policies should be implemented at school level to demolish the strong predictors. Control strategies and understanding epidemiology of tobacco-related health hazards should be strictly implemented in schools. Educational efforts should be focused on dispelling the misconceptions created in the young minds by media. Strong policies should be implemented to bar tobacco usage among adolescents. Adolescents should be motivated with role models such as media persons and doctors. Tobacco cessation advertisements should be flourished on radio, television, magazines and newspapers. Cessation program should be targeted on adolescents so that they may not switch to tobacco consumption due to any reason.

Electronic Nicotine Delivery System

Pradyumna Kumar Sahoo[1], Smita R. Priyadarshini[2]

[1]Associate Professor, Department of Prosthodontics, [2]Associate Professor, Department of Oral Medicine & Radiology, Institute of Dental Sciences Siksha O Anusandhan, (Deemed to be University), Bhubaneswar, Odisha India

Abstract

Electronic Nicotine Delivery System are commonly used substitute for cigarettes to deliver nicotine & have been recently considered to be a very popular& effective mode of tobacco dead diction. The primary aim of this paper is to have a comprehensive idea about the design, the parts, effects and if any safety protocols to be followed along with the potential for cessation.

Keywords: *Electronic cigarettes, smoking cessation, product safety.*

Introduction

Electronic Nicotine Delivery System most commonly known as Electronic cigarettes, e - cigarettes or vaping. Personal vaporizers, advanced personal vaporizers. These are often packaged to appear and feel like conventional cigarettes which provides it a feeling of a cigar or cigarettes. It was invented by Lik Hon in Hong Kong in 2003.[1] This is a new product & very less is known about it in Electronic Nicotine Delivery System, E- Cigarettes or electronic cigarettes are non-combustible cigarettes which deliver nicotine without combustion and are thought to be less toxic and reduce craving and relapse symptom, aid in smoking cessation and in relapse. It aids individuals to quit combustible cigarette smoking and prevent relapse and are said to be less expensive than traditional cigarettes.[2,3] Another important aspect is that it can be smoked without interfering with passive smoking which is a major concern amongst the non-smokers. They also address the psychological social and behavioral aspects of smoking.[4]

These cigarettes are packaged to mimic the features of traditional cigarettes and similar oral sensory experiences of cigarettes. The electronic cigarettes are said to provide more nicotine to the users but the amount of nicotine they deliver is comparatively less than combustible cigarettes.[4,5] Though they were introduced for deaddiction it may attract individuals to smoking. They are sold as single use disposable devices or as reusable devices. The major concern here is that both combustible and non-combustible forms of tobacco pose an adverse health effect.[6]

They are battery operated electronic devices which release aerosolized nicotine for inhalation. The design consists of A cartridge / e liquid container is available in a plastic mouth piece in which the liquid is present that could be vaporized; Atomizer or aerosol generator; Heating element / vaporization chamber in this the liquid present is vaporized to produce aerosol for inhalation; A battery / power source it provides energy for heating; A microprocessor; A LED light that produces a glow, this glow appears on inhalation.

First generation electronic cigarettes/Cig-a-Likes: Look like a combustible cigarette it contains a Cartomizer that combines the vaporing system and electronic cigarette liquid into a single unit. This when puffed the heating coil gets activated and subsequently vaporizes the liquid producing a vapour that can be inhaled with a LED light that glows at the end.

Second generation devices/Mid-size Electronic Cigarettes: Looks less of regular cigarettes and they contain a small receptacle or storage chamber that the user fills with their choice of liquid where in flavour

and strength is decided by the users. Here nicotine concentration ranges from 0 to 24 g/ml. they mostly use large batteries where the power settings can be adjusted and contains replaceable coils and wicks. The storage chamber is also known as tank or "clearomizer" that can be replenished with e-juice.[7]

Third generation devices/ Advanced Personal Vaporizers (APVs): Include adjustable modsfor variable voltage devices. They can hold bigger batteries or multiple batteries and is often replaceable. These adjustable devices have a USB connector for recharging and is referred to as a "pass through" feature.[8]

A fourth generation / Innovative Regulated Mods:Digital e-cigarette: It Contains battery together with chamber of nicotine that is recyclable. Most prominent factor of this generation is the provision of utmost level of user accessibility as well as feasibility. Nicotine content from 0 – 36 mg/ml (max 20 mg/ml in eu from 2016).[9]

Contents

The chemical constituents of the e liquid aerosol are intricate as there are numerous brands and manufactures who use different e- liquids, battery for heating, the heating elements& nicotine concentrations along with the flavoring agents.[10]

Propylene Glycol i.e. propanediol - is an alcohol acts as a solubilizing agent which is used in food substances as a humidifier and emulsifier. A solvent in pharmaceuticals due to its affinity for water and used in aerosolized drug delivery systems in inhalers and nebulizers which is used here to prevent tobacco drying out. The mist produced dries the mucous membranes and eyes& chronic exposure is said to induce rhinitis asthma eczema and allergic symptoms.[10]

Glycerol – is the vegetableglycerin that is purified. Though its pure if overheated it can produce acrolein which acts as an irritant and oxidizing agent which is thought to affect the cardiovascular and respiratory system adversely. The concentration produced in e cigarettes is very less.

Impurities & toxicants – As nicotine is produced from tobacco, the impurities include cotinie, anabasine, anaatabine, myosmine, beta nictyrine & formaldehyde. But the nitrosamines or polycyclic hydrocarbons are absent or very minimal when compared to combustible cigarettes

Metals-Aerosols contain metal particles like:

a. Tin– It is present as an inner and outer cordwith burning of the inner cord. The presence of tin was toxic than the fluids that lacked particles.

b. Lead - present in the solder joints, Nickel, iron was the part of mouthpiece and/or metallic base, silver.

c. Silicate beads with particle like silicon, calcium, aluminum &magnesium originate in the fiberglass wick.

These metallic nano particles tend to penetrate into alveolar sacs increasing the free radicals and antioxidants and thus inflammation in the pulmonary and cardiac tissues. They travel into other organs like liver, kidney, heart, and brain. Inhalation of tin can also cause stannosis.

Fragrances & Aromas: Menthol,floral, fruity, Tabanon (cigarette like), coffee, caramel etc.

Nicotine: Acute exposure to nicotine causes dizziness, nausea, or vomiting when inhaled. Dermal nicotine exposure occurs after spills of nicotine-containing liquids or occupational contact with tobacco leaves leading to toxic body reactions.[12] A concentration ranges from 6 – 36 mg/ml which can be taken in varied concentrations and are labeled as low, medium and high. 100 mg/ml refill solution vials are available online. But the permissible level of nicotine was to be maintained at 20mg/ml by the European Commission. The maximum blood nicotine conc. in electronic cigarettes is 1.3ng/ml where as in cigarettes its 13.4ng/dl.

Safety considerations: Nicotine in e liquid is toxic to infants and children when wrongly manipulated. Therefore, child safety packaging with biometrics and sensors can be used.[13] Use of illegal substances have been reported with slight alteration of the container and refilling it with any other substances like narcotics, steroids, marijuana etc. could be of major concern.[14] Old and contaminated aerosol produces nano particles like tin, iron nickel and chromium which are grouped under potential harmful products by the Food and Drug administration association. Lithium batteries have a characteristic risk of fire and explosion. Therefore, use of low-quality materials, poor design along with any manufacturing defects could attribute to thermal run increasing the temperature causing either fire or even explosion.[15]

Effect of electronic cigarettes on smokers: The food and drug Administration of United Nations or any other government organizations have approved the usage of electronic cigarettes. Although the retail sale been banned in Australia and Canada. Other countries like the United Kingdom are introducing laws for regulating laws for use of nicotine products with medicinal properties. World Health Organization has currently advocated advices so that smokers are initially encouraged to quit smoking and encourage nicotine de-addiction by advocating previously approved treatments protocols.[12]

Effect on health: The effect on health is due to the inhaled vapor which contains nicotine and possible toxicants produced by the atomization process. The respiratory system acts as the primary target for effects of e vapor. 14 In order to measure the pulmonary effects the exhaled nitric oxide is measured which acts as a marker for eosinophilic inflammation.[16] Acute effects reported were increase in both central airway resistance & carbon monoxide in the exhaled air.

Short term use doesn't or have very little adverse effect on the cardiovascular system or the lung function tests. The passive smoke emitted from electronic cigarettes is which is exhaled after inhalation and doesn't generate any additive aerosols and seem to have no effect on the pulmonary function. Patients showed improvement in asthma, bronchitis & chronic obstructive pulmonary diseases with visible decrease in the signs of coughing, throat infections, decrease in appetite and insomnia. The neurological and sensory systems also get affected which is basically due to an overdose or withdrawal of nicotine with symptoms which activates nicotinic cholinergic receptors in the brain. Other Symptoms like anxiety and depression were also either caused by decrease in delivery of nicotine or withdrawal symptoms.[15]

Effect on nicotine levels: Nicotine levels in blood are generally lower from conventional cigarettes when an 18mg/ml nicotine containing vial was used.

a. The aerosol is absorbed from the oral mucosa instead of the lungs
b. Nicotine deposited in mucosa is said to be swallowed and is metabolized in the liver thus reducing the bioavailability.
c. Propylene glycol present in electronic cigarettes also negatively interacts with nicotine absorption from lungs but the nicotine levels in electronic cigarette vials if higher improves the effectiveness & is expected to make it a better substitute when compared to other smoking substitutes.[15,16]

Acute nicotine toxicity occurs when e cig liquid is ingested, which could be accidentally or be a deliberate use as a suicidal overdose, or with dermal exposure. It commonly causes dizziness, nausea, vomiting, pallor, tachycardia, sweating, abdominal pain, salivation, lacrimation, and diarrhea. Confusion, agitation, lethargy, convulsions and possibly death occurs in severe cases due to cardiac arrest. These Symptoms are seen 15minutes of exposure and may resolve within 1 to 2 hours. [16]

Withdrawal symptoms: The possible withdrawal symptoms like feeling awake, calming down, lack of concentration, loss of pleasure & satisfying feeling along with reduction of hunger for food.[15] Along with dependence like craving to smoke, irritability, anxiousness and poor concentration was seen. These symptoms were definite & gender differences in withdrawal suppression was also identified.

Role on smoking cessation: Electronic cigarettes minimize the abuse by acting as a substitute to conventional cigarettes which is less toxic& it helps in minimizing harm. They reduce the withdrawal symptoms immediately 20 min after its use.

Potential for abuse/addiction: Addiction is directly related to the potential of the e cigarettes to cause dependency. It is due to the presence of Nicotine which is the principle component of tobacco. When compared to conventional cigarettes e cigarettes have a very low addiction potential & would depend on the persistent use, rate of absorption of these products. Studies have shown due to minimal increase in plasma nicotine from e cigarettes with a significant decrease in cravings.[17]

Regulations for use of electronic cigarettes by FDA: Marketing, restriction of youth access with labeling& quality control while manufacturing with restriction of free sampling and standards for contaminants should be strictly supervised. There should be proper warning labeling and child proof packing on refill liquids& vials FDA should approve companies who manufacture electronic cigarettes and claim its useful for tobacco cessation.

Regulating taxing by increasing tax on combustible products would prevent its use & may create interest

in switching on to e cig. A tax too high one cig would prevent switching of low-income group users from combustible to e cig.[18]

Regulating marketing & Advertising: Marketing by using celebrities to promote about the flavors etc. tend to glamorize and might be misinterpreted amongst the youth for fun socially acceptable & desirable. Regulations should be implemented on marketing which would prevent its accesses to minors. Researches should be carried out to recognize constructive communication techniques for health information, hazards/ benefits and regulatory issues.[19]

Conclusion

E cigarettes are less harmful in comparison to the combustible cigarettes. The government should enforce efforts to differentiate the potentially harmful or beneficial effects and evaluate its effects on smoker's nonsmokers& persons seriously interested to QUIT. Additional researches & surveys should be enforced for better understanding of the design, functioning as a number of different products have been introduced by different companies with specialized testing protocols. Clinicians should be made to obligate to promote smoking cessation using e cigarettes. But very less is known in India and negligible usage or researches have been advocated here. India being one of the leading nations for Oral Cancer deaths elimination or replacement of the combustible tobacco products could significantly reduce the number of deaths.

Xerostomia: A Comprehensive Review

Sambit Samal

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan(Deemed to be University). Bhubaneswar, Odisha, India

Abstract

The motto of this article is to investigate the manifestation and complications caused by dry mouth and what measures should we take to give respite to the patients. The two different facets of dry mouth are Xerostomia and Hyposalivation. Xerostomia is subjective sensation of dry mouth whereas, hyposalivation is an objective estimation of diminished salivary flow rate. This ailment is found to be more prevalent in the age group of 65 years and older i.e., around 30%. Significant increase in manifestation of having dry lips, mouth, throat, eyes, skin and nose epitomize Xerostomia. For these patients swallowing food becomes an arduous task so they drank water three times more than normal person to make it possible. In comparison to medication-free patients this disorder is found be more established in patients who are consuming drugs that affect the nervous system. Independent risk factors like gender, age and medications pose serious threat in the development of xerostomia. Dentists should be well acquainted with situation and take an active role in diagnosing and managing this situation on time should be taken forward positively by the dentists because any dereliction in this might impair the condition.

Keywords: *Xerostomia, Hyposalivation, Quality of lifestyle, Etiology, Diagnosis, Management.*

Introduction

We as human beings do not get the importance of a thing, unless and until it goes missing as a result of which there is hindrance in our daily livelihood. Now, speaking of lifestyle; chiefly deals with social interactions and relationships with people coming from all walks of life.[1] And thus, having a healthy, comfortable mouth plays a crucial role in building one's quality of life. Saliva is essential to oral health by performing various functions which are, perception/judgement of taste, digestive process, vocal expressions, food bolus formation, and facilitating in mobility of food by lubricating and bathing it.

The fundamental constituents of saliva are water and mucin which function as, disinfecting solvent and lubricating fluid reciprocally. Factors like lysozyme, lactoperoxidase, secretory IgA that are anti-microbial in nature are prevalent in saliva.[2] So the absence of saliva creates a perilous position by inducing dental problems such as; caries, gingival issues, facing hardship during chewing, wearing dentures and speech botheration. Chief salivary glands which are, parotid gland, submandibular gland and sublingual gland plays a crucial part by secreting recurrently in relation to autonomic stimulation, that is on a peak in course of a meal but low else ways. In other respects, numerous minor glands harbour mucus ceaselessly throughout the time in the lips and cheeks arena. Thus, as a consequence, oral function becomes flawed when this activity is diminished. Now, the saliva is basically of two types;

- Stimulated (resting) saliva which has been reported to be between 1-2ml/min, that aids in mastication and digestion.

- Unstimulated saliva emulates the basal flow rate which aims at safeguarding the oral mucosa. It ranges from about 0.29ml/min to 0.41ml/min.

A major cutback of 50% in the flow of saliva implies to the sensitivity of a dry mouth (Xerostomia). An objective estimation of shortened salivary flow rate elucidates the condition of hyposalivation on the contrary, a subjective accusation of dry oral habitat whether its related to malfunctioning of the salivary glands[3] or not clearly indicates a case of xerostomia. Xerostomia if neglected and not taken care of properly in due time cripples a person's social interactions and networks. Patients with xerostomia may be embarrassed by bad breath and difficulty in speech which makes them feel withdrawn, isolated and socially out-casted. A sore, dry mouth affects taste and food enjoyment. Common gestures like smiling, laughing, kissing become a difficult issue for the patients because of cracking in dry

lips. Xerostomia and salivary de-function can debilitate an individual's aspect of life by generating various oral derangements. Through various retrospective studies done before, it is found that women are the once who get affected more than men and its prevalence is highest in the sixth decade of age. Now there are various causes of xerostomia, amongst which the most common etiologic factors are;

- Drug-induced xerostomia-This is the most frequent cause of dry mouth, specifically those that block the central and peripheral nervous system[4] i.e, drugs with anticholenergic properties. Some common drugs causing this ailment are, Narcotic analgesics i.e, opoids; Antiemetics drugs- cyclizine, stemetil; Antihistamines; Antidepressants-amitriptyline; Antimuscarinis for Parkinsonism; Antiepileptic drugs-phenytoin; Antipsychotics drugs–chlorpromazine; Antihypertensive drugs-lisinopril; Antineoplastic; Bronchodilators; steroids.[5]
- Sjogren's syndrome-It is a long-term autoimmune rheumatological disorder characterised by inflammation of exocrine glands particularly of mouth, eyes that result in causing extreme dryness.[6] It affects women more often than men which is in a ratio (9:1), principally in their forties and fifties. A dry, erythematous & sticky oral mucosa alongwith atrophy of the filiform papillae on the dorsum of the tongue is noticed during physical examination. In recent times, Sialometry and newer imaging techniques, including ultrasound and Magnetic resonance sialography of the principal salivary glands are various diagnostic evaluations that have proven to be quite advantageous. Patients with Sjogren's syndrome associated with rheumatoid arthritis and systemic lupus erythematosus have an increased cardiovascular risk.
- Radiotherapy–From many a recollective studies done, it is deduced that radiotherapy for head and neck results in the most severe type of xerostomia. In the radiotherapy procedure, the major salivary glands intermittently receive a high radiation dose[7] and xerostomia arises owing to irradiation of acutely sensitive salivary tissue lying in close proximity to the radiation target. Surgical excision is the most opted treatment procedure for a wide variation of benign salivary gland tumours, but the patients with invasive salivary gland tumors are dealt with surgery followed by radiation therapy.
- Now, keeping in mind the above mentioned causes, there still remains some which are liable for this disorder; Burning mouth syndrome, Alzheimer's disease, Parkinson's disease, Rheumatoid arthritis, Cystic fibrosis, Oral infections, Chronic anxiety, Stress, Diabetes, Renal failure, Diarrhoea, Dehydration, Liver disease, HIV infection, Congenital abnormalities, Sarcoidosis, Chronic parotitis, Salivary duct obstruction, Hepatitis C infection with a long-term inflammation of salivary glands can be conducive to hyposalivation; Rare causes:Amyloidosis, Hemochromatosis, Wegener's disease, Salivary gland agenesis(with/without ectodermal dysplasia), Triple A syndrome.

In order to approach a xerostomia patient, a thorough history of symptoms and examination is crucial, so we need to lookout for painful dry, burning and atrophic tongue and mucosal tissues, cotton wool sensation in the mouth, cracked lips and soreness of mouth, candida infections; difficulty in wearing prosthesis, difficulty in chewing and swallowing dry foods, difficulty in speech, diminished or altered sense of taste, increased thirst, disturbed sleep, Presence of halitosis, deterioration of vocal function, dental caries.[8, 9]

Now in order to check this from making the patient's condition worse certain treatment procedures need to be followed stringently; local treatments like, frequent sips of water, ice-cubes, ice-lollipops, mouthwashes, sugar-free sweets are instructed to the patient. Dry lips need to be moisturised with Vaseline, partly frozen melon or artificial saliva substitutes.

Table 1. Saliva substitutes

Products available	Formulation	pH	Fluoride containing
AS Saliva Orthana (AS Pharma)	Oral spray 50ml	Neutral	Yes
Biotene oral balance (GSK)	Lozenges (30)	Neutral	No
	Moisturising liquid 45ml	Neutral	No
		Neutral	No
BioXtra (RIS products)	Moisturising gel 40ml	Neutral	No
	Gel mouth spray 50ml	Neutral	Yes
	Chewing gum pieces(20)	Neutral	No
		Neutral	No
	Sucking tablets(60)	Neutral	Yes
	Toothpaste 50ml	Neutral	Yes
	Mouth rinse 250ml		
Salinum (Crawford)	Liquid 300ml	Neutral	No
Salivix (Galen)	Pastilles(50)	Acidic	No
Saliva natura (Medac)	Oral spray 50ml	Acidic	No

Bile secretion-stimulating drug: Under the usual dosage of 25mg of Anethole trithione (thrice-a-day),[10] this drug sufficiently vitalizes the salivation and improves xerostomia.

Night guards: Sleep-related xerostomia is a condition where the patient undergoes disturbed sleep due to anomalous movement of the masticatory muscles. The use of night guards can help the patients enhance their sleeping patterns. Factors like; an increment of salivary flow, conservation of saliva amount in oral cavity, or a reduction of saliva vaporisation[11] got influenced with this advancement.

Saliva stimulants: Nonetheless, specifically dentate patients should shun the use of the above portrayed saliva substitutes with an acidic pH, because it may demineralise their tooth enamel and thus make it susceptible to dental decay. Naturally available products like pineapple contains an enzyme named Ananase which promotes the cleaning of mouth [12] making it highly beneficiary for the patients. Drugs like Pilocarpine or Cevimeline have parasympathetic effects which have shown to increase secretions of salivary glands. As a matter of fact, Pilocarpine is more potent than artificial saliva yet it has some side-effects too such as sweating, dizziness, cognitive or psychiatric disturbances, rhinitis, urinary frequency and blurred vision. So, keeping in mind, these drugs should not be prescribed to patients with asthma or chronic obstructive pulmonary disease, patients with cardiovascular diseases, peptic ulcer, renal or hepatic impairment, bowel obstruction or glaucoma.[13] The recommended dose for patients is 30mg (thrice-a-day) for Cevimeline or 5-10mg thrice daily for Pilocarpine to be taken orally.

Patients with low salivary output become susceptible to oral infections which needs attention at the first hand. Fluoride application is the most effective tactic of retaliating the unchecked hyposalivation-induced caries[14] is by using routinely NaF in neutral pH.Decrement in saliva flow results in overgrowth of fungus like Candida albicans which can be treated by antifungal rinses i.e, Nystatin oral suspension (rinse it four times a day) or Clotrimazole lozenges. Denture antifungal treatment is done by soaking the denture for 30mins daily in benzoic acid, 0.12%chlorhexidine.[15]In current years, Intensity Modulated Radiotherapy (IMRT) has explained that the repercussion of radiation on the salivary glands can be diminised by (partly) sparing the glands.[16]

Conclusion

In conjunction with the physical dilemmas of pain, infections and difficulties in eating and speaking, xerostomia undeniably has profound negative psychological and social effects, which detiorate the patient's aspect of life. These patients feel embarrassed in social gatherings. A lifetime of multi-disciplinary care is essential to monitor and treat the distressing effects of salivary de-function. Oral health care practitioners possess this unique opportunity to detect xerostomia and present an appropriate treatment towards an improved well-being.

Abstract

Fluorine is a common element that does not occur in the elemental state in nature because of its high reactivity. It is of vital importance for humans as it maintains and solidifies the bones and also inhibits dental caries. It is abundant in the atmosphere and hence drinking water is the chief source of fluoride for individuals. It has been proved to be advantageous and at the same time it is toxic at higher concentrations has also been well recognized. Prevention can be done by supplying fluoride safe water by using defluoridation techniques. The purpose of the article is to review the various aspects of fluoride and its significance in human life.

Keywords: *Fluoride, Dental fluorosis, Fluoride therapy, Optimum doses.*

Introduction

The term "fluorine" is derivative of the Latin word "Fluore" implicates "to flow". It is the most electronegative element which never exists in free-state in nature, rarely available in its elemental state because of its high reactivity. At room temperature, fluorine is a pale, yellow-green gas. It is commonly described as a 'double-edged sword' as an inadequate ingestion leads to dental caries and too much ingestion leads to dental and skeletal fluorosis which has no treatment.

Sources of Fluorides: The existing sources of fluoride in the environment are schematically presented in Figure 1. The major fluoride reserve is considered from rocks and minerals. Other common sources of fluoride are in soil and ground water. In food high fluoride levels are found in fish products like canned fish such as salmon and sardines, cereals like jowar, vegetables like cabbages, potato and lettuce, fruits like banana, plants like taro, yam, cassava, dried tea leaves, mineral water.[1,2]

The various sources that contributes to fluoride intake and exposure can be categorized as follows:

(a) systemic/planned—water, fluoridated milk, salt, fluoride supplements

(b) systemic/incidental— ingestion of dentifrice, Teflon coatings on pans, fluoride rinse, exposure to food/ pesticides/soil, smoking, prescription drugs and environmental pollution,

(c) topical/planned— toothpaste, home use rinses and gel or professionally applied varnishes and gels

(d) topical/incidental—alginate impression materials

Drugs like fluoride containing benzothiadiazines used as fluoristeroids, diuretics, fluorobutyrophenones and phenothiazines used as methoxyflurane, tranquilizers; halothane and enflurane used as an anesthetic also consists of fluoride.

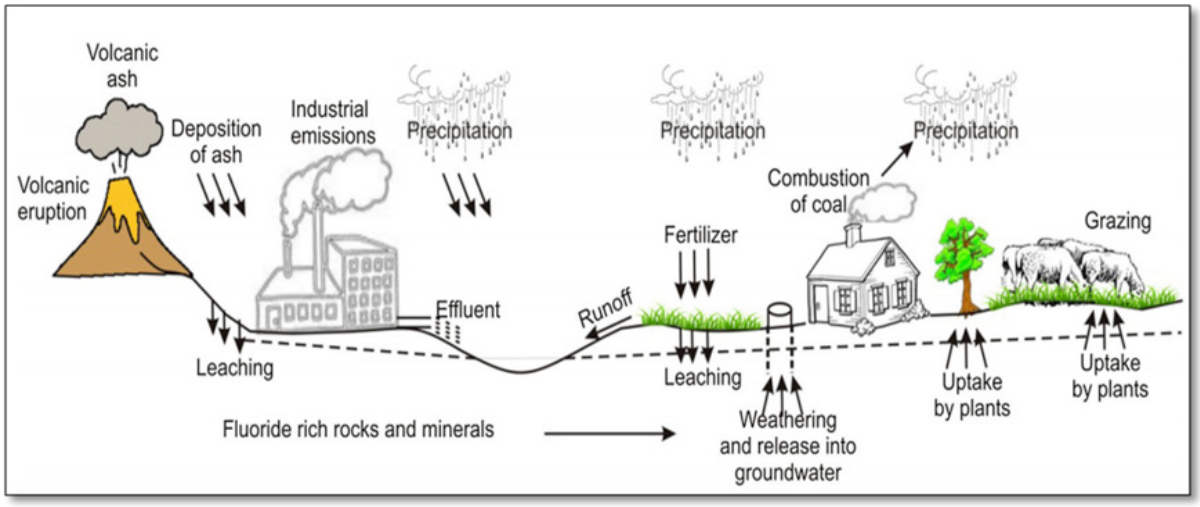

Figure 1. A schematic diagram showing the fluoride-existing sources in the environment

Metabolism: Fluoride containing compounds are very diverse. Hence it is impossible to generalize their metabolism, as it depends on their solubility, reactivity and structure and ability to discharge fluoride ions Figure 2.[3]

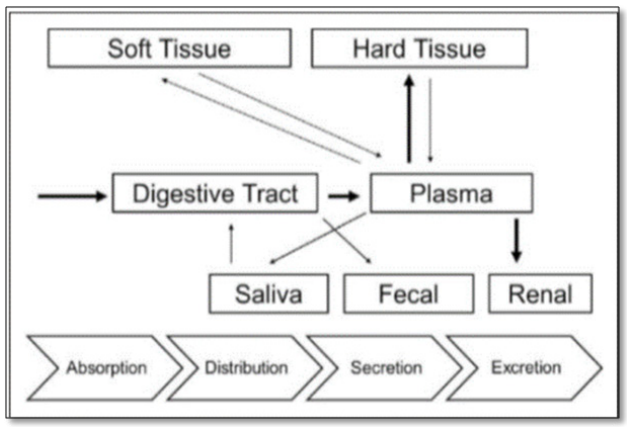

Figure 2. Flowchart of fluoride metabolism

Pharmacokinetics: Fluoride is mainlyabsorbed through the respiratory and gastrointestinal tracts but dermal absorption is insignificant except in cases of hydrofluoric acid burns. Fluoride readily crosses placenta and is absorbed by the fetus. Soluble fluoride compounds are rapidly and almost entirely absorbed to a level of 90 to 95% across the gastrointestinal tract with peak serum levels achieved after 30 min of consumption on a fasting stomach. Large volume of extracellular body fluids dilutes the absorbed fluoride concentration; thereby avoiding elevation in plasma fluoride concentration. Fluoride diffuses from the plasma to the surrounding tissues of the body. Approximately 50% of daily fluoride intake is deposited in calcified tissue like teeth and bone.[4]

- Fluoride in outer enamel is 2200 – 3200 ppm
- Fluoride in dentin is 200-300 ppm
- Fluoride in cementum is 4,500 ppm

The maximum fluoride is concentrated in the skeleton and kidney, which reflects the major pathways to dispose fluoride. It is mainlyexcreted by the kidneys with 40 to 60% of the daily fluoride dose evacuated in urine showing an elimination half-life of about 5 h. Fluoride is also excreted in sweat, saliva, and breast milk.

Estimation of Fluoride Concentration

Collection of samples: Both stimulated and unstimulated saliva should be collected for analysis. The stimulus used may be mechanical (E.g. chewing inert wax) or use of citric acid. If the concentration of fluoride in saliva derived only from the systemic source is to be estimated, then the salivary secretions must be collected directly from the gland ducts. This is done using Carlsson - Crittend or Lashy device or by direct cannulation. If the concentration of fluoride in saliva after enhancement from locally dissolved dietary or therapeutic sources is to be estimated, then whole saliva must be collected. Microorganisms and desquamated epithelial cells contaminate whole saliva. Separation by centrifugation of these cellular components is customary before analysis.

Fluoride analysis

Ionic Fluoride: commonly used method for estimation is the fluoride-specific ion electrode. Ionic fluoride has been measured by isotachophoresis and ion chromatography at about the same level of sensitivity as the micro method, the ion selective electrode.

Bound Fluoride: the bound fluoride should be made free to ionic state before final measurement. Various analytical procedures, including distillation, wet and dry ashing and acid extraction have been used.

Mechanism of Action: The mechanisms through which fluorides increases caries resistance can be categorized as follows:[5]

1. Increase enamel resistance
2. Increased rate of post-eruptive maturation
3. Interference with plaque microorganisms
4. Remineralization of incipient lesions
5. Modification in tooth morphology

Fluoride Delivery System: Anti-caries effect of fluoride started to be exploited by the beginning of the 20th century itself. However, it became more extensive by the middle of the century. Fluoride can be professionally applied and self-applied.

Professionally applied fluorides:

- **Systemic:** Water fluoridation, Milk fluoridation, Salt fluoridation, Fluoride supplements, Diet/ Tablets/ Lozenges
- **Topical:** Fluoride solutions, Stannous fluoride, Neutral Sodium fluoride, Acidulated phosphate fluoride, Amine fluorides, Fluoride prophylactic paste, Fluoride varnishes

Self-applied fluorides: Tooth brushing with dentifrices, solutions or gels, prophylaxis paste, Applying gels in trays, Mouth rinsing with solutions

Table 1. Recommended doses of dietary fluoride supplements[6]

Age	<0.3 ppm F (in mg)	0.3-0.6 ppm F (in mg)	>0.6 ppm F (in mg)
Birth-6 months	0	0	0
6months-3years	0.25	0	0
3-6 years	0.50	0.25	0
6 -16 years	1.00	0.50	0

Table 2. Mode of administration of fluorides in different age group.

Age	Fluoride (mg)	Mode of Administration
0-2	0.25	Drops dissolved in water
2-3	0.50	Chewable tabs /drops
>3	1	Chewable tabs

Table 3. Fluoride solutions[5]

Characteristics	NaF	SnF_2	APF
Percent	2%	8%	1.23%
Ppm F	9,200	19,500	12,300
Frequency of application	4 at weekly intervals at ages 3,7,10 & 13	1 or 2/ year	1 or 2/ year
Taste	Bland	Disagreeable	Acidic
Stability	Stable	Unstable	Stable in plastic container
Tooth pigmentation	No	Yes	No
Gingival irritation	No	Occasional, transient	No
Average effectiveness	29%	32%	28%

Miscellaneous Modes of Fluoride Application: Fluoride impregnated floss; Fluoride Chewing Gum; Intraoral Controlled Release Devices for Fluorides; Iontophoresis

Fluoride Toxicity: Fluoride often called as double-edged sword because ingestion of inadequate fluoride results in dental caries and ingestion of excessive fluoride leads to skeletal and dental fluorosis.

Table 4. Fluoride status in India

States	Fluoride level in India (mg/L)
Andhra Pradesh	0.4 - 29
Assam	1.6 - 23.4
Uttar Pradesh	0.2 - 25
Chhattisgarh	Information Awaited
Delhi	0.2 - 32
Orissa	0.6 - 9.2
Haryana	0.2 - 48.32
Jammu & Kashmir	0.5 -4.21
Jharkhand	0.5 - 14.32
Kerala	0.2 - 5.4
Karnataka	0.2 - 7.79
Gujarat	1.5 – 18

States	Fluoride level in India (mg/L)
Madhya Pradesh	1.5 - 4.2
Maharashtra	0.11 – 10
Bihar	0.2 - 8.32
Punjab	0.4 - 42
Rajasthan	0.10 -0.10
Tamil Nadu	0.1- 7
Uttaranchal	Information Awaited
West Bengal	1.1- 14.47

Fluoride Toxicity: It is divided into: Acute toxicity, Chronic toxicity (Dental fluorosis, Skeletal fluorosis, Non-skeletal fluorosis/ soft tissue fluorosis)

Acute Toxicity of Fluorides: Acute fluoride toxicity occurs due to rapid ingestion of excessive fluoride at one time.

Certainly, lethal dose (CLD): Children: 16-32mg/ kg bodyweight; Adults: 32-64mgof fluoride/kg body weight

Safely tolerated dose: Children: 8-16mg of fluoride/ kg bodyweight; Adults: 16-32 mg of fluoride/ kg bodyweight

Management of acute fluoride toxicity[7]

Less than 5mg/kg:

1. Oral administration of calcium
2. Vomiting is induced (not necessary)

More than 5mg/kg but less than 15 mg/ kg body wt.

1. Stomach is emptied by inducing vomiting with emetic
2. Oral administration of calcium
3. Admitted to hospital & kept under observation for few hours

15mg/kg or more:

1. Immediate admission to hospital
2. Patient is forced to vomit
3. Cardiac monitoring is initiated
4. Slow administration 10 ml of 10% calcium gluconate iv
5. Urine output should be adequately maintained using diuretics if necessary
6. General supportive measures

Chronic Toxicity of Fluorides[7]: Chronic toxicity is caused due to ingestion of lesser amount of fluoride for a long term which usually affects the kidney and hard tissue.

Dental fluorosis: Dosage: Two times optimal; Duration: Till 5 yrs (excluding 3rd molar)

Skeletal fluorosis: Dosage: 10 -25mg/per day; Duration: 10 -20 yrs

Kidney damage: Dosage: 5 -10mg/per day; Duration: 6-12 months

Dental Fluorosis: It is caused due to excessive fluoride intake during tooth development.

Clinical features: Opaque, Lusterless, enamel white patches which may be mottled, pitted or striated; Mottled areas may appear yellow stained or brown; In severe cases, hypoplastic areas is lost; Symmetric occurrence of fluorosis in dental arches

Table 5. Characteristic of mild fluorosis and non-fluoride enamel opacities.

Characteristic	Mild fluorosis	Non fluoride enamel opacities
Affected area	Cuspal tips / incisal edge	Centered in smooth surfaces; affects whole crown
Shape of lesion	Pencil shading; follow incremental lines in enamel	Round and oval
Criteria for demarcation	Shades off imperceptibly into surrounding normal enamel	Opaque appearance easily differentiated from adjacent normal enamel
Colour	“Paper white”; no stain at the time of eruption	“Creamy-yellow”- “dark orange”; Pigmented at time of eruption
Affected teeth	Calcify slowly; rarely seen in lower incisors; rare deciduous teeth involvement; usually bilateral	Any tooth; deciduous tooth may be involved; may affect single tooth
Gross hypoplasia	None; enamel has glazed appearance, feels smooth to explorer tip	Absent in severe cases; enamel surface can be etched, feels rough to explorer
Detecting criteria	On application of high intensity light- line of sight tangential to the crown	On application of high intensity light - line of sight is perpendicular to the tooth surface

Skeletal Fluorosis

Manifestation:

- Severe pain in back bone, joints, hips; stiffness in joints and spine
- Outward bending of legs and hands in advanced stage and these parts lose their shape and contour
- Rise in x-ray density of trabecular bone in lumbar spine, pelvis and elsewhere
- Endosteal/periosteal apposition leads to increase in thickness
- Calcification of ligaments take place

Indices Used for Dental Fluorosis

Fluorosis specific index: Dean's fluorosis index, Tooth Surface Index for Fluorosis, Thylstrup and Fejerskov index, Fluorosis Risk Index

Descriptive index: Developmental effects of Enamel Index, Murray Shaw Index, Jackson Al- Alousi Index

Defluoridation of Water

An excess of fluoride in drinking water is a severe problem. The only way to prevent fluorosis is supply of drinking water with recommended levels of fluoride concentration which can be achieved by **de-fluoridation** of fluoride contaminated water. Defluoridation is "the adjustment of level of fluoride in drinking water to the optimal level".

Defluoridation techniques and the materials used[8]

Defluoridation is done by:

Adsorption: Carbon materials, Calcite, Activated Alumina, Hydroxyapatite, Magnesia, Wood, Tea waste, Tricalcium phosphate, Jute waste, Coir pitch, Bauxite, Fly ash, Serpentine, Lignite, activated charcoal, Fish bone char, Nut shells, Processed bone, Paddy husk, Coffee husk, Avaram bark

Ion-exchange: *Anion-exchange resins*: NCL poly anion resin, Lewatit-MIH-59, Deacedodite FF-IP, Amberlite IRA-400, Waso resin-14 Polystyrene, Tulsion A27

Cation exchange resins: Carbion, Defluoron-1, Defluoron-2

Precipitation: Lime, Lime and alum (Nalgonda technique), Alum, Poly Aluminum Hydroxy Sulphate (PAHS), Alum flock blanket method, Poly Aluminum Chloride (PAC), Brushite

Others: Electrochemical method (Aluminum electrode), Reverse Osmosis, Electro dialysis, Electrolysis

Defluoridationimplementedin India[9] : Prasanti Technology using Activated Alumina, UNICEF in India using Household based defluoridation, KRASS Defluoridation Process, Delfuoridation based on ion exchange Mechanisms, Nalgonda Technique

Recent Advances[10]

New fluoride products available in the markets:

Fluoride foams: Topex neutral fluoride foam; KOLORZ neutral fluoride; Denti-Foam topical fluoride

Fluoride gels: Neutra Gard Home Care Gel; NeutraGard Advanced Gel; Zap Fluoride Gel[11]

Fluoride varnishes: Enamel Pro® Varnish, Profluoride Varnish, Fluoro Dose®, Flor-Opal varnish White, Fluor Protector, Fluoridex Lasting Defense, Waterpik Ultrathin Varnish, Varnish America™, Zooby® Fluoride Varnish.[12]

Fluoridated rinses: Stan-Gard Perio Rinse; ACT Total Care, ACT Anticavity Fluoride Rinse, Cari Free Maintenance Rinse, Orthowash™ Daily Rinse, Listerine Total Care, Previ Dent, Rinse, Gel-Kam Oral Care Rinse, Crest Pro-Health Rinse.[13]

Prophylaxis pastes: Clinpro™ Prophy Paste, Next Prophy Paste, Oral-B Prophy Paste, Waterpik® Prophy Paste, Glitter™, BreathRx Prophy Paste, Glitz Premium Prophy Paste, Enamel Pro®, Ziroxide.[14]

Fluoridated rinses: GC Fuji Triage White and Pink, Riva Protect, Helioseal F, Delton FS Plus Pit and Fissure Sealant, Seal-Rite, Ultra Seal XT plus Pit and Fissure Sealant, Adhe SE One F, Ecu Seal Pit and Fissure Sealant, Versa Flo Light-activated Flowable Composite Resin, Seal and Protect.[15]

Conclusion

Fluoride is the most electronegative element which never exists in free-state in nature. It is most beneficial micro nutrients for our body. Fluoride is a safe and

effective agent to prevent and control dental caries, when used appropriately. But it can be toxic in extremely high concentrations. If government would monitor fluoride concentration in diverse sources of drinking water and ground water and make fluoride map available to the public, it would be much beneficial. Government must include the International/WHO guidelines in circular form to safeguard citizens in case they are in need of fluoride supplements and this would help in preventing health related problems due to deficient/ excess fluoride exposure. For many decades, studies have been conducted to check the function of fluoride in oral health and evidences obtainedsupports topical benefits of fluoride, but not systemic. However, emphasis must be given that dental caries is not caused due to fluoride deficiency. Therefore, fluoride supplements do not reverse carious lesions. Hence for peoples having high caries risk, proper patient counselling with guidance regarding oral hygiene and selection of food is to be done combining itwith the fluoride delivery in order to reduce dental decay.

Invasive Dental Treatment and Associated Risk of First Myocardial Infarction Episode

Saloni Mohanty

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan(Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Invasive dental treatment has been linked to transient increase in the risk for intravascular inflammation and endothelial dysfunction leading to increased cardiovascular risk i.e., Myocardial Infarction. It is known that invasive dental treatment may provide long term reduction in cardiovascular risk but a study has suggested a short termed transient increase in cardiovascular risk during the first four weeks after invasive dental treatment. The study was a self-controlled case series which used U.S Medicaid data to evaluate cardiovascular risk in 1152 patients (who acted as controls for themselves) within 24 weeks post invasive dental treatment. In another study there was increase in levels if inflammatory mediators during the first 24 hours of inflammatory mediators during the first 24 hours of intensive dental therapy with a transient decrease in their levels during the following one week. Certain other studies also support the above-mentioned finding. A randomised case control study conducted within nationwide health care and population registries in Sweden including 1,880 individuals (5 controls each) with first episode of Myocardial Infarction within the course of the study. The study concluded the lack of association of invasive dental treatment and Myocardial Infarction. Hence, the hypothesis that invasive dental treatment associated with development of risks of cardiovascular events is still inconclusive. But the long-term benefits of invasive dental procedures certainly overweigh the short-term transient cardiovascular risk.

Keywords: *Invasive dental treatment; associated risk; Myocardial Infarction.*

Introduction

Invasive dental treatment includes those involving perforation and manipulation of gingival tissues. Those include extraction, scaling and root planning, periodontal surgery and dental implant therapy. According to recent studies, locally invasive periodontal therapy causes a short-term acute inflammation in the body leading to transient endothelial dysfunction. It is proved that systemic inflammation has a major role in the development and pathogenesis of atheroma i.e., atherosclerotic plaque. Myocardial infarction is caused by occlusion of blood vessels by thrombus formation due to atherosclerosis. Hence, it is still a matter of debate if the inflammatory response generated by invasive dental treatment are potent enough to impair endothelial function and contribute to the pathogenesis of atherosclerosis lesion. Cardiovascular diseases are one of the causes of increased mortality in developing countries. On proving the role and contribution of dental treatment in the pathogenesis of atherosclerosis, prophylactic drugs (like anti-inflammatory drugs) can be administered prophylactically to prevent Myocardial Infarction.[1, 2]

The Hypothesis: Various studies have been conducted to test the hypothesis that there is a transient increase in cardiovascular risk due to the acute inflammatory response generated post invasive dental treatment. The objective of the article is to review these studies and draw a conclusion.

Evidence in favour of hypothesis: Inflammation has a role in the pathogenesis of atherosclerosis and not just metabolic disorders like hypercholesterolemia leading to lipid accumulation. The recognition of this fact has an immense impact on the understanding of arterial thrombus formation.[2] Intravascular inflammation results in generation of inflammatory markers which increase the risk for various vascular events.[3,4] A study was conducted using U.S Medicaid database from January 2002 – December 2006. The study was a self-controlled case series i.e., the study relied on within sample comparison to obtain conclusion

within the sample itself. The initial sample population included individuals with a record of first episode of myocardial infarction 24 weeks after the period of enrolment for the study to begin. Individuals below 20 years of age at the time of first episode, individuals with myocardial infarction outside continuous enrolment phase and those not exposed to invasive dental treatment during enrolment phase were excluded from the initial sample population. The final sample included 1152 individuals with first recorded cardiovascular diseases and with invasive dental treatment during the course of enrolment. The period of observation began one day after invasive dental treatment and extended to 24 weeks later. Individuals undergoing at least one invasive dental procedure were observed and those who underwent more than one procedure were observed for 24 weeks after each procedure. Incidence ratios and 95% coincidence interval for events occurring within exposed period were calculated. The study concluded that there is an increase in the rate of vascular events up to 4 weeks after invasive dental treatment (incidence ratio= 1.50 and 95% coincidence interval= 1.09-2.06) with commencement to normal within 6 months. The results remained unchanged even after eliminating individuals with predisposed cardiovascular risk factors.[5,6]

In another study, 120 severe generalized periodontitis patients were randomly assigned to either receive control based periodontal care (n=59) or intensive periodontal care (n=61) in order to analyse the association between systemic inflammation after invasive dental treatment and endothelial dysfunction. Patients with presence of systemic diseases (diabetes, cardiovascular diseases),with chronic or acute infections, receiving antibiotics or any other medications within 3 months prior to study were excluded. The inflammatory biomarkers, flow mediated vascular dilation and endothelial dysfunction were measured from 1day after invasive dental treatment to 6 months. Results indicated a surge in level of C-reactive protein, Interleukin-6 and a reduction in flow mediated dilation in intensive treatment groups within 24 hours. However, at the end of 6 months the levels of the pro inflammatory cytokines reduced drastically with the increase in flow-mediated dilation to the baseline. Neither of the groups had any cardiovascular events.[7] Bacteraemia caused due bacterial dissemination into the blood post invasive dental treatments, causes acute inflammation which is transient. This acute inflammatory response further causes vascular events which may result in the progression of atherosclerosis thus increasing cardiovascular risk.[8,9]

Evidence not in favour of hypothesis: A randomized case-control study conducted on date obtained from Swedish health care and population registries included 51,880 individuals with first episode of Myocardial infarction between 2011 and 2013. Every sample had 5 controls matched on the basis of age, gender and area of residence (n=246,978). Controls were free of any previous episode of Myocardial infarction.[10-12] The Dental Health register provided information regarding invasive dental treatments among sample population. Results showed increased association of case samples with diabetes and previously detected cardiovascular diseases than the control group. Control patients had higher socioeconomic status and educational qualifications. But there was no association detected between invasive dental treatments 4 weeks prior to the date of first episode of Myocardial infarction. Although, the study found an association between socioeconomic status and poor oral health. Patients with lower socioeconomic status opted for less dental treatments and hence poor oral conditions Poor oral health resulted in poor overall health and increased cardiovascular risk.[10, 13]

Discussion

Atherosclerosis is caused due to interaction between immune mechanisms and metabolic risk factors with an inflammatory driving force that results in not only induction and dissemination of lesions in the arterial tree but also as a triggering force. Atheromatas are irregular localised thickening of the subendothelial spaces (intima) of the arteries which are essentially lipid driven. It has grossly two parts – the core and the fibrous cap. The cap is rich in lipid and foam cells (modified LDL engulfed by macrophages) and the surrounding fibrous cap consists of smooth muscles and a collagen matrix. The atheromatas grows in the shoulder region where it is surrounded by an inflammatory infiltration (T-cells, macrophages, mast cells).[14] Various inflammatory molecules, microbes and autoantigens can cause the activation of these inflammatory cells, resulting in production of various pro-inflammatory cytokines like Interferon γ, tumour necrosis factor which reduces the stability of the plaque. Further, these inflammatory infiltration by generating matrix metalloproteinases and cysteine protease attacks collagen in the fibrous cap thus initiating thrombus formation. As an acute phase response to the proinflammatory cytokinesis, the liver produces C-reactive proteins, Interleukin-6, serum amyloid A, fibrinogen and various other molecules as

acute phase reactants. These inflammatory markers are elevated in the serum of individuals undergoing peripheral vascular changes. They may not cause the disease, but they contribute to statistical risk of cardiovascular dysfunction.[15]

Invasive dental treatment may cause dissemination of microbes into the blood. Studies have indicated bacteraemia in blood samples of the patients after lasting up to 15 minutes extraction and oral prophylaxis. Administration of an antibiotic prophylactically may have an impact on bacteria, but it will not eliminate the bacteria. This acute bacteraemia may induce an inflammatory stimulus that aggravates atherogenesis. Recent studies also indicate that invasive periodontal treatment produces transient dysfunction of the endothelium for a duration of one week due to the generation of an acute systemic inflammatory response. Although, this phenomenon is followed by restoration of this inflammatory response to the baseline.[16] It is accompanied with release of acute phase reactants like C-reactive protein, Interleukin-6 and others in the peripheral blood of the patients. C-reactive protein is considered apotent biomarker in the clinical diagnosis of ongoing cardiovascular changes in a patient. A study shows the phenomenon of flow mediated vasodilation concomitant with vascular changes after invasive dental treatments. Flow mediated vasodilation shows nitric oxide induced vasomotor function which provides an insight into the effect of nitric oxide on cell multiplication, adhesion and the coagulation cascade thus causing endothelial dysfunction.[17]

One cannot exclude the possibility of alternate pathways involved in the causation of vascular changes like post invasive dental therapy related pain induced stress, consumption of analgesics post treatment or disruption in salicylate or antiplatelet therapy prior treatment. All these mechanisms tend to support the phenomenon of inflammation induced vascular dysfunction. But is this acute inflammatory response strange enough to cause impairment of the fibrous cap causing plaque rupture and thus myocardial infarction? Although studies have indicated that the inflammatory response is short-lived such as not to result in Myocardial infarction. Studies supporting the hypothesis may have certain amount of bias. Patients with episodes of first Myocardial infarction 2 days after invasive dental treatment may be because the symptoms related to upcoming Myocardial infarction prevented the patient from attending dental appointments (protopathic bias). Also, patients already receiving treatments to decrease cardiovascular risk factors like consuming anti-inflammatory(mostly over the counter), antithrombotic or antihypertensive drugs may have a cardio-protective effect around and after invasive dental treatments. This may act as a source of error.[18-20]

Many therapeutic opportunities can arise from the hypothesis. The administration of immunosuppressants, anti-inflammatory, lipid lowering statins or vaccination with oxidized LDL prophylactically can pave a pathway towards decreased vascular changes and thus reduce cardiovascular risk after invasive dental treatments.[21-23]

Conclusion

There are findings both supporting as well as contradicting the hypothesis. We can infer a conclusion that invasive dental treatments results in acute inflammation and endothelial dysfunction which is transient in nature. But the long-term benefits from such treatment enhances the overall endothelial function. There is very little knowledge about systemic response concomitant with invasive dental treatments. Hence, it is still inconclusive if the acute, short-termed inflammation is potent enough to increase cardiovascular risk and thus causing Myocardial infarction. Further research needs to be conducted in support of the hypothesis. The administration of prophylactic drugs could then be introduced in order to decrease mortality due to fatal cardiovascular diseases like Myocardial infarction.

Lymphagioma of the Tongue: A Case Report

Smita R. Priyadarshini[1], Pradyumna Ku Sahoo[2], Swagatika Panda[3], Sivakumar R.[4]

[1]Associate Professor, Department of Oral Medicine & Radiology, [2]Associate Professor, Department of Prosthodontics, [3]Professor, Department of Oral Pathology & Microbiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University) Bhubaneswar, Odisha, [4]Associate Professor, Department of Oral Pathology & Microbiology Govt. Dental College, Trivandrum, Kerala, India

Abstract

Lymphangiomas are congenital benign focal malformations of the lymphatic system diagnosed after birth & early childhood & predominantly seen in the head and neck region. These are uncommon when oral cavity, subcutaneous tissues and skin in involved. They are associated with a number of syndromes and is one of the causes of macroglossia. Usually the anterior one third and dorsal aspect of tongue is involved & is the common site when there is an intra oral involvement. Treatment consists of sclerotherapy and local excision of the lesion. Here we report a case of a 12-year-old male patient.

Keywords: *Lymphangioma, Benign malformations, Lymphatics.*

Introduction

Lymphangioma is an atypical, benign, congenital disorder of unspecified etiology with the genesis from lymphatic system.[1] This was first reported by Virchow in 1854. It's a tumor like deformation of an embryonic origin occurring in individuals less than twenty years. It is the defect of vascular system instead of a real tumor. It develops as a consequence of sequestrations of elementary embryonic lymphatic as a result of failure of anastomoses with the larger lymphatic channels, thus present as areas of lymphatic blockade. Syndromes associated with lymphangioma are Trisomy, Turners Syndrome, Noonan's syndrome etc.[2]

Case Report: A 12 years old male patient reported to the Oral Medicine & Radiology Department with chief complaint swelling in anterior region of the tongue in the last 9 years. According to the past history there was a slight increase in size of the tongue which causes difficulty in having food. But there was no difficulty while talking and it was not associated with any other symptom like pain or burning sensation. He was average built with moderate nourishment & vital signs within normal limits.

Extra oral examination revealed no abnormality. Intraoral examination revealed tissue tags in the upper and lower labial mucosa with healthy gingival findings. The patients had a Class 1 molar relation with ellis class I fracture wrt 11& decayed 46. Local Examination of the tongue revealed a swelling in the left dorsal surface which was slightly more pink in colour than the surrounding mucosa, measuring about 4x2 cms in size, extending from the tip to post 1/3rd of oral part & left lateral border to 1cm crossing the midline. It was oval in shape with a rough pebbly surface with red nodular - projections. The posterior part was covered with yellow psedomembrane and the surrounding mucosa being normal. On palpation shape and size reduced to 2x3 cms (Figure 1). It was non tender, soft, spongy, compressible and doesn't cross the midline. Rest of the tongue was apparently normal. On the basis of history and clinical features a provisional diagnosis of lymphangioma. MRI of tongue was advised as an investigatory procedure and an excisional biopsy under general anesthesia was planned (Figure-2). On histopathological examination it was confirmed to be a lymphangioma of cavernous origin (Figure 3). There was no evidence of recurrence of the lesion on follow-up of 3 years.

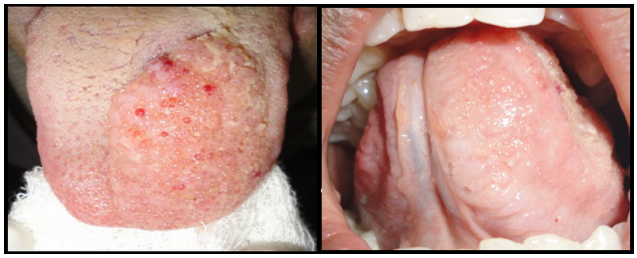

Figure 1. Swelling of dorsal surface of tongue & non involvement of the ventral surfaces

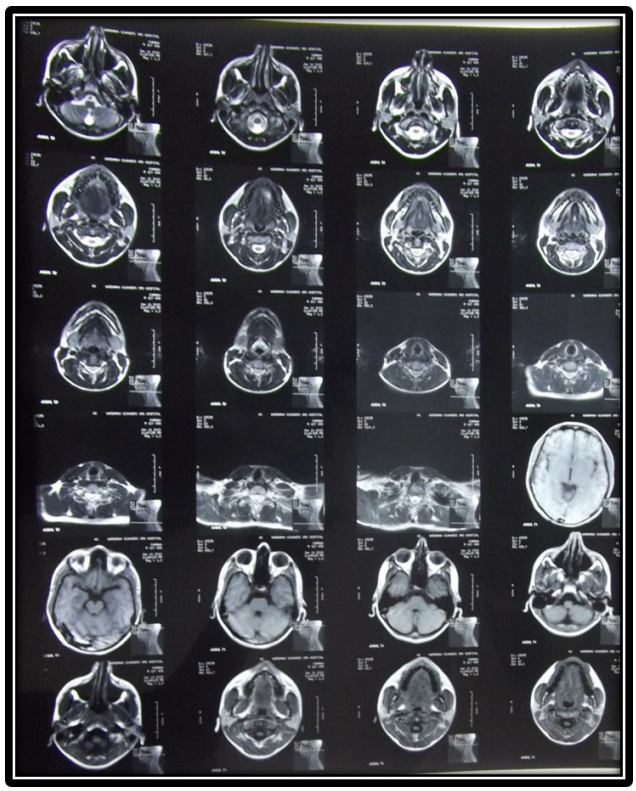

Figure 2: MRI shows Increased signal intensity (24 X 13X 14 mm) in the left lateral border of the tongue & anteriorly near the tip

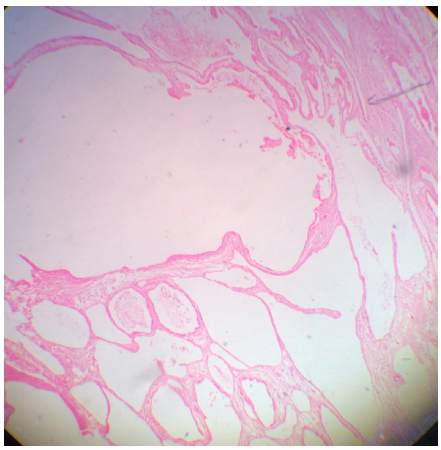

Figure 3: The H & E x 40 reveals cavernous hemangioma

Discussion

Lymphangioma is the unusual functioning of the lymphatics caused due to somatic mutations and obstruction of the drainage of the lymph.

It can be classified into four types depending upon the histological features.

1. Capillary Angioma consists of lymphatics that is small, thin walled & endothelium lined .
2. Cavernous angioma consists of comprised of dilated lymphatic vessels with surrounding adventitia
3. Cystic angioma or hygroma which presents with large lymphatic spaces surrounded by fibrovascular tissues and smooth muscles.
4. Benign lymphangioendothelioma also known as acquired progressive lymphangiona where the lymphatic channels appear to dissect through collagen bundle.[3]

Cavernous variant is rare when compared to cystic hygroma which is the most common variant of lymphangiomas in the head and neck region.

Lingual involvement on the dorsal surface and the tip of tongue is one of the rare locations. Lymphangioma clinically represents as multiple blister like nodular mass with a pebbly rough surface that is present in the dorsal surface of the tongue which appear as translucent vesicles leading to macroglossia in infancy leading to dysphagia, halitosis, airway obstruction and cosmetic deformities when big. Differential diagnosis for lymphangiomas are vascular malformations, hemangiomas, teratomas, neurofibroma, lingual thyroid, dermoid cyst, thyroglossal duct cyst etc. depending upon the involvement of the tongue.[4]

Histologically the lymphatic malformations can be macrocytic or microcystic depending upon the size larger than or less than 2 cms.

Treatment primarily is done to repair and restore breathing and swallowing of food. It is also done to establish normal speech, taste alterations, swallowing and to achieve esthetic corrections. It includes micro surgeries and use of sclerotherapy and in either case spontaneous regression cannot be attained. Non-surgical treatment primarily includes cryotherapy, diathermy, sclerosing agents like sodium morruate, Picibanil (OK-432), boiling water, saline hypertonic, ethanol etc. Intra lesional sclerosing agents are widely used although

there is no consensus regarding which is more effecting and the type of agent to be used.

Amongst the newer treatment modalities Bleomycin is used which is an anti-cancer agent but has various antiseptic, antiangiolytic & antineoplastic properties. It also has sclerosing properties and acts on the endothelial cells producing inflammatory effect & is injected intralesionally along with local anesthesia. Due to the proximity of the vessels and functional importance surgical procedures or excision is difficult and conservative procedures are preferred.[5,6]

Conclusion

Cavernous lymphangioma of tongue are rare and conventional treatment is preferred when compared to surgeries. Early recognition prevents functional deformities. Sclerosing agents and bleomycin are preferred and conservative mode of treatment for lymphangiomas.

Blood Biomarkers for Oral Cancer

Sharmistha Mohanty[1], Dharmashree Satyarup[2], Ramesh Nagarajappa[3], Radha Prasanna Dalai[4], Ipshita Mahapatra[1]

[1]Post-Graduate Trainee, [2]Professor, [3]Professor & Head, [4]Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

In the current scenario, even if there is much advances in treatment modalities, the survival of patients with cancer has not improved significantly owning to late detection and failures. The purpose of this article is to explore the role of blood biomarkers such as Antioxidants, Trace elements, proteins, antibodies etc to detect oral squamous cell carcinoma (OSCC) and premalignant lesions (PML). Key biological molecules or markers that can be linked to cancer development, risk assessment, screening, repetition probability, indicating prognosis, indicating invasion and monitoring therapeutic responses of cancer which are identified with Molecular biology and oncology research studies on oral cancer biomarkers.

Keywords: *Blood Biomarkers, oral cancer, oral squamous cell carcinoma, premalignant lesions.*

Introduction

Oral cancer is one of the major causes of morbidity and mortality all over the world which may vary according to different geographical locations and population. In order to improve diagnostic method, there is advancement in molecular biology and cancer research. Oral cancer is the sixth most common malignancy worldwide. Most of the cancers of the oral cavity are oral squamous cell carcinoma (OSCC).[1] Lesions which are clinically seen helps in easy detection of the cancer, but deep located tumours are not recognised until they have increased in size and reached an advanced stage. Floor of the mouth is second most common location. Oral cancer has various stages of invasion according to which one can determine the prognosis as well as treatment modalities using markers. Oral cancers have a greater rate of metastasis and recurrence which decreases the survival rate in comparison to other cancers.[2]

Indicators for health and physiology-related assessments, such as pathogenic processes, environmental exposure, disease diagnosis and prognosis or pharmacologic responses to a therapeutic intervention can be served by quantifiable biological parameters such as Biomarkers. They can be categorized into genomic, proteomic, or metabolomic. The Serum biomarkers investigation helps finding therapeutic targets and prognosis in different kind of tumours. As shown in literature the increase in levels of some proteins, p53 antibody and VEGF in blood act as an indicator of oral cancer. The biomarkers differ according to race, lifestyle, and carcinogen exposure. It is crucial to keep the knowledge of all the types of biomarkers which would lead to the improvement of diagnostic and prognosis method of tumour recurrence and metastasis in order to assess changes in oral lesions.[2]

Serum biomarkers: Serum biomarkers are defined as substances changing quantitatively in the serum during tumour development. Classically, the tumour synthesizes the marker and release into circulation or expressed at the cell surface in large quantity by malignant cells.[2] Generally, tumour forms a marker and release that into circulation or malignant cells help in expressing them at the cell surface. The malignant tumour formation changes the marker's levels in blood, so they can be used to check metastasis and recurrence.

Types of Biomarkers:

A Imaging biomarkers (CT, PET, MRI):

A1 Molecular biomarkers: These are non-imaging biomarkers with biophysical properties, in order to know their levels in body fluids(e.g., plasma, serum, cerebrospinal fluid) which includes nucleic acids-based biomarkers such as gene mutations or polymorphisms and quantitative gene expression analysis, peptides, proteins, lipids metabolites, and other molecules.[3]

B Tumour marker/substance: These are of two types which are tumour specific and tumour associated. Tumour specific substance are from direct result of oncogenesis, while tumour associated substances are proteins, enzymes, hormones and immunoglobulins found in the blood and are directed by the tumour or by the influence of the involved tissues.[4]

C Disease related and Drug related Biomarkers:

C1 Disease **related Biomarkers:** Disease-related biomarkers shows effect of treatment on patients if disease present already which can be called as diagnostic biomarker, the other one is in which a disease is initiated in an individual despite of the type of treatment is called as prognostic biomarker.[5]

C2 Drugs related Biomarkers specify if a drug will be effective in a specific patient and how the patient's body will link with it.[5]

Advantages of using Biomarkers: In case of chronic diseases, the patients will be consuming medicines for a long period, in that case a proper diagnosis is required, specially where complications are expected. These Biomarkers act as protagonists as they can confirm difficult diagnose.[6] Diseases like Alzheimer's or rheumatoid arthritis, start without any symptom in the beginning. In previous cases the initial stage may or may not progress into symptoms. In these cases, biomarkers identify the high-risk individuals accurately and at different stages so that the treatment can be before onset of the disease or after that.[6]

It is better to obtain the sample material in easiest possible way in order to use the biomarker. This can be a simple blood sample taken through Intra Venous method, a urine or saliva sample, or a drop of blood from the fingertips. The results may not differ from each other for unlike laboratories and the biomarker must have proven its effectiveness for the diagnosis, prognosis, and risk assessment of the affected diseases in independent studies without any intervention. A biomarker for clinical use needs good sensitivity e.g. ≥0.9, and good specificity e.g. ≥0.9[7]. The population should always be kept in mind while choosing the biomarker for the precision of positive predictive value and negative predictive value.

Disadvantages of Biomarkers[8]

(1) Level of Accuracy: Transporting the specimen to laboratory and collection of equipment's can cause a problem in the calculation of biomarker level. Biomarkers measurement can be disturbed by improper storage and change in environment of samples which includes timing so that reliability; validity can be established. Storage determines the longevity of samples. Homogeneity of risk or disease gets difficult to understand if diseases are studied in normal range. Responsibility of Ethical committee and training the handlers of specimens is essential.

(2) Affordability: According to the financial resources and objective the biomarkers should be chosen but mostly important in a small clinical trial. But in case of an epidemiologic study the population increases along with the cost. This excludes the laboratory procedure which is comparatively simple. Even if the sample size is high and if the biomarker is readily available and its inclusion in the study is feasible then the cost decreases.

(3) Acceptability: Human tissues or body fluids origin biomarkers are better for selection, can be a good choice. There is certain degree of risk but it is of less concern in clinical trials as it is done to know the new treatment modalities for the patients.

Blood biomarkers which are most commonly used now a days for detection of premalignant lesions are:

Trace elements[9]:

Copper: Enzymatic actions in the body including cytochrome-c oxidase, superoxide dismutase, metallothene and lysyl oxidase are carried out by copper. In vitro, there is increase proliferation of fibroblasts due to raised copper concentrations. Higher copper levels were observed in patients with pre-malignant and malignant oral lesions. Areca nut shows a high copper content (302 nmol/g), the substantial amount of which is released into saliva 1 after 15-30 minutes of chewing areca nut.[10]

Iron: Iron deficiency for long period leads to increase risk of mucosal exposure to irritants. The reasons could be multifactorial in OSMF patients in Iron deficiency. In collagen formation there is hydroxylation of proline and lysine where Iron is used, also altered epithelial cell turnover rate or depletion of nutrients due to pronounced difficulty in mastication.[9]

Zinc: Zinc (Zn) is an important part of bio-membranes because it is used in managing membrane stability and lipid per oxidation-related injury. Zinc deficiency also contributes to cancer initiation by activation of NF-kB expression and the consequent induction of tumorigenic signaling.[11]

Selenium: It is responsible for immune modulation and cells growth inhibitory properties that effects immune response by making immune cells more resistant to oxidative stress. Selenium is considered as a protective agent and its dietary intake is of great benefit against cancer according to the various epidemiological studies.[9]

Cadmium: In Oral cancer and Oral leucoplakia the cadmium values were decreased. Cadmium accumulates in the body hence cadmium burden increases with age. OSMF patients with low iron status there is increased internal absorption of Cadmium. Cadmium may be one of the causes for malignant transformation of OSMF and its estimation may be a helpful tool in differential diagnosis of premalignant and malignant lesions of the oral mucosa.[9]

Antioxidants[12]: The Carcinogenesis process is highly promoted by Reactive Oxygen species (ROS) whose generation initiates lipid peroxidation (LPO) Antioxidants especially enzymatic antioxidant like Superoxide Dismutase (SOD), beta carotene and Vitamin A, Vitamin E, Vitamin C and Vitamin E play an important role in this process Malignancies results by reaction of hydrogen peroxide with Reactive Oxygen species to form hydroxyl radicals that causes destruction of RNA, DNA and protein resulting in the malignancy. Thus, it can prove an efficient marker of early diagnosis of malignant transformation.[12] Epidemiologic studies have established the role of diets rich in vegetables and fruits in oral carcinogenesis, with important contribution of vitamins and iron in maintenance of oral mucosa.

Superoxide Dismutase[13]: Betel quid generates free radicals in the oral cavity. There is initiation of lipid peroxidation while enzymatic antioxidant superoxide dismutase detoxifies the effect of these harmfulradicals (hydrogen peroxide and hydroxyl). In order to prevent oxidative stress these radicals transfer their unpaired electron to oxygen to form superoxide. Plants and animals are rich in Beta carotene and Vitamin A Beta carotene (red-orange coloured pigment). It is the inactive precursor of Vitamin A. Helper T lymphocytes level rises after ingestion of Beta carotene. It plays an important rolein OSMF and its level decreases with disease progression. An irreversibly oxidised form of Vitamin A is Retinoicacid which is the principal hormone-like growth factor for maintenance of epithelial and other cells So it act as as a great radical trap forhydroxyl and peroxyl radicals, therefore it should be maintained in adequate levels in the blood due to its immune regulatory properties.

Vitamin C (Ascorbic acid)[14]: Vitamin C has several roles such as an antioxidant scavenging free radical, reduces vitamin E degradation, inhibits nitrosamine formation, enhances detoxification via cytochrome P450 andiron absorption by reducing dietary iron from ferric form to the ferrous form. The conversion of proline into hydroxyproline is done by Vitamin C. This hydroxylation reaction requires ferrous iron and Vitamin C. The deficiency of vitamins and iron will result in abnormal repair of the lamina propria. This will result in defective healing and scar formation, which ultimately led to OSMF.[14]

Vitamin E[15]: Vitamin E is the fat-soluble antioxidant that has both tocopherols and tocotrienols. Reactive oxygen radicals (ROS) formed after the oxidation of fat are inhibited by the Vitamin E molecules. Antioxidant parameters and found decreased Vit E level in stage II and III but not instage I OSMF patients.

Immunoglobins[16]: Body protection and recognising the foreign antigen are done by the active immune response in OSMF. IgG were observed increasing among the OSMF patients by which is one of the earliest-recorded in India. IgG and IgA has been noted in OSMF patients increasing in recent studies. A progressive reduction of PTEN (Phosphatase and tensin homolog) expression which is a tumour suppressor gene was seen in OSMF and OSCC. Hence, PTEN alteration is considered as a specific molecular event in carcinogens. Initial genetic events during the malignant transformation of the disease give rise to unpredictable Genomic stages. In case of OSMF cytochrome P450 is considered as the genetic biomarker. There are genetic polymorphisms in

some specific regions of the Cytochrome P450 3A genes which is related to a genetic history, these people could be examined for OSMF as shown by some studies. It is suggested that high risk of OSMF among men if they use arecanutor smokeless tobacco in abundance are due to the polymorphins.

Literature has been showed over expression in serum of some proteins, p53 antibody (9), andVEGF as an indicator of oral cancer.[2]

Proteins

CRP-C-Reactive Protein (CRP) synthesize pro-inflammatory cytokines which is a functional counterpart to immunoglobulin G.

P53 antibody[17] p53 is a phosphoprotein that helps in cellular arrest cellular arrest and apoptosis, and in response to cellular stress helps avoid mitosis of cells with damaged DNA. Early stages of OSCC is preceeded by alteration of its expression alteration, event that precedes the continuous tumoural growth, has been related to loss of proapoptotic function.

VEGF[18, 19] Vascular endothelial growth factor is a cytokine with multiple roles has a crucial role in blood formation. Increased values of VEGF are found to be increasing with disease progression and decreases after treatment. In OSCC patients there is increase in serum VEGF accompanied with lymph node metastasis.

Public health significance[8]

The course of exposure and disease can be described by:

- Establishment of dosage regimen and response
- Early signs of disease
- Relation between exposure and disease
- Misconception about relation between exposure and disease.
- Effect of disease on various variable condition
- Increased disease assessment in individual and group.

Conclusion

Biomarker's origin should begin prior or parallel to any epidemiological studies or reports. Pilot studies are to be completed in order to form the laboratory component, and to determine accuracy, reliability, interpretability, and feasibility. Age and gender like variables should follow normal distributions and this need to be taken care by the investigator. The investigator needs to calculate the extent of intraindividual variation, tissue localization, and persistence of the biomarker Biomarkers play a critical role in improving the drug development process as well as in the larger biomedical research enterprise. For better understanding of normal physiology and for increasing our knowledge of treatments for all diseases it is crucial to know the link between quantifiable biological processes and their consequences.[20]

Oral Submucous Fibrosis: A Warning Towards Oral Cancer

Diksha Mohapatra

Undergraduate Student, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Oral submucous fibrosis is a chronic, insidious and highly potent precancerous condition of the oral cavity and sometimes affecting the pharynx.[2] It is characterized by generalized inflammation and fibrosis of the submucosal tissues (lamina propria and deeper connective tissues).[1] Oral Submucous fibrosis is a debilitating condition of the oral cavity with multifactorial etiology out of which areca nut chewing being the most common cause. There are various methodologies for management of this precancerous condition involving habit cessation, conservative treatment such as nutritional therapy and medical therapy, surgical interventions and oral physiotherapies, but, none of them has been able to provide permanent relief from the signs and symptoms. This review aims to focus various etiological factors behind the disease and treatment modalities available for treating this disease, mainly focusing upon the non-surgical approaches.

Keywords: *Oral submucous fibrosis; precancerous condition; etiological factors; treatment modalities; non-surgical approaches.*

Introduction

Oral submucous fibrosis is a chronic, insidious and highly potent precancerous condition of the oral cavity and sometimes affecting the pharynx. It is characterized by generalized inflammation and fibrosis of the submucosal tissues (lamina propria and deeper connective tissues). It is universally known as a disease of the Asian continent or to be more precise a disease prevalent in the Indian subcontinent. This condition was even prevalent in the ancient era, in the days of Sushruta (600BC), a great practitioner of medicine in his times, who mentioned this condition as 'Vidhari'.

Epidemiology: Oral submucous fibrosis has a prevalence rate of 0 to 1.2% in India, Myanmar and South Africa. In India,0.2 – 0.5% of the population show symptoms of Oral Submucous Fibrosis out of which 5% affected are females and 2% affected are male. Incidences of Oral Submucous Fibrosis is higher in southern parts of India as compared to other regions. Even incidences of Oral Cancerare also highest in southern states of India as compared to other states. About 7-13% chances of malignant transformation are estimated in patients showing signs and symptoms of Oral Submucous Fibrosis.

Etiology: Oral submucous fibrosis has a strong association with bettle nut chewing or quid chewing, although in rare cases non beetle nut chewing habits have also been seen. Excessive chilly consumption in diet, tobacco consumption whether as smoked tobacco such as biddi, chillum, cigarettes or hookahsor smokeless tobacco and lime are seen causing this pre-cancerous condition. Occurrence of oral submucous fibrosis has a dose dependent relationship with areca nut which denotes the unhusked whole fruit of areca palm tree. India being the largest producer of beetle nuts in the world followed by China and Myanmar, has higher reports of Oral Submucous Fibrosis as compared to other countries. Areca nut which is predominant in arecholine as well as tannins, catechins and high copper content stimulates fibroblastic concentration and collagen synthesis, mostly in bilateral buccal mucosa as well as labial mucosa, lingual mucosa and palatal mucosa.[4]

Areca nut is consumed either in 'Paan', which is the most common and ancient practice of smokeless tobacco

consumption in India or as commercially available products such as mawa, khaini, guthka and pan masala. Origin of paan dates back to more than 2000 years and has a strong association with Hindu cultural heritage and religious believes.[6] It has a symbol of auspiciousness and is even offered to the deities in temples and in marriages. It helps in digestion, freshens the mouth, induces euphoria and also has anti-helminthic properties, but, the betel nuts in paan has an adverse effect on the oral mucosa.[7] Continuous consumption of betel nut causes irritation in buccal mucosa. Arecholine in areca nut stimulates the fibroblasts metalproteinase, increasing collagen production and decreasing collagen breakdown thus leading to increased fibrosis of the mucosa. Tannins and Catechins increase cross-linkage and stabilization of collagen fibers and decreased degradation of collagenases thus increasing fibrosis. Increase in level of copper content in saliva, stimulates fibroblastic growth, increasing fibrosis in buccal mucosa.

Signs and Symptoms

Buccal Mucosa: This precancerous condition presents itself with decreased inter-incisal distanceas there is progressive reduction in mouth opening due to formation of fibrous bands in buccal mucosa. Inter-incisal distance is calculated as the distance between the incisal surface of maxillary central incisors and incisal surface of mandibular central incisors. In a normal healthy individual the inter – incisal distance is approximately 45mm or four finger distance. But in an Oral Submucous Fibrosis affected individual the inter – incisal distance gets restricted to two finger distance or even less. Blanching of the oral mucosa is the most common and the earliest findings of oral submucous fibrosis.[3] Blanching is caused due to impairment in blood supply to the buccal mucosa. Due to decreased vascularity the mucosa appears opaque or white in colour thus giving it a marble like appearance. Blanching may take place locally or may be diffused depending upon the area exposed to the causative agents. On palpation leathery consistency of mucosa is felt with presence of circular or elliptical fibrous bands around Rimaoris. Buccal mucosa becomes rough, blanched and inelastic with leathery consistency in later stages which becomes difficult to evert them.

Tongue: Tongue becomes smooth due to loss of papilla. Gradually tongue protrusion gets limited within vermillion border of lip due to fibroblastic concentration in lingual mucosa. Burning sensation of the oral mucosa is a common symptom in the initial stages, aggravated by intake of spicy food, followed by either hypersalivation, i.e. increased saliva production or dryness of the oral cavity. Affected individual faces difficulty in speech, mastication and swallowing due to fibrosis of oral mucosa. Patient complains of trismus and aphagia as a result of fibrous band formation due to increased collagen synthesis and decreased collagen degradation in oral mucosa.

Hard Palate and Soft Palate: Clear delineation of the hard palate from the soft palate is seen due to fibrotic changes in the soft palate. Uvula becomes shrunken giving it a hockey stick appearance which indicates clear involvement of fibrotic changes in the soft palate region. The fibrotic bands radiate from pterygomandibular raphe to the anterior faucial pillars in the soft palate. Soft palate plays an important role in swallowing of food as well as in speech. Due to increased fibrosis of the soft palate, patient with Oral Submucous Fibrosis faces difficulty in swallowing.

Gingiva and Floor of Mouth: When gingiva and floor of the mouth is involved, it becomes fibrotic, inelastic and blanched.

Other Findings: As a rare finding hearing disturbances can be seen in certain individuals due to fibrosis around the Eustachian tube. In advanced stages pharyngeal involvement is also seen if the condition is left untreated. Sometimes vesicle formation, ulceration, petechiae and pigmentation is also seen in advanced stages of Oral Submucous Fibrosis.[5]

Treatment and Management: Oral Submucous Fibrosis is one of the warning signs by nature before occurrence of some carcinomas of the oral cavity. If oral submucous fibrosis is detected early and instructions from the physician is properly followed by the patient then risk of any further malignant condition can be avoided. Oral Submucous Fibrosis can be managed both conservatively as well as surgically. Its management is mostly dependent on the severity of the condition. Cases which are detected early can be managed by conservative approach and medical therapies. But advance cases require mostly surgical intervention with post-op care, long-term postoperative physiotherapy and follow ups to the surgeon.

Habit Cessation: Conservative management mostly involves patient awareness regarding life threatening effects of various habits like smoking, tobacco chewing

or betel nut chewing, motivating patients to discontinue habits involving areca nut chewing, tobacco consumption involving both smoked and smokeless form and providing nutritional support to the patients. Individuals should be made aware about the consequences of this disease through various awareness programs conducted governmentally and non-governmentally. Patients reporting with Oral Submucous Fibrosis should be explained about the outcomes of the disease as well as potent malignant transformation. Many a times improvement like increased inter-incisal distance and relief from burning sensation are seen in patients who discontinue the habit.

Nutrition and Antioxidants: Early stages of Oral Submucous Fibrosis can be treated by medical therapies like consuming diet rich in vitamins and antioxidants, local and systemic administration of steroids, placental extracts, hyaluronidase, use of gamma-interferon, chymotrypsin, collagenase and administration of vasodilators. Antioxidant rich diet intake have in a larger number shown increased inter-incisal distance, decreased fibrosis of oral mucosa and decreased trismus. Some of the antioxidant rich products that are commercially available in India are turmeric,[11] carrot, tomato, spinach,aloevera, kidney beans, barley guava, oranges, mangoes and papaya. Similarly, local administration of steroids in the affected sites or systemic administration of steroids have shown increased vascularity of the area with improvements in clinical features in early stages of the disease.[8]

Human Placental Extract: Placental extract which is rich in enzymes like alkaline and acid phosphatase, glutamic acid and pyruvic acid, nucleotides like ribonucleic acid and adenosine triphosphate, vitamins and fatty acids can also be used for treatment of this precancerous condition. Placenta can be extracted in four forms, i.e. aqueous, extract, lipid extract, immune gamma globulin and tissue coagulated. But only 'Placentix' which is the aqueous extract of the placenta acts as a biogenic stimulator, enhancing regenerative processes, wound healing and anti- inflammatory effects.[9]

Other Medical Therapies: Hyaluronic acid plays an important role in collagen formation. Hyaluronidase acts on hyaluronic acid by reducing cell formation which in turn prevents burning sensation of oral mucosa and improves health of oral mucosa. Gamma interferon is a recently discovered therapy that reduces burning sensation of oral mucosa and increases mouth opening.

Similarly, injecting the sites with vasodilators increases blood flow to the affected region which in turn helps nutrients as well as therapeutic agents to reach the affected areas. Due to increased vascularity there is reduction in blanching to some extent in the affected regions of buccal mucosa, lingual mucosa and labial mucosa.

Surgical Approach: In advanced stages where remarkable changes cannot be achieved by only nutritional therapy or medical therapy any biopsy of the affected region suggests neoplastic changes surgical intervention is used to increase the inter-incisal distance, decrease trismus and avoid asphagia. Excision of the fibrous bands is the main aim in case of surgical management. Fibrous bands that are excised are replaced with grafts which are usually tongue flaps, nasolabial flaps, skin grafts, buccal fat pads, collagen membranes, palatal flaps or free flaps (radial forearm flaps).[10] Proper Oral physiotherapy is a must after surgical excision to avoid post-operative fibrosis and relapse of the condition. Even in early stages oral exercises like ballooning of mouth and forceful mouth opening have been seen to be effective in increasing mouth opening in case of trismus due to increased fibrosis of buccal mucosa. Hot diathermy or Microwave diathermy has been found to be effective in treatment of fibrosis and trismus, and hence can be suggested to patients reporting with oral submucous fibrosis.

Cryosurgery and lasers to some extent have also been applied in treatment of Oral Submucous Fibrosis. In case of cryosurgery the affected tissues are destroyed locally by freezing them in situ. Extremely lower temperature is produced by using chemical agents like liquid nitrogen and liquid argon to destroy the tissues in affected area. The agent is exposed to the affected area by means of an instrument known as cryoprobe. Lasers such as carbon dioxide lasers have also been found to be effective in removing the fibroses tissues as compared to traditional surgical techniques.

Conclusion

Oral Submucous fibrosis is a debilitating condition of the oral cavity with multifactorial etiology out of which areca nut chewing being the most common cause. All the ways available for the management of this disease provide only short-term relief from the symptoms as the exact etiology for the disease has not been understood and this condition is also progressive

in nature. The course and management of the disease is to a larger extent dependent on the severity of the condition and clinical staging. Most the patients report during moderate to advanced staging, when the signs and symptoms associated with the disease becomes irreversible. But if the disease can be caught during the early stage, then, habit cessation can itself limit the progression of the disease. This is possible only if the masses are aware of this premalignant condition, which has a potent malignant transformation if left untreated.

Management of Cyclosporin – A Induced Gingival Overgrowth through External and Internal Bevel Gingivectomy

Gatha Mohanty[1], Rinkee Mohanty[2], Anurag Satpathy[3], Rashmita Nayak[3]

[1]Senior Lecturer, [2]Professor & Head, [3]Professor, Department of Periodontics and OralImplantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Chronic usage of anti-hypertensive, immunosuppressants could result in unwanted effect such as gingival overgrowth. The severity and expression of this tissue specific condition could be also be influenced microbial plaque. Increase in volume of gingiva compromises the esthetics, speech and acts as a hindrance for maintenance of optimal oral hygiene. The management of such cases needs a combination of non surgical and surgical approach. This case report highlights the successful management of drug induced gingival overgrowth by a combined non-surgical and surgical approach. It also focuses on the role of supportive periodontal therapy during 1 year follow-up.

Keywords: *Cyclosporin A, gingival overgrowth, gingivectomy, immunosuppresant.*

Introduction

Common drugs associated with gingival enlargement or gingival overgrowth (GO) are anticonvulsants, calcium channel blockers and immunosuppressants[1]. The expression of this GO could be influenced by variety of factors its prevalence varies from drug to drug. A prevalence of cyclosporine A induced GO of 39. 4%[2], 6-15% for nifedipine and 50% for phenytoin has been reported among adults[3].

The interdental papilla is the most common site for the initiation of GO and involves mostly the facial surfaces of anterior teeth. Although the etiopathogenesis of GO is still unclear, it is of the assumption that certain gingival fibroblasts cells are susceptible to cyclosporine A and its metabolites the interaction of which is enhanced if accompanied by plaque induced gingival inflammation[4, 5]. Also, since the plaque control becomes difficult due to increased gingival volume, there is a vicious cycle of enlargement and inflammation leading to a compromised esthetics and discomfort[6, 7].

Different treatment options are considered that include non-surgical, surgical or a combination of both. While non-surgical approach reduces the inflammatory component in gingival tissue, the surgical approach aims to eliminate the fibrotic component that exists after nonsurgical therapy. We present a case highlighting the successful management of drug induced gingival overgrowth by non-surgical and surgical approach. It also focuses on the role of supportive periodontal therapy during 1 year follow-up.

Case report: A 29 year old male patient reported to the department with complaint of bleeding gums and enlarged gingiva which was causing him a discomfort and an esthetic concern. He was apparently alright six months back when he started noticing swelling and bleeding of gums from anterior teeth region. He revealed that he had undergone a renal transplant two years back and was taking cyclosporine for the same along with other medications. He had no other systemic illness. His family history was not significant.

On examination, the colour of gingiva in the lower and upper anterior teeth region was red and erythematous. Consistency was soft and oedematous. The size of gingiva was increased particularly on the facial aspect. There was also a nodular enlargement of interdental papillae. There was bleeding from gingiva

on slight provocation (Figure1). There was presence of pockets without any attachment loss (pseudo-pockets) in the maxillary arch and presence of combined pockets in the mandibular arch. A clinically significant GO score of 30. 5% was calculated present case[8]. An IOPA X-ray revealed a marginal horizontal alveolar bone loss which in the lower incisors. (Figure 2). Based on the clinical presentation and drug history a diagnosis of Cyclosporin A-induced gingival overgrowth was arrived at. The drug induced gingival overgrowth (DIGO) was associated with localised class II grade B periodontitis with lower anterior.

Since his consulting nephrologist suggested to continue the present immunosuppressant the drug could not be altered. The non-surgical periodontal therapy included full-mouth scaling and root planing with polishing. Detailed oral hygiene instructions were given. An antibiotic regimen of Amoxicillin and Clavulanic acid 1 g orallytwice daily was prescribed for 8 days as suggested by the patient's nephrologist to cover the infectious risk associated with his systemic health status. Re-evaluation after 4 weeks revealed marked reduction in the gingival inflammation with minimal bleeding on probing. However, the patient expressed his esthetic concern owing to the residual gingival enlargement.

A surgical correction of the GO was thus planned for achieving esthetic gingival contour. The surgical planning included external bevel gingivectomy for the maxillary arch and internal bevel gingivectomy for the lower arch. A detailed blood investigation was carried out which revealed normal parameters. After administration of local anaesthesia in the maxillary anterior region, pockets were marked using Krane Kaplan pocket marker. An external bevel gingivectomy incision was then placed using a #15 bard Parker blade (Figure 3). Periodontal curettes were used to completely remove the excised gingiva. Periodontal pack was placed. Pack was removed after one week.

For the mandibular arch, after administration of local anaesthesia, an internal bevel incision was placed (Figure 4) and a mucoperiosteal flap was raised to access the root surfaces. The excess gingival tissue was removed with periodontal curettes after giving sulcular incisions. A thorough debridement was done and flaps were closed using continuous suturing technique (Figure 5). Periodontal pack was placed. Post-operative instructions were given. Suitable analgesics and antimicrobials were prescribed. Sutures were removed after one week.

Healing was found to be satisfactory for both arches. The patient was kept under recall for 12 months for monitoringthe oral hygiene efficiency and to note any signs of recurrence. The self-cleansable contours of the gingiva aided in maintenance ofperiodontal health and achieving satisfactory plaque control. The patient was followed up for 1 year during which good oralhygiene and no recurrence of enlargement was noted. The patientwould no longer cover his mouth and displayed an improved confidence while talking or smiling (Figure 6).

Discussion

Gingival overgrowth is a mild enlargement involving an isolated interdental papilla to marked enlargement affecting either one or both the jaws with diverse etiopathogenesis[9]. Initially it appears as a localized nodular enlargement of the interdental papilla (horizontal growth) and progresses further towards the crown (vertical growth). Some severe cases have shown that gingival tissue may cover the clinical crown to a large extent[10]. The non-surgical periodontal therapy results in a significant reduction in the overall inflammation component of the GO with reduction in the circulating levels of inflammatory markers[11]. However, in most cases fibrotic component does not resolve completely after initial periodontal therapy. Since this does not meet the functional and esthetic demands of the patient, a surgical correction is deemed necessary. Microbial dental plaque is a strong co-factor in the etiology of Cyclosporin A-induced gingival overgrowth[12]. Risk factors that could possibly modify the prevalence and severity of Cyclosporin A-induced gingival overgrowth including age, genetic predisposition, gender, drug variables (serum concentration, drug dosage, salivary concentration) and periodontal variables such as plaque accumulation and pre-existing gingival inflammation[11, 13]. Patient education, motivation and compliance during and after dental treatment are most important factors for a long-term maintenance. Reinforcement of oral hygiene is of importance as there is tendency to revert to their original behaviour[14].

Conclusion

Gingival overgrowth is a well-documented unwanted effect associated with the systemic use of unavoidable immunosuppressive drugs such as Cyclosporin A. Patients with gingival overgrowth face challenges in oral hygiene maintenance. For apredictable outcome of treatment, motivation for oral hygiene should be started at the initial stages of treatment[15]. At least one year follow up for the patient to evaluate the tissues and for oral hygiene maintenance should be ensured.

The Role of Proanthocyanidins in Treatment of Periodontal Disease

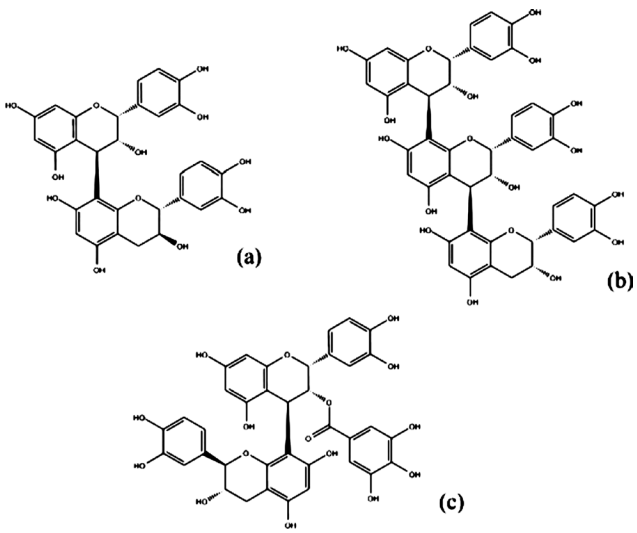
Mohit Das[1], Abhaya Chandra Das[2], Saurav Panda[2] , Rinkee Mohanty[3]

[1]Post Graduate Student, [2]Reader, [3]Professor and Head, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Periodontitis is a chronic inflammatory condition caused due to multiple factors which results in destruction of connective tissue and alveolar bone that support the teeth. Bacterial plaque is one of the main factors that accelerate the process of destruction. Therefore, controlling the destructive effects of this factor by including agents that could reduce or inhibit the ongoing damage is important. Proanthocyanidins (PA) have various properties including antioxidant, antimicrobial, anti-inflammatory, anticarcinogenic thus possessing the ability to enhance gingival health and thus preventing further destruction. There are many studies that have proved these properties both through in vitro and in vivo categories. Thus, this review makes an attempt to discuss the impact of PA's on the pathogenesis of periodontitis and also to show whether PA's could be developed as a therapeutic agent for periodontitis.

Keywords: *Periodontitis, Proanthocyanidins.*



Introduction

Periodontitis is a deep-rooted inflammatory disease which is multifactorial in nature. Its occurrence depends on the local and systemic or environmental factors as well as the host immune response which if are imbalanced results in destruction of periodontium eventually leading to the loss of tooth. Intraoral dysbiosis is the major contributor in the progression of periodontitis, thus restoring the subset of species that are compatible with periodontal health is important for disease resolution. Around 15-20 species of microorganisms are discovered till now which are associated with periodontal disease. Microorganisms like *A. actinomycetemcomitans, P. gingivalis, T. forsythia* are the most virulent and have been found in increasing amounts in periodontally compromised individuals. Imbalance in the ecosystem of microorganisms in the gingival sulcus along with the host's response induced by dysbiosis causes tissue destruction. Hand and ultrasonic instrumentation are the conventional method for reducing the microbial load. The use of antimicrobial therapy like chlorhexidine and betadine solution as an adjunctive treatment to NSPT.[(1)] The use of antimicrobials might lead to development of bacterial resistance thus polyphenols, which are natural products mainly produced by higher plants as secondary metabolites with different functions have become the focus of clinical interest. Tsao and Hussain have classified polyphenols into five main groups: hydrolysable tannins, phenolic acids, polyphenolic amides, flavonoids, and other, with their corresponding subgroups based on chemical composition.[(2, 3)]Proanthocyanidins(PAs) fall under the category of flavonoids.

Proanthocyanidins: Proanthocyanidins are a group of phytochemicals that have been in use since lately since they are easily found in the extracts of certain plants, fruits, seeds, leaves of many plants thus making them easily accessible. PA are the most exuberant flavonoids in the plant kingdom. The richest sources of PA are the grape seed extract (GSE), cranberry extract, cocoa, berries and pine bark (pycnogenol) which consists of potent antioxidant, anti-inflammatory, anticarcinogenic and antimicrobialproperty.[(4)] PAs also inhibit lipid peroxidation, platelet aggregation, capillary permeability and capillary fragility.

Biochemistry of PA

These are high-molecular weight oligomers. Proanthocyanidin are a combination of dimers, trimers, tetramers, oligomers, and polymers. The exceptional feature about proanthocyanidins is its astringency thus possess the ability to coagulate proteins. Most common proanthocyanidins found have been represented in the figure a) procyanidin dimer b) procyanidin trimer c) procyanidin dimer gallate

Mechanisms of Action

Antioxidant Property: ROS or the reactive oxygen species include oxygen radicals like superoxide, hydroxyl, peroxyl, and alkoxyl and non-radicals like HOCl, ozone, peroxynitrite, singlet oxygen, and hydrogen peroxide. PAs reduce the oxidative stress which are created by reactive oxygen species like singlet oxygen, oxygen radicals etc because of their potent antioxidant activity thus they have the ability to terminate the activity of free radicals. Animal studies demonstrate its inhibitory activity on lipid peroxidation and DNA fragmentation. Enzymes that degrade collagen are inhibited by the cyanidins and proanthocyanidins. These effects are perhaps attributable to trapping reactive oxygen species and preventing oxidative injury to vascular endothelium. In vitrostudies found that PAs increase resistance of cell membranes to injury and degradation. PAs also increase the production of nitric oxide which causes relaxation of endothelium and even helps in release of various growth factors that help in initiating wound healing. These properties of proanthocyanidins would definitely help secure the diseased periodontium to its normal healthy state. A study demonstrated the effect of proanthocyanidins on the inhibition of generation of ROS and also reduction of production of lysosomal enzymes.[5] Proanthocyanidins predominantly produces radicals that form oligomeric compounds which effectively reduces the production of oxygen species thus decreasing the oxidative stress.

Anti-Inflammatory Property: Proanthocyanidins exhibit the property of suppressing the extracellular and intracellular collagenases. They also reduce the hyaluronidase activity thus they main the propriety of the extracellular matrix. Prostaglandins and leukotrienes are one of the major contributors of inflammation which are produced by the metabolism of arachidonic acid, an essential amino acid. They are produced from the cyclooxygenase or lipoxygenase pathways respectively. Even the neutrophils containing lipoxygenase create certain chemotactic substance such as cytokines that mediate inflammation. Some of the phenolic compounds including cyanidins and PAs are known to reduce the cyclooxygenase and lipoxygenase activities but the mechanism by which they do so is not exactly stated. Another antiinflammatory feature is the ability of flavonoids to inhibit eicosanoid biosynthesis.[6] Eicosanoid, such as prostaglandins are the end products of the cyclooxygenase and lipoxygenase pathways.[7] PAs also have the ability the decrease the neutrophil degradation, thus prevent the release of mediators of inflammation from the neutrophils as well as other immune cells.

Antimutagenic / Anticarcinogenic Property: Proanthocyanidins possess anti-cancer and anti-proliferative properties which has been proved in various studies both in animal and in humans through clinical trials. Thus it is important to know the molecular mechanism involved in cell growth inhibition and modulation of cellular metabolism. Cancer being a multistage disease is distinctly divided into initiation, promotion and progression stages.[8] Proanthocyanidins induce cell cycle arrest and also induce apoptosis contributing to antimutagenic property. Inhibition of cyclooxygenase is an important mechanism in preventing tumor promotion. Thus, anti-inflammatory drugs like indomethacin, piroxicam have been used for cancer prevention but it includes various side effects which can be excluded by usage of natural proanthocyanidins as a replacement. Since COX accelerates the conversion of arachidonic acid to proinflammatory substances such as prostaglandins, leukotrienes, which stimulate tumor cell growth. Epidermal growth factor receptor (EGFR) is a type I tyrosine kinase receptor. Activation of EGFR is a key factor in tumorigenesis. Grape antioxidants like

proanthocyanidins have been shown to inhibit expression of epidermal growth factor receptor (EGFR) in head and neck squamous cell carcinoma.[9, 10] Uchino et al in 2010 through a study stated that grape seed antioxidants like cyanidins and proanthocyanidins also inhibit NF-κB's DNA binding capacity to prevent tumorigenesis. Although there are many studies that prove the efficacy of proanthocyanidins as an anti-cancer agent, they mostly focus on their in vitro mechanisms. Since proanthocyanidins show a lot of potential in anti-cancer activity, further studies are required to enhance their use in the clinical field.

Antimicrobial Properties: Periodontal diseases include established gingivitis and on persistence, ends up in periodontitis which is a multifactorial chronic inflammatory disease. Microrganisms play a major role in the development of gingivitis to periodontitis as the accumulation of more subgingival microrganisms in the gingival crevice leads to the apical migration of the junctional epithelium leading to the formation of pathogenic pockets.[11] Studies have shown the use of local drug deliveries like atridox, actisite, arestin, elyzol, chlosite etc for controlling as well as reducing the amount of microorganisms subgingivally with no systemic side effects. However, there have been reports regarding developing resistance of microorganisms against these drugs. Therefore, the use of natural antimicrobial agents like grape seed extract, cranberry extract, pine bark extract which contains proanthocyanidins that have antimicrobial properties is to be considered thereby avoiding bacterial resistance. *Porphyromonas gingivalis, Tannerella forsythia*, and *Treponema denticola* are associated with the chronic form of periodontitis, whereas *Aggregatibacter actinomycetemcomitans* is strongly associated with the aggressive form.[12] The study concluded that "PAs inhibit *P. gingivalis* adherence to human oral epithelial cells and Matrigel-coated surfaces". They inhibit biofilm formation and decrease the collagenase activity.PAs have the potential to decrease procreation of *P. gingivalis, T. forsythia,* and *T. denticola* in periodontal pockets, as amino acids and peptides are required for their multiplication. Bodet et al. demonstrated that a "cranberry fraction rich in PAs inhibits the gingipains and dipeptidyl peptidase IV activities of P. gingivalis, the trypsin-like activity of T. forsythia, and the chymotrypsin-like activity of T. denticola."[13] Thus, proanthocyanidins have the capability of reducing periodontal destruction by inhibiting the growth of periodontopathogens and also counterbalance its cytotoxic products.

Effect on Alveolar Bone: One of the major effects or signs of periodontitis is the destruction of alveolar bone which is caused due to the excess resorption of bone. Bone remodeling involves coordination of activity of osteoblasts and osteoclasts. However, the presence of gram-negative anaerobic bacteria in more than required amounts induces a host mediated inflammatory response which leads to disruption in this coordination. Proinflammatory cytokines influences the fibroblasts, lymphocytes and the macrophages to increase the production of RANKL (Receptor Activator of Nuclear factor Kappa B Ligand) causing the production of activated monocytes (osteoclasts) affecting the normal remodeling process. RANKL is expressed by osteoblasts during the normal metabolism whereas at inflammatory sites the RANKL is also expressed by the T-lymphocytes, parathyroid hormone etc. PAs present in cranberry extract is not cytotoxic to osteoclast cells but possess the capacity to inhibit formation of bone-resorbing cells. They also reduce the production of MMP's (Matrix Mettaloproteinases) and pro-inflammatory cytokines as mentioned previously.[14] PAs even prevent boosting of preosteoclasts thus decelerating the process of osteoclastogenesis. The inclusion of PAs in the diet has also proved to revamp bone constitution, confirming its positive association with bone morphology.[15] In vitro studies have shown that PAs have found to inhibit the proteolytic enzyme which causes resorption of bone.[16] Thus, it is suggested that proanthocyanidins do have a potential role in the inhibition of bone resorption and could be potentially very effective in treating periodontal bone destruction.

Safety Concerns: Proanthocyanidins present in the grape seed extract were investigated for the safety dosage. No evidence was reported at dosages of 2g/kg and 4g/kg of body weight in rodents. The US National Center for Complimentary and Alternative Medicine (NCCAM) reported that oral administration of GSE (grape seed extract) was well tolerated for over 8 weeks in a clinical trial.

Conclusion

From the present review it can be easily concluded that proanthocyanidins are a very apt replacement for antibiotics as an adjunct to conventional periodontal therapy for the treatment of periodontal disease. Various sources of proanthocyanidins available in India are grape seed extract, pine bark extract, cranberry extract etc. which is easily accessible and very cost effective.

Thus, its use for treatment of inflammatory diseases like periodontitis clinically is to be considered. As already discussed in the previous studies, its antioxidant effect, antimicrobial effect against the periodontopathogens, anti mutagenic effect, its cytoprotective effect and also its effect on the alveolar bone destruction proves that these compounds have a lot of potential in curing several inflammatory diseases apart from periodontitis. Therefore, they need to be considered in various clinical studies to prove its efficacy on human subjects and in future use it actively in the clinical practice for better result and prognosis.

Neurogenic Switching Mechanism: Probable Link between Periodontal Disease and Systemic Diseases: A Review

Shristi Shankar[1], Rinkee Mohanty[2], Anurag Satpathy[3], Rashmita Nayak[3], Manoj Kumar[4], Gatha Mohanty[5]

[1]Post Graduate Trainee, [2]Professor & Head, [3]Professor, [4]Reader, [5]Senior Lecturer, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Prevalence of systemic diseases by virtue of dental infections, has been widely recognized and accepted by the dental professionals today. In recent times spread of inflammation via neurogenic switching mechanism has found an interest among researchers and reviewers. Neurogenic switching results from the coaction of mast cells and nerves leading to the spread of inflammation from one site of the body to a distant site. *Porphyromonas gingivalis,* a principle bacterium triggering periodontal disease releases an endotoxin, lipopolysaccharide, which has been found to induce neurogenic switching mechanism, leading to an exacerbation of symptoms of various systemic diseases. Lowering in the microbial count of dental plaque, has shown to recuperate manifestation of various neurological, cardiovascular, respiratory and pregnancy induced conditions. The purpose of this review is to explore the probable link between various systemic diseases and periodontal disease through neurogenic switching mechanism.

Keywords: *Neurogenic inflammation, Immunogenic inflammation, Neuropeptides, Substance P, Neurogenic Switching Mechanism, Periodontitis.*

Introduction

Periodontal disease is an inflammatory response to bacterial infiltration through dental plaque and calculus, leading to loss of periodontium. Its interrelationship to systemic diseases, such as Diabetes Mellitus and Hypertension have been extensively researched, reviewed and well established. Certain other systemic diseases and conditions have surfaced off late, concerning the respiratory and neurological systems, pregnancy induced conditions and allergic reactions, symptoms of which have reduced or improved after scaling and root planing, hence establishing a possible association with periodontal disease[1-4].

The process through which the interconnection has been recognized is Neurogenic Switching Mechanism (NSM). It occurs due to the crossover action of neurogenic and immunogenic response to infection, causing inflammation at a site distant from the site of stimulus. The sensory impulse is re-routed via the central nervous system from the site of activation to the second location due to the release of Substance-P (Sub-P) and other neuropeptides. The sensory fibres said to be involved are identified as C-fibres. Branches (sensory fibers) of the Cranial Nerve V (Trigeminal Nerve), supplying the periodontal tissues, might also play a pivotal role in neurogenic switching causing inflammation at other sites. This review explores and explains neurogenic switching mechanism as a probable link between periodontal disease and systemic diseases.

Neurogenic and Immunogenic Inflammation: Due to the formation of antigen-antibody complex, an inflammatory cascade is initiated leading to animmunogenic inflammation. The inflammatory response may be immediate or cell–mediated depending on prior sensitization[5]. Release of Sub-P and other inflammatory neuropeptides, when a chemical combines

with chemical irritant receptors on sensory nerves, results in neurogenic Inflammation[5]. Substance-P can degranulate mast cells and release of histamine can stimulate sensory nerves, implying the coaction between immunogenic and neurogenic inflammation[5].

Modulators of Neurogenic Inflammation:

(A) Neuropeptides: The various neuropeptides involved in neurogenic inflammation are:

(1) Substance-P

(2) Calcitonin gene related peptide

(3) Vasoactive intestinal peptide

(4) Neuropeptide Y

The various properties and location in the nervous system of the neuropeptides are summarized as an overview in Table 1.

Table 1. Overview of Neuropeptides

Neuropeptide	Source	Amino Acid Chain	Properties	Location
Substance P (SP)	Euler and Gaddum (1931)[6] Vasoactive material extracted into powder	11 amino acid peptides	Belongs to the tachykinin family Also called as Neurokinins	Peripheral nerves (enteric neurons and primary afferent neuron - capsaicin sensitive)
Calcitonin gene related peptide (CGRP)	Amara and colleagues in 1982[29] RNA process of the calcitonin gene generated mRNA encodes it	37 amino acid peptides	Strong vasodilator [Brain et al., 1985][30] Found in close proximity with SP	Central and peripheral nervous system Abundant in sensory neurons
Vasoactive intestinal peptide (VIP)	Said and Mutt, 1970[31] Isolated from pig intestinal extracts originally	28 amino acid peptides	Peptide modulating immune response [Bellinger et al 1996][32] Regulates the production of pro- and anti-inflammatory mediators [Pozo et al., 2000][33]	Central and peripheral nervous system
Neuropeptide Y (NPY)	Tatemoto 1982[34] Isolated from porcine brain	36 amino acid peptides	N- and C-terminal tyrosines derivatives Strong vasoconstrictor [Lundberg et al 1985][35]	Central and peripheral nervous system

The sensory neuropeptides are proposed to have a role in causing neurogenic switching, in addition to plasma extravasation, immune cell recruitment and dilating blood vessels thereby regulating the immune cell activity[6]. Increased neuropeptides, in an area of inflammation, results from a sprouting of peptidergic peripheral fibers. Peptidergic peripheral fibers are frequently observed to exist in close proximity to immune cells, especially macrophages[7] and mast cells[8] Also, the presence of functional neuropeptide receptors on immune cells[9, 10] indicates a role of neuropeptides in neuro-immunomodulation.

By the combined participation of N- and C-terminal, Sub-P has indirect and direct effects on histamine and smooth muscle cells respectively, leading to vasodilation. Predominant peripheral effects of tachykinins include elevated microvascular permeability, plasma protein extravasation due to formation of edema, bringing to notice their effectual pro-inflammatory properties.Sub-P is aided by NK-1 receptors, situated on post capillary venules and endothelial cells, in causing increased vascular permeability thereby causing edema[11]. NO, has shown to modulate the characteristic edema formation by Sub-P, laying basis to its interaction with other neurotransmitters[12].

Neutral endopeptidase (NEP) degrades Sub-P. The target cells of SP i.e. ones possessing its receptors, have NEP located on their surfaces. NEP levels are indirectly related to neurogenic inflammation. Neurogenic inflammation is suppressed by human recombinant. Cigarette smoke, respiratory viruses and volatile organic chemical toluene are extrinsic factors inhibiting NEP[13].

(B) Non-neuropeptides: Neurogenic inflammation is a complex process, and its initiation and sustenance depends upon the combined action of factors present neuronally and locally in the environment, which are as follows:

(1) Cytokines

(2) Nerve growth factor (NGF)

(3) Bradykinin (BK)

(4) Nitric oxide (NO)

Cytokine-neuropeptide interactions are two-way—that is, cytokines, released from immune cells. can modulate the neuronal cells and neuropeptides, released from neurons, can influence the immune response[6]. Toll-like receptors (TLRs), have associated,potent stimulation of inflammatory response to LPS through the induction of cytokine production. LPS generally activates TLR4 and there is evidence suggesting the LPS released from *P. gingivalis* can also stimulate TLR-2 [14].

NGF has been shown accountable for a surge in the levels of SP and CGRP, during chronic inflammation[15] and acts directly on B-cells, modulating release of CGRP[16]. Bradykinin (BK) are important mediators of inflammation. Besides directly activating and sensitization of nociceptors, they also are pro-inflammatory, inducing release of SP and CGRP[17]. NO, may act pre-junctionally or within peripheral neuron within the skin microvasculature causing release of neuropeptides and hence leading to neurogenic inflammation[6].

Neuropeptides in Periodontal Health and Disease: Sensory nerve fibers, which make up the great majority of periodontal innervation, originate in the trigeminal ganglion and range in size from C fibers (0.1 to 1.0 µm in diameter) to Aδ (1 to 5 µm in diameter) and Aδ fibers (6 to 10 µm in diameter)[6]. Periodontium being largely innervated by myelinated nerve fibers, during their course through the PDL, lose their myelin sheath and eventually end in multiple specialized receptors or as free non-myelinated endings.

A member of the Protease-activated receptors (PARs), has highlighted the mechanism of enzyme induced sensory nerve activation leading to release of neuropeptide. PAR-2 has an important role in chronic inflammation induced diseases[18, 19]. It may participate in nociception along with mediating neurogenic inflammation as it has been found to be expressed along with SP and CGRP on sensory nerves[20]. The basis for its active role in initiating neurogenic inflammation associated with periodontal disease stems from the fact that it is activated by tryptase, which is found locally in the environment[21]. A neutrophil enzyme, Proteinase-3, has been shown to activate PAR-2 on oral epithelial cells leading to the release of pro-inflammatory cytokine IL-8[22].

In normal human gingival tissues, perivascularly and within the confines of rete pegs, Sub-P has been localized via immunochemistry[23]. Sub-P nerve fibers extensively innervate the junctional epithelium[24] and in the confines of epithelial cells rests of Malassez. Persistence of any one of these factors - Changes in pH, temperature variations, any exposure to endotoxins or traumatic challenges in the oral cavity, may be enough stimuli to induce Neurogenic Inflammation in susceptible tissues. Levels of SP were significantly elevated in diseased sites, compared to healthy sites in periodontally compromised subjects[24]and in addition to showing appreciable correlation to indicators of host response[25].

The levels of SP in GCF noticeably reduced post periodontal treatment, suggesting their release during inflammation associated with periodontitis. SP induces the synthesis of IL-8 in monocytes in the presence of LPS, suggesting dental plaque to be an important factor in regulating the effects of SP[6].

Neurogenic Switching Mechanism via Periodontitis: Periodontitis is a chronic inflammatory disease, caused primarily by *Porphyromonas gingivalis*, a Gram-negative bacterium, containing lipopolysaccharide (LPS) in the outer membrane of its cell wall. Pro-inflammatory cytokines are released as a result of inflammation thereby activating the host immune response. Cytokines induce the release of neuropeptides (Substance-P, CGRP etc) from afferent sensory neurons. Substance P binds to mast cells through neurokinin-1 receptor, causing its activation and degranulation, resulting in the release of histamine and tryptase. This results in Immunogenic Inflammation. The histamine released binds to sensory neurons via protease activated (PAR) receptors, causing Neurogenic Inflammation.

This sends an efferent signal to Central Nervous system, leading to release of Substance P neuropeptide at a different site. Substance P binds to mast cells leading to its degranulation and release of histamine. Histamine along with Substance P have the potential to bind to mucous secreting cells, bronchial smooth muscle cells and mucous secreting cells resulting in inflammation, without local stimulation, at the second site. This is called Neurogenic Switching Mechanism.

Periodontal disease - systemic disease linked via Neurogenic Switching Mechanism: Understanding NSM and how it originates, spreads and causes inflammation at a distant site, periodontal disease can be very well linked to various systemic diseases. The presence of sensory neurons in the periodontal tissues, leading to release of neuropeptides and causing neurogenic and immunogenic inflammation clearly lays down a base for this link. Various case reports are present showing the link of asthma[26], rhinosinusitis[1], uveitis[2], migraine[27], vertigo[27]and allergic symptoms such as eczema[28] to periodontal disease. Removal of dental plaque by Scaling and root planing reduced the symptoms of the aforesaid diseases, as high levels of neuropeptides has been shown to decrease in GCF as a result of periodontal treatment[6]. The release of proinflammatory mediators as a result of scaling and root planing, due to the oozing out of blood, may result in the cutting off of NSM[2].

Conclusion

Reduction in dental plaque through scaling and root planing might relieve a patient of symptoms which otherwise could not be reduced using routine medications and treatment. Therefore, the medical and dental practitioners should keep in mind Neurogenic Switching Mechanism while treating a patient for various systemic diseases and formulate a treatment plan accordingly.

Prosthetic Rehabilitation of a Case of Odontogenic Keratocyst in Anterior Maxilla: A Six-Year Follow-Up

Gunjan Srivastava[1], Subrat Kumar Padhiary[2] Swagatika Panda[3],

[1]Professor, Department of Prosthodontics, [2]Professor, Department of Oral and Maxillofacial Surgery, [3]Reader, Department of Oral and Maxillofacial Pathology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Odontogenic Keratocyst (OKC) defined as a cystic lesion of odontogenic origin characterized by invasiveness and a high tendency for recurrence. This case report describes the treatment of patient presenting with as welling on the right side of face. Clinical and radiological examination revealed a unilocular radiolucent area in maxillary anterior region. Histopathological report confirmed the diagnosis of odontogenic keratocyst. Surgical treatment consisted of complete enucleation with curettage. Occurrence of odontogenic keratocyst in anterior maxilla is a rare clinical finding. Rehabilitation of the patient was required in order to maintain the esthetics as well as the for functional purpose. Therefore,Prosthetic Rehabilitation with fixed dental prosthesis was undertaken after a 5-year period of follow-up after surgery.

Keywords: *Odontogenic Keratocyst; Clinical & radiological examination; Histopathology; Prosthetic Rehabilitation.*

Introduction

Odontogenic keratocyst (OKC) defined as a cystic lesion of odontogenic origin, with a characteristic lining of parakeratinized stratified squamous epithelium and potential for aggressive, infiltrative behavior.[1] Odontogenic keratocysts tend to recur after treatment because of thin, friable wall which is often difficult to enucleate from the bone in one piece and/or presence of small satellite cysts within the fibrous wall. It tends to grow in the anteroposterior direction within the medullary cavity of the bone without causing obvious bone expansion. Displacement of teeth adjacent to the cyst occurs more frequently than resorption.

Posterior body of the mandible and ascending ramus related to impacted third molar are the prime location for OKC. Usually, they are associated with unerupted tooth, pain, paresthesia, purulent discharge and may resorb or displace teeth.[2,3] It shows slightly male predilection with peak incidence in patients between 10 and 40 years of age. Radiographically, OKC demonstrates a well-defined unilocular or multilocular radiolucency with smooth and often corticated margins.[4] Because of high recurrence rates, there are different treatment options for OKCs. These treatment modalities arebased upon conservative and aggressive treatment approach. Conservative treatment modalities include simple Enucleation (with or without curettage) or Marsupialization. And the Aggressive treatment modalities include Enucleation with Peripheral Ostectomy, Enucleation with Carnoy's solution application, Cryotherapy, and/or Resection.[5,6,7]

Case Report: A15-year-old male patient presented to Department of Oral Surgery with swelling on the right side of the face which persisted for the last 6 months. There was slow and gradual drifting of right anterior maxillary teeth. Upon clinical examination, extraoral swelling on right maxillary anterior region was observed which was diffuse in nature. Overlying skin was intact with elevated ala of the nose and right-side upper lip. Intraoral examination revealed swelling with obliteration of vestibule in right anterior maxillary region with deviation of regional teeth. (Figure 1a). The swelling was bony hard in nature with one or two areas

e-mail: gunjansrivastava@soa.ac.in

of fluctuation depicting resorption of labial cortical plate. Palatal expansion was also evident on the right side of hard palate which was bony hard on palpation (Figure 1b).Grade-I mobility was also seen with from teeth number 11 to 14.

With these clinical findings, a provisional diagnosis of a cystic lesion was made and planned for aspiration cytology. On aspiration with 18-gauge needle, a thick dark brownish cystic fluid with lots of cholesterol crystals was aspirated. This aspirate was sent for protein estimation. The total protein content of the cystic fluid was found to be less than 4gm/100ml which is characteristically found in cystic fluid of OKC.[8] Radiological examinationrevealed a unilocular radiolucent area with well corticated margin extending from left side central incisor to right side first molar region. Maxillary sinus was pushed upward with cystic expansion. Incisors, canineand premolars of the right maxillary region were deviated. There was no evident root resorption of any of these teeth. No supernumerary tooth or any calcified mass was seen within the radiolucency. (Figure 1c).

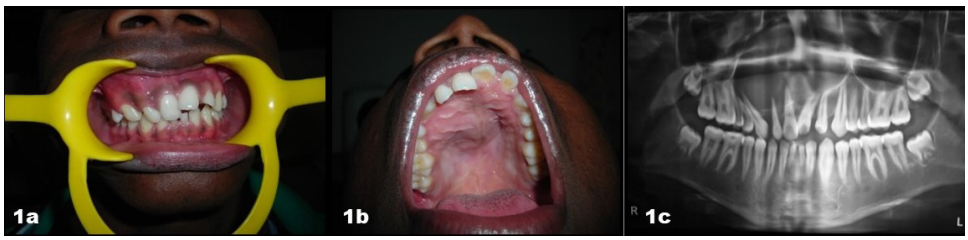

Figure 1. a) Preoperative photograph showing deviation of left central and lateral incisors; b) Preoperative photograph showing palatal enlargement; c) Preoperative orthopantomogram

A wide trapezoidal flap was designed with releasing incisions distal to left side central incisor and right side first molar. Full thickness mucoperiosteal flap was raised beyond the bony expansion on the labial aspect of right maxilla. Expanded labial cortical plate was seen with some areas of resorption. Thinned out labial cortical plate was removed and cystic lesion was enucleated from the healthy bone beneath it. Extraction of right central and lateral incisor, cuspid and first premolar was done. Sharp bony spicules were removed and primary closure of the defect was done (Figure 2a) Biopsy of the lesion was done and result of histopathological evaluation showed a parakeratotic type of Odontogenic Keratocyst. During the 5-year follow-up period, there were no signs of the recurrence of the tumor in the resected area after which the patient was advised for prosthetic rehabilitation. Edentulous span with missing 11,12,13,14 was noted with thin residual ridge with both vertical and horizontal bone loss. Due to removal of labial plate of bone along with the cyst upper lip on right side appeared collapsed. Vitality of adjacent teeth were checked and normal response was elicited (Figure 2b).

Implant supported prosthesis was ruled out because of paucity of bone on the planned site. Also, due to financial constraints, the patient did not opt for grafting. Cast removable partial denture was also suggested but patient wasn't in favor of a removable prosthesis. Therefore, treatment plan comprised of porcelain fused to metal fixed denture prosthesis using left central and lateral incisors and right second premolar and first molar as abutments. Diagnostic impressions of the maxillary and mandibular arch were made using irreversible hydrocolloid (Zelgan, Dentsply, India). Casts were poured using type -III Dental Stone (Kalrock, Kalabhai Karson, India).

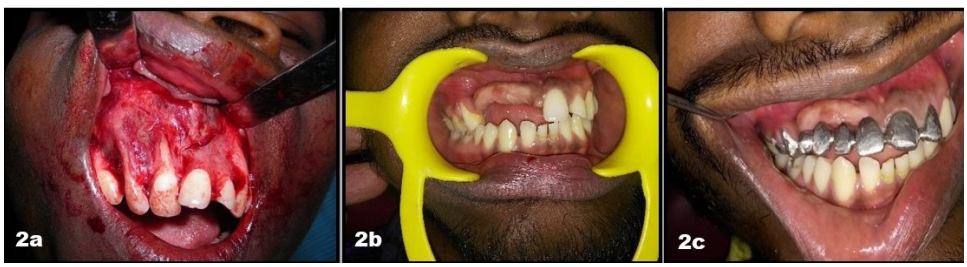

Figure 2. a) During Surgical procedure showing bluish cystic lining; b) Postoperative photograph after 5 years of surgery

A diagnostic mock-up was done for missing teeth and patient approval was obtained. Tooth preparation was done as per the diagnostic mock-up. An impression was made with polyvinyl siloxane impression material (Affinis, Coltene-Whaledent) and poured in type – IV dental stone (Ultrarock, Kalabhai Karson, India).A putty index of diagnostic wax pattern was made using polyvinyl siloxane putty material (Affinis, Coltene-Whaledent) for fabrication of provisional restoration with auto-polymersing resin (Cool Temp, Coltene). Metal copings were fabricated and its trial was doneto check for proper fit. (Figure 3) A porcelain fused to metal fixed dentureprosthesis was fabricated and cemented using type -1 Glass Ionomer Cement (GC, America). (Figure 4a, b)Patient was recalled for a follow-up after 7 days, 3 months, 6 months and 1 year. During which, an OPG revealed complete healed site with adequate bone formation. (Figure 4c)

Figure 3. Metal try in

Figure 4. a) Post-restoration photograph; b) Post-restoration photograph (palatal view); c) orthopantomogram 1 year after prosthesis fabrication

Discussion

OKCs comprise approximately 11% of all cysts of the jaw. They are usually found in mandible involving posterior body and ramus region. Although in this case the location of cyst was in the anterior maxillary region which is an unusual clinical finding. Karaca et al. in their study on 81 patients have also found that only 4 % of patient had the lesion in anterior maxilla.[5] One of the most important characteristics of odontogenic keratocystis a high rate of recurrence that ranges from 5-62%. The majority of cases of recurrence occur within the first 5 years of treatment.[9] Careful and aggressive enucleation with close follow-up has been advocated forthe OKC. Prosthetic rehabilitation in this case was planned after closely following the patient for 5 years after surgery.

Even though the restoration was of long span, the loads on the anterior teeth are comparatively less due to minimum vertical overlap (overbite) of patients existing dentition. To reduce the loads even further, a slight open bite was provided with the incisors. Modified ridge lap pontics were used to improve the appearance in anterior region. Patient was pleased with his appearance and satisfied with improved phonetics.

Conclusion

Cystic lesions of jaws can have a deleterious effect on oral form and function. Surgical treatment results in loss of bone and soft tissues which is difficult to replace with artificial prosthesis. The management becomes even more critical in anterior maxillary area due to esthetic implications. Comprehensive planning and interdisciplinary approach are key to successful rehabilitation of such patients. This case report describes the multidisciplinary management of a young male patient who presented with an unusually large odontogenic keratocyst in the anterior maxilla.

A Rare Case of Neck Pain Elongated Styloid Process

Pradyumna Kumar Sahoo[1], Smita R. Priyadarshini[2]

[1]Associate Professor, Department of Prosthodontics, [2]Assistant Professor, Department of Oral Medicine & Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Styloid process is a complex structure and ossification of this process can illicit a number of signs & symptoms aggravating the patient's condition. Elongated styloid process is also called Eagles syndrome and in majority of times are asymptomatic. But precipitation of certain procedures like tonsillectomy can make it symptomatic as in this case. Here we report a case of 26 years old female patient complaining of pain in the retropharyngeal region.

Keywords: *Styloid process; Eagles syndrome; tonsillectomy; retropharyngeal region.*

Introduction

Watt W Eagle in 1937 was first to define symptomatic elongated styloid process which was later called Eagle's syndrome.[1] It consists of unusually long styloid process, with pain on deglutition, pain on movement of neck in the jaw and throat. These symptoms can be associated with pathological condition of stylohyoid complex calcification.[2]

Anatomy and Embryology: The styloid process is attached to 3 muscles: stylopharyngeal, stylohyoid and styloglossal muscle. 2 ligaments: stylohyoid and stylomandibular ligament.[3] The Stylohyoid chain or complex consists of the styloid process, stylohyoid ligament and lesser cornu of hyoid bone. It forms a complex called the stylohyoid chain or complex which in many cases are found to be calcified that could be symptomatic.[4] The Stylohyoid complex arises from the Reichert's cartilage of 2nd brachial arch. Tympanohyal forms the base of styloid process. Stylohyal forms the shaft of styloid process. Ceratohyal forms the stylohyoid ligament and Hypohyal forms the lesser cornu of hyoid bone (Figure 1).[5,6]

e-mail: smitapriyadarshini@soa.ac.in

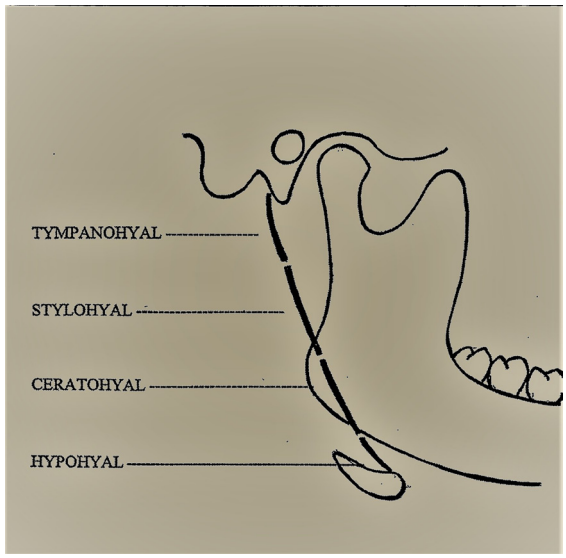

Figure 1. Panoromic radiograph with elongated styloid

Incidence: The styloid process when it is greater than 3 cm is considered elongated. It is seen in approximately 4% of the population amongst them in only 4% of the cases it was found to be symptomatic.[7] Male : Female ratio is 1 : 1 to 1 : 3 which is commonly seen in the middle age group approximately 30-40 yrs. There could be unilateral elongation as well as bilateral elongation of the styloid. [8]

Case Report: A 32 years old female patient reported to the oral medicine department with a complaint of pain the right back tooth region in the last 1 month. Patient give a history of pain that had aggravated

post tonsillectomy. Pain was dull aching type which aggravated while movement of head and while chewing and deglutition. On examination patient had dental caries with respect to 36 & 26 with mild stains and calculus & partially erupted 48. On palpation tenderness was present in the retropharyngeal region which aggravated on deglutition. Provisional diagnosis of Impacted 48, chronic generalized gingivitis and dental caries was given. Patient was advised for a panoramic radiograph & lateral skull that revealed elongation in the styloid process. Diagnosis of elongated styloid process was done in co-relating to the history of tonsillectomy and the panoramic radiograph (Figure 2, 3).

Figure 2. Panoromic radiograph with elongated styloid

Figure 3. Lateral skull radiograph

Figure 2. Lateral skull radiogr Elongated styloid process is usually asymptomatic but pain is elictated amongst the population post tonsillectomy, contracture of scar tissue stimulate 5th, 7th, 9th, and 10th cranial nerves, sensation of raw throat, refer otalgia, especially when swallowing, odynophagia or dysphagia, persistent dull-aching sore throat, pain when extending tongue or changing voice, sensation of hypersalivation.[9] The Stylocarotid syndrome is a variation where impingement of carotid artery occurs with or without tonsillectomy which stimulates perivascular sympathetic fibers causing external compression of carotid artery . It causes facial pain from brow to chin, constant neck pain, tinnitus when turning head, compression of internal carotid artery, headache from ophthalmic region to occipital region[10,11]

Pathogenesis: Styloid process can be elongated when there is congenital alteration causing a part or complete ossification of stylohyoid ligament post-traumatic reactive hyperplasia & could be associated with early onset of menopause. Even degenerative processes of ligament or osteocartilaginous element with secondary calcification could lead to elongation of the styloid process.[12] Most of the times they remain asymptomatic but could become symptomatic after Trauma causing fracture of ossified stylohyoid ligament leading to proliferation of tissue, direct nerve compression, degenerative and inflammatory changes, insertion of tendon, post-tonsillectomy fibrosis, impinging onto carotid artery and rheumatic styloiditis result from pharyngeal infection.[13] Diagnosis is primarily based on the symptoms and palpation of the tonsillar bed that could aggravate the symptoms.

Differential diagnosis

- Unerupted or impacted molar is commonly seen in teenagers or early twenties
- Glossopharyngeal or trigeminal neuralgia where there is momentary piercing or lancinating pain
- Carotidynia causes hyper pulsation and vessel dilation
- Irritation from dental prosthesis could cause prolonged pain
- Oropharyngeal or hypopharyngeal tumor
- Chronic pharyngitis and tonsillitis

Treatment: Management for Immediate relief of symptom is done by infiltrating 1 ml of 2% lidocaine, styloidectomy or non-steroidal anti-inflammatory drugs is given.[14]

Herbal Agents for Dentinal Hypersensitivity: A Review

Akshyata Panda[1], Anurag Satpathy[2], Rinkee Mohanty[3], Rashmita Nayak[2], Saurav Panda[4]

[1]Post Graduate Trainee, [2]Professor, [3]Professor & Head, [4]Reader, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Dentinal hypersensitivity is an age-old complaint of man and a common condition of transient tooth pain related with variety of exogenous stimuli. Several herbs have been found to be suitable in the treatment of periodontal diseases as they have been reported to have no side effects. Herbal products containing spinach, cloves, cinnamon, suryakshara, eucalyptusand propolis have been used for treating dentin sensitivity. Therefore, the significance of these products in therapeutic as well as pharmaceutical technique urged us to exploreherbal agents for dentinal hypersensitivity and to get clues for future scope.

Keywords: *Dentinal Hypersentivity, Desensitizing, Herbal, Sensitivity.*

Introduction

Dentinal hypersensitivity is one of the most common dental complaints in day today life. It is a perception felt when the nerve inside the dentin is visible to the environment often described as a short sharp pain that arises from the exposed dentin in response to thermal, tactile, osmotic, chemical, or evaporative stimuli that cannot be attributed to any other form ofdental defect or pathology[1]. DH affects daily activities such as eating, drinking, speaking etc. and it is clinically challenging for the oral health practitioners to effectively manage it.

Prevalence: Prevalence of the dentinal hypersensitivity depends on people, nutrition, para-functional habits and method of examination[2]. It is approximately 5-85%[3] in patient having non-carious cervical lesions (NCCLs) 2-8% to 74% in adult populations[4]. The most commonly affected age group is around 20-50 years but the most affected age range is 30-40 years[5]. According to sex females are more affected[6]. There are two common method to determine the intensity of DH. One of them is through an interview and the other is through clinical examination. Furthermore, the incidence of DH in canines and premolars is more than other teeth. The buccal surface of mandibular incisor has been stated to be more involved [7-9]. As per dentist there is 10-25% of dentinal hypersensitivity prevalence distribution among their patients and 1% of them are serious category [9].

Indian Scenario: The prevalence of DH inIndia fluctuates from place to place on the basis of the local oral practices. Few studies in Punjab, Chandigarh, Andhra Pradesh etc., specified that the occurrence of dentinal hypersensitivity to be 25%, 47.8%and, 32%, respectively[10].

Dentinal hypersensitivity synonyms: DH is also known as Dentin Hypersensitivity or Dentin Sensitivity, Dentinal Hypersensitivity or Dentinal Sensitivity, Cervical Hypersensitivity or Cervical Sensitivity, Root Hypersensitivity or Root Sensitivity, Cemental Hypersensitivity or Cemental Sensitivity[5].

Etiology: Dentinal tubules are exposed, open with extending to vital pulp loss of enamel causes attrition tooth brush abrasion dietary erosion parafunctional habit combination of these factors expose of root surface due to loss of cementum and periodontal tissue gingival recession chronic periodontal disease following non-surgical periodontal therapy. Incorrect tooth brushing chronic trauma from habits[11].

Prof. Anurag Satpathy
Professor, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University, Bhubaneswar, Odisha, India
e-mail: drasatpathy@gmail.com

Diagnosis: Through Medical history[5] and clinical examination.

Differential diagnosis: Conditions that may mimic DH could be fracture of restorations or prosthesis, cracked tooth, dentalcaries or sensitivity after a tooth restoration[2, 12, 13].

Assessment: Assessment can be of tactile, thermal, osmotic, electric and evaporative[14]

Prevention: Prevention has mostly been through the use of desensitizingtoothpastes, avoiding junk food, use of soft bristledtoothbrushes, proper brushing technique. For those with para-functional habits such as clenching and bruxism, useof mouth-guard.

Pain pathway: Dental pain is dichotomous in nature, sometimes it is localized, sharp, pricking pain of rapid onset due to A-Delta sensory nerve fibres otherwise it is a generalized,dull aching sensation which persists even after the removal of the etiological factor. This pain sensation is carried by C-sensory nerve fibres. It is an established fact that the conduction of impulses is swifter in myelinated fibres than unmyelinated fibres. The A-Delta,interdental beta and Cfibres transmit the mechanical, thermal and the chemical stimulus from nociceptor to the spinal cord and hence play the role1storder neuron. The A-Deltafibres are located mainly in the pulpo-dental-dentinal and they are myelinated with low threshold to excitation. These features make it the 1st nerve fibres to propagate and conduct the pain impulses. They are principally activated during hydrodynamic stimulus causes outward fluid movement leading to hypersensitivity fibres are located deeper into the pulp and is sensitivity to thermal changes. It is slower in conduction velocity and is unmyelinated. Hence, they don't play a significant role in dentinal hypersensitivity[15].

Pain propagation theories in dentinal hypersensitivity: Manyhypotheses have been proposed to expound the pathway of dentinal hypersensitivity. Initial theories stated that dentin was directly innervated by nerves due to which they get activated by the external agents. This theory was ruled out as the electron microscopy unveiled that the nerves innervated mostly the pulpal horns and terminate shortly after entering the inner dentin. The odontoblastic transduction theory hypothesized by Rapp et al stated that odontoblastic processes function as receptor cell which propagate the impulses via the synapses located in the neurons to this terminal ending involving pain at the pulpo-dentinal junction[15, 16]. This theory was criticised and proved to be unconvincing as the odontoblasts are mesenchymal cells of neural crest origin which only play a vital role in the formation of the dentinal matrix and no synapses are seen in the pulpodentinaljunction. The hydrodynamic theory is the most convincing theory till now. It was proposed by Brannstrom that the hypersensitivity dentin experienced nociceptor excitation in pulpodental junction due to the flow of dentinal fluid was caused by physical, chemical, thermal or any other stimulus. This theory highlighted the role of dentinal fluid in the pain due to dentinal hypersensitivity[16]. This gave a new direction to the dentinal hypersensitivity pain pathway. It leads to experiments and research comparing various clinical parameters in sensitive and normal dentin such as increase in the number, radius and the density of the tubules.

Management: Change over from faulty tooth brushing and use of hard bristle tooth brush with excessive pressure to a prescribed method such as Modified Bass Technique, Softer bristles and gentle brushing. Dentifrices with more abrasive content should be avoided. Consuming acid drinks or foods at least one hour after tooth brushing should be avoided due to agonist effect of acidic erosion on tooth brush abrasion. Use of an occlusal splints may be considered for correction of occlusion[5]. Root coverage procedure should be advised in case of recession. Exogenous and endogenous acids exogenous acids include carbonated drinks, citrus fruits, alcoholic drinks, yogurt, dairy products, and occupational hazard endogenous acids include enter the mouth through reflux or gastro-esophageal regurgitation[5] thus must be restricted or avoided. Periodontal disease may cause root exposure due to poor oral hygiene.

Herbal Desensitizing Agents

Suryakshara-kshara: Suryakshara is alkaline in nature. Itis produced as aslag of variousplants, animals and minerals[17]. Main content of suryakshara is potassium nitrate which helps in reducing dentinal hypersensitivity blocking nerve depolarisation[18]. The potassium nitrate causes an increase in the concentration of extracellular potassiumaround the nerve fibres leading to their depolarization[19]. It also avoidsrepolarization of the nerve and blocks the axonic action and passage ofnerve stimulus, thus inactivating the action potential[20].

Palakya (Spinicia oleracea): Palakya or the spinach is one of the most consumed green leafy vegetable in India, possess the capacity to block the dentinal tubules due to the presence of oxalate compound, which helps in producing phyto-complexes on the teeth[18]. The oxalate compounds form a protective film on the tooth surfaces which prevents loss of tooth structure. Palakya leaves on reacting with calcium of dentin form calcium oxalate crystals [21]. These may be deposited inside the dentinal tubules and cause occlusion of orifices[22].

Lavanga (Syzygiumaromaticum): Cloves consist of eugenol (anesthetic agent) which aids in numbness of nerve and controlling pain. The clove also contains an essential oil which act as an antiseptic and eradicate the bacteria from oral cavity[23, 24]. It has commonly been used in house-holds as an obtundent for relief from toothache[25].

Triphala: It is containing of fruits of the plant species Emblica officinalis (Amalaki), Terminalia bellerica (Bibhitaki), and Terminalia chebula (Haritaki). Triphala is therefore a mixture of their dried powders in equal parts. Amla (*Emblica officinalis*) containsvitamin C and can be used either alone or in like combination with other plants to treat the common cold and fever. It also has anti-inflammatory properties. Haritaki or Harada (*Terminalia chebula)* is widely used to treat a variety of health issues including constipation, dementia and diabetes. Ittoo hasanti-inflammatory properties.

Cinnamon (Cinnamomumzeylanicum): The cinnamon has antibacterial activity against the gram positive and gram negative bacteria. Cinnamon oil contains cinnamaldehyde[24, 26] which is an antioxidant. It might have desensitizing effect but the mechanism of action is not clear.

Cineole: 1, 8-Cineole a. k. a11-eucalyptol isan achiral aromatic compound found in plants such as Salvia (*Salvia officinalis*) and Eucalyptus (*Eucalyptus globulus*) leaves. It inhibits the formation of prostaglandins and proinflammatory cytokines which might explain its desensitizing property[27].

Propolis: It is a natural, non-hazardous, resinous substance, which is yellow-brown in colour. It has a complex composition which depends on the accessible plant sources to the bees. Phenolic acids, flavonoids, terpenes, β steroids, aromatic aldehydes, alcohols, sesquiterpenes, naphthalene, stilbene derivatives of benzopyran, benzophenone, caffeic acid, cinnamic acid derivatives, and benzoic acid are the components of propolis. It acts as a sealant[14, 28, 29]. The organic structures are resin 50-60%, wax-30-40%, essential oils-5-10% with calcium and aluminium[14]. Propolis showsproperties such as anti-inflammatory, antioxidant, antimicrobial, antiviral, antiparasitic, anaesthetic, and that of a free-radical scavenger. Varnish and gel are the two available forms of propolis for the treatment of dentinal hypersensitivity. The propolis gel occludes the dentin tubules which decreases the permeability and thereby relieves dentin hypersensitivity[14].

Peppermint (Mentha piperita): It acts as an essential oil. The chemical components of peppermint oil contains menthyl acetate and menthofuran, which helps in blocking the dentinal tubules[24].

Conclusions and Future Directions

There are various treatment options which the clinician may choose for relievingdentinal hypersensitivity depending upon the severity of the condition. As use of herbal products have been associated with no adverse effects and many studies have reported their effect in the management of dentinal hypersensitivity, future research should be carried out to analyse and scrutinize desensitizing property in natural herbs.

Oral Manifestation of HIV Virus

Swastik Mishra[1], Abhishek Ranjan Pati[2]

[1]Intern, Institute of Dental Sciences, [2]Reader, Department of Oral Medicine & Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

HIV is an infection that can lead to AIDS. HIV stands for Human Immunodeficiency Virus. It's a virus that breaks down certain cells in your immune system (your body's defense against diseases that helps you stay healthy). Oral lesions are common in HIV infection. There are over 30 different kinds of oral lesions related with HIV. It is essential to implicit that the oral lesions seen in HIV positive patients are a consequence of immunodeficiency triggered by the Human Immuno-deficiency Virus and not related to the direct influence of the virus on oral tissues. Dental diseases like caries and periodontal disease have greater influence on patients with HIV infection. So, it is crucial that the physician and dentist, together, detect and diminish risk factors for oral diseases associated with HIV infection.

Keywords: *Human Immunodeficiency Virus, Acquired Immune Deficiency Syndrome, Herpes Simplex.*

Introduction

Acquired immune deficiency syndrome was first seen in June 5, 1981 with around five cases in USA. Early cases were a set of injecting drug workers and queer menbut there was no sign ofdebilitated immunity that had signs & symptoms of Pneumocystis carinii pneumonia (PCP), a rare opportunistic infection that used to happen in people with compromised immunity. After that, a sudden amount of gay and queer men developed aprioruncommon skin cancer called as Kaposi's sarcoma (KS). Numerous more cases of Pneumocystis carinii pneumoniaand Kaposi's sarcomaarose later. Specialist had never seen this type of pneumonia and it progressed into chronic condition. In 1981, scientists and specialists had begun to link the dots between the new diagnosis diseases and an amount of further opportunistic infections. That year, the first case of HIV's full-scale disease state, (AIDS), was documented. HIV is a very dangerous and serious disorder of the immune system which damages the body's normal immunity and defenses to infections. So, it makesour body vulnerable to infections /conditions with malignancies that can become dangerous and can cause even death. It is seen that 20 to 50 percentages of patients with HIV will grow some oral lesions related with diseases. These lesions are key markers in disease advancement, and they can be main manifestation in a previously undiagnosed patient.[1] The oral lesions associated with AIDS can be categorized as-Infections (bacterial, viral and fungal), Neoplasm, Diseases of salivary glands, Miscellaneous lesions. Alsoincluding the side effects related to treatment of HIV with Highly Active Anti-Retroviral Therapy (HAART). So due to many of this oral manifestation dentist play an important role in recognizing early signs and symptoms of oral lesions related with human immune deficiency syndrome.

Oral Lesions: Candiadsis, Herpes simplex, Cytomegalovirus, Oral hairy leukoplakia, Kaposi sarcoma, Non- Hodgkin's lymphoma, Necrotizing gingivitis/periodontitis.

Candidiasis: Oral candiasis initiated by Candida albicans is a very and one of the most common lesions, affecting about 90 percentage of patients with HIV+ at some point of time as the progression of disease occurs. These lesions occur when Cluster of differentiation 4 cells counts fall less than 200/mm^3. It was viewed that forty to seventy percent of HIV- infected patients with Cluster of differentiation 4 counts less than 200/mL. Sixty-five

Corresponding Author:

Reader, Department of Oral Medicine & Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: patiabhishek@gmail.com

percentages of patients with Cluster of differentiation 4 count less than 200/mL and the presence of candiasislater developed AIDS or they even died within twenty-fourmonths period of time.[1,2] According to Ranganathan and Hemelatha, and Ranganathan et al, pseudomembranous candidiasis is the most common type seen in these patients. Also presence of angular cheilitis as a recurrent fungal infection was noted.[3,4] But in accordance with Noce et al, Erythematous type of candidias was most regularly seen and noted.[5] Cell mediated immunity plays a part in the pathogenesis of candidiasis in these patients. Erythematous type of Candidiasisalong with pseudomembranous type of oral candidiasis are related with an increase in risk for the subsequent progress of opportunistic infections, thuscategorizing the patient as having Acquired Immune Deficiency Syndrome as defined by the Centre for Disease Control (CDC).

Herpes Simplex: Primary herpes infection along with recurrent intraoral and perioral herpes simplex are common viral infection, with a incidence of five to ten percentages. [6] The clinical significance and features of oral herpes viral infection are mainlyassociated to those seen in HIV (NEGATIVE) patients; but in HIV + patients with severe immunosuppression (where Cluster of differentiation 4 cell counts are less than 100 cells/mm3) extensive, dangerous, and extended lesions develop which resembles the Herpetic Gingivostomatitis. Recurrences of these lesions are tooseen. Drug of choice is usually acyclovir (800 to 1200 mg/dl). [7]

Cytomegalovirus (CMV): Oral CMV lesions may happen in patients where there is progression HIV disease. Usually these lesions are signs of underlying systemic disease related to GI tract or eye. In CMV infection the oral lesions can arise wherever on the buccal mucosa along with other parts of oral mucosa. Usually there is no specific pattern or appearances of Cytomegalovirus ulcers. Presence of white halo around the necrotic surface is common seen. Frequently they are tangled with major apthous ulcers or ulcers present inNUG, necrotizing ulcerative stomatitis and also in many lymphomas. (Eversole 1992) Ganciclovir when administered intravenously along with aciclovir in high doses are usually the drugs of choice.[8]

Oral Hairy Leukoplakia: Hairy leukoplakia of oral mucosa is initiated by Epstein-Barr virus in immuno-supressive patients. Oral hairy leukoplakia occurs in 20 percentages of peoplehaving asymptomatic HIV disease and becomes more frequent as the Cluster of differentiation 4 +T-cell count decreases. Occurrence of Oral hairy leukoplakia is a sign of HIV diseaseand also for immunodeficiency. However, in patients with HIV negative, oral hairy leukoplakiahas been cited, who hadundergone bone transplant, kidney and heart transplant. Hairy leukoplakia is an indication for evaluation and treatment of AIDS disease. HL associates with an arithmetical risk for the progression of AIDS disease very rapidly. Oral hairy leukoplakia is asymptomatic and usually requires no treatment. Antifungal treatment may treat the signs and symptoms of superimposed candidiasis but will not completely resolve the lesions. If the subject assert on removal of the lesion for whatsoever reasons, treatment for Oral hairy leucoplakia is acyclovir (high dose), antiretroviral drug (zidovudine), surgical excision [9]

Kaposi Sarcoma: Kaposi sarcoma (KS) is the single most frequent neoplasms happening in subjects with HIV+[10] but after the initiation and administration of HAART there has been a noteworthy reduction in its occurrence.[11] It happens in around fifteen to twenty percentages of the patients with HIV+Kaposi Sarcoma is caused by HHV-8 Virus. Decrease Cluster of differentiation 4 counts, homosexuality and Cytomegolovirusinfection are well-known to increase the chances of KS. Kaposi sarcoma is well known to occur among gays. In HIV it may extant as the 1st sign and symptom of AIDS. The histopathological features are flat, nodular or ulcerated mass depending on the stage of the growth of the tumour and diagnosis. Multifocal Lesions along with involvement of skin usually seen in connotation with oral Kaposi sarcoma. Kaposi Sarcoma is more common in males rather than females and children. Palate, Gingiva and tongue are the main sites where Kaposi sarcoma occurs. Three clinical stages can be illustrious: patch, plaque, nodular. Sometimesa yellowish mucosa surrounding the Kaposi sarcoma is seen histopathologically. Oral Kaposi Sarcoma lesions may increase can become ulcerated and sometimes may become infected. So, good and healthy oral hygiene is the key factor to reduce these problems. The early lesions of Kaposi Sarcoma are asymptomatic, flat and red or purple in color. As the disease progresses the advanced lesions usually exhibit nodular appearance, may become painful and can destroy the underlying bones. treatment of choice is surgical excision, radiation therapy (in case of large lesions)

Non-Hodgkin"s Lymphoma: Non-Hodgkin's

lymphoma (NHL) is the 2nd most happening intraoral neoplasm seen in patients having HIV +. Patients with AIDS are at 60 to 70 time's higher risk of developing Non-Hodgkin's lymphoma than HIV negative patients. Contrasting Kaposi Sarcoma, the incidence of Non-Hodgkin's lymphoma has not condensed with the initiation of HAART therapy, and it is predictable the frequency can in fact surge as patients' lives longer.[1,12] It can occur inany place in the oral cavity. It is more frequently seen in males rather than females. Clinical features include a presence of soft tissue swelling (painless) with or without presence of ulcerations. Hard and Soft Palate and gingiva are frequent locations where the lesion can be seen. Lesions are usually single and extremely painful. The prognosis of the disease is poor and people usually die within first year after the disease is diagnosed in their body. Treatment depends on the stage of the progression of the disease: Radiation therapy (during early stage of the disease); Systemic Chemotherapy (for extra nodal disease).

Necrotizing Ulcerative Gingivitis/Periodontitis: Necrotizing ulcerative periodontitis (NUP) is a disease affecting gums and surrounding regions and is one of the deadliest periodontal disease affecting patients with AIDS, and it occurs in immunosuppressive patients. Occurrence of Necrotizing ulcerative periodontitis is five percent or less than seven percentages. It is a fusospirochetal infection which is usually related with severe nutritional and/or immunodeficiency. Clinical significance of necrotizing ulcerative periodontitis include destruction of 1 or more interdental papillae with necrosis and presence of ulceration with sloughing which is limited to the marginal gingival tissues. The gingival tissues are burning red in color and are swollen, and are complemented by yellowish-grey necrotic tissue that can bleed easily. Bad breath is commonly seen. Regional lymph nodes may increase in size and can be enlarged and fever and sicknessare also seen. Cratered appearance of the ulcers is seen when healing takes place. Treatment comprises of ultrasonic scaling or hand scaling (for plaque and calculus removal), mechanical debridement of dead and necrotic tissue, irrigation with betadine solutions on the wounds and administration of antibiotics (metronidazole 250 mg qid, Augmentin 250 mg qid).

Conclusion

AIDS is a debilitating disease, with a plethora of oral manifestations like-oral candidiasis, herpes simplex infection, Kaposi sarcoma, Non-Hodgkin's lymphoma, necrotizing ulcerative gingivitis, oral hairy leukoplakia etc. All these oral conditions depend on CD4/CD8 ratio which can vary according to the anti-retroviral therapy given to the patients. An oral diagnostician should take into consideration the oral manifestation of HIV and must strive to give palliative treatment, psychological counseling and one should make the patient aware of these conditions in the mouth so that patient can maintain good oral hygiene with regular follow ups which can later reduce the signs and symptoms of the disease.

Abstract

Background: Surface electromyography (EMG) has been found to be an effective tool to evaluate Masticatory muscle activity in order to diagnose dysfunction of masticatory apparatus.

Aim: The current study aims to indicate the practical difference between temporomandibular joint (TMJ) disorder and muscles of the jaw on symptomatic and asymptomatic subjects by comprehensive electromyography analysis.

Method: To evaluate the significance of EMG parameters, jaw-muscles EMGs were recorded in 10 normal (Group N) subjects and 10 TMD symptomatic (group S).

Result: In TMD symptomatic (Group S), at rest position (RP) the integrated (IEMG) was larger within anterior temporalis (Ta) whereas maximal voluntary clenching (MVC) was smaller and the masseter (Ma) and temporalis (Ta) was protruded (P).

Interpretation and Conclusion: The functional efficiency is weak and may have hypertonic activities of the jaw elevators in TMD. Following a muscle twitch, the jaw muscles in TMD become less relaxed and get easily fatigued during functional effort. TMD symptoms result in alteration of functional adaptation of jaw muscle activities and occlusion.

Keywords: *Electromyography; Temporomandibular disorders; Muscle Engram; Muscle Fatigue.*

Introduction

Temporomandibular disorders (TMDs) are a collection of general and oro-facial conditions affecting the physiology of temporomandibular joint (TMJ) and/or masticatory muscles, and the contiguous tissue components. The increased or dysfunctional muscular activities leads to the aggravation of TMDs and are triggered by peripheral factors such as TMJ disease or occlusal disturbances and/or by the central factors such as psycho-emotional effects.[1]

Electromyography (EMG) (Figure 1) has been commonly used to estimate the dysfunction in situ or the orofacial muscle function. In normal subjects, the muscle activity should be laterally symmetrical, during both rest and clenching. Electromyography asymmetry would provide useful information with regard to stemmatological diagnosis and monitoring.

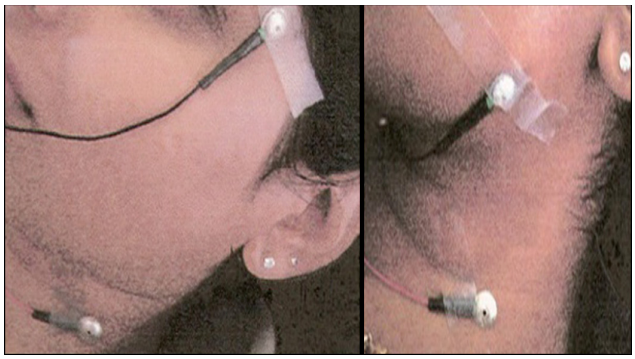

Figure 1. A) Electrode placed for recording temporalis muscle activity, B) Electrode placed for recording masseter muscle activity.

Aim: The aim of this particular studyis to denote jaw muscle's differences in their functions that is amidst asymptomatic and the symptomatic TMD subjects.[1]

Objectives: The objective of the study focus on:

1. To assess the clinical signs and symptoms of internal derangement of TMJ, and to find its effect on masticatory muscle by using Electromyography.
2. To correlate the electrical activity of masticatory muscles in a patient with temporomandibular internal derangement and masticatory muscle disorder.

Methodology

Subjects: The study was conducted at A.B Shetty Memorial Institute of Dental Sciences, Department of Prosthodontics – Crown and Bridge and Implantology, Mangalore in conjunction with Department of Neurology, Justice K.S. Hegde Charitable Hospital [A Unit of NITTE Education Trust], Mangalore. The subjects comprised of students, members of the staff and patients in the ranges of age 13 - 55 (in years). A clinical examination was done and subjects with signs/ symptoms of TMD may be one or more comprising of subjects, 10 in number and were classified under (group S) the symptomatic group.The asymptomatic group (group N) were subjects without past history concerning TMD or any TMD signs/symptoms and comprised of 10 subjects. In the age and gender ratio,there were no differences in the both groups. Prior to the experiment, full consent was obtained from the subjects.

Examination, clinically: Clinical examination and radiographic examination collected for all the subjects, were based on the following inclusion criteria:

1. Palpable TMJ pain
2. Audible TMJ sounds
3. Palpable pain in the jaw, facial, neck and back muscles
4. Muscle quality (muscle asymmetry, stiffness)
5. Limited mouth opening i.e. maximal opening less than 40mm
6. Deflection/Deviation of the mandible at the maximal mouth opening
7. Limitation of condylar translation at the maximal mouth opening
8. Variables of tooth alignment, tooth loss & attrition were the contents of static occlusion
9. Variables of occlusal interference and premature contact were the contents of functional occlusion

This study was approved by the ethical committee. The subjects were seated on a chair with the head unsupported and naturally oriented. The following conditions were recorded with 5 minutes interval between each of the EMG activities:

a. The subject was asked to keep his/her jaw at rest position(RP) is the Mandibular Physiological RP for a period greater than 30 seconds
b. The subject was asked to clench the molar teeth at the intercuspal position (ICP) as hard as possible is the maximal voluntary clenching position of mandible (MVC) for a period greater than 30 seconds
c. The Mandibular forward position of mandible (Protrusion) his/her jaw of the subject was asked to keep at maximum forward position (P) for greater than 30 seconds.

EMG Recording of Temporalis Muscle: The electrodes to temporal muscles were placed at 1-inch posterior and 1-inch superior to the outer canthus of the eye. The ground electrodes were placed over the skin of the sternocleidomastoid muscle. After the electrodes were attached, the patients were instructed to move the mandible to the above mention positions (Figure 1A).

EMG Recording of Masseter Muscle: Electrode in the masseter muscle were placed 2 cm above the lower margin of the mandible, half way between the mandibular angle and the anterior border of the muscle (the position of the anterior border of the mandible and mandibular angle were identified by palpation).

The ground electrodes were placed over the skin of the sternocleidomastoid muscle. After the electrodes were attached, the patients were instructed to move the mandible to the above mention positions (Figure 1B).

EMG data processing: The following EMG parameters were analyzed:

a. The integrated EMG activities at Physiological rest position of mandible (RP) (IEMG-RP). From the first 10-s period of the sampling, the EMG-RP was computed.

b. Of the mandible, (IEMG-MVC) is the integrated EMG activities at maximal voluntary clenching. The final 5-seconds periods of the 30-s sampling and the first seconds, IEMG-MVC was calculated. (Figure 2A & B).

c. The integrated EMG activities at Protrusion of mandible (IEMG-P). Fromboth the first (periods of the 30-s sampling) and final5-seconds, IEMG-P was calculated. (Figure 3A & B).

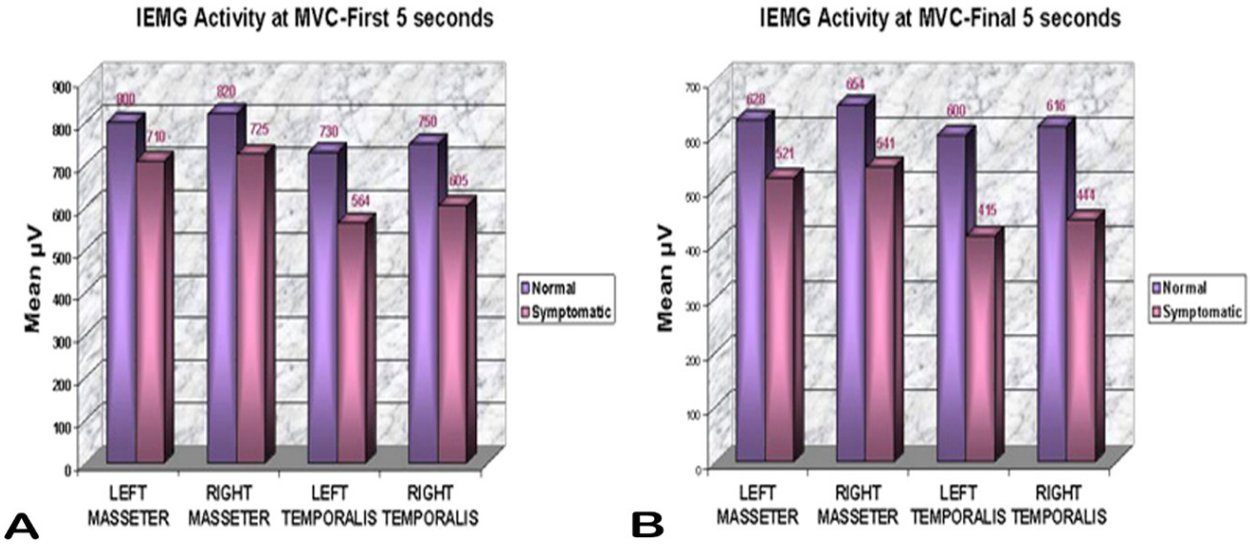

Figure 2. (A) Graph Showing the Reduction in Activity of Masseter and Temporalis in TMD Symptomatic as Compare to Asymptomatic Subjects (first 5 sec). (B) Graph Showing the Reduction in Activity of Masseter and Temporalis in TMD Symptomatic as Compare to Asymptomatic Subjects (final 5 sec).

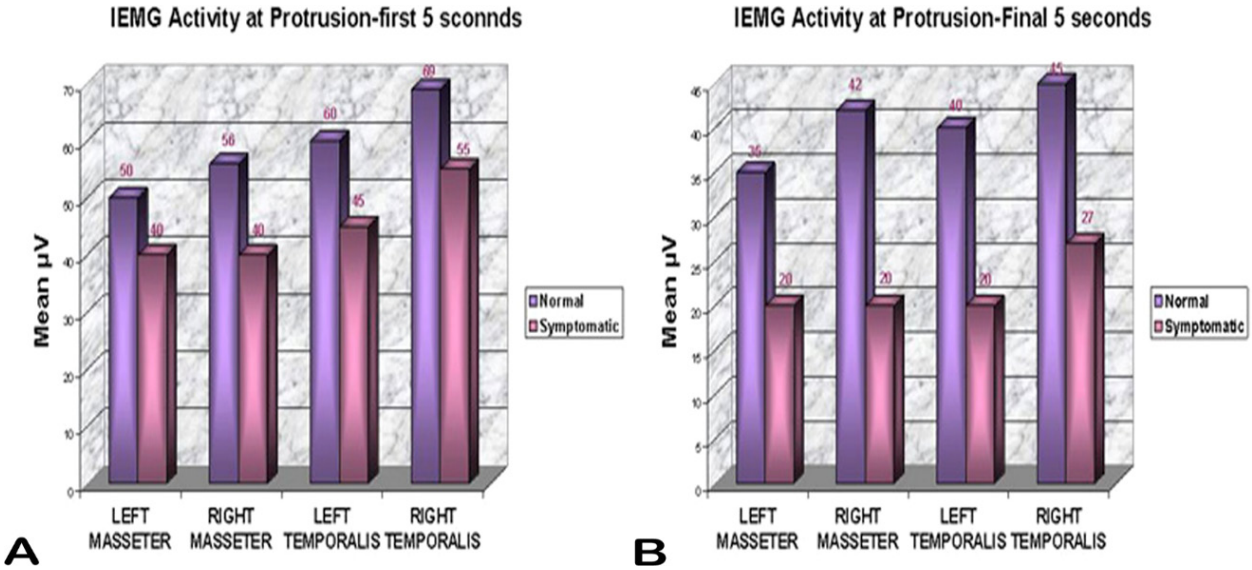

Figure 3. (A) Graph Showing the Reduction in Activity of Masseter and Temporalis in TMD Symptomatic as Compare to Asymptomatic Subjects (first 5 sec). (B) Graph Showing the Reduction in Activity of Masseter and Temporalis in TMD Symptomatic as Compare to Asymptomatic Subjects (final 5 sec).

Statistical Analysis: The readings obtained were tabulated and statistically analyzed with an independent t-test. Study data was analyzed and results are being presented in tables 1 - 5. It represents the mean vales of the electromyographic activity for the masseter and temporalis muscles in TMD symptomatic as compared to asymptomatic subjects during Rest position, maximal voluntary clenching (MVC) and protrusion (P). The electromyographic activity is recorded in micro volts (μV).

Results

Result – 1: Statistical analysis of the fore mentioned data reveals a very highly significant increase in the activity of masseter and temporalis in TMD symptomatic group than in asymptomatic subjects at physiological rest position of mandible (RP). A significant difference ($p<0.05$) in overall contractile activity was seen between normal (23.85μv) and symptomatic (28.675μv) groups (Figure 1B).

Result – 2: Statistical analysis of the fore mentioned data reveals a very highly significant lower in the activity of masseter and temporalis in TMD symptomatic group than in asymptomatic subjects at maximal voluntary clenching position of mandible (MVC) (Figure 3A).

Result – 3: Statistical analysis of the fore mentioned data reveals a very highly significant lower the activity of masseter and temporalis in TMD symptomatic group than in asymptomatic subjects at maximal voluntary clenching position of mandible (MVC) (Figure 3B).

Result – 4: Statistical analysis of the fore mentioned data reveals a significant lower the activity of masseter and temporalis in TMD symptomatic group than in asymptomatic subjects at protrusion (P).

Result – 5: Statistical analysis of the fore mentioned data reveals a highly significant lower the activity of masseter and temporalis in TMD symptomatic group than in asymptomatic subjects at protrusion (P).

Discussion

The etiology of craniomandibular disorder is not always fully understood and has been investigated from both the structural and functional point of view. The studies have concluded that the etiology is multifactorial with muscle hyperactivity being one of the main factors. Electromyography (EMG) has been often used[2], to comprehend the underlying neurologic process of muscle hyperactivity. Currently focus has been to use Electromyographic recordings in the diagnosis and treatment planning of TMDs. Electromyography (EMG) provides excellent information on muscle function. Studies have also inferred isometric muscle tension, changes and relation between a reliable reproducible and in the changes in the EMG amplitude. The conjunction with relaxation and biofeedback therapy along with that are used as a treatment tool for EMG.[2]

Periodontal receptors are important for the reflex control of masticatory muscles. The mesencephalic nucleus is activated by the stretch of jaw elevator muscles and pressure stimulation of the teeth.[3]In jaw opening and jaw closing muscles, the central sensitization process induced in the trigeminal brainstem complex by deep nociceptive afferent inputs. A type of 'splinting' effect is represented by these neuromuscular changes which protects the articular or muscular tissues from further damage and counteracts excessive movements.[5]

In TMD subjects the EMG evidences:

Jaw muscles, activity levels: The TMJ signs/ symptoms existed when hypertonic activity of the jaw muscles is also observed. To discriminate the hyperactivity of muscles of the jaw, an useful tool is the integrated electromyography (IEMG).

At Physiological Rest Position of Mandible (RP): By this study the levels of the activity of muscle on physiological rest position of mandible in groups is elevated, temporalis being specifically. It may reflect compensation for an abnormal mandibular position.[6]Due to functional over-shortening of muscles as seen in TMDs subjects, such spontaneous hyperactivity in rest position is likely seen.

Within the perimeters of its normal physiologic length when it is called upon to contract, the muscles work most efficiently. The tension recorded in muscle and tendon proprioceptors is altered if this perimeter of muscle length is changed.The excessive muscle shortening is brought by these alterations in tension, which by reflex sets up the pattern of spontaneous hyperactivity and are then imposed on the neurocentral system.[7]

At Maximum Voluntary Clenching Position of Mandible (MVC): EMG readings in the muscles of masseter, in this study and temporalis in TMDs declined in comparison with normal individuals. In TMD subjects

the jaw elevators activity are lower at maximum voluntary clenching position of mandible as it has been reported.[1]

In TMD patients, the reduction in muscle activity during clenching indicates the reduction of compressive force transmitted on the temporomandibular joint. This may reflect an involuntary pain-avoidance response. In TMD patients, the muscle is already in a contracted position due to presence of any pathological condition, such as occlusal interference, which interferes with the normal closure of the mandible. Hence, the muscles, which regulate the mandibular movements, try to close the mandible in a least damaging pattern, thus acquiring ENGRAMS according to that condition. This is the body's protective mechanism. The normal physiologic length cannot be attained during this condition the muscles are in a contracted position.[8] The tension recorded in muscles and tendon proprioceptors is altered if this perimeter of muscle length is changed. The reduced contractile activity of the muscles is in question is reflected due to these alterations in tension. This may reflect an involuntary pain-avoidance response.

At Protrusive Position of Mandible (P): The EMG readings in the muscles of masseter,in this study and temporalis in TMDs declined in comparison with normal individuals. In TMD subjects the activity of the jaw elevators are lower at protrusion as it has been reported.

Protrusion, i.e. forward movement of mandible, is mainly governed by Lateral Pterygoid muscle. This is the muscle which is most frequently involved in TMDs. Temporalis is the antagonistic muscle for lateral Pterygoid. Therefore, this muscle is also active in protrusion. This phenomenon is known as PROTECTIVE CO-CONTRACTION. This response has also been called '*protective muscle splinting'*.

During a movement pain may result in agonist muscles becoming less active whereby this has led to the concept of 'Pain Adaptation' thatis Lateral Pterygoid and its antagonist muscle (Temporalis) there by limiting jaw mobility and possibly aiding healing and becoming more active in this movement.[5]

Conclusions

At physiological rest position of mandible (RP), the muscles activity was higher and highly significant in TMD symptomatic group than in asymptomatic subjects at physiological rest position of mandible (RP). At maximal voluntary clenching position of mandible (MVC), the muscles activity was significantly lower in TMD symptomatic group than in asymptomatic subjects at maximal voluntary clenching position of mandible (MVC). During protrusive position of mandible (P), the muscles activity was significantly lower in TMD symptomatic group than in asymptomatic subjects at protrusion (P). The IEMG readings for TMD patients (at MVC and P), less activity was seen in the left side muscles than in the right-side muscles. These findings reflect higher incidence (75%) of TMDs seen on left side.Analysis of fatigue shown by the muscles symptomatic of TMDs showed greater values than the fatigue seen by normal muscles on both maximum voluntary clenching position of mandible and protrusive position of mandible. The IEMG-P readings showed higher activity in the temporalis (50 μV) as compared to masseter (40 μV). Jaw elevators in TMD showed hypertonic activities, weak functional efficiency and less relaxed following a muscle twitch and following a functional effort becomes easily fatigued. In EMG activities the severity of the pain could not be reflected and it showed increased tonic activity with functional effort due to impaired jaw movement. The functional adaptation of jaw-muscle activities and occlusion may alter due to TMD symptoms.

Carcinogenesis: A Comprehensive Overview

Pradyumna Ku Sahoo[1], Smita R. Priyadarshini[2], Shruti Sharma[3]

[1]Associate Professor, Department of Prosthodontics, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, [2]Associate Professor, Department of Oral Medicine & Maxillofacial Radiology, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [3]Researcher, Karolinska Institute College and University, Stockholm, Sweden

Abstract

Carcinogenesis is the process of tumor induction which occurs by the oncogenes which signal the molecules at various stages of growth. Apoptosis also leads to membrane dissolution of nucleus and cytosolic skeleton, chromosome degradation and fragmentation of nucleus. Even presence of various chemical, viral, radiation carcinogens that enhance carcinogenesis. In this article we have elaborated factors & process leading to carcinogenesis.

Keywords: *Oncogenes, Host Defense, Pathogenesis.*

Introduction

Is a multi-stage process that involves induction of tumors by carcinogens. Carcinogens are agents that cause changes in the interactions between cells and their environment causing invasion and metastases. Genetic bases of cancer involve phenotypic mutation or alteration by genes.[1,2]

(a) Proto-onco genes: These importantly involved in normal growth, regulation and cell differentiation.

(b) Oncogenes: There are mutated and / or dysregulated protooncogenes[3,4].

This oncogene activation can occur by

1. Genetic over expression due to acquisition of novel transcriptional promoter
2. Chromosome dislocation e.g. Philadelphia chromosome
3. Amplification of genes due to increased gene copy number
4. Point mutation that results in altered protein

(c) Tumor suppressor genes: expression of these genes inhibits malignant transformation of cells.

Hallmarks of Cancer

Acquisition of autonomous proliferation signaling: These depend on growth factors which are signaling molecules. Various stages in transmission of growth signal include (Growth factor and Growth factor receptor) -Transduction – transfer of Second messengers - RNA and protein synthesis - DNA synthesis **.**A number of growth factors have been studied but epidermal growth factors (EGF) and transforming growth (TGF). Growth factors may act on adjacent cells (paracrine effect) or on the same cell (autocrine effect). Some of the receptors contain G proteins and they may act in various ways[5]. E.g. activation of phospholipase C, these act themselves as tyrosine kinases, other e.g. include phosphorylation of various cell enzymes. In any event arrival of growth signal at nucleus, phosphoproteins which can bind with DNA appear to be involved in regulation of transcription.

Role of oncogenes: Oncogenes play an important part to produce abnormal products so that central mechanisms have altered to allow gene over expression and normal constraints are lost. The products oncoproteins are closely relate to normal cell growth receptors.

- **Inhibition of growth inhibitory signals:** The phase of cell cycle, G_1, S and G_2 and M is tightly

controlled. These are controlled by group of molecules called cyclin dependent kinase (CDKs) and cyclin-dependent kinase inhibitors (CDK Is). Any molecule which affects these CDKs or CDKIs has profound effect in cell growth[6].

Retinoblastoma gene (RB): RB and its protein product pRB are referred as gateway to cell cycle. Active form, pRB prevents progression through the cell cycle by binding to and inactivating factors (E2F) necessary for DNA synthesis.

Hypophosphorylated RB complexed to E2F transcription factors bind to DNA and inhibits transcription of genes. RB is phosphorylated by cyclins, E2F released → causing transcription. Thus, phosphorylated of RB is inhibited by CDK inhibitors[7].

TP53: Guardian of genome: It is located on short arm of chromosome 17. It acts by regulating gene transcription, by arresting cell cycle causing DNA repair by inducing programmed cell death. The rise in Tp53 is crucial defense mechanism, preventing division of cells with mutation .Other inhibitory factors include transforming growth factor β (TGFβ), interferons, interleukins etc.

- **Evasion of programmed cell death or apoptosis:** Apoptosis is a critical step in cell homeostasis, which leads to membrane dissolution of nucleus and cytosolic skeleton, chromosome degradation and fragmentation of nucleus. Any mutation of TP53 has an inverse correlation to extent of apoptosis in oral Carcinoma. Apoptosis is carried out by cathepsins especially initiator and effector cathepsins. Another mechanism of apoptosis include release of cytochrome (from mitochondria which controlled by BCZ family). Some antiapoptic members like BCL2 overexpression cause inhibition of apoptosis and is over expressed in HNSqCC[8].
- **Immortalization:** Tumor cells replicate infinite indefinite times. And this is necessary for progression of tumors. It is found in the activity of telomerase; prevent the destruction of telomeres which act as protective caps and hence the cell survives the replicative cycle.
- **Acquisition of nutrient blood supply:** Growth of tumors also requires nutrient supply. This occurs by mutating endothelial proliferation of cells causing formation of new blood vessels. It is regulated by various positive (Vascular endothelial cell growth factor) and negative angiogenesis regulators (Interferons)[9].
- **Tissue invasion and metastasis:** Steps critical for this process include:

  (A) Attachment and basement membrane e.g. Integrins are cell adhesion molecules released from Ca cells Proteolysis and migration is the next important step e.g. of molecules include matrix metalloproteinase area which help in invasion and metastasis in various kinds of tumors.

Etiology of cancer and mechanisms of carcinogenesis[10]: Carcinogenic agents can be divided into 3 categories:

Chemical carcinogenesis: Sir Percival Pott in 1775 gave the first evidence of any cause of neoplasia through its observation that prolonged exposure to chemicals could cause cancer. Of which oral cancers are mainly a result of these chemicals.

Initiation of carcinogenesis: The change is produced by a single dose of these agents for a short time, though larger dose for longer duration more effective. The change so induced is sudden, irreversible and permanent.

Two types:

(I) Direct acting: they don't undergo any metabolic activation

They are

a. Alkylating agents – Especially anticancer drugs. E.g. cyclophosphamide, epoxides, p propiolactones

b. Acylating agents: e.g. acetyl imidazole

(II) Indirect acting: require metabolic conversion within the body to become ultimate carcinogens. They are also called as procarcinogens.

Various steps involved:

(a) Metabolic activation: Majority of chemical carcinogens are procarcinogen and mostly activating by cytochrome R450 system located in ER or in nucleus.

(b) Following activation procarcinogens as well as directly acting carcinogens become electron deficient and bind to electron rich electrophiles of other molecules of DNA, RNA and other proteins.

(c) Changes lead to initiated cell → changes in DNA are seen, repair may occur in absence of which further progression

(d) E.g. of procarcinogen

Benz (a) anthracenes → polycyclins, aromatic hydrocarbon Benzo (a) pyrenes in tobacco, smoke, tar etc.

Aromatic amino and nitrogen compounds: Naphthylamine & Acetylamino fluorenes

(2) Promotion of carcinogenesis

Next step

- They do not produce sudden changes
- Require application or administration, for insufficient time and dose
- Change induced may be reversible
- Don't damage DNA per se but instead enhances effect of direct act of carcinogens with or pro-carcinogens.

e.g. Phorbol esters especially TPA

Phenols, hormones (estrogen) drugs (phenoparbital), artificial sweetness e.g. Sauhorn

Radiation carcinogenesis: UV light and ionizing radiation are two main forms of radiation carcinogens. Usually the appearance of carcinogenic effects occurs long after exposure 10 – 20 years or even later. The process occurs in 2 steps: **Initiation**: occurs by mutagenic carcinogenesis & **Spontaneous mutation**

Ultraviolet carcinogenesis:

Various effects of UV rays on cells include

- Inhibiting cell division
- Inactivation of enzyme
- Induction of mutation
- Insufficient damage – killing of cells

The UV light also activate T suppressor cell and so inhibit cell mediated immunity

Viral oncogenesis:

RNA oncogenic viruses: T cell leukemia in humans is caused by type 1 virus i.e human retrovirus associated with cancer.

DNA oncogenic viruses: DNA oncogenic viruses are classified into 5 subgroups each of which is capable of producing neoplasms in different hosts.

Papova viruses, Herpes viruses, Adeno viruses,Pox viruses &Hepadena viruses

Papova viruses: 3 members which have role in various of benign and malignant neoplasm

Human papilloma virus

- HPV – HPV 1,2,4, and 7 cause Benign neoplasm & papillomas (Warts)
- HPV 16 & 18 → associated with Ca of cervix, oncogenic
- Other animals: Polyoma virus, SV – 4 virus
- Herpes viruses: Important members involved in tumors and cancers.

EBV – Burkitt's lymphoms, Nasopharyngeal Ca, immuno suppressed individuals

Herpes simplex 1 – cervical carcinomas

HHV 8 – Kaposis sarcoma

- Hepadna virus: Hepatitis B virus is a member of this family. The oncogenesis effect is multifactorial
- Pox virus – molluscum contagiosum

3. **Host defense against tumors – Tumor immunity:** Human defense system is also known as "Immune Surveillance "i.e survey of the body from emerging malignant cells and its destruction. .

Tumor antigens: These are classified broadly into two categories

Tumor specific antigens that is produced by oncogenic viruses & Altered cell surface with glycolipids and glycoproteins.

Antitumor effector mechanisms: Both cell mediated and humoral immunity have been demonstrated principal mechanism of tumor immunity is killing of tumor cells by CD8 + T cells. Various cells involved are – Cytotoxic T lymphocytes, Natural Killer cells, Macrophages and Antibodies.

Immune surveillance: where selective outgrowth of antigen negative variant, Loss of reduced expression of MHC molecules & Immuno suppression etc occurs

Various other host related factors[5]:

(a) Heredity:	Though not yet found for oral cancer, there are known hereditary dominant autosomal as well as hereditary recessive autosomal disorders predisposing for certain cancers
(b) Racial constitution:	e.g. Immunity of dark skin races to carcinogenesis action of sunlight
(c) Developmental factors:	Inherent forces of growth and differentiation responsible for the proper development of a tissue or organ. These forces may be disturbed during development of tissue so those cells lose their ability to continue differentiation
(d) Age:	Higher incidence in individuals over 40 years of age. Certain tumors are common in children below15 years. E.g. Wilm's tumor
(e) Social class:	Besides specific occupational factors, there is statistical evidence that cancer of skin, mouth, and esophagus is common lower social groups
(f) Diet:	dietary deficiencies or exams can lead to biochemical malfunction which may in turn initiate or promote neoplastic process.

Theories of tumor biology: With considerable progress in genetic basis of cancer development, various theories and concepts related to tumor biology have been put.

Clonal evolution theory: Proposed by Nowell in 1976. Repeated carcinogenic results or "events" occur. With in a cell, at genetic or epigenetic level, when enough events occur, a selective growth advantage is conferred on affected cells. Though most of progeny do not survive, a dominant clonal population of cells is produced that flourishes as evolution occurs in this clonal population, new clones are produced with additional features.

Molecular progression model: Nowell's model is well accepted and usually 6 – 10 events are required for development of most tumors including Head and Neck.

Field carcinogenesis: Based on Slaughter's hypothesis – constant carcinogenic pressure, the entire upper aerodigestive tract is at increased risk of development multiple primary tumors. According to here multiple genetic events occurred throughout the involved mucosa, allowing development of molecularly multiple clonal progression. Recently however this theory is modified and it is thought that single lesion is involved in multiple aero-digestive tract lesions through the process of intra–epithelial migration.

Though both the mechanism evidence exists and it is hypothesized that both mechanisms explain the concept of field carcinogenesis.

Biology Of Metastasis: A common Denominator to all malignancies is their ability to metastasize. It varies and some tumors have greater tendency for local invasion without metastasis, whereas others produce organ-specific metastasis early on the development.

Approx, 4 million Tumor cells/gm of Tumor are released into the blood streams on a daily basis and yet only less than *1% of malignant cells* entering the Blood stream go on to survive. (Butler and Gullino, 1975), due to the efficient lymphatic system.

The filtration efficiency of a single lymph node has been shown to be better than 95%.

If so, then why does metastasis occur?

Exact Reasons are not fully understood. However, an influence of factors related to tumor and the environment may play a role in metastasis[2].

I. Tumor Factors:

(a) Cytologic Features: Phenotypic Mutations: Tumor cells generated are not inhibited by the host which eventually become Dominant and resistant allowing successful metastasis. These metastatic cells by their very nature are super selected clones which are more likely to survive

(b) Histologic Features: The phenotypic cells penetrate the Basal lamina of the epithelium into C.T. spaces and are forced into lymphatic capillaries by the high interstial pressure created by the tumor. These cells then enter the lymphatics and spread to the regional lymph nodes. However, the lymph nodes are a much less efficient barrier to the lymph borne cancer cells (Phenotypically Mutated). These may accumulate in nodes and ultimately find their way into the efferent lymph to be carried to other sites in the body. These successful metastatic cells adhere to the microvasculature of the organ, extravasate, establish a micro environment and proliferate. These factors also dictate other histologic features such as depth of Invasion, perineural Invasion, infiltrating as opposed to pushing, pattern of Invasion.

(c) Molecular Features: The successful invasion and metastasis by a tumor is almost certainly related to the elaboration of certain enzymes and growth factors.

(1) Enzymes:

- Type IV Collagenase - directed towards basement membrane.
- Zymogen Activation - by extracellular and membrane associated proteases and matrix metalloproteins (MMP) which lead to cascade of reactions modifying the extra cellular environment thus promoting tumor progression and degradation of tissue barriers.

(2) Growth Factors:

- Angiogenesis factors – Tumor Neovascularization
- EPGF – Epidermal Derived Growth Factor
- PDGF – Platelet Derived Growth Factor

II. Environment or Host Factors: Ability of the Tumor cells to survive at their termination site (Lymph node) depends on the internal environment and Immune Status of the host. Immune- elimination of altered cells after tumor activation of active and passive immunity occurs These work in a coordinated manner to protect as well as helps in progression.

Conclusion

Oral cancer is a multifactorial disease here alterations activate or oncogenes and inactivates tumor suppression genes. These altered genes are inherited but are also acquired form the environment through chemical carcinogen, radiation & viruses.

A Rare Site for Oral Cavity Schwannoma: A Case Report

Santosh Kumar Swain[1], Priyanka Debta[2], Swayamprabha Sahoo[3], Smrutipragnya Samal[4], Mahesh Chandra Sahu[5], Jatindra Nath Mohanty[6]

[1]Professor, Department of Otorhinolaryngology, IMS and SUM Hospital, [2]Professor, Department of Oral Pathology and Microbiology, [3]PhD Scholar, Medical Research Laboratory, IMS and SUM Hospital, [4]PhD Scholar, Medical Research Laboratory, IMS and SUM Hospital, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [5]Scientist B, Department of Microbiology, ICMR-National institute of occupational Health, Meghaninagar, Ahmadabad, [6]Research Medical Research Laboratory, IMS and SUM hospital, Siksha 'O' Anusandhan University, K8, Kalinga Nagar, Bhubaneswar, Odisha, India

Abstract

Schwannomas are benign tumororiginating from peripheral Schwann cells of the neural sheaths. These tumors present as solitary and encapsulated lesions. Intra oralschawannoma is not commonly seen in the palate and extremely rare at junction between soft and hard palate. These benign lesions are slowly expanding tumors with less risk for malignant transformation and need complete excision of the mass. As it has rare and non-specific presentations, the diagnosis is usually established by histopathological examination and immunohistochemical evaluation. Here we report a case of a large schawannoma at the area where hard and soft palate unite, which is an extremely rare location of this tumor.

Keywords: *Oral cavity, palate, Schawannoma, Benign tumor.*

Introduction

Schwannomas are uncommon benign tumor arising from peripheral or autonomic or cranial nerves which possess Schwann cells.[1] This neoplasm is slow-growing, solitary and encapsulated. The prognosis of schawannoma is usually very good as they do not recur and rarely transfer to malignancy.[2] Around 25 - 45% of the schwannoma seen in head and neck region whereas only 1% have an intra-oral origin.[2] The involvement of the palate by schawannoma is very rare. The rare location of this tumor in palate has similarityto other diagnosis likeminor salivary gland tumors and pyogenic granuloma as differential diagnosis. As it is a benign lesion, require complete excision. Although there are very few cases of palatal schwannomas are reported in literature, clinician should think of this rare clinical entity in of the mass located in the palate. Here, we report a rare location for schawannoma at the meeting point of soft andhard palate.

Case Report: A 48-year-old man presented with a gradually increasing swelling over the palatefor 3 years. He had pain over the swelling since last 4 months. On examination the mass was at the meeting point of softand hard palate with 7cm × 5cm in size (Fig. 1). The mucosa over the palatal mass was normal except a whitish patch over the mass. The mass was firm in consistency, mildly tender and fixed. There was no cervical lymphadenopathy. He had no history of any systemic medical diseases. Clinically the mass was thought of minor salivary gland benign tumor. Fine needle aspiration cytology (FNAC) showed benign squamous cells and a single bunch of spindle cells with bland nuclear pictures. Contrast enhanced computed tomography (CT) showed irregular mass at the point hard and soft palate junction (Fig. 2). There was no bone erosion. Wide excision of the palatal mass was done along with healthy margin (Fig. 3). Gross examination of the excised mass revealed, the resected tumor was encapsulated. On cut section of the mass, there was

whitish tumor showed focal hemorrhage. Histopathology picture showed an encapsulated neoplasmconsists of bundle of spindle cells exhibiting alternate cellular and hypocellular fascicles of spindle cells showing alternatecellular and hypocellular (Antoni-A and Antoni-B) (Fig. 4). Immunohistochemistry (IHC) test shows, S-100 is positive where as negative for smooth muscle cell of tumor. The post-operative period was uneventful. After six months, and one year there was no evidence of recurrence. At the follow up visit, the surgical site of the palate is completely healed without any evidence of recurrence.

Discussion

Schawannoma is a slow growing benign, encapsulated neoplasm, solitary in nature and originating from Schwann cells of the peripheral nerve sheath. It is usually seen in head & neck region and surface flexors of the lower and upper limbs.[3] Most schwannomas in the head and neck region are solitary, slowly growing, non-tender and encapsulated mass. Schwann cells are derived from neural crest derived glial cells which form myelin insulation of the peripheral nervous system axons. There are notable 2 locations of the head and neck which lack Schwann cells which are optic nerve and olfactory nerves. The most common locations of the schawannoma in the oral cavity are tongue then palate,

floor of oral cavity, gingival, lips, buccal and vestibular mucosa.[4] Schwannomas of head and neck area may be seen at any age group but usually prevalent during 2nd and 3rd decades of life. Few cases of Schwannomas are reported as malignant schwannomas which accounts for five percent among all sarcomas of soft tissues. Out of these, 9-14% areseen in the head & neck area.[5] Approximately 1% of schwannomas are seen in oral cavity and commonly found in tongue, palate, floor of the mouth, oral mucosa and jaw. [6]The area between soft and hard palate is an extremely rare location for schwannoma. Extra-cranial head & necklesions (Schwannoma) are commonly solitary and properly delineatedtumor. Schwannomas are often seen in 4th and 5th decades of life and show 1. 6:1 female predilection. [6]

The clinical presentations depend on the site of the lesion and its mass effect or involvement of the nerve. Patients of head and neck schwannomas may presentclinical symptoms such as pain, voice change, difficult to swallow, cranial nerve involvement and also Horner's syndrome. [7] Schwannomas on the palate often mimic to the minor salivary gland pleomorphic adenoma in their clinical and radiographical presentations. Here, we present this case to highlight the rarity and particularlyat the junction of hard & soft palate of the oral cavity. Patient's clinical presentation of a submucosal mass and his clinical features provide thinkingfor minor salivary gland tumor which is considered in the differential diagnosis. Other possible differential diagnosis are benign lesions such as granular cell tumor, leimoyoma, malignant lesion such as squamous cell carcinoma and sarcoma.[8]

The preoperative diagnosis of schwannomas is often difficult only by routine clinical examination. For diagnosing schwannomas, radiographs have little role as they do not have any characteristics which differentiate schwannoma from other lesions. CT scan may help to rule out extension of the tumor and bony erosion. MRI provide important information for pre-operative diagnosis and planning for the treatment.[9] In MRI imaging, schwannomas have a low-signal intensity on T1-weighted imageand signal hyper intensity on T2 weighted image, revealing either heterogeneouslyor homogeneously high intensity.[10] FNAC is inadequate for diagnosis of neural tumors. The accuracy of preoperative diagnosis of schawannoma by FNAC is approximately 25%.[10] In this case, the tumor was initially thought as minor salivary gland pleomorphic adenoma on its clinical presentations.

Immunohistochemistry techniques are important method used for the diagnosis of suspected schwannomas which typically show positivity to S-100 protein. Schwannomas often shows a strongly positive to S-100 protein in all tumor cells in comparison to other neural tumors like neurofibromas or peripheral nerve sheath tumors.[11] The tumor cells of this case were strongly positive forvimentin, S-100, CD56 and negative for cytokeratin which support towards the diagnosis of schawannoma. Most of the tumor cells of the tumor mass shows Antoni type-B tissues with focal areas of Antoni type-A pattern.

Treatment at the palatal schwannomas includes surgical resection. Soft palate defect greater than 1 cm need surgical reconstruction as simple closure is not sufficient. In the present case, tumor was completely excised as it was pedunculated arising from the junction of the hard and soft palate. Complete excision of tumor is required along with emphasis is given for preserving the nerve (tumor originating) if seen during surgery. Completeexcision of this tumor of the oral cavity, its recurrence has not been documented.[12] During surgical excision of the schawannoma over the palate, importance should be given to consider function of palatal muscles such as tensor veli palatine and levator veli palatini. Closure of the wound after excision and proper epithelialization have risk for scar contracture which may lead to velopharyngeal insufficiency.[13] Defect of the soft palate more than 1 cm need surgical reconstruction as simple closure of the wound would be insufficient. There are different types of flaps according to the size and site of the defect at soft palate. In case of malignant lesions at the soft palate, it needs free flapsdue to large area of reconstruction. The free flap reconstruction lead to static reconstruction, which often results in velopharyngeal insufficiency.[14] In present case wound was small in size and closed easily without any tension and followed by no scar formation.

Conclusion

Schwannomas at the junction of meeting point of soft and hard palate of the oral cavity are extremely rare and should be included as differential diagnosis among benign lesions of the palate including minor salivary gland pleomorphic adenoma. It is imperative that the clinician must aware of this tumor with its clinical manifestations. Due to its rarity, multicenter reporting of the head and neck schwannomas should be used to identify their pattern of incidence and required surgical treatment.

Unicystic Ameloblastoma of Maxilla: A Case Report

Santosh Kumar Subudhi[1], Sthitaprajna Lenka[2], Sanchari Sinha Roy[3], Radha Prasanna Dalai[4]

[1]Professor, [2]Reader, [3]Post Graduate Trainee, Department of Oral and Maxillofacial Surgery, [4]Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Unicysticameloblastomasare those cystic lesions that exhibitcharacteristics clinically and radiologically of a cyst from odontogenic originhistologically depictsan ameloblastomatous epithelium which lines part of the cyst cavity, with or without proliferation of luminal & mural tumor. These grow inside the jaw and cause displacement of the bone, teeth and their roots. Sometimes they infiltrate the bone and spread into the soft tissue. Mostly seen in posterior mandible, but it may also arise in the maxilla and the jaws anteriorly. This is one of the rarevariants of the ameloblastoma. We report a case of unicystic ameloblastoma of maxillary region in a male patient of 35 years.

Keywords: *Unicystic Ameloblastoma; Maxilla; cystic lesions.*

Introduction

It has been reported that ameloblastoma is the second most common odontogenic neoplasm. Robinson has illustrated it being a tumor that is 'usually unicentric', 'nonfunctional', 'intermittent in growth', 'anatomically benign' and 'clinically persistent'. It is believed to be originated from residual epithelium of the tooth-forming apparatus, such as the epithelial cell rests of Malassez; epithelium of odontogenic cysts; basal cells of the surface epithelium; epithelium of the enamel organ; and heterotopic epithelium from extraoral sites, such as the pituitary gland. These are aggressive and destructive in nature, and have the potential to reach greater dimension, infiltrate bone and breach surrounding structures. Based on the World Health Organization (WHO) classification of head and neck tumours, there are four forms of ameloblastomas: 'multicystic', 'peripheral', 'desmoplastic' and 'unicysticameloblastomas'. Robinson and Martinez in 1977 described unicystic ameloblastoma as a distinct entity. These are clinically and radiographically related to jaw cyst but histologically the unicystic ameloblastoma depicts an ameloblastomatous epithelium which lines part of the cystic cavity. Normally these are less aggressive in nature, affects patients of younger age group, and responds very well to enucleation or curettage. Unicystic ameloblastoma normally occurs in posterior part of ramus region of mandible, and hardly in posterior part of maxillary region.[1,2]

Case Report: A male patient of 35 years reported to the outpatient department of Institute of Dental Sciences, Bhubaneswar, and had a complaint of swelling in the left side of face adjacent to the nose since 2 months (Figure 1).

Figure 1. Frontal view photograph showing left maxillary swelling obliterating the nasolabial fold and displacing the ala of nose.

Corresponding Author:

e-mail: alamwaseem4@gmail.com

The patient was apparently asymptomatic 2 months ago. Then he observed swelling over the left side of face which was asymptomatic and at the beginning was of a smaller dimension that gently progressed in dimension up to the present dimension with no discharge and mild tenderness. He had no other physical abnormality.

On extraoral examination: Well circumscribed, non-fluctuantswelling of hard consistency present adjacent to the left ala of nose extending superiorly from infraorbital region till commissure of lip, anteriorly from ala of nose till 4cm ahead of the TMJ obliterating naso labial sulcus region measuring 3*4cm in size approximately. Skin over the swelling is of normal skin colour with no secondary changes and tender on palpation.

On intraoral examination: Bicortical expansion noted in the alveolobuccal sulcus area extending from 12 region till 27 region measuring 3*3 cm in size obliterating the vestibule and palatally extending from the left maxillary canine region to the greater palatine foramen.

On palpation the lesion is nontender, having areas of depression. Egg shell cracking and Crepitus was felt buccally. Vitality test revealed 11, 12 to be vital and 21, 22, 23, 24, 25, 26 to be non vital. Needle aspiration revealed yellow straw-colored fluid.

Radiographic examination revealed unilocular lesion starting from right maxillary lateral incisor to left maxillary first molar. There was complete involvement of left maxillary sinus and lateral wall of piriform aperture. Displacement of left central incisor of maxilla to the first molar with significant root resorption was noted [Figure 2].

Figure 2. Orthopantomograph (OPG) showing unilocular radiolucency in the left maxilla displacing and causing resorption of the involved teeth.

The patient was operated under general anaesthesiausing intraoral approach. The lesion was exposed using crevicular incision and was enucleated [Figure 3]. Extraction of left maxillary lateral incisor to first molar was done. Peripheral ostectomy was done. Soframycin gauze pack was placed and the surgical site was closed with 3-0 vicryl suture. Excised specimen was sent for histopathological examination.

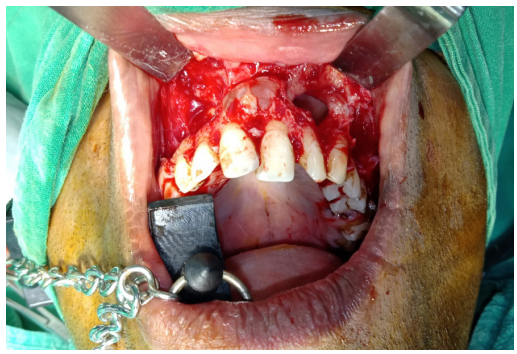

Figure 3. Intraoperative photograph showing the extent of the lesion.

Histologic analysis of the surgical specimen revealedunicystic ameloblastoma, mural form. The lesion was fully encircled by a capsule of fibrous nature and has a lining of ameloblastic epithelium, with basal layer of columnar cells, subnuclear vacuoles, reverse polarity of nucleus, and stellate cells in centre.

There was no sign of recurrence during follow-up and the patient's condition improved significantly.

Discussion

Radiographically unicysticameloblastomas are typically unilocular with a round area of radiolucency. It is mostly misinterpreted as an odontogenic keratocyst or a dentigerous cyst. It accounts for 10–15% of all extraosseous ameloblastomas.[3] Mostly the lesions are asymptomatic and occur in the posterior mandibular region. The chances of recurrence are 3.6% and 30.5% for resection and enucleation respective, 16% and 18% for enucleation followed by Carnoy's solution application and marsupialization followed by enucleation respectively. The ageof the patient is an important component which determines the treatment to be followed.[4] Prognosis depends on the method of surgical treatment and not on the tumor's histology. Recurrence of this tumor depicts the insufficiency of the primary surgical procedure. A recent systematic review demonstrated that enucleation resulted in a highest recurrence rate and the lowest was observed with resection of tumor. Therefore, thorough preoperative diagnosis o and long-term follow-up should be done in these kinds of lesions.[5,6]

An Unusual Cause of Throat Pain: A Case Report

Santosh Kumar Swain[1], Priyanka Debta[2], Swayamprabha Sahoo[3], Smrutipragnya Samal[3], Mahesh Chandra Sahu[4], Jatindra Nath Mohanty[5]

[1]Professor, Department of Otorhinolaryngology, IMS and SUM Hospital, [2]Professor, Department of Oral Pathology and Microbiology, Institute of Dental Sciences, [3]Scholar, Medical Research Laboratory, IMS and SUM Hospital, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, [4]Scientist B., Department of Microbiology, ICMR-National Institute of Occupational Health, Meghaninagar, Ahmadabad, [5]Research, Medical Research Laboratory, IMS and SUM hospital, Siksha 'O' Anusandhan University, Bhubaneswar, Odisha, India

Abstract

A 42-year man complained with unilateral throat pain and foreign body sensation in throat since last two years. Patient had tenderness over the left tonsillar fossa when palpated. Computed tomography (CT) imaging of the neck showed bilateral enlarged styloid process, measuring 6.8 mm on right side and 5.1 cm on left side. The salivary and thyroid glands, as well as pharyngeal and laryngeal findings, were normal. The patient was taken up for surgery after complete diagnosis. The pain and discomfort were relieved after Styloidectomy.

Keywords: *Throat pain, Eagle's syndrome, Elongated styloid process, Styloidectomy.*

Introduction

Eagle's syndrome is an uncommon clinical entity related to the prolongation of either styloid process or calcified stylohyoid tendon which is clinically portrayed by throat pain or odynophagia, emanating towards the ear. It is known to happen when either the absolute styloid process length is bigger than 2.5 cm or hardening of the stylohyoid or stylomandibular tendons. The agony brought about by Eagle's disorder is a kind of nerve torment, which means it is brought about by irregular nerve signals, not harm to the excruciating area.[1] The torment is commonly depicted by the patient as a dull and throbbing hurt that may incorporate an inclination that something is stuck in the throat. A few people may likewise encounter tinnitus.[2] Since the side effects are variable and vague, patients look for treatment in a few unique facilities, for example, otolaryngology, nervous system science, neurosurgery, psychiatry, and dentistry. We depict the instance of a 52-year-old male patient who gave left neuralgic torment, going on for around 2 years, confined in the throat and neck and some of the time transmitting into the ear.

Case report: A 42-year man displayed to us with a background marked by unilateral throat pain with foreign body sensation in throat. He was able to pin point the area of pain. He went to several institutions before coming to us but the correct diagnosis could not be made and his pain was not relieved even after taking the prescribed medications. We performed a laryngeal endoscopy under local anesthesia which came out to be normal. Then the tonsillar fossa of both sides was palpated and the patient had severe tenderness in the left side. Suspecting it to be an elongated styloid process, we advised the patient to go for a CT scan neck with 3D reconstruction. The report uncovered two-sided lengthened Styloid process, estimating 6.8 mm on right side and 5.1 cm on left side with typical salivary and thyroid organs, just as expected pharyngeal and laryngeal discoveries. The surgery was performed only on left side as the right side was asymptomatic. Tonsillectomy done by coblation method followed by styloidectomy, which is the excision of the excessive length of styloid process was done on the left side 6.8 cm of the styloid process was excised. Pain and

Corresponding Author:
Dr. Priyanka Debta
Professor, Department of Oral Pathology and Microbiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: debtapriyanka@gmail.com

foreign body sensation disappeared immediately after the surgery. Diagnostic workup: The various potential reasons for pain like odontogenic, oral sore, dental, neuralgic, solid, and temporomandibular infections were discounted. The differential diagnosis included were neuralgic pain arising from glossopharyngeal nerve, neuralgic pain originating from superior laryngeal nerve, neuralgic pain originating from occipital nerve, neuralgic pain arising from sphenopalatine nerve, intermedius nervous neuralgia, cephalic headache, neck related cerebral pain, mandibular abnormalities, TM (temporomandibular) joint issue, mutilated or Unerupted 3rd molar, Defective dental prostheses, salivary gland infections, tonsillar infections, mastoiditis, oncologic procedures in the oropharynx and oesophagus and in some cases of psychosomatic illnesses. Palpation of the oral cavity and oropharynx were finished utilizing forefinger under neighbourhood anaesthesia utilizing 15 % lignocaine splash. Palpation at the lateral wall of the oropharynx uncovered a hard and pointed feeling beneath the pharyngeal delicate wall. The delicacy on palpation uncovered extended styloid forms which was missing on opposite side and subsequently finding of longer styloid process was detected. Analysis was upheld on CT scan of neck with 3D reconstruction which was showing elongated styloid process on left side (5.1 cm) (Figure 1).

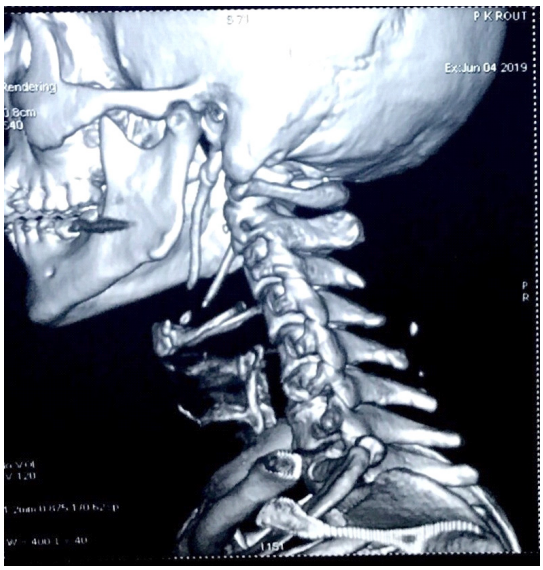

Figure 1. CT scan picture showing elongated left styloid process.

To remove the elongated styloid process, intraoral approach was used. After through examinations, understanding was planned for medical procedure under general anaesthesia. The piece of the styloid procedure was extracted trans orally (Figure 2).Preoperative prophylactic anti-infection agents were given as Amoxicillin with dose of 500 mg by oral route, one hour before medical procedure which was then proceeded as two times each day for five days. Firstly, tonsillectomy (grade 3) of left side was done using coblation method followed by dissection of the tonsillar bed. Then the styloid process was mobilized from the underlying muscle attachments and bared off the attachments using the dissector. Then the process was cut off using the Kerison's punch. Haemostasis was achieved and wound closed. Postoperative Care and Follow Up: Patient was given postoperative analgesics and antibiotics and was discharged after 24 hours with appropriate postoperative instructions and regular follow ups were done. Patient was relieved with pain in follow up visit after one month.

Figure 2. Excised styloid process via trans oral approach.

Discussion

Eagle's syndrome disorder is identified with the nearness of a strangely extended styloid process with or without variant bearing as well as solidified styloid tendon. Cranio-facial torment may take after neuralgia originating from glossopharyngeal nerve and it is auxiliary to the bothering of the encompassing neuro-vascular and strong anatomical entities (muscles, carotid course and cranial nerves) [3]. Anatomically, the styloid procedure emerges from the worldly bone and afterward passes downwards, advances, and medially. The styloid procedure is a meagre, prolonged, barrel shaped hard projection, arranged anteromedially to the mastoid procedure. The length of this procedure shifts from two to three centimetre. Back to this is facial nerve, which rises up out of the stylomastoid foramen though average to it (moving back to front) are the IJV (internal jugular vein (with 9th, 10th, 11th and 12th cranial nerves) and ICA (Internal carotid artery). Tip of the styloid

processes is attached to the predominant constrictor muscle and pharyngobasilar belt lying neighbouring the tonsillar fossa. Sidelong to tip, is outer carotid supply route that bifurcates into shallow transient and maxillary conduits. The stylohyoid tendon stretches out from the styloid to lesser cornu of hyoid. Embryologically, it is gotten from Reichert's cartilaginous part of 2nd branchial curve. Solidification of the styloid procedure and the stylohyoid tendon prompts an expansion in the thickness and length of the styloid procedure, which at that point pushes on the neighbouring structures like the carotid supply route, inside jugular vein, vagal nerve, facial nerve, hypoglossal nerve, and glossopharyngeal nerve, which results in different weight side effects. The pathophysiological cause behind ES are: neural compression of the 9th cranial nerve, 5th cranialnerve, or potentially the corda dueto the extended styloid process. Crack of the hardened stylohyoid tendon, trailed by multiplication of granulation tissue that causes weight on encompassing structures and results in agony. Compression on the carotid artery by the elongated styloid bone, creating disturbance of neural elements in the blood vessel sheath. Degenerative and fiery changes in the tendinous segment of the stylohyoid addition, a condition called inclusion tendinosis. Bothering of the pharyngeal mucosa by direct pressure by the styloid procedure. Extending and fibrosis including the 5th, 7th, 9th, and 10th cranial nerves in the post-tonsillectomy period. The analysis of this clinical substance regularly made first by radiologically then affirmed by palpation at the tonsillar fossa as it ordinarily not palpable[4]. Palpation of the tip of styloid process for the most part exasperates the symptoms.[5] Computedtomography (CT) examine give detail data of styloid procedure including its length thus supportive before careful arrangement and extraction of the styloid procedure through extra-oral or intraoral approach. CT output ought to be finished with slender thickness in sub-millimetre with hub, coronal and sagittal plane. There is a few imaging accessible for analysis of Eagle's disorder like anteroposterior head radiography, Towne or all-encompassing radiography and parallel angled perspective on head and neck.[6] These have numerous disservices like superimposition and frequently hard to gauge the length of the styloid procedure. The treatment of decision for Eagle's disorder is to abbreviate the styloid procedure, called as styloidectomy. Advantages of extra-oral approach include better visualization whereas disadvantages are scar mark and damage to facial nerve. Advantages of trans-oral approach are less time consuming, simple and no scar formation. The disadvantages of trans-oral approach include poor visualization, iatrogenic damage to deep structures and neck space infections.[7] In our case, trans-oral approach was adopted without any intra-operative and post-operative complications. The medical treatment includes use of medications to relieve pain and inflammations and/or steroids.

Conclusion

Eagle's syndrome is a rare clinical entity and often presented with diversity of symptoms. It often poses a diagnostic and therapeutic challenges to clinicians. It usually presents with chronic throat pain and refractory to traditional treatment. It should be properly evaluated and confirmed by imaging followed by excision of the styloid process.

Central Giant Cell Granuloma: Contradicting the Usual Picture

Alkananda Sahoo[1], Swagatika Panda[2], Subrat Padhiary[3], Neeta Mohanty[4], Debkant Jena[5]

[1]Senior Lecturer, Department of Oral and Maxillofacial Pathology and Microbiology, [2]Professor, Department of Oral and Maxillofacial Pathology and Microbiology, [3]Professor, Department of Oral and Maxillofacial Surgery, [4]Professor & Head, Department of Oral and Maxillofacial Pathology and Microbiology, [5]Professor, Department of Conservative Dentistry and Endodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Jaffe in 1953 differentiated Central Giant Cell Granuloma (CGCG) from Giant Cell Tumor of bone. This intra-osseous lesion has been described by various authors' as a reactive lesion or as a developmental anomaly or as a non neo-plastic lesion. Though inflammation, haemorrhage, local trauma has been suggested as some of the aetiological factors but actual aetiology is still unclear. Genetic aetiology has also been hypothesized. Mandible is the common site of occurrence, frequently crossing the midline. Incidences in females are more and less than 30 is the age of occurrence. The clinical behaviour of CGCG ranges from a slow-growing asymptomatic swelling to an aggressive lesion with pain, local osteolysis, root resorption and tooth displacement. Most widely accepted treatment is surgery. Nonsurgical treatments with alpha-interferon, calcitonin and corticosteroids have been described and their benefits may be worthy of consideration. Contrary to the age, gender and site here we present a case of CGCG in a 52-year-old male patient presenting with a swelling in the right anterior maxilla.

Keywords: *Central giant cell granuloma, swelling, maxilla.*

Introduction

Central giant cell granuloma (CGCG) is an infrequent benign intra-osseous lesion affecting both the jaws. CGCG is also termed as reparative giant cell granuloma. The lesion consists of substantial fibro-histiocytic proliferation and multinucleated giant cells with excessive amount of hemosiderin.[1, 2] It has been defined by World Health Organization as "an intra-osseous lesion consisting of cellular fibrous tissue with multiple hemorrhagic foci, aggregations of multinucleated giant cells, and occasionally trabeculae of woven bone".[3, 4]

Incidence of CGCG is <7% of all benign pathologies of the upper and lower jaws.[5] Clinically, have a greater predilection for females and mostly seen in patients less than 30 years of age.[6] Common site of occurrence is in the anterior mandible involving incisor, canine, and premolar regions, often crossing the midline. Moreover, CGCG has variable clinical features ranging from slow growing asymptomatic swelling to a painful aggressive lesion with destruction of bone, perforation of cortical plates, resorption of root and repetition. The most common indication isa painless swelling leading to facial asymmetry.[7] There is no definitive etiopathogenesis, but some authors believe it as a reparative response rather than neo-plastic while others regard it to have a neo-plastic potential.[5, 6, 8.]

Depending on clinical and radiographic examination the case in this report was misdiagnosed and root canal treatment was initiated but later on was histopathologically established as CGCG. Hence, we are describing this case of CGCG in the anterior maxilla to draw attention of the general dental practitioner and to raise awareness about the significance of histopathology in the identification of this enigmatic lesion.

e-mail:alkanandasahoo@soa.ac.in

Case Report: A 52-year-old male patient reported with the chief complaint of pain and swelling in the right side maxillary anterior teeth region since 3 to 4 months. Initially the patient noticed a small swelling which gradually increased to the present size. There was sporadic pain which was relieved on taking medication. Past dental history showed root canal treatment was in progress in teeth 12, 13, 14 and 15 as they were diagnosed to be non-vital. But there was no significant relief. There was no relevant medical history of the patient or any systemic disease or any allergy to drugs.

On extra-oral examination, facial asymmetry was noticed with swelling on the right side of maxilla which may have caused nasal deviation also (Figure 1a). Skin overlying the swelling appeared normal. The swelling was non tender on palpation and firm in consistency.

Figure 1a. Extraoral view showing the swelling over the zygomatic bone causing nasal deviation.

Figure 1b. Intraoral view showing the palatal swelling extending from midline till the second pre-molar.

On intraoral examination, there was bucco-palatal swelling more prominent palatally,measuring approximately 3 cm × 2.5 cm extending from the midline till the mesial aspect of the 1st molar of the right side with normal appearing overlying mucosa (Figure 1b). The swelling was firm in consistency. On radiological examination, orthopantomogram exhibited multiple and diffuse radiolucency in relation to canine and second pre-molar extending from the distal aspect of right lateral incisor till the mesial aspect of the right first molar (Figure 2a). Contrast Enhanced Computed Tomography (CECT) suggested there is a large well defined soft tissue leison of size 47 x 32 x 34 mm with adjacent bony remodelling and sclerotic rim is noted. There is widening of the right osteomeatal unit. Mild soft tissue swelling seen in the right maxillary region. Bony Deviated Nasal Septum towards right (Figure 2b).

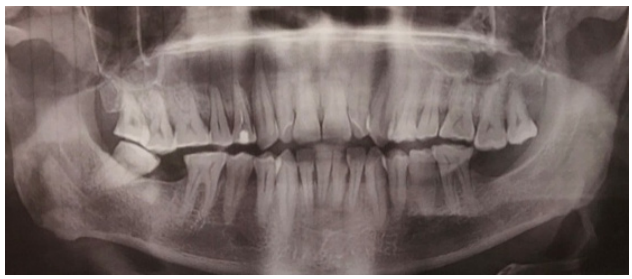

Figure 2a. Panoramic view showing the radiolucency in relation to 12,13,14,15

Figure 2b. CECT correlation suggesting a mild soft tissue swelling seen in the right maxillary region

On the basis of clinical and radiological features differential diagnosis of the radicular cyst, keratocystic odontogenic tumor, central giant cell granuloma and ameloblastoma were given. All the blood investigations of the patient were within the normal range. Incisional biopsy was done from the intra-oral site under local

anaesthesia. Buccal mucoperiosteal flap was raised, bony window created (bone was paper thin) and underlying tissue was found to be solid in nature like that of granulation tissue. Tissue was taken in multiple chunks and sent for histopathological examination (Figure 3).

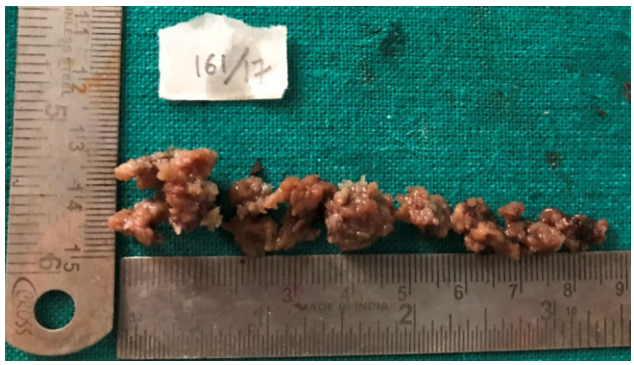

Figure 3. Macroscopic evaluation: multiple bits of formalin fixed tissue, brown in colour, irregular shaped, with irregular surface, firm in consistency and gritty on palpation and measuring about 1.5x8.5 cm (aggregate size)

H and E stained section showed numerous diffusely distributed multinucleated giant cells in a background of highly cellular connective tissue stroma. Minimal amount of chronic inflammatory cells but diffusely arranged along with numerous extravasated red blood cells were seen in the stroma. Multiple bony trabeculae were seen in the periphery as well as inside the lesion (Figure 4).

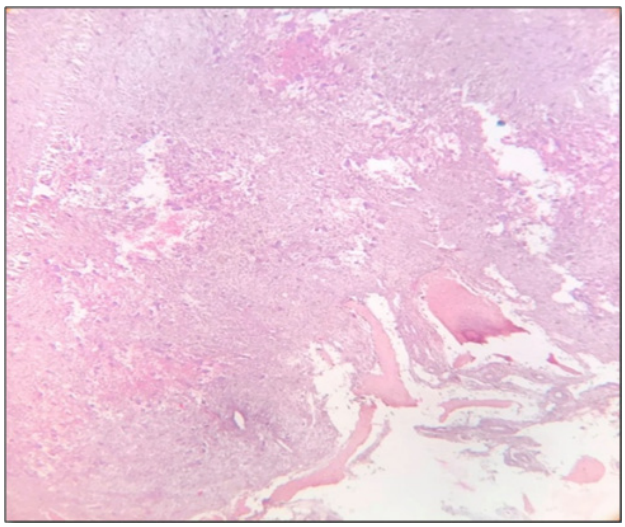

Figure 4. Photomicrograph 4x: Numerous diffusely distributed multinucleated giant cells in a background of highly cellular connective tissue stroma. Multiple bony trabeculae are seen in the periphery and extrvasated RBCs.

All the above findings were compatible with diagnosis of CGCG. Histologically CGCG is difficult to differentiate from Brown tumor of hyperparathyroidism. Hence the patient was advised to check for serum levels of calcium, phosphorus and alkaline phosphatise. All the parameters were found to be in normal limits hence Brown tumor of hyperparathyroidism was excluded,thus central giant cell granuloma of the anterior maxilla was established. Complete surgical excision of the lesion was done.

Discussion

Central giant cell granuloma is a non-neoplastic proliferative lesion of unknown etiology. This entity has more predilections for lower jaw than the upper jaw. Most common site for the mandibular lesion isin the area anterior to 1st molar and often crossing the midline. Right mandible is more affected than the left.[9] Certain clinical features are contradicting which makes this case unusual. The lesion is in the right maxilla, anterior to the 1st molar but not crossing the midline. CGCG also occurs in other areas of head and neck bones like facial skeleton and cranial vault. The lesion although very rare also has been documented in the short tubular bones of feet and hands.[10]

Giant cell granulomas of the jaw bones are of two types peripheral and central. Central lesions are endosteal while peripheral lesions are pedunculated or sessile lesions on the gingiva. Incidences in female are more than in male and found in the ratio of 2:1. Children and young adults are most commonly affected. The patient in our case is a male aged 52 years which also contradicts the above.[11-13]

Trauma is asignificant etiological factor in the instigation of this lesion. Here patient doesn't give a history of traumabut all the teeth involved in the pathology are non vital. The lesion enlarges by build up of tissue, produced by sluggish, minuscule, constant haemorrhages of multicentric nature because of trauma and some fault in the smaller blood vessels[11]. There has been reports of association of t (X; 4) (q22; q31.3) in the etiology of giant cell granulomas.[14]

CGCG has variable clinical behaviour, which ranges from slow enlarging painless swelling to a destructive pathology associated with pain. The most significant indication of CGCG is a slow growing swelling in the face causing an obvious facial asymmetry, not associated with pain. The lesion may be incidentally disclosed

during routine radiographic examination of the jaws made for a discrete cause. The lesion is accompanied by pain in about 25% cases. Bone area may elicit tenderness on palpation. The lesions are not associated with paresthesia. There may be mobility of the involved teeth but remain vital.

Central giant cell granuloma has varied radiological appearance. The radiolucency may be unilocular or multilocular, well-circumscribed or diffuse. Varied degree of expansion and destruction of cortical plates can also be seen. The radiological appearance of the lesion is a lot similar with many other jaw bone pathologies hence cannot be pathognomonic. Since the clinical and radiological features are not very precise hence the final diagnosis ultimately rests on histopathology.

Central giant cell granuloma of the jaws commonly present as a lone, radiolucent expansion but without pain. A few lesions are more caustic with a marked inclination to reappear. Hence for this type of destructive lesion further radical approach is advocated.There is marked evidence of treatment failure within the first two years of therapy indicating that the rate of recurrence to be 13-22%.[15]Management of CGCG is all based on its clinical and radiological findings. The rate of recurrence is less in well circumscribed, localized curetted lesions. In widespread lesions with radiographic substantiation of perforation of cortex, a more radical excision should be the line of treatment even partial maxillectomy is advocated. Steroids or calcitonin is used as an adjunct to surgery in the medical management of CGCG because of their anti-osteoclastic property.[16] The anti-angiogenic property of Interferon-alpha makes it useful in the management of aggressive CGCG.[17] Intravenous administration of Bisphosphonates has also shown promising results in CGCG.[18]

Conclusion CGCG has an unpredictable and inconsistent clinical behaviour. Though CGCG has a striking predilection for anterior mandibular region, for any swelling in the anterior maxillary region, the dental surgeon should also contemplate to consider Central Giant Cell Granuloma in the differential diagnosis.

Crouzon Syndrome in a Female Patient with Classic Craniofacial Features

Satya Ranjan Misra

Professor & Head, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

When there is premature fusion of sutures in the cranial bone, it is called Craniosynostosis. There are many syndromes arising from craniosynostosis, among them Crouzon syndrome is the most common. It is inherited as an autosomal dominant trait but has variable features, characterized by mid-face hypoplasia, exophthalmos, and small maxilla with a prognathic mandible. Fibroblast growth factor receptor-2 gene (FGFR-2) mutation is the cause of this condition and the affected individuals with abnormally shaped heads are a therapeutic challenge for the dentist.

Keywords: *Craniosynostosis, Crouzon Syndrome, Exophthalmos, Prognathic Mandible.*

Introduction

Craniosynostosis affects brain growth and the growth is restricted perpendicular to the synostosis but increased growth is seen in the areas where the sutures are open. Hence the brain growth is asymmetric causing alteration in the shape of the base of the skull and the craniumresulting in typical deformities.[1] There are numerous syndromes associated with craniosynostosis and the common ones are Crouzon syndrome, Carpenter syndrome, Apert syndrome, Treacher Collins syndrome and Marie Sainton syndrome.[2] We are reporting a case of Crouzon syndrome who reported with a gingival growth and was incidentally diagnosed due to the characteristic facial features.

Case Report: A 28 years female patient reported to the dental hospital with the complaint of growth in the mandibular anterior gingiva and unaesthetic appearance.

History revealed that the deformity was present from birth and the growth on the gingiva first appeared when she was pregnant about 2 years back which was excised 6 months after the delivery but it again reappeared 1 month later.

On physical examination, characteristic eye changes along with nose and jaw changes were seen. Mid face hypoplasia with relative prognathism of the mandible, short upper lip and drooping lower lip along with bilateral exophthalmos, hypertelorism, slanting of the outer canthi of the lower eyelids and strabismus were observed. [Figure 1] The bridge of the nose was depressed giving a parrot beak appearance. Intraorally anterior crossbite, diastema in mandibular anterior teeth, malocclusion and high arched 'U' shaped palate was seen. [Figure 2,3]

Figure 1: Clinical pictures showing mid face hypoplasia with relative prognathism of the mandible, short upper lip and drooping lower lip along with bilateral exophthalmos, hypertelorism, slanting of the outer canthi of the lower eyelids and strabismus.

Intra-orally, a single localized irregularly shaped gingival growth in relation to 41, 42, and 43 was seen. The growth was sessile, erythematous, having an ulcerated surface, firm in consistency and slightly tender on palpation. [Figure 2, 3].

Figure 2: A single localized irregularly shaped gingival growth in relation to 41, 42, and 43 which is sessile, erythematous, having an ulcerated surface and anterior crossbite.

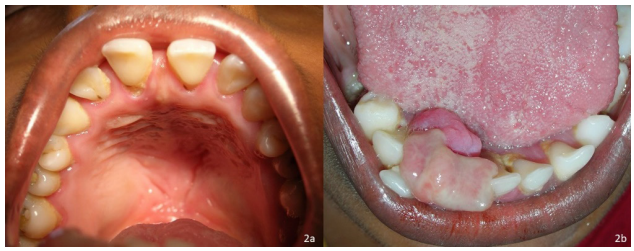

Figure 3: U shaped high arched palate and single localized irregularly shaped gingival growth in relation to 41, 42, and 43 which was sessile, erythematous, having an ulcerated surface.

In view of the facial deformity present right from the birth, it is a congenital defect. Since the facial deformity is a syndrome of maxillary hypoplasia, relative mandibular prognathism, malocclusion, exophthalmos, hypertelorism and parrot beaked nose, this syndrome can be provisionally diagnosed as Crouzon syndrome.

Radiologic investigations revealed mid face hypoplasia with depressed nasal bridge, underdeveloped maxilla, relative mandibular prognathism and class III malocclusion. Numerous markingswere seen on the skull giving an appearance of 'beaten metal'. [Figure 4a, b]. Panoramic radiograph showed relatively large mandible in compared to the maxilla, maxillary sinus is small. [Figure 4c]

Figure 4: Mid face hypoplasia with depressed nasal bridge, underdeveloped maxilla, relative mandibular prognathism and class III malocclusion. Numerous markings were seen on the skull giving an appearance of 'beaten metal'. (4a, b) Panoramic radiograph showed relatively large mandible in compared to the maxilla and a small maxillary antrum. (4c)

The gingival growth was excised under local anesthesia and evaluated histologically. A lobular pattern of vascular proliferation with inflammation and oedema were seen resembling granulation tissue. [Figure 5]. Correlating the history, clinical and radiological findings the diagnosis of Crouzon syndrome was made with pyogenic granuloma in lower gingiva.

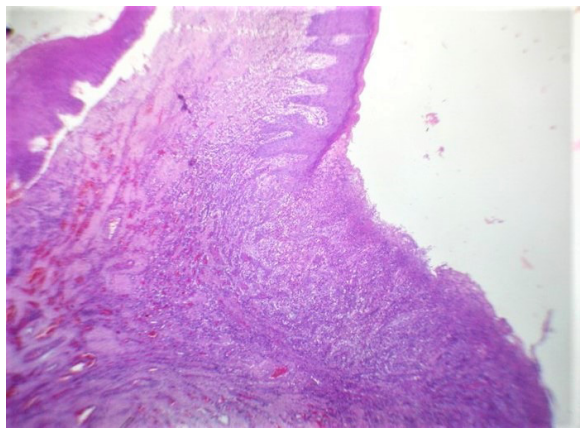

Figure 5: H&E section showing lobular pattern of vascular proliferation with inflammation and oedema were seen resembling granulation tissue.

Discussion

This syndrome was first described by Octave Crouzon in 1912. Since then it has been discovered through gene mapping that a genetic mutation in FGFR-2 gene is the cause. About 4 in every 100,000 patients suffer from this syndrome.[3] If detected in foetal ultra-sonograms, premature termination of pregnancy or

proper planning for therapeutic management after birth can be done. There is premature fusion of the parietal and frontal sutures leading to the characteristic appearance.

The patient's appearance varies with the severity of the disease and ranges from mild midface hypoplasia to multiple fused sutures resulting in severe facial and ocular problems. In some patient'sairway obstruction can cause respiratory distress.[4] Though mentally normal but these patients could be blind as a result of optic atrophy secondary to increased intracranial pressure. Ocular proptosis, hypertelorism, skeletal class III malocclusion, anterior cross-bite, shallow orbits, frontal bossing, maxillary hypoplasia, high arched palate and dental malocclusion are common findings which were also seen in the present case.[5]

The patients must undergo orthodontic check-up and orthodontic treatment at an early age can prevent anterior cross-bite and the development of skeletal class III malocclusion and associated functional problems. [5] While in adulthood the management of this disease is mostly surgical, non-surgical approaches like orthodontic and orthopaedic therapy can be considered. Rapid maxillary expansion (RME) with facemask could be used to enhance proliferation of cells in the inter-maxillary sutures and maxillary tubercles thereby facilitating forward movement of maxillary arch in growing children.[6] The surgical approaches can be used to advance the midfacial region to correct the discrepancies in the sagittal plane as well as lessen the intra-ocular pressure serving dual function: improvement of aesthetics as well as function.[7,8]

Radiographic appearance is classic with obliteration of cranial sutures, small rudimentary para nasal sinuses, shallow orbits with maxillary hypoplasia, short cranial fossa, large hypophyseal area and typical surface markings of the cranial vault called as beaten metal appearance.[9] Therapy for patients with craniofacial abnormalities requires a multi-disciplinary team-based approach. It starts with the early diagnosis of the condition so that orthopedic referral is fast and growth modifying procedures are performed.[10] Early interventions can avoid major surgeries and also help in the over-all psychologic well-being of the patients.

Role of Azithromycin in Periodontal Diseases

Tanisha Swami[1], Manoj Kumar[2]

[1]Intern, [2]Reader, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Azithromycin,a macrolide drug has been used for the cure of variety of microbial infections since a significant amount of time. It has been found to possess a far more enhanced performance in discouraging the development of the bacteria than its predecessor drugs like Erythromycin and Clarithromycin. It hasbetter structuraland pharmacokinetic properties which makes it a better version of a azalide drug in terms of itshalf-life,acid-stability,durability, intracellular penetrations and anti inflammatoryfunctioning. Having the accessible route of administration it has got a good amount of patient approval. In many cases the recurrence of the infection is common where the antibiotics are not able to reduce the symptoms associated with the disease for a longer period of time. Unlike those medications, Azithromycin focuses solely on the cure and acts as an apt option which puts a brake on the biofilm to mature.In the periodontal context, Azithromycin has especially shown that it prevails at the areas invlolving the pathology. Research has proven that Azithromycin,being the non-essential therapeutic agent for the periodontal wear and tear,has been effortlessly used as a supplement to the non-surgical method for the cure,as it has been challenging to get rid of the debris present in the inaccessible areas. It is also being involved as a mode of therapy in addition to the surgeries involved, it has been able to validate itself in reversing the periodontal conditions for the better. Being administered both in the local and systemic manner,it has been found to be fairly effective in reducing the bleeding on probing,inflammation and tenderness in the gingiva,periodontal pocket depth and the plaque build up.

Keywords: *Azithromycin, Periodontics; Diseases, non-essential therapeutic age.*

Introduction

Azithromycin was searched-out by a group of clinicians at Yugoslavia in 1980.It got it's acclaimation by the Food and Drug Administration (FDI) in 1991.[1] Azalides which are a sub-class of a group of drugs called macrolides constitutes Azithromycin (Azith) as the chief functioning component. This drug which has been proven to be effective against a good amount of gram negative bacterias,is used to treat variety of bacterial infections such as bronchitis,pneumonia, infections of the ear,non-definite urethritis,genital ulcers mainly in the men and many more.[2] It is also effective against simplified dermal and tonsillar infections. Following its metabolism in the liver, Azithromycin exhibits superior properties of pharmacokinetics than the congener-erythromycin. It has the least interference with the gastric acids,with rapid oral absorption and deep penetration inside the cells including the periodontium.[3] It shows potential actions against the pathogenic organisms which are resistant to it's analogue drugs like erythromycin and tetracycline. Azithromycin has been successfully able to show exceptionally better sustainability and drug synergies as it shows its centralization in the white blood cells(WBC's) constituting mainly of macrophages and fibroblasts,and actively gets transported to the site of infection.[3]

Recent studies have shown that gram negative bacterias such as Prophyromonas Gingivalis and Treponema Denticola which dwell in a complex microbial community within the oral cavity have been responsible for variety of chronic periodontal disease.[3] Apart from being capable of inhibiting the growth of these disease causing pathogens, Azithromycin also

releases protein molecules from the immune system against a wide variety of microflora.[4]

Morphology: (9-deoxo-9a-aza-9a-methyl-9a-homoerythromycin) the 15-membered ring azalide Azithromycin differentiates itself from the 14-membered ring Erythromycin in its structure by the extension of a new nitrogen atom which is infused into the macrocyclic lactone ring. This nitrogen atom makes Azithromycin far more potent against the bacteriasthan drugs like Erythromycin. It has been revealed that the chemical properties in the Azithromycin lead to an increment in the balance of the acids than in the Erythromycin and therefore the former has better absorption,metabolism and longlastingness in the tissues in adequate and deep concentrations. Microbiologically it shows in-vitro actions against those micro-organisms which resist against Erythromycin and other complimentary drugs.[5]

Application: Azithromycin usually follows the oral route of administration through capsules,tablets or suspension. Opthalmic solution can be given in some patients depending on the condition.Intravenous approaches are also exercised on those who find oral route difficult to endure. Extent of therapy can fluctuate with the intensity of the disease.[6] Since Azithromycin possesses a long half life,it can easily be dosed once a day for 3-5 days keeping the age,systemic conditions and allergic reactions to the drugs in mind.[5]

Reported cases have shown a marked minimization in the prevalence of micro-organisms when Azithromycin was being given orally,once a day for 3 days before the oral prophylaxis was being performed than when conventional treatments were offered without the usage of Azithromycin. Apart from having its potential in combating with the pathogenic microflora, Azithromycin also acts as an immunomodulator. This property of Azithromycin has an anti-inflammatory response at the site of the pathosis. This feature of Azithromycin comes into action particularly in those cases which do not relate to the microbes. COPD (Chronic Obstructive Pulmonary Disease), Cystic Fibrosis, Diffuse Pan-Broncholitis are some of such examples. Azith excels as an immunomodulator when compared to other antibiotics as it revealed large scale integral circulation through oral route of administration and adequate diffusion to the tissues with minimal negative reactions to the body.[1]

The process of phagocytosis was seen to be improved in quite a few instances with the application of Azithromycin. It also inhibited the growth of inflammatory cells which persisted and curtailed the formulation of Interlukin (IL-8)in the oral epithelial cells. Efficient durability and persistence of the drug in the gingival and periodontal soft tissues and alveolar bone was appreciated.[1]

Mechanism of Action: The pathogens find their ways to combat with the drug. Either they strive to alter their purpose of action or they cut-back their intrabacterialaggregation. Azithromycin gets abundantly high in the WBC's during the process,especially at the site of the inflammation,perhaps due to the rise in the vascular properties.[7] Azithromycin rules out the bacterias from developing by attaching with the bacterial ribosome in alterable manner,thus inhibiting their process of protein synthesis and hampering the translation of m-RNA keeping the nucleic acid synthesis stable. Henceforth there is no origination of the mucus. Azithromycin has been found to be actively working immediately after the very first dose of 500mg given orally.[6] Azithromycin has been found in much abundance in the periodontal cells than in the plasma. The drug's measure outspaces the MIC(Minimal Inhibitory Concentration)and that supposedly aids the scaling down of the infection.[6] Pharmakokinetically it is safe with the acids. Absorption follows an easy and immediate pathway when devoid of food.It increases it's mass when it is involved in the process of ingestion of bacteria. The time after the drug is givenwhen the maximum plasma concentration is reached is about 2.1-3.2 hours for the oral mode of usage. The mechanism of action of Azithromycin constitutes the amalgamation of its functions (anti-microbial and anti-inflammatory) taking place in action in sync incorporated with the stability in its accretion in the inflamed tissue[7] .It undertakes the pathway of biliary excretion .

Contraindications and Adverse Effects: In general, the drug has a good rate of acceptance,but gastric disturbances and mild to moderate inconveniences related to loss of balance have been acknowledged in occasional cases.[6]Some patients had shown mild levels of altering responses which gradually increased it's severity when the application of the drug was intervened. In any circumstances if the patients have a history of allergic reactions towards erythromycin or any such complimentary drug, Azithromycin should be avoided. People who develop rapid muscle fragility and fatigue should take proper consent of the clinician prior to the usage of the drug. The state of lactation and pregnancy

are safe with Azithromycin. It is also advisable to contraindicate the drug if there had been any disorders related to the liver which had been associated with the use of Azithromycin in the past.[8]

As an adjunct to non-surgical periodontal therapy: It is being seen that chronic periodontal conditions can be healed with therapeutics which require no surgical remedies. The extent of the pocket may be the determining factor in the level of the improvement. The application of the systemic medication along with the non surgical therapies have been found out to boost up the prognosis of the treatment. Experiments had been carried out regarding the treatment protocol involving the antibiotics and its effects on the outcome. Lately Azithromycin was being advocated as a favourable supplementation to the Non-Surgical Periodontal Therapy (NSPT). Its superior properties have been able to make sure that it enhances the conclusion of the analysis.[8] On various cases examined significantly it had come to notice that Azithromycin was strongly capable enough to lower the intensity of the pocketinvolved, inflammation and bleeding associatedwith the soft tissues and thereby reduced the loss of attachment level (CAL-Clinical Attachment Loss). It was seen particularly in the cases of severe periodontal destruction which initially revealed pocket depths greater than 6-7 mm,after the action of Azithromycin presented a convincing rate of minimization in the degree of the damage involved. On the microbiological aspect,when Azithromycin was being exercised to cases where non-surgical attempts had been made,it resulted in a lower rate of presumed oral micro-organisms.[9]

Regenerative functions on the periodontium: Evidence states that application of this drug has led to reformation of the alveolar bone,irrespective of the presence or the absence of the deep calculus and debris. Investigations justified the usage of Azithromycin for the soft tissue regeneration in addition to the procedure of basic oral prophylaxis being performed. When prescribed at a dose of 500mg/day for a duration of 3 successive days before the periodontal surgery being performed,had a markdown in the amount of the infection present in the area when compared to the state before the conventional therapy. Better results have shown in a lot of chronic cases with systemic conditions in the presence of Azithromycin where the therapy follows a phase-wise plan in required intervals. Significantly the prognosis was indicative of limited grade of furcation involvement, pusdischarge, supra and sub-gingival plaque accumulation with greater patient compliance and least discomfort.[8] The metabolism and ossification of the bone has shown to increase and provide better support to the tooth and hence it leads to the reduction of the grade of the tooth mobility,if involved.[10]

Azithromycin acts as a promising drug of choice in cases where individuals have been found suspected to Diabetes and positive family history of Periodontitis havebeen detected. When the patient's co-operation would suffice during the extent of the regimen,it would result in the resolution of the minimal scoring of the periodontal index in due course of time.[10] Evidently when intoxicating habits like severe smoking had been seen it implicated to chronic condition of periodontal destruction and suppuration which had a tendency to reappear again and again. Having Azithromycin as the first line of the medicational therapy in such cases has have been manifested to show improvement in a gradual manner. Here the etiotrophic phase should be taken care of with proper counselling and Nicotine Replacement Therapy(NRT) to be followed with complete oral prophylaxis and deep curettage to be performed at regular intervals. Azithromycin has shown thriving results in the reduction of the loss of attachment by following a proper treatment plan considering the age,systemic health conditions and oral habits involved.[4]

Conclusion

It would be justified enough to conclude it as a fact that Azithromycin has revealed impressive outcomes as an ancillary drug therapy in periodontally involved sites.It plays a major role as an asset in providing advantageous consequences to patients who undergo chronic cases of Periodontitis.It works by eliminating the root causative organisms involved behind the disease and significantly lessening the degree of abnormal increase in the deepening of the gingival sulcus and regenerating the lost bond between the tooth,periodontal ligament and alveolar bone. It thereby minimizes the associated gingival inflammation, colour changes and bleeding,recurrence of supra and subgingival plaque and hard calculus and the configuration of the loss of support of tooth from the bone.

Pemphigus Vulgaris in the Oral Cavity: A Diagnostic Challenge for the Dentist

Satya Ranjan Misra

Professor & Head, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar-751003, Odisha, India

Abstract

Pemphigus represents a group of auto-immune muco-cutaneous, potentially fatal vesiculo-bullous-ulcerative characterized by intraepithelial acantholysis. Pemphigus vulgaris is the most frequently occurring subtype and is often diagnosed by the oral physician from the oral mucosal ulceration which are often the only manifestation in this disease. The pathogenesis involves, production of immunoglobulin G auto-antibodies against the desmoglein 1 glycoproteins present on the desmosomes. Since this disease can be life threatening if it is progresses, early diagnosis and prompt treatment is a priority. Immunosuppressants remain the mainstay of the therapeutic interventions and many patients recover to lead a normal life.

Keywords: *Auto-Immune Disease, Desmoglein 3, Vesiculo-Bullous Lesions, Immunosuppressants.*

Introduction

Pemphigus is a group of chronic muco-cutaneous, inflammatory auto-immune vesiculo-bullous-ulcerative disorders. It is a relatively rare disease seen in the elderly population with a definite female gender predilection. There are many variants of this disorder, pemphigus vulgaris (PV), pemphigus vegetans, pemphigus foliaceus, pemphigus erythematosus, paraneoplastic pemphigus (PNP) and drug related pemphigus are the ones frequently reported.[1] However, the bulk is the vulgaris subtype of Pemphigus which accounts for about four fifths of all cases.[2] Since the oral mucosa is affected in PV, which may sometimes be the only lesions in the patients, they sometimes pose a diagnostic challenge as there are no pathognomonic features. It is of paramount importance that the disease is diagnosed early before there is morbidity or mortality as it progresses over time.

Oral lesions are seen almost anywhere in the mucosa especially the buccal, palatal, labial and lingual mucosa. Though the gingiva may not be frequently affected but gingival desquamation occurs with gingival involvement. The clinical manifestation of the disease differs as in some patients the oral lesions are the only lesions, in others the oral lesions are preceded by the cutaneous ones and in some the oral lesions occur after the development of cutaneous lesions.[3] Hence initiation of immunosuppressive intervention prior to the development of cutaneous lesions delays the progression of the disease. The present case describes a middle-aged female patient with oral and skin lesions who was diagnosed by the oral physician and treated in conjunction with dermatologists by glucocorticoids and cyclophosphamide regimen with success.

Case Report: A 41-year-old female patient reported to the dental hospital with the complaint of multiple painful ulcers in the mouth and difficulty in eating food since the past 1 ½ years.

History revealed that patient developed multiple oral ulcers 1½ years back. She initially had blisters in the mouth which spontaneously ruptured to forming ulcers. These ulcers were present in many parts of the mouth and were associated with pain and burning sensation causing difficulty in eating. She has taken medications from a dentist but the lesions did not subside. In the past 10 days she developed blisters and ulcers on the face, hands and arms.

On physical examination, extra-orally a freshly ruptured bulla was seen on the right side of the face about 2cm below the medial canthus of the right eye. [Figure 1a] Tissue tags were seen and the base of the ruptured bulla was erythematous and with a shallow ulcer. There was a watery discharge from it and tenderness on palpation.She had bullae and ulcers present on her upper arms, the ulcers were covered with crustation, bled on provocation and were extremely painful. [Figure 1b, c]

A single ulcer was present on the lower lip on the right side about 2 × 1 cm in size; with irregular margins and covered with a black crustation. [Figure 2] The superior margin of the ulcer was erythematous and tender.

Intra-orally, multiple shallow ulcerations were seen in the buccal mucosa, palate and labial mucosa. [Figure 3] Each ulcer was surrounded by erythema and had irregular margins, and the surface covered with slough which could be peeled off by probing revealing a bleeding surface. The ulcers were tender and there was blood tinged exudation on palpation.

In view of the oral ulcers being present for the past 1½ years, this is a chronic condition. Since the ulcers were preceded by vesicle formation, had irregular margins, surrounded by erythema, covered with slough which can be peeled off, were painful with sanguineous exudates, this could be chronic vesiculobullous disorder. Pemphigus vulgaris and bullous pemphigoid were considered in the differential diagnosis as similar cutaneous lesions were present with positive Nikolskysign.

An incisional biopsy was performed from the peri-lesional tissue which revealed para-keratinized surface epithelium, acanthosis and acantholysis, the cells of the spinous layer in some areas appear to fall apart and arrange themselves loosely assuming a round shape. (Tzanck cells) Down below the basal cell layer shows a split from superficial layer. The basal cells are arranged parallel resembling a row of tombstones and the split area shows some acantholytic cells and extravasated RBCs. The underlying connective tissue is made up of moderately dense collagen fibres with spindle shaped fibroblasts, dense chronic inflammatory infilltrate, predominantly lymphocytes. [Figure 4] Histopathology was suggestive of Pemphigus vulgaris.

The patient was hospitalized and started with dexamethasone cyclophosphamide pulse (DCP) therapy. The treatment was done in 3 phases. Initially 100 mg of dexamethasone was mixed in half liter of 5% dextrose and administered as a slow infusion along with 50mg of cyclophosphamide given orally for 3 days. This therapy was continued for 9 months and the patient was on remission. Though all the lesions healed completely, 50mg of cyclophosphamide was given orally for 9 more months to prevent recurrence. [Figure 5,6]

Figure 1:

Figure 2: Ulcer was present on the lower lip on the right side about 2x1 cm in size; with irregular margins and covered with a erythematous, black crustation.

Figure 3: Multiple shallow ulcerations were seen in the buccal mucosa, palate and labial mucosa.

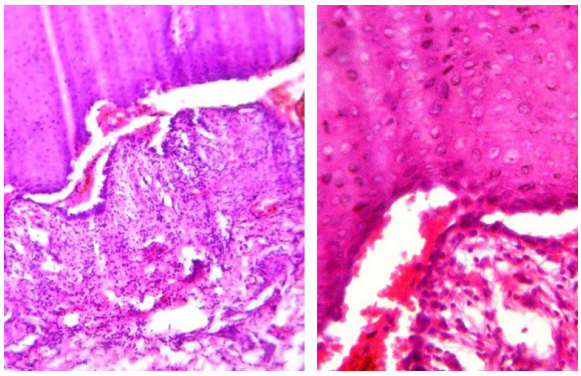

Figure 4: H&E stained sections showing para-keratinized surface epithelium, acanthosis and acantholysis, the cells of the spinous layer in some areas appear to fall apart and arrange themselves loosely assuming a round shape. (Tzanck cells) Down below the basal cell layer shows a split from superficial layer. The basal cells are arranged parallel resembling a row of tombstones and the split area shows some acantholytic cells and extravasated RBCs. The underlying connective tissue is made up of moderately dense collagen fibres with spindle shaped fibroblasts, dense chronic inflammatory infilltrate, predominantly lymphocytes.

Figure 6: Ixtra-oral pictures showing complete healing of oral lesions following immunosuppressive treatment.

Discussion

Pemphigus vulgaris (PV) is a B-lymphocyte mediated auto-immune disease. In this disease auto-antibodies are produced against the antigens present in the junction of tonofilament-desmosome in the epithelial layers.[4] Vesiculo-bullous lesions are the presenting features in both oral and cutaneous lesions, which are thin walled and flaccid lesions which subsequently ulcerate.

The mechanism behind thesesub-epithelial lesions in PV is due to conjugation of immunogloblin G auto-antibodies to desmoglein 3, which is a trans-membrane glyco-protein adhesion molecule, present on the intercellular cementing substance, desmosomes.[5] When the antibodies bind to the desmosomes, protease enzyme is activated and block the adhesion of desmoglein. This leads to acantholysis i.e. Separation of the cells in the stratum spinosum leading to the formation of an intraepithelial bulla. Since this bulla spreads in the under the skin/mucosa it leads to separation of large areas of the skin/oral mucosa.[6, 7]

Clinically, thin walled flaccid bullae are seen un PV on otherwise normally appearing oral mucosa/skin. Intact bullae are rarely seen in the oral mucosa due to relative humidity of the oral cavity and trauma while mastication. Hence intact bullae are more commonly seen on the skinand typically these bullae increase in size, spreading on applying pressure onto adjoining normal area. This phenomenon is known as Asboe-Hansen sign.[8] Another sign is the development of new lesions, on applying pressure to apparently normal skin/mucosal surface, called Nikolysky sign.[9] But the Nikolsky sign is also seen in a few other mucocutaneous diseases like cicatricial pemphigoid and Lyell's disease.

For confirmation of the diagnosis, biopsy is performed, mostly on the intact vesicle or bulla that is less than a day old. And the incision is made on the apparently normal border or the perilesional mucosa, so that the pathognomonic supra-basilar split is observed in the histologic specimen. The histo-pathologic demonstration of a sub-epithelial split excludes the sub-epithelial bullous diseases like, cicatricial pemphigoid, bullous oral lichen planus and erythema multiforme.[10] An important step for confirming the diagnosis of PV is to detect the circulating intercellular antibodies. Although Western blot of recombinant and cell derived forms of the target antigens, enzyme-linked immunosorbent assay

(ELISA) and immunoprecipitation can be performed the gold standard is indirect–immunofluorescence (IIF).

Early diagnosis is of paramount importance in the management of patients with PV because lower doses of immunosuppressive agents can be curative even when given for short duration. Hence oral physicians/dentists ought to be aware of the oral features of the disease so that the disease is diagnosed and treated early thereby reducing the morbidity and mortality associated with it. PV is treated with glucocorticoids withor without other immunosuppressive agents.[11] This can be performed in 2 phases, a loading phase to heal the lesions, causing remission and a maintenance phase which prevents exacerbation or relapse. Glucocorticoids used vary from prednisolone to dexamethasone depending on the patients' needs and compliance.[12] If the lesions are widespread then systemic therapy is initiated. Prednisolone 0.5-2mg per kg body weight is started and the dose is increased as per response.[13]Since the disease is chronic so long term therapy involves addition of adjuvants like Azathioprine or Cyclophosphamide. Newer drugs like mycophenolate mofetil or targeted therapies using monoclonal antibodies are now being tried with less side effects and better results, though the cost of the therapy increases manifold.[14]

Nasopalatine Duct Cyst: A Diagnostic Dilemma

Neeta Mohanty[1], Shubhangi Pareek[2], Sreepreeti Champatyray[3]

[1]Professor and Head, [2]Post Graduate Trainee, [3]Assistant Professor, Department of Oral and Maxillofacial Pathology and Microbiology, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Nasopalatine duct cyst is the most commonly encountered epithelial non odontogenic cyst of the maxilla. Epithelial remnants of the nasopalatine duct triggered due to some sort of irritation in the form of infection or spontaneously may give rise to Nasopalatine duct cyst. The final diagnosis can only be made based upon the clinical, radiological and most importantly histopathological findings. Treatment strategies mainly incorporate enucleation of the lesion followed by marsupialization as indicated in some cases. We present here a case of Nasopalatine duct cyst in a 45-year-old male which was diagnosed clinically as dentigerous cyst in association with an impacted tooth but a conclusive diagnosis of nasopalatine duct cyst was finally made based upon the histopathological findings.

Keywords: *Nasopalatine Duct Cyst; Marsupialization; Histopathology; Radiology.*

Introduction

First explained by Meyer in the year 1914, nasopalatine duct cyst (NPDC) or incisive canal cyst originates from the epithelial remnants of the nasopalatine duct which may be triggered spontaneously or due to some type of irritation in the form of infection. They are usually located in the midline of maxilla in the anterior part in close proximity to the incisive foramen. [(1)] It is quite common of all the non-odontogenic cyst of the oral cavity with a prevalence rate of 1%.[(2)]

The age predilection for NPDCs is wide but it is most common during the 4th-6th decades of life. Males are more commonly affected as compared to females with a ratio of 2.5 : 1.[(3,4)] More commonly such lesions are accidentally discovered during routine radiography as they are often symptomless but some patients may also present with few symptoms. Most common complaints include that of an infection in association with a previously symptomless cyst with problems such as swelling, pus drainage or pain.[(5,6)] Sometimes endodontically treated teeth may also be noticed on radiographs in association with NPDC as they are often misdiagnosed and treated as periapical cyst or granuloma.

The case presented in this paper had a typical presentation and was misdiagnosed clinically as a dentigerous cyst but was finally diagnosed as nasopalatine duct cyst after the histopathological evaluation.

Case Report: A 45-year-old male patient presented with swelling in left maxillary anterior palate since 2 months which had gradually increased to the present size. Upon intraoral examination, a well-defined, firm and tender swelling was present in left anterior palate region of size 2 cm in greatest diameter.

Figure 1: A well-defined swelling present in relation to left maxillary anterior palate region.

Dr. Shubhangi Pareek
Post Graduate Trainee, Department of Oral and Maxillofacial Pathology and Microbiology, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: pareek.shubhi@gmail.com

Radiological Findings: Radiographs revealed a radiolucent lesion present in the left anterior palate region along with an impacted supernumerary tooth. (Figure 2& 3).

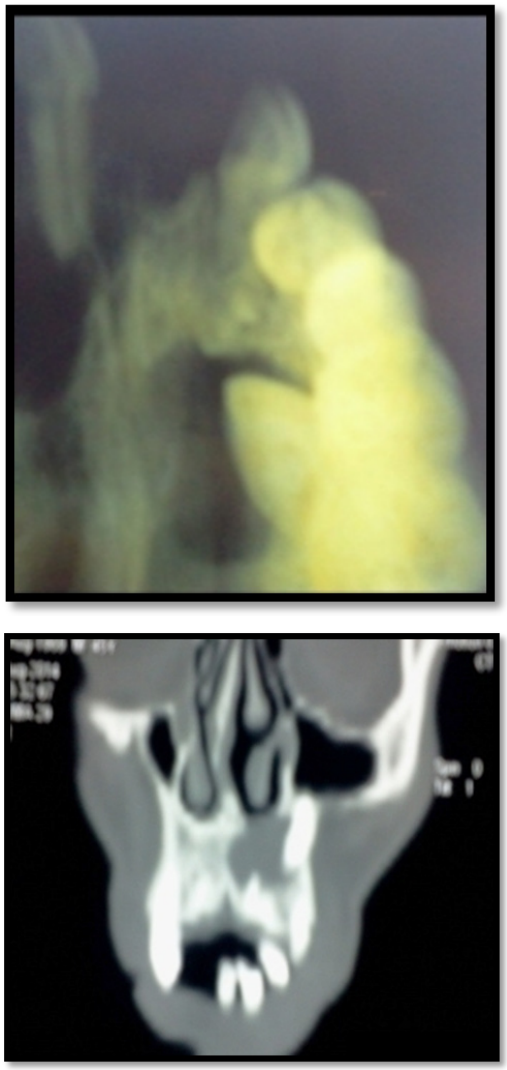

Figure 2 & 3: A radiolucent lesion present in the left anterior palate region along with an impacted supernumerary tooth.

Based upon these clinical and radiological findings a provisional diagnosis of Dentigerous cyst in association with an impacted supernumerary tooth was given. Complete surgical enucleation was done and the biopsy was then sent for processing.

Histopathological Findings: The hematoxylin and eosin stained section of the specimen showed a pseudostratified ciliated columnar epithelium supported by a connective tissue capsule. Few nerve bundles, mucous acini and ductal cells were also evident in the cystic capsule.

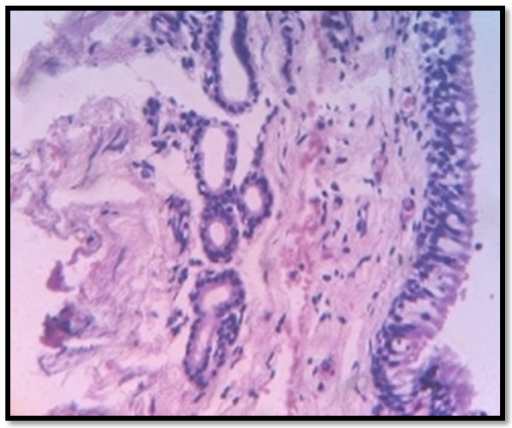

Figure 4 (4x view): The photomicrograph of H & E stained section showing a pseudostratified ciliated columnar epithelium supported by a connective tissue capsule.

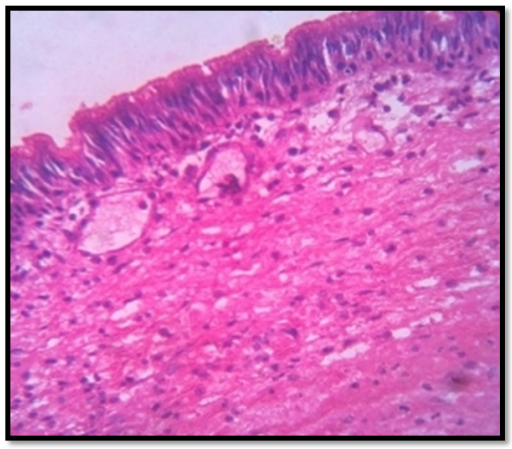

Figure 5 (10x view): The photomicrograph of H & E stained section showing a magnified view of the pseudostratified ciliated columnar epithelium of nasopalatine duct cyst.

Based upon these findings a final diagnosis of Nasopalatine Duct cyst was given.

Discussion

Nasopalatine duct cyst may occur unilaterally or centrally with no particular side prevalence. Upon radiographic examination, a well-defined round or oval radiolucency is seen in the midline while some lesions may also appear heart-shaped[7]. This heart shaped appearance is due to the notching of the cyst by the nasal septum during its expansion or due to superimposition of the nasal spine in the radiograph. NPDC is often misdiagnosed as a periapical lesion because of the same signs and symptoms and thus many authors have a belief that its incidence is much higher than actually

reported in the literature[8]. Out of the total 71.8% NPDCs reported, the type of epithelium may vary from squamous, columnar, cuboidal or as a combination of all these types. However in 9.8% cases, respiratory epithelium has also been noticed [6,9,10].

The case presented in this paper had typical clinical, radiographic, and histopathological features of a nasopalatine duct cyst. This caseenlightens us about the proper diagnosis of such lesions that are easily misdiagnosed as any other lesion followed by an in appropriate treatment plan. The treatment of nasopalatine duct cyst is complete surgical enucleation with or without marsupialization as indicated in some cases. It usually has a good prognosis with recurrence ranging from 0-11% [1].

Conclusion

NPDCs are one of the most common non odontogenic cysts and should not be confused with any other radiolucent lesions of the anterior maxilla. Clinically a vitality testing of the involved or adjoining teeth may help to rule out the differential diagnosis. A confirmatory final diagnosis is however only possible after proper histopathological examination. This case highlights the importance of the role of an oral pathologist in the final diagnosis of such lesions and hence the inevitable part of histopathology.

Idiopathic Thrombocytopaenic Purpura in a 30-Year-Old Male: The Dentist's Nightmare

Satya Ranjan Misra

Professor & Head, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Hemorrhagic bullae, petechiae, hematoma, ecchymoses in the oral mucosa with unprovoked uncontrolled gingival bleeding is often a cause of concern for the dentist as it indicates an impaired bleeding or clotting mechanism. Such patients are seeking dental treatment are a therapeutic challenge and the dentists are not especially trained to handle the complications that could arise due to hematologic disorders. More so, investigations for the diagnosis of these disorders are not readily available in a dental set up as well. Idiopathic thrombocytopenic purpura (ITP) is a relatively common bleeding disorder, which occurs due to impaired production or pronounced destruction of platelets. Though the cause is uncertain, immune related mechanisms, drugs and infections may be implicated. The disease is often diagnosed based on the history and clinical examination, backed by complete blood counts and a peripheral blood smear examination.

Keywords: *Bleeding disorder, hemorrhage, platelet defects.*

Introduction

Idiopathic thrombocytopenic purpura (ITP) is a bleeding disorder in which there is a significant decrease in the number of thrombocytes in the peripheral blood, resulting in haemorrhage in capillaries and smaller blood vessels which especially seen in the mucosa of the gastro-intestinal tract as well as the genito-urinary tract.[1] The individuals typically have bleeding from the body cavities, including the oral cavity as well as nasal cavity, blood in stool, urine. Rarely there can be intra-cranial haemorrhage and death due to bleeding.[2] The oral manifestations of ITP depend on the severity of the disease, and manifest as petechiae or haemorrhages in the buccal mucosae and the palate.[3] Sometimes haemorrhagic vesicles or bullae are seen with gingival bleeding. [3,4]

Case Report: A 30-year-old male patient reported to the dental hospital with the complaint of bleeding from gums for the past 2 weeks.

History revealed that the bleeding started spontaneously and was continuous in nature and he also had bad smell in the mouth. There was no associated toothache or tooth mobility. This condition was not recurrent and there was no history of bleeding anywhere else in the body.

On physical examination, conjunctival pallor and subconjunctival ecchymosis in the left eye were seen. [Figure 1a] Gingiva appeared oedematous, with loss of stippling and the presence of purpuric spots. Areas of clotted blood were present in the anterior gingiva. [Figure 1b, c&e] Gingiva was soft and bleeding on probing in the absence of any local factors like plaque or calculus. Bleeding was aggravated on pressure. A hematoma was present on the right buccal mucosa and as well as a palatal ecchymosis. [Figure 1d]

Figure 1. Patient with Conjunctival pallor and subconjunctival ecchymosis in the left eye (a) oedematous gingiva with loss of stippling and the presence of purpuric spots (b, c) and areas of clotted blood were present in the anterior gingiva. (e) Presence of a hematoma on the right buccal mucosa (d) and as well as a palatal ecchymosis.

In view of continuous and spontaneous gingival bleeding for a short period of time without any local pathology, fever, weight loss or lymphadenopathy, these may be the oral manifestations of any bleeding disorder, and hence may be provisionally diagnosed as a Haematological disorder.

Haematological investigations were advised:

Table 1: Complete blood count

	Results	Range
White blood cell count	6,800/dl	4000 to 11000/dl
Red blood cell count	2 x 10^6 /dl	4-5 x10^6/dl
Haemoglobin	6gm%	11-16gm%
Haematocrit	24.5	34-48
Mean corpuscular haemoglobin MCH	26.1 pg	26-33 pg
Mean corpuscular volume MCV	91.2fl	78-98 fl
Mean corpuscular haemoglobin concentration MCHC	28.7 g/dl	32-34 g/dl
Red cell distribution width RDW	27.4 %	12-17%
Platelet count	9600/dl	1.5x 10^6-4.5x10^6
Mean platelet volume MPV	8.6fl	7-11fl

Peripheral blood smear revealed normocytic normochromic anaemia. The platelets were scanty and the white blood cells appeared normal in distribution. The bleeding time was prolonged at 8minutes while the clotting time was normal.

Correlating the history, clinical finding and haematological investigations and peripheral smear examination, the gingival bleeding is diagnosed to be the oral manifestation of Thrombocytopaenia.

Discussion

The exact cause of ITP is unknown but the destruction of thrombocytes occurs by different immune mediated mechanisms and there is decreased production of platelets.[4] Depending upon the duration ITP can be classified as acute or chronic and on the basis of age as juvenile or adult types.[5] It has been characterized into 3 types: newly diagnosed, persistent and chronic based on the duration in 2009 by an international working group, from 3 months, 3 months to 1 year and more than 1-year duration.[6] The present case will therefore come in the newly diagnosed category. While ITP in children is self-healing occurring after a viral infection or immunization with the child recovering with 6 months, the adult onset ITP is truly idiopathic and follows a long chronic course and does not show signs of spontaneous resolution.

To diagnose ITP all other secondary causes of thrombocytopaenia have to be excluded, including drugs, leukemia, acquired immune deficiency syndrome, hepatitis, etc.[7] For a confirmatory diagnosis of ITP as per the American society of haematology, patient's history, clinical examination, blood counts and peripheral blood smear examination.[8] The sign and symptoms depend on the severity of the disease, from being asymptomatic to severe bleeding. Easy bruising and bleeding from the mucosae of the oral cavity and gastro-intestinal tract are common, though spontaneous bleeding from multiple sites have been reported. Gingival bleeding, haematuria, epistaxis, malena, menorrhagia and severe haemorrhages in the skin have been seen in patients with a platelet count of below 10,000/µl. [9]

The therapy for ITP patients is aimed at controlling the bleeding as well as increasing the number of platelets in the circulation. When the platelet count is between 20x 10^3 and 50x 10^3 without any haemorrhagic complications, then no treatment is needed. However, if the patients are hypertensive, have cardiac disease and are on anticoagulants or need to undergo surgery, then the platelet count has to be elevated by transfusion. [10] The therapy comprises of targeting the immune

mechanisms behind the disease with glucocorticoids, intravenous immunoglobulins and anti-D antibodies. [11] Some patients may not respond to steroids or immunoglobulins and may need specific thrombopoietin receptor agonists like Eltrombopag and Romiplostim.[12]

Conclusion

In conclusion, it may be emphasized that often intra-oral haemorrhagic manifestations are the sole manifestations of ITP and are diagnosed by the oral physicians. Hence unusual gingival bleeding, haemorrhagic vesicles, haematomas in the oral mucosa warrant immediate haematologic evaluation for diagnosis and haematologist referrals.

Customized Ocular Prosthesis: A Case Report

Gopal Krishna Choudhury[1], Bodhisatta Mukherjee[2], Abhijita Mohapatra[3], Mirna Gharnayak[3], Upasana Panda[2]

[1]Professor & Head, [2]Post Graduate Trainee, [3]Professor, Department, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar

Abstract

Loss of eye might be acquired or congenital. Congenital anomaly or pathology may require surgical intervention and removal of eyeball. Stock ocular prosthesis are readily available in market, stock prosthesis has some disadvantages such as ill-fit, improper shade matching, etc. whereas the custom-made ocular prosthesis has better adaptability, better movement of the eyeball and iris position can be matched with the adjacent eye. This article describes a case report of replacing left eye with ocular prosthesis of a lady patient and improving her well-being. Distribution of force of the tissue bed and co-ordinated movement of the prosthetic eye makes the prosthesis much more acceptable and real like.

Keywords: *Congenital anomaly; Rehabilitation; Ocular prosthesis; Prosthetic eye.*

Introduction

One of the finest senses of human being are the pair of eyes. Beauty of a face lies in the eyes of an individual. Loss of eye might be acquired or congenital. Congenital anomaly or pathology may require surgical intervention and removal of eyeball. (1) The surgical removal of an eye are classified by Peyman, Saunders and Goldberg (1987) into three types: Evisceration (where the contents of the eyeball are removed leaving the sclera intact), Enucleation (most common, where the entire eyeball is removed after severing the muscles and the optic nerve) and Exenteration (where the entire contents of the orbit including the eyelids and the surrounding tissues are removed).(4) The loss of an eye can cause social, physical, psychological impact on the affected patients.(2) Maxillofacial Prosthetics is that branch of prosthodontics that deals with rehabilitation of lost orofacial structures, building confidence and well-being of the patient.(2) Social acceptance, physical and psychological acceptance can only be promoted by immediate replacement of the lost eye.(4) Anophthalmia socket can lead to growth retardation and disfigurement of the face(4). Ocularprosthesis is a maxillofacial prosthesis that artificially replaces an eye missing as a result of trauma, surgery, or congenital absence; the prosthesis does not replace missing eyelids or adjacent skin, mucosa or muscle(7). Ocular prosthesis can be either stock or custom made. Stock ocular prosthesis are readily available in market, stock prosthesis have some disadvantages such as ill-fit, improper shade matching, etc. whereas the custom made ocular prosthesis has better adaptability, better movement of the eyeball and iris position can be matched with the adjacent eye.(1) Nobel metals andprecious stone were used as ocular prosthesis back in Egyptian and roman civilisation. Stock glass eyes were very popular in Germany and European Nation. But during second World War there was extreme scarcity of eye glasses, then dental acrylic took its position replacing the glass eye in United States Naval School.(3) This case report describes about custom made ocular prosthesis fabricated for a young female patient to restore her well-being.

Case Report: A lady aged 22 years came to Department of Prosthodontics, Crown and Bridge, Institute of Dental Science, SOA University, Bhubaneswar had been referred from the Department of Ophthalmology, IMS & SUM Hospital, SOA University, Bhubaneswar, after evisceration surgery of the left eye

[Fig No. 1]. On history taking patient informed that she had undergone an injury to the left eye from pressure cooker burst. The patient was carefully examined before deciding the treatment option, whether the operated area had healed or not. After examining the entire procedure of treatment for the prosthesis was described to the patient. On approval of the treatment by the patient, customised tray is fabricated by visible light cured denture base resin which is attached to a syringe needle cap [Fig No 2]. Holes were made on the custom tray to provide retention to the light body impression material. The cured custom tray was polished with sand paper and pumice stone and was tried in the patient eye. When the tray was found to proper and comfortable to the patient, light body impression material (3m) was injected in to a syringe from the auto mixing tip, the syringe was placed on the needle cap attached to the custom impression tray and the impression material was introduced inside the custom tray [Fig No 3]. The patient was asked to move the eyes in all possible directions, adequate time was given for the light body to set. [Fig. No. 4].The impression then carefully removed from the eye. A rubber bowl was taken and reversible hydrocolloid material (plastagin; septodont) was mixed in that bowl. The impression removed from the eye was dipped in the alginate material mixed in the bowl and waited till set. The set reversible hydrocolloid was cut carefully and the impression was removed. The area achieved in the reversible hydrocolloid was filled with white coloured inlay wax and was allowed to set. The wax thus achieved will acts as a future sclera, is tried in the patient's eye and was checked whether the patient's eye lid approximating or not. After manipulation of the wax sclera and through examination, iris was placed in the wax sclera guided with marked leucoplast on the fore head [Fig. No5]. The syringe needle cap was glued to the iris and was flasked with plaster of paris. Then dewaxing procedure followed, after dewaxing the mould was packed with heat cured white coloured Poly-methyl methacrylate DPI Tooth Moulding Powder; Dental Products of India LTD. After bench curing, curing was done, and polished. Disinfection of the prosthesis was done with 70% isopropyl alcohol and 0.5% chlorhexidine solution, after disinfection the prosthesis is cleaned with and rinsed thoroughly with saline water to prevent irritation to the underlying tissue. After insertion of the prosthesis movement and fit of the prosthesis was checked [Fig. No. 6]. equally on the tissue bed but also mimic the movements of the eyeball.

Fig. No. 1: Patient before prosthesis

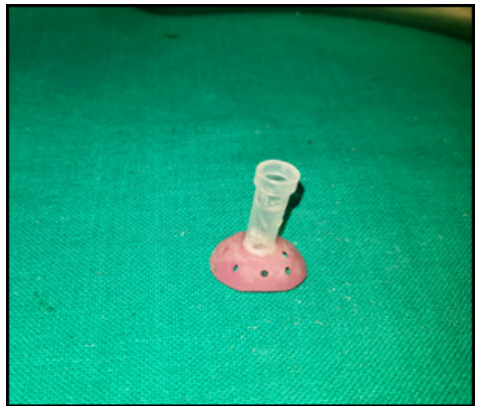

Fig. No. 2: Customized tray with needle cap attached

Fig. No. 3: Impression material was introduced inside the custom tray

Fig. No. 4: Movement of the eyeball was recorded

Fig. No.: 5: Sclera fit checked with marked leukoplast

Fig. No. 6: Prosthesis Placed

Discussion

Custom made ocular prosthesis fits accurately with the defect and reproduce the movement of the eyeball. Replication of ocular prosthesis with the adjacent eye can be very well matched with the custom made procedure whereas stock eye shells lacks the fit and movement replication.[1] According to Beumer*et al*., intimate contact between the ocular prosthesis and the tissue bed is needed to distribute even pressure, so a prefabricated prosthesis should be avoided.(6)custom made ocular prosthesis helps to add characterisation and stating which make it look life-like and due to functional recording of the defect movements of the prosthesis very smooth.Custom ocular prosthesis provides more eyelid competency than stock prosthesis. (3)

Conclusion

Rehabilitation to normal of a patient who has undergone evisceration surgery of eyecan be achieved by restoring the function andesthetics. Custom made prosthesis having natural appearance and excellent adaptability increases the confidence of the patient and aids in adding the well-being of the patient. Custom made ocular prosthesis not only distribute the force

A Versatile Material for Dental Applications: PEEK

Debarchita Sarangi

Assistant Professor, Department of Prosthodontics and Crown & Bridge, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha

Abstract

The need of good dental materials makes the material scientists to continuously experiment and innovate new materials. There are three basic requirements of a material i.e. they should have good mechanical properties, esthetic properties and should be bio-compatible. Polyether Ether Ketone (PEEK) is very close to satisfy all these properties for which it has been used in numerous clinical situations. This article is a review of properties, utility in conventional situations and additive manufacturing and about the limitations of PEEK, as a dental material.

Keywords: *PEEK, Polymer, Polyether Ether Ketone, Dental Application, Dental Implant.*

Introduction

Polyetheretherketone (PEEK) was developed by a team of English scientists in 1978 and was applied for industrial use. It was used as a material of the interbody fusion cage in vertebral surgery during the late 1990s.[1] This material has been widely used in automotive, chemical and electronics works. PEEK exhibits good biocompatibility and mechanical properties, resistant to high temperature, resistant to chemical wear. All these properties are available in PEEK material, thus making it suitable for use in dentistry.[2]

PEEK is a thermoplastic,semi crystalline material with a linear structure (-C6H4-OC6H4-O-C6H4-CO-) n. It is polycyclic and aromatic in nature. The binding of ketone and ether functional groups in between aryl rings produces PEEK. It is white in color, unlike the tan color in pure-form.[3] Etheretherketone is the monomer unit. Step-growth dialkylation reaction of bis-phenolates occur to form the polymer polyetherether-ketone. 4,40 difluorobenzophenone reacts with disodium salt of hydroquinone in a polar solvent such as diphenyl sulphone at 300 degrees C to synthesize PEEK. Addition of functionalized monomers before polymerization or sulphonation, amination and nitration after polymerization modify the material.[4]

Properties: PEEK is a sulfonated thermoplastic, used by injection molding. Its Young's modulus is 3.6 GPa which is close to that of human bone, enamel and dentin.[5] Tensile is Strength is 90-100 MPa.[6] Thermal conductivity 0.25 W/m K. Thermal stability up to 335.8°C.[7,8] Flexural modulus is 140-170 MPa and density – 1300 kg/m^3 i.e. it is a very light material. PEEK exhibits stability at high temperatures (like sterilization processes); resistance to most substances apart from deconcentrated sulfuric acid and resistance to wear. It is non-toxic, non-allergic and exhibits low plaque affinity, thus making it one of the best bio-compatible dental materials. It has least solubility and has least water absorption values compared to poly methyl methacrylate PMMA and composite resin.[9] PEEK Young's modulus can be increased with the addition of carbon fibers.[10,11]

Clinical Applications:

A. **Removable Partial Denture Frameworks:** PEEK is a good esthetic alternative to cobalt-chromium clasps due to its white color even though it has less retentive strength. It also does not produce any metallic taste, allergic reactions and also is light weight. It can be used an alternative to artificial teeth, when used in combination with polymer. The property of low plaque affinity makes it a hygienic option. Torque and the stress on abutment are reduced in distal extension cases as the material is elastic in nature.[3,7,12]

B. **Indirect Restorations:** PEEK bonds to composites with very less surface abrasions. This property is utilized in resin-bonded bridges produced from PEEK material.[13] Surface roughening can be done with acetone, phosphate-based methacrylate linings or tribochemicals. Only Sulfuric acid or a mixture of sulfuric acid and hydrogen peroxide roughen

the PEEK surface and sand-blasting increases the wettability.[14,15] PEEK can be also used in fabrication of CAD-CAM framework.[16]

C. **Fixed Partial Denture Frameworks:** PEEK restorations were able to bear masticatory forces 300 N in the anterior region and 500-600N in the posterior regions.[17] It is a suitable option for patients with metal allergy and sensitivity to metallic taste.[12,13] PEEK is also more bio-compatible than Porcelain-Fixed to Metal restorations and is less reactive with other materials.It is highly resistant to wear also .[3]

D. **Implants and Implant Abutments:** The first dental application of PEEK was its use as an esthetic abutment in 1992. Later, it was used as an implant material.[2] The elastic moduli of bone are nearly the same as that of PEEK. This property would reduce the stresses occurring on the bone i.e. would have stress shielding effects which in turn would result in bone remodeling and also would protect the bone. Numerous cases have been reported with use of PEEK in implantology like gingival formers,abutments, implant-supported prostheses due to the properties exhibited by PEEK. The surfaces can be easily modified to improve osteo-conductive activities. Nano-modifications can be done in different techniques to achieve better osseo-integration. There is homogenous distribution of stress in the bone- implant interface due to its iso-elasticity property. They have shown good strength, fracture resistance and satisfactory bio inertness.[2,3,7]

E. **Orthodontic Wires:** PEEK is used as orthodontic wire due to higher strength compared to polyethylene sulfone (PES) and polyvinyl difluoride (PVDF). The orthodontic forces generated are similar to that of titanium-molybdenum (Ti-Mo) and nickel-titanium (Ni-Ti) wires.[3]

F. **Peek as Maxillofacial Prosthesis:** There have been very limited reported maxillo-facial cases, using PEEK,But the properties of PEEK can be utilized for successful esthetic, functional outcome for patients.[2,18]

Peek in Additive Manufacturing: Additive manufacturing is an industrial method utilized in dentistry to create customized 3D printed models,implants, prostheses, guides, etc. with the assistance of 3D printing technologies, scanners and software. PEEK is a compatible material for 3-D printing.[19]

Conclusion

PEEK has mechanical properties close to that of dentin and bone. The color of this material makes it esthetically acceptable. It is light-weight and has less plaque adherence. It can be easily modified. This material is compatible with CAD-CAM technology and most importantly, 3-D printing. The use of this material can be an economic solution for the clinician and the patient. These altogether make PEEK a potential replacement for conventional materials. With the support of further research, this material can be utilized in fields like maxillo-facial prosthodontics, endodontics and other branches of dentistry.

Oral Health Challenges During Pregnancy

Saplin Pradhan

Intern (BDS), Institute of Dental Sciences,Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Pregnancy is a vehement phase that leads to physiologic transitory changes in various systems of the body which also includes the oral cavity. Any dental treatment must not be withheld for maintaining good oral health. Special considerations are involved in dental supervision for pregnant women. The following review article explains some general dental issues that a pregnant lady has to face alongside the danger of several medications for both the mother and the fetus and; all the treatment implications that are suitable for the pregnant patients. In addition, supervision and execution of the associated dental issues in pregnant women and a proper time management of the surgical dental conduct during the period of pregnancy has been discussed.

Keywords: *Pregnant woman, Dental problems, Oral care.*

Introduction

Pregnancy is phase of physiological predicament which carries out several alterations in the oral cavity with other physiologic reversals that take place throughout the body of a lady.[1] Generally, it is known of a phase when women strive to be precisely knowledgeable about the urgency for what should be done in order to accomplish topmost extent of the well-being for herself and her developing child. In addition, most of the women are not very much known about the existing relation present between their general and oral health. Role of the steep levels of flowing estrogen hormones is well established which is correlated with high predominance of gingival hyperplasia and gingivitis.[2] In the serum, progesterone is also found to associate with melasma, demonstrating brown patches or pigmentation present bilaterally in middle region of face.[2] A common view of the physiological changes in the various systems of the body during pregnancy is described in Figure1.

Despite of all these goals, neglecting oral health is very common during pregnancy. Several studies have found evidence that links together the pregnancy outcomes, low maternal oral well-being with dental well-being of the child.[3] These may extend from low birth weight and preterm delivery to greater risks such as early childhood caries in case of infants. Disease prevention, oral health promotion, timely intervention and early detection are important features for both maternal and oral health of the offspring.[4] Plenty, if not all preventive and routine dental treatments can be performed securely with certain precautions throughout the period of pregnancy is widely established.

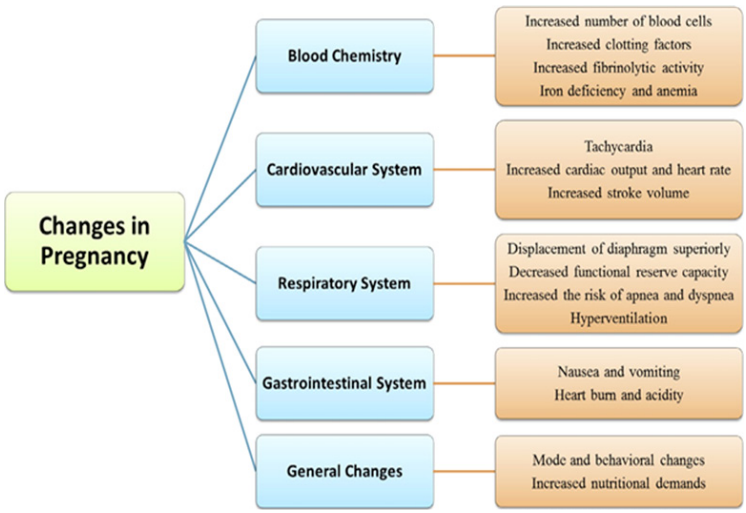

Figure 1. Key physiological changes observed in various body systems during pregnancy[5]

Management of Dental problems during Pregnancy: During pregnancy, the oral cavity also exhibits a number of changes like any other system (Figure 2), therefore, special care and action is required by the dentists. Some generalized dental problems and their management are mentioned below that the pregnant women face.

(a) Dental Caries: Pregnant patients are most likely to have dental caries because of acidic environment upsurge in their oral cavity, increased sugary diet consumption and negligence towards their oral health.[6] The acidic environment in the oral cavity is enhanced by the recurrent vomiting that is common in pregnancy which leads to progression of carious microorganisms and increased demineralization that makes teeth more likely to have caries.[7] The untreated dental caries lead to an increased occurrence of cellulitis and abscess.

Thus, it is advised by the dentists to limit the sugary diet for pregnant women, brush with toothpaste containing fluoride regularly and to use over the counter mouthwash that are fluoridated in order to counteract the demineralization of teeth caused due to vomiting. The purpose of topical fluoride applications for the prevention of dental caries is widely accepted.[8] Some restorative materials that release fluoride for example glass ionomer can prevent the growth of secondary caries.[8] Also, drugs eg. methamphetamine should be avoided which may aid to exasperation of dental caries.

(b) Gingivitis: Tender bleeding gums or gingivitis is one of the general dental problems which adds to around 60-70% of pregnant patients. These conditions are more common due to the fluctuations of progesterone and estrogen hormones, decrease in the immune response and changes in the natural oral flora.[9]

The commendations for improving the condition comprises of professional oral prophylaxis i.e. scaling, root planning and polishing, brushing twice daily with fluoridated toothpastes and flossing, saline mouth rinses in order to help in easing the irritant. For an added benefit, chlorhexidine mouth rinses may also be advised.[10]

(c) Periodontal Disease: About 30% of the pregnant patients experience some or the other periodontal disease.[11] While appearance of the increased levels of estrogen in larger predominance of gingival hyperplasia and gingivitis is well established at the time of pregnancy, the correalation between oral infections such as periodontitis and pregnancy need further investigation.[2] The act of the higher levels of the inflammatory markers such as interleukin 8, interleukin 6 and prostaglandin 2 are formed in amniotic fluid of the pregnant patients having periodontal infections, which can be considerably correlated with low birth weight and premature labor.[12]

Current data demonstrates evidently that scaling and root planning can be regarded secured at the time of pregnancy which enhances both the maternal health and health of the neonate.[12] The execution method in order to conquer the periodontal infections in pregnant women enfolds accurate diagnosis by the dentists, deep scaling/root planning and daily prescription of 0.12% chlorhexidine mouthwashes so as to restrict the progression of diseases. Chlorhexidine is classified to be FDA Class B and considered secured to be practiced in pregnant patients.[13]

(d) Tooth Erosion: This is one more undesirable dental issue that is regarded to occur due to pregnancy persuaded vomiting. The fact is accepted that the dental erosion may effectively be restrained with application of a compound that contains sodium bicarbonate which neutralizes acid and forbids kind of dental damages.[14]

It is advisable to discuss with the patient's specialist and gastroenterologist in order to manage all the relevant medical circumstances.

(e) Tooth mobility: Mineral alteration takes place in the lamina dura because of the hormonal rush and the disruption in attachment of periodontal ligament influence mobility of teeth which further leads to the periodontal diseases.[15]

This condition of the gingiva can be made reversible by the removal of local gingival irritants along with prescription of therapeutic doses of vitamin C.[16]

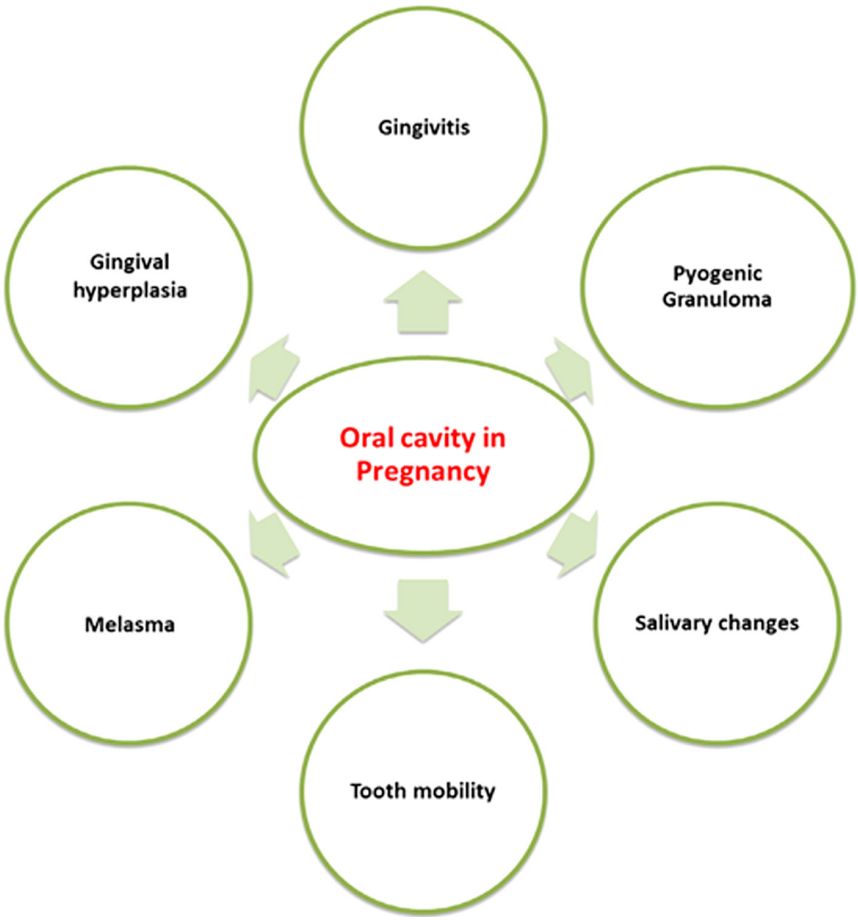

Figure 2. Key oral cavity changes and conditions in pregnancy[5]

Guidelines for oral health management in Pregnancy: Dental and oral health management is treated as one of the very important aspect in pregnant patients. To estimate the patient's present dental situation is recommended and then the patient is required to be educated about all the familiar changes at the time of her pregnancy and the measures to avoid any kind of pain and distress that can be helpful. During the second and third trimester, no harm is caused due to the dental examination and treatment in contrast to being left untreated, for example, infant caries can be caused due to dental decay at a subsequent stage.[17] Other such procedures as restorations and extractions, periodontal therapy and diagnosis do not cause any harm and are suggested to be executed during second trimester as organogenesis is expected to be completed by then.

(a) First trimester: The first trimester is considerably not the appropriate time for performing all the dental procedures. During this period, organogenesis takes place and the fetus is more likely to face danger of teratogens. Also, there is increased danger of instinctive abortions. The following guidelines are to be followed:

- Patient must be informed about all the changes that take place.
- The directions given to retain the oral hygiene should be followed.
- The therapy performed should be confined to emergency treatment and oral prophylaxis.
- Periodic radiographs should be avoided.

(b) Second trimester: The organogenesis phase gets completed in this trimester and procedures for example developing dento-alveolar and any other elective procedures are unharmed to be performed. The following are the recommendations during this phase:

- The oral hygiene should be maintained along with plaque control.
- If necessary; scaling, polishing and curettage is safe to be performed.

- The active oral diseases need to be restrained.
- Elective procedures such as restorations, root canal and extractions are also safe to be performed.

(c) Third trimester: During the third trimester, short dental procedures are appropriate to be performed as the fetus is not at a significant risk. However, there is an increase in danger of uneasiness to the pregnant woman which can be reduced by proper positioning to a larger extent (Fig.4). The middle third of the trimester is the recommended time for the procedures to be performed. The following are the measures suggested during the third trimester:

- The oral hygiene should be maintained along with plaque control.
- If necessary; scaling, polishing and curettage is safe to be performed.
- The active oral diseases need to be restrained.
- The use of radiographs should be reduced.
- After the mid time of third trimester any procedure should not be performed.

Suitable timings for treatment and dental management: At any stage of pregnancy; scaling, root planning and polishing are recommended in order to conserve and improve oral health.[18] However, to execute the common dental measures is strictly advised such as elective extractions, endodontic treatment and routine restorations after organogenesis of the fetus has taken place. Lengthy and extensive dental treatments must be delayed till delivery.[2] The treatment procedures should particularly target on prohibition of the oral infections with periodic care and follow up of the current infection (Fig.3).

Figure 3. Key oral health care measures that are adopted during pregnancy[5]

Dental Chair Positioning in Pregnancy: It is very important while performing chair side procedures that pregnant women are in a secured and appropriate seated space (Fig. 4) which aids to avoid complications for example supine hypotensive syndrome on the dental chair. If a pregnant woman, for example, is seated in a supine position, chances are high for an abnormal arterial oxygen gradient and progression to medium hypoxemia. Similarly, there is a danger of compression of aorta and vena cava due to gestating uterus which leads to postural hypotension. Thus, it is necessary for the dealing dental health care professional to get her seated in the correct

setting i.e. by placing a tilt of 5-15% on the left side of the patient or make her seated with an elevation of 10-12cm of her right hip so that the pressure is reduced on the vena cava. The pregnant woman could be advised to be seated in a full left lateral position if hypotension is not reconciled. However, these alterations are suggested during the third trimester.[7]

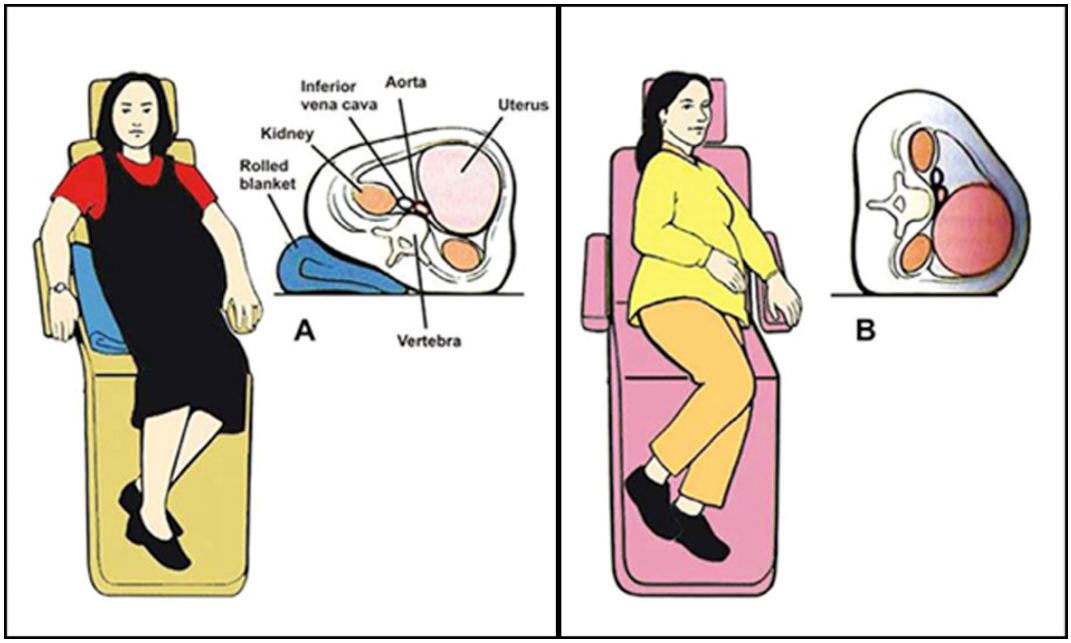

Figure 4. Schematic representation of correct chair positioning of pregnant patients[5]

Table 1 FDA risk categories of drug used during pregnancy and their potential risk factors.

Category	Risk factors	Antibiotics	Analgesics	Sedative hypnotics	Local anesthetics

		Nitrous oxide (avoided in the first trimester as it may result in neonatal depression and spontaneous abortion)			

Pharmacodynamics in Pregnancy: Pregnancy is a phase which has a decline in maximum plasma concentration, high volume of drug distribution, reduced plasma half-life, acceleration in rate of clearance and lipid solubility.[15] Such dynamics compromise the health of the fetus by contributing a quick entry of several drugs through placenta. These drugs, in addition, can lead to teratogenicity, low birth weight and further adverse effects may lead to abortion. The usage of drugs during this phase is therefore not advised, especially in the first trimester i.e. first 13 weeks. For a safer approach because of the potential adverse effects, drugs have

been classified on the basis of hazards and risks to the developing child.[4] "Food and Drug Administration (FDA), USA has categorized drugs on the basis of their potential risk factors during pregnancy" (Table.1).[5]

(a) Analgesics: Analgesics are practised for a limited span or short term period to minimize, heal and treat the commotion of pain. The acetaminophen is the safest and most general analgesic advised in pregnancy which is classified in Group B in FDA categorization.[19] Hepatotoxicity is the most recorded acetaminophen reaction. Due to their different formulations availability, to exceed more than a 4 grams per day is not advisable for a pregnant woman.[19] Other analgesics for example ibuprofen categorized in the category B categorization in first and second trimesters while in the third trimester, it changes to category D as this drug is correlated with immature heart valve termination, lower amniotic fluid and restricts vaginal opening at the time of labor.[13] Acetaminophen with codeine or oxycodone should be recommended by the dentist but is not suggestive of prolonged use as this may lead to neonatal abjection. This is probably not a thing to get concerned since the dose administration is approved customarily in association with dental therapy.[19]

(b) Antibiotics: Most of the authorized antibiotics fit to category B in FDA categorization with exception of doxycycline and gentamicin both of which fit into category D (Table.1). Fetal ototoxicity has been reported to cause by gentamicin whereas tetracycline stains in teeth and the adverse outcomes on developing bones is caused by doxycycline and its derivatives. A broad-spectrum antibiotic, ciprofloxacin is generally recommended for periodontal infections. Recent advancing evince is suggestive of the drug being convoluted in arthropathy and having serious consequences on developing cartilages thus should not be prescribed to pregnant patients.[20] Metronidazole categorized in group B has teratogenic effects which is also prohibited to use.[21]

(c) Local and General anesthetics: The localized practice of anesthesia, when administered accurately and with specific dose is considered safe. The anesthetic solutions like, prilocaine and lidocaine are classified under class B while epinephrine, bupivacaine and mepivacaine fit into class C in FDA categorization.[13] Epinephrine when administered with local anesthetsia through an intravenous pathway, theoretically, it may be correlated to a deficiency of utero-placental blood movement but the recorded cases in healthy pregnant ladies are 1:1,00,000.[21] The epinephrine concentration in local anesthetics administered in dental procedures is to be declared secured after there is an evaluation of pregnancy and the probable risk elements.

Conclusion

Pregnancy should not be acknowledged as the sheer inference in order to postpone the requisite dental treatment. Oral health care at the time of pregnancy is really crucial which comprises of input of patient herself, physicians and the dentists. The pregnant women must be properly educated about the expected changes in oral cavity, importance of good oral hygiene and regular dental check-ups. The dentists should be knowledgeable of the modernized updates about circumstances associated with pregnancy and appropriate execution without causing any inconvenience to the mother or the fetus. Consultation and referral to the patient's gynecologist or a specialist must be done considering top zone of the patient's requirement. Drug regimen must be accomplished presisely and should be limited. It is the best to abstain from any kind of radiography and electotal surgery. Expecting females or female women of parturiency age must be quarantined for oral diseases and caries for appropriate management.

Life Threatening Effects of Oral Habits

Anwesha Ray[1], Diksha Mohapatra[1]

[1]Intern, Institute of Dental Sciences, Shiksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

An oral habit is a practice which may be constant or may be occasional, that has been acquired by frequent repetition. Life threatening oral habits can be either tobacco involving habits or non-tobacco involving habits. Most of the life-threatening diseases occurring due to oral habits have aetiology of tobacco usage with few instances of non-tobacco induced. Tobacco whether consumed as smoked form or smokeless form, affects the human body in one way or the other. These habits developed by the body can be peer pressure induced, stress induced, can be due to social stigma or can even be a habit that once started as an adventure has now converted into a compulsion. Favourably there are various therapies available for managing tobacco abuse that can ultimately curb the deadly situation arising after tobacco use, hence decreasing the rate of occurrence of various preventable diseases as well as increasing the life expectancy of the masses. This review article focuses on the various tobacco and non-tobacco induced oral habits that can be life threatening for the human body, consequences of these habits, their treatment and management.

Keywords: *Habits, Tobacco, Smoking, Oral cancer.*

Introduction

An oral habit is a practice which may be constant or may be occasional, that has been acquired by frequent repetition.[1] An individual develops oral habits either due to mental stress, peer pressure, social stigma or as a custom that once started as a thrill or an adventure and gradually got converted into a compulsion. Some habits such as nasal breathing can be helpful for an individual, but on the other hand thumb sucking and tongue thrusting are considered to be harmful, whereas, lip biting and cheek biting can be life threatening.

Life threatening oral habits can be either tobacco involving habits or non-tobacco involving habits. Tobacco involving habits can involve consumption either as smoked form or in smokeless form. Smoked form of tobacco consumption includes bidi, chillum, chutta, cigarettes, dhumti, hookah and hookli. Smokeless tobacco consumption forms are khaini, Manipuri tobacco, mawa, mishri, paan, snuff, zarda, gutka, pan masala and gudakhu.[2] In India smokeless tobacco consumption is more amongst the mass than smoked form of tobacco. Uses of smokeless tobacco is more in the eastern and central zone than other places. North-eastern states have equal consumption rates of both smoked and smokeless forms. The rate of tobacco consumption habit is seen more in males than females in the Indian sub-continent. Various studies indicated that tobacco consumption rate is more in males, poor, uneducated masses and the backward sections of the society. They even lack the resourses required for treatement of detoriating health issues which are seen further after.[12] Non-tobacco induced habits like cheek biting and lip biting can be life threatening for the human body.These habits mostly have a history of psychological issues, but help of a physician can be useful for an individual who is willing to give up the practice.

Tobacco Habits

Preparation and Components of Tobacco: Tobacco is prepared from the cured leaves of several plants in the Nicotiana genus and the Solanaceae family. Tobacco is the reason behind maximum number of preventable deaths that occurs across the world. It is

estimated that tobacco contains around 4000 compounds which are proven toxic, mutagenic and carcinogenic. Out of the various known carcinogens, forty-three itself are found to be in tobacco smoke only. In India, tobacco was 1st brought by Portugese traders in the late 16th and early 17th century. With the Introduction of hookah during the Mughal rule, tobacco smoking became a symbol of aristocracy. Use of tobacco is associated with many harmful diseases like cancer, cardiopulmonary diseases and many health problems.

Nicotine, tar, carbon monoxide, nitrogen oxides and hydrogen cyanide are some of the components found in tobacco that have deadly effects on the body.

Nicotene is the most toxic component in tobacco. It is the reason behind the tobacco smoke, for which the smokers get addicted to it. Nicotene releases Dopamine from the human brain which is also known as pleasure hormone, which is the reason why the consumer has a feeling of euphoria after intake of tobacco. The particulate matter inhaled by the smoker is known as tar which consists of nitrogen, oxygen, hydrogen, carbon dioxide, carbon monoxide and volatile and semi volatile organic chemicals. Hydrogen cyanide in tobacco has a deleterious effect on cilia which forms the inner lining of the respiratory system. Metals like Nickel, Cadmium which are carcinogenic are also found in tobacco along with the clear presence of radioactive compounds such as polonium-210, potassium-40, radium-226, radium-228 and thorium-228.

Smoked Tobacco and its Consequences: Tobacco which is consumed in smoked form consists of two types of smoke, which are 'side stream smoke' and 'main stream smoke'. Side stream smoke is produced from the burning tip of the cigarette, whereas main stream smoke is formed from the filter present in mouth end of cigarette. Bidi is one of the traditional practices of smoking tobacco in India, which was introduced in the 19th century. About 34% of tobacco produced in India goes for manufacturing of bidi. Cigarette smoking is more common in the urban belt whereas bidi is found to be more prevalent in the rural areas and amongst the backward classes of the society.

Hindu monks also known as 'Sadhus' are seen snuffing tobacco smoke from a 10-14cm long, straight, conical clay pipe known as chillum which dates back its origin to the 18th century. Another common form of smoking tobacco are cigarettes in which 1gm of sun dried or artificially heated tobacco is wrapped with a paper. Along with tobacco, sugars, aromatic agents and flavouring are added, but, the harmful effects of tobacco remaining the same. Smoking increases gingival inflammation, periodontal damage, with increased pocket dept, bone loss and attachment loss. Severity of periodontal disease is directly proportional to the rate of smoking.[7] Aggressive periodontal damage is seen in case of smokers as the host-bacterial interactions get aggravated in smokers as compared to non-smokers. There is marked alteration in neutrophil count, rate of phagocytosis with increased chemotaxis and respiratory burst. Increased production of PGE_2 and increased level of TNF-alpha is seen in Gingival Cervicular Fluid (GCF).[4] Initially smoking causes a nicotine related transient increase in gingival fluid flow rate and decreased vascularity of gingival due to prolonged vasoconstriction. As a result, there is difficulty for the physician to find out gingivitis in early stages. Women who are addicted to smoking have a higher risk of developing miscarriage, sudden unexpected death of infants, premature birth, ectopic pregnancies or complications during childbirth. Newer studies have suggested that smoking is one of the major risk factors behind tuberculosis in India. It is seen that chances of occurrences of tuberculosis is three times more potent in smokers than non-smokers.[5]

Now day's youngsters are seen trending use of e-cigarettes or electronic cigarettes popularly known amongst them as ENDS and hookahs which can be easily purchased from markets and internet. Smoking is stimulated by handheld battery powered vaporizer in e-cigarettes that provides the same aspects as smoking but without burning tobacco. It produces an aerosol-based component known as 'Vapor' instead of the smoke as produced by traditional cigarettes.[11]Studies have revealed that youngsters using e-cigarettes are more prone to opening the gateway towards developing the habit of using regular cigarettes later in their life. ENDS or e-cigarettes have been announced causing DNA damage, cellular, molecular and immunological toxicity along with being carcinogenic with cardiovascular, respiratory and neurological disturbances with known foetal damages during pregnancy.

Smoking tobacco not only has an adverse effect on smokers, but can also affect the health of passive smokers.[3] People who smoke tobacco with the 'mouth end' of the pipe attached to their mouth are known as active smokers, whereas the other individuals present in the same environment in which the smoke spreads

are known as passive smokers. Passive smokers also have a greater chance of showing health risks like increased chances of occurrence of lung cancer and heart diseases like stroke and respiratory illness like asthma, bronchitis and pneumonia. Compounds like ammonia, formaldehyde and sulphur causes irritation in the eyes, throat, nose and lungs.

Smokeless Tobacco and its Consequences: Smokeless tobacco is consumed in two different forms-chewable form and snuffed of tobacco. In India the various forms of chewable tobacco are khaini, Manipuri tobacco, mawa, paan, zarda, gutka and pan masala out of which Paan chewing being the commonest form. Paan also known as betel leaf is derived from the Sanskrit word 'Parna' meaning leaf. The presence of paan is not only seen in Indian Mythological texts but also in Ayurveda due to its medicinal values. These leaves are a rich source of vitamins like, Vitamin-C, niacin, thiamine, riboflavin and carotene with a considerable part of calcium too. Paan leaves are not harmful for the body, but additional consumption of ingredients like areca nut, tobacco and lime makes its after effects worse.

When tobacco leaves are sundried or heat dried and inhaled through the nasal cavity it is known as snuff that shows remarkable morphological and functional changes in the constituency of nasal mucosa. Another form of smokeless tobacco commonly seen in eastern India is gudakhu. It is a paste of powdered tobacco mixed with molasses, red kharia, jiggery and other ingredients primarily used for cleaning the tooth.

These varieties of tobacco are greatly associated with an increased risk causing oral carcinomas. It slows down wound healing after dental surgery, induces periodontal diseases,bad breath and other forms of oral infections. Smokeless tobacco not only causes oral cancers like squamous cell carcinomas, verrucous carcinomas, salivary gland carcinomas, lymphoma, leukoplakia, erythroplakia, or lip cancer but also enhances the chances of pharyngeal cancer and oesophageal cancer.

Non-Tobacco Habits and Consequences: Some of the non-tobacco habits that can be injurious for the health are lip biting habits and cheek biting habits. Lip biting or lip sucking habits can be due to malocclusion or emotional stress. Anatomy of the normal lip carries out many important functions like speaking,eating and maintaining a balanced occlusion but these deleterious habits can lead to protrusion of upper incisiors, retrusion of lower incisors,lip trap,muscular imbalance,redness of the lip and in severe cases ulceration,bleedings and blisters formation.[6] Morsicatiobuccarum commonly known as cheek biting or cheek chewing is considered to be a body-focused repetitive behaviour (BFRB) which is an anxiety related problem. BFRBs is an anxiety related behaviour that is repeatedly reduced by the body even after the individual tries to stop it. It mostly starts in childhood and continued through adulthood. Cheek bite can cause damage to the buccal mucosa leading to mouth soreness and formation of ulcers. Studies have shown that continuous mechanical irritation to the buccal mucosa from the teeth can promote oral carcinoma induced from other agents.

Therapies for Habit Cessation: An individual can develop a habit either due to stress, peer pressure or social stigma. This developed habit can be curbed by behavioural therapies as well as medical therapies. People should be made awareness of these deleterious habits which can be harmful for the body later in their life in some way or the other. Initiatives should be taken by government agencies and non-government organisations to spread awareness across world wide area. Habit cessation in a larger extent can reduce risk of occurrences of preventable life-threatening diseases. Dental physicians play a crucial role in helping patients for quitting tobacco induced habits. They can council the patients, influence them to live a tobacco free healthy lifestyle by showing them the actual effects and dangers of tobacco in the oral cavity.[8] Various guidelines are also available for counselling the patients which can also be helpful in providing guidance. In case of tobacco induced habits various medical aids are available to prevent them. Nicotine present in tobacco is the main reason behind tobacco addiction. This can be prevented by using nicotine replacement therapies like nicotine gums,nicotine inhalers,[10] nicotine patches,nicotine nasal sprays and nicotine lozenges. In case of stress induced tobacco habits, anti-depressants can be helpful in patients who have tried a several times to quit the habit but have been unsuccessful.

Lip biting and cheek biting is usually stress induced. In order to avoid it authorised physician help is beneficial. Psychological counselling, stress management through conservative or medical therapy and behaviour management can be essential. Dental physician also plays a crucial role in managing this non-tobacco induced habit. Removable crib and vestibular screen can be used to avoid cheek biting habit as well as

lip biting. If lip biting is seen due to malocclusion then help of an Orthodontist and dento-facial orthopaedic can be beneficial.[9]

Conclusion

Deleterious oral habits as a whole or as a part has a considerable effect on oral health. Even if a life-threatening condition does not persist in the oral cavity, a dental physician can easily recognise the presence of these deleterious habits from the physiological and anatomical changes that occurs in the mouth due to the occasional or persistent practice of these habits. In such case the individual should be made aware of the consequences that may arise in the future.

Smoking Cessation: The Aromatherapy Way

Rinkee Mohanty[1], Rashmita Nayak[2], Gatha Mohanty[3], Abhaya Chandra Das[4], Saurav Panda[4]

[1]Professor and Head, [2]Professor, [3]Senior Lecturer, [4]Reader, Department of Periodontics and Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Smoking is one of the major risk factors for cancer affecting the respiratory tract, oesophagus, stomach, pancreas, uterine cervix, kidney and bladder. Smoking tobacco is responsible for approximately 30% of cancer deaths world over. Nicotine dependence is now considered a disease by WHO (World health organization). The widespread use of tobacco in different forms leading to its addiction is among the biggest preventable cause of death today.

Smoking cessation can not only easily result in the decline of premature deaths but also improve the quality of life. Smoking cessation comprises an integral component of various national and international tobacco control policies. Tobacco quitting programs focussing on diagnosis, treatment and prevention of Nicotine dependence should form a major part of primary health care. Smoking cessation can reduce the chance of carcinomas, strokes,and several cardiovascular and respiratory diseases. The habit of smoking is very difficult to quit and requires a very strong will power, motivation and assistance. Several method like Nicotine replacement therapy (NRT), other pharmacological intervention, psychotherapy and counselling are employed to help the tobacco users to quit smoking. In recent years there is a lot of interest in the use of complementary and alternative medicine (CAM) techniques, like essential oils and acupuncture as therapeutic alternatives for cessation of smoking. Essential oils and aromatherapy,play a very important role in smoking cessation and their role in smoking cessation should not be ignored even though very little information is available regarding their use. This review shall help in understanding the different essential oils available and their uses which can prove beneficial in smoking cessation.

Keywords: *Smoking cessation, nicotine dependence, essential oils, aromatherapy.*

Introduction

Tobacco is produced by two plant species– Nicotiana tabacum and Nicotiana rustica, comes from the Equatorial and the Peruvian Andes. These plants have been in existence over 18,000 years, since the migration of the Asiatic populations to America.[1] By the time Christopher Columbus discovered the Indian sub-continent the cultivation and use of tobacco was already rampant over the continent. Tobacco was not only smoked in pipes, it was inhaled, chewed, eaten, and also drunk as tea.

In 1850, England became the first country to manufacture and sell cigarettes, the consumption of which increased during World War I. Today, around the globe there are more than a billion tobacco users out of which 90% have started the habit in their adolescence. (2) The rise in incidence of lung cancer was observed in 1920 sand documented in several studies.[1] Presently, the WHO reports nearly more than six million victims affected by smoking every year caused by cigarette.[2] Smoking is attributed to nearly 30%of the preventable deaths worldwide caused due to cancer. It is now one of the major risk factors for oral, pharynx,lungs, larynx, oesophagus, stomach,and many other carcinomas affecting different organs of the body.[3] In 1988, it was found that Nicotine found in cigarettes and in other tobacco products is a drug that causes dependence.

Nicotine dependency today, is one of the mostcommon ailments affecting the world population.[4]

Nicotine affects both the body and brain of the smokers. Nicotine in a cigarette, gets absorbed through the lining of the nose, mouth, and lungs and then enters the bloodstream. When nicotine reaches the brain, it activates the pleasure centres of the brain by boosting the levels of the neurotransmitter dopamine. Changes in the balance of chemical brain neurotransmitters occurs when people use nicotine for an extended period. Therefore, when a person suddenly stops using nicotine, there is a disruption of this chemical balance which results in physical and psychological side effects, such as cravings and low mood. This disruption of brain chemicals is termed as nicotine addiction, and is a major reason why people find it so difficult to reduce or quit smoking. About 25% of the adult world population show Nicotine dependence.[5]

It hence becomes imperative to diagnose properly and effectively treat this Nicotine dependence in these patients, by promoting smoking cessation. A huge marketand industry areout there to helpsmokers dedicatedly to quit smoking, starting from nicotine replacement therapies (nicotine gum, the nicotine patch, etc.) to pills, e-cigarettes and several different products and treatment options to pick and choose.

Recently Complementary and Alternative Medicine (CAM) method like cognitive behavioural therapy, acupuncture,etc are garnering a lot of attention in many countries as parallel therapeutic interventions for smoking cessation.[5] Among the various CAM method, one of the promising ways is using aromatherapy and essential oils for cessation of smoking habit. This review shall discuss the various essential oils used for smoking cessation, their effectiveness and their mode of action.

Aromatherapy: The practice of using essential oils obtained from different parts of plants like petals,leaves, stems, and roots, to treat several physiological, physical and psychological maladies. People who practice aromatherapy are known as Aromatherapists. The toughest part for most people, while trying to quit smoking is to control the withdrawal symptoms and the cravings for tobacco.

Aromatherapy treatments are carried out in the following ways:

- By diffusion in the air
- By direct inhalation from vaporizers
- By directly applying on the skin

The various essential oils used in smoking cessation are,

Black Pepper Oil (Piper nigrum) is believed to effectively help quit smoking because its inhalation stimulates the respiratory system in a way quite similar to cigarette smoke, thereby reducing anxiety and tackling the cravings. Black pepper provides the airway sensation of smoking resulting in short-term satisfaction and also reduce craving for cigarette smoking.[7, 8]

Angelica Oil (angelica archangelica)is known as the "oil of angels", which when inhaled,curbs down the cravings and helps better in stopping the habit than without inhalation of the vapour.[9]

Lavender, Chamomile and b\Bergamot oils when mixed together and appliedtopically, directly on the skin lower the cravings and alleviate the anxiousness associated with smoking.

Citrus Oils (Lemon, Grapefruit, Orange) on inhaling cause positive feelings,which helps in alleviating the irritability and nervousness caused due to nicotine withdrawal. Lime being easily accessible it can be used as an alternative to help in smoking cessation. A randomized controlled trial was conducted by Researchers from Thailand's Srinakharinwirot University to determine the efficacy of fresh lime in smoking cessationas compared to nicotine gum. This study shows that lime can be effectively used as asmoking cessation agent. Lime has an antibacterial activity against several *E. coli* strains and smokers usually have compromised immunity. [10,11,12] However, further studies are recommended to find out the effectiveness of lime in smoking cessation.

Ylang-Ylang oil is preferably used to induce sleep. Adding a few drops of the oil on a tissue or the pillow and placed near the head while sleeping reduces stress and restlessness. It can also be used during the day when the cravings are increased.

St John wort: St John wort is an herb containing pharmacologically active ingredients like phloroglucinols derivatives, naphthodianthrones, and flavonoids. Besides its role as anantidepressant, it is also effective in smoking cessation.[13] St John's wort extract basically works by inhibiting the re-uptake of

norepinephrine and serotonin (5-HT) intopresynaptic axons.[14] Studies also confirmed that it is well tolerated in smokers. However, there are other studies which have not found it to be effective in tobacco cessation.[15]

Calamus: Calamus is well known for its medicinal properties and it has many traditional applications since ancient times. Several essential oils have been isolated and identified in calamus. It plays an effective role as an antibacterial, antidepressant, and antioxidant. According to some studies, calamus also has an effective role in smoking cessation. The exact mechanism of action of calamus in smoking cessation has however not been found due to paucity of clinical trials. Therefore, more clinical trials should be conducted to find the mode of action of calamus in smoking cessation.[16]

Other essential oils for relieving the different withdrawal symptoms include:

Withdrawal effects like, anger, irritability, and anxiety.

Bergamot: lowers anxiety, uplifts mood

Immortelle: controls anger and destructive tendencies

Lavender: calming effect, soothens anxious behaviour

Turmeric: calms down strong stressful emotions

Rose: controls and calms anger, reduces frustration

Ylang Ylang: Lowers anxiety

Withdrawal effects: Difficulty on focussing or clarity

Lavendin – Dispels mental fog

Lemon – brings clarity to the mind, regulates swinging moods

Lemongrass – clears mental fog

Rosemary – enhances mental clarity

Tea Tree – regulates thought process

Withdrawal effects: Tobacco cravings

Angelica – strong and spicy aroma, purifying

Black Pepper – stimulates respiration

Ylang Ylang –reduces daytime cravings due to the strong aroma

Clove – Hot, spicy, purifying, rebuilds inner strength

Clary Sage – improves respiration and circulation, rejuvenates

Withdrawal effects: Hunger pangs

Cinnamon –controls indigestion

Lemon – improves mood and helps digestion

Peppermint – helps in digestion

Ginger – better digestion

All the oils discussed above can be used inpure form or can be blended together and dispensed in the following ways -by diffusing, by inhalation, in aromatic bath, mixed in a massage blend, direct application on skin

Does Aromatherapy actually help?: It cannot unless the tobacco user actually wants to. There are innumerable programs and pharmacotherapeutics that can help, but the main factor for success in quitting is one's willpower. This is where aromatherapy can step in to actually make a difference. The biggest benefit essential oils can offer someone trying to quit, is by relieving some of the withdrawal symptoms like cigarette cravings, irritability, anger, anxiousness, unusual hunger pangs,lack of focus and clarity etc. Essential oils thus help reduce or easecravings and withdrawal symptoms, even though it cannot eliminate them altogether.

Aromatherapeutic oils are a part of complementary therapy, which workhand in hand with the routine standard tobacco quitting therapy like NRTs, e-cigarettes, smoking cessation tablets etc.

- convenience in use and relativelycheap.
- nomajor sideeffects.
- useful adjunct to other smoking cessation treatments.

Essential Oil Vaping: Vaping is the act of inhaling and exhaling the vapor from a vape pen or e-cigarette. Though the popularity of e-cigarettes and vaping has increased over the last few years, there is also a lot of controversy regarding their safety. Hence essential oil vaping provides a lot natural, organic,healthier and refreshing alternative.

Diffuser sticks, also called personal diffusers, are aromatherapy vapepens,which use a combination of essential oils, water, and vegetableglycerine that, when heated, creates a cloud of aromatherapy vapor.Essential

oil vape pens don't contain nicotine, but contain Volatile Organic Compounds (VOC) which when heated over 150 to 180°Fahrenheit can convert to abnormal compounds and damage the lungs, mouth, teeth, and nose on contact with the burning compound.

Essential oil vape pens are very new, and there isn't much researchavailable on vaping essential oils.The side effects of vaping essential oils depend on the oil used, and may include,coughing, bronchospasm, aggravation of asthma, itching and swelling of the throat.The long-term effects of vaping with or without essential oils is however still not clearly understood.

Aromatherapy Vaporiser

Anti-Cig Aromatherapy is an on-the-go atomising diffusing aromatherapy

vaporiser that self-activates when inhaled through the mouth, producingpure, inhalable vapours of wellness.Itcontains the highest grade & specially blended inhalable Moroccan essential oils, enriched with naturally occurring wellness herbs & plantextracts. It can be used in conjunction with other smoking cessation products or by itself.

Discussion

Five centuries,since its discovery, tobaccohas ironically gone from being a medicinal plant used even to prevent cancer to one of the worst health hazards globally causing nearly 6 million deaths each year due to tobacco use. Nicotine dependence has been identified as a disease, and according to the International Classification of Diseases 10th revision,smoking behaviour falls under the category of 'mental andbehavioural disorders due to psychoactive substance use'.[17,18] Smoking being a habitual behaviour, a very strong will power and patience is required for cessation of the habit. Therefore, for better and consistent results to achieve complete cessation, apart from the effectiveness of the intervention used, the satisfaction of the tobacco user is also very crucial. There are several smoking cessationmethod presently used,like cutting down firstbefore quitting, nicotine replacement therapy (NRT),behavioural counselling therapy etc.[18] CAM technics like Aromatherapy using essential oils too,can provide not only an effective method for smoking cessation but can also improve the emotional and mental wellbeing of the participant.[18] Essential oils are easily available, less expensive, have minimal side effects or dependence and quite beneficial to smokers who wish to quit smoking and are unwilling for any pharmacotherapeutic intervention. An appropriate combination of pharmacotherapy like NRT, psychotherapy and CAM techniques can ensure a more reliable and long-term success of quitting tobacco,than NRT or psychotherapy alone. WHO has predicted a rise in tobacco related deaths to 8 million by 2030 if adequate and effective smoking cessation policies are not implemented?[19].

Conclusion

Natural substances like essential oils and aromatherapy can therefore play a more important role in aiding tobacco cessation. However, more studies using aromatherapy alone or along with the conventional cessation techniques are needed in future to make the essentialoils an irreplaceable component in tobacco cessation measures all over the world.

Field Cancerization: Perception, Clinical Implications and Future Prospective in HNSCC

Devi Prasad Mandal[1], Neeta Mohanty[2]

[1]PhD Scholar, [2]Professor & Head, Department of Oral Pathology & Microbiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Head and neck squamous cell carcinoma are usually associated with multiple premalignant lesions. This is derived from the idea of field effect in cancer. The concept of "FIELD CANCERIZATION" was introduced by Slaughter et al in 1953 while studying the presence of histologically altered tissue adjacent to oral squamous cell carcinoma (OSCC) cases. It explains the initiation of several primary tumours and locally recurrent cancer. Advance technology and cautious study design using suitable control is helpful in detection of important molecular biomarkers in genetically transmuted but histologically normal cells. These tumor specific biomarkers should improve clinical implications and effectiveness in early diagnosis and treatment modalities. In this review we discuss the perception, clinical implications and effectiveness of field cancerization in head and neck squamous cell carcinoma.

Keyword: *Field cancerization, Head and neck squamous cell carcinoma.*

Introduction

In the global scenario head and neck squamous cell carcinoma (HNSCC) are found within the top 10 cancers and in developing countries of Southeast Asia HNSCC are the most common cancers.[1] In India, prevalence of HNSCC is one fourth of male cancers and one tenth of female cancer.[2] The 5-year average survival rate has not significantly improved during the last two decades.[3] The term field cancerization was first put forward by Slaughter et al.in 1953 to define the histologically abnormal tissues surrounding the primary cancer.[4] Slaughter et al.studied 783 HNSCC patients to understand the histological alteration outside the margins of the primary tumor, in which 11% of the patients had more than one primary lesion. They believed that cancer does not originate as an isolated cellular phenomenon. Cancer has an anaplastic affinity comprising of many cells at one stage and develops at many satellite lesional centres. This results in repeated carcinogenic attack and develops at various rates in the entire field. The multiple patches of premalignant lesions, describe a higher than expected occurrence of multiple local second primary tumors in the same field and influence the presence of distant tumors.[4] Tobacco, alcohol and environmental carcinogens influence large areas of the mucous membrane leading to damage of a large proportion of epithelial cells. Effect of this causes premalignant states within the entire exposed surface.[4] Use of carcinogenic agent like tobacco and alcohol have an independent risk factor while the combination have a synergistic consequence.[5] Advanced molecular techniques have described the genetic changes developed in mucosa exposed to carcinogens.[6] In this review, we have discussed about the perceptions,the clinical implications and effectiveness of field cancerization.

Oral Field Cancerization: Braakhuiset al gave the genetic explanation of Slaughter's Concept of Field Cancerization[7] and stated that head and neck cancer develops in multiple areas as a pre-cancerous change, these are histologically abnormal cells adjacent to the primary tumor, a single primary tumor may occur due to assimilation of many autonomous lesions, if abnormal tissue persists even after surgery it may lead to a second primary tumor and recurrences.

Warren and Gates described the criteria for diagnosis of multiple primary carcinomas, which was later revised by Hong et al.[8,9] These criteria are that every cancerous lesion must be structurally separate and multi-centric primary cancer reveals dysplasia in its superseding mucosa. The probability of the second primary carcinoma must be ruled out from metastasis or a local relapse. The second primary lesion might be away from the main tumor by minimum 2 cm of normal mucosa or might arise at least 3 years later to the primary diagnosis.

The concept of field cancerization can be understood in the ways that explain the phenomenon of secondary primary tumors.[10] In classic opinion, oral tissue are mostly affected by long-term exposure to carcinogens. In this preconditioned epithelium, multi-centric carcinomas can developas a result of independent genetic modifications. Monique GCT van Oijen et al proposed clonal theory in which, a single cell is transmuted and gives rise to one pre-malignant area by clonal expansion and regular replacement of normal mucosa.[11] It was described on the basis of two types of migration polyclonality and monoclonality

Polyclonality: The presence of multiple primary tumors (MPTs) could be due to self-regulating molecular events affecting various cells in the complete field that has been exposed to carcinogens (Figure 1).[11]

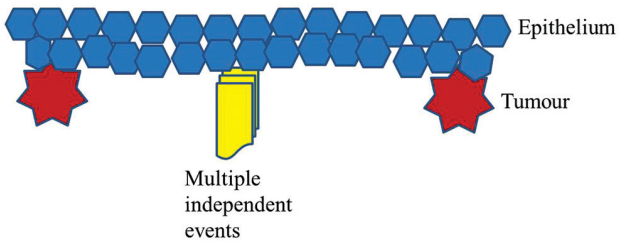

Figure 1. Schematic representation of polyclonality theory.

Monoclonality: Intra epithelial migration of genetically altered cell where the molecular events occurred in a single precursor cell with common expansion across the mucosa. There are two types of migration: these are migration of tumor cells via saliva-micro-metastasis (Figure 2a) and intra-epithelial migration of the progeny of the initially transformed cells (Figure 2b). There are three theories to describe the common clonal origin in MPTs based on similar genetic changes that are malignant cells transfer through submucosa in small islands, cells that are rests in the lumen of an organ at one place can regrow at another place and genetically altered cellsshed in the epithelium from which multiple related cancerous lesions develop which help in lateral clonal spread of cancer and subsequent occurrence of new primaries.

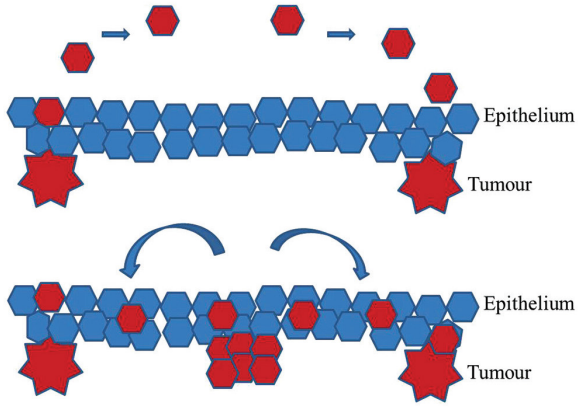

Figure 2a. Migration of tumour cells via saliva-micro-metastasis.

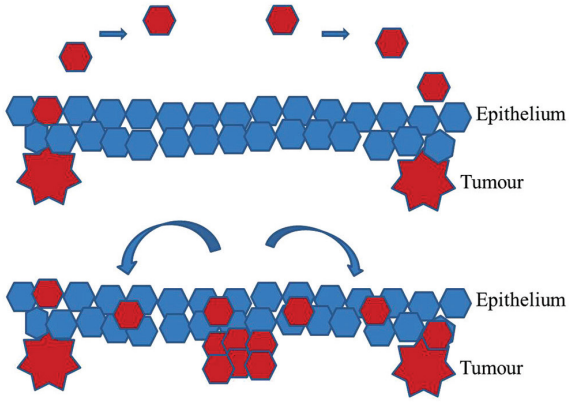

Figure 2b. Intra-epithelial migration.

Clinical Implication: The genetically altered cells of field cancerization is a threat for cancer. The huge number of pre-neoplastic cells in the proliferating area is likely to increase the malignancy risk.[12] The possibility of second primary tumor development in a patient who once had HNSCC is nearly 20%. The initial genetic changes may help in clonal expansion of premalignant cells in a specific field cancerization. Histologically, these transformed cells are diagnosed as cancer.[13] Thus, a bunch of newly formed cells with early genetic alteration without histological changes,which remains in the surrounding represents the concept of Field cancerization. However it is important to

identify the molecular biomarker for those genetically transformed but histologically normal cells to counter the transformation of premalignant lesions into invasive cancer.[14] Loss of chromosomal material at 3p and 9qin oral dysplasia is associated with cancer risk.[15–17] Further losses at 17p increases the cancer risk.[18]

Surgically treated HNSCC cases might have been at a high risk for SPT (second primary tumor)that has to be ruled out by examining the risk outline of a genetically transformed field. Additional, information of the geneticallyaltered cells can provide a basis for a rational therapy for pre-cancerous lesions.

Recently many biomarkers are studied for specific cancer field diagnosis. These biomarkers are used to recognise if multiple cancers developed due to immigration of malignant cells from a primary tumor, whenthe cell sex press the similar genetic expressions or when they express different genetic expressions from independent origin.[19] Various biomarker for detection of field cancerization are listed (Table-1).

Table 1. Biomarker for detection of Field cancerisation

Category	Biomarker
Specific genomic markers	Tumor suppressor/oncogenes or cell cycle control genes p5, p16, p21 Cyclin D1 Retinoblastoma gene C-Jun 3p (unidentified) Proto-oncogene alterations Ras (H, K, N ras) ErbB1
Growth factors / receptors	EGF/EGFR VEGF CD34 TGF-α
Vascular markers	VF CD31 αVβ3 α-SMA
Genomic markers	Genetic studies chromosomal anomalies/ aberrations Loss of heterozygosity DNA sequence analysis Gene profiling Mitochondrial genome changes Nuclear aberrations Micronuclei

Future prospective: Though the concept of field cancerization is widely accepted, further research is required to understand the knowledge. In the last decades studies reveal significant relationships between cancer and inflammation, the discovery of epigenetic and new theoretical models of cancer stem cells biology or tumour heterogenecity have disclosed new potential mechanisms and pathways of carcinogenesis.

Mignogna et al., studied 45 OLP (oral lichen planus) caseswithin a thorough follow up programme for diagnosis and effectiveness of the treatment given to the patients at an early intra-epithelial stage and micro-invasive stage, lead to long-term survival and suggested that in the theory of field cancerization, chronic inflammation should be taken into account as carcinogenic-conditioning agent.[20] Therefore, the triggered pro-inflammatory cells and cytokine complex may act as carcinogenesis promoters, and thus influence the clonal spreading. Thus field cancerization process is sustained.

Field cancerization as a new area of research interest should discover many answers including the importance to study the surrounding affected mucosa in relation to primary tumor to overcome the hazard of cancer burden. In due course monoclonal and polyclonal tumors produce different biology. More research is required to study the specific spreading of genetically altered cancer cells in environment adjacent to the macroscopic and microscopic border with respect to the site of tumor, surgical margin, and remaining cells in situ. Carcinogenic habits like smoking, smokeless tobacco and alcohol consumption or cessation has a significant effect in disease progression. The assessment of histopathological staging and molecular grading of the surgical borders are important for the suggestion of added treatment modality. Furthermore, the research for an appropriate molecular biomarker to detectlesioned cells in the tumor micro-environment should be evaluated to rule out field cancerization. More significantly, a protocol to manage the severe consequences are essential to develop and verify by conducting multi-centric longitudinal studies with large scale patient groups affected by both single and multiple HNSCC.

Conclusion

Field cancerization poses a greater challenge, as it influences the morbidity and mortality of HNSCC patient. The genetically altered cells present adjacent to

the primary tumor in a field is encumbrance for cancer treatment. The probability of developing a second primary tumor in a patient who once had HNSCC is around 20%. Early identification and management of field change is a vital determinant for prevention of cancer mortality and morbidity. Understanding the pathophysiological changes occurring in the cells within a cancerous field is the key to successful identification and treatment of the disease.

Decoding the Link between Chronic Kidney Disease and Periodontitis

Lipsa Nayak[1], Manoj Kumar[2]

[1]Intern, [2]Reader, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

An increased rate of morbidity and mortality due to chronic kidney disease is a commonly witnessed issue these days. Hypertension, diabetes and other heart-related issues are some of the many factors that induce and at times, can worsen the cases of chronic kidney disease. Periodontal diseases, usually getting originated by gram negative bacteria and associated with systemic inflammatory response, cause degeneration and loss of attachment of the supporting tooth structure, which gradually makes up low grade to severe inflammation of the periodontium.

Not only during the various phases of the disease,but also during various treatment modalities like hemodialysis, renaltransplant, the supplement of various elements and intake of certain drugs also worsen the status of periodontal diseases. Stress and other psychosomatic disorders associated with chronic kidney disease also play a vital role in neglecting one's regular oral hygiene measures. Uremia, one of the most highlighting features associated with later stages of chronic kidney disease causes a great disruption in the fluid and electrolyte balance. Not merely the bacterial biofilm cause senormous loss to the periodontium; but also, the host inflammatory response adds on to the deprivation and contributes highly to the severe attachment loss of the supporting structures of the tooth. This review aims at understanding the mechanisms which interconnect these two chronic diseases and the role of dentists in managing a patient with chronic kidney disease.

Keywords: *Chronic Kidney Disease; Periodontitis; Psychosomatic Disorders; Interlink; Disease Management.*

Introduction

In our body,the volume and composition of the body fluids alter within narrow physiological limits. The kidneys hold a major responsibility in maintaining this state, by retention of substances that are vital to the body economy, by excretion of waste metabolic products and by various hormonal and metabolic functions.[1] Chronic kidney disease is a progressive and irreversible deterioration in the renal function, characterized by hydroelectrolytic, metabolic and immune disorders which proves to be a global problem affecting about 5-10% of the world population, sparing no geographical, cultural or racial groups.[1,2] Periodontal disease is an infection caused by gram-negative bacteria leading to a chronic inflammatory state, thereby causing the destruction of the alveolar bone and loss of tissue attachment.[3, 4] Studies have revealed that chronic kidney disease imparts a negative impact on the oral health of the patient by affecting the teeth, oral mucosa, periodontium, salivary glands and tongue.[5] On the contrary, periodontitis increases the systemic inflammatory burden leading to worsening of chronic kidney disease which in succession has been found to negatively affect the chronic kidney disease patients on hemodialysis therapy by reorienting their serum albumin and C-reactive protein levels.[6]

It has been noted from various studies that, patients having chronic kidney disease who are not yet on dialysis or any other treatment modalities respond poorly to the surgical periodontal therapies due to poor immune function. Whereas, chronic kidney disease patients with predialysis, responded well to non-surgical periodontal therapies, exactly in a similar way as that of non-chronic kidney disease patients.[3]

Stages of Chronic Kidney Disease: Chronic kidney disease has five different stages, which are deliberated based on Estimated Glomerular Filtration Rate (eGFR), which is a calculation based on a serum creatinine test. This test measures the level of creatinine in the blood and uses the result in a formula to calculate a number that reflects how well the kidneys are functioning. In the earlier stages of chronic kidney disease, abnormal urine test, diminished blood cell count, feeling of lethargy and tingling sensation are most common. But as the disease progresses, even mental disability is witnessed associated with abnormal thyroid level and disturbances in body's fluid and electrolyte balance which ultimately leads to complete kidney failure. The summarized way of various stages of the disease is as follows:

Table 1. 5 stages of chronic kidney disease[5]

Stage	Description	Possible signs and symptoms	Egfr
Stage 1	Normal kidney function with minor kidney damage acknowledged.	Abnormal urine test associated with hypertension; urinary tract infection is seen.	90 or higher
Stage 2	Kidney function is minimally deteriorated.		89 to 60
Stage 3	3(a) mild to moderate loss of kidney function. 3(b) moderates to severe loss of kidney function.	Diminished blood cell count associated with feeling of numbness and tingling sensation. Also sometimes associated with diminished mental ability.	3(a) 59 to 45 3(b) 44 to 30
Stage 4	Kidney functioning gets extremely deterioted.	Abnormal levels of blood calcium, phosphorus and vitamin D. Anemia associated with bone mineral disease and loss of appetite is also seen.	29 to 15
Stage 5 End stage kidney disease	Renal failure with immediate need for kidney transplant or dialysis is obligatory.	Uremia is one of the characteristic finding. Fatique, nausea, vomiting, severe body ache; swellings of various parts of the body with abnormal thyroid levels are also associated.	Less than 15

Pathophysiology of Periodontal Diseases: In case of periodontium, a majority of the tissue breakdown occurs mainly due to host's inflammatory responses. The subgingival biofilm establishes and augments the inflammatory responses in the gingival and periodontal tissues. These subgingivally hidden pathogens release various noxious substances to their surroundings which gradually causes tissue destruction. Certain periodontal pathogens like *P. gingivalis* and *Aggregatibacteractinomycetemcomitans* keep the abilities of invading the connective tissue even whereas certain bacterial fimbriae like *P. gingivalis* play their role by initiating immune responses, such as IL-6 secretion, ultimately leading to long-term inflammation of the periodontal tissues. The various inflammatory mediators that mobilize and carry on the host responses are divided into cytokines, prostanoids and the matrix metalloproteinases.[6]

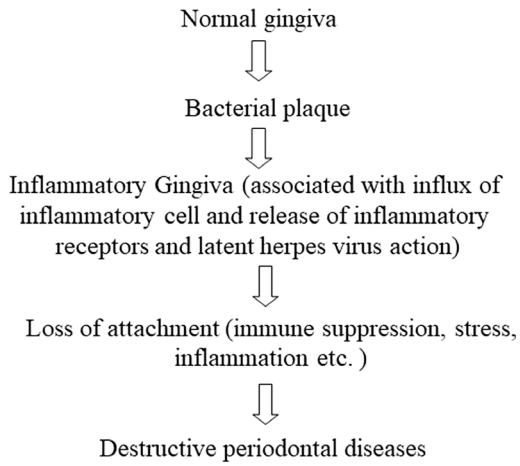

Figure 1. Pathophysiology of periodontal diseases

Periodontal Changes in Chronic Kidney Disease Patients: No specific oral signs and symptoms are observed in CKD patients however secondary oral manifestations are quite prevalent to the disease. Poor health condition resulting from chronic kidney disease may aggravate more infection and maintenance of

systemic inflammation.[2] Varying oral manifestations related to chronic kidney disease include fast formation of dentalcalculus, dysgeusia, xerostomia, hyposalivation and pH salivary alteration.[2] Based on various controversies, these alterations that occur during chronic kidney disease evolution may be related to immunosupression, fluid consumption restriction, various drug interaction measures, renal osteodystrophy and bone loss.[2] The concomitant symptoms and systemic diseases associated with chronic kidney disease causes some crucial changes in the periodontum resulting in exacerbation in gingival crevicular fluid (GCF) leading to degeneration of the gingival tissue and prolonged inflammatory response. Moving forward,it is an utmost important point to note that uremia is a condition that emanates in the later stages of chronic kidney disease. Uremia is an apparent clinical syndrome which is characterized by an elevated urea concentration in the blood associated with hormone, fluid and electrolyte imbalances and various metabolic abnormalities.[2]

Besides that,uremia also induces lymphocyte reaction suppression,granulocyte dysfunction and cell-mediated immunity suppression. Higher concentration of urea in saliva is related to Dysgeusia. Qualitative and quantitative changes in the saliva are also witnessed.

Very fast built-up of dental calculus is the most common finding in chronic kidney disease patients due to various interruptions in the renal mineral proportion. Calculus built-up mostly results due to the precipitation of various minerals present in the saliva and gingival crevicular fluid (GCF).Both organic (cellular and extracellular matrix) and inorganic (minerals) make up the constitution of calculus. Decreased magnesium level and increase in the level of urea and phosphorus can lead to calcium-phosphorus precipitation and calcium oxalate which keep their pace in calculus formation.

Dry mouth sensation is another common finding reported among chronic kidney disease patients mostly accompanied with bicarbonate decrease and calcium increase in saliva.[2] Another striking concern in chronic kidney disease patients is the alteration of the pH value in their saliva. This increase in pH value of the saliva is due to presence of urea in it. This urea containing saliva swiftly gets dispersed into the dental plaque, gets metabolized there by bacterial urease enzymes released from the bacteria adherent to the dental plaque and ultimately release ammonia and carbonic gas apparently causing an elevation in the pH value of the saliva. This ammonia which happens to be the end product of the entire process finally proves to be cytotoxic to the periodontal tissues, causing tissue breakdown and attachment loss which again causes apical shift of the gingival margin leading to gingival recession[4.]

The salivary fluid happens to be a major diagnostic medium in measuring several biological alterations in the human body.[3] Various biochemical markers and enzymes in the saliva keep pace for all these findings. Various studies reveal that due to disturbances in bone mineral content in chronic kidney disease, the serum alkaline phosphatase level gets aggravated in CKD patients. Serumalkaline phosphatase is one of the phenomenal salivary biomarker for chronic periodontitis. This serum alkaline phosphatase is a membrane-bound glycoprotein manufactured by cells like polymorphonuclear leucocytes, osteoblasts, macrophages and fibroblasts. This production process in the oral cavity occurs within the periodontium and gets diffused into the saliva which is highly indicative of inflammation of degeneration of the tissues of the periodontium. The measure of alkaline phosphatase directly corresponds to the intensity of the periodontal tissue destruction.

Othernotsomajorsymptomslikexerostomia,halitosis etc are also reported by many chronic kidney disease patients.[2] End stage renal failure is the terminal stage of chronic kidney disease,which usually results in a general state of dysfunction creating massive ill oral hygiene practices that results in alveolar bone destruction due to renal osteodystrophy. Patients in end stage renal disease do not usually respond to invasive periodontal procedures due to impaired immunity and diminished wound healing.

Periodontal Changes Seen During the Treatment Procedures of Chronic Kidney Disease: To elongate the longevity of the affected kidneys, various renal replacement procedures can be moderated. Hemodialysis is a trademark artificial method of removing nitrogenous wastes and other lethal products of metabolism from the blood. Another standby management is the Renal transplant Method. Regular oral hygiene is neglected by the patients undergoing hemodialysis which in turn create an adverse environment for the biological flora of the oral cavity leading to progression of the bacterial dental plaque which ultimately gets precipitated and calcified when left untreated to form hard dental calculus. This also occurs due to ingestion of high amount of calcium-based phosphate chelator and decreased

salivary clerancer in chronic kidney disease patients undergoing hemodialysis. Emotional disturbances like stress and anxiety during the prolong therapy session of hemodialysis, is considered another important factor for the prevailing poor oral habits.[2]

Various medications allocated to renal transplant patients like immunosuppressant drugs (cyclosporine and tacrolimus) and other hypertensive drugs that are responsible in causing extensive gingival enlargement which is considered another obstacle to the periodontium. Various supplements endowed on patients like erythropoietin and cholecalciferol cause high grade periodontal destruction.

Conclusion

Immediate diagnosis of the periodontal disease followed by appropriate periodontal therapy is enforced to diminished the risk factors associated to the periodontium in chronic kidney disease patients. When a patient suffering from chronic kidney disease walks into a dental clinic, it is an utmost important role of the dentist to take into consideration the various underlying periodontal diseases that get aggravated because of chronic kidney disease. The CKD patients should also be informed about the possible complications and consequences of the poor oral health status. They should be thoroughly educated that, in addition to their whole bodily health, it's also their oral health they should take care of Maintaining proper oral hygiene initiates the oral cavity to keep itself free from various noxious substances both directly and indirectly which ultimately throws a positive outcome for the treatment procedures undertaken in chronic kidney disease patients.

Microbial Analysis in Dry Socket

Pritymanjari Nayak

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Dry socket is known as the most common and painful complication in the healing of extraction wounds. It is a focal osteomyelitis. And in this the blood clot has been disintegrated or lost in the socket. It produces foul odour, throbbing type of pain and subsequent infection of the exposed bone. There is no suppuration. The reported occurrence of dry socket's frequency is 1% to 3.2% of all extraction. It was first described by CRAWFORD in 1876. It is one of the common complicationsin Paget's disease& those who are undergoing radiotherapy and patients who are taking oral contraceptives as the estrogen component increases fibrinolytic activity. It is commonly observed in 40-45 yr patient. Mandible is affected more commonly than maxilla. Dry socket starts by the 2nd& 3rd post operative day till 7-10 day and is having throbbing type pain. Dry socket is a result of physiological,mechanical, chemical and factors. Mainly it is caused by certain bacteria. Certain previously present bacteria in the oral cavity can cause the break down of the blood clot in the dry socket.

Keyword: *Microflora; Dry socket, Streptococcusmutans, Fusiform.*

Introduction

The main symptom of dry socket is having throbbing type of pain and patient mainly complains of bad breath and foul taste in the mouth. Because of having pain, we get to know that proper healing of the socket is not done. In this condition inflammation of alveolar bone has been seen after the extraction of tooth. Basically, it is known as "focal osteomyelitis" and in this the clot has been lost or disintegrated with foul odour and throbbing type of severe pain. Most importantly there is no pus formation. Here the blood clot is lost. That is giving a dry appearance. Becauseofthe fact that the bone is exposed. In women or tobacco users this is most common and most importantly associated with the extraction that has been undergoing lots of trauma and difficulty. Sometimes it is also a sequence of normal exodontia, that is a result of disintegration of a dislodgement of the blood clot. And the subsequent infection of the bone that is exposed. In the first few days after extraction, this complication arises but it has been known occurring Ben a week or longer after tooth extraction. It has been also reported that the teeth removed in toto has a less chance of having dry socket than a toothwhich got fracture during extraction. [1-4]

Occurrence of Microorganisms in dry socket and mechanism of infection: There is no significant relationship between the presence of dry socket and the general health of an individual. But it is the most common complication in Paget's disease and in radiography undergoing patient. And there is loss of oxygen supply to the bone caused byendarteritis. Patients who are taking oral contraceptives, dry socket is common in them because the estrogen component of oral contraceptives induces the fibrinolytic activity.[5] On the occurrence of proteolytic enzymes, whichare produced by the bacteria, the clot has been destructed. And this fibrinolytic activity in current scenario has thought to be the cause of loss of the clot prematurely and sharp throbbing type of pain. Lysis of clot occurs by two mechanisms-(1) plasminogen dependent pathway (2) plasminogen independent pathway. Plasminogen is synthesized in liver and released in to the circulation. It transfers in to plasmin, which acts upon the fibrinogen and fibrin and that causes dissolution of the clot. And here come the anaerobic microorganisms that those are playing the most important role in the occurrence of the condition.[6-9] Some previously present infection that is there in the mouth before tooth extraction for example some periodontal disease can also destroy the blood clot. Some bacteria that is present in the oral cavity can prevent clot formation also. Not only bacteria but some chemical, mechanical and physiological factors are also responsible for clot dissolution. Nicotine used by smokers can cause

less presence of blood in the oral cavity. So, from this, the clot can not be formed at the site of recent minor surgery.[10] Dense jaw bones, hormones or lessvascular supplyare some causes that isagainst the formation of clot. Dragging on a cigarette, aggressive rinsing, sucking through a straw can also cause dislodgement of clot. BIRN's articlegave a good Interpretation about this mechanism. Heinterprets that, cause for the dry socket is increase the quantityof fibrinolysis that is making a path for dissolution of bloodclot. This process of fibrinolysis results in outcome of making plasminogen cycle, which is achieved via physiologic or non-physiologic activator. Indirect or non-physiologic activators are elaborated by bacteria whereas direct or physiologic activators are coming after traumatized alveolarbone. It hasbeen seen that active plasmin gotinactive in the physiologiccirculation. It is caused due to the presence of antiplasmin in the physiologic circulations. Birn again analyzethe dissimilarity in the fibrinolytic pathway with uterine tissues & bone from the skeletal muscle, spleen, lung, liver, thyroid tissue.[11-14] In 1960s and after 1970s oral contraceptives became famous by showing more onset of alveolarosteitis in females who are taking oral contraceptives. Sweet and butler interpret,increase taking of contraceptives related to the dry socket. Catellaniet al again given a conclusionas increasing expectation of dry socket is more with higher estrogen level in the antipregnancy drugs. Some scientist told if we want to decrease the occurrence of dry socket endocrinal cycle must be maintained when appointing the patient for extraction. Mac Gregonsuggested that in women dry socket is seen 50% more than men, while Colby reported there is no difference seen in the onset of dry socket according to gender. Many studies support that bacterial infections are main and important cause for the incidence of dry socket. It is shown that the occurrence or frequencies of alveolar osteitis increases in patients having poor oral hygiene. Local infection that is present before such as periodontitis, pericoronitis are some of them. Many attempts have been made to detect the exact causative organisms. Rozantis et al, studied a possible mutual association of Streptococcus mutant and Activities viscous in dry socket. They were studying this on animal models. This study shows late healing of exodontiaplace after immunization of these bacteria in the models. Nitzanand others studied more plasmin like fibrinolytic actions of Treponema denticola. Another scientist Catenalli observed bacterial pyrogens and shown that these pyrogens are indirectly activating the fibrinolysis process. Wald in 1932 discovered that the bacteria are the reason of dry socket. Here antiseptic and aseptic conditions have been considered upon the assumption.[14-17]

Microbial Analysis: The nature of bacteria has been shown by few observations. Belding and Belding (1934), Schroff and Bartel(1929) developed Fuso-spirochaetalorganisms. Archer in 1961 assumed,*Streptococci* was the main organism. Grandstaff in 1935 experimentingon both normal and diseased healing socket and got *Fusiforms, bacilli, spirochaetal* and *streptothrix*. But these microorganisms didn't have such a distribution as to indicate any abnormal effect upon healing of the socket. From another study of microbial analysis in dry socket we got to know that a specific microbial pattern, which included *Peptostreptococcus, Parvimonas*, *Fusobacterium, Prevotella, Oribacterium, Slackia* and *Solobacterium* species abundantly appeared in the patients having dry socket. Here also *Peptostreptococcus, Parvimonas, Prevotella, and Fusobacterium* had much more important roles in distinguishing dry socket patient and other normally treated patient. From another study data was collected that among 10199 intra-alveolar extractions in 6182 number of patients, 4047 patients had only single tooth extraction and in 2135 patient s more than one tooth was extracted. From these patients the dry socket occurrence in multiple extraction is 2.1% and in single tooth extraction is 5%.Similarly,the dry socket occurrence is showing that it is increased from 2.7% at 15 to 19 yr to maximum value of 8.6% at 30 to 34 yr. Therefore, they concluded that occurrence of dry socket seems to be age dependent with a value in the age range 30-34 yr. [18,19]

Antibiotic treatment: Certain sulphonamides and antibiotics are used for prevention and cure. Davis and his colleagues found that by using sulphanilamide and sulphathiazole, frequency of complicated healing reduced by 38%. Olech also studied the effect of penicillin insertion in to the socket but ended at same conclusion that it was not significantly decrease the post operative complication. MYOSPHERULOSIS, known as a diseased condition of an exodontia. In this an antibiotic ointment with petrolatum base is placed. It concludes in making of hollow space in the healing site and the presence of altered erythrocytes which assumes the appearance of clusters of spherules. The ideal treatment of choice of dry socket is to irrigate with lesshotantiseptic. That should be covered with obtundent. The generally placed socket dressing is

zinc oxide-eugenol and iodoform gauze. Then dressing should be change everyday.[20]

Conclusion

Dry socket is a result of physiological, mechanical, chemical and factors. Mainly it is caused by certain bacteria. Certain previously present bacteria in the oral cavity can cause the breakdown of the blood clot in the dry socket. antibiotics are the major drugs used for prevention and cure.

Arthroscopy of TMJ

Suchismita Ghadai[1], Sthita Prajana Lenka[2], Karishma Rathor[3], Arkaja Sahoo[1], Madhumita Sahoo[1]

[1]Intern, [2]Professor, [3]Tutor, Department of Oral and Maxillofacial Surgery, Institute of Dental Science, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Temporo-mandibular joint disorder is painful, reduced mouth opening production of sound from it. Although the open surgery of this treatment is good but for healing it takes long time and presence of scar is uncomfortable for patient. In some cases of TMJ disorder we can use arthroscopy technique for treatment. Therefore, the surgery can be done within few times. This technique is useful for surgeon to do their surgery under direct vision. As a result, the complication rate decreased accordingly. For this technique the proper instrumentation and knowledge of the anatomy is more important by which we can also use tracing paper for measurement of condylar position. With few numbers of surgeons this technique can be treated. The article reviews the manner in which the technique of treatment of temporo-mandibular joint surgery in endoscopic approaches and we can evaluate the long-term effects of this technique.

Keyword: *Temporo-mandibular joint, arthroscopy, temporo-mandibular joint disorders.*

Introduction

In an open surgery of temporomandibular joint (TMJ) disorders shows many complication and poor prognosis. The arthroscopic treatment is simple, minimally invasive, inexpensive, and highly effective. It takes less time to reduce pain then open surgery. It is relatively low complication rate and leaves fewer scars on face. Indication of endoscopic approaches is restricted to the patients which recommends for surgery like; tumors, ankylosis, and congenital growth disturbances of TMJ may require for open surgical treatment. Arthroscopy is a procedure which helps in direct vision through the interarticular joint structures, during the biopsy and other surgical procedures the arthroscopy helps in visualization also. Arthroscopy was 1st described by TAKAGI in 1939. Ohnishi in 1975 published 1st report on TMJ Arthroscopy. He used no. 24 watanabe 1.7mm telescope 5. This technique indicated in internal derangements, osteoarthritis, pseudotumors, to perform biopsy etc. In 1982, Murakami and Hoshino urbanized the nomenclature of TMJ arthroscopic anatomy 5. Arthroscopic lysis and Lavage (ALL) were good technique for the treatment of TMJ ID. In 1991, Nitzan and Colleagues proposed a customized method, which was based on the inclusion of 2 needles in the superior joint space for lavage devoid of direct visualization of the joint5.

Anatomy of TMJ for arthroscopy: TMJ is otherwise known as synovial joint and present in; i) superior spaces(the temporal bone) & the inferior spaces (the mandibular condyle). The superior joint space (SJS) is cranially restricted by an articular surface joint which covers the articular prominence& the mandibular fossa[2] inside the SJS, 7 areas can be marked; 1. Medial synovial drape, 2. Retrodiscal synovium : Zone 1 : oblique protuberance, Zone 2: retrodiscal synovial tissue attached to posterior glenoid process, Zone 3: lateral recess of retrodiscal synovial tissue shadow, 3. pterygoid shadow 4. Articular disk, 5. Intermediate zone, 6. Posterior slope of articular eminence & glenoid fossa,7. Anterior recess (Disk synovial crease, Midportion, Medial-anterior corner, Lateral-anterior corner)[3].

There are seven areas to be observed are;"1) The medial synovial drape is the first area, which looks like gray-white has a translucent lining and a tense form with distinct higher to lower striae. 2) The pterygoid shadow

is the second area, which looks purple. It is positioned anterior to the medial synovial drape. 3) The retrodiscal synovium is the third area, where the synovium membrane covers the lateral inclusion of the disk and is reflected superiorly to the temporal fossa. The posterior insertion covered by synovial lining appears as a crest or crease is found during the mouth is open and this is known as oblique protuberance. 4)The upper joint is the lateralgradient of the articular prominence is the fourth area to. The fibrocartilage is white in color and reflection is high and the back slope of the eminence is thick[5]. 5) The articular disk is milky white, highly reflective, and without striae which is the 5th area. The disk glides fluently present beside the articular prominence therefore roofing is known as the cover on condyle is articular disk. The roofing can be marked by arthroscopoic technique with the help of posterior band of articular disk and its position according to articular prominence. 6) The sixth area is the intermediate zone and in normal condition, the intermediate zone has a white form. 7) The frontal recess starts with the condyleseated & at thatpart, the anterior disk synovial fold, which has 4th classic anatomic landmark, is known as 7th area. The proper place for placing of second cannula at the anterolateral site, this is the junction of: i) tangential synovial capsule & ii) the frontal disk synovial crease".

The requirements for diagnostic arthroscopy: Skin marker, for drawing straight line the ruler is needed, the scalpel, two instruments are used to create the working space or access point the at are; i) Arthroscopic sheath, ii) trocar with sharp obturator and Prepared irrigation liquid.

TMJ Puncture technique for diagnostic arthroscopy: After palpation and inspection of TMJ region & the position of the condylar head has been determined by passive movement of the TMJ, the trocar sites are marked by Blaustain & Heffez (1990) & Reich (1995):Locate & mark the center of tragus. Locate & mark the lateral canthus of eye. Draw a straight line between the centre of the tragus & the lateral canthus. Measure & mark a point on the line i.e. 10mm from the centre of the tragus & mark a point (A) locate 2mm below it. The trocar with obturator will be inserted at that point & the obturator will be removed for insertion of the arthroscope. Measures & mark a point on the original line i.e. 20mm from the centre of tragus. Drop a perpendicular at that point, measure 10mm down from the site where the trocar with sharp obturator will be introduced. Palpate the TMJ region before inserting the trocars, & moved the joint to confirm that the points have been marked correctly, since some distortions may occur due to shifting of the skin.

Inspect & palpate TMJ, determine position of condylar head by passive movements of TMJ.

Arthroscopy of Temporomandibular Joint:

Single puncture technique; this technique is appropriate for both diagnostic and operative needs. Usually for arthroscopic procedure general anaesthia is used for sedation of patient. To reduce contamination and swelling,the antibiotics and corticosteroids are given before treatment starts. The patient position should be in supine and for nutrition use the nasogastric tube, for artificial respiration use endotracheal tube. After the isolation of the surgical field than the anatomical landmarks are identified to avoid possible complications. Then firstly the cannula puncture point is done at tragocanthal line (i.e. the point 10mm anterior and 2mm inferior along the tragal canthus line). Before puncturing, 2ml of local anesthesia is administered into the superior joint capsule by using a 22-gauge needle for increase the size of the structures. For backpressure can be felt, use a 3ml syringe when the needle entered into the interarticular space. Administration of epinephrine into interarticular space may affect the visual accuracy. The rate of inflammation can be marked by the pattern and character of synovial vessel so any administration of local anesthesia as vasoconstrictor should be after the allergy test. Use inferiolateral technique for insertion of cannula into the superior joint space; use a sharp trocar for puncture to a 25mm depth. Withdraw the trocar after insertion of cannula then insert a blunt obturator for incision of soft tissue from the TMJ. Put the Arthroscope into the middle connector is inserted through the middle connection of the three- way female Luer lock[7].

Double puncture technique: After the diagnostic examination is completed, arthroscopic results are interrelated with clinical and imagine studies,then the necessity of double puncture technique can be determined. After determination of double puncture technique and the type of cannula is required for this technique. Then insert the second cannula at the site of surgery. Through a second cannula operative maneuvers are performed with the operative site frequently in vision. The position of the second entrance is decided by the operational site, using a scheme of vectors[1]. The anterior incline of the articular distinction and the anterior disk-synovial joint

and medical synovial joint can be seenby stirring the arthroscope to the most onward and tangentialsegment of the joint. The extent of the deepness of arthroscope is measured. From the fossa puncture a point is marked on the skin represents a distance in millimeters equal to the screening cannula deepness. Secondly cannula is insertedat right angles to this site. At this puncture site a ridge of bone can be felt at the anterior incline of the articular eminence. The bone should be touch with a trocar slant but periosteal dissection is discouraged because of articular friction and potential injuring 7th cranial nerve. Then the next cannula is conceded into the joint beneaththrough arthroscopic illustration. At this point it is not essential to modify the obturator, since triangulation will let the cannula system to be seen as it enters the anterior joint space, thus sinking offriction.

Triple puncture technique: sometimes a triple puncture is needed after double puncture because[8]; a) if the two cannulas are not in proper angulations than it is difficult to recognize the anatomy of joint, b) for different angulation of instrumentation more place is required, c) the second working instrument- helps to separate the tissue within TMJ easily and to avoid wasting materials. For the third puncture the two portals are required; a) the transmetal area and b) crest of the articular eminence. For the insertion of articular eminence, the position is "20mm anterior to the mid portion of the tragus-canthus line and 10mm inferior to tragus-canthus line".The crest of the articular eminence is a round protuberance and holds it with the index finer or the thumb,downward from tangential to medial on palpation of the lower surface. Cannula position method are formerly used to increase access to this area. However, this location impinges on the teemingtransitional zone, where there is extensivefirm tissue and tiny open space to tricklackingfriction or disc deflateconsequently this deflate is not used normally[8]. The different site for a third deflates is transmeatal portal; it allows admittance of either the higher or lowers joint space.

Complications: Hematosis, Broken instruments, iatrogenic articular injuries,Bleeding may be found within the superior TMJ space, Paresia of facial nerve may present(i.e. neurologic injuries to 5th cranial nerve &7th cranial nerve),revision of illustrationprecision of the ipsilateral eye may present immediately after the surgery, Otologic complicationl, damage of tympanic membrane, with slit of external auditory canal,temporary hearing loss,plugged of ear,Vertigo.

Results

According to gonazalez garcia R," Complicationss were observed[3] in whole series 1.34% complications rate was found, but blood clots were not found within external auditory canal. Other complications were: paresia of the facial nerve was found in 4 patients(0.6%), ipsilateral eye was found immediately after surgery in a patient". According to Tsuyama M; "Complications were observed in 31(10.3%) of 301 cases of arthroscopic lysis and lavage,26 cases(8.6%)of Otologic complications, 9 cases of blood clots in the external auditory canal, 5 cases of partial hearing loss, 2 cases of ear fullness were found, one case of perforation of tympanic membrane with laceration of external auditory canal, 7 cases of laceration of external auditory canal, one case of vertigo, 5 cases (1.7%) of the Neurologic injuries were i.e. 3 cases of 5th cranial nerve injuries and 2 cases of 7th cranial nerve injuries were found".

Indications of arthroscopy: Patients with pain and jaw dysfunction not responsive to non-surgical dental and medical management,Frequent mandibular dislocation, Disc displacements, Resistant preauricular atypical facial pain, Osteoarthritis, Post-traumatic complaints,Pseudo tumors,Chronic form of arthritis,Degenerative arthritis,To perform biopsy.

Contraindication: Bony and advanced fibrous ankylosis, ankylosing osteoarthritis, Need a open surgery,Overlying skin infection puncturing through an infected skin can cause aseptic joint postoperatively,Malignant tumors,Advanced resorption of glenoid fossa, Increased risk for hemorrhage may cause hemarthrosis.

Advantages: There will no remarkable scar on face; injury percentages of 7th cranial nerve will be reduced; results of diagnosis are good.

Disadvantages: Chances of bending of instrument, price of apparatus

Conclusion

During arthroscopic procedure and by paying attention to essential points of the arthroscopic technique at the time of instrumentation, the complication rate will decrease consequently and it is necessary to have a brief idea about TMJ[2]. The liberation of fibrillations and adherences improves the joint mobility and reduces pain. Arthroscopic surgery is less invasive, needs less time and associated with lower mobility.

Focal Cemento-Osseous Dysplasia: An Unusual Case Report

Swagatika Panda[1], Sreepreeti Champatyray[2], Alkananda Sahoo[2], Neeta Mohanty[3]

[1]Professor, [2]Assistant Professor, [3]Professor & Head, Department of Oral Pathology and Microbiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar. Odisha. India

Abstract

Focal cemento-osseous dysplasia (FCOD) is a fibro-osseous lesion that is a nonneoplastic reactive lesion. Fibro-osseous lesions are disturbances in bone metabolism in which normal bone is replaced by a connective tissue matrix that then gradually develops into cemento-osseous tissue. Typically, the lesion is asymptomatic and is detected on routine radiographic examination. Radiologically, this lesion has three stages of maturation: pure radiolucent, radiopaque/mixed radiolucent, and radiopaque appearance. During these stages the lesion can be misdiagnosed. In this case report a 57-year- old patient complaint of painless swelling of the right mandibular front tooth region which is presented along with a review of the differential diagnosis considered in order to reach a final diagnosis of focal cemento-osseous dysplasia.

Keywords: *Cemento-osseous dysplasia, fi bro-osseous lesion, focal cemento-osseous dysplasia, periapical cemento-osseous dysplasia.*

Introduction

Focal cemento-osseous dysplasias (FCOD) are benign fibro-osseous lesions of the jaw. The term focal cemento-osseous dysplasia was coined by Summerlin and Tomich.[1] Formerly Waldron reported the case and named it as localized fibro-osseous cemental lesion observing its localized nature.[2] The etiology is unknown but is thought to be reactive in nature secondary to injury like former tooth extractions. Mostly FCOD is asymptomatic and is discovered only on radiographic examination.[3] When FCOD is present in close approximation or attached to the tooth root, the diagnosis can be bewildering with periapical pathology or other lesions thus necessitating a histological examination. In this article, the case of a 57-year-old patient with FCOD is presented with a review of the literature.

Case Report: A 57 Year male presented to the department of oral surgery with painless swelling in the right lower anterior teeth region since 5 years. There was no other relevant medical history. On Extra oral examination findings there is presence of bony hard swelling in in relation to mandibular angle on the right side. Intraoral examination revealed a bony hard swelling in the edentulous alveolus in relation to mandibular canine region (Figure 1).A single well circumscribed ovoid swelling in the alveolar ridge of mandibular right canine region, measuring about 1×1.5 cm in size. Generalized attrition, chronic localized periodontitis and root stump of 31, 32, 36, 41, 42 were present. Intra-oral periapical radiograph shows a mixed radiopaque and radiolucent lesion seen mesial to 45 measuring about 1x1.5 cm in diameter (Figure 2). On the basis of the patient's clinical and radiographic findings ossifying fibroma, osteoma, cementoblastoma, osteoblastoma, odontoma were considered. Surgical intervention and contouring of the swelling were performed under local anaesthesia. The lesion was totally excised & was sent for histopathological examination. The microscopic examinations revealed bony trabeculae and cementum like calcifications in a fibrocollagenous stroma (Figure 3).

Figure 1-A single well circumscribed ovoid growth present in the alveolar ridge with respect to 43 region, measuring about 1x1.5 cm with surface ulceration, bony hard in consistency, non tender on palpation. missing teeth 31, 32, 36, 41, 42.

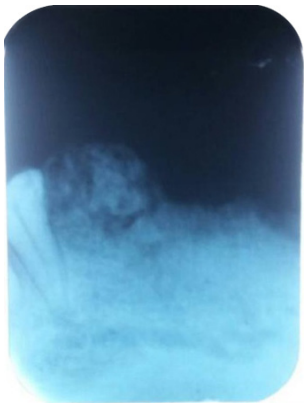

Figure 2 - Intra-oral periapical radiograph shows a mixed radiopaque and radiolucent lesion seen mesial to 45 measuring about 1x1.5 cm in diameter

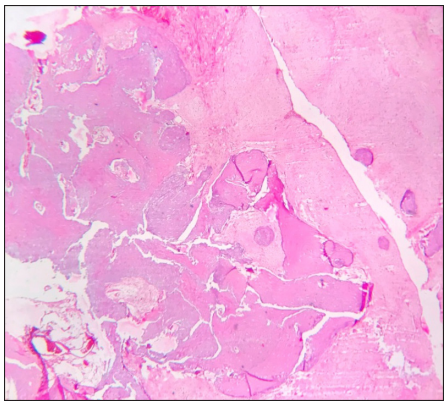

Figure 3 - Photomicrograph of hematoxylin eosin stained tissue showing foci of cementum and bone like calcification (4x)

Discussion

Recent classification of bone-related lesions, released in 2005 by the WHO preferred the use of 'osseous dysplasia' rather than the 'Cemento Osseous Dysplasia'[4]. This classification includes focal cementoosseous dysplasia under benign fibroosseous lesions[4]. FCOD is considered to be a reactive or dysplastic process with unknown pathogenesis[5]. The association of FCOD with teeth does not mandate the odontogenic nature of the lesion but suggests the possibility of influence of odontogenesis on its development[4]. Above the mandibular canal is the usual location of FCOD confining the lesion in the alveolar process. FCOD is usually unifocal and can occur in any tooth-bearing area. Generallyit occurs in the posterior mandible (86%)[6] and shows a greater frequency in women than in men (~10:1)[7,8] with a mean age in the mid-30s and a slightly higher incidence (64%) among African Americans[5]. Usually FCOD is free of symptoms (62%)[9] and is diagnosed incidentally during routine radiography. Radiolucency followed by mixed radiolucency and radiopacity followed by only radiopacity are three stages of development of FCOD observed radiologically. The third stage shows an ill-defined border with thick curvilinear bony trabeculae described as gingerroot pattern[8,9]. Our case was showing a mixed radiolucency and radiopacity. This case is consistent with the usual histopathological features consisting of bony trabeculae and cementum like calcifications in a vascular stroma. Waldron and colleagues[10] reported that most of their symptomatic cases occurred in edentulous areas, consistent with the finding of Ohkura[11] that FCOD was discovered more frequently in these areas. In our case, FCOD was also seen in an edentulous area.

FCOD has been reportedly associated with Adenomatoid Odontogenic[14], Aneurysmal bone cyst[15], benign cementoblastoma[16] and residual cyst[17]. It is very important to understand the rare occurrence of FCOD which makes exclusion from periapical granuloma, periapical cemental dysplasia, simple bone cyst etc.

Plaque Disclosing Agent

Sahita Patra

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Dental caries and periodontal diseases,also known as plaque mediated diseases leads to poor oral hygiene. Plaque is a highly specific variable structural entity formed by the colonization of microorganisms on the tooth surface. So plaque is not easily visible through naked eye which is difficult to remove, therefore disclosing agent is used for removing dental plaque and maintaining oral hygiene. Preparations containing dyes or other disclosing agents for identification of bacterial plaque help in maintaining good oral health.

Keywords: *Dental Caries, Plaque Disclosing Agent; Oral Health.*

Introduction

It is important for maintaining oral health for removal of dental plaque, as deposits of dental plaque brings about the inflammatory changes which leads to the destruction of tissues and also cause dental caries in long term[1]. It is usually transparent and resilient and cannot be seen through naked eye. It helps in evaluating the knownledge, attitude and practice among dental students regarding disclosing agents. Plaque is clinically defined as a structured, resilient, yellow grayish substance that adheres tenaciously to the intra oral hard surfaces, including removable and fixed restoration.

Plaque control is defined as removal of microbial plaque and prevention of its accumulation on the teeth and adjacent gingival tissues. It also deals with the anticipation of calculus formation. It includes usage of mechanical procedures as well as chemical agents which retards plaque formation. The mechanical plaque control seems to be the most dependable form of plaque control method and chemical plaque control have been used only as an adjunct to mechanical means and not as a substitute. Plaque disclosing solution is a liquid, lozenge or tablet like substance from which contains a dye or other disclosing agent, which is used for the identification of bacterial plaque.[2]

Why to Use the Plaque Disclosing Agent?

1. To aid in plaque identification.
2. It has capable to penetrate the hard plaque deposits and wipe them easily to keep the tooth clean and healthy.
3. It serves as preventive and disclosing agents to tooth infectious materials.

Types of Disclosing Agents-[2]: There are different types of disclosing agents which are available in day to day life. They aid in removing the unwanted stains on our teeth and gums. They are as follows:-

A. Iodine preparations

- Skinners iodine solution
- Diluted tincture of iodine

B. Mercurochrome preparations

- Mercurochrome solution 5%
- Mercurochrome disclosing solution

C. Bismarck brown

D. Merbromin

E. Erythrosine

FD&C (Federal Food Drug and Cosmetic Act).red no3/no 28

F. Fast green

FD&C green no.3

G. Flourescien

FD&C yellow no.8 (Used with Special Ultraviolet Source to Make the Agent Clearly Visible).

H. Two tone solutions

FD&C blue no.1 (thicker)

FD&C red no.3 (thinner)

I. Basic fuschin.

Composition:

1. FD&C green no.5
2. FD&C blue no. and D&C yellow no.5
3. FD&C red NO.3 & Hercules green shade 3
4. Fd&C red no.3(erythrosine) & FD&C blue no.1
5. FD&C blue no.2
6. FD&C red no.40
7. D&C yellow no.8(flourescein)
8. FD&C red no.22(eocine)
9. FD&C red no.3 & FD&C green no.3

Ideal Aspects [2]:

1. Duration of intensity-This colour should not rinse off with ordinary rinsing method or it can be removable by the saliva for the period of time to complete the examination and instructions procedures.
2. Irritation to the mucous membrane-The agent should not cause irritation of the oral mucosa.
3. Diffusibility-The solution should be thin enough so that it can be easily applied readily to the exposed surfaces of the teeth and yet it is thick enough to impart an intensive colour to bacterial plaque.
4. Astringent and antiseptic properties-It is quite frequently recommended that an antiseptic be applied prior to scaling. If an antiseptic disclosing agent is used, one solution serves as a dual purposes.
5. Intensity of color-A distinct staining of deposits should be evident. The colour should contrast with normal colors of the oral cavity.
6. Taste-The patients should not be made uncomfortable by an unpleasant on highly flavoured substance. The use of the agent should be pleasant and encourage cooperation.
8. Good flavour
9. Water soluble and biocompatible.
10. Non allergic to oral mucosa.

Method of Application: Disclosing solutions can be applied by the following method:

1. Direct application for solutions-The patient is asked to rinse his mouth properly to remove all the food debris and heavy saliva. Then the water based lubricant is applied cautiously so that the lips don't get stained. After that the teeth are made air dried properly. Now the agent is carried to the teeth with the help of cotton swab or small cotton pellet or it may be rinsed after the proper dilution. The solution is applied to all the crowns of the teeth. Then the patient is instruct to spread the agent over all the surfaces of his tooth with his tongue. Finally, the distribution of the solution over the tooth surfaces is examined properly and the patient is advised to rinse his mouth properly.[1]
2. Rinsing agents-A few drops of concentrated preparation are placed in a paper cup and water is added for the appropriate dilution. Instruct the patient to swish and rinse with the solution so that it is applied on all tooth surfaces.[1]
3. Tablets and wafers-The tablets or wafers may be chewed or swished around the mouth for 30 to 60 seconds and rinsed.[1]
4. Dentrifrices-Plaque disclosing agents can be incorporated in dentifrices and thus they can help in dental plaque observation.[7]

Technical Hints for Plaque Disclosing Agents: The following things should be checked before applying disclosing agent:

- On the teeth having tooth coloured restoration this agent cannot be used, as this material can stain the restoration.
- The solution containing alcohol should not be kept longer than 3 months, as the alcohol may evaporate by making the solution highly concentrated to use.
- Before applying the sealant disclosing agent not to be used.
- By dipping the cotton pliers with pellet directly into the container may contaminate the solution, so its better to transfer the required amount of the solution to a dappen dish during application.[1]

Mechanism of Action: It is worked by changing the colors of dental plaque so that it contrasts with the white tooth surface. It has the ability to retain a large number of dye substances which can be used for disclosing in various purposes. This property is related to relationship,because of the polarity difference between the components of the dental plaque and dyes. These particles are bound to the surfaces by electrostatic interactions (proteins)and hydrogen bonds (polysaccharides). [1]

Uses of Disclosing Agents:

1. It is useful for preparation of plaque indices.[3]
2. In recent studies, there are effectiveness of the plaque control devices like toothbrushes, dentifrices, dental floss etc.[4]
3. Useful for self evaluation of the patient.
4. Useful for the effectiveness for oral hygiene maintenance.[5]
5. Useful in patient instructions and motivation.
6. It is faster more efficient and minimally invasive.

Recent Advancements for Plaque Disclosing Agent:

1. Caries risk assessment: The new advances is found by three tone plaque disclosing agent which is effective in identifying pathological plaque. It can be used in identifying cariogenic microorganisms in caries risk assessment. It is based on the principle of PH selective response of three different dyes, i.e-Rose Bengal and brilliant blue and FCF. It is used to detect the age of the plaque and production of acid.[6]
2. Photodynamic therapy-It is the established treatment for localized tumours, involving the application and retention of an applied photosensitizing agent in malignant tissues.[7]
3. A plaque disclosing solution comprises dispensing toothbrush:

A. It comprises head portion and a grasping portion, an upper surface and lower surface and a hollow interior defining a reservoir.

B. A variety of bristles positioned on and attached to the upper surface of head portion of the handle.

4. The handle is partially transparent.[4]

Conclusion

Identification of dental plaque with the help of disclosing solution is one of accurate, easiest and fastest ways to examine dental plaque. It favours subsequent removal of the plaque. There is no more evidence of disclosure of dental plaque in office which aids in patient's motivation by improving the plaque control. The quality of professional supervision of oral hygiene plays a relevant role in the efficacy of dental plaque removal as a disclosing factor. The motivational effects results in study participation and anticipation of oral examinations. Self checking with plaque disclosing agents may plays a important role in improving the proper oral hygiene of school children at home. In case of periodontal diseases,it accounts for a majority of missing teeth in adults and results in tremendous social and economic burdens both to the society and to the indivisuals.

Peripheral Osteoma: A Case Report with Review of Literature

Rajat Panigrahi[1], Abhishek Ranjan Pati[1], Sanath Kumar Bhuyan[2], Smita R. Priyadarshini[1]

[1]Reader, [2]Professor, Department of Oral Medicine and Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Osteoma is a benign osteogenic lesion manifesting from compact or cancellous bone. These can be classified into three types according to their origin. Slow growing osteomas are benign tumours. The recurrence rate is very rare. A very rare neoplastic lesion in the maxillofacial region like Peripheral osteoma is more frequently found in mandible. This is an unusual case of peripheral osteoma present in the buccal aspect of premolar region of mandible corresponding to apical 2/3rd of root. The radiograph provides sufficient information for diagnosis but CT scan is the choice for planning surgery. Completely removing the tumour surgically is the most preferred treatment.

Keywords: *Peripheral Osteoma, mandible, benign bony neoplasm, mandible.*

Introduction

Osteoma is a benign osteogenic lesion manifesting from compact or cancellous bone. These can be classified into three types according to their origin. a) Central osteoma originates from endosteum b) peripheral from periosteum c)extra skeletal osteoma develops from the soft tissue. Peripheral osteoma is an unusualtumoroccurs usually in young age and both the genders are equally affected. This lesion mostly occurs in the frontal bone, mandible and maxillary sinuses in orofacial region. Among the above-mentioned sites the incidence ofOsteoma in mandible is higher involving the angle, condyle followed by body of mandible and ascending ramus. Intraorally Osteomas presentunilaterally as pedunculated masses, mostly in the lingual aspect of premolar and molar region. Facial asymmetry and occlusal dysfunction are often associated with condylar osteoma. These osteomas present as dense peripheral type in mandible rather than cancellous type.

Multiple osteoma in jaw bones are characteristic feature in gardener syndrome[1.] Diagnosis of these lesions are extremely importantfor the confirmation of Gardener syndrome due to its tendency to develop colorectal adenocarcinoma. As these maxillofacial features in Gardener syndrome can appear very early before the patient develops intestinal polyposis. The Diagnostic value of these lesions is very important in early diagnosis of Gardener syndrome which is a precancerous condition[6]

In mandible dense peripheral osteoma is very common rather than cancellous osteoma.[6] The pathogenesis of osteoma is still to be confirmed as they are considered to be of developmental anomalies, true neoplasm or reactive lesions caused due to trauma, muscular spasm or any infectious disease.[7] Various etiopathogenic hypothesis have been proposed for osteoma formation which includes that lesion is caused by congenital anomalies or by neoplastic proliferation caused by chronic inflammation.[8]

The osteomas grow slowly and progressively to attain a definite shape and size although it is still unclear if the osteomas are benign hamartomous lesion. In radiograph they appear as well circumscribed radiopaque circular or ovoid shape masses depending on constitution and shape of lesion.[9] Usually osteomas are asymptomatic in nature until they interfere with aesthetics if the individual.So often it is a coincidental finding in radiographic investigations.[10] Osteomas are bony hard in consistency and are covered with normal

Rajat Panigrahi
Reader, Department of Oral Medicine and Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

mucosa with no surface ulcerations until and unless they are associated with secondary trauma.

We report here an unusual case of peripheral osteoma present in the buccal aspect of premolar region of mandible corresponding to apical 2/3rd of root.

Case Report: A male patient, aged 60 years reported to department of oral medicine and radiology of Institute of Dental Sciences with the chief complaint of a hard swelling in the left lower facial region. The history revealed that the patient noticed a slow growing mass on left lower jawfor 5 years with no history of trauma, toothache, pain or discharge from the swelling. The past medical, surgical, dental, personal and family history did not reveal any abnormality.

On extra oral examination a single unilateral diffuse swelling was present in the left lower 1/3rd of face measuring approximately 1cm x 1cm in size, spherical in shape & smooth surface without any change in overlying skin(**Figure 1a**). The swelling extended 1cm below the corner of lip till 4cm below the midline of lower eyelid anteriorly and 1mm above the inferior border of mandible posteriorly. There were no secondary changes, no discharge, no pigmentation no vascular change or other changes associated with it. The inspectoryfindings of site, size, shape and borders were confirmed. It was a non-tender, hard and afebrile swelling with smooth diffuse edges which did not yield to pressure and the overlying skin was pinchable. Swelling was attached to the bone with a pedunculated base, which is notfluctuant, compressible and reducible.

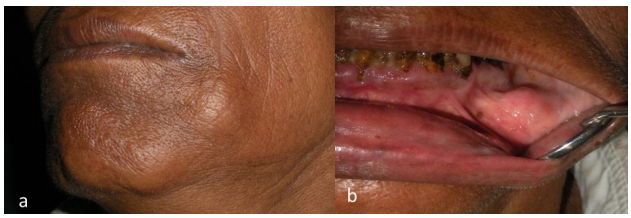

Figure 1a. Extra oral manifestation of osteoma; 1b. Intra oral picture of the lesion with normal overlying mucosa

On intraoral examination a single diffuse growth was present in left buccal sulcus measuring 1cmx1cm in approx in diameter. Shape of the swelling was roughly oval with no change in mucosal colour extending anteriorly in the buccogingival sulcus in relation to 35 till 36 posteriorly causing obliteration of the vestibule (**Figure1b**). On palpation the swelling was non tender bony hard in consistency & non fluctuant. Co-relating all the history and clinical features a provisional diagnosis of benign bony neoplasm was given & differential diagnosis of central haemangioma, bony exostosis, osteoid osteoma, osteoblastoma and osteoma was considered.

Intra oral periapical radiograph revealed a single well defined radiopacity in the periapical region of 36 which appears more opaque resembling the opacity of enamel of corresponding teeth (Figure2a). Multiple irregular radiopacities are seen with varying intensity in the periapical region of 46, 47 (Figure2b). Lateral occlusal view of left side revealed a well-defined outgrowth of a pedunculated radiopaque area,round in shape,measuring approximately 1cm x1cm in the buccal aspect of mandible (Figure2c). The Panoramic radiograph revealed multiple irregular radiopacities with varying intensity was present in periapical region irt 36 37 46 47. Periapical radiopacity in relation to 36 appears more opaque resembling radiopacity of enamel of corresponding teeth. A lateral oblique radiograph was advised which revealed a well defined radiopacity in the periapical region in relation to 36 which was more radiopaque than irregular radiolucency present in the periapical region of 37. Right lateral oblique radiograph shows radiopaque lesions in the periapical region of 36 37.

Figure 2a. Occlusal radiograph showing the extension of the lesion; 2b. OPG showed a radio-opaque mass in the left side of the jaw; 2c.Right lateral oblique radiograph shows radiopaque lesions in the periapical region of 36 37

Figure 3a. Axial CT scan view of the lesion showing hyperdense mass protruding to the buccal side; 3b. 3D reconstruction image of the lesion; 3c. 3D reconstruction image of the lesion showing the extension and shape "pedanculated" mass

Computed Tomography Axial CT scan view of the lesion showing hyperdense mass protruding to the

buccal side(Figure 3a)of the lesion was done along with 3D reconstruction(Figure 3b). It revealed a well-defined radio dense outgrowth from left hemi mandiblemeasuring 1.5cm x 1cm**.** Thus, on basis of radiographic findings a final diagnosis of osteomas was given (Figure 3c).

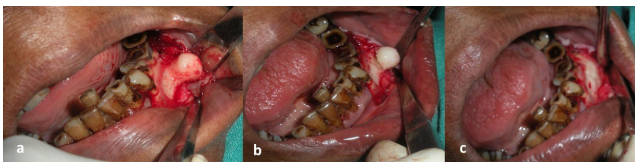

Figure 4a. Intraoral full thickness buccal mucoperiosteal flap was reflected irt 35 till 37; 4b. During excision the lesion appeared hard and homogenous; 4c.The residual bed was debrided, smoothened and flaps were sutured

Surgical excision of the growth was planned under local anaesthesia. Intraoral full thickness buccal mucoperiosteal flap was reflected irt 35 till 37 (Figure 4a). During excision the lesion appeared hard and homogenous(Figure 4b).The residual bed of the growth was debrided, smoothened and flaps were sutured(Figure 4c). After surgical excision, the specimen was sent for histological diagnosis(Figure 5a, b).

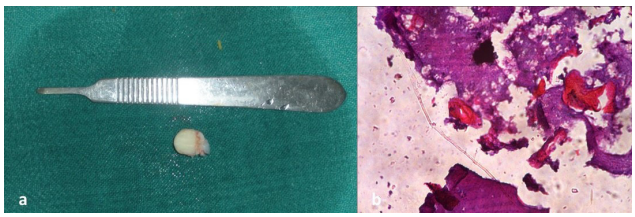

Figure 5a. The excised mass; 5b. Photomicrograph showing dense compact bone with no haversian system

The report revealed normal appearing dense compact bone with features suggestive of osteoma with missing haversian systems. And the patient was scheduled for regular follow-ups.

Discussion

The peripheral osteomas are very uncommon neoplasms. Schneider et al, Kaplan et al, Woldenberg et al (2005), Jonan et al (2005), Cincik et al(2005) and Larrea/ Oyarbide et al described as the region affected frequently is body of mandible. However in the maxillofacial region peripheral osteoma is most commonly reported in frontal bone followed by mandible and maxilla as reported by Sayan et al. According to Bodner et al peripheral osteoma mostly occurs in paranasal sinus. They are observed that they are very uncommon to be found in mandible. On analysing the reported cases of osteomas of mandible in literature it is widely agreed that the most affected region is the body of mandible followed by condylar process,angle of mandible, ramus, coronoid process and mandibular notch.[11]

The lingual side in the body of mandibular and the inferior border of mandibular angle are the frequently affected sites in the mandible but in this case the osteoma is present in the buccal aspectof 36 which is very unusual site for development of such lesions as the density of cortical bone is less in these areas.

It also cannot be ruled out few lesions described to be osteomas may also be preffered to be classified as bony exostosis. Correlating the theories responsible for growth of such lesions and the site affected in this case,the theory of trauma including such lesions can be justified [2]. Whereas infiltration of interdental bone and disturbance of the bone structure might help the neoplastic nature of this lesion. As seen in the present case the origin of osteoma could be peripheral as it appeared as a lobulated mass at the buccal cortex of mandible.[3]

According to developmental and embryological theory,osteomas probablydevelop from sutures between bones of different embryological derivation,but usually they develop in adults and not during younger age. The inflammatory theory derives that long-standing inflammatory lesions of paranasal sinuses could arouse proliferation of periosteum related osteogenic cells,it is infrequently impossible to define whether it is the infection or osteoma that developed first. However, this doesnot enumerate pathogenesis of osteomas in other structures.Few investigators also explained osteoma as a reactive lesion caused by trauma. As peripheral osteomas are generally located on lower border or buccal aspect of mandible,which is often an area vulnerable to trauma[2]

Radiographically, osteomas show a well circumscribed densely sclerotic radiopaque mass. Peripheral osteomas should be classified from several pathologic entities such as bony exostosis, osteoblastoma, osteoid osteoma and complex odontoma.The most important clinical feature differentiating bony exostosis and osteoma is that bony excrescences that usually stops growing after the individual crosses the puberty period. Osteoblastomas and osteoid osteomas are painful and fast growing than peripheral osteomas. Recurrence of peripheral osteoma after surgical excision is rare. The

goal of followup is to search for new growths or other signs suggestive of Gardner syndrome,which was not ruled out in our case,as the OPG revealed many mixed radiopaque and radiolucent areas which were present on both sides of mandible. Malignant transformation of peripheral osteomas has not been reported in literature.[3]

Histologically, osteomas consist of dense compact bone with no haversian system.

Conclusion

Slow growing osteomas are benign tumours. The recurrence rate is very rare. A veryrare neoplastic lesion in the maxillofacial region like Peripheral osteoma is more frequently found in mandible. The radiographprovides sufficient information for diagnosis but CT scan is the choice for planning surgery. Completely removing the tumour surgically is the most preferred treatment.

Abstract

Dentinogenic ghost cell tumor DGCT) is a rare, locally invasive and aggressive, benign odontogenic neoplasm which is considered to be a solid variant of calcifying odontogenic cyst COC) with locally aggressive behavior.These resemble other epithelial odontogenic tumors having proliferation of odontogenic epithelium, an abnormal keratinization in the form of ghost cells and dysplastic dentine. There are no characteristic clinical or radiologic pathognomonic features of this rare neoplasm and is confirmed by histopathological evaluation. The present report describes an extremely rare presentation of a DGCT in the posterior body-ramus of the mandible of a 13-year-old male child, which is an unusual age of occurrence.

Keywords: *Calcifying odontogenic cyst, dentine, ghost cells, aggressive tumor.*

Introduction

The jaw bones are affected by a perplexing variety of odontogenic cysts and tumours, and some of them are heterogeneous lesions which can present as central and peripheral or cystic and benign neoplastic or malignant variants. Dentinogenic ghost cell tumor DGCT), is a rare odontogenic neoplasm which is a benign neoplastic variant of calcifying odontogenic cyst COC). Gorlin et al described COC as a distinct entity in 1962 and it was eponymously referred to as Gorlin cyst.[1] In 1971 it was included in the WHO classification of odontogenic cysts and tumours. Later in 1981, COC was classified by Praetorious *et al*. into cystic and solid neoplastic variants and because of dentinoid production in the tumour it was called DGCT.[2] The WHO classification of odontogenic tumours and cysts also recognizes DGCT as a mixed epithelial-mesenchymal) odontogenic tumour.[3] DGCT is considered as a locally aggressive and infiltrative odontogenic having a high recurrence rate after resection. We report a case of DGCT in a 13-year-oldboy.

Case report: A 13 years old male patient reported to the department with chief complaint of swelling in the lower jaw in the last 1 month. History revealed that swelling was slow-growing in nature, gradually increasing to the present size. There was no pain, tenderness or discharge associated with the swelling.

On examination, there was facial asymmetry with asingle diffuse swelling was present on the right side of the mandible which was ovoid in shape, measuring 4x3cm in size, having smooth surface, bony hard in consistency and no tenderness was elicited on palpation. **Figure 1a)**The same swelling was seen intra-orally, obliterating the buccal sulcus in relation to 44 to the right retro-molar region. **Figure 1b & c).** There was bi-cortical expansion, with grade I mobility of the involved teeth. The swelling was bony hard in consistency with few areas yielding to pressure and soft in consistency.

Bony irregularity/discontinuity in the cortex were palpable both buccally and lingually in some areas, with mild tenderness. 47 was missing.

Correlating the history of a slow growing swelling and clinical findings of a bony hard swelling having bi-cortical expansion and possible cortical perforation in the tooth bearing region with a missing mandibular second molar, a provisional diagnosis of benign bony odontogenic neoplasm was made. A clinical differential diagnosis of Unicystic ameloblastoma, Ameloblastic fibroodontoma, Complex composite odontome were considered.

The patient was subjected to conventional radiography. Intra-oral periapical radiographof the 44 to 47 regions revealed well circumscribed radiolucency periapicaly with the presence of bony septae within the radiolucency, the border was corticated. Peri-coronally irregular calcified flecks were seen distally in relation to 46. Root resorption was evident in 46 with loss of lamina dura in 45 and 46.**Figure 2a)**

Right mandibular lateral occlusal radiograph revealed bi-cortical expansion with evidence of irregular cortical perforation both lingually and buccally distally in relation to 46. The borders were well-defined, internal structure radiolucent with patchy calcifications. Lingually expansion of cortex also evident in relation to 43-46 region. **Figure 2b).**

Panoramic radiograph revealed an extensive, well localized radiolucent lesion in the right body and ramus of the mandible extending up to the coronoid process, measuring 3x7cm in size, with well-defined corticated margins. Internal structure was radiolucent with presence of large radiopaque septa and irregular calcified flecks of calcification distal to 46. There is loss of lamina dura in 45 and 46, root resorption in 46 and distally displaced 47 at the angle of the mandible on the right side with expansion of the inferior border of the mandible. The tooth bud of 48 was also absent [Figure 2c]. The radiologic differential diagnosis consisted of calcifying epithelial odontogenic tumour, calcifying epithelial odontogenic cyst, unicystic ameloblastoma and ameloblastic fibrodontoma. Fine needle aspiration cytology was done but did not yield any aspirate. Since the lesion was extensive and the patient was only 13 years old, a conservative approach was adopted for treatment. Marsupialization of the lesion was done under local anaesthsia, preserving the mandible. The entire lesion was curetted and disorganized irregular calcific masses were seen. **[Figure 3a & b]**The impacted tooth, 47 was not extracted avoiding a fracture at the angle of the mandible.

The curetted mass was sent for histopathologic evaluation. Hematoxylin and eosin stained section showed a lesion composed of cystic epithelial lining supporting the underlying vascular connective tissue. This gave an impression of calcifying odontogenic cyst. Evaluation of further sections demonstrated multiple foci of odontogenic epithelial cells with calcifications, ghost cells and dentinoid in the connective tissue wall. **[Figure 4a & b].** These findings suggested the diagnosis of DGCT. Immunohistochemical evaluation using Van Gieson's stain **[Figure 4c]** further confirmed the presence of ghost cells and dentinoid favouring the diagnosis of DGCT.The patient was kept under follow up and evaluated after every week and after 3 months a panoramic radiograph was taken revealed bone formation in the cavity. **[Figure 5]**

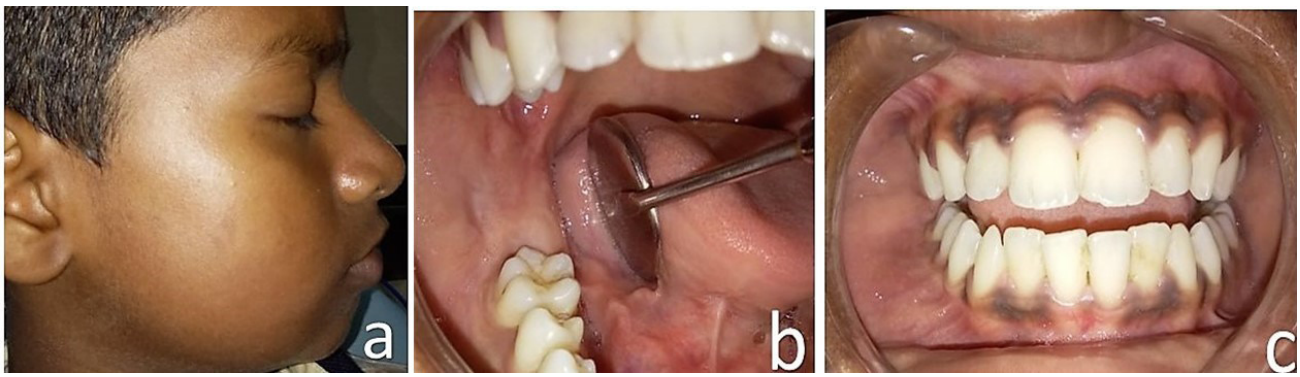

Figure 1: a. Facial asymmetry with diffuse swelling was present on the right side of the mandible. b. Missing 47 with intra-oral swelling. b. Intra-oral swelling obliterating the buccal sulcus.

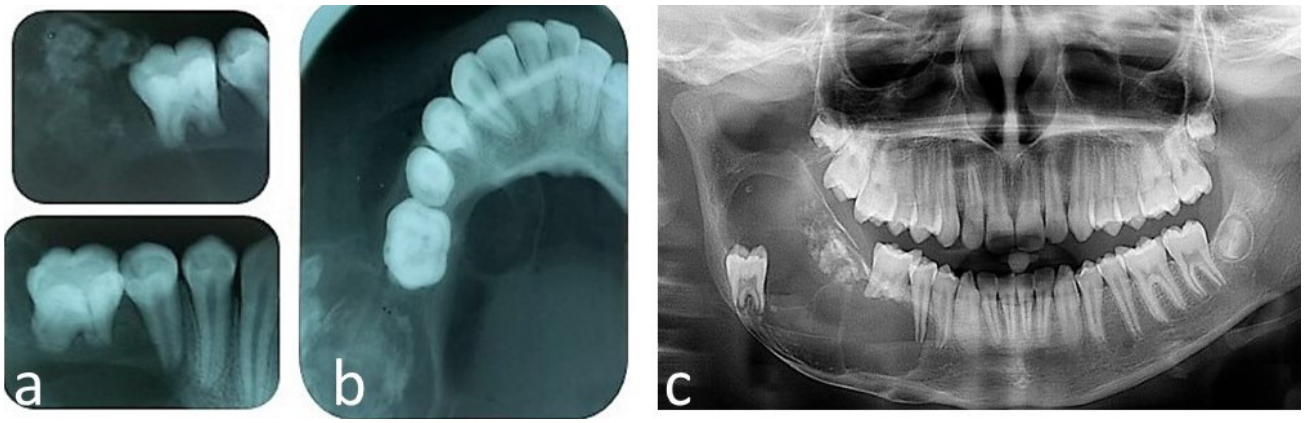

Figure 2 a. Intra-oral periapical radiograph showing well circumscribed radiolucency periapicaly with the presence of bony septae within the radiolucency, and irregular calcified flecks seen distally in relation to 46. b. Right mandibular lateral occlusal radiograph revealed bi-cortical expansion with evidence of irregular cortical perforation both lingually and bucally distally in relation to 46. The borders were well-defined, internal structure radiolucent with patchy calcifications. c. Panoramic radiograph revealed an extensive, well localized radiolucent lesion in the right body and ramus of the mandible extending up to the coronoid process, measuring 3x7cm in size, with well-defined corticated margins.

Multiple foci of odontogenic epithelial cells with calcifications, ghost cells and dentinoid in the connective tissue wall suggestive of DGCT. [original magnification 40x] c. Immunohistochemical evaluation using Van Gieson's stain stained positive confirming the diagnosis of DGCT. [original magnification 40x]

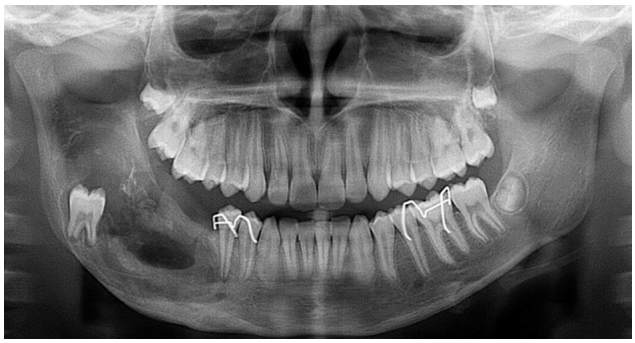

Figure 5. Panoramic radiograph at 3 months post-operative follow up showing bone formation in the cavity.

Discussion

Dentinogenic ghost cell tumor is an uncommon benign odontogenic neoplasm, and was recognized by Praetorius et al. In 1981 for the neoplastic variety of COC and then Colmenero et al proposed the term odontogenic ghost cell tumour.[4] It is also recognized as an intra-osseous neoplastic variant of the calcifying odontongenic cyst COC) by some authors, comprising of only 2-14% of COC as solid neoplasms.[5]

DGCT is a tumour which is usually seen in middle aged individuals with a slight male gender predilection. While both jaw bones are equally affected, the common site is between the canine and the first molar. [6] The intra-oesseous variety of DGCT is commonly seen, though a peripheral mucosal/gingival tumour has been reported in few cases. The clinical presentation is generally in the form of an asymptomatic swelling, rarely pain and tenderness has been reported.[7] The present case is indeed a rarity, as the age of occurrence is in the teens, the site being posterior mandible with pain a presenting complaint.

Asymptomatic DGCT may be incidentally be diagnosed on routine radiography for dental treatment. It does not have a pathognomonic radiographic appearance and is generally localized with well-defined margins. [9] It may be entirely radiolucent or radiopaque or even mixed radiopaque-radiolucent lesion with uni or multi-locularity. Resorption of roots, adjacent teeth displacement or association with impacted teeth have been reported. Bicortical expansion and scattered calcified masses are observed in the lesion. [10,11]

Histologically DGCT has sheets and rounded islands of odontogenic epithelium in a mature connective tissue. The tumour island epithelia resemble ameloblastoma and may have mior cyst formation. Some epithelial cells swell up, become ellipsoidal and lose their nuclei, form foreign body granuloma and dystrophic calcifications as a result of apoptosis. Such cells are called ghost cells. [12] However ghost cells are not characteristic of DGCT but can be seen in Odontomes, Ameloblastoma and ameloblastic fibro-odontome. Many scattered homogenously basophilic granules are seen which represent the osteoid or dentinoid material which stain with connective tissue stains like Van Gieson, Heidenhain and Goldner stains.[13]

Treatment of DGCT is surgical resection, either en-block or segmental resection with long term follow-up due to reports of recurrences after resection. Intra-osseous DGCTs are locally aggressive lesions which are invasive with a high recurrence rate of about 70%. [14] Owing to the fact that the child was in the growing age, marsupialization with curettage was performed to save the mandible and the patient was kept for regular follow-up every 3 months.

Orofacial Changes Due to Metals, Chemicals and Osteodystrophies

Satya Ranjan Misra

Professor & Head, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha

Abstract

The maxilla and mandible are unique compared to other bones in the body in more ways than one. They develop from migration of cells from the neuroectoderm in the embryo making them embryologically unique. The anatomy of the maxilla and mandible is also unusual as they bear tooth buds which eventually form teeth. Diseases arising in other bones also affect the jaw bones, in addition to those osteogenic diseases, they also get afflicted by various odontogenic lesions which has bizarre manifestations. Not only that metabolic diseases can manifest in the jaw bones, metals and chemicals also affect the jaw bones and the oral cavity. In this paper, a brief description of the metals, chemicals and osteodystrophies on the orofacial region is discussed to increase awareness among dentists about the said diseases.

Keywords: *Bone disease, Metabolic defects, Oral manifestations, Osteodystrophy.*

Introduction

This overview ofthe orofacial lesions illustrates the variable manifestations that can possibly occur in the maxilla and mandible. The dentist who diagnoses and treats the patients with swelling in the jaw bones must be fully aware that these lesions may mimic one another, not only clinically, radiologically but also histologically confounding the diagnostician.[1] Mistakes in diagnosis can lead to inappropriate treatment which can complicate the pre-existing scenario. What is even more confusing about these lesions is that they may initially manifest as dental or periodontal problems, and an unsuspecting inexperienced dentist may not be aware of the more serious afflictions of the jaw bones. Hence this article aims to clear the diagnostic confusion and bring clarity in the acumen.

Lead: In clinical examination of mouth, sometimes we will find a bluish line along the margin of the gingiva. This bluish line is called "Burtonian Line" and suggests that the patient is suffering from lead poisoning'. [2] Lead poisoning is an occupational disease in which individuals who works in lead factory, painting and other occupations involving lead, are exposed to lead. The lead fumes enter the mouth and combine with hydrogen sulfide which develops from fermentation of accumulated food in gingival margin and form as lead sulfide. Thus, the patient who is suffering from lead poisoning will have recurrent attacks of diarrhea and constipation. Thus, the Burtonian line will help to diagnose, lead poisoning.

Bismuth: In the gingiva sometimes blue – black line appears. It is called "Bismuth line". This bismuth line is due to the action of Bismuth with hydrogen sulfide. Bismuth reaches the mouth from occupations like Bismuth factory. Hydrogen sulfide comes from the fermentation of food particles. The blue-black bismuth line is well demarcated in the gingiva.[3] The Bismuth line is diffusely distributed compared to lead line. Sometimes it occurs only in interdental gingiva or lingual gingiva. In lead poisoning, there will be burning sensation of the mouth.

Mercury: Sometimes the patient will have burning sensation in the mouth, in the form of hot mouth associated with itching sensation. There will be profuse salivation with metallic taste, swollen lips with superficial cracks, grayish pigmentation of gingiva. Diffuse oral mucosal ulceration with areas of necrosis will be there. The tongue will be enlarged and the covering mucosa will be ulcerated.[4] This lesion is due to mercury poisoning with systemic involvement. Mercurialism is an occupational disease in which the patient is dealing with mercuric compounds. Exposures to mercurial compounds and industrial mercury hazards, use of mercurial diuretics, exposure to dental amalgam are the factors that are

concerned in mercury ingestion. The patient will have intestinal colic, diarrhea, headache, tremor of fingers. Thus, mouth lesion will help to diagnose mercury poisoning.[5]

Fluoride: Some patients may have brownish discoloration of teeth. The discoloration may vary from white opaque flecks to pitting and corroded appearance resulting in mottled teeth and enamel hypoplasia. The brown staining is evident on exposure to sunlight after tooth eruption. This is the oral manifestation of Fluorosis which is caused due to excess consumption of fluoride, more than 1 ppm in drinking water during the time of formative stage of tooth development. This higher level of fluoride interferes with the calcification of the enamel matrix. This is called as dental fluorosis which is an endemic disease and it may be associated with skeletal fluorosis affecting bones and joints and non-skeletal fluorosis affecting soft tissues and organs. These patients may also complain of severe bone pain, stiffness in back bones with outward bending of legs, hands with loss of shape and contour resulting in knock–knee syndrome. Restriction of spine movements, calcification of soft tissues like tendons and ligaments are characteristics findings of fluorosis.[6]All dental fluorosis is not associated with skeletal fluorosis. Only those individuals who are exposed to fluoride toxicity throughout life in childhood, adulthood and adolescences, are associated with skeletal fluorosis. [7] If patients are exposed to fluoride in childhood, and not exposed to fluoride in adulthood, they only develop dental fluorosis and not skeletal fluorosis.Thus, gingival enlargement helps to diagnose systemic diseases like epilepsy and hypertension.

Tetracycline: Some children may present with grayish – brown discoloration of both deciduous and permanent teeth, which is more pronounced at the time of eruption. Positive history of tetracycline therapy taken by the child's mother during pregnancy is suggestive of tetracycline hypoplasia. Dimethyl chlortetracycline has been reported to produce severe staining while oxytetracycline and doxycycline produce less staining. The reason for staining is mainly due to chelating property of tetracycline, which binds with bivalent metal ions such as calcium and phosphorus in hydroxyapatite crystals of enamel, producing enamel hypoplasia with absence of pitting or mottling as seen in fluorosis, but an increased incidence of dental caries is noticed.[8] The severity of staining depends on the duration, and dosage and the time of initiation of therapy. Observable tooth discoloration is present during the period of crown calcification. Total dosage exceeding 3 gm with duration of treatment longer than 10 days produces staining of the teeth. Tetracycline itself fluoresces under ultra violet light and the affected teeth also fluoresces a bright yellow colour which gradually diminishes in time.

Osteogenesis imperfecta: In certain patients, the teeth will appear as yellowish or yellowish gray in colour with opalescent hue. All teeth are affected and the teeth will appear as bulbous crown, stunted root with pulp obliteration. On clinical and radiological observation, incisal attrition and hypersensitivity will be present. This is called dentinogenesis imperfecta and is associated with mandibular prognathism, high arched palate and macroglossia.[9] This dentinogenesis imperfecta is the oral sign of osteogenesis imperfecta, an osteodystropy of bone. Osteogenesis imperfecta is a generalized bone disease in which bone collagen is affected due to genetic disturbances. The bone will become brittle, fragile deformed and tends to fracture and on healing defective bone is formed. As this disease is a mesodermal involvement of genetic disturbance, other mesodermal structures are also affected resulting blue sclerae, deafness and dentinogenesis imperfecta as dentin is a mesodermal origin.

Osteopetrosis: Sometimes the patient will have retarded teeth eruption, hypoplastic crowns with arrested root growth. There will be a marked predilection for osteomyelitis following tooth extraction. If these oral signs occurs associated with other manifestations such as stunted growth with marble bones, thickened skull with frontal bossing, depressed nasal bridge with hypertelorism, nerve compression with hepatospelnomegaly and genu valgum and slow walk, it is suggestive, that the patient is suffering from osteopetrosis.[10] In osteopetrosis or the marble bone disease there is normal appositional bone growth, but failure of physiological bone resorption. The osteoclasts are defective in function due to deficiency of RNA.

Cleidocranial dysostosis: If the patient has underdeveloped maxilla, narrow arched palate unerupted buried teeth, absence or paucity of cellular cementum and retained deciduous teeth and these signs occurs along with large cranium absence of clavicles or rudimentary clavicles, moving shoulders to the midline and frontal bossing of the skull, then these signs are indicative hat the patient is suffering from cleidocranial dysostosis.[11] It is a genetic disease.

Crouzon syndrome: In some patients, maxilla appears hypoplastic with 'v' shaped maxillary arch, cleft and high arched palate with mandibular teeth completely overlapping the maxillary teeth resulting in cross bite, crowding of maxillary teeth causing skeletal class iii malocclusion. Partial anodontia, unerupted teeth, macrodontia are associated oral findings.[11] They may appear with bilateral exophthalmos, parrot beaked nose, hypertelorism, divergent strabismus with frontal bossing suggestive of Crouzon syndrome. Craniofacial dysostosis without syndactyly is called crouzon syndrome is caused by genetic disturbance characterized by premature closure of cranial sutures.

Achondroplasia: In some patients, retruded maxilla, relative prognathism of mandible, congenital missing teeth disturbance in shape of existing teeth are present and these features of mouth are suggestive of achondroplasia. Achondroplasia is a condition of absence of cartilaginous growth, in which bones are developed abnormally due to genetic disturbance.[12] Patient appear with stunted growth, bowed legs, brachycephalic skull, stubby fingers, lumbar lordosis, prominent buttocks, protruding abdomen, laxity of ligaments with limited mobility of joint. These patients cannot straighten their elbows and hang their arms freely at the sides.

Rickets: Sometimes the patient may present with open mouth, hypoplastic teeth. If these signs occur associated with manifestations like skull of a scholar, chest of a pigeon, tummy of a drum, knock knee genu valgum and if the child walks slowly, then it is suggestive of rickets. Rickets is a disease caused by deficiency of vitamin – D which is essential for calcium absorption in the intestine. During the development of tooth, if calcium is deficient in a particular period, the enamel developing at that time is affected with improper calcification resulting in hypoplastic teeth.[10]

Cherubism: Patients may present with chubby face due to painless progressive bilateral symmetric swelling of posterior mandible manifested in early childhood by the age of three years. Oral findings include enlarged palate, widening and distortion of alveolar ridge with premature exfoliation of deciduous teeth, and displacement of existing teeth.[12] Radiographic examination reveals multilocular cystic spaces with floating teeth in cystic spaces. Patient on examination reveals cherubic appearance with eyes upturned to heaven due to wide rim of exposed sclera below the iris which are characteristic findings of cherubism. It is considered to be a familial fibrous dysplasia of jaws.

Fibrous dysplasia: In some patients, unilateral painless expansion and deformity of jaws, mainly maxilla, not crossing the midline with displacement of teeth, delayed eruption of teeth due to loss of normal support of developing teeth are present. In some cases, maxillary sinus is obliterated and facial deformity is present due to prominence of zygomatic process, with expansion extending backwards to the base of skull, involving the floor of orbit.[13] Intra oral pigmentation of lips buccal mucosa associated with skin lesions unilateral in distribution involving the affected side are characterized by pigmented brown melanotic spots (café-au-lait) spots and endocrine disturbances such as precocious puberty, hyperthyroidism and diabetes mellitus are present.

In these patients bowing or thickening of long bones with hockey stick deformity, recurrent bone pain and fracture are commonly seen. These features are suggestive of albrights syndrome which consists of polyostotic fibrous dysplasia, café au- lait pigmentation and endocrine disturbances.[14] In some cases mono ostotic fibrous dysplasia, in which only single bone is involved with jaws more frequently affected and painless swelling of maxilla resulting in leonie appearance of face is present. Radiographic examination of fibrous dysplasia reveals buccal plate expansion more than lingual plate with ground glass or peau–d orange appearance. Fibrous dysplasia is a fibro–osseous lesion of developmental in origin in which bone forming mesenchyme in jaw fails to form bone and calcification occurs in the fibrous tissue present.[15]

Paget's disease of bone: The patient has enlarged maxilla, widened alveolar ridge, flattened palate. The teeth are loose with spacing, open mouth, exposing the teeth. If these oral manifestations occurs along with signs like short square figure, long arm sunken chest, curved back, bent shoulder large head hanging forward, waddling gait, bowed legs, outturned toe and the patient walks with an aid of stick, then it is indicative that the patient is suffering from Paget's disease, which is a chronic disease of bone with unknown etiology.[15]

Conclusion

The oral cavity and the face are affected by diseases which are neither inflammatory nor neoplastic but are reactive or genetic or idiopathic. A brief discussion on the effects of metals and chemicals is shared for

documentation. In this era of new age diagnostics, the importance of a proper history taking and a meticulous clinical examination cannot be undermined, and we as dentists play a vital role in the detection of systemic diseases from tell-tale oral signs.

Wegener's Granulomatosis Presenting as a Diffuse Palatal Swelling, a Rare Presentation: Case Report

Satya Ranjan Misra[1], G. Maragathavalli[2]

[1]Professor & Head, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, India, [2]Professor & Head, Department of Oral Medicine & Radiology, Saveetha Dental College & Hospitals, Chennai

Abstract

Wegener's granulomatosis (WG) is an uncommon idiopathic, systemic inflammatory disease which is characterized by necrotizing granulomatous inflammation and pauci-immune small vessel vasculitis of the kidneys and respiratory tract resulting in significant tissue destruction. The clinical features are generally non-specific thereby posing a diagnostic challenge. Oralmanifestations of the disease are rare and again non-specific. Oral ulceration and gingivalenlargement is often seen. Though some authors suggest a 'strawberry' like gingivitis to be acharacteristic sign of WG, it is not consistently seen in all cases. Histopathological evaluation of the lesion showing granulomatous inflammation may not be pathognomonic but helps inexclusion of other diseases but in conjunction with a positive anti-neutrophil cytoplasmic antibodies (ANCA) test confirms the diagnosis. The disease is not curable and hencetreatment is aimed at inducing and sustaining remission. Glucocorticoids with other immunosuppressants are the most accepted form of therapy.

Keywords: *Anti-neutrophil cytoplasmic antibodies, immunosuppressants, strawberry gingivitis, vasculitis.*

Introduction

Wegener's granulomatosis (WG) is a rare disease and affects multiple organs although often it may be limited to few organs. Characteristically a typical presentation is involvement of the upper respiratory tract, lungs and kidneys. Oral involvement is uncommon and may present as a non-specific mucosal ulceration. Gingival manifestations of the disease, especially the maxillary anterior region is seen in cases of oral involvement of WG. It may manifest as telangiectatic hyperplastic gingivitis considered being a diagnostic feature of WG.[1] WG is a rare systemic auto-immune disease which is a primary systemic vasculitis (PSV). Necrotizing vasculitis and purulent inflammation of tissues with granuloma formation occurs in blood vessels which results in ischaemia in vital organs and extensive tissue destruction which can be life threatening.[2] It is currently known as Granulomatosis with polyangiitis (GPA), an ANCA-associated necrotizing vasculitides.[3] The aetiology is unknown but a number of microbial exogenous factors like *Staphylococcus aureus*, *Mycobacterium avium-intracellulare* or parvovirus B19 have been considered.[4] Clinically it was considered to be of 2 types: localized and generalized, though varioussubtypes have been described.[5] The annual incidence of WG is estimated at 1:100,000 and about 90% of the patients are Caucasians.[3] There is no gender predilection and the average age of incidence is 50 years. There are few common prodromal constitutional symptoms like fever, weight loss, night sweats, and stiffness in joints.[5] Nasal stuffiness or epistaxis may also be present. Such prodromal symptoms can last for months before the disease progression occurs. All organ systems can be involved with different signs and symptoms of the disease which are however nonspecific.

Case Report: A 42-year-old female patient reported to the dental hospital with growth in the palate for 6 months. History revealed the patient underwent excision of the growth 2 months back however there was recurrence. There was mild pain and pus discharge associated with the growth. The patient had several episodes of fever and cough within the past one year. There was no known drug allergy or no other significant medical, personal or family history

On clinical examination extensive palatal swelling

was seen bilaterally restricted to the hard palate only, (Figure 1a) with gingival swelling both buccally and palatally/lingually in both the jaws. (Figure 1b) The palatal swelling measured 4x5cm bilaterally, was smooth surfaced, firm in consistency and slightly tender on palpation. The gingival enlargement involved both the free and attached gingiva with purulent discharge from the gingival sulcus on probing. The maxillary anterior gingiva was enlarged; erythematous and appearing somewhat like strawberry. (Figure 1c) The maxillary teeth were demonstrated excessive mobility while the mandibular teeth were within physiological limits.

Figure 1a. Diffuse, extensive, bilateral swelling of the hard palate; Figure1b. Generalized gingival enlargement of the maxilla and mandible with pus discharge from the gingival sulcus; Figure 1c. Anterior maxillary labial gingiva showing minute, white punctate granular 'strawberry' like appearance.

Correlating the history and clinical findings the following lesions were included in the differential diagnosis:

- Deep fungal infections like: Mucormycosis, Histoplasmosis, Aspergillosis
- Tuberculosis
- Kaposi's sarcoma
- Plasma cell gingivostomatitis
- Sarcoidosis
- Wegener's granulomatosis
- Crohn's disease
- Leukemia
- Non-hodgkin's lymphoma
- Carcinoma maxillary antrum

The following investigations were performed to reach a definitive diagnosis:

- Complete blood count (CBC) was performed and was within normal limits.
- Maxillary occlusal cross-sectional radiograph revealed alveolar bone loss anteriorly with haziness in the maxillary antra. (Figure 2a)
- Panoramic radiograph revealed generalized extensive alveolar bone loss. (Figure 2b) Water's view of skull showed antral cloudiness bilaterally. (Figure 2c)
- Chest radiograph did not reveal any abnormality.
- Computed Tomography scan of the maxilla, coronal view revealed homogenous soft tissue density involving right antrum completely and left antrum partially with thickening of the soft tissue lining of the nasal cavity and turbinates. (Figure 2d) Destruction of maxillary alveolar bone was evident in axial view. (Figure 2e)
- An incisional biopsy was taken from the palatal growth under local anaesthesia and histopathologic evaluation exhibited orthokeratinized stratified squamous epithelium pseudoepitheliomatous hyperplasia. (Figure 3a) The underlying fibrous connective tissue showed numerous vascular spaces with dense chronic inflammatory cell infiltrate presenting as perivascular infiltrate (Figure 3b, c) associated with foreign body giant cells. (Figure 9d) The histopathologic features were suggestive of Vasculitis.
- Cytoplasmic pattern of antineutrophil cytoplasmic

antibodies (c-ANCA) test was performed and was positive. (A titre of 15 units was obtained where greater than 5 units is considered positive)

- Liver function tests and renal function tests were all within normal limits.
- Urine analysis yielded normal results.

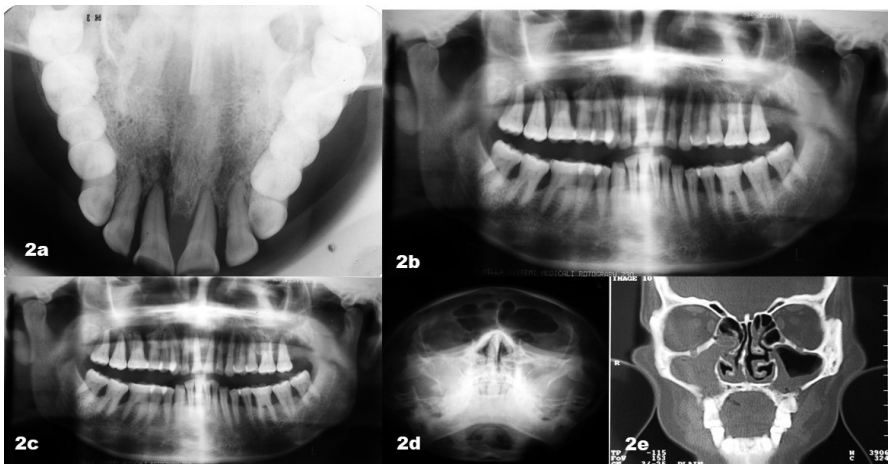

Figure 2a. Maxillary cross-sectional occlusal radiograph showing alveolar bone loss anteriorly. 2b. Panoramic radiograph showing extensive generalized alveolar bone loss. 2c Water's view of skull showing antral cloudiness bilaterally. 2d. CT scan of the maxilla, coronal view showing homogenous soft tissue density involving right antrum completely and left antrum partially with thickening of the soft tissue lining of the nasal cavity and turbinate. 2e. CT scan of maxilla showing destruction of maxillary alveolar bone in axial view.

Correlating the clinical, histopathologic and serologic findings a final diagnosis of Wegener'sgranulomatosis was made. The patient was referred to a rheumatologist for treatment. She was treated with oral prednisolone 60mg/day in divided doses with Cyclophosphamide 100mg/day for 3 months. The patient had remission of the disease and the drugs were tapered but the patient did not turn up for follow-up.

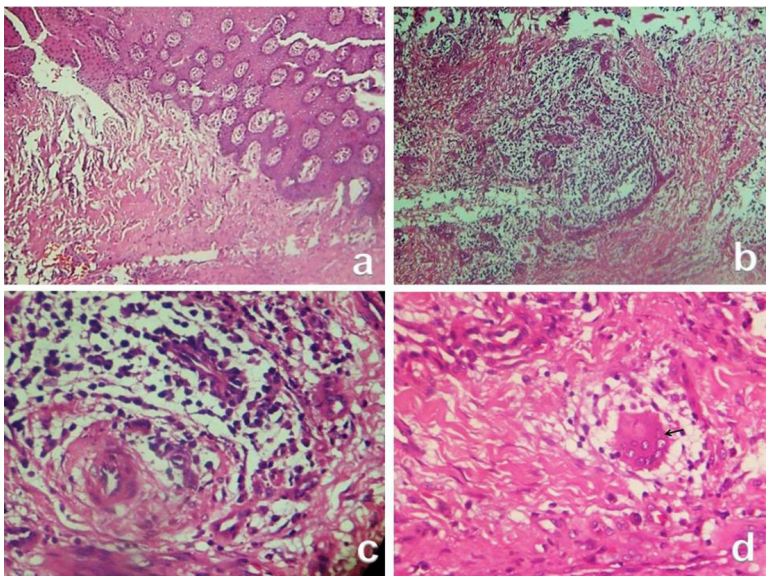

Figure 3: H & E stained section showing orthokeratinized stratified squamous epithelium with pseudoepitheliomatous hyperplasia. (Original magnification 10X, 9a) The underlying fibrous connective tissue showed numerous vascular spaces with dense chronic inflammatory cell infiltrate presenting as perivascular infiltrate (Original magnification 10X, 9b and 40X, 9c) associated with foreign body giant cells. (Original magnification 40X, 9d)

Discussion

Oral manifestations occur in approximately 6-13% of patients with WG with about 5-6% patients having oral lesions as the sole manifestations of the disease.[6] Oral mucosal ulceration, delayed healing of extraction wounds, lingual necrosis, osteonecrosis of the palate, oral-antral fistulae, swelling and desquamation of the lips and salivary gland enlargement have been reported.[7] Gingival involvement is common, especially the maxillary anterior gingiva manifests as enlarged, erythematous free gingiva, attached gingiva and the interdental papillae with gingival pain and bleeding.[8] The colour may vary from red to purple and have a petechiae or a granular appearance with white punctate lesions resembling an over ripe strawberry.[9] Later ulceration, osteomyelitis and necrosis of the underlying bone may occur with mobility and tooth loss.[10]

Palatal ulceration, growth and inflammatory destruction are uncommon, but it can occur as an extension of the disease from the nasal cavity.[11] Non-tender, nodular masses or diffuse swelling of the lip also has been reported.[7] Along with the airway involvement the salivary glands may be affected rarely presenting as unilateral or bilateral parotid gland enlargement.[12,13]

Histopathologic features of WG include necrosis, granulomatous inflammation and vasculitis.[5] The granulomatous inflammation is characterized by collections of macrophages, multinucleated giant cells and chronic inflammatory cells. Typically, the vasculitis of WG shows fibrinoid necrosis affecting the walls of small to medium sized arteries and veins.

The diagnosis of WG is based on the recommendation of the American College of Rheumatology, which has 4 criteria.[14] Fulfilment of any 2 criteria gives a positive diagnosis of WG. The criteria are: 1) oral ulcers or epistaxis/nasal inflammation, 2) nodules,fixed infiltrates or cavities in chest radiograph, 3) abnormal urinary sediment and 4) granulomatous inflammation on biopsy. In the absence of granulomatous inflammation onbiopsy a positive-ANCA test can fulfil the diagnosis of WG.

There are a group of antineutrophil cytoplasmic antibodies- (ANCA-) which cause the inflammation in WG. Therefore serum ANCA determination aids in the diagnosis of WG, but ANCA positivity does not always lead to a definitive diagnosis and ANCA negativity does not always exclude WG.[15]

Different immunosuppressive treatment protocols have been devised for the management of WG of which glucocorticoids in combination with cytotoxic agents (cyclophosphamide, methotrexate, or azathioprine) are used commonly with 95% survival at 5 years but with serious systemic side effects which include life threatening opportunistic infections.[16]

Recently Rituximab anti-CD20 therapy, mycophenolate mofetil–leflunomide, antithymocyteglobulin, and 15-deoxyspergualin, have shown promising results as alternative treatment modalities for WG with less side effects.[17,18]

Conclusion

The present case of a middle-aged female with palatal swelling and generalized maxillary gingivalenlargement in the absence of other significant medical problems shows oral manifestations could be the sole presenting features of this multisystem autoimmune disease. Hence a dentalsurgeon/oral physician may play a vital role in early diagnosis of this otherwise fatal diseaseensuring prompt treatment thereby decreasing the morbidity and mortality associated with Wegener's granulomatosis.

Digital Model in Orthodontics

Anamika Kumari[1], Tusar Kanti Nayak[2], Snigdha Pattanaik[3]

[1]Post Graduate Student, [2]Professor, [3]Associate Professor, Dept. of Orthodontics. Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University). Bhubaneswar, Odisha, India

Abstract

The purpose of 'digital imaging' in orthodontics is to display *anatomical structure of a patient for proper diagnosis and treatment planning*. Until now, imaging technology was limited to two dimensions. Some 3-dimensional (3D) imaging techniques have been developed but they are limited by the amount of information they can display and by their static nature. The development of an interactive 3-Dimensional digital model of a patient's anatomy would greatly improve our ability to determine different treatment options, to monitor changes over time, to predict and display final treatment results, and to measure treatment outcome more accurately. But the main disadvantage is that it cannot be articulated. Digital orthodontic models are as reliable as traditional stone models and probably will become the standard for orthodontic clinical use. Now a days Study model, Digital radiograph and digital photography plays vital role in diagnosis and treatment planning of orthodonticpatient. This article describes about indication,advantages, disadvantage and the procedure of digital model.

Keywords: *Digital model, 3-dimensional Imaging, Orthodontic treatment planning.*

Introduction

The digital cast models have very important role in digitization of everyday life of orthodontics. Now a days Studymodel, Digital radiographs and digital photography plays vital role in diagnosis and to decide treatment planning of orthodonticpatient. Electronic study casts are recent advances. Traditional method include dental and medical history, photography, radiograph, patientrecords in digital format. So, in this scenario digital study model has become moredesirable.[1] Plaster study models are true 3D information that is routinelyused today, and these models can't be properly intermixed or measured with the other diagnostic parameters. After 3 years of testing, in 1999 the American board of orthodontics (ABO) suggested a grading system for posttreatment orthodontic study cast and extra oral radiographs, for making the phase III Examination more accurate. According to ABO'S, seven occlusal parameters have been suggested whichincludes teeth Alignment, vertical position of marginal ridges, buccolingual angulations of molars and premolars, occlusal relation, occlusal contacts, overjet, andmesio distal contacts; measurement on plaster study castand this assessment considered as an important parameter to establish patient's final occlusion.[2]

A plaster dental study cast is a patient's record in all dimensions(3-Dimensional). Study models gives vital information about the inter proximal dimensions of tooth, arch length discrepancy, dental asymmetry, and arch length relationships in all dimension. A study model can also give a 3D evaluation of a treatment planning known as dental ''setup. Other techniques are also available that simulate digital study cast in all plane which can be seen on adigital screen. Digital ortho cad™ is software which was considered as the most precise system for doing measurements on study models. Ortho CAD was the 1st company which proposed a digital study castfacility to market of orthodontics in 1999 followed by electronic-models of Geo Digm Corp in 2001. Later, different digital modelsystems: such as E-model™, Suresmile™, Orthoproof™ and Ortholab™ came to the market from worldwide (Figure 1).[3]

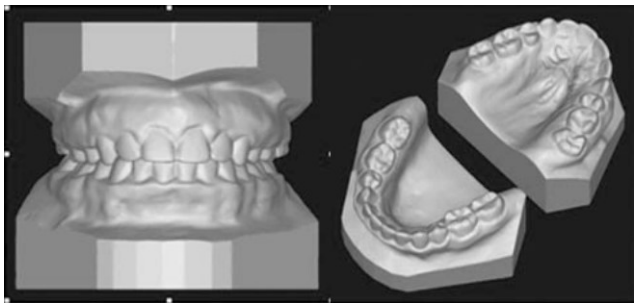

Figure 1. Emodel by Geodigm Y Corporation (Anterior view of digital model 3-D view)

Study model either plaster or digital have 2 important function:

✓ Providing information for proper diagnosis and treatment plan.

✓ Providing 3Dparameters of the actual malocclusion at any stage

But these manual models (plaster/stone) have a many **drawback** such as:

✓ More space is required forstorage and retrieval.

✓ Provides 2D information only

✓ Difficult to transfer

Table 1. Advantages of Digital and Plaster Model

Plaster Model	Digital Model
i. Easy to produce ii. Inexpensive iii. Measurementcan do Easily on plaster casts andcan be mountedon the articulator for study in 3-dimensional evaluation.	i. Easyto store and retrieve. ii. Quickevaluation of 3-dimensional information. No need of retrieval and storage of models in storage area. iii. Ease of interoffice transferability, iv. Possibly equal or better diagnostic capabilities.

Disadvantages: Only disadvantage of 'digitalmodels' is that it cannot be mounted and articulate on articulatoraccording to patient's TMJ function, while it can be partially assessed with jaw alignment assessment software.[4]

Indication: With the software in the computer, the digital cast can be useful to measure:

1. Vital treatment parameters such as overbite, overjet, and arch length.
2. Reliable measurements for: Tooth size, Arch length, Space analysis, Overjet, Overbite, Bolton ratio.

Procedure: Ortho CAD technology makes 3D digital study cast. The designing of this technologyisin such a way so that it canovercome the drawback of traditional study models. 'Digital study cast may allow the use of a proper digital patient record for the orthodontic treatment. Ortho CAD™ software has been designed by Cadent, Ind (Computer-aided Dentistry, Fairview, NJ, USA).[5]

Ortho CAD, gives orthodontista Digital 3-dimensional sets of study cast, that can be altered three dimensionally;can view sectionally in all plane of space and measurement can be done in all desirable plane with accuracy. Ortho CAD uses art and science of computer aided design i.e. CAD to optically scan the '3D cast' duplicated from a 'plaster model'. These are then described to orthodontist by the original Ortho CAD software user line which allows both construction and free alteration of the 'study cast' in 3-Dplane and collection of data by a variety of parameter for diagnosis.[6]

Production and use of digital Study cast

High quality impression: Good quality impressions and registration of bite are essential. The impression should be taken in a good quality alginate, polyvinyl silicone or polyether impression material. The aim is to produce a set of impressions that will be accurate and dimensionally stable as much as possible, considering that they have to be sent to the USA. After taking high quality alginate,such as Orthoprint (Zhermack, Rovigo, Italy) taken inrigid plastic impression trays. The alginate impressions are disinfected, packed in damp paper towel and then sealed with plastic bags to keep it moist. It will ensure that the impression will remain workable and stable at least 5 days.[7] If impression will not reach up to 5 days, then we will use polyether like Impregum (ESPE Dental AG, Seefeld, Germany).

Scanning of Impression by Cadent: After receiving of impression, plastermodel is produced from that impression and scanned optically, any distortion of the 'plaster equivalent', should not incorporated in the Ortho CAD digital system.

Approximately after 10 days of dispatch to the USA, the patient's 3D digital model can be downloaded on to your computer (Figure 2).[8]

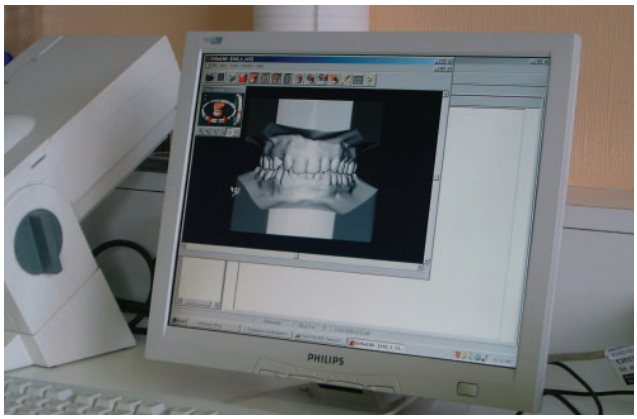

Figure 2: Visual image of 'Digital study models by Ortho CAD on Computer screen

Alteration of the Digital models: Alterationcan be done by Ortho CAD software,which facilitates'Grab and Drag' function so that alterations can be done in all planes of space. The models can be viewed statically from any perspective. Sectioning can be done in anydesired plane. Occlusal surfaces will have better visibility with highlighting the occlusal contacts. Diagnostic procedures like measurement of tooth widths, space assessment, Moyer and Tanaka-Johnston prediction, Bolton analyses, arch width measurement,and, overbite and overjet measurements can be done (Figure 3).

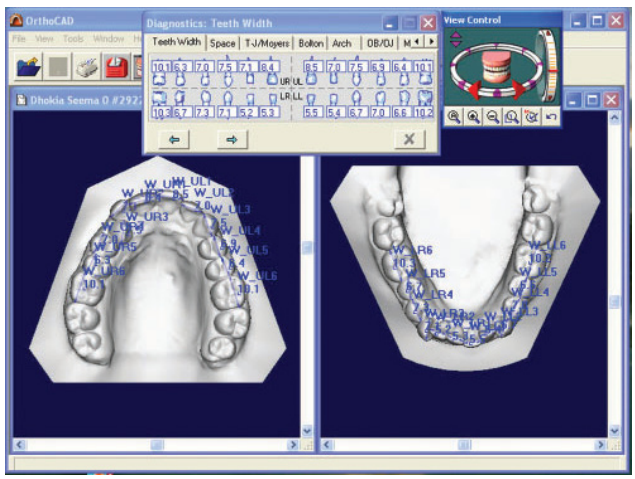

Figure 3. Visualization on digital screen of a measurement function on OrthoCAD

Measurement is made by a digitalcalliper and can be stored automatically. Then arch form and arch size are calculated for evaluation of spaced is crepancies to do all the necessary analysis as per requirement.[9] Post treatment American Board of Orthodontist assessment: Jaw alignment assessment can be sent to the patient in the form of images with all measurements in the printed or it can be mailed to the patient or orthodontist as well. All tasks are properly explained in the division of the software known as help section.

Method of involvement with Ortho CAD™: After Registration on Ortho CAD www.OrthoCAD.com, initiate the delivery of the Ortho CAD software CD with all instructions. This software is simple to load, and provided computer is designated for 'model' download, software for storage and manipulation can be used on many work offices who ever want. The hardware system requirement is properly explained on website. To download on computer, our server, require a good internet and will be 'on line' to act as gateway to download automatically that usually takes overnight. The time taken for transfer depends on the speed of internet connection, but if this takes overnight also, usuallyit's not an issue. Folder which contains the downloaded 'Digital model' files is created on the designated work office or server and each of these files usually take approximately 500 Kb of space. There is no requirement of space storage, while a separate hard drive for all digital model file that are not in active use could be use.[10] At the time of writing the cost of Ortho CAD digital model is $36.00 each set of models about £20.00. plus,shipping charge of approximately £30.00 (the author typically shipped 3 or 4 set of impression per box) and after addition it bring a total cost for a set of models to around £28.00–£30.00. 346 L. Joffe Features Section JO December 2004. The software for the digital studymodel is provided without anyprice.[11]

Conclusion

Byusing digital models, clinician can move, rotate, or zoom in any plane or orientation. Various model analysis, arch length discrepancy and curve length measurement can easily be done by pointing and clicking mouse. Many orthodontic and surgical prediction can be done on the digital models which will increase the accuracy of the prediction of treatment outcome.

An Insight into Oral Verruciform Xanthoma: A Report of Two Cases

Shubhangi Pareek[1], Swagatika Panda[2], Tariq Soyab[3], Anurag Satpathy[4] Rashmita Nayak[4], Neeta Mohanty[5]

[1]Post Graduate Trainee, [2]Professor, Department of Oral and Maxillofacial Pathology and Microbiology, Institute of Dental Sciences, [3]Post Graduate Trainee, Institute of Dental Sciences, Department of Oral and Maxillofacial Pathology and Microbiology, [4]Professor, Department of Periodontics and Implantology, Institute of Dental Sciences, [5]Professor and Head, Department of Oral and Maxillofacial Pathology and Microbiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Oral Verruciform xanthoma (OVX) is a benign mucocutaneous, rare, asymptomatic lesion of unknown etiology and ambiguous nature involving the oral mucous membrane of the middle-aged during the fifth to seventh decadeof life. Clinically it may be presented as a verrucous, polyploid or sessile mass mostly solitary and slow growing in the hard palate,gingival, tongue or buccal mucosa. Colour of the lesion may vary from white, pink or red and there is a slight male predilection. The histopathological features of OVX are however pathognomonic, characterized by the presence of lipid- laden foam cells confined to the papillary areas of connective tissue. The final diagnosis is always histopathological as its clinical features are not distinct and OVX must always be considered in the differential diagnosis of other verrucous and papillary lesions. Treatment of OVX is complete surgical excision with follow up to avoid its recurrence. We present2 cases of oral verruciform Xanthoma, which were provisionally misdiagnosed as pyogenic granuloma and traumatic fibroma respectively based upon their clinical presentation and after a thorough histopathological examination revealed an entirely different diagnosis in both the cases.

Keywords: *Oral verruciform xanthoma, OVX, mucocutaneous lesion, foam cells.*

Introduction

Oral Verruciform Xanthoma (OVX) being a quite rare, benign mucocutaneous lesion is often difficult to diagnose clinically as it may have a varied presentation. It was first described by Shafer in the oral cavity in 1971 but same lesions have also been reported to occur in penis, vulva and the scrotum or in chronic inflammatory skin diseases such as Epidermolysis bullosa, epidermal nevi, discoid lupus erythematosus and graft versus host disease When there is involvement of the oral cavity, the lesion is usually symptomless and solitary, well demarcated from the surrounding mucosamainly involving the gingiva or hard palate, however, cases involving tongue and buccal mucosa have also been reported. It may have a papillary, verrucous, polyploid or plaque like appearance with colour of the lesion varying from whitish to red or pink. Most cases have been reported to occur during the fifth to seventh decades of life, more so in male.[1-6]

The histopathogical picture of OVX is pathognomonic with collection of lipid-laden foamy cells or "xanthoma cells" within the papillary areas of connective tissue. The overlying stratified squamous epithelium is hyperkeratotic with extended rete pegs and displays papillary or verrucous proliferations into the underlying connective tissue stroma. Within the projections of surface epithelium there may be presence of keratin clefts occasionally. Neutrophilic exocytosis within the parakeratin layer along with lymphocytic and plasma cell infiltration in the stroma may also be evident.[6-8]

This paper throws light upon 2 cases of Oral Verruciform Xanthoma in a 35-year-old female which was diagnosed clinically as Pyogenic granuloma and in a 25-year-old female which was diagnosed as traumatic fibroma based upon its clinical presentation. Both the lesions were surgically excised and sent for histopathological examination and finally diagnosed as Oral Verruciform Xanthoma.[9]

Case Reports

Case 1: A 35-year-old female presented with the chief complaint of growth in mandibular anterior teeth region in the last 3 months. On intraoral examination a gingival overgrowth was present in relation to the lingual aspect of 41 and 42. The growth was erythematous and soft in consistency, fluctuant, and oval in shape measuring about 1.1cm x 0.5cm in the greatest diameter. The associated teeth were mobile and radiographical findings revealed interdental bone loss in relation to 41 and 42. A provisional diagnosis of Pyogenic granuloma was made based upon these findings. The growth was surgically excised completely and the biopsy specimen was sent for processing and histopathological evaluation.

Histopathological Findings: The hematoxylin and eosin stained section of the specimen revealed a hyperplastic acanthotic parakeratinized stratified squamous epithelium overlying a moderately vascular fibro-collagenous connective tissue stroma. Large foamy macrophages resembling xanthoma cells were noticed in the connective tissue papilla and sub epithelial connective tissue. Ossifications intermingled with spindle shaped fibroblasts along with moderate amount of chronic inflammatory cells chiefly plasma cells were evident in the stroma.

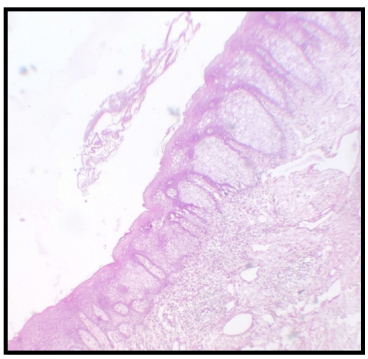

Figure 1: (4x view): The photomicrograph of H & E stained section showing hyperplastic acanthotic parakeratinized stratified squamous epithelium with underlying moderately vascular fibrocollagenous stroma.

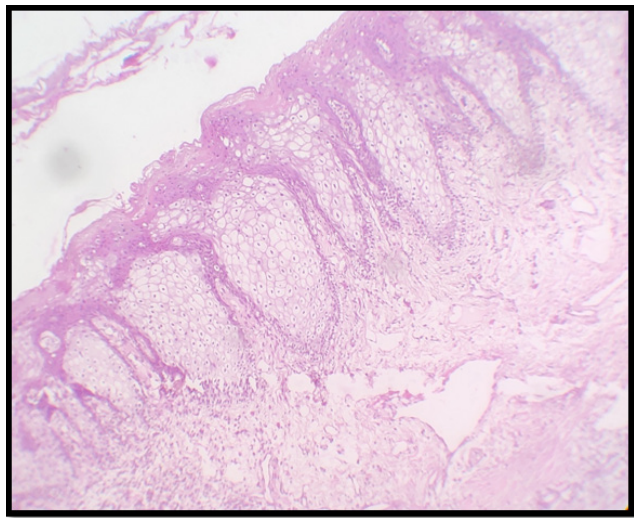

Figure 2 (10x view): The photomicrograph of H & E stained section showing large foamy macrophages resembling xanthoma cells in the connective tissue papilla and sub epithelial connective tissue.

Based upon these findings a final diagnosis of Oral Verruciform Xanthoma was made.
