between the age group of 18 and 71 years.Among the study subjects; 87, 78, 75 and 64 were diagnosed with schizophrenia, mood disorder, organic brain damage and other psychiatric illnesses respectively. Among the 304 study subjects, 78(26%), 120(39%) and 106 (35%) were diagnosed with psychiatric illness 5 years, 6 to 10 years and >10 years ago .

Among 159 male study subjects, 105 (66%) had smoking habit, 66(42%) consumed alcohol and 27(17%) had pan chewing habit. Among 145 female study subjects, none of the participants had smoking or alcoholism habit, while 28(19%) had pan chewing habit . The usage of tooth brush and tooth paste was highest in the < 19 yrs age group (100%) and least in the > 50 years age group (Figure 1). 89% of the subjects cleaned their teeth by themselves and 11% cleaned their teeth with the help of an assistant. The association between frequency of cleaning teeth and OHI-S score was found to be statistically very highly significant [$X^2 = 138.79$, $p = 0.000$].

Among males, the maximum number of subjects having good, fair and poor oral hygiene were found in the 20-29, < 19 and > 50 years age group, respectively. Among females, the maximum number of subjects having good, fair and poor oral hygiene were found in the < 19, 20-29 and > 50 years age group, respectively (Table 1).

Table 1: Distribution of study subjects based on oral hygiene status

Age (Years)*	Gender	Oral Hygiene Status*					
		Good		Fair		Poor	
		n	%	n	%	n	%
<19	M	0	0	9	100	0	0
	F	3	33.3	6	66.7	0	0

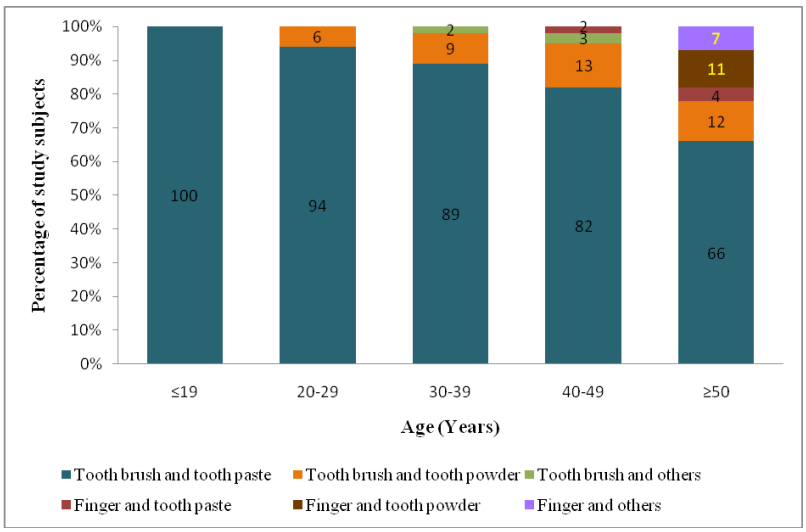

Figure 1: Distribution of study subjects based on mode and materials used for cleaning teeth

Discussion

Apathetic nature, poor diet and xerostomia inducing medications predispose psychiatric patients to significantly higher risk of dental diseases. Routine dental health care is provided to institutionalized psychiatric patients. However, only 2.35% of psychiatric patients are users of mental health services[7] .For community dwelling psychiatric patients, the onus of arranging for dental care lies with the patients themselves. Hence it is imperative that patients and their care takers are aware of the responsibility that lies with them.

Age of the participants in this study ranged from 18 years to 71 years. The inclusion of a wide array of ages facilitated the assessment of disease trends across the age groups. Among the study subjects; 87, 78, 75 and 64 were diagnosed with schizophrenia, mood disorder, organic brain damage and other psychiatric illnesses respectively. These diagnostic subdivisions were considered in this study because they are most commonly associated with the occurrence of dental caries[7,13,14,15].

In our study, the use of tooth brush and tooth paste as the preferred mode and material for cleaning teeth was maximum among the < 19 years age group and minimum among > 50 years old age group. This may be due to the increased awareness and increased willingness to adopt new lifestyle modifications among the younger generation. 11% of the participants in the present study cleaned their teeth with the help of an assistant. This is similar to studies conducted by Peter Horst G[16] et al in Netherlands and by Angelilloet al[17] in Italy where 8% and 9.4% of the study subjects received assistance in maintaining oral hygiene.

On eliciting the number of subjects who had dental problem in the past one year, it was found that 40% of the subjects in our study had some dental problems. This finding is similar to the results obtained by BorgeHedeet al[6] in Denmark (40%). Of the 40% subjects in our study who had dental problems in the past one year, 20% preferred the dentist to be the care provider. This is higher than a study by Angelilloet al[17] where only 7.4% of the subjects preferred a dentist to be the care provider. 9% and 6% of our study subjects sought treatment from physician and pharmacist. This finding reiterates the gravity of the responsibility that lies with physicians and pharmacists to redirect patients with dental problems to seek care from a dentist.

Thus, results of this study show that psychiatric patients have extensive dental diseases, many of them requiring complex treatment. However, prevention should be the main objective because patients with advanced psychiatric illness are often anxious and uncooperative for extensive curative therapy.

Recommendations:

1. Psychiatrists should ensure that oral hygiene is part of routine care.
2. Patients, family members and care takers should be made aware of the importance of tooth brushing with tooth paste containing fluoride.
3. Suitable dental services must be provided for psychiatric patients taking into account their special needs.
4. Multi–disciplinary approach to psychiatric patients should be encouraged

Biological Considerations in Use of Dental Impression Materials: A Review Article

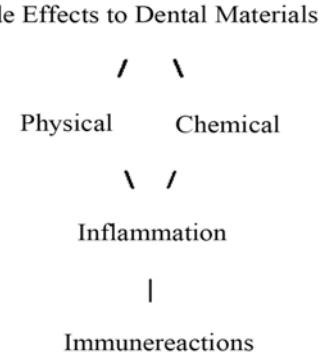
Shiva Kumar N.[1], Narayana Reddy[2], Niranjana R.[3], Sanjna Nayar[4]

[1]Reader, [2]Professor, [3]Student, [4]Professor and Head of the Department, Department of Prosthodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Chennai, India

Abstract

Background: The science of dental impression materials must be necessity encompass a knowledge and appreciation of certain biological consideration that are associated with the selection and use of materials designed for the oral cavity. The minute amounts of components that leach out of impression materials are most unlikely to cause toxic reactions, locally or systemically. Reliable analysis data is therefore necessary to clarify the varied issues of safety and frequency of adverse reactions normally medicine, together with dentistry treatment.

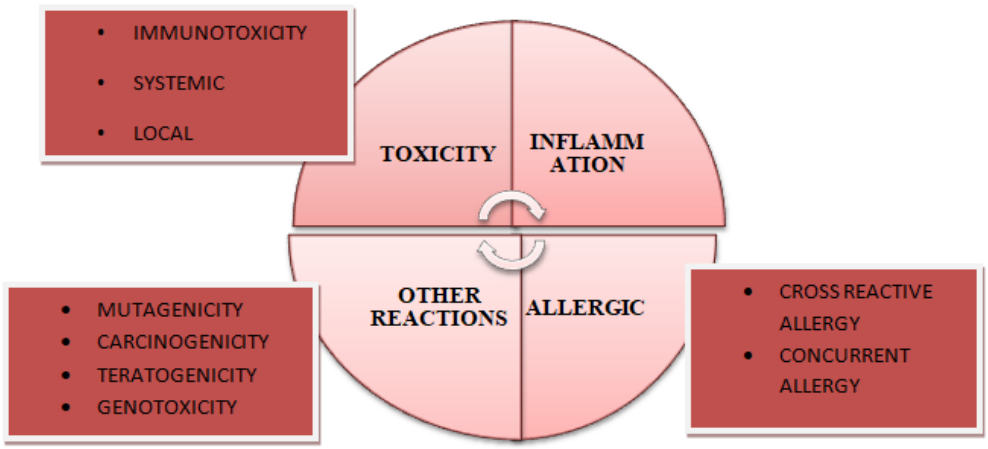
Method: A literature review was done to analyse the biological considerations of dental impression materials and its hazards.



Conclusion: Many potential problems exist, but few documented adverse reactions have been published. It is expected that one requirement will be for clinicians and manufacturers to report biological side effects associated with use of the materials to certifying bodies or health authorities. Reliable research information using robust methodology is therefore required to clarify the varied questions of safety and frequency of adverse reactions in general dentistry, including Prosthodontic treatment.

Keywords: *Biocompatibility, Biological Effects, Impression Materials, Adverse Effects.*

Introduction



The development in Prosthodontics is characterized by an increasing number of new prosthetic materials. There are, however, a outsized range of properties of the prosthetic materials, which must be as close to ideal as increasing demands of the patients, biologic, physical, chemical, and aesthetic compatibility that have to be taken into consideration[1]. Biocompatibility is nothing but the capability of existing in harmony with the surrounding biological environment[2]. A single material might not be biologically acceptable all told applications. Placement of the material in the body creates an interface which depends on location of the material, its duration in the body, its properties and health of the host[3]. Biological facet effects to materials employed in dental field are rare. An overall estimate indicates the frequency of such adverse effects to occur within 1:1000 to 1:10,000 of all dental treatments[4], but it is dependent on the type of practice and the materials used[5].

Adverse reactions may occur in different ways[6]:

Corresponding Author:

Frequent dermatological reactions include transient redness, irritation or decreased tactile sensitivity to seriously incapacitating blisters, desquamation, soreness, bleeding fissures, and pain. Frequent causes embrace acrylic resins, latex gloves, impression materials, eugenol containing temporary cements. Non dermatological reactions embrace injury to eyes because of UV light and visual light in everyday follow. Respiratory reactions are attributed to vapours from acrylic resin monomers and cyanoacrylates. Materials left within the inaccessible areas like sub gingival regions wherever elastomeric impression materials don't seem to be removed, cell viability is affected. Due precautions should be practiced in handling the materials and equipments to avoid occupational hazards on one hand and due care taken to avoid any insult to oral tissues and general health of patients on the other[7].

Historically, numerous materials are accustomed create impressions for removable and fixed prosthodontics. Early materials enclosed rigid and semi rigid compositions like plaster, zinc oxide eugenol, impression compound, and waxes; these materials still have restricted uses in dentistry. Different materials, enclosed metals, polymeric materials, ceramics, and variety of cements are used while fabricating and fitting Prosthodontic appliances for patients. More than 75th of all the prevailing dental materials are directly or indirectly used or concerned when fabricating and providing prosthodontics restorations to be placed within oro-facial complex of patients[8].

A number of factors need to be taken into account when estimating adverse biological reactions to prosthodontic materials. Among these include: the type, form, contour, extent of the corrective, any medication used by the patient, salivary flow rate, xerostomia, oral hygiene, quality of fit, and function of the prosthesis. All these conditions may affect local reactions in addition to those caused by the materials[9].

However, a definite distinction exists between material reactions intraoral and extra orally, with those on skin being more frequent and more severe. Skin patch testing is therefore of limited value, even if specifically designed series of tests for dental materials are employed[10].

Biocompatibility Tests: Many preclinical biocompatibility tests are available to minimize the risk of adverse reactions to dental materials[11]. These tests are categorized on the basis of their applicability

levels. Initial tests embrace cell culture tests, hemolytic tests, systemic toxicity tests, and tests estimating teratogenic and carcinogenic effects and potential. Secondary tests include implantation tests, skin and mucous membrane irritation tests, and sensitization tests. Usage tests take into consideration the way within which the materials are supposed to be employed in clinical practice. Oral mucosa tests based on reactions to materials in contact with the hamster cheek pouch is considered to be a short term usage test for prosthodontic materials and relatively less invasive and traumatic especially to suturing the skin to secure the material in contact with the mucosa[12].

Adverse Effects of Prosthodontic Materials: Unexpected biological side effects to prosthodontic materials might occur as a result of their direct contact with soft or mineralized tissues, or by exposure to leachable components resulting from corrosion and degradation products[12]. Concurrent and combined presence of dental prosthetic restorations created in additional than one alloys with differing compositions will tend to enhance the corrosion caused by galvanic action. Prosthodontic materials and their corrosion/degradation products comprise components that are known to be allergic, toxic, and carcinogenic in specific situations. Local mechanical irritation due to an overhanging margin of a restoration or associate overextended dental plate should even be considered as adverse effects. Thus, a number of potential problems exist. However, few side effects of prosthodontic materials have been reported in the literature. It should be kept in mind that prosthodontic materials are manufactured with the aim of being inert and insoluble. Contact allergic reactions (type IV reactions) are the most common side effects to prosthodontic materials[6].

Incidence of Adverse Effects: An overall incidence of facet effects to dental materials of one per 500 patients, or of 1 patient per close to three.5 years of practice was reported in one study. Over 13,000 patients were examined for acute and long-standing adverse effects during a 2 week period. A questionnaire survey among Prosthodontists indicated adverse patient reactions in one out of three hundred patients or one patient in close to 2 years per Prosthodontist[13].

Adverse Effects to Prosthodontic Materials: Due to the low incidence of side effects to prosthodontic material, it will be pertinent to limit this discussion to groups of materials instead of specific styles of materials including polymeric materials, alloys, implant materials, and cements. Ceramic materials are generally regarded as inert, but dust particles of these materials arising during handling, manipulating, adjusting, and finishing the fabrication represent a possible drawback, each for the laboratory and clinical personnel as well as patient[14].

Polymeric Materials: Polymerization of resin based materials may be initiated by heat, light, or by chemical activators at room or mouth temperature. Apart from containing accelerators (amines), they contain co-polymers, such as butyl-methacrylate (BMA), plasticizing agents such as dibutyl-phthalate, and inhibitor such as hydroquinone. In addition, cadmium salts-based coloring agents are also added, these ingredients as well as the added cadmium salts are not considered to represent any issues for patients however they will create potential hazard to technicians routinely grinding and finishing prosthesis made in resin based materials. Methyl methacrylate (MMA) monomer may result in toxic reactions and allergic responses in previously sensitized individuals, especially in under cured appliances. It is often difficult to differentiate between these two fundamentally different types of reactions because the clinical manifestations are similar, that is, redness and swelling of the affected mucosa. Physical trauma caused by overextended or poorly fitting dentures may also present as local reactions. These are difficult to differentiate from other types of local lesions. It is important to keep in mind that FORMALDEHYDE is a degradation product of several monomers used in dentistry, including denture base polymers and restorative resin based composites. Heat cured acrylics area unit well tolerated by the gingival tissues. In comparison, cold curing acrylic resins may result in gingival reactions, due to presence of higher concentration of the residual monomer in cold cured resins as compared with heat cured acrylics. The consequent diffused or localized burning sensation in the mouth because of direct mucosal irritation may be erroneously taken for the entity of "Burning Mouth Syndrome (BMS)". In fact the burning sensation might result from the intra-oral manipulation of organic compound or due to the presence of residual monomer. Allergic reactions to an ethylene amine activator used in several polymeric materials, including impression materials and temporary crown materials area unit one of two most commonly reported adverse effects to prosthodontic materials[15]. Recurrent facial dermatitis was observed with dental work because of epoxy acrylate bisphenol-A glycidildimethacrylate (BIS-GMA) [16].

Prosthodontic Alloys: Some of the metals utilized in dental alloys are proverbial to be biologically active or potentially hazardous, such as nickel, chromium, cobalt, cadmium and beryllium. About one in four reactions to materials used in prosthodontic treatments are associated with metals, particularly metallic element, metal nickel and gold alloys used for metal ceramic restorations. Literature indicates that allergic reactions to gold based restorations were more common than to nickel containing alloys[17]. Hildebrand et al. reviewed 139 published cases of allergy to base metal alloys in removable partial dentures[18]. Gingivitis and stomatitis

were the most common clinical symptoms, but remote reactions occurred in almost 25% patients. However, no correlation seems to exist between mucosal reactions to fixed prosthesis and corrosion and tarnish. Palladium alloys are generally better tolerated than base-metal alloys or gold alloys for metal–ceramic restorations, although they tend to tarnish more than other casting alloys. Alloys are among the materials used for the making of conventional cast posts and cores. A variety of metal combinations are in common use, sometimes with stainless steel pins. Of particular concern is to exercise care not to combine the simultaneous use of two different alloys for the post and forged core/crown once getting ready post retained crowns because the galvanic corrosion may cause root fractures[11].

Implant Materials: A wide sort of materials are employed in dental implants, including polymeric materials, alloys, ceramic, and synthetic hydroxyl apatite. The most frequently used materials have been cobalt–chromium alloys, vitreous carbon, titanium, and aluminium oxide. Numerous investigations have been performed to assess the biological properties of dental implants. Much attention has focused on the bone tissue/implant interface and on the in growth of bone into the porous implant fixture. The concept of "osseointegration" associated with the titanium implants, as demonstrated by Branemark, has proved much of the biological basis for modern implantology. The failure commonly results because of improper surgical procedures, problem with the loading of the implant, and infection. So far our understanding is evident concerning the inert nature of pure titanium implants. Much attention has been paid to the nanoparticles (NPs) that are produced for applications in various areas. With an increasing application of nanotechnology in life sciences and medicine, further studies are required on biosafety evaluations of NPs with attention to nanotoxicology not only from the angle of ecology however conjointly primarily based on the aspect of biomedical applications[19].

Conclusion

Many potential problems exist, but few documented adverse reactions have been published. Much attention has been focused on the presence of nickel, based on the fact that, nickel could be a potent substance, a matter and might be distributed to various organs in experimental studies in animals. It is expected that one requirement will be for clinicians and manufacturers to report biological side effects associated with use of the materials to certifying bodies or health authorities. With the low incidence of adverse effects of the materials in gift use, this will satisfy the needs of the patients and people handling the materials. Reliable research information using robust methodology is therefore required to clarify the varied questions of safety and frequency of adverse reactions in general dentistry, including prosthodontic treatment.

Colour and Shade Selection in Complete Denture: A Systematic Review

Sanjna Nayar[1], Niranjana R.[2]

[1]Professor and Head of the Department, [2]Student, Department of Prosthodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Chennai, India

Abstract

Statement of Problem: Colour and shade selection is an important parameter which is essential in aesthetic replacement, thereby enhancing the psychology of the geriatric patient. Though its effectiveness is well known, its use is seen to be restricted. With current advancements in shade matching, its utility needs a systematic review.

Objective: The objective of this is to review about the improvement in aesthetics in the construction of complete denture by selection of the appropriate colour and shade matching similar to natural tooth in geriatric patients.

Method: Using various key words, an electronic search was performed from several databases-Medline/ Pub med, Cochrane Library and Google scholar. Furthermore, a manual searching of relevant journals and bibliographies of reviews was performed. Studies, which met the relevant criterias were selected for full text reading.

Results: This systematic review started with search various relevant articles, which were finally narrowed down to eighteen according to the inclusion criteria.

Conclusion: A thorough knowledge about the science of colour and shade selection is essential to the success in the field of Prosthodontics. It should be approached in a methodical manner. This enables the dentists to make the best choice and communicate it appropriately to the laboratory.

Clinical Significance: Even though the benefits of Shade matching are yet to be proven, evidences so far have not shown any adverse effects associated to shade matching. This means that the decisions made by clinicians whether or not to use shade matching depends upon clinical evaluation, patient physical and psychological health.

Keywords: *Colour, Shade Selection, Esthetics, Shade Guides, Colour Matching.*

Introduction

Colour and shade selection is an important method in providing esthetics in patients seeking complete denture prosthesis[1]. It becomes a complex process in achieving a closer shade match of an artificial tooth with the natural tooth due to its variety of colours[2]. Dentist requires an understanding of colours and shade selection to clearly communicate the instructions to the laboratories in order to obtain aesthetically pleasing denture[3].

During the 18th century, Sir Isaac Newton experiments demonstrated that white light passing through prism divided into a pattern of colours termed as spectrum and he also demonstrated that colour does not exist without light[4].

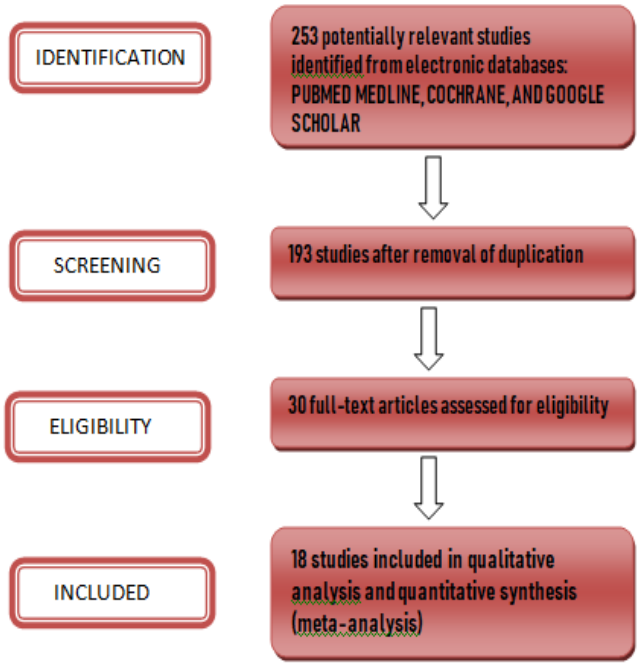
e-mail: nayarsanjna@gmail.com

Dimensions of Colour: Prof. Albert Munsell gave a colour wheel in the 20th century gave a colour wheel which includes 3 attributes of this system called Hue (particular colour), Chroma (intensity) and Value (darkness/lightness)[5]. Teeth are often polychromatic since it have variation in hue, chroma and value within the teeth and gives 3 dimensional depth and characteristics[4].

According to Black, he believed that value was given more preference than the hue. He recommended that value be assessed first followed by chroma and hue[6].

In addition to hue, chroma and value, there are certain properties which contribute natural appearance to teeth. They are translucency, opacity, opalescence, surface gloss, surface texture and fluorescence[7].



Selecting a shade is always done under different lighting conditions to avoid metamerism. Northern daylight around noon hour on the bright day is considered best as the incident daylight is most balanced within the visible light spectrum[8].

Methodology

This systematic review was performed according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement. Systematic electronic literature search was conducted in MEDLINE via Pub Med, Cochrane and Google scholar. In addition, manual searches were conducted in these principal periodicals specific to the area of study: Journal of Prosthetic Dentistry, International Journal of Prosthodontics, Journal of Dentistry and Oral care Medicine, International Journal of Oral Health Sciences, The Journal of Indian Prosthodontic Society. The search included peer-reviewed publications, with no publication year. The following search terms and their combinations were used: **"COLOUR", "SHADE SELECTION", "ESTHETICS", "SHADE GUIDES", "COLOUR MATCHING"**. Potentially relevant studies were identified according to the titles and abstracts. The full-text articles were subsequently reviewed and cross-matched against the predefined inclusion criteria.

Results

The electronic search identified 253 articles. Following analysis of the titles and abstracts, 193 articles were excluded, leaving only 60 articles suitable for inclusion. After the application of the inclusion criteria, 30 articles were deemed suitable for full-text analysis. Of these, a total of 18 articles were considered acceptable for this systematic review.

Discussion

Shade matching might be unimportant to the physiologic success of dental prosthesis but it could be the deciding factor in patients acceptance.

Colour matching is done by two ways–visual and instrumental[9]. Clinical shade selection involves picking a tab from shade guide and matching it with teeth that already existed[10]. The commonly used shade guides are Hyashi shade guide, Clark shade guide, Spectatone, VITA Shade guide (VITAPAN CLASS-I), Vitapan 3D Master shade guide and visually optimal shade guide[11].

Instrumental method of colour and shade matching are Colorimeters, Spectrophotometer, Digital cameras as filter colorimeters, Spectrophotometers and spectroradiometers[11].

There are six currently commercially available systems ranging from simple to complex. They are generally one of three types–colorimeters, spectrophotometers or digital colour analysers and various measuring geometries:

i. Shofu's Shade Chroma Meter

ii. The Vita Easyshade

iii. The Shadescan

iv. Shaderite Dental Vision System

v. The Spectroshade

vi. ClearMatch System[12.]

According to Judd and Wyszeeki[13] listed seven synonymns for shade of which desirable term is colour standard.

According to Culpepper[14] he pointed out the unawareness among dentists in matching natural teeth and duplicates their own shade selection from time to time.

According to Kuzmanovic and Lyons[15] study found no significant difference in accuracy of shade matching when using conventional visual assessment technique or a colorimetric assessment but a minor discrepancies occur when two shade techniques were used to compare for shade selection of same tooth.

According to Goodkind et al [16] used Chromascan and reflection spectrophotometer to compare the shade matching in vitro of natural with human eye which showed equal results to both techniques.

According to Berna et al [17] found that colour deflective dentists make more mistakes in hue selection than individuals with normal perception.

According to Miyajiwala et al[18] he concluded that the reliable method for colour matching in clinical set up is digital photography method.

Conclusion

One of the integral part of prosthetic and esthetic dentistry is the detailed study about colours. Matching the correct shade satisfies both dentist patient and gives pleasing appearance to the patient. Both traditional and technology based shade systems should be used to achieve better esthetics.

Laboratory Remounting of Complete Denture: A Systematic Review

Sanjna Nayar[1], Preeti Patel[2]

[1]Head of Department, [2]Post-Graduate Student, Department of Prosthodontics, Sree Balaji Dental College and Hospital, BIHER, Chennai

Abstract

Statement of Problem: Simpler processing method has been tried in fabrication of complete denture but the importance of inclusion of laboratory remounting procedure is uncertain.

Purpose: The purpose of the systematic review was to assess the relevance of laboratory remounting procedure on complete denture.

Materials and Method: One electronic database (PubMed) was searched through in July 2019. The terms "laboratory remounting" AND "occlusion" were chosen. The titles and abstracts were screened and the studies which performed laboratory remount were selected.

Results: After duplicate removal, the database search showed 10 studies. Out of which 5 were retrieved for full text assessment. 5 randomized control clinical studies were included and 1 review study.

Conclusion: A laboratory procedure is advised to reduce occlusal disharmony and provide comfort to patients and reducing recall appointments.

Keywords: *Remounting, occlusion, selective grinding, dentures.*

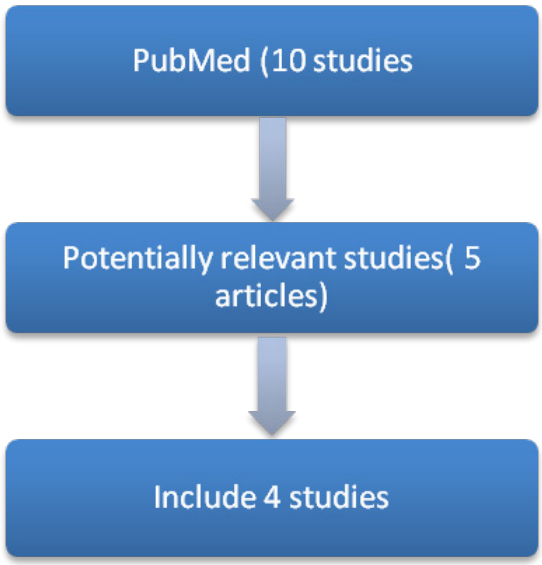
Introduction

Complete dentures are prosthetic replacements for missing teeth and surrounding structures which are made to restore the missing functions and aesthetics. Properly constructed denture offers tissue comfort, good function and aesthetic, harmoniously. Correct obtainment of occlusion provides comfort, functional movements of mandible while maintaining the muscular tonicity which itself gives good aesthetical appearance. Error in any one procedure disrupts the entire occlusion in the denture.

The failure to achieve proper occlusion of teeth in complete denture happens due to many reasons including improper jaw relation, improper posterior teeth placement, incorrect curing method and changes due to polymerisation shrinkage and water sorption. When the occlusal adjustments are not corrected, it causes loss of alveolar bone as it undergoes remodelling to relieve the soft tissues from the pressure of occlusal disharmony. The errors occurring in the processing of the denture can be corrected by laboratory remounting.

Laboratory remounting is the repositioning of the polymerised denture on the mean value articulator and correcting the occlusion through the process of selective grinding(reducing the high contacts while maintaining the proper form of the tooth) in the centric and eccentric occlusion to assist any changes occurred after the processing of denture and deflasking using split cast mounting technique[1].

In India, both the laboratory and clinical remounting procedures have been taught to the students in dental schools but these procedures are not being implemented in the daily clinical situation. Reasons for lack of remounting procedure implementation could be either due to investment of extra time and manwork or ill-belief that denture will "settle in" within some time or dentists being unaware of the errors encountered while implementing remount procedure[2].



Our aim is to inculcate laboratory procedure into the routine fabrication procedures of complete denture which is often skipped during the fabrication process.

Method

The Preferred Reporting Items for Systemic Review (PRISMA) protocol was followed as much as possible. Numerous online databases were searched systematically to find trials of laboratory remounting of complete denture prosthesis. The search method included the use of keywords and Medical Subject Headings (MeSH) using the terms "laboratory remounting" AND "occlusion" in PubMed during 1st-2nd July of 2019. An evaluation of the search results were done at first selection process. The abstracts of potentially relevant studies were checked and finally some articles which included authors, objectives, treatment groups, follow-up, outcomes and significant results were selected.

Results

The online databases search resulted in a total of 10 studies. After the titles were reviewed in the first selection criteria, 5 potentially relevant articles studies remained. Out of which, 4 studies were included for which the titles appeared relevant and 6 were excluded and the reasons were inclusion of clinical remounting procedure, remount procedure being used in removable partial denture and survey studies. The online database search was followed by a manual search through the references of the included studies, one review articles was selected through the process. The 4 studies were randomized controlled trial.

Discussion

Qualitative lab procedures were found to show minimal occlusal changes but could not completely remove the occlusal disharmony. In 1972, a survey of British practitioners and dental students rarely used the remounting procedure in their clinical practice, only 6.5% of them used the remounting procedures to correct the occlusal discrepancy. On the contrary, Levin conducted a survey within US and Canadian dental school, where they taught the students the use of laboratory remounting procedure, clinical remounting and the use of disclosing paste to check the pressure development in the underlying soft tissues[3]. In 2008, Shigli did a study to find whether correction in occlusion was in co-relation with patient comfort and the number of visits after insertion. He found laboratory remounting with clinical remounting and selective grinding improved patient comfort level comparing with the patient who didn't receive either or both of the remounting procedure[4].

It is seen that denture base changes in contour when kept storage in water due to water sorption phenomenon. Campbell summarized that denture retention increases due to water sorption property. Skinner and Cooper expressed water sorption compensate the shrinkage occurring the acrylic resin base. On the contrary, Woelfel and Paffenbarger said that linear changes which shows up after processing is greater than its rehabilitation. McCartney demonstrated that there is 25% of average midpalatal base distortion is seen when resin is boiled in curing cycle. Also, 50% of the occlusion disharmony is seen dentures with short-cure processing.

So, the occlusion disharmony created by processing is usually corrected by remounting the master cast with the denture base in place, without removing it and equalize the occlusion on the articulator[5].

Conclusion

The choice is not whether to remount but when to remount the denture.

Any complex procedure requires patience and practice to get the desired results. Remounting of dentures is one of such similar case, where the inclusion of this step saves up lot of chairside time and provides comfort to the patient by providing short time period appointment and denture with occlusal harmony[6].

Loss of the Epigenetically Inactivated-X-Chromosome (Barr Body) a Potential Biomarker for Breast Cancer Development

Chemiaa Adel[1], Fadhel M. Lafta[2], Manwar A. Al-Naqqash[3], Abdul-Ameer N. Ghaloub Al-Rekabi[1]

[1]Mustansirya University, [2]University of Baghdad, College of Science, Dept. Biology, [3]University of Baghdad, College of Medicine, Surgical Department, Oncology Hospital, Baghdad-Iraq

Abstract

Background: Attention has recently reawakened to loss of the epigenetically inactive-X chromosome ‘‘Barr body’’ as a key prevalent event in development of breast cancer and other malignancies. . This study was aimed to investigate the incidence of Barr body loss as well as the expression levels of *XIST*, X-inactive-specific-transcript, in a set of Iraqi breast cancer patients.

Method: Eighty peripheral blood samples were collected from 60 patients diagnosed with breast cancer and 20 healthy age- matched controls for Barr body blood smears screening and *XIST* qPCR gene expression analysis.

Results: The results showed significant reduction in Barr body count (percentage mean) in breast cancer patients in comparison with controls (0.15 vs. 0.56,P= $1.14 * 10^{-21}$). Also, Barr body count was able to discriminate between breast cancer patients and their healthy controls. The *XIST* gene expression was also down regulated in the vast majority (95%, 57/60) of studied breast cancer patients, suggesting a potential key role for this gene in the development of breast cancer.

Conclusion: This study produced results which corroborate findings from a great deal of the previous work and showed strong association between loss of Barr body and down regulation of *XIST* in breast cancer patients. In addition, Barr body and *XIST* expression could be investigated further for their utility as an early screening or diagnostic method especially in high risk individuals for breast cancer and possibly for other malignancies.

Keywords: *Barr body, XIST gene, breast cancer, blood smear, PCR.*

Introduction

Breast cancer is the most common women cancer worldwide with more than 1.7 million new cases diagnosed in 2012 that accomplished for 516,868 cancer-related deaths in that year according to latest global record [1,2]. While the disease incidence in the developing countries is still less than that recorded in the developed ones, burden of breast cancer mortality is much higher in women from low-middle income countries. Breast cancer accounts for more than one third (34%) of cancers affecting women in Iraq[3]

In normal cells, the nuclear architecture integrity is maintained by the epigenetic marks that consist of both DNA methylation and histone modifications which differentiate euchromatin from heterochromatin. These modifications are considered as the guardian of our genome and are responsible for chromosomal stability, suppressing mobile genomic elements, genomic imprinting, heterochromatin inactivation and tissue/cell-type specific gene expression[4]. Heterochromatin inactivation is the mechanism by which one of the two female X-chromosomes becomes silent and inactivated forming a dark body in the periphery of the nuclear envelope that is called” Barr body”[5-8] . This gene was shown to be responsible for the initial random inactivation of one of the X-chromosomes early in development through the expression of non-coding RNA *XIST*that coats one X chromosome, replacing the euchromatic histone marks with the inactive heterochromatin epimarks such as H3K27me3, H3K9me2 and gene promoters of DNA methylation[9]. *XIST* expresses from only the inactive X-chromosome and its ongoing expression is shown to be required for the nucleolar

localization of the Barr body in mice[10]. Also *XIST* mutant mice showed loss of X chromosome inactivation and died early due to severely malformed growth[11]. It is thought that *XIST* loss leads to the degradation of DNA methylation and this could lead to reactivation of the epigenetically silenced X- chromosome[12].

The loss of the epigenetically-inactivated X chromosome is believed to contribute to tumorigenesis through the reactivation of cancer-related silenced genes [13].Both epigenetic/genetic alterations could contribute to loss of Barr body that leads to duplication of the active X chromosome which would result in over-expression of X-linked genes [14].. Previous studies had reported loss of the inactivated X chromosome "Barr body" in breast cancer patients especially those with poor prognosis[15,16,17].

This study was aimed to investigate the incidence of Barr body loss among Iraqi breast cancer patients. The Barr body count in breast cancer cases would be assessed for its association with the disease clinical features such as microscopic grade and other factors that might influence breast cancer development.

Materials and Method

Blood Samples: Eighty peripheral blood (PBL) samples were collected, during the period from November 2017 till July 2018, for blood smears preparation and RNA extraction. These blood samples were obtained from 60 patients with breast cancer attending the Oncology Hospital in the Medical City-Baghdad, Iraq and from another 20 healthy women as controls. Blood samples were collected according to the ethical considerations and the hospital ethical committee.

Blood smears preparation and Barr body count: Blood smears were prepared for breast cancer patients and healthy controls by spreading a drop of peripheral blood on a clean slide (2-3 slides were prepared for each subject). The smears were stained with Leishman stain for 2mins., the number of Barr body per 100 neutrophil cells was counted using oil immersion microscopic field and presented as a percentage value. Student's *t*-test was performed to compare the percentage average of Barr body counts between the two studied groups.

RNA extraction and XIST gene expression using qPCR: RNA extraction from peripheral blood samples (250µl) of breast cancer patients and healthy controls was performed using AccuZol^{TM} extraction kit the protocol provided by Bioneer Company (South Korea).. cDNA was synthesized from the extracted RNA samples using AccuPower^{R} RocketScript^{TM} RT PreMix kit (Bioneer). *XIST* gene expression was quantified by real time PCR technique using the following primer set: *XIST*-forward GCAGTTTGCCCTACTAGCTCCT and *XIST*- reverse TCCTCAGGTCTCACATGCTCA. This gene maps to chromosome X: 11302-11456. For the gene expression comparison, *GAPDH* was used as a reference gene with the following primers sequence: *GAPDH*-forward TGCACC ACCAACTGCTTAGC and *GAPDH*-reverse GGCATGGACTGTGGTCATGAG. Comparative Ct method was used to analyze the obtained real time PCR data.

Results

Barr body could be a useful biomarker for breast cancer diagnosis: Blood smears screening analysis showed significant decrease in the percentage of Barr body in breast cancer patients in comparison to their age-matched healthy controls. Barr body percentages meanfor healthy controls was 0.56% (ranged from 0.34 to 0.8) while their mean dropped to 0.15% (ranged from 0.08 to 0.25) in breast cancers patients (Table 1). This approximately four-fold reduction in Barr body count in breast cancer patients was reflected byhighly significant differences as compared to control group (P= 1.14 $*10^{-21}$).

Table 1-: Barr body numbers in breast cancer patients and their age-matched healthy controls

Group	No. of Barr bodies		t- test
	% Average/ Mean	Variance	
Breast cancer (n= 60)	0.15	19.84	P= 3.2 *10-11
Healthy controls (n=20)	0.56	0.021	

Of interest, our results also showed that the percentage of Barr body could distinguish breast cancer patients from healthy controls .This was clearly evident when all of breast cancer patients had Barr body percentages below 0.26 (ranged from 0.077 to 0.25) while all healthy controls had Barr body percentages above 0.34 (ranging from 0.34 to 0.88).This could be a promising biomarker for the diagnosis of breast cancer and possibly in other malignancies and diseases .

Number of Barr bodies is significantly reduced in advanced breast cancer grades and stages: Our

results showed a significant reduction in the percentage mean of Barr body through disease progression. This was clear when breast cancer patients in grades II and III had lower percentage meanof Barr body than those in grade I (0.121, 0.137 and 0.191%, respectively, Table 2). Differences in the number of Barr bodies were significant when grade I breast cancer was compared with those in grade II and III (P=0.000062 and P= 0.006, respectively). However, no significant difference was recorded from comparing grades II and III (P=0.249).

Table 2: Average number of Barr bodies in different breast cancer grades and stages

Breast cancer grade	**Barr body (% average)**	**t-test**
Grade I (n=12)	0.191	Grade I vs. Grade II (P=0.000006) Grade I vs. Grade III (P=0. 006)
Grade II (n=39)	0.137	
Grade III (n=7)	0.121	
Breast cancers stage	**Barr body (% average)**	**T-test**
Stage 1 (n=12)	0.183	Stage 1 vs. Stage2, P= 0.015 Stage 1 vs. Stage3, P= 0.001 Stage 2 vs. Stage3, P= 0.05
Stage 2 (n=28)	0.143	
Stage 3 (2=18)	0.124	

Similar to the association with breast cancer grade, the Barr body showed significant reduction with advanced disease stages (Table 2). Breast cancer patients in stages II and III had lower percentage mean of Barr body in their blood smears than those in stage I disease (0.124, 0.143 and 0.183%, respectively).

Furthermore, no significant reduction in percentage mean number of Barr bodies was found when pre- and post-menopausal breast cancer patients were compared (Table 3).

Table 3: Percentage mean number of Barr bodies in breast cancer patients with different clinical features

Breast cancer features		**Barr body%**	***t*-test**
Cancer development	Family history (n=14%)	0.139	(P=0.567).
	Sporadic (n=46)	0.147	
Menopausal Status	Pre-menopausal (n=32)	53.33	(P=0.138).
	Post-menopausal (n=28)	46.66	

X-inactive-specific transcript (XIST) expression is significantly reduced in breast cancer patients: In female cells, X inactive-specific transcript (*XIST*) RNA is involved in X chromosome silencing, allowing X chromosome equilibration with males[18]. Our results showed that *XIST* expression was down-regulated in the vast majority (95%, 57/60) of studied breast cancer patients (Figure 1). Of interest, more than two thirds, (76.7%, 46/60), of breast cancer patients had *XIST* expression level below 5%.

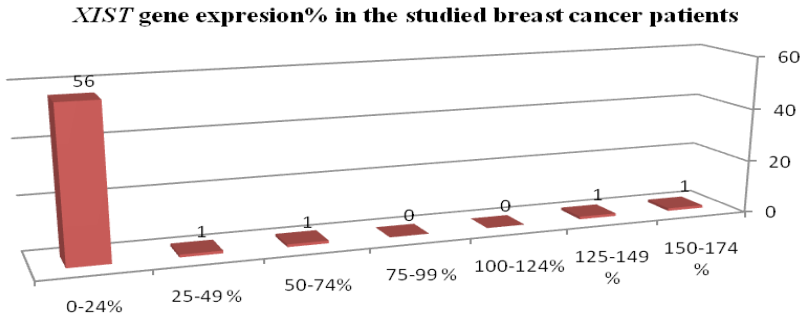

Figure 1: Expression levels of XIST gene in studied breast cancer patients. Each bar in the figure represents number of cases within each expression category.

Low XIST expression levels associated with breast cancer progression: Breast cancer patients with grade I disease showed lower level of *XIST*gene expression in comparison to those with Grade II and III. The average of *XIST* gene expression in grade I patients was 1.07% compared to 6.56% and 27.05% in patients in grade II and III, respectively (Table 3). However, these differences were not significant when statistically analyzed (GI vs. GII, P= 0.46; GI vs. GIII, P= 0.26; GII vs. GIII, P= 0.105).

Breast cancer patients with stage I disease showed lower level of *XIST* gene expression in comparison to those with stage II and III. The average of *XIST* gene expression in stage I patients was 1.95% compared to 23.95% and 14.6% for patients in stage II and III, respectively. No significant differences were found in the expression average of *XIST* gene among different breast cancer stages (Table 4).

Table 4: XIST gene expression average levels in breast cancer patients with different disease grades and stages

Breast Cancer Grade	**XIST expression%**	**t-test**
Grade I (n=13)	0.107	GI vs. GII (P= 0.46) GI vs. GIII (P= 0.26) GII vs. GIII (P= 0.105)
Grade II (n=39)	6.56	
Grade III (n=8)	27.05	
Breast Cancer Stage	**XIST expression%**	**t-test**
Stage 1 (n=12)	1.95	Stage 1 vs. Stage2 (P= 0.015) Stage 1 vs. Stage3 (P= 0.001) Stage 2 vs. Stage3 (P= 0.05)
Stage 2 (n=29)	23.95	
Stage 3 (2=19)	14.6	

In respect to other clinical features, breast cancer patients who underwent adjuvant therapy showed lowest levels of *XIST* gene expression (1.61%), while patients received hormonal treatment showed highest *XIST* gene expression levels (15.66%). The *XIST* expression level in this group of patients was two folds higher than that in patients given chemotherapy (7.17%). In the latter group, *XIST* expression level was approximately four folds higher than that in patients under adjuvant breast cancer therapy (Table 5). Furthermore, breast cancer patients with family history of the disease showed lower average levels of *XIST* gene expression (3.37%) compared to those with sporadic breast cancer (10.55%, Figures not shown). However, these differences were not significant (P= 0.43). Regarding the menstrual status, pre-menopausal breast cancer patients showed two folds higher levels of *XIST* gene expression than post-menopausal patients (11.77% and 5.60%, respectively). However, these differences were not statistically significant (P = 0.41).

Table 5: The average of XIST gene expression in breast cancer patients with different clinical features

Breast cancer features		**XIST expression%**	**t-test**
Treatment type	Adjuvant + AC (n=9)	1.61	P≥0.05.
	Hormone therapy (n=24)	15.66	
	Chemotherapy (n=27)	7.17	
Cancer development	Family history (n=14%)	3.37	P=0.43.
	Sporadic (n=46)	10.55	
Menopausal Status	Premenopausal (n=32)	11.77	P=0.138.
	Postmenopausal (n=28)	5.60	

Discussion

Results of current study showed significant reduction in number of Barr bodies in breast cancer patients in comparison to their age-matched healthy controls. Additionally, our results showed that number of Barr bodies was significantly reduced in advanced breast cancer grades and stages in studied patients.

Previous studies had shown interesting findings regarding loss of heterochromatic Barr body in breast cancer[6]. The disappearance of Barr body is believed to be linked to activity of *BRCA1*, a commonly disrupted gene in breast cancer cases. However, the frequent loss of heterochromatic inactivated X- chromosome in breast[8,16] and ovary cancers[19] and some haematological malignancies[13] may suggest even more general role for the reactivation/dysregulation of genes mapped to X chromosome in cancer development [7].

Furthermore, our study showed down-regulation of *XIST* expression in vast majority (95%, 57/60) of patients. This result confirms the proposed association between loss of Barr body and *XIST* gene in breast cancer patients[20]. Loss of Barr body could also due to epigenetic aberrations, which are hallmarks of almost all cancers, mediated by loss of *XIST* expression. Down regulation of *XIST* genes in breast cancer cases might lead to insufficient X-chromosome coating and contribute to disruption of silent nuclear compartments that are normally maintained in cells expressing adequate levels of *XIST*[21,22].

Overall, this study produced results which corroborate findings from a great deal of previous work and showed strong association between loss of Barr body and down-regulation of *XIST* in breast cancer patients. Both potential biomarkers, Barr body and *XIST* expression, could be investigated further for their utility as an early screening or diagnosis method especially in high risk individuals with breast cancer and possibly for other malignancies.

Correlation of Parenchymal Thickness of Kidneys with Ultrasonography in Various Clinical Stages of Chronic Type II Diabetes

M. Jayanth[1], V. Chandrasekhar[2], M. Prabakaran[3]

[1]Post Graduate, [2]Professor, Department of Radiodiagnosis, Sree Balaji Medical College, Bharath Institute of Higher Education and Research, Chennai-73

Abstract

Ultrasonography is used as a first line imaging technique to differentiate between acute and chronic kidney diseases in type 2 diabetes . The renal parenchymal thickness of left and right kidneys were compared and a detailed documentation was made. Our study included adult male and female population who were known case of Diabetes Mellitus, above 18 years of age and biochemically diagnosed for nephropathy . All patients were subjected to ultrasonography evaluation of the renal parenchymal thickness and the findings were documented.

Keywords: *Ultrasonography, Type II Diabetes.*

Introduction

Ultrasound images are useful at characterizing the pelvis, assessing renal dimensions, parenchymal thickness and evaluating their characteristics and distribution[1-4]. Cortical thickness should be estimated from the base of the pyramid and is generally 7–10 mm[5]. If the pyramids are difficult to differentiate, the parenchymal thickness can be measured instead and should be 15–20 mm[4]

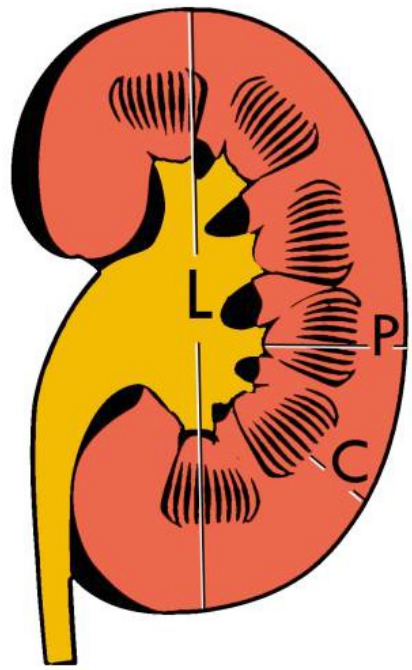

Figure 1: Measures of the kidney. L = length. P = parenchymal thickness. C = cortical thickness

Findings: Based on the measurement of right and left renal parenchymal thickness sonologically in diabetic nephropathy subjects, the following were interpreted.

Table 1: Distribution of Renal parenchymal thickness for Right Kidney (in mm)

Groups	Min	Max	Mean	SD	Median	IQ Range
Control	13.7	14.3	13.9	.17	13.9	13.8, 14.0
Diabetic nephropathy Group I	14.0	15.3	14.9	.30	15.0	14.9, 15.1
Diabetic nephropathy Group II	13.8	14.4	14.1	.28	14.15	15.0, 14.3
Diabetic nephropathy Group III A	13.2	14.3	13.5	.23	13.5	13.4, 13.67

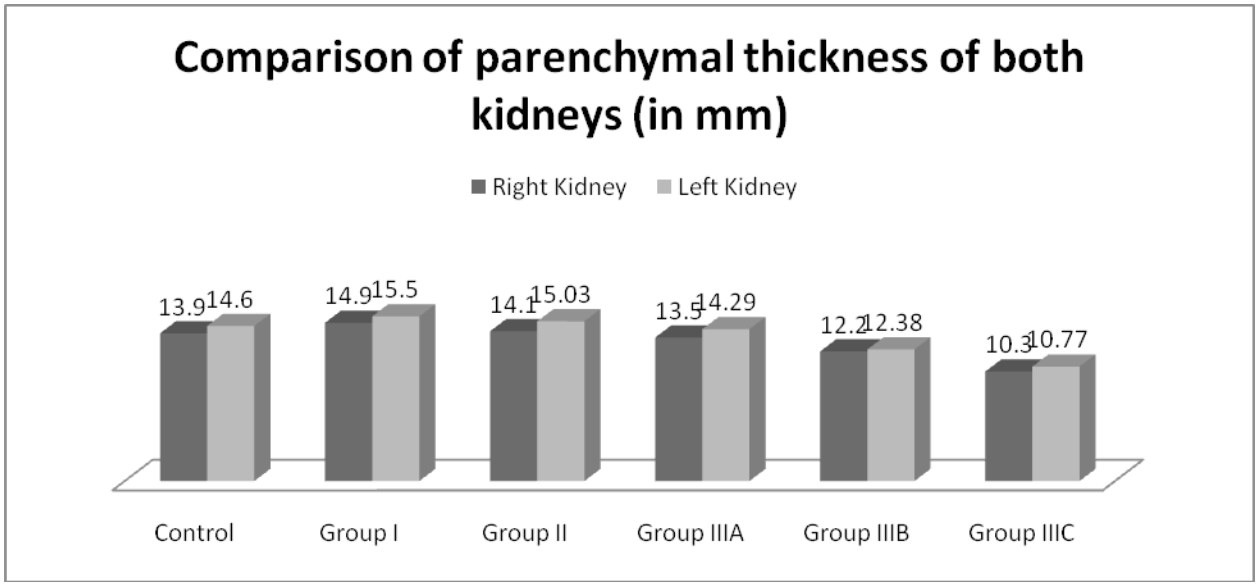

Figure 4: Comparison of parenchymal thickness of both kidney

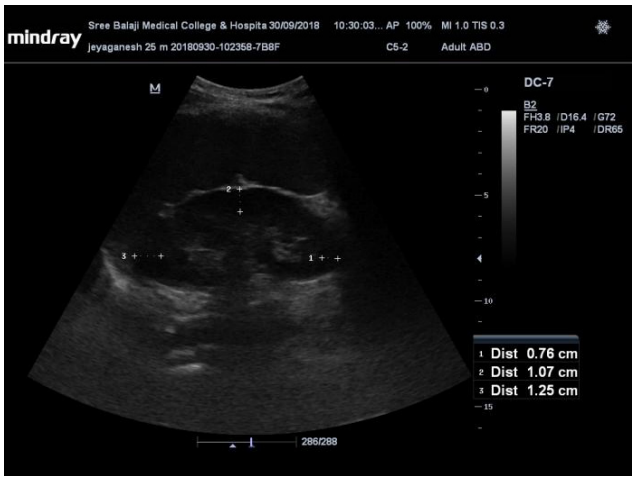

Discussion

The renal parenchymal thickness between the groups of right kidney was evaluated. The range, mean and standard deviations, median and inter-quartile range were decimated. The mean and SD of controls, group I, group II, group IIIA, group IIIB, group IIIc were 13.9 ± .17, 14.9 ±.30, 14.1 ± .28, 13.5 ± .23, 12.2 ± .47, 10.3 ± .10 millimeters respectively. Their lparenchymal thickness ranged from 13.7 to 14.3, 14.0 to 15.3, 13.8 to 14.4, 13.2 to 14.3, 11.8 to 13.5 and 10.2 to 10.4 among the controls, group I, group II, group IIIA, group IIIB, group IIIc respectively. The median (50th percentile) parenchymal thickness (inter-quartile range, i.e between 25th percentile and 75th percentile) fluctuated with values of 13.9 (13.8, 14.0), 15.0 (14.9, 15.1), 14.15 (15.0, 14.3), 13.5 (13.4, 13.67), 12.05 (11.9, 12.27) and 10.3 (10.22, 10.3) respectively among controls, group I, group II, group IIIA, group IIIB, group IIIc that have been included in this study. Florini F et al.[1] in their study have observed progressive parenchymal thickening in parallel with the stages of DKD and thence the results support our evidence convincingly.[2]

The renal parenchymal thickness between the groups of left kidney was evaluated.[3] The range, mean

and standard deviations, median and inter-quartile range were decimated. The mean and SD of controls, group I, group II, group IIIA, group IIIB, group IIIc were 14.6 ± .19, 15.5 ±.23, 15.03 ± .21, 14.29 ± .20, 12.38 ± .13, 10.7 ± .09 millimeters respectively. Their parenchymal thickness ranged from 13.7 to 14.3, 14.0 to 15.3, 13.8 to 14.4, 13.2 to 14.3, 11.8 to 13.5 and 10.2 to 10.4 among the controls, group I, group II, group IIIA, group IIIB, group IIIc respectively. The median

Figure 5: Ultrasound image of the measurement of renal parenchymal thickness

(50th percentile) parenchymal thickness (inter-quartile range, i.e between 25th percentile and 75th percentile) fluctuated with values of 14.6 (14.5, 14.72), 15.6 (15.4, 15.7), 15.0 (14.9, 15.2), 14.25 (14.12, 14.47), 12.4 (12.3, 12.5) and 10.75 (10.7, 10.87) respectively among controls, group I, group II, group IIIA, group IIIB, group IIIc that have been included in this study.

Conclusion

Based on the measurement of right and left renal parenchymal thickness sonologically in diabetic nephropathy subjects, it was interpreted that the renalparenchymal thickness diminished while the disease was getting progressed.

Soluble Cytotoxic T-Lymphocyte Antigen-4 (CTLA-4) in Chronic Myeloid Leukemia and its Association with Total and Differential Leukocytes Count

Ayad M. Gaidan[1], AyaSaad Yasen[1], SariaNaji Muhsin[1]

[1]College of Science/Tikrit University/Iraq

Abstract

Background: Chronic myeloid leukemia (CML) is a myeloproliferative disorder characterized by the presence of Philadelphia chromosome in the vast majority of cases. Although tyrosine kinase inhibitors (TKIs) are very effective in the treatment of this disorder, they cannot completely eliminate the leukemic cells indicating other players in the body fighting against this malignancy.

Aims: To evaluate serum concentrations of soluble cytotoxic T-lymphocyte antigen-4 (sCTLA-4) and its correlation with total and differential leukocytes count in patients with Chronic myeloid leukemia.

Subjects and Method: This case-control study included 48 imatinib-resistant Chronic myeloid leukemia patients, and 42 family unrelated, age-matched healthy subjects. Blood samples were obtained from each participant, from which sera were separated and soluble cytotoxic T-lymphocyte antigen-4 concentration was measured by enzyme-linked immunosorbent assay (ELISA). Demographic data for patients and controls were recorded through direct interview, with laboratory data for patients were extracted from their records.

Results: Serum concentration of soluble cytotoxic T-lymphocyte antigen-4 was found to be significantly dropped in Chronic myeloid leukemia patients compared to controls (26.38± 4.35 pg/ml *vs*. 37.19±11.08 pg/ml). Furthermore, soluble cytotoxic T-lymphocyte antigen-4 was inversely (although not significantly) associated with the total number of leukocytes and neutrophils, while this concentration was positively and significantly with lymphocytes count ($r = 0.606$, $P<0.001$).

Conclusions: Soluble cytotoxic T-lymphocyte antigen-4 is down-regulated in imatinib-resistant Chronic myeloid leukemia patients which is associated with increased neutrophil counts.

Keywords: *Chronic myeloid leukemia, soluble cytotoxic T-lymphocyte antigen-4.*

Introduction

Chronic Myeloid leukemia (CML) is a pluripotent hematopoietic stem cell disorder characterized by the presence of a balanced translocation t(9;22)(q34;q11), which juxtaposes the ABL gene located on chromosome 9 with the BCR gene on chromosome 22 to generate a chimeric protein, BCR-ABL[1]. Nearly 1.5 million people worldwide suffer from CML[2]. Reports from several European CML registries consistently show a crude annual incidence of 0.7-1.0/100,000, a median age at diagnosis[3].

The standard first-line therapy against CML is imatinib, a molecular-targeted drug that inhibits the *abl* tyrosine kinase[4]. However, imatinib does not completely eliminate residual leukemia cells and patients inevitably relapse after stopping treatment[5]. Thus, a comprehensive understanding of immune response to this malignancy may help to overcome this relapse.

Generally, immune response to tumors mainly depends on the activation of immune cells, especially natural killers (NKs), macrophages and T-lymphocytes[6,7]. Inactivation of these cells for any reason can promote the disease progression even with appropriate therapy and increase the relapse after TKI discontinuation.

Human cytotoxic T-lymphocyte antigen-4 (CTLA-4)

is a homodimeric glycoprotein belonging to human immunoglobin (Ig) superfamily[8]. Physiologically, this protein has a negative role in T-cell activation. Thereby, it facilitates the physiological termination of immune response[9,10]. It was found that expression of CTLA-4 is associated with a decreased ability of immune system to detect and eliminate tumor-associated antigen (TAA) [11]. Furthermore, anti-CTLA-4 was used for enhancement of antitumor immunity through the suppression ofregulatory T-cell (Treg)[12].

In fact, there are two isoforms of CTLA-4: a membrane-bound receptor isoform (mCTLA-4) which has both extracellular and intracellular domains, and a soluble isoform (sCTLA-4) with only extracellular domain for ligand-binding[13]. The latter isoform is not produced by enzymatic cleavage of mCTLA-4; rather there is an alternative spilicing of mRNA which results in the production of this isoform which is secreted into the extracellular space[11].

Interestingly, sCTLA-4-4 could interact with same ligands of mCTLA-4 causing the inhibition of activated T-cells. Blocking of sCTLA-4 was found to enhance Ag-driven peripheral blood mononuclear cell response[14].

Accordingly, measuring of serum level of sCTLa-4 could reflect the activation status of T-cell. Therefore, this study was aimed to measure serum levels of sCTLa-4 in imatinib-resistant CML patients.

Patients and Method

Patients: A total of 48 imatinib-resistant chronic phase CML patients were enrolled in this case-control study. The age range was 18-80 years. The diagnosis of CML was established on the basis of the peripheral blood parameters and morphological analysis of peripheral blood. Bone marrow aspirates were carried out in a single center (Iraqi National Center of Hematology for Research and Treatment/Baghdad) and confirmed by the presence of Philadelphia chromosome by conventional cytogenetics. Clinical and laboratory data were obtained from patients' records and database of the center. Other, family unrelated age-matched, 42 subjects were recruited to represent the healthy control group. Demographic data including age, gender, height, weight, educational level, dwelling and family history for hematological malignancies from both groups were collected through a direct interview. Peripheral blood samples were obtained, from which sera were separated and kept at-20ºC until used.

Immunoassay: A ready commercial kit (Legend Max™ Human Soluble CTLA-4 ELISA kit with pre-coated plate/Biolegend/USA) was used for measuring serum level of sCTLA-4. The manufacturer's protocol was followed precisely. Briefly, after a proper dilution of some reagents, 500µL of 2500pg/ml standard were prepared by diluting 62.5µL of the standard stock solution in 437.5µL of the assay buffer A. Six two-folds serial dilutions were prepared in separated tubes. A total of 50µL of Matrix C was added to each well of the plate that is allocated for standard dilutions, while 50µL of assay buffer A were dispensed to the wells that allocated for samples. Fifty µL of standard dilutions or serum samples were poured into their corresponding wells, and the plate was sealed and incubated at room temperature (RT) for 2hr with shaking. The contents of the plate were discarded, and the plate was washed 4 times. Human sCTLA-4 Antibody solution (100µL) was dispensed into each well followed by an hour of incubation with shaking, then washing. One hundred of Avidin-HRP were added to each well of the plate which was sealed and incubated for 30min with shaking. After content discarding and plate washing, 100µL of substrate solution F were dispensed in each well, followed by incubation for 25min in the dark. Stop solution (100µL) was added and the absorbance was read at 450nm with 30min.

Statistical analysis: Descriptive statistics including frequency, percentage, mean and standard deviation (SD) were computed. Student's *t*-test was used to compare age, BMI, and serum level of sCTLA-4 between patients and controls, while Chi-squared test was used to calculate the significant differences between the two groups regarding the categorical variables. Pearson's correlation and linear regression with scatter plot were used to find out the correlation between sCTLA-4 and total and differential leukocyte count. A P value of ≤0.05 was considered a cut-off value for statistical significance.

Results

Demographic Characteristic of the study population: Overall, there were no significant differences between CML patients and controls regarding all studied demographic data (Table 1). The only notable exception was the family history where 6(12.5%) of patients had first relative with a hematological malignancy compared to only one subject (2.38%) had such a history. Even so, the difference did not reach a significant level (P=0.074).

Table 1: Baseline demographic characteristics of the study group

Variables	CML patients(n=48)	Controls (n=42)	P-value
Age/Yr (mean±SD)	54.8±11.4	51.61±12.7	0.412
Gender/No (%)

BMI: Body mass index

Hematological Characteristics of CML Patients: The characteristic hematological features of CML patients in the current study were mild anemia (evidenced by slight decrease in total red blood cell count, packed cell volume% and hemoglobin%), and leukocytosis with absolute increase in almost all subtypes of white blood cell, especially neutrophils (Table 2).

Table 2: Hematological parameters of the CML patients

Hematological parameter	Mean±SD
RBC×10^{12}/L	3.7±0.71
WBC ×10^9/L	35.42±9.59
Neutrophil ×10^9/L	22.33±4.75
Lymphocyte ×10^9/L	3.84±0.46
Monocyte × 10^9/L	0.63±0.23
Eosinophil × 10^9/L	0.14±0.05
Basophil× 10^9/L	0.02±0.01
Platelets × 10^9/L	386.5±122.71
PCV%	36.21±7.2
Hb (g/dL)	12.31±1.69

RBC: red blood cell, WBC: white blood cell, PCV: packed cell volume, Hb: hemoglobin

Analysis of circulating sCTLA-4 in the serum: Mean serum concentration of sCTLA-4 was higher in CML patients than healthy controls (26.38±4.35pg/mL, range from 15.5 to 33.9pg/mL vs. 37.19±11.08pg/mL, range from 21.8 to 67.14pg/mL) with a significant difference (*P*=0.026) as illustrated in Figure 1.

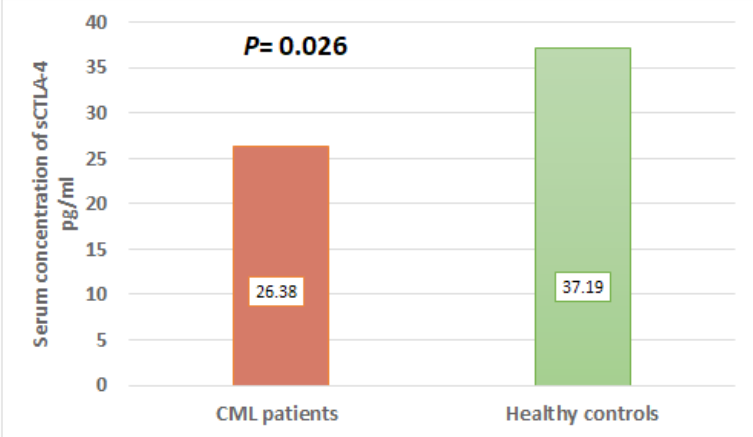

Figure 1: Serum concentration of sCTLA-4 in CML patients and controls

Correlation between sCTLA-4 and total and differential leukocytescount

Serum concentration of sCTLA-4 was inversely correlated (although not significant) with each of total WBC, neutrophils, monocytes and basophils (Figure 2). In this regard, the most prominent correlation was with neutrophils which was very close to a significant level (r = 0.267, *P*= 0.066). More importantly, there was a significant moderate positive correlation between sCTAL-4 and lymphocytes count (r = 0.606, *P*<0.001).

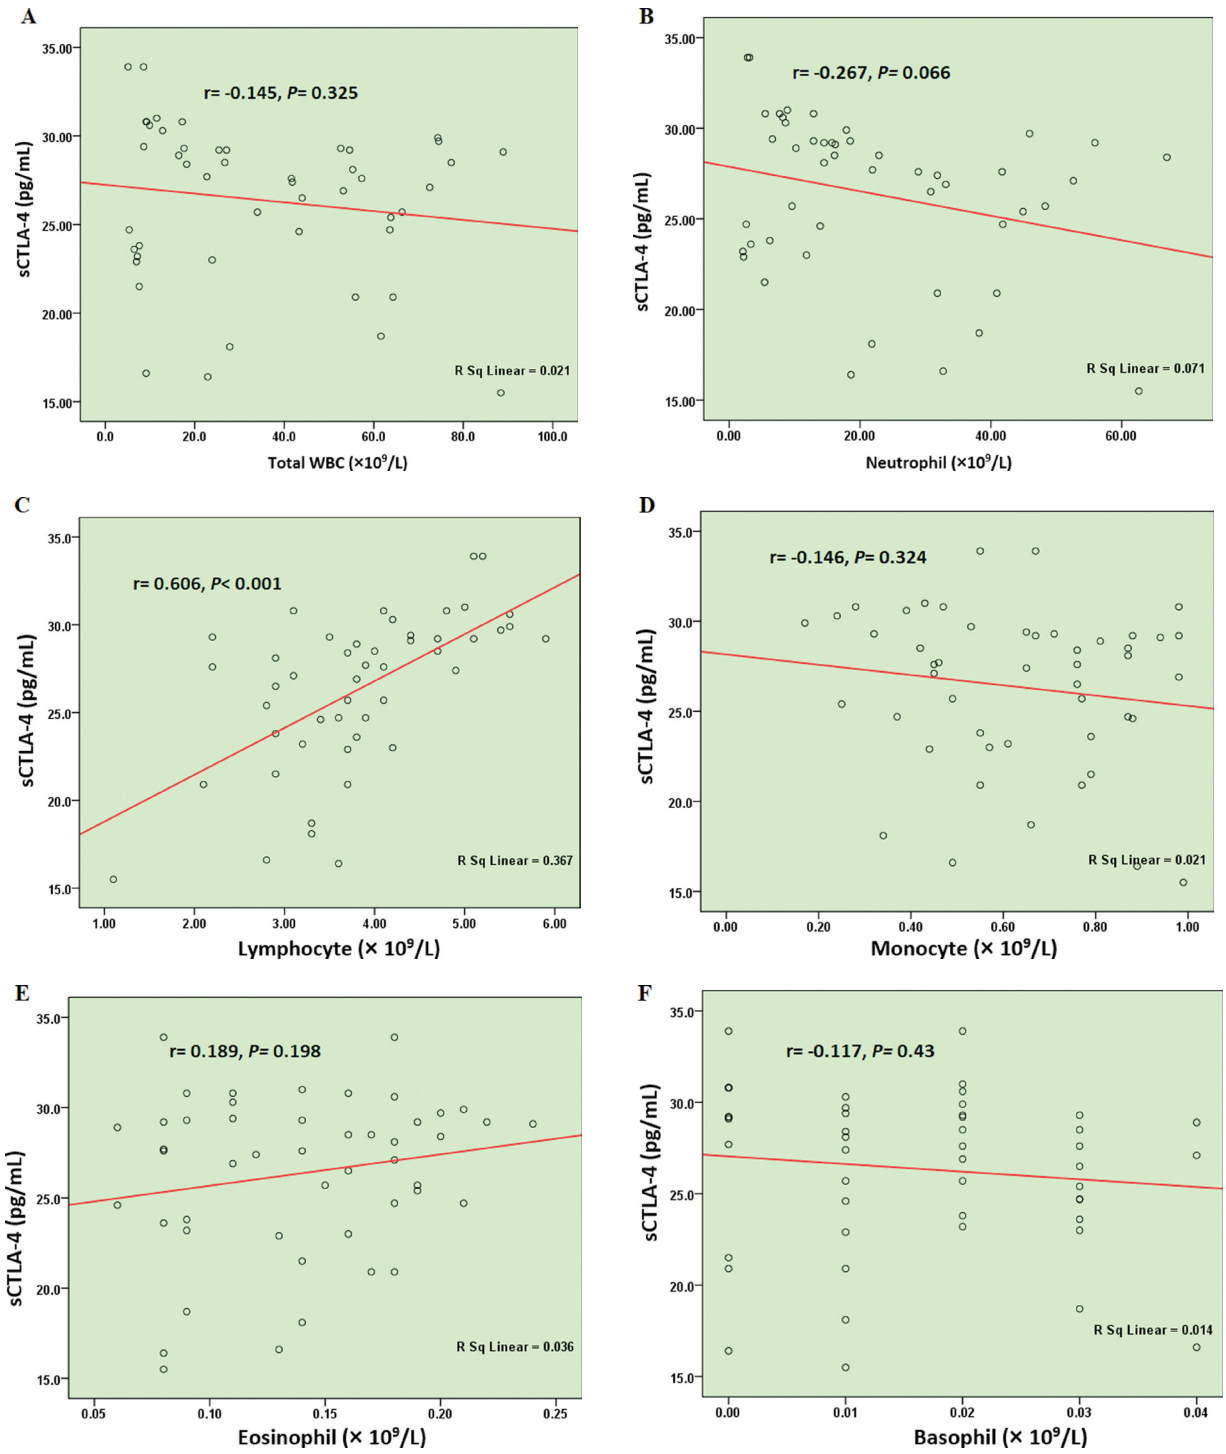

Figure 2: Correlations between serum concentration of sCTLA-4 and total numbers of WBC (A), neutrophils (B), lymphocytes (C), monocytes (D), eosinophils (E)and basophils (F) in peripheral blood of 48 CLM patients

Discussion

In newly diagnosed CML patients, the immune system has been shown to be dysfunctional, with T-cells display decreased T-cell receptor (TCR) chain, reduced cytokine activity, with no production for immunoregulatory cytokines[15,16]. Treatment with TKI can restore the normal function; however, there is a growing resistance for these therapies, and the discontinuation of this treatment is associated with relapse within 6 months in a considerable percentage of patients [17] which indicated a role for immune response in this regard.

The current study revealed a significant decrease in sCTLA-4 in imatinib-resistant CML patients compared with healthy controls. This finding suggested a potential role of sCTLA-4 in the pathogenesis of CML. To the best of our knowledge, this is the first study which investigated serum levels of sCTLA-4 in CML patients. On the other hand, in B-acute lymphoid leukemia (B-ALL) it as reported that a significantly elevated sCTLA-4 in 70% of the patients with active disease[11]. On the other hand, several studies reported relatively high levels of this protein in sera of patients with autoimmune diseases such as autoimmune thyroid disease and type 1 diabetes mellitus [18-20].

Considering the essential role of mCTLA-4, these findings were somewhat conflicting. Although sCTLA-4 could also interact with B7 and thus inhibits the T-cells activity through the interfering with CD28 signaling, studies showed that the normal function of sCTLA-4 was more complicated. Soluble CTLA-4, on the one hand, competes to bind CD80/CD86 and suppresses T-cell activation. On the other hand, the absence of transmembranous domain in sCTLA-4 disabled it to down regulate immune function while it blocks the negative signal of mCTLA-4 [11]. The effect of sCTLA-4 binding to CD80/CD86 possibly depends on the activity of the cell involved. Thus sCTLA-4 could either inhibit the immune response if present at the initial stage of the disease (by blocking the CD80/B7 binding) or enhance the immune response if present during the latter stages of the disease (blocking the mCTLA-4–B7 binding)[21].

In light of results of these studies, the relatively low concentrations of sCTLA-4 in CML patients in the current study could explainthe of overall suppression of immune response in those patients which implied that there is no enough sCTLA-4 to impede the activity of mCTLA-4.

The other important results of current study were the negative and positive correlations of sCTLA-4 with absolute number of neutrophils and lymphocytes, respectively. In one study on patients with asthma, [21] reported highly significant positive correlation between sCTLA-4 and lymphocytes number. For neutrophils, the inverse correlation could be referred for the status of immune suppression associated with deceased sCTLA-4, while increased neutrophils. For lymphocyte, the highly positive correlation could indicate that the source of most sCTLA-4 in lymphocytes, which when increase in number, they produce more protein.

In conclusion, these results indicated the down-regulation of sCTLA-4 in imatinib-resistant CML patients which is associated with increased neutrophils count. More studies are needed to reveal the causes behind this down-regulation.

Salivary Interleukin 17 (IL17) Level among Iraqi Patient with Chronic Periodontal Diseases

Mohammed Qays Mahmood Fahmi[1], Maha Jamal Abbas[2], Lubna Abdulelah Abdulrahman Almallah[3]

[1]Lecturer, [2]Assistant Professor, Department of Orthodontic, Pedodontic and Preventive Dentistry, College of Dentistry, Iraq, Mustansiyriah University, [3]Assistant Lecturer, Department of Orthodontic, Pedodontic and Preventive Dentistry, Dentistry Department, Dijlah University, Iraq

Abstract

Background: Saliva has been suggested as a non-invasive diagnostic fluid that may be used in the diagnosis of oral and systemic diseases. The salivary levels of IL-17 could be used as a substitute to distinguish periodontal healthy from periodontitis subjects. Therefore, the goal of the present investigation was to determine if the levels of IL-17 in saliva would differ between a group of periodontal healthy and periodontitis subjects. Correlations between the concentration of IL-17 and clinical parameters of periodontal disease were also examined.

Subjects and Method: Unstimulated saliva was collected from each individual (24 patients with periodontitis and 24 healthy age-and gender-matched individuals as control group). Salivary interleukin 17 level was evaluated for both groups using enzyme-Linked Immuno-sorbent assay technique.

Results: Mean values of IL-17 levels were highly significantly increased in patients with chronic periodontitis patients as compared to healthy control subjects.

Conclusion: Interleukin 17 has special importance could be used as a positive predictive factor for prediction and diagnosis of periodontitis.

Keywords: *IL-17, ELISA, periodontitis, saliva, biomarkers.*

Introduction

Periodontitis can be defined as an inflammatory disease of tooth supporting tissues and is categorized into various types based on clinical, radiographic, laboratory and historical features of the disease. Chronic periodontitis is the most common form of the disease. In this type of disease, the amount of periodontal tissue destruction is consistent with local factors and the disease progression rate is slow to moderate[(1)]. Periodontal disease is characterized by irreversible destructions of gingival tissue, periodontal ligament and alveolar bone resorption that results in periodontal pocket formation, clinical attachment loss with gingival recession, gingival bleeding, alveolar bone loss, root furcation exposure and increased tooth mobility[(2)]. Biomarkers can be demarcated as a quantifiable and calculable biological parameters which can serve as indicators for health and physiology-related assessments, such as pathological processes, environmental exposure, diagnosis and prognosis of disease or pharmacologic responses to a healing intervention[(3)].

Interleukin-17 a cytokine that acts as potent mediator in delayed type immunological reactions by increasing chemokine production in various tissues to recruit monocytes and neutrophils to the site of inflammation. Interleukin-17 is a newly introduced pro-inflammatory cytokine, produced by T-helper cells with a wide range of protective and destructive activities[(4-6)].

IL-17 comprises a family of 6 cytokines which are structurally related. Some of these factors can cause tissue degeneration and hypersensitivity reactions and some others haveessential role in resisting bacterial infections. The architecture of these cytokines and their receptors is different. IL-17A is one of the most specific members of this group and is produced by different cells including T-helper 1, 2 and T cell CD4+[(7)].

In relation to chronic periodontitis, a significant rise of the total amount of IL-17 had been established in the gingival crevicular fluid samples and culture supernatants of gingival cells in periodontitis patients compared to healthy controls that submitted a role for IL-17 in the pathogenesis of chronic periodontitis[8]The involvement of IL-17 in the host response of periodontal disease is further supported by [9] who reported an increased concentration of IL-17 in gingival tissue supernatants at sites with moderate to severe clinical attachment loss and had found a positive correlation between them at the site-based level.

However, uncertain results had been reported regarding IL-17 and chronic periodontitis. For example, [8,10] demonstrated undetectable results of IL-17 cytokine level that was close to 0 pg/μL in the GCF samples of healthy, gingivitis and chronic periodontitis groups. In spite of the role of IL-17 in inflammation has been calculated by a number of investigators, it is still ambiguous and little evidence have has been stated regarding the serum level of inflammatory mediators such s IL-17 in chronic periodontitis subjects. This study was aimed to compare the serum IL-17 concentrations between chronic periodontitis and healthy subjects and to measure the relationship between the IL-17 serum and the clinical periodontal parameters in chronic periodontitis patients.

Materials and Method

The present study was conducted at the Department of Periodontics, collage of dentistry, Mustansiriyah University, Iraq. It included 48 subjects (24 males and 24 females) within the age range (20-50)years. Exclusion criteria included history of smoking, the subjects recruited in the study were free from any other oral or systemic illness and subjects who had received periodontal therapy, antibiotics or non-steroidal anti-inflammatory drugs within preceding 6 months. Unstimulated saliva was collected in the morning between 8 and 11 am. Salivary samples were centrifuged at 4000rpm for 10 minutes then 100μl of supernatant were withdrawn and stored in sterile Eppindorf tube at (-20°C) for analysis of IL-17. Interleukin 17 production was measured using ELISA kits (IL-17 ELISA Kit) Shanghai Yehua Biological Technology/China.

The study groups included patients who had chronic periodontitis diagnosed by measuring clinical attachment loss and examining bleeding on probing, a minimum of 15 teeth present during the periodontal examination, with regards to the patients within chronic periodontitis group had a minimum of four teeth with at least one site each with probing depths and clinical attachment loss of ≥ 5mm presence of bleeding on probing and radiographic evidence of generalized alveolar bone loss in at least 2 quadrants.

On the other hand, control group included no history of periodontitis, probing depths of ≤ 3mm, no evidence of attachment loss other than facial recession, < 25% of sites with bleeding on probing and absence of generalized alveolar bone loss in the radiograph. All statistical analysis was conducted using IBM SPSS®-version 20 software. The demographic variables were presented as simple descriptive statistics calculating the mean value and standard deviation (SD) of numerical data such as age of the subjects. The concentrations of studied salivary cytokines were preented as mean and standard error of mean (SEM). Independent samples *t*-test was used to compare the levels of salivary cytokine in studied groups.All tests were performed at a significance level of 0.05.

Results

Results Table 1 shoed the mean and standard error of salivary concentrations of IL-17 in chronic periodontitis subjects as well as in healthy subjects. The highestIL-17 concentration(217.16079 pg/mL) was detected in saliva of subjects have chronic periodontitis group compared with healthy control subjects (128.30767 pg/mL)

Results also showed that patients with chronic periodontitis had a higher salivary IL 17 concentration than healthy control subject with statistically highly significant ($t=10.321$, $df=46$, $P<0.01$).

The application of the coefficient partial correlation revealed a strong correlation between subjects have chronic periodontitis and salivary concentration of IL-17 which was positive and statistically highly significant ($r=+1.000$, $P<0.00$).

Table 1: Comparison of salivary levels of IL-17 (pg/ml) between chronic periodontitis patients and control grop

	Group	No,	Mean	Std. Deviation	Std. Error Mean

Equal variance salivary IL-17	t	df	Sig.(2-tailed)		
	10.321	46	0.000		

Discussion

Chronic periodontitis characterizes long lasting inflammation of periodontal tissues where microbes are a major etiological factor and the hallmark of periodontal diseases is bone loss.

Virulence factors produced by *P. gingivalis* such as Arg-and Lysgingipain proteinases are key factors for host tissue invasion which lead to activation of immune-inflammatory processes. Subsequently, various molecules (proteases, MMPs, cytokines, etc.) are activated leading to destruction of connective tissue attachment and alveolar bone loss[11]. Th17 cell differentiation and expansion is directed by IL-6 and other cytokines. IL-17A, the pro-inflammatory cytokine secreted by the activated Th17, has been involved in a number of human autoimmune and inflammatory diseases[12]. The role of IL-17 in chronic periodontitis is still an open question whether IL-17 stimulates bone resorption or protects bone in chronic periodontitis although increasing evidence indicates increased IL-17 expression in both chronic and aggressive periodontitis[13]. In the present study, mean±SD of IL-17 in saliva was high in chronic periodontitis compared to healthy controls. Previous studies had documented increased level of IL-17A in saliva, serumand gingival crevicular fluid (GCF) in periodontitis compared to healthy subjects and also reported important role of IL-17 in gingival inflammation and bone loss[14-16].

Conclusion

Salivary levels of IL-17 were significantly higher in patients with associated CP compared to healthy subjects. Therefore, the salivary levels of IL-17 may help in the sub-categorization of periodontitis.

Effect of Aqueous Extract of Nigella Sativa and Trigonella Foehum on Entamoeba Histolytica

Siham. N. Lefta

Department of Biology, College of Science, Mustansirya University, Iraq

Abstract

Background: *Entamoeba histolytica* is a protozoan parasite that is considered as the causative agent of amoebiasis and is considered a leading parasitic cause of human mortality. Nigella sativa (black seed) is an annual herbal plant belonging to the family . Ranundaceae. Trigonella foenum is an annual herb from the family fabaceae. The aim of current study was to study the efficiency of the aqueous extracts of nigella sativa and trigonella foenum as alternative treatments for E. histolytica infection.

Method: From October 2017 to December 2017 collected 100 feces sample in Ibn Al-balady hospital and Al-kadimiyah teaching hospital in Baghdad from patients in hospital. their age ranged from (4-32) yea. This study was conducted to determine the effect of aqueous extracts of Nigella sativa and Trigonella fornum plant on 120 (80 mice) treated with N. sativa and T. foenum (20) mice positive control and 20 mince negative control. Swedish mice aged (5-12) weeks and the range of their weight (16-22), infected with parasite of Entamoeh histolytica experimentally and then knwong some his to pathological (in vivo) changes in those mice after using the extracts as a treatment for those mice from E-histolytice and then compare it with metronidazole.

Results: data from current study showed diverse histopathological changes in the intestines, liver, kidney in animals infected with E-histolytice and treated by N-sativa and T-foenuu extract included shortness in intestinal villi, inflammntory cellular infiltration, hyperplasia, necrosis, bloody vessel congestion and accumulation of fats. The best results were recorded in group that treated with flagyl/aqueous N, sativa 10mg/ml. *In vitro*, the aqueous extract of Niqella sativa killed 280.000 amoeba or%70, but 10mg/ml extract killed 320.000 ameoba by 70%. The aqueous extract of trigonella foenm (5mg/ml) killed 240.000 amoeba by 70%. However, mestronidazole killed 360.000 amorba by 90%

Keywords: *Entamoeba histolyrica, Nigella sativa, trigonella fornum, liver, intestine, histopathology.*

Introduction

Entamoeba histolytica is a protozoan parasite that is considered as the causative agent of amoebiasis and is considered a leading parasitic cause of human mortality[1].

The prevalence of infection is high in developing countries where transmission of *E. histolytica*via untreated drinking water and contaminated foods is common[2].It was reported that children are the most infected persons[3].

*E. histolytica*has four distinct stages in its life cycle: trophozoite, precyst, cystand metacyst.

The vegetative and motile froms that are termed trophozoite, while the other stage is the infective stage [2,4,]. Fecal-oral route is the pathway forcysts transmission, either through ingestion of contaminated food or water or by person to person contact[5].

Clinical amoebiasis appears when trophozoites disrupt the mucosal barrier and penetrate the colonic wall causeing ulcers that lead to amoebic dysentery[6].

Nigella sativa (black seed) is an annual herbal plant belonging to the family Ranundaceae[7]. The moisture concentrate ranged from 5.52-7.4% crud protein, 20-27% ash, from 3.77-4.42%carbohydrate from 23.5-33.2% and ether extractable lipid from 34.49-38-72%[8].

Trigonella foenum is an annual herb from the family fabaceae indigenous to the Mediterranean area.

T. foenum seed is good source of protein 20-30%, high intryptophan and lysine, fat 6-53%, free amino acids 4-hydroxy(solencine, arginine, lysine, histidine) and 25.8% ash content crude fiber and energy (394-46kcal/100g secd)[9].

Aim of Study:

1. Finding alternative treatment for *Entamoeba histolytica* instead of using metronidazole.
2. Study the efficiency of the aqueous extracts of nigella sativa and trigonella foenum in the treatment of *Entamoeba histolytica*.

Materials and Method

Blood and stool samples were obtained from 100 patients with diarrhea clinically presented with bloody and mucoid diarrhea.The samples where collected from outpatientclinic for pediatricsatIbn Al-balady hospital and Al-Kadimiyah Teaching hospital. The patients have not received antibiotics.

Microscopy used as ascreeing method for the diagnosis of *Entamoeba histolytica*stool specimen could be examined, either unstained or stained, with lngolsiodine[10].

Blood sample collection: A 3-ml sample venous blood was obtained from each patient and collected in gel tube, centrifuged at 3000rpm for five minutes, then serum from each sample was collected in Eppendorf tubes and stored at-20ºC.

Preparation of nigella sativa aqueous extract: N-sative seeds were washed, to remove any debris, and air dried. Then, an amount of 150g crushed and boiled in 50ºC° indistilled water (1500ml) for 30 minutes and filtered through muslin. The filtrated water extract was transferred to tube and hold process of centrifugal (3000 rotation/min) for 15 minutes.

After that, the filtrate was evaporated under reduced pressure and lyophilized to give aqueous extract[11].

The aqueous extract was dissolved in distilled water then preserved in the deep freezer (20ºC) till it is used.

The present study involved evaluation of two concentrations of N. sativa; 5mg/ml and 10mg/ml.

Preparation of Trigonella foenum aqueons extract: T. foenum seeds were washed and then leftto dry and crushed. Then, an amount of (100g) added to (1000ml) of distilled water and the mix put in the incubator at 40ºC° for 24 hours[12]of the grat (40x) using dual wet strips and ipbizd wet strips the first helps in the detection of trophozoites and the second helps in the detection of cyst.

Assessment of parasite vitality using of water Eosine solution, was used as the dye of the Eosine stant all contents except the living Protoplast.

Culture Media: That used by using the media of locke diphasic and the media was introduced in accordance with Brand method[13] with some modification. After the distribution of the pro complex protein emulsion that was added (6ml) and placed in a boiling water bath for 15-20 minutes, the tubes were then cooled and 6 ml of the lockesolution was added and the two stage sterility was stabilized for 14 minutes then the following substances were added to each tube; 1 ml serum inhibitor and 0.2 ml of antibiotic solution like anpclition streptomycin.

Percentage of dead amoeba

$$= \frac{\text{Number of Eosin Dyed Amoeba}}{\text{Number of Total Amoeba}} \times 100$$

For determining the number and biological density of the amoeba grown in glass[11]. Eosin dye were used depending on the ron-permeability of the Eosin layer to the live parasite cell. Amoeba was used extensively (400,00) amoeba liter and 92% vitality Histopathological study.

The mice were killed and extracted the organ (liner kidney in teatime) according to the method described by[15].

Statistical Analysis: Mintab software version 6 was used data. ANOVA test has been done calculate previous studies. Least significant difference–ISI test was done [16].

Result and Discussion

Table 1: Showed the number of parasites and compared between all treatments during days with control positive

1	2	3	4	5	6	7	8
Metronidazole							
470.001±	238.001±	112.00±	58.00±	28.00±	0.00	0.00	0.00
18.40	18.55	9.60	3.70	2.00

T. Foenuextract (10mg/ml)							
508.00±	316.00±	210.00±	116.00±	20.00±	28.00±	0.00	0.00
27.6	18.6	9.5	5.10	4.46			
N. Sative Extract (10mg/ml)							
475.00±	298.00±	216.00±	116.00±	58.00±	28.00±	0.00	0.00
16.30	8.60	12.00	675	4.80	3.70		
N. Sative Extract (5mg/ml)							
784.00±	625.00±	476.00±	244.00±	128.00±	56.00±	20.00	
42.00	34.00	20.1	16.30	5.80	5.10	4.1	
Positive Control							
1086.00±	1196.4±	1238.00±	1349.20.00±	1150.000±	945.60±		
9.11	8.60	8.60	8.46	7.75	8.91		

756.8±8.70, 590.00 ±9.11

The result showed that metronidazole killed the parasite within 6 days, but the T. foemem 5mg/ml killed it in the 8th day and 10mg/ml killed amoeba in the seventh day and also N.sative extract compared with positive control.

In Vitro: The result of the extract of plant and metronidazole in ameobiasis. The plants extract 5mg/ml of N.sative which killed 280.00 or 70%, but the 10mg/ml of N.sative which killed 320.000 or 80%.

The concentration of T. foenm (5 mg/ml) which killed 240.00 by 60%, but other concentration killed 280.00 by 70%.

The metronidazole killed 360.000 by 90%.

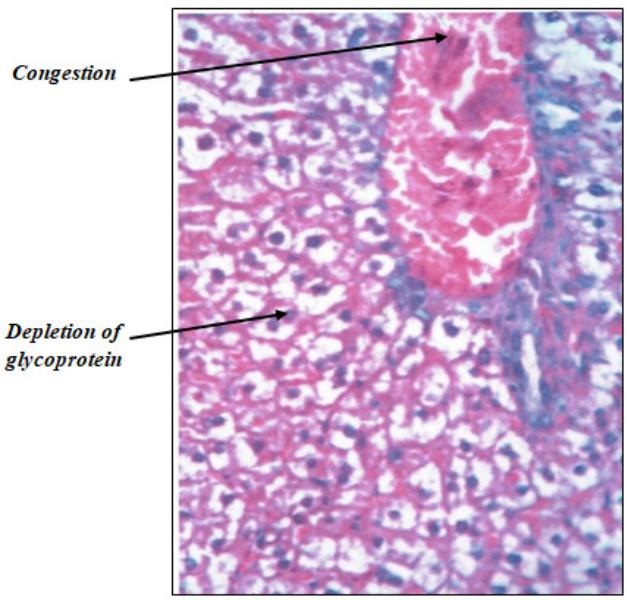

Figure 1: Section of liver infection with Entamoeba histolytica (H&E) (2000x)

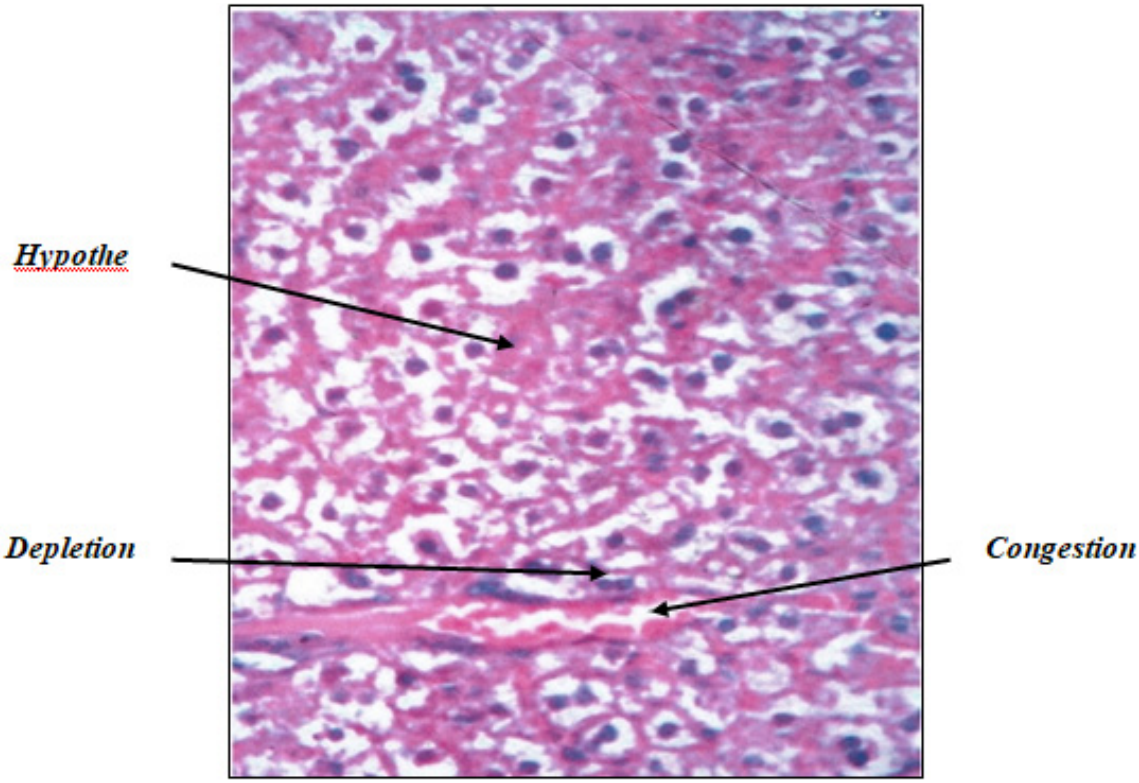

Figure 2: Section of liver treated with 10mg/ml of extract of N. Sative (H&E) (2000x).

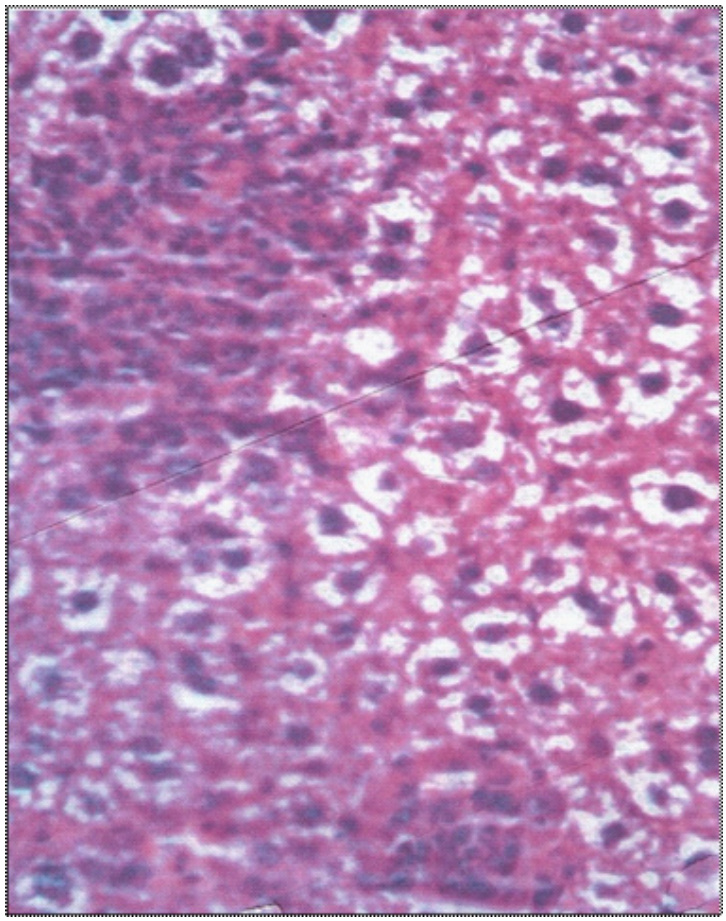

Figure 3: Section of Kidney treated with 10mg/ml extract of T. foenum (H&E) (2000x).

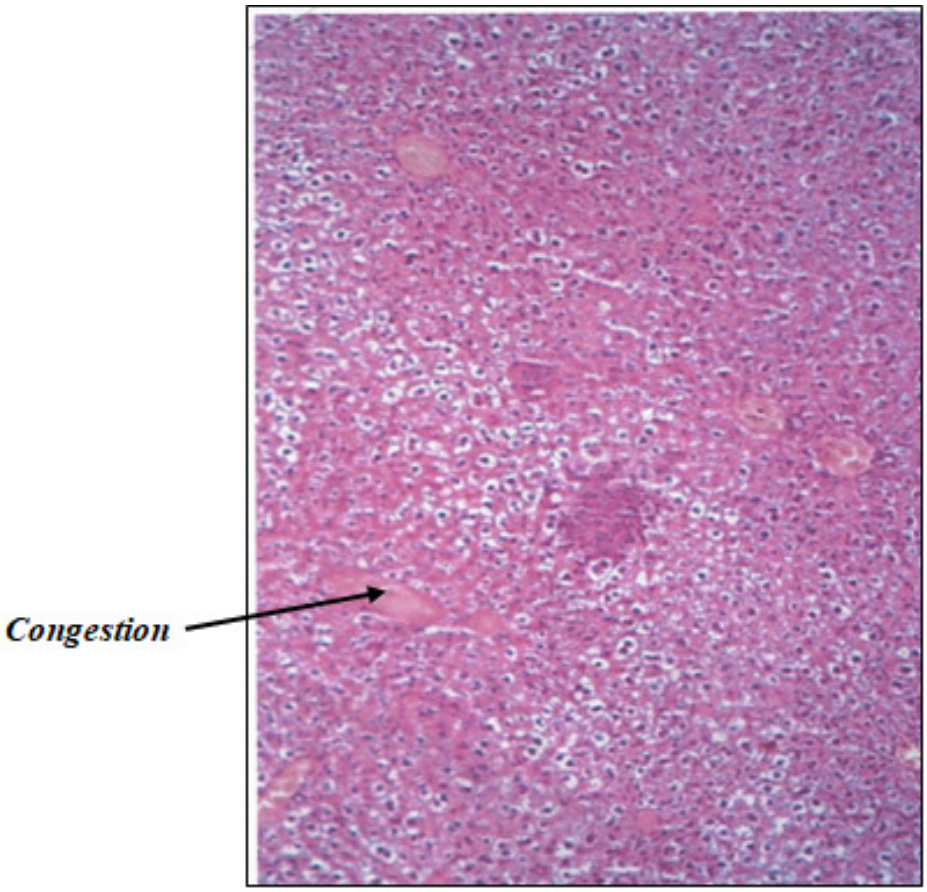

Figure 4: Section of Kidney infected with Entamoeba histolytica.

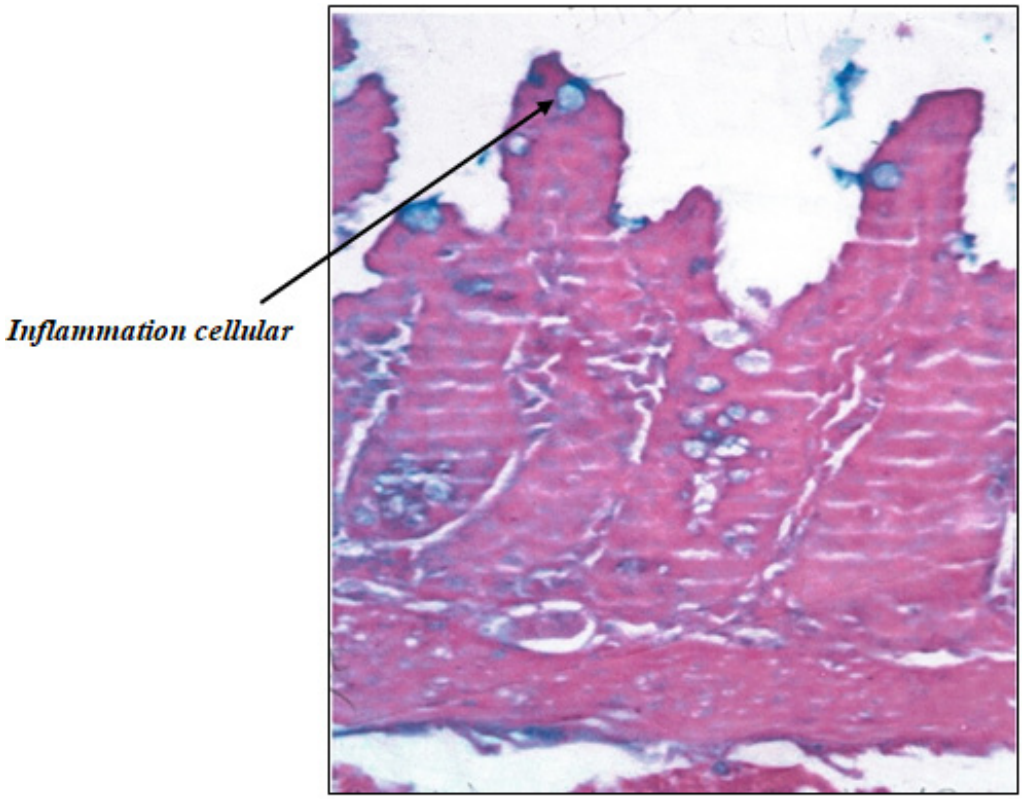

Figure 5: Section of intestine infected with Entamoeba histolytica (H&E) (2000x)

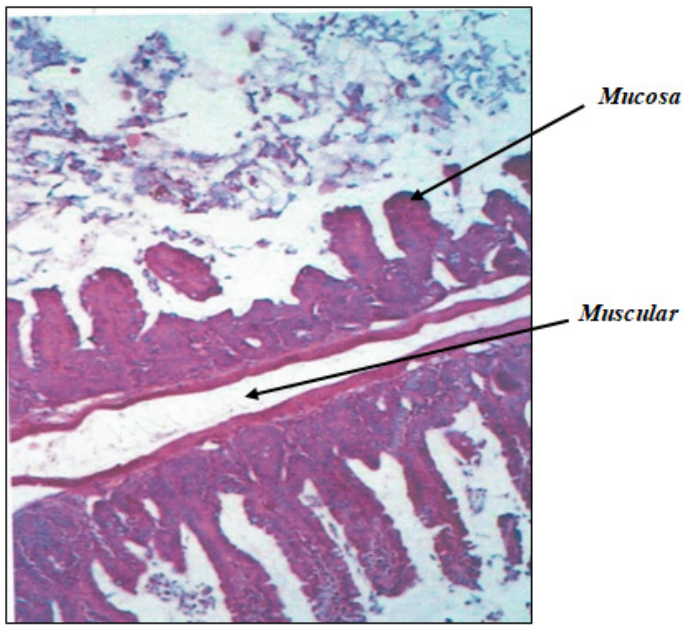

Figure 6: Section of intestine control (H&E) (2000x)

Histopathological study of the histological section of the liver ofinfected animals showed (Figure 1) presence of beginning of necrosis in some of its parts with the infiltration of monocyte inflammatory cells. Theses changes were close to the changes recorded by[19], where the infection ledto hyperplasia of Kupffer cells as a result of the presence of the parasites inside and infiltration of monoctye inflammatory cells as an immune response to liver tissue[20].

The study was consistent with Malachi [21] where he studied the liver treated with papa extracts (Figures 2).

the presence of bloody congestion with simple inflammatory infiltration (Figure 3). Figure (4) showed the normal structure appearance of kidney with presence of simple congestion change in the kidney is.

The present study agreed with the changes that occurred in the kidney were a slight and consisted occurrence of bloody congestion with infiltration of inflammatory cells and is similar to those concluded by[17] as that in spite of the inclusion of the kidney in injury, but that have occurred have been reflectivity that mean return the tissue[18].

Histological results in negative control showed the normal structured appearance which consists of the intestinal villi as in Figure (5) and showed prominent global cells and its murinesection, but histological result for infected animals with Entamoeba histolytical showing degeneration and shortening of intestinal villiin Figure (6).

High Level Aminoglycoside Resistance in Clinical Isolates of Enterococci

Alexander Kiruthiga[1,2], Kesavaram Padmavathy[3], Praveen Shabana[4], Sumathi Gnanadesikan[5], Jeevan Malaiyan[6]

[1]Research Scholar, Department of Microbiology, Research Laboratory for Oral and Systemic Health, Sree Balaji Dental College and Hospital, BIHER, Chennai, [2]Senior Lecturer, Department of Microbiology, Priyadarshini Dental College and Hospital, Pandur, Thiruvallur, [3]Associate Professor, Department of Microbiology, Research Laboratory for Oral and Systemic Health, Sree Balaji Dental College and Hospital, BIHER, Chennai, [4]Head, Department of Laboratory Medicine, Meitra Hospital, Calicut, [5]Professor & Head, Department of Microbiology, Sri Muthukumaran Medical College Hospital and Research Institute, Chennai, [6]Associate Professor, Department of Microbiology, Sri Muthukumaran Medical College Hospital and Research Institute, Chennai, India

Abstract

Introduction: Enterococci though being intestinal commensal flora have gained significance as a serious nosocomial pathogen owing to their exceptional ability to survive in the harsh environments and increasing high level resistance to antibiotics. The emergence of high level aminoglycoside resistant (HLAR) clinical enterococcal isolates is of serious concern worldwide and thwarts the available therapeutic options.

Materials and Method: A total of 25 non-repetitive isolates of *Enterococci* (*E. faecalis* (n= 15), *E. faecium* (n= 10)) recovered various clinical samples were screened for HLAR among the isolates was performed by disk diffusion method using High Level Gentamicin and High Level Streptomycin disks. The isolates were further confirmed as HLGR and HLSR by agar dilution method. Genes encoding Aminoglycoside Modifying Enzymes (AGMEs) were detected by multiplex PCR. Susceptibility to linezolid was determined by Kirby Bauer disk diffusion method.

Results: All the 25 isolates of enterococci exhibited HLAR phenotype (resistant to HLG and/or HLS). Majority (96%) of the isolates were resistant to HLG and 64% were resistant to HLS. MIC of gentamicin was >500 µg/mL for HLG^R isolates and MIC of streptomycin was MIC > 2000 µg/mL for HLS^R isolates. In our study, 92% of the enterococci harbored *aac(6')-Ie-aph(2'')-Ia* and/or *aph(3')-IIIa.* Of note, 15(60%) of the enterococci exhibited dual resistance to gentamicin and streptomycin (HLG^RHLS^R). Nevertheless, 92% of the isolates were found to be susceptible to linezolid.

Conclusion: Prompt detection and characterization of HLAR among clinical strains of Enterococci within our setting is very essential as few of them exhibit co-resistance to glycopeptides and have lost synergism with the cell wall active agents.

Introduction

Enterococci though being commensal intestinal microflora are recognized as potent etiological agents causing mild to serious infections including urinary tract infections (UTI), endocarditis, bacteremia, neonatal infections, central nervous system infections and intra-abdominal and pelvic infections.[1,2] Enterococci possess an exceptional ability to sustain in an environment

of ponderous antibiotics.[1] With over 20 species of enterococci reported so far, *Enterococcus faecalis* and *E. faecium* are the predominant cause of nosocomial infections, the most common being UTI.[3,4] Inappropriate use of antibiotics had resulted in the emergence of high level aminoglycoside resistant (HLAR) enterococci. [5] Thereby, the long practice of treating serious enterococcal infections with a combination of β-lactam and an aminoglycoside becomes impractical.[6] With this background this study was designed to assess the prevalence rate of HLAR among enterococci isolated from various clinical samples.

Materials and Method

A total of 25 non-repetitive isolates of *Enterococci* (*E. faecalis* (n= 15) and *E. faecium* (n= 10) recovered various clinical samples (Urine (n= 17), Pus(n=7), Body fluids (n= 1)) were included in the present study. Antibiotic susceptibility profile of the isolates against linezolid was determined by Kirby Bauer disk diffusion method. Screening for HLAR among the isolates was performed by disk diffusion method using High Level Gentamicin (HLG:120µg) and High Level Streptomycin (HLS:300 µg) disks (HiMedia Laboratories Pvt Ltd, Mumbai, India). *E. faecalis* ATCC 29212 was included as control. The isolates were further confirmed as HLGR and HLSR by agar dilution method using BHIA plates supplemented with gentamicin (500 µg/mL) and streptomycin (2000 µg/mL) and spot inoculated with 10µl of *E. faecalis* isolates (cell density adjusted to1.5 x 10^8 *cfu*/mL using 0.5 McFarland). Appearance of > 1 colony was scored as resistant as per CLSI guidelines. [7]

All the isolates were screened for 6 aminoglycoside resistance genes, *aph(2")-Id*, *aph(3')-IIIa, ant(4')-Ia*, *aac(6')-Ie-aph(2")-Ia*, *aph(2")-Ib* and *aph(2")-Ic* by multiplex PCR using previously described primers.[8]

Results

Of the 25 isolates of enterococci that were screened for high level aminoglycoside resistance, all the isolates 25 (100%) were exhibited HLAR phenotype (resistant to HLG and/or HLS). Majority 24 (96%) were resistant to HLG (HLG^R) and 16 (64%) were resistant to HLS (HLS^R) respectively. Screening of MIC for the enterococcal isolates by agar dilution method showed gentamicin MIC >500 µg/mL for HLG^R isolates and streptomycin MIC > 2000 µg/mL for HLS^R isolates. Of note, 15(60%) of the enterococci exhibited dual resistance to gentamicin and streptomycin (HLG^RHLS^R) while, none (0%) isolates were susceptible to both the aminoglycosides (HLG^SHLS^S). Among the enterococcal isolates studied, 9(36%), 1(4%) isolates exhibited HLG^RHLS^S and HLG^SHLS^R phenotype respectively (Table 1). However, 92% of the study isolates was found to be susceptible to linezolid.

In our study, 92% of the enterococci harbored *aac(6')-Ie-aph(2'')-Ia* and/or *aph(3')-IIIa.* The majority of the isolates (*E. faecalis* (100%) and *E. faecium* (66.7%)) (p=0.428) from pyogenic infections harbored both *aac(6')-Ie-aph(2'')-Ia* and *aph(3')-IIIa* genes, while only 45.4% and 50% of the urinary isolates of *E. faecalis* and *E. faecium* harbored both the genes. While, the *E. faecium* isolated from body fluid was found to be harbor only the bifunctional gene, *aac(6')-Ie-aph(2'')-Ia* (Table 2).

Among the isolates that exhibited HLG^R HLS^R phenotype(n=15), 12(80%) harbored both *aac(6')-Ie-aph(2'')-Ia* and *aph(3')-IIIa* while, 1 isolate harbored *aph(3')-IIIa* and 2 isolates did not possess any of the genes encoding AME that were screened. Interestingly all the pus isolates of HLG^R HLS^R phenotype (n=5), *E. faecalis* (n=4) and *E. faecium* (n=1) harbored both *aac(6')-Ie-aph(2'')-Ia* and *aph(3')-IIIa.*

Table 1: HLAR profile of the Enterococcal isolates

Phenotype	E. faecalis (n=15)	E. faecium (n=10)	Total (n (%))
HLG^R HLS^R	11(33.33)	4(40)	15(60)
HLG^R HLS^S	4(26.77)	5(50)	9(36)
HLG^S HLS^R	0(0)	1(10)	1(4)
HLG^S HLS^S	0(0)	0(0)	0(0)

Table 2: HLAR profile of the Enterococcal isolates

Phenotype	E. faecalis (n=15)		E. faecium (n=10)			Total (n=25)
	Urine (n=11)	Pus (n=4)	Urine (n=6)	Pus (n=3)	Fluid (n=1)	
aac(6')-Ie-aph(2'')-Ia	2(18.2%)	0(0%)	3(50%)	1(33.3%)	1(100%)	7(28%)
aph(3')-IIIa	2(18.2%)	0(0%)	0(0%)	0(0%)	0(0%)	2(8%)
aac(6')-Ie-aph(2'')-Ia and aph(3')-IIIa	5(45.4%)	4(100%)	3(50%)	2(66.7%)	0(0%)	14(68%)
All 6 AME encoding genes Negative	2(18.2%)	0(0%)	0(0%)	0(0%)	0(0%)	2(8%)

Discussion

Since 1980, high level aminoglycoside resistance in *Enterococci* is being often reported with increasing frequencies among clinical samples from hospitalized patients.[9] In our study, the majority (100%) of the isolates were found to be HLAR. Owing to its substantial ability of acquiring and disseminating resistant genes, therapeutic management of infections associated with HLAR strains is of serious concern.[1] Hence, screening for high level aminoglycoside resistance among the enterococcal isolates gains significance as infections caused by HLAR strains can no longer be treated by the β-lactam-aminoglycoside combination.

Our study results indicate a higher incidence of HLG^R phenotype (96%) than HLS^R phenotype (64%) (P=0.005, OR=13.5, 95% CI=1.5558-117.142). Our results are in line with previous studies which document a higher occurrence of HLG^R than HLS^R.[10-12] On the contrary, a few studies have reported HLS^R phenotype to be more common than HLG^R phenotype (45% vs 4% in *E. faecalis* and 42% vs 8% in *E. faecium*[13], (48.3% vs 48.3% in *E. faecalis* and 65.4% vs 71.4% in *E. faecium*).[14]

Furthermore, increased (60%) rate of HLG^R HLS^R phenotype observed among our isolates is worrisome as high level aminoglycoside resistance usually mediated by aminoglycoside modifying enzymes (AMEs), *aac(6')-Ie-aph(2'')-Ia* and *aph(3')-IIIa* in Enterococci dismisses the synergistic bactericidal efficacy of a cell wall active agent and an aminoglycoside. affecting the bactericidal activity.[8] Linezolid susceptibility among the HLAR indicates that this would serve as an effective drug in the therapeutic management of enterococcal (HLAR) infections.

Conclusion

Emergence of HLAR pattern among clinical isolates of Enterococci is strongly evident in our geographical setting. The current situation poses a serious threat in the treatment of such serious Enterococcal infections. Therefore, the need of the hour is to investigate the presence of aminoglycoside modifying enzymes and the genes encoding such high level aminoglycoside resistance among clinical Enterococci which will further help in clearly detecting and characterising HLAR pattern within our setup and assist us in the better management of therapeutic options.

Service Quality Perceptions towards Health Insurance Products

Mahfuja Begum

Research Scholar, Department of Economics, Gauhati University

Abstract

A healthy and competent workforce is the biggest asset of any nation and therefore, it is an important objective of every progressive government to ensure health for all. In this regard, insurance is the backbone in managing the risk of the country. In today's globalised world of fierce competition, providing a quality service to the customers is the key for existence and success of any business. Service quality or quality of service is said to be a function of three variables, viz., expectation, perception and performance. The main objective of this paper is to identify the service quality of health insurance products and services offered by the public and private health insurance companies and to identify the key factors contributing to the service quality. The study is based on primary data. The gaps between perception and expectation scores on various dimensions of service quality of health insurance products have been captured by the SERVQUAL tool.

Keywords: *Insurance, Health, SERVQUAL, Dimensions, Service quality*

Introduction

Health is a state of physical, mental, social well being and not nearly the absence of disease or infirmity. Providing a security net for ensuring availability of quality and affordable healthcare to the population is the prime goal every nation aspires for. According to NFHS–3, in spite of the emergence of a number of health insurance programmes and health schemes, only 2 percent of households in Assam reported that they have any kind of health insurance that covers at least one member of the household. But some evidences show that steadily the health insurance coverage is increasing. It may be because of the fact that people become aware of the high health care cost, incoming of the private players in insurance field and government health care/insurance schemes along with involvement of community based health insurance schemes. Assam now stands at the threshold of transition of the industry to the next level. Health insurance would be one of the key tools to supplement and compliment the present health financing options.[1] The Health Insurance Company's main aim to create an ideal environment for health insurance business with a satisfied customer at the core. Three core areas are identified namely service quality, customer satisfaction and role of hospitals for studying the marketing perspective in health insurance. Parasuraman, Zeithaml and Berry (1990) mention that service quality is an extrinsically perceived attribution based on the Customer's experience about the service that the Customer perceived through the service encounter.[2]

Objectives: To find out the gap between expectation and perception score in health insurance product service quality.

Research Questions: In order to guide the study and achieve the above objective, the following research questions are formulated.

1. How is the service delivered by the health insurance providers perceived by their customer and does it meet the expectations of their customers?
2. Which dimension is doing well among all five dimensions in health insurance sector?

Data Sources and Methodology: The geographical location for the present study has been selected purposively as Tinsukia district of Assam. The district is further stratified into development blocks. Tinsukia district has seven developmental blocks namely, Guijan, Hapjan, Itakhuli, Kakopothar, Margherita, Saikhuwa and Sadiya. Since the study is mainly concentrated in rural areas, thus the top three blocks namely Margherita, Kakopothar and Hapjan have been selected as these blocks have highest number of rural population respectively. In the next step, one Gaon Panchayat (GP) from each sample block having the highest population is

taken as sample GP. Again Lekhapani GP of Margherita block, Kakojan GP of Kakopathar block, Hatijan GP of Hapjan block has highest number of rural population in their respective block. Thus these three GPs are selected as sample GP. 10% of the total villages of each sample GPs have been taken as sample villages. Lastly a total of 208 households have been selected for the field survey. A five pointlikert type scale is used in this study to evaluate the 5 health insurance service quality dimensions. Respondents were asked to provide ratings of both expectation and perceptions on the provided statements related to service quality. The service quality statements used in the study were rated by using five pointlikert scale with 1 indicating 'strongly disagree', 2 indicating 'disagree', 3 indicating 'neutral', 4 indicating 'agree', and 5 indicating 'strongly agree'. Thus the difference obtained from subtracting the expectation scores from the perception score revealed the gap between customer's expectation and their perception of the service quality. The study period has been selected from May–July 2019. Respondents are basically the customers of New India Insurance Company (Public Sector Insurance Company) and Bajaj Allianz (Private Sector Insurance Company). According to the SERVQUAL tool, services quality of health insurance companies can be measured by the gap between expectations and perceptions of consumers on 5 dimensions of service quality namely reliability, assurance, responsiveness, professionalism and fairness in dealings.[3]

Reliability Gap: Reliability implies the ability to perform promised service dependably and with accuracy. Reliability is connected to the consistency of performance and dependability on the service. Here it is determined if the company give the service in the right way the first time and keeps to its promises every time.[4] The term reliability refers to the ability of a health insurance company to consistently perform according to its specifications.

Table 1: Mean score/Standard deviation of perception and expectation on Reliability

Reliability Attributes	Mean of perception score (P)	SD of perception score	Mean of expectation score (E)	SD of expectation score	Gap score P-E
The company gives all the required information	2.2260	0.94	3.2596	1.04	-1.0336
The company pointed out the best choice for me	1.6875	0.76	2.4087	0.78	-0.7212
I feel more confident when I purchase a policy	2.4087	0.82	3.1971	0.96	-0.7884
The Company's promises are reliable.	2.0529	0.85	2.9904	1.01	-0.9375
The company is consistent in providing quality services	2.1250	0.93	3.3317	0.94	-1.2067
Total	**2.10002**	**0.86**	**3.0375**	**0.946**	**-0.93748**

Source: Compiled from field survey.

The table 1 shows the mean and standard deviation on the reliability dimension in the service quality of insurance policy holders about their companies. The total mean score and standard deviation on the perception on reliability attributes towards the service quality of insurance companies are 2.10002 and 0.86 respectively and for reliability expectation scores it is 3.0375 and 0.946. It is found that the mean perception score for 'feeling more confident when they purchase a policy is highest i.e. 2.4087 whereas it is highest for the fifth attribute which is related to consistency in providing quality service i.e. 3.3317. Again for all four statements on reliability, it is seen that the mean expectation scores are greater than the mean perception scores which shows some difference in magnitude of gap score among the five items. It can be noted that attribute 2 has the lowest mean gap score (-0. 72) which is related to "pointing out of Best Choice for the customer by the health insurance company. It indicates that people are comparatively less dissatisfied in this attribute than the other four attributes. Again attribute 5 has the highest mean gap score (-1.2067) which is related to consistency in providing quality service.

Assurance Gap: Assurance means that employees' behavior will give customers confidence in the firm and that the firm makes customers feel safe.[5] It also means that the employees are courteous and have the necessary knowledge to respond to customers' questions.

Table 2: Mean score/Standard deviation of perception and expectation on Assurance:

Assurance Attribute	Mean of Perception Score (P)	SD of Perception Score	Mean of Expectation Score (E)	SD of Expectation Score	Gap Score (P–E)
I feel that I can always trust this company.	2.1827	0.89	2.4471	0.88	-0.2644
The company follows the motto "Customer is the king".	2.3510	0.91	2.5481	0.89	-0.1971
The company gives sincere commitment in servicing the claims.	2.3077	1.02	3.0625	0.85	-0.7548
The company deserves recommendation for new Customers.	2.1346	0.78	2.8976	0.76	-0.763
Company gives more importance to the satisfaction of customers rather than profit gain.	2.673	0.95	2.956	1.78	-0.283
Total	**2.32988**	**0.91**	**2.78228**	**1.032**	**-0.4524**

Source: Compiled from field survey

It can be observed that the process execution time and kind and politeness of the employees are noticeable factors contributing to the average assurance gap. Employee's expertise and knowledge on the company's operations hold a big hand in satisfying the customers in terms of service quality. Efficient and knowledgeable employees are always a big boon for any organization. It can be noted that, out of all the attributes for assurance, attribute 7 i.e. "The company follows the motto customer is the king" has the lowest mean gap score (-0.1971) In terms of expectation, attribute 6 i.e. "I feel that I can always trust this company" has lowest mean, whereas in terms of perception attribute 9 i.e. "Company gives more importance to the satisfaction of customers rather than profit gain" has lowest mean gap score. Few respondents think that some of the staffs appear not to be quick and efficient, as they tend to make errors or ask seniors to help them.

Responsiveness Gap: This means that the employees of a service firm are willing to help customers and respond to their requests as well as to inform customers when service will be provided and then give prompt service.

Table 3: Mean score/Standard deviation of perception and expectation on Responsiveness:

Responsiveness Attribute	Mean of Perception Score (P)	SD of Perception Score	Mean of Expectation Score (E)	SD of Expectation Score	Gap Score (P–E)
The Company tries to understand The specific needs.	2.4327	0.91	3.3798	0.96	-0.9471
The company actively responds to the inquiries regarding policy matters.	2.4423	0.96	3.3173	0.91	-0.875
The company timely informs us about the new offers.	2.4663	0.93	3.6587	0.99	-1.1924
The company properly informs me as and when my policy becomes due.	2.9758	0.94	3.7564	0.94	-0.7806
Information provided by the company is always Accurate.	2.5477	0.89	3.0567	0.96	-0.509
Total	**2.57296**	**0.926**	**3.43378**	**0.952**	**-0.86082**

Source: Compiled from field survey

This table 3 shows the perception and expectation gap score of various responsiveness attributes. It is evident the attribute 15 i.e. "Information provided by the company is always accurate" has lowest gap score

(-0.509). It can be noted that, out of all the attributes for responsiveness, attribute 11 i.e. "The Company tries to understand the specific needs" has the lowest overall mean gap score (2.4327) In terms of expectation, attribute 6 i.e. "I feel that I can always trust this company" has lowest mean, whereas in in terms of expectation attribute 15 i.e. "Information provided by the company is always accurate" has lowest mean gap score. It is seen that in all cases policy holders are not satisfied.

Professionalism Gap: Professionalism is defined as the strict adherence to courtesy, honesty and responsibility when dealing with policy holders or stakeholder in the business environment.

Table 4: Mean score/Standard deviation of perception and expectation on Professionalism

Professionalism Dimension	Mean of Perception Score (P)	SD of Perception Score	Mean of Expectation Score (E)	SD of Expectation Score	Gap Score (P–E)
The company gives the correct information about the service charges and related charges	2.5962	0.86	3.2981	0.82	-0.7019
The company timely informs any new Government Regulations regarding policies	2.7163	0.84	3.4760	0.88	-0.7597
I never felt any communication problem	2.7429	0.81	3.6399	0.85	-0.897
The company tries to avoid probable conflict	2.6754	0.87	3.7462	0.90	-1.0708
Total	**2.6827**	**0.845**	**3.54005**	**0.8625**	**-0.85735**

Source: Compiled from field survey

The above table 4 deals with the mean and standard deviation on the professionalism of service quality received by policy holders of the insurance policy. The total mean score and standard deviation on the perception professionalism dimension in the service quality of Health Insurance Company are 2.6827 and 0.845 respectively, whereas in case of expectation professionalism dimension the mean score and standard deviation are 3.54005 and 0.8625 respectively. Among the four attributes of professionalism dimension attribute 19 i.e "The company tries to avoid probable conflict" has highest mean gap score (-1.0708) and attribute 16 i.e "The company gives the correct information about the service charges and related charges" has least gap score (-0.7019)

Fairness in Dealings: Factors consist of trustworthiness, believability and honesty comes under the fairness dimension of any service organization. It means to the level the company has the customers' best interest at heart and job. Factors that affect the fairness are the company name and fame, reputation, personal characteristics and the degree to which the company is connected to intersections with customers.

Table 5: Mean score/Standard deviation of perception and expectation on Fairness in dealings

Fairness in dealings	Mean of Perception Score (P)	SD of Perception Score	Mean of Expectation Score (E)	SD of Expectation Score	Gap Score (P–E)
The company openly discusses the problems	2.5962	0.86	3.2981	0.82	-0.7019
The company has an effective Grievance Redressal mechanism	2.7163	0.84	3.4760	0.88	-0.7597
Company tries to solve the problems at the office level itself	2.8521	0.88	3.8546	0.90	-1.0025
The company handles the conflicts as speedy as possible	2.9745	0.85	3.8123	0.89	-0.8378
Total	**2.784775**	**0.8575**	**3.61025**	**0.8725**	**-0.825475**

Source: Compiled from field survey

The table 5 shows that the total mean score and standard deviation on the perception fairness dimension in the service quality of Health Insurance Company are 2.784775 and 0.8575 respectively, whereas in case of expectation fairness dimensions the mean score and standard deviation are 3.61025 and 0.8725 respectively. It is found that the mean perception and expectation score for 'Company openly discusses the problems' are 2.5962 and 3.2981 respectively for insurance policy holders, perception and expectation mean score for 'The company has an effective grievance redressal mechanism' are 2.7163 and 3.4760 respectively for insurance policyholders, perception and expectation mean score for "Company tries to solve the problems at the office level itself" are 2.8521 and 3.8546 respectively for insurance policy holders, the perception and expectation mean score for "The Company handles the conflicts as speedy as possible" are 2.9745 and 3.8123 respectively for insurance policy holders. It is evident the attribute 20 i.e. "The company openly discusses the problems" has lowest gap score (-0.7019). It can be noted that, out of all the attributes for fairness dimension, attribute 22 i.e. "Company tries to solve the problems at the office level itself" has the highest mean gap score (-1.0025). The policyholders feel that all the activities starting from the fixation of premium and claim settlement is not fair and scientific. It demands for more transparency in dealings so that the grievances can be reduced. Seamless movement of information and integration of different stakeholders in health insurance is necessary in this direction.[6]

Gap score for the overall dimension of health insurance services

Table 6: Mean and gap score for the overall dimension of health insurance services

Dimension	Perception Score	Expectation Score	Gap Score
Reliability	2.10002	3.0375	-0.93748
Assurance	2.32988	2.78228	-0.4524
Responsiveness	2.57296	3.43378	-0.86082
Professionalism	2.6827	3.54005	-0.85735
Fairness in Dealings	2.784775	3.61025	-0.825475

Source: Compiled from field survey

As most of the responses were negative, indicating significant shortfall in meeting customer expectations across all service areas and dimensions of health insurance policies. It is clear that reliability gap (-0.93748) which is highest followed by responsiveness gap (-0.86082), Professionalism gap (-0.85735), fairness in dealings gap (-0.825475), assurance gap (-0.4524). This entire gap can be reduced by minimal promise and maximum performance thus leading to customer satisfaction.

Conclusion

The health insurance sector has undergone many changes after the adoption of new economic policy which is based on privatization, globalization and liberalization. Customer is the king in the present day market. Today the customer's service preference and demands are keep on changing at a rapid speed. The aim of the health insurance providers is to make the customers comfortable and happy. Health insurance companies should not only have to satisfy the customer but should also trigger to the attitude of the customers towards their insurance company. Each company follows different procedure. So, it is very difficult for the customer's to follow all these procedures. Personal communication is the most influencing medium considered for taking health insurance selection decisions by the policy holders. Customer retention in health insurance is beneficial to both the company and insured in many ways. Immediate attention is needed from the part of the companies to check the percentage of people renewing the policy from the same company.

Factors Affecting Risk of Cardiovascular Diseases among Hotel Employees in Udupi District, Karnataka

Thirugnanasambantham K.[1] , Lalitha Ramaswamy[2]

[1]Principal, WGSHA, Manipal Academy of Higher Education, Manipal; Ph.D. Research Scholar, Bharathiar University, [2]Head and Associate Professor, Department of Nutrition and Dietetics, PSG Arts and Science College, Coimbatore, Tamilnadu.

Abstract

Several research has indicated the increasing morbidity and mortality across the globe. Diet, lifestyle habits, stress are the most common risk factors associated with cardiovascular disease (CVD) risk. Hotel employees have been reported to have increased workload and stress which increases their risk to CVD related morbidity and mortality. This paper is a pilot study of the cross-sectional research study undertaken to identify risk factors associated with CVD risk among hotel employees in Udupi district of Karnataka. A structured questionnaire was used to elicit information pertaining to medical history, lifestyle habits, stress, sleep, bowel toxicity, inflammation and pain, blood glucose, blood lipids, diet, blood pressure and weight status. Research identified abnormal blood sugar levels, lipid profile, high blood pressure, high waist circumference and lifestyle habits like smoking and alcohol consumption as common risk factors among hotel employees. Over 69% had moderate to high risk of CVD due to the above mentioned risk factors. A good diet and lifestyle management can modify these risk factors and reduce risk of CVD among hotel employees.

Keywords: *CVD risk, modifiable risk factors, hotel employees, diet and lifestyle habits, stress.*

Introduction

According to the Global Burden of Disease study age-standardized estimates (2010), closely a quarter (24.8%) of deaths in India are attributable to CVD. The age-standardized CVD death rate of 272 per 1,00, 000 population in India is greater than the global average of 235 per 100000 population[(1)]. Cardio vascular diseases affect Indians a decade earlier and in their most productive midlife years as compared to the people of European ancestry[(2,3)]. High blood glucose, blood pressure, body mass index (BMI), and serum cholesterol have been recognized as foremost metabolic risk factors driving this epidemic[(4)]. Nutritional, behavioral, and developmental risk factors together with diet, smoking, alcohol use, and physical activities have also been identified as major underlying determinants of CVD risks[(5)].

Dietary practices, physical activity requirements, and job-related stress differ among different occupational groups. Due to a deviation in lifestyle factors across job-related groups, some occupations are at higher risk of metabolic risk factors and consequent non-communicable diseases[(6,7)]. Although there are abundant researches on the CVD risk factors in connection with various industries and occupations, there is scarcity of research on the prevalence and antecedents of CVD risk factors among hospitality employees.

Earlier, occupational health was related more on physical and chemical hazards in an occupational setting rather than cardiovascular and other non-communicable diseases that are often thought to be connected with the lifestyle of a person rather than her/his occupation. This is true for hospitality despite being an industry that produces and/or serves food including fast food that is linked to obesity. Prolonged disease risk factors among hotel employees need to be studied and this study one

such effort to understand the present status of well-being among the employees of hotels. Within the hotel industry, jobs can be further classified as managerial, executive, clerical, administrative, skilled, semi-skilled, and un-skilled labor. It was initially assumed that upper grades are more at risk because of managerial desk level jobs but later it was realized that occupations may also act independent of these transitional behavioral risk factors. Junior job levels have been associated with greater chances of mortality due to coronary artery disease. Lower occupational levels are associated with low income and minor social recognition. People with low socio-economic status are more susceptible to conditions of ill-health and frequently do not have resources to manage with the consequences of diseases ensuing in discrepancies in health. Hence this study includes employees across the various departments of classified star category hotels in Udupi district. It targets to obtain the risk factors prevalent among hotel employees.

Methodology

A cross-sectional study was conducted a part of pilot study with the aim of identifying factors associated with risk of cardiovascular diseases among hotel employees. Institutional Ethics committee approval was obtained from Institutional Ethics Committee–Kasturba Hospital, Manipal. This paper is a pilot study involving 26 hotel employees in Udupi District who were assessed using a structured interview schedule. Informed consent was taken from all participants before collecting the data. The interview schedule consisted of sociodemographic information, medical history, CVD risk assessment questionnaire[8], physical activity, workload and stress. Physical activity level was calculated using Mets and classified as per ICMR classification. Blood pressure and biochemical tests like blood glucose level and lipid profile, anthropometric measurements like height, weight, waist circumference and hip circumference was assessed with due precautions. CVD risk assessment questionnaire comprised of medical history, lifestyle habits, stress, sleep, bowel toxicity, inflammation and pain, blood glucose, blood lipids, diet, blood pressure and weight status. Based on the sum of score obtained in each of this components, each participant was classified as Low risk (score=-88 to 100; RR<1), Moderate risk (Score= 101 to 220; RR= 1-3), High risk (Score= 221 to 350; RR= 3-5), Very high risk (Score >=351; RR>5). Data thus collected was coded and analyzed using SPSS (v. 16.0).

Findings:

General Information: Table 1 represents general information of participants. Most of the hotel employees were males (84.6%) and belonged to the age group of 30-40 years of age. About of 76.9% of the participants were Hindus followed by 19.2% Christians and remaining (3.8%) were Muslims. Most of the participants were married (92%).

Medical History: None of the participants had a history of CVD or diabetes. About 7.7% of participants' mothers history of cardiovascular disorders followed by 11.5% of fathers who has history of cardiovascular disorders. About 15.4% of the participants had history of type 2 diabetes mellitus among both parents.

Lifestyle Habits: It is recommended to undertake moderate intensity activity for at least 5-6 days per week. Only 11.5% of the participants were involved in exercise as per the standard recommendations. About 34.6% were involved in moderate intensity activity but the frequency of performing exercise was less than 3 times per week. About 30.8% were sedentary activity. This pilot study revealed that most of the subjects were involved in moderate exercise but the frequency per week was less for most of the participants. Physical activity level as recorded as calculated using their activities and the corresponding mets indicates that most of them fall under sedentary or light activity (78.3%) followed by 15.4% of the participants who were moderately active and only 3.8% who were vigorously active. About 42.3% had adequate sleep of 7-8 hours however 15.4% of them snored during sleep.

Majority of the participants (84.6%) never smoked whereas the remaining participants (15.4%) smoked less than 20 cigarettes a day. About 19.2% were exposed to passive smoking which is equally considered to be dangerous as first hand smoke.

Most of the participants (57.7%) never consumed alcohol while 23.1% consumed 1 drink daily followed by 7.7% who consumed about 2 drinks per day and about 11.5% who consumed more than 3 drinks per day.

Bowel Toxicity: About 15.4% of the participants complained of bowel related symptoms like lower abdominal pain, bloating, constipation, diarrhea, foul smelling stools etc. Only 3.8% of participants were on oral contraceptives pill for more than 6 months in the last one year. Similarly, only 7.6% of the participants consumed antibiotics for more than 2 weeks.

Inflammation and Pain: Only 7.7% of participants reported signs of inflammation like wheezing, sneezing whereas 3.8% complained of heart palpitations or headache after consuming certain foods.

Blood Sugar: About 11.5% of the participants were diabetics of which only 3.8% reported signs of hypoglycemia like energy level dropping, craving for sweets or chocolates or experience headache or lack of concentration that is relieved by eating.

Biochemical Assessment: Lipid profile, blood glucose level was assessed. About 50% of the participants showed low HDL level whereas, 80.8% showed high LDL, 69.2% showed elevated serum cholesterol level and all participants had a high triglycerides.

Cardiovascular disorders risk assessment

Table 1: Cardiovascular risk assessment of Hotel employees

Modifiable Risk Factors	Priority based on the score	Percent
Cardiovascular History	Low priority (0-30)	96.2
	High priority (51 and above)	3.8
Lifestyle	Low priority (-35 to-10)	30.8
	Medium priority (-9 to 21)	46.2
	High priority (22 and above)	23.1
Stress	Low priority (-19 to 20)	100.0
Sleep	Low priority (0-5)	69.2
	Medium priority (6-11)	19.2
	High priority (12 and above)	11.5
Bowel Toxicity	Low priority (0-3)	76.9
	Medium priority (4-9)	19.2
	High priority (10 and above)	3.8
Blood sugar	Low priority (0-19)	46.2
	Medium priority (20-49)	34.6
	High priority (50 and above)	19.2
Inflammation and Pain	Low priority (0-19)	96.2
	Medium priority (20-42)	3.8
Diet	Low priority (-19 to 6)	92.3
	Medium priority (7 to 13)	7.7
Lipids	Low priority (-15 to 9)	7.7
	Medium priority (10 to 34)	38.5
	High priority (35 and above)	53.8
Blood Pressure	Low priority (0-9)	42.3
	Medium priority (10-29)	26.9
	High priority (30 and above)	30.8
Weight Management	Low priority (0-11)	69.2
	Medium priority (12-25)	7.7
	High priority (26 and above)	23.1
CVD Risk	Low risk (score=-88 to 100; RR<1)	30.8
	Moderate risk (Score= 101 to 220; RR= 1-3)	50.0
	High risk (Score= 221 to 350; RR= 3-5)	15.4
	Very high risk (Score >=351; RR>5)	3.8

Data pertaining to cardiovascular history, lifestyle, stress, sleep, bowel toxicity, blood sugar, inflammation and pain, diet, blood lipids, blood pressure and anthropometric measurements were scored and classified to prioritize based on risk of cardiovascular disorders (Table 1). These findings showed 50% of the participants in the moderate risk, 15.4% high risk, 3.8% very high risk and about 30.8% were classified under low risk of CVD.

Gender wise comparison of CVD risk clearly indicated that females had either low (25%) or moderate risk (75%) of CVD whereas among the males, the CVD risk was distributed across the risk classification with a highest percentage showing moderate risk (45.5%) followed by 31.8% with low risk, 18.2% with high risk and 4.5% with very high risk of CVD.

Discussion

It is evident from the result that personal history or family history is not a risk for hotel employees in South Canara. Family history has been studied for many years as an independent risk factor for CVD risk and mortality[9]. Very few participants performed exercised as per recommendations. American College of Sports Medicine and the Centers for Disease Control and Prevention recommends 30 minutes of moderate intensity activity for atleast 5 days in a week or 20 minutes of vigorous intensity activity for atleast 3 days in a week. Sedentary lifestyle or not performing exercise besides the regular routine is considered as a major risk factor for chronic diseases like heart disease[10].

The study clearly showed that although most of them never smoked, they were exposed to passive smoking. Passive smoking negatively affects the coronary circulation causing increased risk of endothelial dysfunction among healthy non-smokers[11] and also precipitates acute manifestations of CVD[12]. Alcohol is yet another risk factor that has been reported to cause mortality. Among the participants who consume alcohol, only a few had the habit of binging. Although, moderate

consumption of wine and beer has cardio-protective effects on both CVD patients and healthy people, binge drinking can cause increased morbidity and mortality[13].

Some of the participants had gastrointestinal symptoms indicating dysbiosis. Dysbiosis is a change in gut microbiota which has been speculated to play a role in cardiovascular health[14]. Consuming antibiotics over a long period of time affects gut microbiota[15] thereby increasing risk of CVD[6]. Inflammation increases WBC count which is an independent predictor of CVD risk[16]. A small number participants reported signs of inflammation like wheezing, sneezing etc. An elevated triglycerides, LDL and a low HDL poses an increased risk of CVD[17].

Most of the participants in low priority for cardiovascular history, stress, sleep, bowel toxicity, blood sugar, inflammation and pain, dietary habits, blood pressure and weight. Most of the participants did not have either personal history or family history of CVD and diabetes. Disturbed sleep is a common symptom that is associated with stress. Since most of the participants were not affected by stress, sleep was also not affected. The main focus of treatment has to focus on abnormal lipid levels and weight status. Abnormal weight status is a risk factor for CVD related death[18].

Majority of the participants were falling in moderate to high risk attributed to abnormal blood glucose, lipid profile, obesity and blood pressure. The study also highlighted a higher risk of CVD among male as compared to females. This risk can be attributed to difference in physical activity, stress, sleep, diet pattern, blood glucose and lipid abnormalities between the gender.

Conclusion

Most of the hotel employees are young adults and also they had a low family history of CVD. The risk of CVD due to these non-modifiable risk factors is not influential. The most common risk factors identified were abnormal blood sugar levels, lipid profile, high blood pressure, high waist circumference and lifestyle habits like smoking and alcohol consumption. Over 69% had moderate to high risk of CVD due to the above mentioned risk factors. The intervention strategies should focus on these modifiable risk factors with an aim to reduce risk CVD risk. A good diet and lifestyle management can modify these risk factors and reduce risk of CVD among hotel employees.

To conclude in general, a research base specific to hotel employees in India is essential to assist employees at all levels to become aware of the risks associated as well as provide basic training to employees periodically. Seek treatment interventions by association with primary health care centers for additional training in the management of CVD. We may need more resources and facilities to tackle the health risks associated with CVD due to the socio-economic differentials through capacity building and awareness programs and involvement of all stakeholders.

Dental Caries as an Ill Effect of Long Term Medication

Sangeetha Priya P.[1], N. Aravindha Babu[2], N. Anitha[3], L. Malathi[4]

[1]Post Graduate Student, [2]Professor, [3]Reader, Department of Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital Bharath Institute of Higher Education and Research

Abstract

By definition Dental caries is an irreversible microbial disease of the calcified tissues of the teeth, characterized by demineralization of the inorganic portion and destruction of the organic substance of the tooth, which often leads to cavitations. The etiology of dental caries is generally agreed to be a complex problem complicated by many indirect factors that obscure the direct cause or causes. There is no universally accepted opinion for the etiology of dental caries. The oral flora and the saliva plays a very important contributing factor in dental caries. Saliva is the most valuable oral fluid is critical to the preservation and management of oral health. Saliva containing various organic and inorganic substances provides primary natural protection for teeth and soft tissues in the oral cavity assists in mastication, deglutition and digestion of food. The secretion of saliva can be affected due to various local and systemic causes. However if a patient is taking medication and has altered salivary secretion the differential diagnosis should include the possibility of an adverse drug reaction. The drugs may lead to alteration in the flow rate of saliva. Salivary dysfunction as a clinical entity has received considerable attention in recent years. This article critically reviews the dental hard tissue alterations especially dental caries that are caused due to reduced salivary secretion as a result of long term medication.

Keywords: *Dental caries, Medication, dry mouth, hyposalivation.*

Introduction

Saliva is an aqueous, hypotonic solution which protects all the tissues of the oral cavity. It is secreted by the major salivary glands–the parotid, submandibular or submaxillary, and sublingual. In the oral cavity there are also a large number of minor salivary glands found on the surfaces of the buccal, palatine, and labial mucosa, as in the tongue, sub-lingual area, and in the retromolar region[1]. The salivary glands are under the control of the autonomic nervous system and hence their function can be affected by a variety of drugs. An adverse drug reaction (ADR) is defined by the WHO as a drug response that is noxious and unintended and occurs at doses normally used in humans for the prophylaxis, diagnosis or therapy of a disease or for the restoration, correction or modification of a physiological function. All noxious and unintended responses to a medicinal product related to any dose should be considered adverse drug reactions[2]. The term "Xerostomia" is well known as a subjective complaint–symptom of dry mouth and may be or may be not related to objectively measured hyposalivation. Several studies indicated that xerostomia is associated with a wide range of factors including local or systemic condition[3,4]. In addition, the condition is likely to be more severe amongst older patients as they could suffer from various diseases and take numerous involved medications that may result in a reduction of saliva secretion. As a consequence, drug–induced xerostomia has still challenged clinicians regardless of how they could diminish appropriately the side-effects of medications that sometimes replacement should be considered.[5]

How decreased salivary secretion is associated with dental caries?: The fact that the teeth are in

constant contact with, and bathed by saliva would suggest that they could profoundly influence the dental caries process. The complex nature of saliva and variation in its composition are the challenges involved in establishing those factors which may directly influence dental health. A study of saliva and its tooth-protective components reveals at least four important functions of saliva:

i. buffering ability,

ii. a cleansing effect,

iii. antibacterial action, and

iv. maintenance of a saliva supersaturated in calcium phosphate.

Although the etiology of dental caries is reasonably well established, the chemical-physical process that results in the demineralization of enamel and dentin often is less appreciated. Nearly everyone's normal oral flora contains microorganisms that are capable of metabolizing fermentable carbohydrates, leading to the production of a variety of acidic by-products. Furthermore, people need to ingest foods containing fermentable carbohydrates to meet their nutrient and energy requirements. Thus, the stage is set for the oral flora to metabolize the ingested carbohydrates, leading to the production of acids that are capable of demineralizing enamel and dentin. The production of acids by microorganisms within the dental plaque continues until the carbohydrate substrate is metabolized. It also is known that the plaque's pH goes from acidic to normal (or the resting level) within a few minutes and depends on the presence of saliva. This is due primarily to the carbonate and phosphate pH buffering agents in saliva[6,7].

This can be summarized in short:

Dry mouth/Reduced salivary secretion

↓

Inability to self-cleanse the oral cavity

↓

Increase in the production of microorganisms

↓

Oral pH is acidic due to the acid produced by the microorganisms

↓

Caused demineralization of enamel and dentin

↓

Dental caries

Therefore saliva plays a very important factor in the development of caries.

Drug induced Xerostromia: From an etiological perspective, xerostomia is most frequently associated with medication. It is the side effect of a large number of drugs and 70% of adults taking some kind of medication can suffer from it[8]. Few medications that could cause reduced salivary secretion are:

Antidepressants: Antidepressants are a type of medicine used to treat clinical depression. They are a class of drugs that reduce symptoms of depressive disorders by correcting chemical imbalances of neurotransmitters in the brain. Chemical imbalances may be responsible for changes in mood and behavior. Antidepressants can also be used to treat a number of other conditions, including obsessive compulsive disorder, generalized anxiety disorder, post-traumatic stress disorder. Antidepressants such as fluoxetine, with a serotoninergic action have xerostomia as a common side effect. Xerostomia is also observed in other kinds of antidepressants (monoamine-oxidase inhibitors, tricyclics, heterocyclics, and others) and antipsychotics, many of which are anticholinergic agents[9].

Examples: Selective serotonin-reuptake inhibitors: citalopram, fluoxetine, paroxetine, sertraline, venlafaxine Tricyclic antidepressants: imipramine, amitriptyline, desipramine, nortriptyline Monoamine oxidase inhibitors IMAO: phenelzine Other antidepressants: bupropion, nefazodone, mirtazapine Typical (first generation) and atypical (second generation) antipsychotics: haloperidol, pimozide, clozapine, olanzapine

Antihypertensive: Antihypertensives are a class of drugs that are used to treat hypertention (high blood pressure). Antihypertensive therapy seeks to prevent the complications of high blood pressure, such as stroke and myocardial infarction. Antihypertensive drugs such as the inhibitors of the angiotensin-converting enzyme (captopril and enalapril) may cause the accumulation of bradykinin-tissular mediator which is responsible for a large number of adverse reactions. Up to 8% of patients taking captopril, enalapril, and lisinopril present xerostomia[10,11].

Example: Captopril, clonidine, clonidine/ chlorthalidone, enalapril, guanfacine, lisinopril, methyldopa.

Sedative: Prescription drugs used to treat anxiety

(antianxiety drugs) and induce sleep (sedatives, or sleep aids) can cause dependence .Anxiolytic, sedative, and opioids drugs may provoke xerostomia as a secondary effect in patients who are taking them chronically[12,13].

Examples: Alprazolam, diazepam, furazepam, temazepam, triazolam.

Antihistamins: Antihistamines are drugs which treat allergic rhinitis and other allergies. Typically people take antihistamines as an inexpensive, generic, over-the-counter drug that can provide relief from nasal congestion, sneezing, or hives caused by pollen, dust mites, or animal allergy with few side effects. Some antihistamines, particularly those of the first generation and some of the third, for instance, desloratadine, have an antimuscarinic effect which may lead to xerostomia and sedation. Second and third generation antihistamines effectively antagonize H1 receptors without any special affinity for the muscarinic receptors[14,15].

A number of non-steroidal analgesic and anti-inflammatory drugs (diflunisal, ibuprofen, naproxen, and piroxicam), anorexigens, anti-acne, anti-parkinsons, and anti-smoking agents amongst others, may cause a decrease in salivary secretion as a secondary effect[16].

Example: Astemizole, brompheniramine, chlorpheniramine, diphenhydramine, loratadine, meclizine

Adrenergic agents: Adrenergic drugs are medications that stimulate certain nerves in your body. They do this either by mimicking the action of the chemical messengers epinephrine and norepinephrine or by stimulating their release. These drugs are used in many life-threatening conditions, including cardiac arrest, shock, asthma attack, or allergic reaction. Adrenergic agents may induce dry mouth syndrome. Amphetamine and MDMA (also known as ecstasy) can act directly or indirectly on a number of receptors, including the α2-adrenergic one, thus causing xerostomia. Occasionally, this effect may also lead to an acute localized periodontal pathology. Several reported cases of necrotizing ulcerative gingivitis (NUG) have been associated with the consumption of MDMA. The possible mechanism may be due to a direct contact between the drug and the oral mucosa, the acid components of the tablet, and the dry mouth induced by MDMA. Other illicit drugs, for example cannabis, produce short-term hyposalivation due to the action of delta-9-tetrahydrocannabinol (THC)[17].

Conclusion

Sometimes patient will need medication for their underlying systemic disorders, which cannot be avoided or discontinued for the purpose of these side effects such as dry mouth/xerostromia . As well maintance of oral cavity and teeth as particular is equally important. Alternatives could be explaining the concern physician regarding these side effects as they could help in advising the lowest effective dose or switching to an alternative medication. Even then if dry mouth is associated with correctable causes and correction of underlying causes doesn't improve the condition, several additional steps are critically to be followed. Patients should see a dentist and have fluoride-containing sealants applied to seal pits, fissures, and rough restorative margin[18,19]. The dentist may recommend a regular dose of fluoride and an antibacterial dental varnish containing 1% chlorhexidine and 1% thymol to prevent dental caries. Chewing xylitol gum enhances salivary flow, but note that elders who wear dentures may be unable to chew gum. Patients should be encouraged to conduct a daily mouth examination, checking for red, white, or dark patches, ulcers, or tooth decay.

Sipping water or sucking on ice chips throughout the day may moisturize the mucosa and possibly alleviate symptoms. If this is not effective, artificially moisturizing the mucosa is a possible next step. Saliva substitutes are available in several dosage and forms . They are best used at bedtime and periodically throughout the day; their relief is temporary and efficacy varies.

Rather than using a commercial product, some patients find that mixing equal parts water and glycerin and spraying the mixture regularly in the mouth offers periodic relief. In addition to using exogenous moisturizers, patients will find that choosing low-sugar, low-acid, moist foods will make eating easier. They should avoid alcohol-containing mouth rinses and washes that may desiccate the oral mucosa, choosing a commercial mouthwash designed for people with dry mouth instead[20,21]. Thereby drymouth and dental caries caused due to drymouth can be managed.

Autoimmune Blistering Diseases: A Short Review

Ryhanath gulshan[1], N. Aravindha Babu[2], N. Anitha[3], E. Rajesh[3]

Post Graduate Student[1], Professor[2], Reader[3], Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education,Chennai

Abstract

Autoimmune blistering diseases are a group of disorders in which the body attacks the healthy tissue, causing blistering lesions primarily affecting the skin and mucous and membranes. The symptoms and severity of blistering diseases vary from one person to another, even among individuals with the same disorder. In some cases, blistering lesions can involve a significant portion of the skin. Although, there is no cure for autoimmune blistering diseases, they can often be controlled with treatment. In other cases, autoimmune blistering diseases if left untreated can eventually cause life-threatening complications.

Keywords: *Blisters,lesions,diagnosis, tretament.*

Introduction

A blister can be either tiny or large and consists of a fluid-filled bubble that forms underneath the surface of damaged or dead skin. . Most blisters develop in response to irritation or injury of the skin. In autoimmune blistering diseases, blisters form because the body creates antibodies that attack certain proteins required for the health and function of the skin. In many cases, blisters can rupture becoming wounds. In some autoimmune blistering diseases, blisters or lesions can also form on the mucous membranes, the thin, moist coverings of many of the body's internal surfaces. Mucous membranes line the esophagus and anus, the inside of the mouth, the nasal passageways, the genitals and the throat. The most accurate diagnosis when performing biopsies includes the tissue for hematoxylin and eosin (H&E) should be taken from the edge of a blister and the sample for direct immunofluorescence (DIF) should be taken from perilesional skin.[1]

There are several different categories of autoimmune blistering diseases including

- pemphigus,
- pemphigoid,
- IgA-mediated dermatoses and
- epidermolysis bullosa acquista.

Causes:

Causes of blistering

Non-immunological causes of blistering

- Genetic-Epidermolysis bullosa e simplex (dominant)

Epidermolysis bullosa e junctional (recessive)

Epidermolysis bullosa e dystrophic (dominant and recessive)

Bullous ichthyosiform erythroderma

- Physical-Heat and/or cold

Irradiation (e.g. ultraviolet light)

Contact with hazardous chemical or irritants

Friction/rubbing

- Inflammation/infection-Staphylococcal (e.g. bullous impetigo caused by Staphylococcus aureus, staphylococcal scalded skin syndrome)

Streptococcal (including necrotizing fasciitis)

Herpes simplex

Corresponding Author:

Department of Oral Pathology, Sree Balaji Dental College and Hospital, Chennai

Herpes zoster Varicella

Hand, foot and mouth disease (coxsackievirus)

Fungal

Eczema

Erythema multiforme (including StevenseJohnson syndrome)

Insect bites

- Immunological causes of blistering-Bullous pemphigoid

Mucous membrane pemphigoid

Pemphigus (vulgaris, foliaceus)

Dermatitis herpetiformis

Pemphigoid gestationis

Linear IgA disease

Epidermolysis bullosa acquisita

Lupus erythematosus Vasculitis

Bullous lupus erythematosus

Lichen planus

- Drug reactions-Fixed drug eruptions (e.g. barbiturates, aspirin, paracetamol)

Photosensitive eruptions (e.g. phenothiazines, naproxen)

Pemphigus (e.g. penicillamine, angiotensin-converting enzyme inhibitors)

Toxic epidermal necrolysis (e.g. non-steroidal anti-inflammatory drugs, sulphonamides)[2]

Pemphigus: The term pemphigus is a general term for a group of related autoimmune blistering diseases. The two main types of pemphigus are pemphigus vulgaris and pemphigus foliaceus. Pemphigus vulgaris is the most common form. It is characterized by blisters that rupture easily and causes painful erosions. In most cases, pemphigus vulgaris first develops in the mouth, followed by blistering of the skin. Any area may potentially be affected. The blisters are usually not itchy.

Pemphigus foliaceus is characterized by multiple small, blisters that quickly break apart to form itchy (pruritic), scaly, crusted lesions that affect the uppermost layer of the skin. The scalp and face are usually affected first. Eventually, the chest, upper back may become involved. The lesions are usually not painful. The mucous membranes are usually not affected.

Paraneoplastic pemphigus is a rare disease that occurs in individuals who have cancer, especially blood (hematologic) cancers such as leukemia or lymphoma. Paraneoplastic pemphigus is characterized by painful lesions affecting the mucous membranes, especially those found in the mouth and the lips. The mucous membrane lining the inside of the eyelids (conjunctiva) is also frequently affected.

Pemphigus IgA, also known as intraepidermal neutrophilic IgA dermatosis, is characterized by the development of fluid-filled blisters on the skin. The mucous membranes are usually not affected. In most cases, the trunk and the upper arms or legs are affected. The scalp can be extensively affected in some people.

Pemphigoid Pemphigoid is a general term for a group of related diseases characterized by blistering skin eruptions. The main forms of pemphigoid are bullous pemphigoid, mucous membrane pemphigoid, and pemphigoid gestationis.

Bullous pemphigoid: It is a chronic skin disease usually affecting the elderly that is characterized by firm, large blisters that develop on normal-appearing or reddened skin on the trunk or skin folds, sometimes around cuts or scars. Within weeks, blisters often spread to the groin, armpit, abdomen, and the skin where muscle contracts or flexes (flexor muscles).

Mucous membrane pemphigoid (MMP) is a rare group of chronic autoimmune diseases characterized by blistering lesions that primarily affect the various mucous membranes of the body. The mucous membranes of the mouth and eyes are most often affected. The symptoms of MMP vary among affected individuals depending upon the specific site(s) involved and the progression of the disease. Blistering lesions eventually heal, sometimes with scarring. Progressive scarring may potentially lead to serious complications affecting the eyes and throat. In some cases, blistering lesions also form on the skin, especially in the head and neck area.

IgA Mediated Bullous Dermatoses IgA-mediated bullous dermatoses are disorders characterized by

elevated levels within the body of a specialized protein known as immunoglobulin A (IgA). In these disorders, IgA has a particular tendency to accumulate in the skin. Dermatitis herpetiformis and linear IgA disease are IgA-mediated bullous dermatoses. When liner IgA disease affects children, it may be known as chronic bullous disease of childhood.

Dermatitis herpetiformis, also known as Duhring disease, is characterized by red clusters of extremely itchy (pruritic) blisters. The elbows, knees, scalp and buttocks are most often affected. The mucous membranes are rarely involved. Most cases of dermatitis herpetiformis are associated with Celiac disease, a digestive disorder characterized by intolerance to dietary gluten, which is a protein found in wheat, rye and barley.

Linear IgA disease: It is characterized by blistering eruptions on the skin. The elbows, knees and buttocks are most often affected. New blisters may arise in areas where older blisters are–a finding that creates a small group of blisters that may be described as a "cluster of jewels". In some cases, itching (pruritis) may be develop and may occur before the development of skin lesions. About 50 percent of cases, mucous membranes are affected as well, especially the mouth and eyes. Eye involved can cause blurred vision, irritation, light sensitivity, and corneal scarring.

Epidermolysis Bullosa Acquista: Epidermolysis bullosa acquista is a rare autoimmune disorder of the skin that typically affects middle-aged and elderly people. The skin of affected individuals is extremely fragile. The elbows, knees, pelvis, buttocks, and/or scalp are most often affected. Specialized protein known as immunoglobulin G are usually found around the blisters. The mucous membranes are rarely involved. A subset of patients with epidermolysis bullosa acquista has a widespread, inflammatory form of the disorder that develops rapidly and often involves the mucous membranes.[3,4,5]

Diagnosis: A diagnosis may be confirmed based upon a variety of specialized tests including blood tests or skin biopsy. Blood tests can reveal the characteristic antibodies associated with specific autoimmune blistering diseases. A skin biopsy is a small sample of affected tissue that is taken and examined under a microscope, which may reveal characteristic findings. Direct immunofluorescence (DIF) on a skin biopsy presents a gold standard in the assessment of patients with bullous disorder. This is a test in which the sample is stained with special dyes that allow antibodies to seen under a special microscope. Determining the specific antibody present confirms a diagnosis a specific autoimmune blistering disease.[3,4,5]

Treatment: The treatment of autoimmune blistering diseases is directed toward the specific symptoms that are apparent in each individual and preventing complications potentially associated with these diseases. Although there is no cure for these disorders, they can be controlled medically. The mainstay of treatment for autoimmune blistering diseases is treatment with corticosteroids such as prednisone. Corticosteroid therapy is not effective in all cases and long-term treatment with high-doses of corticosteroids can cause serious side effects.

Additional drugs have been used to treat which may be either alone or in combination with corticosteroids. These drugs include drugs that suppress the immune system (immunosuppressive drugs) such as mycophenolate, azathioprine or cyclophosphamide, immunosuppressive biological therapies such as rituximab, and intravenous immunoglobulin G (IVIG). Plasmapheresis also is a well-established form of treatment for severe cases of autoimmune blistering diseases.[3,4,5]

Conclusion

More people will need treatment for autoimmune blistering skin diseases in future as the population ages and improved diagnostic testing makes diagnosis more likely. New standardized tests for all these diseases are being developed. Specific and well tolerated treatments are urgently required. Precise diagnosis is a prerequisite for accurate prognosis and effective treatment.

Beauticians' Health Related Antecedents on Presenteeism in Korea

Byung-Yoon Chun[1], Jeong-Yeon Park[2]

[1]Professor, Department of Tax & Management, [2]Professor, Department of Beauty Science, Gwangju University, 277 Hyodeok-ro, Nam-gu, Gwangju 61743, Korea

Abstract

Objectives: The current study is to determine the differences, to find out correlates, and to verify the causal relationships among occupational stress, psychosocial stress, and presenteeism, taking beauticians' demographic characteristics and individually perceived health into consideration.

Method: With 246 samples collected from beauticians currently working at different locations in Korea, quantitative analyses were performed with SPSS 23 and LISREL 8.54 software and CFA, t-test, ANOVA, Scheffe test, correlation analysis, and hierarchical regression were implemented.

Results: Individually perceived health was the major differential factor to affect the perceived stresses and presenteeism. And the older in age group, the longer tenure, and the higher position of beauticians were likely to get less occupational and psychosocial stress. And the perceived health was significantly and negatively correlated with the two stresses and presenteeism. Presenteeism was significantly and positively correlated with occupational stress and psychosocial stress. Beauticians' perceived health had significant and negative effects on presenteeism (-.171, $p<.01$), and both occupational (.252, $p<0.01$) and psychosocial stress (.391, $p<0.001$) beauticians perceived to possess were significantly and positively related to presenteeism. And psychosocial stress had stronger effects on presenteeism than occupational stress.

Conclusion: This study provides evidences that beauticians' perceived health and stresses may increase the risk of presenteeism. Given the findings from the current study, managers and management are recommended to pay more attentions to this counterproductive phenomena, presenteeism, and to pay further attempts finding initiatives to improve beauticians' health problem and to reduce their occupational and psychosocial stress, which would in turn lead to presenteeism.

Keywords: *Health, Occupational Stress, Psychosocial Stress, Presenteeism, Beautician.*

Introduction

Approximately more than 200 thousands of beauticians were reported working in 133 thousands of beauty salons in Korea. And 87.7% of the beauticians were reported females[1]. Most of the beauticians also used to conduct functions as hairdressers, cosmetologists, skincare specialists, nail artists, and makeup artists. Moreover, in some cases, beauticians perform various roles reciprocally.

They also use a wide range of chemical products including shampoos, dyes, various types of cosmetic, chemical sprays, permanent wave solutions, etc. Besides being vulnerable to the chemicals, beauticians' work involves physical effort, inconvenient postures, last long standing, irregular eating, short break, fine dust inhaling, and so on. These occupational activities result in having beautician adverse impacts on their health and having especially female beauticians a negative outcomes of pregnancy[2]. And the high risk in occupational contact dermatitis was also reported for beauticians[3]. Thus those make their health worse, coupled with conflicts

Corresponding Author:

Professor, Department of Beauty Science, Gwangju University, 277 Hyodeok-ro, Nam-gu, Gwangju 61743, Korea

with coworkers, job demand, lack of reward, and perceived undue treatment by company. Those all lead to occupational stress[4]. Perceived occupational stress is related to various physical and psychological disorder[5]. In addition, most of their works may be labor and effort intensive, and in their job requirements there also exist emotional labor attributes as arguing by Gimlin[6] that 'beauticians provide services to their clients while soliciting to build a personal relationship, tuning in and memorizing the minute details of their lives and taking emotional attachment to them'[7]. Therefore, psychosocial stress can also be exposed and associated with ensuring employer and client satisfaction[2]. With these stresses derived from daily works and life within organization and social domain, beauticians are likely to have health problems. Nevertheless, in return, they go to work, but psychologically out of work due to ill, which most of researchers call it "presenteeism".

Presenteeism refers to 'physically attend but psychologically absent'. Presenteeism occurs when employees are at work, but their cognitive energy is not devoted to their work[8] because of their medical and psychological conditions which are not performing at ultimate levels. This phenomenon appears as negative and as something that should be avoided because of the loss in individual and organizational productivity due to an employee's health problems[9]. Moreover, undoubtedly presenteeism is a widely spread global phenomenon in organizations[10]. And it is more likely to attend ill rather than not to attend for people working in jobs where clients rely on them(e.g., sales representatives, government workers, nurses, school teachers) and where there has no other workforce available to replace them (e.g., scheduled duty in a call center)[11]. Likewise, it goes without saying that beauticians are more likely to engage in presenteeism because clients rely on their services and they could hardly get any replacement when sick because the required roles per their position and tenure are relatively distinct[12]. Therefore, it would be worthy investigating to what extent beauticians are involved in presenteeism and worthwhile to verify if and to what extent their perceived health, occupational and psychosocial stress could predict presenteeism.

Accordingly, the aims of the current study are (1) to identify the differences of occupational stress, psychosocial stress, and presenteeism, taking beauticians' individual characteristics and perceived health into account; (2) to find out the correlates among those variables; and (3) to verify the relations affecting presenteeism from the perceived health and the two dimensional stresses after controlling the control variables.

Material and Method

Research Sample: Survey data was collected from beauticians working at beauty salons in Korea and conducted in Korean. We used measures with satisfactory reliability and validity from the previous studies. After removing missing responses, 246 survey samples were utilized to examine the study.

Measures: All the measures except demographic variables were rated on a 5 Likert scale ranging from 1 to 5 ("strongly disagree" to "strongly agree"), unless otherwise indicated.

Occupational Stress was defined as the harmful physical and emotional responses that occur when the requirements of the job do not match the capabilities, resources, or needs of the worker. To reflect Korean context, it was measured by KOSS-SF (Korean Occupational Stress Scale-Short Form) which was developed by Chang et al.[13] and composed of 24 items.

Psychosocial Stress was defined as a person-environment relationship that is evaluated by the individual as regarding his or her welfare and in which the person's resources are burdened or surpassed. To assess perceived psychosocial stress, 12 items were employed from Bank et al.[14], which was a revised version of GHQ (General Health Questionnaire).

Presenteeism was defined as a phenomenon in such a status when employees are physically at work but, due to medical and psychological conditions, they are not performing at utmost levels. To test this adverse behavior, SPS-13 (Stanford Presenteeism Scale) developed by Turpin et al.[15] was employed. SPS is composed of 10 items.

Control Variables: In addition, demographic factors such as gender, age, education, and so on was recorded and these were intended as control variables. And we also used attendance management and perceived health as additional control variables because those may have effect on the presenteeism as recommended by Iverson & Deery[16].

Data Analysis: To test the validities of variables, CFA was conducted and in return three items (two in psychosocial stress and one in presenteeism) were

deleted because those items showed unacceptable as suggested by Stevens[17] that to be acceptable the factor loading should be over 0.4.

To test the internal consistency, we conducted reliability test with Cronbach's alpha. The Cronbach's alphas were 0.90 for occupational stress, 0.87 for psychosocial stress, and 0.75 for presenteeism. All the scales in the current study exceeded 0.7 as suggested by Nunnally & Bernstein[18].

Results

General characteristics of the study samples were comprised of predominantly female (78%), 30s (44.7%), college graduate (41.1%), married (55.3%), permanent employee (78.9%), and average 8.66 years of tenure. Details are shown in Table 1 below.

Statistically significant differences in occupational stress were found for age group, employment type, tenure, title, and health with 95% of CI (confidence level). Specifically, there were statistically significant mean differences in age group between over 50s and all the other age groups (0.429, $p< 0.05$ for 20s; 0.389, $p< 0.05$ for 30s; 0.388, $p<0.05$ for 40s), in tenure between less than 1 year and over 15 years(0.828, $p< .01$), in title between staff and manager(0.302, $p<0.05$), staff and executive (0.543, $p< 0.001$), associate and executive (0.592, $p<0.001$), and associate and manager (0.352, $p<0.05$), and in health between bad and good (0.323, $p<0.05$), moderate and good (0.225, $p<0.225$).

Table 1: General Characteristics and Differences of Health, Occupational Stress, Psychosocial Stress, and Presenteeism (N=246)

Variables		N	%	Occupational Stress		Psychosocial Stress		Presenteeism	
				Mean±SD	t or F (p)	Mean±SD	t or F (p)	Mean±SD	t or F (p)

	≥15 years	30	12.2	2.38±0.64		2.09±0.68		2.55±0.58	

Variables		N	%	Occupational Stress		Psychosocial Stress		Presenteeism	
				Mean±SD	t or F (p)	Mean±SD	t or F (p)	Mean±SD	t or F (p)
Title	staff	81	32.9	2.84±0.50	10.301 (0.000)	2.58±0.60	5.130 (0.001)	2.89±0.43	9.042 (0.000)
	Associate	54	22.0	2.89±0.49		2.56±0.62		2.97±0.40	
	Manager	61	24.8	2.54±0.59		2.40±0.64		2.77±0.48	
	Chief	13	5.3	2.52±0.48		2.20±0.52		2.48±0.49	
	Executive	37	15.0	2.30±0.53		2.11±0.56		2.47±0.56	
Health	Bad	35	14.2	2.85±0.47	0.6448 (0.002)	2.68±0.53	15.649 (0.000)	3.02±0.48	20.305 (0.000)
	Moderate	110	44.7	2.76±0.56		2.58±0.60		2.92±0.41	
	Good	101	41.0	2.53±0.57		2.18±0.60		2.57±0.49	

According to the differences for psychosocial stress, statistically significant differences were found in age group between 20s and over 50s(0.554, $p<0.05$), in tenure between less than 1 year and over 15 years (0.710, $p<0.05$), 1~5 years and over 15 year (0.525, $p<0.01$), in title between staff and executive (0.466, $p< 0.01$), associate and executive (0.454, $p<0.05$), and in health between bad and good (0.499, $p<0.001$), moderate and good(0.398, $p<0.001$) were found.

And statistically significant mean differences were found for presenteeism in tenure between 1~5 years and over 15 years (0.347, $p<0.05$), in title between staff and executive (0.425, $p<0.001$), associate and manager (0.491, $p<0.05$), associate and executive(0.504, $p<0.001$), manager and executive (0.305, $p<0.05$), in health between bad and good (0.446, $p<0.001$), moderate and good (0.348, $p<0.001$).

Before the causality testing, Pearson correlations for all the variables were calculated and stated in the below Table 2. The presenteeism of beauticians was significantly related to both occupational stress and psychosocial stress ($p<0.001$ for all). And age and tenure were shown negatively strong correlations with presenteeism (-.138, $p<0.05$;-.183, $p<0.01$). Perceived health was also strongly and negatively correlated with two stresses(-.218, $p<0.01$;-.319, $p<0.001$) and presenteeism (-.359, $p<0.001$). Table 2 shows the details.

*: $p<.05$, **: $p<.01$, ***: $p<.001$, 1. Dummy coded for male = 1 and female = 0, 2. Transformed to continuous variable such high school as 12, college as 14, university as 16, and above graduate school as 18, 3. Dummy coded for married = 1, never married and others = 0, 4. Dummy coded for permanent employee = 1, temporary = 0, 5. Transformed to continuous variable such <1 year as 0.5, 1~5 years as 2.5 years, 5~10 years as 7.5 years, 10~15 years as 12.5 years, and over 15 years as 17.5 years

To verify the causal relations of the perceived health and (occupational and psychosocial) stresses on presenteeism, a hierarchical regression analysis was conducted as seen in Table 3 below. After controlling the control variables and attendance management, employees' perceived health had significant and negative effects on presenteeism (-.171, p<.01). That is, the better perceived health beauticians have, the less likelihood to involve in presenteeism. And both occupational stress(.252, p<0.01) and psychosocial stress (.391, p<0.001) were significantly and positively related to presenteeism.

This finding indicated that the two types of stresses among beauticians had positive and strong effects on presenteeism. That is, presenteeism shall be increasing along with the rise in either or both stresses and the impact on presenteeism is much stronger from psychosocial stress rather than occupational stress. Details are shown in Table 3.

Table 3: Hierarchical Regression Analysis predicting Presenteeism

Variables	Dependent Variable: Presenteeism[1]	
	Step 1	Step 2
	β	β

Tenure	-.088	.014
Attendance Management	.106	-.063
Health	-.351***	-.171**
Occupational Stress		.252**
Psychosocial Stress		.391***

*: p<.05, **: p<.01, ***: p<.001, 1. Standardized regression coefficients (β)

Discussion

In the current study, we identified the differences among employees' perceived health, the stresses, and presenteeism, taking beauticians' demographic characteristics into account and then found out the associations between the health and two types of stresses (occupational and psychosocial) on presenteeism.

From the test results, we found that (1) the older gets less occupational and psychosocial stress than the younger beauticians in age group, (2) beauticians with shorter tenure are likely to expose to both stresses and presenteeism rather than the ones with longer tenure, (3) lower positioned beauticians such as staffs and associates are likely to have more stresses and to involve in more presenteeism, compared to the ones in higher position such as chiefs or executives. (4) Individually perceived health was the major differential factors affecting both stresses and presenteeism.

Another findings were that occupational and psychosocial stress had strong associations with presenteeism. This notion is also fully supported from many previous studies. And from the hierarchical regression analysis, we revealed that beauticians' perceived health had significantly negative effects on presenteeism and both stresses beauticians perceive to possess had positive effects on presenteeism. In this relations, psychosocial stress had stronger impact on presenteeism than occupational stress.

Conclusion

There may have little researches conducted regarding the comprehensive relationships among beauticians' perceived health, occupational and psychosocial stresses with presenteeism, taking beauticians' individual and contextual factors into account. In this regard, the current study would be a fresh attempt to shed light on the implications of their perceived health status and the two dimensional stresses on the presenteeism phenomenon from beauticians in Korea. Therefore, it is hoped that these findings would offer a preliminary empirical basis for managers and management to better understand the importance of managing their perceived health issues and reducing stress level, which would in turn lead to presenteeism behaviors.

Relative Effect of Conventional and Specific Hockey Skill Training on Selected Motor Fitness, Physiological Variables and Playing Ability of Hockey Players in Tamil Nadu

K. Govarthanan[1], K. Vaithianathan[2]

[1]Ph.D. Scholar, [2]Director of Sports, Dept. of Physical Education and Sports Science, SRMIST, Kattankulathur, Chennai, Tamil Nadu, India

Abstract

The purpose of the study was to study conventional and specific hockey skill training on Motor fitness, physiological and playing ability of Hockey players. There were selective three motor fitness and three physiological components which were used as a criterion measures for this study. For analysis the data and to find out the relationship between selective motor fitness, physiological and playing ability Pearson product moment correlationship was applied. Level of confidence was set at .05 levels. Firstly, selective motor fitness, Second, physiological components were evaluated. The result of the study clearly disclosed that specific hockey skill training has considerable relationship with the playing ability of Hockey players in SRM University, Tamil Nadu. On the basis of results and associated discussion it may be concluded that conventional training and playing ability had low correlation. There might be some reasons of the low correlation in the perspective of good scientific coaching. There was the possibility of the lack of coaching aspects, which shows clearly in the findings that the specific hockey skill training was less correlated with playing ability.

Keywords: *Conventional training, specific hockey skill training, playing ability.*

Introduction

Hockey is one of the favourite of all. Hockey is the game of skill; it is a well-known concept of ancient Indian hockey which elaborates the importance of conventional and specific of skills training. Hockey is a dynamic field game, played by male and female, requiring high level skills, excellent conditioning and well coordinated team efforts[1]. Hockey is one of the most popular and attractive sports in the world. Hockey is a sport with many complex techniques and tactics that can be seen speed, power, endurance and movement frequently in it[5].

Research in the field of Physical Education and Sports is highly demand of the today. Researches in this field brought so many fitness in and various skill training. We can say that the progress of the field directly linked with research. It is fact that at present situation research in Physical Education, and Sports is an important area of study to improve the sports performance. The past decades have seen the rise of an area of study called futurism or futuristic, which attempts to scientifically examine the future[2].

A physiological benefit available, through motor activity is positively associated with aspects of psychological well-being. In particular, significant relationships have been identified between self-perceived health and motor activity. The argument exists, therefore, that the promotion of sports participation and achieve leisure pursuits may at least be rewarded by better health perceptions. The poor performance of Indian sportsman and sports women in the international competitions is the result of lack of motor fitness. Therefore, it is felt that there is a dire need to improve the motor fitness level of Indian youth for raising the performance and standard in games and sport[4].

Motor fitness, physiological variables have been considered as important prerequisite for sportsmen to secure the top level performance in the game. A good hockey player must have the following physical activity. He must have the motor fitness to perform the specific skills training that the game of hockey requires. These include speed endurance, muscular endurance, and aerobic endurance with precision accuracy and confidence. Perfection in vital capacity, respiratory rate, and respiratory volume is most important for all good players irrespective.

Coaching in the sports would be based on scientific and systematic information derived from research[3]. With regard to physical fitness there are several factors that a number of overlapping activities. The term physical fitness has been divided into two distinct categories: skill-related and physiological-related motor fitness.

Methodology of the Study

Selection of Subjects: For the purpose of present study forty five field hockey players from SRM University, Department of Physical Education and Sports Science, Kattankulathur, Chennai, Tamil Nadu State, India were selected as subjects at random and their ages ranged from 18 to 25 years. These subjects were divided in three groups. Each group would be consists of 15 players.

Selection of Variable: Twelve weeks conventional training and specific hockey skill training acts as an independent variable and motor fitness, physiological acts as dependent variable for the present study.

Research Design: The selected subjects (N=45) were divided into three groups equally and randomly. Of which one group was undergoing conventional method of training to develop selected dependent variables whereas the other group underwent specific hockey skill training to develop the selected motor fitness, physiological variables and playing ability and the third group acted as control group.

Collection of data: Before the administration of conventional and specific hockey skill training, the motor fitness, physiological test were administered on both the experimental and control groups to collect pretest data. After the completion of 12 weeks of specific hockey skill training again the same tests were conducted to collect the post training data. Necessary instructions were given to the subjects before administration of the tests.

Experimental Design: For the study pretest & posttest randomized group design, which consists of no training group (n=15) and two experimental group (n=30) was used. Equal numbers of subjects were assigned randomly to the group. Two groups served as experimental group (conventional training and specific hockey skill training group) on treatment.

- Experimental Group I: subjects were considered as Conventional training on regular male field hockey players.
- Experimental Group II: Subjects were allowed to perform Specific hockey Skill training on regular male field hockey player.
- Control Group III: Subjects were not given special training other than the training on regular male field hockey players respectively.

For experimental group I & II the present study training given for three days per week (alternate days) for twelve weeks. Every training session lasted for 60 to 90 minutes. The training program was scheduled for the morning between 6.00 am to 8.00 am.

However, they were participating in their regular physical activities and game practice. The subject underwent their respective programme under strict supervision prior to and during every session. Subject underwent training for & 90 minutes including warm up and cool-down exercises which included jogging, stretching, striding and warm-ups. Measurement of motor fitness, physiological variables, and playing ability was taken for the three groups.

Hence the results concluded that specific hockey skill training influences the speed endurance, muscular endurance, aerobic endurance, vital capacity, respiratory rate, and respiratory volume, of the players. It was also proved that the better effect was seen in regular male field hockey players in group II.

Statistical Procedure: To find out the effect of static and conventional training and specific hockey skill Training on motor fitness, physiological and playing ability of the subjects the pretest and post test scores were analyzed by using descriptive statistical and Analysis of Co-Variance (ANCOVA). To test significance of difference among means test was applied. The data analyzed with the help of (IBM) SPSS (20.0 version) software and the level of significance was set at 0.05 level of confidence.

Findings of the Study

Table-I: Analysis of covariance of means of conventional training and specific hockey skill training and no training groups on speed endurance

	Conventional Training	Specific Hockey Skill Training	No Training	Source of Variance	Sum of Squares	df	Means Squares	F-ratio
Pre-Test Means	6.08	6.23	6.05	BG	0.27	2	0.14	1.31
				WG	4.47	42	0.10	
Post-Test Means	5.76	5.85	5.32	BG	2.37	2	1.18	8.55*
				WG	5.83	42	0.13	
Adjusted Post-Test Means	5.76	5.85	5.32	BG	2.304	2	1.15	8.10*
				WG	5.830	41	0.14	

*Significant at 0.05 level of confidence.

The table-I indicated that the pretest means conventional training and specific hockey skill training and no training groups group were 6.08, 6.23 and 6.05 respectively. The obtained F-ratio for the pre-test was 1.31 and the table F-ratio was 3.22. Hence the pre-test mean speed endurance F-ratio was insignificant at 0.05 level of confidence for the degree of freedom 2 and 42. The post-test means of the conventional training and specific hockey skill training and no training groups group were 5.76, 5.85 and 5.32 respectively. The obtained F-ratio for the post-test was 8.55 and the table F-ratio was 3.22. Hence the post-test mean speed endurance F-ratio was significant at 0.05 level of confidence for the degree of freedom 2 and 42. The adjusted post-test means of the conventional training and specific hockey skill training and no training groups were 5.76, 5.85 and 5.32 respectively. The obtained F-ratio for the adjusted post-test means was 8.10 and the table F-ratio was 3.23. Hence the adjusted post-test mean speed endurance F-ratio was significant at 0.05 level of confidence for the degree of freedom 2 and 41.

Table-II: Analysis of covariance of means of conventional training and specific hockey skill training and no training groups on muscular endurance

	Conventional Training	Specific Hockey Skill Training	No Training	Source of Variance	Sum of Squares	df	Means Squares	F-ratio
Pre-Test Means	11.45	11.59	11.19	BG	1.23	2	0.62	1.35
				WG	19.28	42	0.45	
Post-Test Means	10.61	11.12	9.52	BG	20.20	2	10.10	18.73*
				WG	22.65	42	0.53	
Adjusted Post-Test Means	10.64	11.10	9.51	BG	19.99	2	9.99	18.33*
				WG	22.36	41	0.54	

*Significant at 0.05 level of confidence.

The Table-II indicated that the pretest means conventional training and specific hockey skill training and no training groups were 11.45, 11.59 and 11.19 respectively. The obtained F-ratio for the pre-test was 1.35 and the table F-ratio was 3.22. Hence the pre-test mean muscular endurance F-ratio was insignificant at 0.05 level of confidence for the degree of freedom 2 and 42. The post-test means of the conventional training and specific hockey skill training and no training groups were 10.61, 11.12 and 9.52 respectively. The obtained F-ratio for the post-test was 18.73 and the table F-ratio was 3.22. Hence the post-test mean muscular endurance F-ratio was significant at 0.05 level of confidence for the degree of freedom 2 and 42. The adjusted post-test means of the conventional training and specific hockey skill training and no training groups were 10.64, 11.10 and 9.51 respectively. The obtained F-ratio for the adjusted post-test means was 18.33 and the table F-ratio was 3.23. Hence the adjusted post-test mean muscular endurance F-ratio was significant at 0.05 level of confidence for the degree of freedom 2 and 41.

Table-III: Analysis of covariance of means of conventional training and specific hockey skill training and no training groups on aerobic endurance

	Conventional Training	Specific Hockey Skill Training	No Training	Source of Variance	Sum of Squares	df	Means Squares	F-ratio
Pre-Test Means	42.40	44.33	42.40	BG	2	18.68	2	1.01
				WG	42	18.44	42	
Post-Test Means	51.53	52.46	47.93	BG	2	85.95	2	3.77*
				WG	42	22.77	42	
Adjusted Post-Test Means	50.35	53.05	48.52	BG	2	77.99	2	10.52*
				WG	41	7.41	41	

*Significant at 0.05 level of confidence.

The table-X indicated that the pretest means conventional training and specific hockey skill training and no training groups were 42.40, 44.33 and 42.40 respectively. The obtained F-ratio for the pre-test was 1.01 and the table F-ratio was 3.22. Hence the pre-test mean aerobic endurance F-ratio was insignificant at 0.05 level of confidence for the degree of freedom 2 and 42. The post-test means of the conventional training and specific hockey skill training and no training groups were 51.53, 52.46 and 47.93 respectively. The obtained F-ratio for the post-test was 3.77 and the table F-ratio was 3.22. Hence the post-test mean aerobic endurance F-ratio was significant at 0.05 level of confidence for the degree of freedom 2 and 42. The adjusted post-test means of the conventional training and specific hockey skill training and no training groups were 50.35, 53.05 and 48.52 respectively. The obtained F-ratio for the adjusted post-test means was 10.52 and the table F-ratio was 3.23. Hence the adjusted post-test mean aerobic endurance F-ratio was significant at 0.05 level of confidence for the degree of freedom 2 and 41.

Discussion on Findings

The prime intention of the researcher was to analyse the relative effect of conventional training and specific hockey skill training on selected motor fitness, physiological and playing ability of field hockey players. The theme behind this study was to observe the influences of conventional training, specific hockey skill training and no training as a alternate means to develop the selected physical, physiological and playing ability of field hockey players. To achieve this, two different training were designed as conventional training group, specific hockey skill training group and no training group. The results of the effect of two training packages on variables used in this study are analysed so as to reach the theme of the present study, and sources behind such similarities and variations observed on variables between the training groups, have been discussed here using scientific studies and logical in nature.

Conventional training is using another sport, activity or training techniques to help improve playing ability in the primary sport activity. Specific hockey skill training is specifically designed to develop the playing ability related field hockey players.

Hence, compared the effects of three different training improvements in vertical jump performance and leg strength[6]. Speed endurance training facilitates aerobic endurance processes, whereas resistance training increases muscular endurance and vital capacity[7].The speed endurance, muscular endurance and aerobic endurance and agility increased significantly after training[8]. Compared the changes in running economy, foot impact shock, run performance, and resting respiratory rate and respiratory volume elicited by increases in training volume via run training and conventional and specific hockey skill training[9].

In a field hockey game players need a high level of energy and analytical skill to fulfill the requirements. Sports-specific physical training is paramount in field hockey [10].There was no significant improvement in the shooting, passing and dribbling ability of the control group. The developed an effective testing battery for male field hockey by using anthropometric, physiological, and skill-related tests to distinguish between regional representative male field hockey players. These sprinting speed, agility, dribbling control, aerobic and muscular power, and shooting accuracy can distinguish between male field hockey players [11].

Conventional training effects never exceed those induced by the specific hockey skill training mode. For the general population, conventional training may be highly beneficial in terms of overall fitness. Similarly, conventional training may be an appropriate supplement during rehabilitation periods from physical injury and during periods of overtraining or psychological fatigue. Since, conventional training was one of the most advanced forms of sports training the combination with specific hockey skill training produces significant changes. Anyhow these two different training when in conjunctional nature, the effect might have been strengthened as a value added one.

Conclusion

The result of the present study reported that participation in the specific hockey skill training program; improve playing ability in experimental group. Hence significant difference was found between the regular male filed hockey players of SRM University, Chennai in relation to motor fitness, physiological and playing ability.

- The specific hockey skill training group had shown significant improvement in all the performance variables than the conventional training group.
- The specific hockey skill training with conventional training group had shown significant improvement in all the selected motor fitness, physiological and playing ability.
- The control group has shown significant no improvement in all the selected motor fitness physiological and playing ability variables.

Risk Factors for Pediatric Intensive Care Admission among Asthmatic Children in Aseer, South-West Saudi Arabia

Mohammed Abdullah Alshehri[1], Mohannad Mohammed Al gossadi Alsheri[2], Reema Mohammed Al Gossadi Alsheri[3], Renad Mohammed Al Gossadi Alsheri[3]

[1]Professor, Department of Child Health, [2]Medical Intern, [3]Medical Student, College of Medicine, King Khalid University, Abha, Saudi Arabia

Abstract

Background: The burden of childhood asthma continues to rise with increasing rates of asthma prevalence, severity, and death. Asthma is the one of the most chronic pediatric disorder and is frequent caused for hospitalization and pediatric intensive care unit (PICU) admissions.

Objective: To determine risk factors for PICU admission in children with asthma.

Patients and Method: The study used a retrospective case-control design. The cases included children admitted to the PICU and controls were children admitted to the hospital general ward.

Results: A total of 320 charts of asthmatic children were reviewed: 72 (22.5%) admitted to the PICU and 248 (77.5%) admitted to the general ward. Univariate analysis indicated that asthmatic children admitted to PICU were more likely to be older ($p<0.001$), have longer asthma duration ($p<0.001$), higher use of: inhaled corticosteroids ($p<0.0001$), cromolyn ($p=0.03$), long acting β_2 agonists ($p=0.001$), and poor adherence to treatment ($p=0.002$). However, multivariate analysis revealed that longer duration of asthma ($p=0.03$), use of inhaled corticosteroids ($p=0.01$), and non-compliance with therapy ($p=0.02$) were associated with an increased risk of PICU admission.

Conclusions: This study identified a significant number of risk factors associated with PICU admission. Early recognition could help to develop preventive strategies, improve efficacy of treatment and reduce admission to PICU.

Keywords: *Asthma, Risk factors, Children, Pediatric intensive care.*

Introduction

Bronchial asthma is a common and potentially serious health problem globally, with estimated 300 million affected individuals, with great variation between countries[1]. The incidence and prevalence of asthma have increased during the last 20 years[2,3]. Asthma is considered one of the most common chronic disorders in the Kingdom of Saudi Arabia as 2 million Saudis suffer from asthma[4]. It imposes a substantial burden on family, health care services, and society as a whole[5].

Asthma can cause episodic coughing, wheezing, shortness of breath, chest tightness and exacerbations that sometimes require urgent health care services and may be fatal. Around 30% of asthmatic exacerbations attended to the emergency department of a hospital require hospitalization and up to 20% require intensive care management[6,7]. In the past two decades, hospital admissions for asthma have been increasing despite improved knowledge about the disease and the availability of better treatment modalities. Severe acute asthma in children is associated with substantial

morbidity and may require Pediatric Intensive Care Unit (PICU) admission. Understanding the risk factors for hospitalization for asthma is important for treating and reducing their effects on society[8]. This study was designed to determine the potential risk factors for PICU admission in Saudi children with asthma.

Patients and Method

We performed a retrospective case-control study at the Abha Private Hospital, Abha, South-west Saudi Arabia between January 2014-December 2018.

Study Design: The inclusion criteria were as follows: all children aged 2-14 years who admitted to the PICU with acute asthma which was previously diagnosed by pediatricians or pulmonologists before PICU admission were eligible as cases. The admission criteria to PICU were clinically predefined and did not change during the study period. They included respiratory failure, imminent exhaustion, no clinical benefit after continuous nebulization of bronchodilator drugs, and/or the need for mechanical ventilation. The control group included patients aged 2-14 years diagnosed with asthma who admitted to the General Pediatric Ward of the Hospital with an acute asthma exacerbations. Controls were recruited during the same period of the study.

The exclusion criteria: Patients younger than 2 years were excluded because bronchiolitis an acute wheezing illness occurring mainly in children younger than 2 years, closely resembles asthma and may affect our data. Patients admitted to the Hospital whose diagnosis code changed to non-asthma during hospitalization also were excluded. Children who had not been diagnosed with asthma prior to their admission and presented with their first asthmatic attack were excluded from the study because defining controls would not be feasible.

Materials

The medical records of patients and controls were reviewed and the following information extracted: Demographic variables: age, gender, number of siblings, and consanguinity. Disease variables: age at first symptoms of asthma, duration of the disease, previous admission to the PICU, and family history of asthma. Variables related to medications: inhaled/ oral corticosteroids, cromolyn, long-acting β_2 agonists, leukotriene receptors antagonists, and compliance to therapy. Variables related to exposure and atopy: history of parental smoking, inhaled allergens, eczema and presence of pets in the home.

Statistical Analysis: Data were analyzed using the Statistical Software Package SPSS 19 (SPSS, Inc., Chicago, IL). Quantitative data were presented as mean+ standard deviation (SD), while qualitative data were demonstrated as frequency and percent (%). Differences between cases and controls were analyzed by Student's *t*-test for continuous normally distributed variables. Categorical data were assessed by chi-square test. The dependent variable was PICU/General Pediatric Ward admission. Variables found to be significant on univariate analysis were subsequently evaluated by multiple logistic regression. For all analysis, statistical tests were two-sided, and $p < 0.05$ was regard as significant.

Results

A total of 320 asthmatic children were enrolled in the study: 72 (22.5%) were admitted to PICU, and 248 (77.5%) to the General Pediatric ward. The mean age was statistically older in patients who admitted to PICU than in those who admitted to the General Pediatric ward (6.3 + 0.4 vs 4.6 + 0.3 respectively, $p < 0.001$). Females were preponderance in both groups but this finding was statistically non significant. Cases and controls were matched in terms of breast fed for 6 months, number of siblings, and first degree consanguinity (table 1).

Disease characteristics and risk factors in the two groups are shown in (table 2). Disease features: the duration of asthma was significantly longer in the PICU group than in the General Pediatric Ward group (25.1 + 0.2 months vs 21.0 + 0.7 months respectively, $p < 0.001$). Parental smoking and exposure to inhaled allergens were significantly reported more frequently in the group with PICU admission, $p < 0.05$).

Medications: significant differences between the two groups were noticed including higher use of inhaled corticosteroids ($p < 0.0001$), cromolyn ($p = 0.03$), and long acting β_2 agonists ($p = 0.001$) in the PICU group. More patients in the PICU group had poor compliance with therapy (40.3% vs 22.2%, Odds ratio (OR) = 2.36, Confidence interval (CI) (1.35-4.13), $p = 0.002$). Other factors: asthmatic children who admitted to PICU had more frequent prior admissions to the PICU ($p = 0.0003$).

Multivariate analysis (table 3) revealed that longer duration of the disease ($p = 0.03$), use of inhaled corticosteroids ($p = 0.01$), and non-compliance with therapy ($p = 0.02$) were significantly associated with an increased risk for admission to the PICU compared to the General Pediatric Ward.

Table 1. Demographic characteristics of asthmatic patients admitted to PICU and General Pediatric ward

Characteristics	PICU (n = 72)	General Ward (n = 248)	OR (95% CI)	p-value
Age (year)[a]	6.3 ± 0.4	4.6 ± 0.3	1.30 (1.78-1.61)	< 0.001
Gender[b]				
Male	30 (41.7)	106 (42.7)	0.95 (0.56-0.61)	0.9
female	42 (58.3)	142 (57.3)		
Breast-fed 6 months[b]	29 (40.3)	102 (41.1)	0.97 (0.57-1.65)	0.8
Number of siblings[b]				
> 4	22 (30.6)	75 (30.2)	1.01 (0.57-1.79)	0.9
< 4	50 (69.4)	173 (69.8)		
First-degree consanguinity[b]	32 (44.4)	106 (42.7)	1.07 (0.63-1.81)	0.7

[a]Values are means + SD, [b]Number (%), OR: odds ratio; 95% CI: confidence interval, PICU: pediatric intensive care unit

Table 2. Disease characteristics and risk factors in patients admitted to PICU and General Pediatric ward

Risk factors	PICU (n = 72)	General Ward (n = 248)	OR (95% CI)	p-value
Disease features				
Age at first symptoms of asthma (Year)[a]	3.1 ± 0.1	3.2 ± 0.5	1.6 (0.01-0.21)	0.09
Duration of asthma (month)[a]	25.1 ± 0.2	21.0 ± 0.7	3.1 (4.26-3.93)	<0.001*
Family history of asthma[b]	18 (25.0)	52 (20.9)	1.2 (0.67-2.32)	0.4
Exposure and atopy[b]				
Parental smoking	31 (43.1)	75 (30.2)	1.74 (1.01-2.99)	0.04*
Inhaled allergens	24 (33.3)	40 (16.1)	2.60 (1.43-4.70)	0.002*
Pet cat	15 (20.8)	57 (22.9)	1.91 (0.96-3.79)	0.06
Eczema	31 (43.1)	95 (38.3)	1.2 (0.71-2.07)	0.5
Medication[b]				
Inhaled corticosteroids	38 (52.8)	41 (16.5)	5.6 (3.18-9.99)	<0.0001*
Oral corticosteroids	9 (12.5)	15 (6.0)	2.2 (0.92-5.30)	0.07
Long acting β_2 agonist	17 (23.6)	22 (8.9)	3.17 (1.57-6.38)	0.001*
Cromolyn	12 (16.7)	20 (8.1)	2.28 (1.05-4.92)	0.03*
Non-compliance with therapy	29 (40.3)	55 (22.2)	2.36 (1.35-4.13)	0.002*
Co-morbidities[b]				
GERD	4 (5.6)	11 (4.4)	1.26 (0.39-4.10)	0.6
Previous admission to PICU[b]	10 (13.9)	5 (2.0)	7.83 (2.58-23.76)	0.0003*

[a]Values are means + SD, [b]Number (%), OR: odds ratio; 95% CI: confidence interval, GERD: gastroesophageal reflux disease; PICU: pediatric intensive care unit, *Significant *p* value

Table 3. Significant risk factors on multivariate analysis

Factors	OR (95% CI)	*p*-value
Duration of asthma	2.17 (1.23-4.30)	0.03
Use of inhaled corticosteroids	3.01 (1.48-5.90)	0.01
Non-compliance with therapy	1.46 (1.01-1.07)	0.02

OR: odds ratio; 95% CI: confidence interval

Discussion

The impact of childhood asthma on the health care system is considerable. As one of the most chronic diseases of children, bronchial asthma is frequently caused for emergency room visits and hospital admission[3]. An admission to PCU with asthma is potentially life threatening and is a recognized risk factor for subsequent death[9].

This retrospective study was conducted to identify risk factors for PICU admission. Our study showed that asthmatic children who were admitted to the PICU were significantly older than those who admitted to the General Pediatric Ward. Children in the PICU group were approximately 2 years older than the control group. The possible explanation may be due to the severity of

the asthmatic attack and PICU admission were related to a longer duration of asthma in older children and perhaps the development of remodeled airways. This explanation is supported by the longer history of asthma in children with PICU admission. Many studies reported a longer duration of asthma in children admitted to ICU suggesting a link between asthma duration and severity that may account for the findings[10-12]. Female gender was pronounced as a risk factor for hospitalization and readmission in studies conducted by Nunez et al[13] and Kargar et al[14]. In our study although there was a female preponderance but statistically was non-significant.

Previous admission to the PICU was higher in group admitted to the PICU and the difference was statistically significant (p = 0.0003). This finding is consistent with previous studies that reported previous admission to emergency department and PICU were also linked to hospital readmission[15-17]. However, other studies did not reported significant differences.[10,13] Parental smoking and inhaled allergens have adverse influences on asthma and hospital admission[18]. In the present study, parental smoking and exposure to inhaled allergens were significantly reported more frequently in children with PICU admission ($p < 0.05$). This confirms the previous reports in which a history of exposure to smoking and being in continuous contact with allergens have been known as risk factors for morbidity, asthma severity, and hospitalization for asthma[19-21].

Atopy is a recognized risk factor for severe asthma[1]. We found that eczema was not linked to PICU admission possibly because of small patients number. Serum IgE levels provide a quantitative definition of atopy and may have been a better measure to use, but serum IgE were not recorded in a sufficient number of patients files for analysis.

In their systemic review, Alvarez et al[22] reported that the use of inhaled corticosteroids measured in a dose-independent fashion did not significantly increase or decrease the risk for near fatal and fatal asthma in adults. Some studies in children observed that inhaled corticosteroids prophylaxis is effective controlling symptoms and reducing hospitalization and death[23-25]. These findings are in contrast to our results. The difference would be explained by greater severity of asthma and non-compliance with therapy in the PICU group. Similar findings were noted in a comparable study of asthmatic adults[26]. Similarly, the higher numbers of patients receiving treatment with long acting β_2 agonists, the use of asthma management plans, and asthma management by a respiratory specialists are factors likely to be related to asthma severity and PICU admission[12]. Differences between the routine patient care, respective guidelines for treatment of asthma, age and other characteristics of the patients complicate the comparisons between these studies.

Our study noted that asthmatic children admitted to PICU were significantly had poor compliance with therapy. This finding is consistent with several studies that have suggested that poor adherence with asthma management predisposes asthma patients to more severe attacks and death[12]. The barriers to adherence to asthma management may be the medications (steroids), the patients, their families, and physicians[27,28].

Previous admission to emergency department, general Ward and PICU admissions were linked to higher hospital readmission in studies by Lasmar et al[16], Visitsumthorn et al[17] and Kargar et al. [14] In the present study, previous admission rate to PICU was higher in group admitted to PICU and the difference was statistically significant (p = 0.0003). After multivariate analysis, 3 risk factors remained significant for PICU admission in children with asthma. These included, longer duration of the disease, use of inhaled corticosteroids, and non-compliance with therapy.

A limitation of the present study is that we used a retrospective study design, with information collected from the medical records. For this reason, several variables could not be analyzed reliably such as quality of the home, and instructions by a specialized nurse.

In conclusion, this study identified duration of asthma, use of inhaled corticosteroids, and non-compliance with therapy as significant risk factors for PICU admission in Saudi children with asthma. Future prospective standardized studies are needed to validate these results. Early identification of children at risk for PICU admission may result in development of preventive strategies, improvement of efficacy of treatment and thus in a reduction of PICU admission for asthma.

Acknowledgment: The authors would like to thank all the staff at the medical record department of Abha Private Hospital, Abha, Saudi Arabia for their help in obtaining the necessary information.

Ethical Clearance: Taken from the ethics committee of Abha Private Hospital, Abha, Saudi Arabia.

Ethical Statement: The material has not been published anywhere. Authors of the manuscript have no financial ties to disclose and have met the ethical adherence.

Disclosure of Interest: The authors declare that they have no competing interests.

Declaration of Authorship: All authors have directly participated in the planning, execution, analysis or reporting of the research paper. All authors have read and approved the final version of the manuscript.

Conflict of Interest: None.

Financial: None.

Understanding the Basics of Research as a Beginner: A Highlighter

Ravishankar M.V.[1], Vidya C.S.[2]

[1]Assistant Professor, [2]Associate Professor,
Dept. of Anatomy JSS Medical College JSS Academy of Higher Education & Research, Mysuru

Abstract

Research has grown beyond leaps and bounds; scientific progress solely depends on inquisitiveness and tireless coordination of teamwork. The word research is so attractive for a beginner, the student fraternity is overwhelmed about this process. Irrespective of any field, now the research is becoming an indispensable part of the educational system. This article is intended to create basic awareness about research and its components, especially for the research-oriented students in the field of medical, paramedical, allied health sciences, etc.

Keywords: *Research, bioethics, clinical trials, good clinical practice.*

Introduction

Biomedical research is based on fundamental biological scientific principles, which will focus on personal healthcare to public health. Basic research is also called as bench side research; it deals with in-vitro and in vivo experimental models involving the organisms or animals to obtain a valid outcome to further try on the humans. When the basic research results are tried on humans/clinical patients it is called translational research, which is solely intended to test the results of basic research from bench side to bedside, clinically by using patients virtually[1].

Research is practiced by humans since the time of evolution on earth. In history, the ancient practice of folklore medicine stands as the best example for the oldest model for clinical research; with the time it has gradually evolved through trial and error method. India is at the forefront of contributing to the field of clinical research; medical science like Ayurveda, Siddha, Unani and their medical literature has mentioned the use of medications for several human ailments for thousands of years. Based on its principles, Ayurveda has mentioned therapeutic interventions, and a number of herbs and mineral formulations, which directly to the human subjects with the sole purpose of alleviating human sufferings[2,3].

Classification of type of study: Basic research: the basic medical research deals with understanding the functional, behavioural or molecular mechanisms in primates through in vivo or invitro studies.

Preclinical research: preclinical research deals with the study on humans, which further supports the clinical trials on patients.

Clinical research: it is conducted on patients in the hospital or on the selected population; it is supervised by physicians.

What is the research question..?: It is the main inquiry of the issue which needs to be addressed through research. The research question should be clear, targeted and simple.

What is a pilot study..?: It is the study performed on a small scale by using a minimum number of participants/subjects. This study gives every opportunity to the researcher/investigator to understand all aspects of

Corresponding Author:

e-mail: vidyacs@jssuni.edu.in

the of the main study in including its feasibility, sample size determination, time duration, troubleshooters, etc.

What are the study parameters..?: Parameters are study exponents in the research; which are later subjected to analysis.

Bioethics: Bioethics deals with the study of ethical dimensions of medicine and biological sciences. Important principles of bioethics are including Autonomy (respect to self-governing), Beneficence (best interest of the subject), Non-maleficence (causing no harm) and Justice (fair treatment)[4]

Basic research in non-human primates: Research on non-human primates is a prerequisite for conducting trials on subsequent levels. Animal experiments mean, the use of animals preferably mammals in the experiments for education and research. The basic experiments use nonhuman primates like rats, mice, rabbits, hamsters, guinea pig, monkey, chimpanzee, dog. It can also be done by using fruit flies, cell lines, fish, etc. There are millions of animals are will be sacrificed worldwide for the sake of research every year. Experiments are performed by using both vertebrates and non-vertebrates, but using the vertebrates will be taken into account as they are under more strict ethical vigilance. For research, all these animals should be procured from the authorized breeders who are registered under CPCSEA (committee for control and supervision of experiments on the animal) guidelines or from the recognized higher research centres.

Importance of animal testing in biomedical research: In the field of biomedical research, the use of the animal model experiments stands as "Hall Mark" of an interventional research study. The great scientists like Aristotle, Erasistratus Galen, etc. have tried their initial experiments on the animals for scientific purposes[5]. Age back, the use of animals got much attention, particularly to test the surgical procedures or use of drugs or devises before applying them clinically to humans. In spite of heavy criticism by the public and the animal protection activists there is a rise in several basic research experiments on animals; because in history, we have learned about the adverse effects of drugs that were used directly on patients. Causing harm to the animals can't justify the human benefit. But still,animal-based research outcome retains its importance in several aspects including, toxicological studies, where the animal experiment model stands as an inevitable tool in supporting the increasing hierarchy of evidence.

In the present situation to justify the rationality and inevitability of the use of animals in the experiments we need to follow principles of 4R.

Replacement: Use of alternate to animal model Ex: in silico i.e. use of computer modeling, in vitro cell line studies, etc.

Reduction: Method which minimizes the number of animals in experiments.

Refinement: It deals with the reduced invasiveness, by adopting improved, non-invasive, non-painful procedures by using the most appropriate method[6].

Rehabilitation: As a 4th component, the rehabilitation of animals will be done after its justified usage[6].

Toxicity study: It is a branch of science deals with the toxins and poisons and their effect and treatment. As per US food and drug administration (FDA),for the development of a new drug entity, it is essential to conduct toxicity tests under basic research models[7].

Trials before regulations: In the olden days, before formulating guidelines for clinical research activities, any individual or group of people would be a part of the research event; it was tried on the helpless community like war prisoners or people who convicted under crime, children, patients, aged people, etc. The direct use of drugs like thalidomide and Elixir Sulfanilamide on humans has resulted in the death of the study participants. Based on such consequences of unethical trials on humans, the present era has formulated a code that is mainly focused on obtaining voluntary consent. By considering the above discrimination in the clinical research, a judgment formulated with a code known as "Nuremberg code" which has streamlined the research at all levels with the sole intention to protect the safety and dignity of the participants to achieve more precise and valid outcome[8].

History of Clinical trials: The credit of clinical research goes to a Scottish physician Dr. James Lind, M.D. (1716–1794) has treated the disorder called scurvy in sailors, where patients were presented with the sign of bleeding through their gums. He has noticed that the administration of the orange and lemon has shown drastic improvement in their condition[9].

Regulations of clinical trials:

Good Clinical Practice (GCP): It is an international ethical and scientific standard protocol for conducting biomedical and behavioral research involving human participants; which protects participants' safety, rights and confidentiality at all levels[10].

International Conference on Harmonization (ICH): It is an international council that bringing together the regulatory authorities and pharmaceutical industry to discuss the technical aspects of drug registration. ICH's regulations are intended to achieve greater harmony worldwide to ensure safety, effectiveness, and quality of medicines; which are developed and registered in a hassle-free manner[11].

Institutional Ethics Committee (IEC): It plays a role in appointing members; it will review the protocol and informed consent forms (ICF), and periodic progress of the study[12]

World medical declaration of Helsinki: It is developed by the World Medical Association (WMA) in the year 1964; it is including ethical guidance for physicians and all other participants in the research team involving in clinical trials on human subjects. This rule binds all the research participants to the applicable law under its declaration[13]

Role of the investigator: All trial investigations are conducted by qualified and trained persons who are personally supervising the work.

Sponsor for trials: The sponsor fora clinical trial may include an individual, anindustry, aninstitution, etc. which takes the responsibility of initiation, management, financing, and auditing. They are also taking the responsibility of subjecting the study participants under sufficient insurance coverage, and compensating the subjects in any untoward incidence or reactions[14].

Role of statistics in research: Since the time of conception of the research protocol, the statistics play an important role to format different components of research like study design, conduct, sample size, data analysis, reporting, etc. they are essential to derive a valid and precise conclusion.

What is the placebo effect..?: Placebo is an inert substance without any therapeutic value; it is used to compare with standard control groups. The psychosomatic profile is an important factor to be considered in assessing the placebo drug response. The placebo effect can be better appreciated in the alleviation of symptoms of the pain rather than any other condition[15].

Clinical Trials: Clinical trials are research study on human subjects, which is intended to evaluate the effect of biomedical interventions like vaccines, drugs, treatments, devices, new ways of using known drugs or to study drug interactions, etc. The study may also include the evaluation of behavioral interventions[16].

The ultimate goal of CT is to ascertain the drug safety on the subject, its risk and benefit ratio before its final approval for marketing. There are many factors involved in research, out of which some are can be controlled, and some others are beyond one's control. Randomization means being nonselective to any application or intervention. Randomization in clinical trials is considered as the basis for the "Evidence-based Medicine"[17].

Blind Experiments: Bias is the main concern of the clinical trials where blinding becomes essential to reduce the bias and increase the validity of the outcome. Blinding is a process where one or the other participants in the study were deliberately kept unaware of intervention. Blinding is an important factor to ensure objectivity in the clinical trial by avoiding or preventing the possible bias in the study[18].

Types of blind trials:

Open clinical trials: it is the trial where all the level of study participants in the research group will be knowing the intervention.

Single-blind study: where the subject alone in the research study is unaware of intervention.

Double-blind study: where the subject, as well as the researcher both, are unaware of the intervention

Triple-blind study: where the subject, researcher, and analyser are unaware of intervention.

At the end of the study result analysis, all masked or blinded interventions will be disclosed.

Protection of subjects: The protection of the clinical trial participants at all levels is an important issue. Concerned authorities should take care of all necessary precautions to address personal, social and legal issues during and after completion of trials. Any relevant issues should be addressed, and it should be

properly compensated for the loss. It is essential to ensure proper compensation for all the study participants who are involved in the clinical trials.

Importance of Informed Consent (IC): Clinical trial participants are strictly volunteer in its true sense without coercing them for any benefit. Informed consent is an important prerequisite before allocating any human subject to the clinical trials. Privacy and confidentially of IC should be maintained in all the circumstances. It is very much essential to know whether the subject is a literate or illiterate, or whether he is fit to give valid consent. The investigator should explain and clarify all the doubts of participants regarding the research protocol before taking consent[19].

Types of clinical trials:

Screening trial: screening for the possibility of occurrence of diseases in a healthy population

Prevention trail: it deals with the prevention of disease by using supplements, vaccines, devices, lifestyle modifications, etc.

Diagnostic trail: it deals with the accuracy of the disease.

Treatment trail: it deals with the effectiveness of treatment in diseased.

Conventionally the CT is having the following phases:

Phase 0: It is an Exploratory Investigational New Drug (IND) Study. It will be conducted first on humans; it is also known as human micro-dosing studies by using the sub-therapeutic dose. It is conducted by using 10-15 numbers of limited volunteer healthy human subjects to understand the pharmacokinetics, pharmacodynamic activity,and safety of a new drug or a molecule.

Phase I or Clinical pharmacology trial: It is also called "First in Man", done in small groups with 20-100 in number in healthy volunteers. It is to assess safety through pharmacovigilance and the details of the pharmacokinetic and pharmacodynamic effects of a drug. Dose escalation trial can give an idea about the appropriate maximum tolerable dose which can be used under subsequent trials.

Phase II or Exploratory Trial: The third phase of the clinical trial can be done in 200-300 number of larger healthy human volunteers. It is done in Phase I A is to assess the clinical efficacy or biological activity, and Phase II B is to assess and match the optimum dose, benefit with minimum side effects

Phase III trial or Confirmatory trial: It is a randomized control multicentric trials in a large number of volunteer patients in a group of 300-3000 or more. Such trials are more expensive, time-consuming and difficult to handle, especially while dealing with chronic disease conditions or disease with a long latency/ incubation period.

Phase IV or Post-marketing surveillance: Called post-marketing surveillance trial. It involves a pharmacovigilance study after receiving permission to market an approved drug. If the drug/treatment is found satisfactory in the above-mentioned initial phases, then it will be approved under the country's national regulatory authority for its use in the general population. Phase IV trials are invariably always under the research radar.[20,21]

Multicentric Clinical Trials: It includes a large number of participants from different parts of the world, including a wide range of populations; which will compare the results of different centers.

Accessibility of clinical trial reports: Accessing clinical trial data or information is an important prerequisite to tackle the challenges before considering them under policy making. Archiving the clinical trial documents is a must, which helps to analyze the data retrospectively in a systematic manner. Now online updates are available on the registered websites which are developed at the national institute of health under the national library of medicine. CT information is always accessible to any common man, through website clinicaltrials.gov and also through Cochrane Library, it is a collection of databases in medicine and other healthcare specialities[22,23]. The ultimate goal of accessing the clinical trial results is to introduce newer government policies and regulations to provide improvised health care facilities for the benefit of the population at large.

Conclusion: This review is solely intended to highlight some aspects of basic, preclinical and clinical research, especially for the student fraternity.

Ethical Clearance: Obtained from Institution ethical committee.

A Study on Cord Blood Zinc Levels with Age and Parity in Sgapregenant Mothers

Archana Rajasundaram[1], S. Jayakumari[1]

[1]Professor, Department of General Medicine, Sree Balaji Medical College & Hospital, Bharath Institute of Higher Education and Research, Chennai

Abstract

Zinc deficiency is one of the most common micronutrient deficiencies in developing countries. Maternal zinc deficiency is associated with fetal growth retardation and other adverse fetal outcomes. The study aimed to determine cord blood zinc level in correlation with age and parity in the term SGA mothers. This is a prospective cross-sectional study conducted in 50 terms SGA babies and their mothers and 50 term AGA babies and their mothers. Maternal and cord blood samples were taken at delivery and zinc was estimated by endpoint nitro PAPS dye binding colorimetric method. Out of 50 study participants in parity of SGA groups, 29 were primigravida and 21 were multigravida mothers. Most of the mothers were having zinc levels ranging from 95.1 to 110 followed by 80.1 to 95. The result shows that there is no statistical significance between cord blood zinc and parity of mothers in the SGA group. Out of 50 study participants in the mode of delivery of SGA groups, 30 were NVD and 20 were LSCS mothers. Most of the mothers were having zinc levels ranging from 95.1 to 110 followed by 80.1 to 95. The zinc levels were seen more than 140 among one NVD mothers. The result shows that there is no statistical significance between cord blood zinc and mode of delivery in SGA groups. Maternal zinc level influences the cord blood zinc level. Cord blood zinc level influences the birth weight of the baby. Thus we conclude that zinc deficiency can also be one of the reasons for low birth weight babies and providing zinc supplementation to the pregnant mothers can be recommended

Keywords: *Zinc, maternal blood, appropriate gestation age, [AGA] small gestation age [SGA].*

Introduction

A trace element is an element that constitutes less than 0.01% of the total body weight. They play a vital role in metabolic processes as they are components of many enzyme systems. Trace element deficiencies are being reported in humans and they have deleterious effects on the health, growth, and development. In trace elements, zinc stands second in order of importance next to iron. It also stands second next to iron in order of abundance in the human body.[1] Zinc plays an important role in early development, both prenatal and postnatal. Thus its basic biochemistry, physiology and its metabolism in the maternal-placental unit and in the neonate have to be discussed to analyze its effects on the neonate. By active transport, zinc is absorbed from the duodenum. Zinc homeostasis is maintained by both uptake and endogenous secretion by the ZIP family [1-5] and ZnT family transporters 6. ZIP-4 is a transporter that is expressed at the luminal side of enterocytes through the small and large intestines.[2] Zinc is exported from enterocytes into the portal blood by zinc transporters 1&2. More than 20% of individuals are zinc deficient worldwide, especially in developing countries. Zinc is needed for the development of the oocyte and the embryo. Acrodermatitis enteropathica is an inherited deficiency of the zinc carrier protein ZIP4 resulting in inadequate zinc absorption. Zinc regulates the expression of metallothionein, which has multiple functions such as intracellular compartmentalization

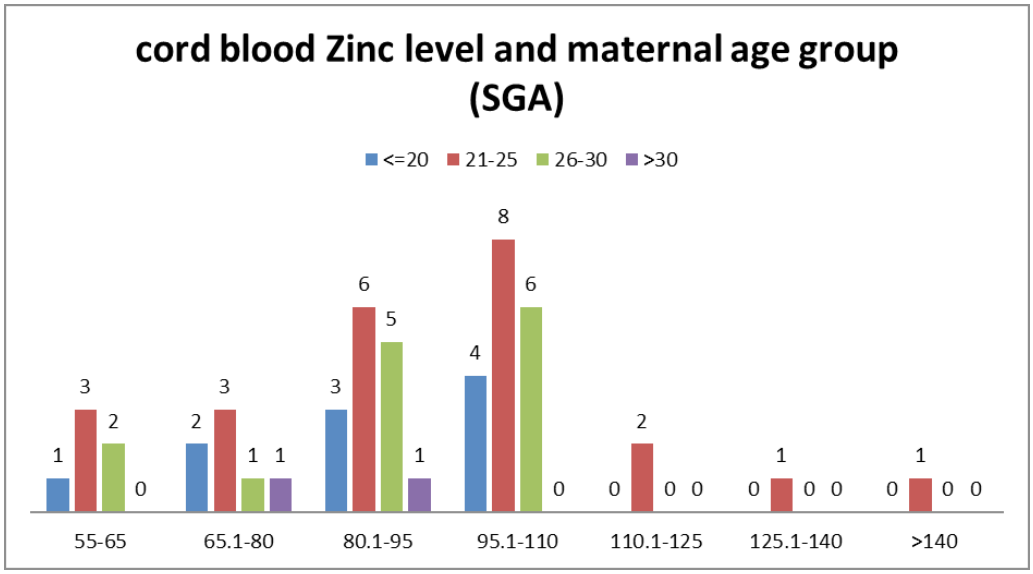
e-mail: archana09@yahoo.com

and antioxidant function.[6-10] Thus zinc deficiency results in impaired growth and development, and disruption of reproductive and immune function. Severe zinc deficiency can result in neural tube defects and other congenital malformations.[3]

Materials and Method



The study included 50 term-small for gestational age neonates and their mothers and 50 term- appropriate for gestational age neonates and their mothers who satisfy the inclusion and exclusion criteria. Detailed maternal history was taken and thorough physical examination of the neonate was done. Birth weight was plotted against gestational age in Lubchenco growth charts to assess if they are small for gestational age or appropriate for gestational age. After obtaining informed consent from the parents, cord blood sample for serum zinc was collected from term-SGA and term-AGA babies and 2ml of blood from the peripheral vein of their mothers immediately after delivery was collected respectively for serum zinc level estimation and sent to our central laboratory.

Stastical Analysis: The data was entered in excel sheet and analyzed using SPSS (Version 16). Descriptive statistics with mean, standard deviation and proportion (%) was calculated for quantitative variables. To test the hypothesis ANOVA, Z test and Chi-Square test was used. a p-value <0.05 was considered as statistically significant. Out of 50 study participants in parity of SGA groups, 29 were primigravida and 21 were multigravida mothers. Most of the mothers were having zinc levels ranging from 95.1 to 110 followed by 80.1 to 95. The result shows that there is no statistical significance between cord blood zinc and parity of mothers in the SGA group.

Graph 1: Cord blood zinc levels and parity

Among the 50 study participants of SGA groups, 10, 24, 14 and 2 were belonging to less than 20, 21 to 25, 26 to 30 and more than 30 years of maternal age respectively. In the majority of maternal age group, the zinc level was ranging from 95.1 to 110. The result shows that there is no statistical significance between cord blood zinc and maternal age in the SGA group.

Graph 2: Cord blood zinc level and maternal age group

Discussion

Birth weight is the vital factor of perinatal and neonatal outcome. A newborn baby weighing less than 2.5 kg at birth irrespective of the gestational age is termed as a low birth weight baby. Low birth weight babies can be term SGA or preterm babies. While a lot of importance is being given to protein and energy deficits, micronutrients other than iron are often forgotten. It has been argued that micronutrient deficiency during pregnancy can lead to LBW. [4] In particular zinc deficiency is associated with abnormal conditions during pregnancy including congenital malformation (anencephaly) and abortion. Though zinc is needed only in small quantity, they have several vital functions in our human body. As their requirements are small, their adequacy have to be checked carefully and moreover many of the trace elements have interactions with each other.[5] Thus their needs have to be adequately met with a concern over their interactions and toxicity. Among several micronutrients, iron stands first whose importance have been extensively studied and practiced. Next lies zinc whose importance is slowly brought in to light by several research trials and studies. Hence this study of serum zinc levels in the cord blood of term SGA babies & their mothers and term AGA babies & their mothers was done. In our study, The mean maternal age in AGA was 24.22 and in SGA was 23.88 Which shows that there is no statistical significance in the maternal age between AGA and SGA groups.[6] In a study the maternal age of the control and cases were comparable. The average age of controls was 27.54 and that of cases was 27.5. Thus the two groups were well matched in this study. Thus the mean maternal age in the two groups were comparable similar to the study conducted by Benjamin W et al.[7] In our study The primiparous mother was 46% and 58% in AGA and SGA respectively, whereas in multiparous it was 54% and 42% in AGA and SGA respectively which shows that there is no statistical significance in the parity of mother between AGA and SGA groups which was similar to the study done by Christine A et al. [8]In our study, The LSCS were 42% and NVD was 58% in our study which was not similar to a study conducted by Ronald E et al were the LSCS were 54% and NVD was 46%.[9,10]

Conclusion

It was found that cord blood zinc levels were low in term SGA babies when compared to term AGA babies. There was also low maternal zinc levels in the term SGA babies when compared to mothers of term AGA babies.

In Vivo Effect of Levan Purified from Leuconostoc Mesenteroides ssp. Cremoris Against Candida Albicans

Adnan Yaas Khudair[1], Hamzia Ali Ajah[1], Jehan Abdul Sattar Salman[1]

[1]*Department of Biology, College of Sciences, Mustansiriyah University, Baghdad, Iraq*

Abstract

Toxicity of levan purified from *Leuconostoc mesenteroides* ssp. *cremoris* on mice was studied, and observed that no death of mice was recorded at 100 mg/ml, also antagonistic activity of levan against *C. albicans In vivo* was determined with histological study on small intestine and liver tissue of mice, and the results showed that the levan had the ability to treat the infected tissue with *C. albicans* also had less damage to the tissue compared with the fluconazole.

Keywords: *Levan polymer, Leuconostoc mesenteroides, Candida albicans, Toxicity, Histological study.*

Introduction

Candida is a genus of yeasts that is considered the most common cause of fungal infections worldwide [1]. Many species, including *Candida albicans,* are found in gut flora, oral cavity and vagina in mammalian hosts, whereas others live as endosymbionts in insect hosts [2,3,4]. *Candida* spp. are commensal in healthy humans and may cause systemic infections in immunocompromised patients due to their great adaptability to different host niches [5]. The pathogenicity of *Candida* species is attributed to certain virulence factors, such as the ability to evade host defenses, biofilm formation (on medical devices and on host tissue), adherence and the production of tissue – damaging hydrolytic enzymes such as phospholipases, proteases and haemolysin [6].

Levan is a homopolysaccharide which is composed of D-fructofuranosyl residues joined β -2,6 [7]. Levan is naturally obtained from both microorganisms and plants [8]. Microbial levans are more advantageous, industrially and economical with numerous applications [9]. Bacterial levans are much larger than those produced by plants with multiple branches and molecular weights ranging from 2 to 100 million Da [8].Synthesis of levan is catalyzed by a group of enzymes referred to as levansucrases using sucrose as a substrate [10, 11]. Microbial levans have wide range of applications in food, pharmaceutical, medicine, commercial industrial and cosmetic [12]. Some microbial levan exhibit biological activities such as antitumor, immunostimulating and antidiabetic activities [13].

Materials and Method

***Leuconostoc mesenteroides* ssp. *cremoris* isolate:** *Leuconostoc mesenteroides* ssp. *cremoris* was isolated from local fish intestine then identified throughout cultural, microscopical and biochemical tests according to [14] and Vitek 2 system.

***Candida albicans* isolates:** Fourteen *Candida albicans* isolates were obtained from oral and vaginal swabs. All isolates were subjected to the cultural, microscopical and biochemical tests [15] as well as Vitek 2 system.

Production and purification of Levan from *L.mesenteroides* ssp. *cremoris:* This process was done according to the procedure described by [16], 250ml Erlenmeyer flasks containing 100 ml of levan production medium was inoculated with 2% of *L. mesenteroides* ssp. *cremoris* (LF_5) suspension containing (9×10^8 cfu/ml) (compared to 0.5ml of McFarland standard absorbance at a wavelength of 600 nm about 0.134), incubated at 30ºC for 24 h. After incubation the culture were centrifuged at 10000 rpm for 10 min the supernatant was used for precipitation of levan by adding 1.5 volumes ice – cold ethanol. The precipitated pellets were washed twice by distilled water and collected by centrifugation at 10000 rpm for 10 min. The levan dry weight determined after oven - drying at 110ºC for 24h.

The precipitated levan polymer was resuspended in demineralized water at 4ºC during 16 h and then dialysis

(MWCO 14,000 Da) overnight against demineralized water. The polymer was precipitated with 2 volumes of 96 % ice - cold ethanol, centrifuged for 10 min at 10.000 rpm [17], then the purified levan was dried at (40-45ºC).

Investigation of levan toxicity *In vivo:* Twelve healthy mice were administered 1 ml of levan (100 mg/ml) via gastric for 30 days.

Antagonistic activity of levan against *C. albicans* *In vivo:* Fifteen male albino mice aged 8-12 weeks, weighing 20-28 g were obtained from National Center for Drug Control and Research, Baghdad, Iraq, housed under standard conditions in the animal house of biology department in the College of science, AL-Mustansyriah University. Nine mice were injected, for three days with dexamethasone 2.5 mg/kg/day intramuscularly [18], also nine mice were infected by being injected with 0.1 ml of *C. albicans* (CO_2) that contain (1.5×10^8) yeast/ml intraperitoneally. After three days, all mice were divided in to five groups each group consist of 3 mice, each group was inoculated as a follows:

Group 1 (non - infected and non - immunological suppression): inoculated orally by gastric tube with (0.1 ml/day) of normal saline for 14 days considered as negative control group.

Group 2 (infected): inoculated orally by gastric tube with (0. 1 ml/day) of normal saline for 14 days considered as positive control group.

Group 3 (non infected): inoculated orally by gastric tube with levan (0.2ml/day) that contain 100 mg/ml for 14 days considered as levan control group.

Group 4 (infected): inoculated orally by gastric tube with levan (0.2 ml/day) that contain 100 mg/ml for 14 days considered as treatment group.

Group 5 (infected): inoculated orally by gastric tube with Fluconazole drug 10mg/kg body weight for 14 days considered as fluconazole treatment group.

Histological study: Liver and small intestine of mice were removed and fixed in 10% formalin. The fixed organs were dehydrated and sectioned by microtome and stained with Hematoxylin and Eosin for studying histopathological changes [19].

Results and Discussion

Investigation of levan toxicity *In vivo:* The results showed that no death of mice was recorded after 30 days, and showed no toxicity of levan. This result encourages to use of levan as a treatment.

Histological Study: The results of histological sections, small intestine and liver tissues taken from immunosuppressed mice that infected with *C. albicans* and treated with purified levan produced from *L. mesenteroides ssp. cremoris* (LF5), the negative control of intestine tissue which administrated with normal saline only showed normal appearance of tissue, villi and epithelial cells (Figures 1).

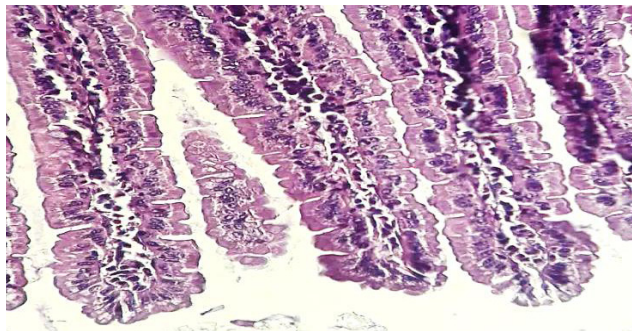

Figure 1: Small intestine section for non - infected mice tissue shows the normal intestine structure, villi and epithelial cells (H&E. 40X).

While in control positive group that administrated with *C. albicans* only, intestinal tissue section shows infiltration of lymphocyte, and damage in villi (Figure 2).

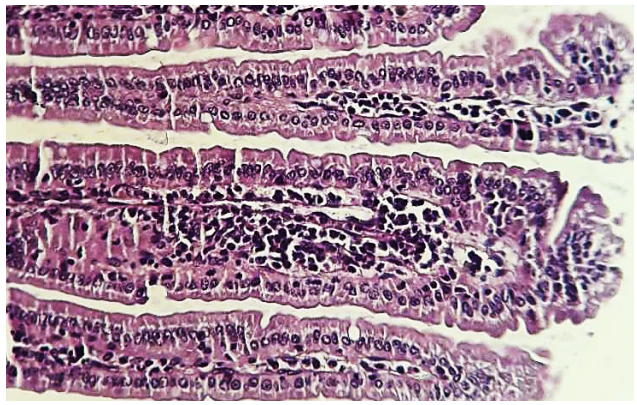

Figure 2: Section in intestinal infected mice showing infiltration of lymphocyte and damage in villi (H&E. 40X).

In levan treatment group intestine tissue with levan administration only, intestine sections showing increasing in goblet cell (Figure 3)

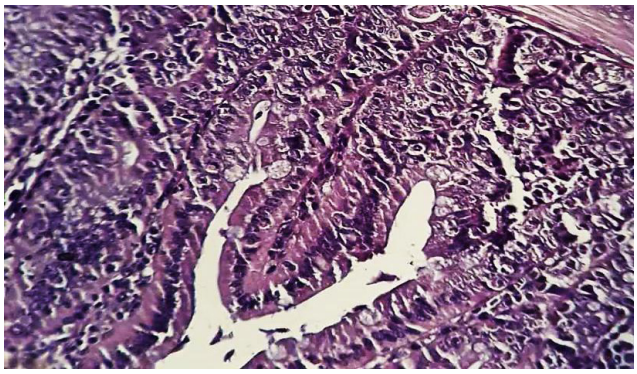

Figure 3: Section in small intestine non infected mice treated with levan after 14th day showing increasing in goblet cell (H&E. 40X).

Whereas the intestinal positive results of infected mice with *C. albicans* treated with levan showed normal structure with increasing in goblet cells (Figure 4).

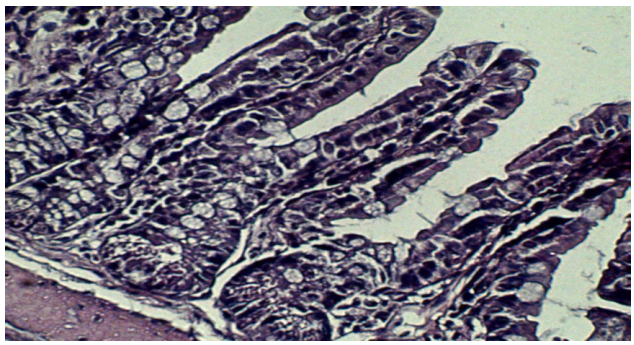

Figure 4: Section in intestine infected with *C. albicans* mice treated with levan after 14th day showing normal structure with increasing in goblet cells (H&E. 40X).

While in the intestinal positive results of infected mice treated with fluconazole showed shorting in villi and infiltration of lymphocyte (Figure 5).

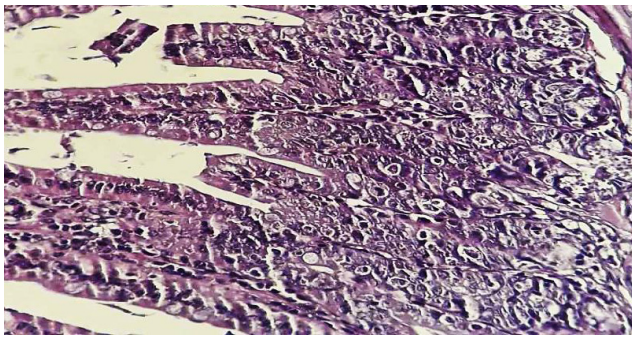

Figure 5: Section in intestine infected mice with *C. albicans* treated with fluconazole after 14th day showing shorting in villi and infiltration of lymphocyte ‹ (H&E, 40X).

On the other hand, the negative control of liver tissue which administrated with normal saline only shows normal appearance of tissue, hepatocytes, central vein and sinusoids (Figures 6).

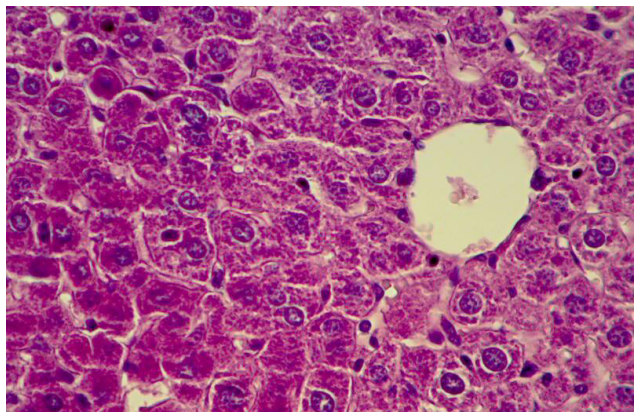

Figure 6: Liver section shows the normal liver structure for non - infected mice tissue, show hepatocytes, central vein and sinusoids (H&E, 40X)

While in control positive group that administrated with *C. albicans* only, liver tissue section shows infiltration of lymphocyte, reduced of glycoprotein and hemorrhage

In levan treatment group liver tissue with levan administration only, liver sections showing hydropic degeneration, depletion of glycogen. While in the liver positive results of infected group that treated with levan showed approximately repair tissue with few infiltration of lymphocyte and reduced of glycoprotein. Whereas in the liver positive results of infected mice treated with fluconazole showed aggregation of lymphocyte and fatty changes.

The effects of *C. albicans* invasion on its intestinal epithelial cells include cellular necrosis, apoptosis and pyroptosis. De Repentigny *et al*.[20] reported that the ability of *C. albicans* to cause lysis of microvilli and then progressive invasion of villi in the small intestine. Tong and Tang [21] showed that *C. albicans* had regulatory role in intestinal polymorphonuclear leukocytes. Han *et al*. [22] used polysaccharides produced from Acanthopanax senticosus in preventing *Escherichia coli* lipopolysaccharide in the intestinal mucosal barrier and found that the intestinal mucus layers were improved by the polysaccharides, this observation also explain the distinct protective role of polysaccharides against injurious agents via promoting the formation of viscoelastic gel overlying the mucosa due to secretions of goblet cells. Hepatosplenic candidiasis may be

caused by *Candida* species, including *C. albicans* and *C. tropicans*, through candidemia or the portal vasculature from the gut with degenerated barriers of gastrointestinal mucosa[23]. Coash *et al*.[24] explained that hepatic candidiasis is characterized by granulomas with suppurative central areas containing variable necrosis and giant cells. Zwolińska- Wcisło *et al*. [25] mentioned that the fungal colonization of gastrointestinal tract in mice can be attenuated by probiotic therapy. Mohamed *et al*.[26] reported that the ability of *C. albicans* to cause clinical pathological effect in mice tissue organs (liver, intestine, stomach, kidney) can be reduced by administration of *Lactobacillus acidophilus*. Soliman *et al*.[27] had been studied the therapeutic effect of chitosan against invasive candidiasis in mice and found that the liver sections of control and chitosan groups showed normal histological structures. Leão *et al*.[28] reported that the mice consumed probiotics and infected with candidiasis had lower histological and inflammatory infiltrates compared with candidiasis infected mice.

Conclusion

Levan purified from locally isolated *Leuconostoc mesenteroides* ssp. *cremoris* had inhibitory effects on the *C. albicans* isolates *in vivo* with no toxicity effects on mice and no damage on liver and intestinal tissues compared with the fluconazole.

Immediate Effects of Self-Manual Therapy and Supervised Manual Therapy in Individuals with Knee Osteoarthritis

Cheawthamai Kornkamon[1], Kuwiboonsilp Wanitcha[2]

[1]Lecturer, Faculty of Physical Therapy, Saint Louis College, Bangkok, Thailand, [2]Lecturer, Faculty of Physical Therapy, Saint Louis College, South Sathorn Road, Yannawa, Sathorn, Bangkok 10120, Thailand

Abstract

Background and Objective: Knee osteoarthritis is the degenerative disease that leads to pain, impaired mobility, poor function and frequent absence from work. The self-manual therapy affects to decrease pain and improve knee motions. However, the evidence of the different of the self-manual therapy and supervised manual therapy is lacking. This study aimed to compare the immediate effects of self-manual therapy with and without supervised manual therapy in individuals with knee osteoarthritis.

Materials and Method: Twenty four participants with knee osteoarthritis were randomly assigned into three groups; self-manual therapy group (n=8; 2 men and 6 women [age 74.00 ± 10.82 years]) PT manual therapy group (n=8; 2 men and 6 women [age72.25 ± 10.75years]) and control group (n=8; 8 women [age73.25 ± 8.84 years]). The participants were received self-manual therapy or physical therapist's manual therapy. Repeated measures ANOVA were used to determine effects for pressure pain threshold, knee range of motion and time up and go within group and between groups.

Results: These results showed that the self-manual therapy group significantly decreased pain after treatment. The PT manual therapy group showed significantly decrease pain and improves knee flexion and extension. No significant differences. There was no significant different in time up and go.

Conclusion: The self-manual therapy is an alternative treatment for pain reduction in individuals with knee OA. However, the PT manual therapy had superior benefits in improving knee range of motions.

Introduction

Knee osteoarthritis (knee OA) is one of the most common rheumatic disease as reported in the community Oriented Program for Control of Rheumatic Disorder (COPCORD) world studies[1]. It was especially higher prevalence in Asia region both rural and urban areas[2]. Knee OA affects all structures within joint, characterized by inflammation in the synovium and the cartilages. It contributes to the progressive loss of articular cartilage, subchondral bone remodeling or osteophytes, capsular stretching, weakness of periarticular muscles, synovitis and ligament laxity[3]. These pathological changes lead to pain, impaired mobility, poor function and activity daily living example walking, stairs climbing[4]. Physiotherapy is the one management for knee OA which aims to improve patient's understanding about their disease and self-management capacities as well as to enhance the muscle performance and joint movement[5]. In a survey study, the physical therapist utilized exercise program, electrotherapeutic modalities, acupuncture and manual therapy[6]. Supervised manual therapy affects to decrease pain and improve knee function[7,8]. However, patients have limited accessibility to receive the physical

therapy such as the treatment cost and transportations. The previous study showed the effectiveness of self-manual therapy for home-based exercise in knee OA. It affects to decrease pain and increase knee motions[9]. The evidence of the different of the self-manual therapy and supervised manual therapy is lacking. Therefore, the purpose of this study was to determine the immediate effects of self-manual therapy and supervised manual therapy in individuals with knee osteoarthritis.

Material and Method

Thai participants from Ban Bang Khae Social Welfare Development Center for Older Persons, Bangkok Thailand with a diagnosis of knee OA based on the clinical criteria of the American College of Rheumatology[10]. The participants were able to walk in their daily living with or without aid. They were able to communicate and follow the orders. They were excluded if they had rheumatoid gout or other systemic joint disease cerebrovascular conditions such as acute or recurrent myocardial infarction unstable angina pectoris neurological conditions such as Parkinson's disease undergone knee surgery corticosteroid injection to the knee within previous thirty days and an injury or accident at back and lower limbs within previous six weeks. Ethical approval was received by Saint Louis College Ethics Review Committee for Research involving Human project (E. 021/2557).

Twenty-four participants were randomized into three groups: self-manual therapy group Physical therapist manual therapy group (PT manual therapy group) and control group using sealed envelopes. Then participants were received the clinical examination (palpation at soft tissues around knee joint knee range of motion and passive accessory movement of tibiofemoral and patellofemoral joint) and education about knee OA (pathology signs and symptoms and exercise program). The clinical examination results that limited or reproduced symptoms were used to guide the manual therapy instruction. The self-manual therapy group received manual therapy that consisted of joint mobilizations applied primarily to the patellofemoral and/or tibiofemoral joints and soft tissue massage[9], according to the results of clinical examination. The participants were taught from the physical therapist with handout and video then practiced until they could perform correctly. They were rechecked the manual therapy skill and knowledge before they treated by themselves. The PT manual therapy group received the same manual therapy by physical therapist. The manual therapy intensity (mobilization grade and repetitions) were determined according to the participant's tolerance, severity of joint limitation and soft tissue tightness of each participant. The control group received education about knee OA disease and home-based exercise program (active ROM exercise, muscle strengthening and muscle stretching)

Pressure pain threshold (PPT) was measured using digital pressure algometer in side lying position[11,12]. The PPT was measured on the worse side of knee, if they had problem in both knees. Participants were instructed to mark the level of pain that they had experienced the most. The PPT was measured twice, and the average degrees were used. Knee range of motion (knee ROM) was measured by active knee flexion and extension using goniometer with the participants in supine position[13]. The angles were measured twice, and the average degrees were used. The ROM was recorded at the end point of movement when ROM was limited by pain or tightness of the soft tissues. Functional activity was measured by time up and go test (TUG)[14,15]. The TUG was recorded sit to stand time and total time. The outcome measurements were measured before and after treatment by the same evaluator.

Data were analyzed, using SPSS for Windows program. The scores were assessed for between-group differences in the change of before and after outcome measures (PPT knee ROM TUG-sit to stand and TUG-total). Komogorov-Smirnov Goodness of Fit test was used to analyze the distribution of the data. Repeated measures ANOVA were used to determine the difference among all data. The mean differences (MD) between and within groups were also undertaken using the Bonferonni's correction test. The significance level was set at 0.05.

Results

Twenty four participants with knee OA were included and randomly assigned to a self-manual therapy group (n = 8) or PT manual therapy group (n = 8) or control group (n=8) by drawing a sealed envelopes. Forty-three participants completed the present study. No differences were observed between groups in ages, gender, BMI, and side of pain at baseline. The primary and secondary outcome score within and between group are shown in Table 1. PPT, knee flexion and knee extension showed significant difference between

before and after treatment (p=0.004, p=0.038, p=0.008 respectively). No significant different was found in time up and go between before and after treatment (p=636 and p=0.732 respectively).

The ANOVA repeated measures with Bonferroni post hoc test showed a significant increased PPT in self-manual therapy group (p=0.004) and PT manual therapy group (p=0.005) compared to control group (Figure 1), but there was not significant differences between self-manual therapy group compared to PT manual therapy group (p=0.753). For knee flexion, a significant effect was present for PT manual therapy group (p=0.018) compared to control group (Figure 2), but there was not present for self-manual therapy group (p=0.090). For knee extension, a difference was shown for PT manual therapy group compared to control group (p = 0.006) and self-manual therapy group (p=0.015) (Figure 3). No significant different was found in time up and go between groups (Figure 4 and Figure 5)

Discussion

In this study, the patients with knee OA who received both self-manual therapy and PT manual therapy had immediately decreased pain. However, patients who received only PT manual therapy showed immediately knee range of motions improvement. These results implied that the PT manual therapy group had only superior effects on knee extension improvement.

The manual therapy consisted of patellofemoral joint and tibiofemoral joint mobilization and soft

tissue massage. This finding supports other studies that knee mobilization could eliminate pain. A meta-analysis of RCT found that exercise therapy with manual mobilization had more effect size on pain than exercise alone (combination of strength training with active range of motion exercises and aerobic activity) or strength training[16]. The previous study combined knee mobilization with conventional physiotherapy that consisted of the thermal therapy with hot pack and same exercise program of this study, found 44% pain reduction with VAS scale[17]. Pain reduction following joint mobilization might complement more widespread hypoalgesic effects[18]. The mobilization may initiate local neurophysiological and peripheral mechanism to work optimally then the biomechanic forces in both intra-articular and periarticular tissues were adapted[19]. However, the psychological factors may also be involved[20].

Improvement of knee joint motion especially knee extension following PT manual therapy was shown in this study. The mechanical strain applied during soft tissue massage oriented in all directions of muscle fibers and several planes could rearrange bundles of connective tissues which aid in the remodeling of immature and weak scar tissue[21]. The passive mobilization mechanism is well known[22]. Therefore the soft tissue massage and joint mobilization was used to increase joint flexibility. However, we did not show any significant increased knee motions in self-manual therapy group. We suggest that our manual therapy intervention program could be done longer. Cheawthamai et al. found that the patients with knee OA in the self-manual therapy group gradually increased knee flexion and extension at 4 and 12 weeks[9].

This study showed no significant differences in TUG. The previous study found increase physical activity in six minute walk at 4 and 12 weeks[9]. Deyle et al demonstrated the six minute walk at 4 weeks but no significant change at 8 weeks[23]. Difficulty in performing physical activity in individual with knee OA can be attributed by many factors such as quadriceps inhibitor, obesity, knee laxity, knee alignment, fear of physical activity and self-efficacy[24]. Therefore these factors could not be changed immediately. The intramuscular adaptation gained in strength was obtained after 12 weeks of resistant exercise training[25].

The benefits of treatment in the present study were achieved immediately after treatment procedures. Most previous studies have also demonstrated in 6-8 treatment sessions over 3-4 weeks[7,9,17,23.] Moreover, this study is the first study that determined the effects self-manual therapy compared to supervised manual therapy. However, the physical therapist still play important role for individually assessing the impairments, assigning the treatment program and adjusting the intensity, frequency of the treatment procedures. Thus, this active treatment is an easier and effective alternative treatment for pain reduction in individuals with knee OA.

While these results provide important self-manual therapy for knee osteoarthritis, they should be interpreted with respect to several limitations. First, the larger study populations and long term study are needed in the future study. Second, the ages of our participants were more than seventy years old. This variable might lead to differences of the improvement in pain, knee range of motion and functional activity.

Conclusion

In conclusion, our results showed that the self-manual therapy immediately reduced pain in patients with knee OA. However, the supervised manual therapy had a greater effect in knee motions improvement.

Abstract

In this research, we have to study some vital variables in the blood, in order to determine the status of the college where we sought samples of people who are used to filtered water as well as samples of male people used to non-filtered water and comparing these results in one area are the village of Bishcan. This study showed a change in results as we found a significant increase ($p \leq 0.05$) of the level of both sodium and potassium in the people who use the ordinary water compared to people who drink the filtered water, and there was no significant increase ($p \leq 0.05$) in the level of the creatinine and uric acid compared to control group, there was no significant decrease in urea level ($p \leq 0.05$), when comparing the control group in the people who use unfiltered water compared with those who drink water filtered.

Keywords: *Chronic Kidney Disease, potassium, sodium, creatinine, Urea, Uric acid.*

Introduction

Characterized contamination as any substance or vitality acquainted with the earth by human exercises that could effect sly affect human wellbeing, harm living assets, and biological systems, condition. Decimate the structure, or meddle with the real utilization of the environmental [1]. Environmental wellsprings of lead introduction incorporate water from lead funnels (normal in homes worked before 1986). What is more, sullying of air, soil, and water in regions near lead smelters, old mines, or carports [2]. The majority of the synthetic concoctions created by man will, in the long run, end up in our water supplies. These perilous items from industry, agribusiness and other human exercises enter the waterways, lakes, and underground water, and can debase our drinking water. Water contamination is a worldwide concern. New water specifically, which is Resource basic to human life, is turning into a constrained asset because of the impact [3]. The populace of development, contamination and worldwide. Ecological lead danger happens basically through ingestion, in spite of the fact that introduction can likewise happen through tobacco smoke. Lead flows in the blood and can either be discharged by the kidneys or can store in the bone[4]. Affected people gave weakness, extreme bone agony and osteomalacia, and kidney danger including decreased kidney work and eventually passing owing to kidney disappointment [5]. Natural wellsprings of arsenic incorporate groundwater, pesticides (by causing sustenance pollution), fish [6]. High drinking water arsenic levels have been related to expanded mortality from CKD [7]. Arsenic dimensions in serum and platelets correspond with declining kidney malady[8].With the improvement and movement of CKD credited to arsenic-incited oxidative pressure [9]. There is clashing proof of nephrotoxicity auxiliary to dental amalgam White. It is sifted by the glomerulus and reabsorbed in the proximal tangled tubules, bringing about cylindrical danger with low sub-atomic weight proteinuria and enzymuria[10]. Introduction to uranium is for the most part oral, through groundwater and nourishment, albeit dermal presentation has been accounted for kids playing in sullied zones. Concentrates in occupationally uncovered populaces have likewise revealed aminoaciduria and low atomic weight proteinuria.The point of this investigation is to decide the connection between contaminant drinking

water and its effect on human wellbeing. Incessant kidney infection (CKD) is an overall general medical issue, and it is getting expanded worldwide consideration in view of the quick spread of the illness. Maturing, diabetes, hypertension and nephrotoxic medications use are known to be essential hazard factors for CKD. Be that as it may, CKD of obscure etiology (in the future CKD) is additionally common and quickly advancing in certain areas of the world outstandingly in Africa, Central America, and Asia [11]. The term ''obscure etiology'' alludes, in light of the fact that the sickness isn't related with any realized hazard factors. If not appropriately treated, CKD can prompt end-organize renal sickness and frequently demise[12].

Material and method

The study: The study took two groups.The first group is the control group that took persons who drink distilled water (water with filter) while the second group is a testing group that took persons who drink river water(water without filter).

Sampling: Around 5 ml of venous blood were pulled back from people (patients and controls), utilizing an expendable syringe. The gathered blood was then permitted to clump in a plain cylinder at room temperature, after which the serum was isolated by centrifugation at 3000 rpm for 10 minutes. Every serum test was gathered in numerous compartments to limit wrong outcomes from solidifying and defrosting, serum was kept solidified at - 20 °C to be examined later on.

Data Collection: The samples collected according to up to 30 samples, to person males only, who drink filter water and others who drink non-filter water and their ages ranged aging between (18 to 38) years old.

Biochemical measurements: A number of equipment were used to biochemical measurements, and some of the chemical materials were prepared, Determination of sodium concentration, and Determination of potassium concentration, creatinine, urea, uric acid in blood serum.

Results

The aftereffects of the investigation Showed a huge increment in the potassium, sodium, and no significant increase in level the creatinine and uric acid compare to control group but the urea no significant decrease in the result (test group) compare with the control group. The following table shows the biometrics of this study:

Tests	Control Group	Test Group
Potassium	9.1300 ± 1.75756 a	12.6900 ±3.28344 b
Sodium	145.2800 ± 8.54132 a	158.4600 ± 11.64085 b
Creatinine	0.8000 ± 0.42164 a	1.0700 ± 0.29078 a
Urea	28.7600 ± 7.54132 a	24.8200 ± 5.75013 a
Uric Acid	5.7700 ± 0.84334 a	6.5400 ± 0.93714 a

The table shows the biological variables studied in the present study: The Horizontal different letters mean a significant difference or difference at the probability level of $p \leq 0.05$, the above values refer to the mean ± standard deviation.

Discussion

The outcomes appeared in the table demonstrate a huge increment in the level of sodium in the serum of people using normal water (non-filter) in drinking compared with people who drink filtered water and from the same area and the reason that there is a rise in the proportion of salts in water taken, High sodium blood . And because salt has an effect on the target organs, especially the kidneys because it leads to decreased nephrons in the kidney and leads to chronic kidney failure[13].

Raise the rate of chloride salt in water from allowable level more than (250 mg/l) its have conjugate with increasing of sodium rate in blood,sodium is one of the factors that forming kidney stones, because the salt has an effect on the target organs, especially the kidney due to lead to a decrease in the nephron of the kidney and lead to chronic kidney failure [13].

The consequences of the present examination demonstrated a noteworthy increment in the potassium level in the serum of people who use normal drinking water in the region compared to people who use filtered water due to the role of the kidney in the release of approximately 90-95% of potassium within the body when chronic renal insufficiency The efficiency of this process decreases. This is consistent with the two researchers, Excessive Potassium can occur in the blood due to the utilization of an excessive amount of Potassium salt and kidney inability to discharge the Potassium

particles in the pee and the spillage of Potassium from the cells and tissues into the circulatory system. The most common cause of Potassium hyperactivity is renal diseases which is about three quarters of all cases[14].

The examination demonstrated that there was a no huge increment in creatinine focus in the serum of individuals who drink ordinary water contrasted and individuals who drink sifted water. This expansion demonstrates that they are in danger of kidney disappointment. This is steady with specialists [15, 16, 17]. The purpose behind the expansion in creatinine in the serum to the way that creatinine of the metabolic waste that is raised normally with the pee of the kidneys and on account of kidney lack gets a kidney issue keeps them from the selection and the dumping of waste builds the grouping of creatinine in the blood and is conversely relative to the speed of glomerular filtration decay Simple J GFR prompts expanded centralization of serum creatinine[18, 19].The damage of renal lead to expanded convergence of serum creatinine and embrace this increment and the speed of progress in the blood on the seriousness of the complete damage and speed of development of creatinine[20].

The study showed that there was no huge increment in the dimension of uric acid, and may increase in cases of taking more than the samples and wider ages, because the height was very acidic but did not appear in the statistical analysis may be due to the high level of serum uric acid to Because this compound is a metabolic product that is introduced by the kidneys with the urine and if kidney failure occurs (kidney failure), a defect occurs in putting the compound out with the urine leading to an increase in blood. As renal injury increases the concentration of uric acid in the blood and depends on the increase and rapid change in the blood on the severity of the kidney injury unit and the speed of the formation of uric acid [20].

The outcomes appeared in the table demonstrate a no noteworthy reduction in urea focus in the serum, which is an impression of the aftereffects of examination[21]. The reason is that urea is the essential nitrogenous material of the metabolic waste, which is for the most part framed in the liver from the proteins, With urine, and that the increase or decrease in the proportion of urea depends on the condition of the kidney and the rate of intake of proteins and the rate of compensation, the low intake of protein may lead to a decrease in the proportion of urea.

The presence of heterogeneity in some of the results may be because the samples taken were for small ages less than 38 years This means that the kidneys, even if they are damaged, are still in the case of helping to regulate some of the products, which explains why the urea is low as well as the rise in creatinine Is large enough to prove that there is renal failure but these are at risk of kidney failure.

Conclusion

My study concluded then water without filter possess effects on the kidney for persons who drinking this water due to the changing in the tests by increasing in this tests from persons who drinking water with filter except the urea test is oppositely from them is decreasing.

ABSTRACT

Aim: To determine the effect of Eugenol based temporary cements on bond strength of RMGIC and RelyX ARC.

Materials and Method: A total of fortymolars were sectioned 3mm below the occlusal surface and roughened surface was smoothened by 60-grit sand paper. Zinc oxide eugenol was given as a temporary restoration for 20 molars and the rest were not exposed to eugenol. Zinc oxide eugenol was removed using ultrasonic scaler and viewed under magnification for precise removal.20 molars not exposed to eugenol were divided into group 1 (RMGIC) and group 3 (Resin).Other 20 teeth which were exposed to Eugenol were also divided similary into group 2(Eugenol+RMGIC) and group 4 (Eugenol+Resin).Shear bond strength(SBS) testing was done using knife edge blade in the universal testing machine(INSTRON) at CIPET in Chennai.

Results: On comparing Shear Bond Strength using t-test, no statistical significance ($p>0.05$) was found between RMGIC groups whereas between Resin groups statistical significance was found.

Conclusion: When ZOE was used as temporary cement there was a decrease in shear bond strength for resin cement but no difference was observed in RMGIC groups.

Keywords: *Shear bond strength, Eugenol, Polymerization, Chemical polyalkonate- hydroxyapatite bonding, Micromechanical interlocking.*

Introduction

Luting cementsseal the space between the tooth and the restoration[1]. Their basic requirements of luting cements include: not deleterious to tooth or oral tissues, adequate working time to place the restoration, enough flow to seat the restoration completely, able to resist functional forces, radiopacity, and should be insoluble to maintain an intact seal[2]. Provisionalization prior to final cementation is necessary to avoid sensitivity and micromovements [3]. Temporary cements are of Eugenol and non-Eugenol based.Eugenol containing cements have sedative effect on sensitive teeth, low cost,ease of removal and excellent seal against leakage [4]. The use of eugenol containing temporary cements might affect the quality of bonding [5].Commonlyused luting cements are Zinc phosphate, Zinc polyarboxylate, GIC, RMGIC and Resin cement [6].Resin cements are used in a diversity of clinical applications. With the inclusion of resin monomer to GIC, RMGIC is proven to have improved mechanical and physical properties when compared with conventional GIC[7].RMGIC shows better cohesive strength and lower modulus of elasticity

than conventional GIC[8].RMGIC powder contains fluoroalumina glass particles,photo and chemical initiators and liquid contains polyacrylic acid with pendent methacrylate group with 10% HEMA.. The basic composition of self–etch adhesives is aqueous solution of acidic functional monomers, with a pH higher than that of phosphoric acid etchants. The role of water provides medium for ionization and action of these acidic resin monomers. Self-etch adhesive systems also contain HEMA monomer because most of the acidic monomers are low water-soluble and also to increase the wettability of dentin surface. Resin cements are preferred because it has superior compressive and tensile strength with low solubility[9]. These cements have higher capacity of adhesion and stability after aging process which helps to bind metal oxides. Hence, these luting cements have some advantages when used for final cementation due to its physical characteristics such as insolubility in oral fluids, high bond strength to dentin and enamel, thin cement film and good esthetics. Clinical success of all ceramic crowns are influenced by the type of luting agent and the technique for definitive cementation. The main parameter to be considered is adequate adhesion between the crown and the tooth structure through the luting cement. Hence better retention and marginal adaptation that prevents microleakage and increased fracture resistance is obtained by high quality bonding between dental substrate and prosthetic crown[10].Eugenol affects the bond strength of resin cements during final cementation by inhibiting the polymerization reaction[11].Previous studies have evaluated the differences between eugenol and eugenol free cements in the retention of permanent cementation and have found that eugenol caused a remarkable decrease in retention of resin cements [12]. Till now, there is no proper evidence to check the shear bond strength of RMGIC luting cements after temporary restoration. So, our study aims to compare the shear bond strength of eugenol with luting cements (RMGIC and SELF-ETCH adhesives).

Materials and Method

Forty extracted human molars stored in distilled water at 4°C. The teeth were sectioned 3mm transversely to expose dentin with water cooled diamond saw. The crowns were embedded in chemically activated polyester resin into poly vinyl chloride pipes in such a way that the occlusal surfaces faced up. After resin polymerization, the surfaces of the teeth were grounded with 60 grit sand-paper to remove overlying dentin and expose flat dentin surface. The temporary cement Zinc Oxide Eugenol (ZOE) were prepared according to manufactures instructions and cemented on 20 teeth. The remaining 20 teeth were used as control. After 24 hours, ZOE was removed using ultrasonic scaler and viewed under magnification for precise removal.20 teeth which were not exposed to Eugenol (control) were divided into group 1 (RMGIC) and group 3 (Resin). Other 20 molars (ZOE exposed) were also divided similar as Group 2 (Eugenol + RMGIC) and Group 4 (Eugenol + Resin).To achieve uniform shape and size of luting cements, drinking straws of 4mm length and 5mm diameter were mounted over the teeth. removal, RMGIC was packed into the straws without any voids. For self adhesive resin groups, cement was applied to the dentinal surface through the straws. Resinous cement excess was removed with brush and was polymerized from each phase for 40 sec, according to manufacturers recommendations without any primer or adhesive. Nail varnish was applied onto the interface of the straws and the tooth surface to prevent entry of water. After cementation, all specimens were stored in distilled water at 37°C.Thereafter, shear bond strength(SBS) testing was done using knife edge blade in the universal testing machine (INSTRON, CIPET Chennai) running at a cross head speed of 0.5mm per min.SBS mean values were recorded in kgf/cm and converted into MPa. Data were statistically analyzed by t-test and tabulated.

Results

Shear Bond Strength values in MPa for RMGIC groups are given in table 1 and its line chart in figure 1. There was no statistical significant difference ($p > 0.05$) between the groups.

Table 1: Shear Bond Strength in MPa

Group 1	Group 2
0.58	0.55
0.37	0.51
0.38	0.41

3.24	2.69
3.16	2.75

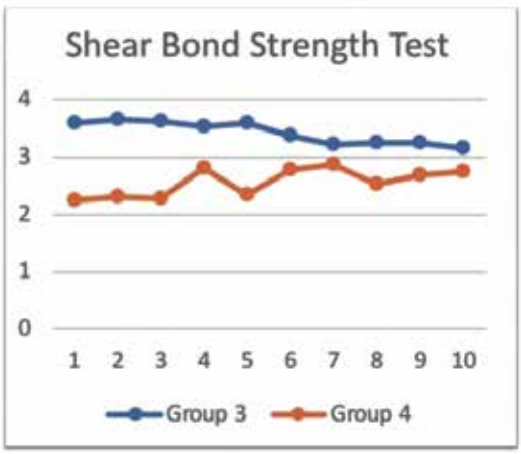

Figure 2: Graph showing comparison of SBS of Resin and Resin+Eugenol

Mean values for RMGIC (group 1) and Eugenol + RMGIC (group 2) were 0.58 MPa and 0.55 MPa respectively, showing no much of difference in their shear bond strength. Whereas for Resin (group 3) and Eugenol + Resin (group 4) mean shear bond strength values were 3.42 MPa and 2.56 MPa respectively, showing significant difference. Mean, Standard Deviation and P values are given in table 3.

Table 3: Statistical analysis

Groups	Mean	Standard Deviation	P value
Group 1	0.58	0.108	0.083
Group 2	0.55	0.076	
Group 3	3.42	0.196	0.0001
Group 4	2.56	0.245	

Discussion

Luting cements which comprises a wide array of materials used for cementation of crowns and indirect restorations to the prepared teeth recently include GIC, RMGIC and Resin cement[13]. GIC have been very popular due to ease of use, good flow properties, adhesion to tooth structure and base metals, fluoride release, sufficient strength, and moderate cost. Its primary indication is for metal and porcelain fused to metal restorations[14]. Although glass ionomers form intermediate layers on dentin they do not bond to materials etched by hydrofluoric acid or treated with silane and are considered passive.Clinical success of full veneer crowns are affected by type of cementation[15]. Retention properties of GIC with zirconia showed lesser life when compared to resin cements containing MDP[16]. Resin modified glass ionomers were introduced, formed by replacing part of the polyacrylic acid in conventional glass ionomer cements with hydrophilic methacrylate monomers[17]. Setting reaction of RMGIC is by both acid base reaction and photo chemical polymerization. The initial and rapid setting of RMGIC is through their polymerization of resin monomer. Slow acid base reaction also takes place within the resin matrix. This reaction is responsible for maturing process and the final strength and water content is too little to complicate the polymerization. RMGIC shows better cohesive strength, lower modulus of elasticity, higher strength, lower solubility and fracture toughness than conventional GIC[8]. Resin luting agents are distinctive because a

polymer matrix forms to fill and seal the space between the tooth and the restoration as opposed to regular cements, which combine a powder and liquid to form a hydrogel[18]. The qualities of resin cements are favourable to enhance aesthetics of all-ceramic restorations, lab-processed composite resin restorations, resin bonded fixed partial dentures and for the cementation of either metal or fiber posts[2].In combination with a dentin bonding agent, resin cements have superior properties and are frequently used for the cementation (bonding) of porcelain laminate veneers [19].The use of adhesive resins, in the restoration of teeth with short, tapered clinical crowns or other unfavourable geometric configurations, may be particularly advantageous because an approach less destructive than traditional crown preparation. Hence, RMGIC and resin cements are preferred over GIC for luting all ceramic crowns. Shear bond force acts on the axial wall whereas tensile force acts on the occlusal surface. Since surface area of axial wall is greater than the occlusal surface area, testing shear bond strength would be more appropriate. In previous studies, final cementation was done 24 hours after removal of ZOE, but we have luted RMGIC and resin immediately after removal of ZOE to mimic clinical practice [10]. Mean SBS for Resin was 3.42 MPa and Resin after ZOE removal 2.56 MPa. Hence, statistical significance was found between Resin with Eugenol and control group. ($p<0.05$) .When zinc oxide is mixed with eugenol chelation reaction takes place and results in a set mass of unreacted zinc oxide particle in a matrix of zinc eugenolate. When set cement contacts water, eugenolate at the surface undergoes hydolysis to liberate eugenol. The hydroxyl group of eugenol tends to protonize the free radicals formed during polymerization of resin based matrix, thereby blocking their reactivity. In a study conducted by Cecinunes Carvalho et al. it is concluded that eugenol-containing temporary restorations negatively influences the resin-dentin shear bond strength [20]. Mean SBS for RMGIC was 0.58 MPa and RMGIC after ZOE removal 0.55 MPa. No statistical significance was found between these two groups. ($p > 0.05$).RMGIC bonds to tooth structure through both micromechanical interlocking chemical polyalkanoate – hydroxyapatite bonding. Though RMGIC contains resin components, it was found unaffected by eugenol in our study. This indicates that acid base reaction dominates the micromechanical interlocking. De Munck et al., 2004 and Coutinho et al., 2007 concluded that there is a greater glass ionomer character in RMGIC thereby increasing the chemical bonding nature and its durability. Thus the acid base reaction in RMGIC continues for a longer time periods and additional acid base reaction would be expected to continue if not disturbed [21].

Conclusion

Based on the findings of this study and within the limitations of in-vitro investigations, there is a decrease in shear bond strength for resin cement when ZOE used as temporary cement. No difference in shear bond strength was observed in RMGIC after ZOE temporary cementation when compared with control groups.

Surgical Decompression to Treat Periapical Cyst: A Review of Literature

Alagarsamy Venkatesh[1], Sahithi Reddy[2], Nagarajan Geethapriya[3], Arumugam Karthick[4]

[1]Professor, [2]Second Year Postgraduate Student, [3]Reader, [4]Associate Professor, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayanapuram, Pallikaranai,Chennai, Tamilnadu, India

ABSTRACT

Periapical cyst accounts up to half of cystic lesion of jaws. Large periapical cysts, generally true cyst are self sustaining are less likely to be resolved by conventional root canal therapy. Hence, a surgical intervention is needed. Of all the surgical procedures decompression is a more conservative option to treat periapical cyst. It includes surgical exposure of a cyst wall and insertion of a tube or any drain to decompress the lesion during healing and reduces the necessity of surgical enucleation. The decompression technique has a potentially high success rate with low morbidity and reduced loss of bone support, and should be considered for treatment of these lesions. It can reduce risk of perforation in lesions adjacent to the nasal floor, sinus floor, mandibular nerve, and neighboring tooth apices. Despite certain limitations like need for patient compliance and long-term follow-up, decompression is a viable and less invasive method which can counterbalance the fallacies and should be considered as an alternative to conventional surgeries. This review article describes the origin, methods, clinical outcomes, advantages and drawbacks of decompression procedure for periapical cyst.

Keywords: *Decompression, periapical cyst, marsupialization, surgical drainage.*

Introduction

Back in 500 AD a Greek physician dentist, Aetius performed incision and drainage of acute abscess. It was the first recorded surgical endodontic procedure. Endodontic surgery is often considered as last resort in failed non surgical treatment. The field of surgical endodontics has progressed and evolved with introduction of micro endodontic surgical procedures and lesser invasive procedures. In mid 19th century the concept of decompression was introduce which was less invasive than traditional surgery and root-end resection. Hence, it is often important for the clinician to understand about the pathology of a periapical cyst and choose an effective treatment protocol.

Understanding Periapical Cyst: Periapical cyst accounts up to half of cystic lesion of jaws [1,2], and it was found to be about 7%-54% of all the extracted tooth lesions on histologic examination[3]. It is important to differentiate between true cyst and pocket cyst [4,5], as the tissue dynamic of a true cyst is self sustaining are less likely to be resolved by conventional root canal therapy. Of all the periapical cysts 8%-13% constitute true cysts [4-6]. Cyst is histologically characterized by a stratified squamous epithelium lining developing from epithelial cell rests of Malassez, but may also be related to the crevicular epithelium, the sinus lining, or the epithelial lining of the fistulous tracts. It is of inflammatory origin and has a connective tissue in outer wall and an inner wall of epithelium. As the epithelium desquamates into the cyst, there is an increase in the protein content. To equalize the osmotic pressure, liquid enters the lumen.

Hence, the cavity has a watery, semisolid, or colloidal content. It gradually increase in size due to a combination of osmotic pressure [8] and prostaglandin and growth factor release [8]. Due to the expansion pressure exerted on the bony walls along with biomolecules has an additive effect on bone resorption.

History: A polish Professor Carl Franz Maria Partsch applied this principle of reducing the pressure by drainage of the cyst, which helps in preventing its enlargement and further leading to bone growth. And in 1892 introduced the concept of cystostomy also known as Partsch I or marsupialization and cystectomy or Partsch II in 1910. He reported suturing the lining to the mucosa of the oral cavity and the conversion of a cyst into a pouch. In 1958, Kurt Thoma described decompression and stated its benefits, like maintenance of pulp vitality, preservation of the inferior alveolar nerve or maxillary sinus, prevention of fracture of the jaw, and low risk of recurrence.

Procedure for Decompression: Decompression and marsupialization are often interchangeably used terms. But decompression is quite different from marsupialization. "Marsupialization is deroofing the outer wall of the cyst by making a surgical incision, evacuating its contents, and establishing a large permanent opening by suturing the remaining part of the cystic membrane to the mucosal surface around the periphery of the opening" [9]. Whereas, decompression is a more conservative treatment option which includes, surgical exposure of a cyst wall and insertion of a tube or any drain to decompress the lesion during healing. It reduces the necessity of surgical enucleation. The drain should be an inert radiopaque material like, polyvinyl tubing, suction catheter, "I" shaped pieces of rubber dam, polyethylene tube with a stent, radiopaque latex tubing or hollow tubes to prevent aspiration [9-11]. There is no standard protocol for the duration necessary to leave the drain. It may be different for different kinds, sizes or locations of lesions. It can vary between two days to five years [10]. The length of tubing can be reduse to create space for healing gradually [12]. To debride the cavity saline or chlorhexidine rinse irrigation must be done periodically, which also favours healing [10,12] and can be done by the patient or the dentist. On appearance of signs of healing clinically and radiographically the drain must be removed.

Review of Clinical Outcome: By using small polyethylene tubes, Marker et al.,in 1996 concluded that decompression resulted in new bone formation and thickening of the cyst wall, while conserving bone and anatomic structures after successful decompression of 23 odontogenic keratocysts [13]. Panoramic radiographs of 57 patients were evaluated by Anavi et al., they concluded decompression on average showed 79.3% reduction in area of cyst and the result was good to moderate in 89% [14]. Ricardo et al., reported a case of an extensive radicular cyst involving teeth 11, 12 and 13, extending posteriorly, limited at the posterior wall of the maxillary sinus. Transalveolar decompression was performed with a mechanical device, after removal of tooth 12. One year and nine months after the decompression procedure, complete regression of the lesion was observed, with no bone sequel and with maintenance of the results over five years of clinical and radiographic follow up [15]. Tian et al., have reported three cases with large periapical cystic lesions which were treated with decompression after root canal treatment, and has observed Healed lesions or lesions in healing were after 1 to 2 years [16]. Johann et al., reported an inflammatory radicular cyst, carried out the cystic decompression. After 6months, radiographically, bone neoformation was observed [17]. Vasconcelos et al., performed the treatment of a large cystic lesion there was a significant reduction of the lesion in all its extension [18].

Drawbacks: The decompression technique is contraindicated in cases of large dental granulomas or any solid cellular lesion, as there is absence of a fluid-filled cavity to decompress [19]. Other drawbacks are, need for long-term follow-up and patient compliance, regular cavity irrigation, unavailability of biopsies for histopathological examination, and possible infection of the exposed cavity.

There is no documented CBCT evidence of complete healing of the apical lesions for through-and-through–type lesions after decompression[16]. For odontogenic keratocysts, decompression or marsupialization has been reported to have a higher recurrence rate, which necessitates secondary enucleation surgery[20]. Tube can be disloged overtime, and can be prevented by stent fixation.

Conclusion

Decompression has minimal risk, as compared to the risk of damaging other vital structures with aggressive surgical enucleation. Hence should be considered as an alternative to conventional surgeries.

An Update of Pain Management in Endodontic Flare-Ups: A Review

Rajendran Devakar[1], Dhakshinamoorthy Malarvizhi[2], Suresh Mitthra[3], Venkatachalam Prakash[4]

[1]Second Year PG Student, [2]Associate Professor, [3]Reader, [4]Professor, Department of Conservative Dentistry and Endodontics, SreeBalaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayanapuram, Pallikaranai,Chennai, Tamil nadu, India

ABSTRACT

Flare-up can be defined as the occurrence of swelling, pain or the combination of these during the course of root canal therapy, which results in unscheduled visits by patients. Inter appointment pain is caused mainly by microbial injury to the periradicular tissues and to some extent by iatrogenic factors which are chemical and mechanical in nature. The offending agents cause inflammation in the periradicular tissues which result in pain and swelling. While post endodontic flare-up is a relatively rare occurrence, the sudden increase in patient symptoms demands for a focused and active treatment plan. This review article discusses these many facets of the flare-up: definition, aetiology, clinical symptoms and management of the situation after its occurrence.

Keywords: *Endodontic flare up, periradicular tissues, apical periodontitis, Inter appointment pain*

Introduction

Mechanical and chemical injuries are often associated with iatrogenic factors. The inter appointment flare-up is a true complication in developing pain, swelling or both after a few days on root canal procedure. The causative factor of inter-appointment flare-ups comprise mechanical, chemical and microbial injury to periradicular tissue or pulp (Torabinejad et al. 1988 seltzer & Naidorf 1985) the article will generally give a consensus of the majority findings or will represent those studies with the best analyses.

Definition: The interappointment flare-up has the following criteria [(1)]: Within a few hours to a few days after an endodontic procedure, a patient has a significant increase in pain or swelling or a combination of the two. The problem is so severe that the patient initiates contact with the dentist. The dentist determines that the problem is of significance such that the patient must come for an unscheduled visit. At the visit, active treatment is rendered. That may include incision for drainage of any abscess that may have formed, canal debridement, opening the access, prescribing appropriate medications, or doing the necessary to solve the problem. [(1, 2)] Because of their nature, these interappointment endodontic flare-ups, when they occur, create difficulties for both patient and dentist. Although there are a few reports on the incidence, aetiologies, and treatment of flare-ups, most related factors remain unspecified.

Etiology: Dr.Seltzer discussed a number of hypotheses thought to be related to the aetiology of flare-ups [(3).] (Figure 1)

1. Alteration of the local adaption syndrome.
2. Changes in periapical tissue pressure.
3. Microbial factors.
4. Effects of chemical mediators.
5. Changes in cyclic nucleotides.

6. Immunological phenomena.

7. Various psychological factors.

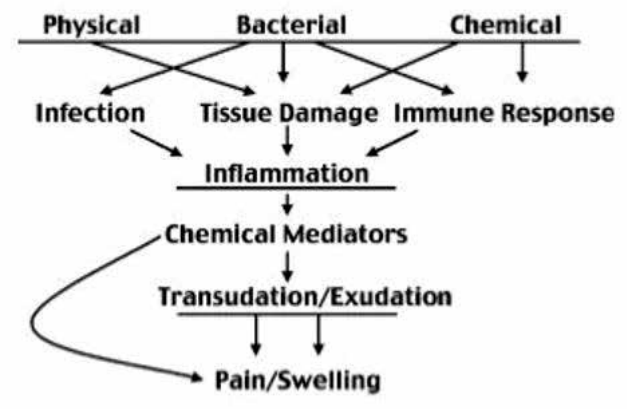

Figure 1: Bacteria, chemical and physical irritants likely act in combination to produce changes at the periapex that results in inflammation and ultimately pain and swelling

Microbial causes: Microorganisms can cause interappointment pain as a result of an imbalance in host–bacteria relationship induced by intracanal procedures. The most important goal of root canal therapy is to minimize the number of microorganisms and pathologic debris in root canal systems to prevent or treat apical periodontitis [7] Bacteria residing in certain anatomical areas of the root canals such as isthmuses, apical ramifications, irregularities, deltas and dentinal tubules may be left untouched and unaffected by disinfection procedures [8] An inadequate seal of root canal filling can allow seepage of tissue fluids and provide a substrate for bacterial growth. The bacteria can also gain access to the periradicular area and cause inflammation [9].

Presence of pathogenic bacteria: Some of the pathogenic bacteria include Porphyromonas endodontalis, Porphyromonas gingivalis, and Prevotella species. (4) A recent study revealed that F. nucleatum, Prevotella species, and Porphyromonas species were frequently isolated from flare-up (4, 2)

Microbial synergism or additism: Most of the endodontic pathogens show virulence when they are in association with other species.[11,12] This is because of synergistic or additive microbial interactions, which can certainly influence virulence and play a role in symptom causation.(5)

Apical extrusion of debris: Extrusion of infected debris to the periradicular tissues during chemo mechanical preparation is one of the principal causes of postoperative pain. (5, 6)

Clinical Symptoms: The next factor determining the post-operative pain is clinical symptoms that were before the treatment such as tooth pain when biting, chewing or by itself and sensitivity to percussion. (10) 80% of patients who feel tooth pain before the beginning of the treatment usually feel the pain and after it (11) Signs and symptoms act as an important predictor for flare-ups.

A patient probably reports on pain are more likely to experience an interappointment flare-up than a patient with no prior symptoms.(12) It is intriguing to note that patients in pain, which would also increase stress levels, have been shown to have adversely impacted immune functions.(13) The clinician can prevent flare-ups in most instances. Proper diagnosis is mandatory which includes Identifying the correct tooth causing pain. The vitality of the tooth has to be ascertained along with its association to any periapical lesion. The correct working length has to be determined using radiographs and apex locators. Complete extirpation of vital pulp has to be done followed by preferably using a combination of irrigants such as sodium hypochlorite and chlorhexidine. Filling too close to the radiographic apex has to be avoided. Apical trephination must be performed only if necessary. Placement of appropriate intercanal medicaments is important to make sure the treatment is a success. The tooth is to be relieved from occlusion especially if the apex is severely violated by over instrumentation. Mild analgesics and antibiotics can be prescribed whenever the condition warrants it. (14)

Managements and Drugs: Using non-steroidal anti-inflammatory drugs (NSAID) must be the first option for endodontic flare-ups and pain (e.g., 400 mg ibuprofen or 100 mg flurbiprofen). If NSAID cannot be used, paracetamol (1000 mg) and opioid combination is an excellent alternative medication for acute pain syndrome too.(Table-1)

Table 1: Dosage Of Analgesic Drugs

Analgesic Agent	Dosage (mg)	Max Daily Dose (mg)
Paracetamol	325-1000	4000
Aspirin (acetylsalicylic acid)	325-1000	4000
Diclofenac Potassium	50-100	200
Etodolac	200-400	1200
Meloxicam	200-400	1200
Nimesulide	200-400	1200

Conted…

Fenoprofen	200	1200
Flurbiprofen	50-100	300
Ibuprofen	200-400	2400
Ketorolac	10	40
Naproxen sodium	275-550	1650
Naproxen	250-500	1500
Ketoprofen	20-75	300
Tenoxicam	20	20
Lornoxicam	20	20

Conclusion

A Endodontic flare-up has no significant influence on the outcome of endodontic treatment, its occurrence is extremely undesirable for both the patient and the clinician and can undermine clinician-patient relationships. Prompt and effective management of flare-ups is a vital part of the overall endodontic treatment.

Successful Management of Calcified Canal with Perforation—A Case Report with Six Months Follow Up

Nagarajan Geethapriya[1], Arunajatesan Subbiya[2], Newbegin Selvakumar Gold Pearlin Mary[1], Alagarsamy Venkatesh[3]

[1]Reader, [2]Professor & Head, [3]Professor, Department of Conservative Dentistry & Endodontics, Sree Balaji Dental College & Hospital, Bharath Institute of Higher Education and Research, Narayanapuram, Pallikaranai, Chennai, Tamil Nadu, India

ABSTRACT

Calcific metamorphosis is the obliteration of pulp canal space due to trauma or injury. Hemorrhage and blood clot formation in the pulp after injury is a nidus for calcification if the pulp still remains vital. Calcification replaces the cellular components of the pulp. Teeth with pulp canal obliteration prove to be a challenge to endodontic treatment. This case report describes the successful management of a tooth with calcified canal and perforation with six months follow up.

Keywords: *Pulp canal obliteration, perforation, root canal treatment*

Introduction

Calcific metamorphosis is a slow and normally occurring physiological aging process. The pulp canal obliteration (PCO) may also be a pulpal response to trauma wherein there is rapid deposition of hard tissue within the root canal space[1]. There is uncontrolled mineralization in these teeth due to failure of the enzyme pyrophosphatase, reduced capillary permeability and reduced blood supply leading to calcifications. Though the exact mechanism of root canal obliteration is unknown, it is believed to be related to damage to the neurovascular supply of the pulp at the time of injury[2]. Due to these reasons the pulp canal space is obliterated and an effort to negotiate the canal may remove large amounts of dentin leading to perforation or root fracture[3].

Case Report: A male patient aged 45 years reported with pain in upper front tooth region. Patient gave history of attempted root canal treatment in 11 about 8 years back. On clinical examination there was a perforation on the cervical third of labial aspect of 11(Figure 1). There was also an eccentrically placed access on the lingual surface due to the attempted root canal treatment (Figure 2). The maxillary central incisor was tender on percussion.

Figure 1: Pre operative photograph–Labial view

Figure 2: Pre operative photograph–Palatal view

Radiographic interpretation showed a narrowed down root canal in 11 with periapical radiolucency in relation to 11(Figure 3). It was diagnosed as Acute apical periodontitis with perforation and sclerosed root canal in 11. The treatment plan was to seal the perforation and non surgical endodontic treatment in 11.

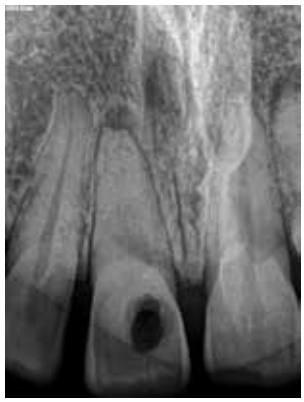

Figure 3: Diagnostic radiograph

Local anaesthesia was given and the tooth was isolated under rubber dam. The attempted access cavity was redefined with utmost care to stay centered in the canal. The calcified pulp chamber was visible as a darkened line and the center spot was the root canal. The canal was located and negotiated with a size 6 k file(Figure 4). The perforation site was sealed with composite resin from within the canal. Cleaning and shaping was done very carefully and copious irrigation was done with sodium hypochlorite and saline. The canal was enlarged upto size F3 and obturation was done by lateral condensation using Sealapex as sealer. There was a slight extrusion of sealer as seen in the post obturation radiograph(Figure 5). The patient was asymptomatic on the follow up visits and a metal ceramic crown was given. Six months follow up radiograph showed complete healing of the lesion, bone deposition and complete resorption of the extruded sealer (Figure 6).

Figure 4: Working length determination radiograph

Figure 5: Obturation radiograph

Figure 6: Six months follow up radiograph

Discussion

Calcification commonly occurs as a result of trauma and frequently affects the anterior teeth of young adults. Holcomb & Gregory examined 882 servicemen and reported that 34 out of them had a total of 41 anterior teeth exhibiting partial or total obliteration of the pulp spaces, representing an incidence of 4% [4]. Andreasen assessed 108 patients and reported that PCO was found in 42 teeth (22%)[5].

A yellow discolouration or reduced transparency of the crown has been reported to occur in teeth with pulpal obliteration [6]. In the present case, yellowish brown discolouration of the crown was seen in 11. In cases of PCO, pulp sensibility tests are unreliable [4]. In our case the tooth did not respond to EPT. A progressive decrease in the response to thermal and electrical pulp testing has been reported as PCO becomes more pronounced [7,8,9].

Significant difference to electric pulp testing has been observed between partially obliterated teeth compared to those that were totally obliterated [9]. Teeth with partial pulpal obliteration were more responsive than those teeth with total obliteration. Teeth undergoing calcification are generally asymptomatic [9] or exhibit mild symptoms. In our case the patient had pain in the affected tooth. Though the mechanism of pulp canal obliteration has not been exactly explained, there are various studies which have proved certain facts about calcfifcation. Torneck et al reported that the deposition of hard tissue is either a result of stimulation of the preexisting odontoblasts or a result of the loss of their regulatory mechanism which contains a maze of small irregular spaces and cul-de-sacs, which extend from the pulp chamber to the apical foramen [10].

Andreasen et al described that calcific metamorphosis as a response to severe injury to the neurovascular supply to the pulp, which after healing leads to accelerated dentin deposition, resulting in pulp canal obliteration. This is closely related to the loss and re-establishment of the pulpal neural supply[11].

The odontoblasts which are located at the periphery and the undifferentiated pulp cells produce osteoid tissue very similar to that of dentin along the periphery or with in the pulp. In the end, these tissues fuse with one another, producing a rapid and complete pulp canal obliteration[12]

Ten Cate, explained the process of canal obliteration as the deposition of tertiary or reparative dentin in response to irritation or trauma. Reparative odontoblasts formed by this process differentiate from dental pulp cells in the absence of any epithelial influence. During the development of the tooth, the undifferentiated ectomesenchymal cell of the dental papilla divides into two daughter cells among which, one is influenced by the epithelial cells and differentiates into an odontoblast, while the second daughter cell that is not exposed to the epithelial influence persists as a subodontoblast cell. This subodontoblast cell, under certain influences like trauma, differentiates into odontoblast-like cells and deposits dentin-like hard tissue [13,14]

There is a debate whether the mineralized tissue so formed is true dentin. The original odontoblasts express type I collagen and phosphophoryn, whereas the reparative dentin is produced by newly differentiated cells and incorporates type I and III collagen in its matrix, which exhibits diminished Phosphophoryn content [15,16].

In our case, hand K files such as #6, #8 and #10 were used for negotiation and estimating the working length, since the canal was severely calcified. These files aid in determining the minor constriction of the root canal. The common mishap associated while negotiating canal in a calcified tooth is gouging or perforation. In our case, since it was an attempted root canal treatment, the patient reported with a perforation at the coronal level, which was evident on the labial view. The perforation was sealed with composite resin from within the canal. The tooth was obturated and a metal ceramic crown was given. The patient was asymptomatic on six months follow up and the lesion had completely healed.

Conclusion

Calcified canals can be effectively managed by patient and diligent sequential negotiation. Successful management of calcified canals lies in appropriate use of the recent armamentarium under adequate illumination and magnification.

Ceramics in Dentistry—A Review

Arumugam Karthick[1], Dhakshinamoorthy Malarvizhi[1], Ramachandran Tamilselvi[2], Seenivasan Niveditha[3]

[1]Associate Professor, [2]Reader, [3]Undergraduate Student, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

The word Ceramic originated from the Greek term keramos meaning "potter or pottery". (7)

Dental ceramics have long been recognized for their similarity to dental enamel. They can be made to closely mimic the shades and textures of the natural tooth. Porcelain provides the practitioner with the clinical ability to restore a patient›s dentition to its original appearance and function. The biocompatibility and user-friendliness of dental ceramics are unmatched in any other restorative material. Demands for more esthetic and metal free restorations as well as soaring metal prices are causes for the increase in all ceramic prosthesis. (10) Over the past two decades, the use of bonded porcelain has expanded exponentially owing to the increasing demand for esthetic restorations and prosthesis. This article is an attempt to summarise the many facets of dental ceramics.

Keywords: *CAD-CAM, ceramics, feldspar, fillers, glass-based system*

Introduction

Ceramics are defined by literature as inorganic, non-metallic materials made by man by heating of raw materials at high temperatures. Ceramics and glasses are brittle which means that they show a high compressive strength but have low tensile strength and fracture under very low strain that is 0.1% or 0.2%. [1] All ceramics display low fracture toughness when compared to other dental materials such as metals. Metal ceramic systems integrate both the excellent esthetic properties of ceramics and the exceptional mechanical properties of metals. Some metals used as restorative materials in dentistry may comprise a problem for some patients. These problems may reveal themselves as allergies, gum staining and release of metallic ions into the gingival tissue and gingival fluid. These drawbacks, as well as the search for more esthetic materials, have stimulated research and development of metal-free ceramic systems.

Processing techniques novel to dentistry have been formulated, such as heat-pressing, slip-casting, and Computer Aided Design-Computer-Aided Machining (CAD-CAM).(4) The introduction of vacuum-fired porcelains and the bonding of porcelain to gold alloys (introduced by Weinstein et al4 in the early 1960s) were key breakthroughs in dental esthetics. (5)

Classification: Ceramics can be classified by the microstructure and also by their processing technique.

Microstructural classification: At the microstructural level ceramics can be defined by the nature of their composition of glass-to-crystalline ratio.

1. Glass based systems
2. Glass based systems with fillers, usually crystalline
3. Crystalline based systems with glass fillers
4. Polycrystalline solids

Classification based on processing technique

1. Powder/liquid, glass-based systems

2. Machinable or pressable blocks of glass-based systems
3. CAD-CAM or slurry, die processed, mostly crystalline systems

Glass-ceramics: Glass-ceramics were first formulated by Corning glassworks in the late 1950s. The sufficient mechanical properties of these materials reflect in the promising longevity of such dental restorations. [6] In principle, an article is formed by liquid and metastable glass, which results on cooling. During following heat treatment, regulated crystallization occurs, with the nucleation and growth of internal crystals. This process ranging from a glass to a partially crystalline glass is called ceraming. Thus, a glass-ceramic is a multiphase solid encompassing a residual glass phase with a finely dispersed crystalline phase. The controlled crystallization of the glass results in the formation of tiny crystals that are evenly dispersed throughout the glass. Time and temperature of the ceraming heat treatment determines the number of crystals, their growth rate and thus their size. By the There are two important aspects to the formation of the crystalline phase: crystal nucleation and crystal growth. The thermal treatment known as ceraming is comprised of two operations : glass is heated up to a temperature where nuclei form (750° to 850°C) and this temperature is kept for a duration of time ranging from 1 to 6 hours so that crystalline nuclei form in the glass through a procedure called as nucleation. Then, the temperature is increased to the crystallization point(1000° to 1150°C) and this temperature is retained for a period ranging from 1 to 6 hours until the necessary level of glazing is attained through a process known as crystallization.

Glass based systems with fillers

Lucite reinforced feldspar glass ceramics: Glass based systems are built from materials that contain mainly silicon dioxide, which contains different amounts of alumina. Aluminosilicates found in nature which comprise various quantities of potassium and sodium are recognized as feldspars. Feldspars are modified in various ways to create the glass that is used in dentistry. Pressed glass-ceramics are materials containing high amounts of lucite crystals. The basic component of this ceramic is feldspathic porcelain, consisting of 63% silicon dioxide, 19% Al2O3, 11% K2O 4% Na2O and traces of other oxides.

This material is manufactured through a process known as heat pressing, which is performed in an investment mould. This mould is filled with the plasticized ceramic thus avoiding the sintering process and the subsequent pore formation. This ceramic undergoes dispersion strengthening under the guided crystallization of leucite. Dispersion strengthening is a process by which the dispersed phase of different material is used to stop crack propagation as these crystalline phases are more difficult to penetrate by cracks.

Lithium disilicate and apatite glass-ceramics: According to Kelly a ceramic is a glass-ceramic when the filler particles are added mechanically while manufacturing precipitate within the glass by special nucleation and growth heating procedures. [3] The crystalline phase that forms is a lithium disilicate and makes up about 70% of the volume of the glass-ceramic. A second crystalline phase consisting of a lithium orthophosphate of a much lower volume is also present. The mechanical properties of this ceramic are way more superior than that of the leucite glass-ceramic with a flexural strength of 350-450 MPa and fracture toughness nearly three times that of the leucite glass-ceramic. This glass-ceramic is claimed to be highly translucent due to the optical compatibility between the glassy matrix and the crystalline phase, which minimises the internal scattering of light as it passes through the material. The processing technique is the same as the hot pressing technique described above except that the processing temperature is 920°C which is lesser than that of the leucite glass-ceramic.

Crystalline based systems with glass fillers: The addition of alumina to the feldspathic glass during the pre fritting process restricts the amount of alumina that can be incorporated to about 4250vol%. And an alternative strategy has been adopted in a system called In-Ceram. This core material has an alumina amount of 85%. A ceramic core is fabricated onto a refractory die from a fine slurry of alumina powder by a method known as slip casting. After the die has dried, it is sintered for 10 hours at 1120°C. The melting temperature of Alumina is too high to generate full densification of the powder by liquid phase sintering, and the solid phase sintering independently happens. Consequently, the coping thus created is only just held together at the contact points between the alumina particles, and a porous structure is a result. The strength of this porous structure is only

about 6-10 MPa. The porous structure is then infiltrated with the lanthanum glass, which has a low viscosity when fired at 1100°C for 4-6 hours which increases strength. Glass is able to infiltrate into the pores, creating a dense ceramic. The esthetics and functional form are then attained by the use of traditional feldspathic dental ceramics. The In-Ceram system was evolved by the French dental material scientist Michael Sadoun based on the glass infiltration of partially sintered porous aluminum oxide ceramics [7]

Some of the common In-Ceram systems used are

- In-Ceram Alumina
- In-Ceram Spinell
- In-Ceram Zirconia

Polycrystalline ceramics

Transformation toughened zirconium oxide: Zirconia exists as a natural mineral named baddeleyite. This mineral comprises of 80 to 90% zirconium oxide. This oxide occurs in three different crystal structures monoclinic, tetragonal and cubic. Zirconium oxide is converted from one crystalline state to another during firing. In the late 1980s ceramic engineers learned to balance the tetragonal form at room temperature by adding small quantities of calcium and later yttrium or cerium. Although stabilized at room temperature, the trigonal form is metastable, implying that trapped energy exists within the material to send it back to the monoclinic state. Two key improvements allowed fully crystalline ceramics to become logical for fixed prosthesis.

1. The variability of highly controlled starting powders
2. The application of computers to ceramics processing

Polycrystalline ceramics are formed from powders that can be packed only to 70% of the theoretical density. Hence polycrystalline ceramics around 30% by volume when made completely dense during firing for the final processes to conform to well, the percentage of shrinkage needs to be accurately foreseen and reimbursed for.

CAD-CAM technologies and materials: Using in-office CAD/CAM Technology, clinicians can design, fabricate and insert all-ceramic inlays, onlays, crown and venues in a single patient visitation. The ceramic restorations manufactured by this method have revealed excellent fit, strength and longevity. Two main techniques can be used for CAD/CAM restorations

1. Chairside single visit technique
2. Integrated chairside laboratory CAD-CAM procedure

Chairside CAD/CAM technique

The CEREC system: The CEREC system gives an in-office alternative for Porcelain restorations. The processing starts with the smooth, rounded, well-tapered restoration. This preparation is sprinkled with titanium dioxide contrast powder in the patient›s mouth. An infrared camera reads the powder and builds a 3D optical impression on the computer. This image can be altered by the dentist to create favorable anatomy and contacts before processing. The shade for porcelain is selected by the dentist, and this shade selection is entered into the computer. The computer then instructs the dentist on what block of porcelain or composite is to be used. This block is then milled in office, according to the computer design. The restoration comes out of the milling machine with ceramics sprue that needs to be eliminated. This restoration is then tried in the patient›s mouth and any adjustments essential can be done and it can be cemented in using composite.

Integrated chairside side laboratory CAD/CAM technique: An integrated chair side laboratory technique needs two visits. The clinician either can scan the preparation directly and send the scan to the laboratory or can take a conventional impression after which stone model is poured and then the laboratory scans the stone model.

Restoration Design and Fabrication: Building the virtual restoration is similar to that conventionally executed at the laboratory. The die margins are then trimmed and altered and the restoration is designed. Rather than manually building up the restoration using layers of porcelain, however, the clinician is presented with a fully controlled 3D model of the restoration to refine. Using a CAD-CAM restorative technique, a number of phases can be simplified or removed. Conventional impressions can be replaced by using a handheld scanning device that digitally records the form and margin of the preparation.

Solid sintered monophase ceramics: Solid sintered monophase ceramics are materials that are manufactured

by directly sintering crystals together without any intermediate matrix to form a dense, glass-free, polycrystalline structure. There are many different processing techniques that enable the fabrication of either solid centred Aluminium oxide or oxide frameworks. There are three basic methods for constructing the solid simple framework for porcelain application.

1. One system, DCS Preciscan machine the final desired framework shape from a solid sintered block of material.
2. Secondly, the Procera system utilizes an oversized die where a slurry of either Aluminium oxide or zirconia oxide is applied to the die, subsequently fired, fully sintered and shrunk to match the scanned die.
3. The third method machines an oversized coping from a partially sintered block of zirconium oxide material, which is then fired to the full sintering temperature and then shrunk to fit the die. Most of the systems in the market today utilize some deviations of this type of Technology. Examples of these systems are Lava (3M) and Cercon(Dentsply).

Strength and fracture toughness

Strength: Mechanical downfall of ceramic materials is almost entirely controlled by brittle fracture. Increased crystalline silica content within the glass Matrix with a more balanced distribution of particles and a fine particle size, has yielded significant developments in the flexural strength of ceramic materials. However, district improvements are still restricted by the innate weakness of the glass matrix. Techniques to strengthen the brittle materials comprise the development of residual compressive stress within the surface of the material and interruption of crack propagation through the material.[11]

Fracture toughness: More crucial physical property is fracture toughness, which has been documented to be between 8MPa $m^{1/2}$ and 10MPa $m^{1/2}$ for zirconia. This is significantly greater than any previously documented ceramic, and approximately twice the amount reported for the Alumina materials. Fracture toughness is a gauge of the material›s ability to resist crack growth.

Clinical Indications[2]: Feldspar based and lucite reinforced ceramics according to their low flexural strength are implied for single-tooth restorations such as veneers, inlays, onlays, partial crowns, and anterior and posterior crowns. Zirconia reinforced lithium silicate can also be used for fabrication of implant-supported crowns. Having the high crystalline content, lithium disilicate ceramic can be used not only for single-tooth restorations but also for the fabrication of hybrid abutments, hybrid abutment crowns and three-unit bridges as well. densely sintered, high purity Alumina can be used for primary elements of conical and telescopic crowns, crowns in the anterior and posterior, as well as for bridges only in the anterior area with not more than one pontic. Yttria stabilized Zirconia is indicated for fabrication of anterior and posterior crowns, implant abutments, implant-abutment crowns, primary telescope grounds, 3 unit inlay and only bridges, cantilever bridges with minimum of two abutment teeth and maximum of one pontic and no more than one premolar width, anterior adhesive bridges as well as multi-unit long span and curved bridges with a maximum of 4 pontics next to one another in the anterior area and the maximum of three pontics next to one another between abutment teeth in the posterior area.

Conclusion

This modern generation of ceramic materials presents interesting options, both in terms of material choice and fabrication techniques. Manufacturers are frequently introducing newer ceramic materials and enhancing their present systems, which has resulted in a boost in all-ceramic restorations and fewer porcelain-to-metal restorations. [9] A deeper understanding of the dynamics of these materials with respect to the design of the restoration and its planned use is important to facilitate these restorations to perform productively. Advances in CAD/CAM technology have catalyzed the development of esthetic all ceramic restorations with superior biomechanical properties. Although none of these materials show ideal clinical properties for universal applications, intense research undertakings are under way to improve the strength, esthetics, accuracy, and a capacity to reliably bond to the varying dental substrates. [12]

Hazards of Dental Waste Disposal—A Review

Dhakshinamoorthy Malarvizhi[1], Arumugam Karthick[1], New Begin Selvakumar Gold Pearlin Mary[2], Niveditha Seenivasan[3]

[1]Associate Professor, [2]Reader, [3]Under Graduate Student, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

Waste is a direct consequence of human activity and the quantity of generated waste is often an indicator of the economic strength and development of a community. Dentistry is a profession which is dedicated to promoting and enhancing oral health and well being. Dentists use a variety of materials and equipment to accomplish this goal. Unfortunately, some of these materials present potential challenges to the environment. This article is an effort to discuss the various materials the hazards caused by them and their appropriate disposal technique.

Keywords: *biomedical waste, disposal, recycle*

Introduction

Clinical waste is defined as any waste which contains wholly or partly of human or animal tissue, blood or other body fluids, excretions, drugs or other pharmaceutical products, swabs or dressings, syringes needles or other sharp instruments. Waste is defined as hazardous when the waste itself or the material or substances it contains are harmful to humans or the environment. According to an estimation by a US medical waste tracking system, the dentist generates only 3% of the total medical waste. The proportion of dental waste can significantly contribute to the number of pollutants generated in the environment if its disposal is not well managed. [(1)] Additionally, there are cross-infection risks associated with mismanaged waste. Such cross-infection may be from human scavengers who are reported to visit dunghills to pick victuals and are predisposed to deadly infections. [(2,4)]

Healthcare waste legislation: There are many controls in place to ensure that clinical waste is managed safely and disposed of in a way that ensures human health and the environment remains free from harm. These controls are listed under the environment protection act 1990 where it states that 'it is unlawful to deposit, recover or dispose of controlled waste without a waste management license, or in a way that causes pollution of the environment or harm to human health.

All clinical waste handling and disposal procedures must comply with the following regulations:

- The environmental protection act 1990
- Controlled waste regulations 2012
- Hazardous waste directive 2011
- Carriage of dangerous goods regulation

The statutory duty of care applies to everyone involved in the waste management industry. It states that as a producer of any controlled waste it is your responsibility to ensure the proper management of the controlled waste your business produces. [(2)]

Categories of waste generated in dental practices[(3)]

- Biomedical waste – non-anatomic waste and anatomic waste, sharps
- Silver containing waste - used fixer solution and unused x-ray films

- Lead containing waste - lead aprons and lead foils inside the X-ray films
- Mercury-containing waste- element Mercury, scrap amalgam
- Chemicals, disinfectants and sterilizing agents

Mercury

Dental amalgam: Mercury, as amalgam has been used as a dental restorative material for more than 150 years. Mercury is a toxic and bioaccumulative metal. Mercury usually occurs in nature as sulfides and in a number of minerals. It exists in inorganic, organic and elemental forms. The use of mercury by the dentists represents approximately 6% of the total annual domestic use and estimated to significantly contribute to the discharge of mercury. Amalgam is not only one of the most hazardous waste produced at dental clinics, it also acts as a neurotoxin and is considered to be the most toxic non radioactive element and the most volatile heavy metal known in nature (EPA 2000, Al-Khatib & Darwish 2004) Other harms caused by dental amalgam include oral galvanism, soft tissue toxicity, allergenicity and ecological grievances. Mercury is toxic to the nervous system, particularly the developing nervous system of a fetus or young child. Effects seen in children with elevated mercury exposure include lowering cognitive abilities, impact on hearing, poor coordination. Chronic elevated exposure to mercury also affects the kidney, liver and immune system. [4]

Waste Products: During the placement and removal of dental amalgam restorations, a variety of waste products are generated

- Elemental mercury vapour released from dental amalgam alloy
- Dental amalgam scrap- amalgam particles that have not come in contact with the patient
- Amalgam waste- the particles that have come in contact with patient secretions
- amalgam sludge- the fine particles present in the dental office wastewater, commonly trapped in chair-side traps and vacuum filters [1]

Best management practices: Dental amalgam contains both Mercury and silver and therefore must be properly handled. It cannot be mixed with biomedical waste because if incinerated, mercury is released into the air. The waste was never be put in the regular trash. For mercury, the best management practices are designed to address the various forms that are used and generated in the dental office. Practitioners are advised to use pre capsulated dental amalgam to reduce the risk of liquid mercury spill or clinic environmental contamination. Alternative restorative materials can be used when indicated. Limiting the amount of dental amalgam triturated for a procedure also reduces the amount of waste generated.

Amalgam separator: An amalgam separator is designed to remove waste amalgam from the rinse water in the vacuum line before discharge to the sewer. The separator systems are used to capture scrap amalgam which is too fine to be removed by a trap or a screen. Amalgam separators can remove up to 99% of the Mercury from the wastewater before it is discharged from the dental office. Separation technology is based on sedimentation, filtration and centrifugation of the amalgam particles from wastewater. [1]

Silver: Dental offices generate a very small amount of silver waste relative to other photographic processing facilities. Silver is used in fixer solutions in the form of silver thiosulfate complexes which are extremely stable and have very low dissociation constants. There is virtually no free silver iron in used fixer solutions. Wastewater treatment processes convert the silver thiosulfate into mostly silver sulphide with metals in the sludge. Because of these high silver levels, it is illegal to put used fixer down the drain into a septic system or into the garbage. Unused films should not be placed in general waste. Unused films contain unreacted silver that can be toxic in the environment. [1]

Best management practices: Used x-ray fixer used in dental clinics to develop X-rays is a hazardous material that should not be easily rinsed in the drain. The fixer with a recovery unit can be mixed with water and developer and disposed of down the septic system or sewer after desilvering. Spend developer is permitted to be discharged the above systems after dilution with water. The silver should be handed over to the CWC. Using a dental x-ray system without chromium x-ray cleaner is another suggested safety measure. Undeveloped x-ray films include a high level of silver and must be treated as hazardous waste. New film purchases can be minimized by using a digital x-ray unit.

Lead: An additional byproduct of traditional radiography is Lead Shields contained in each film packet. Although the lead shield themselves are relatively small, the accumulative waste produced can be considerably high. Like mercury and silver, lead is toxic and persists in the environment. Lead is a hazardous metal that can contaminate soil and groundwater if placed in regular garbage and send to a landfill. Lead waste is generated at dental offices in foil form, intraoral film packets and discarded lead aprons and collars. Lead has been implicated in causing neurological disorders in children and reproductive problems among women following either acute or chronic exposure. (4)

Best management practices: The lead Shields from film packets have to be collected and returned periodically to the manufacturer for recycling. Lead foils and aprons can be collected and dropped off at a local recycler for free or picked up by a recycling service. Lead aprons can be used for several years with good management.

Others: Chromium and cadmium have been known to have adverse effects on humans.

Chromium is known to have a potential to cause liver, kidney and respiratory damage while Cadmium may cause kidney disorders and lung cancer.

Routinely used consumables such as gloves, rubber dams and other chlorine-containing materials are usually disposed of by insulation. This process is known to release vapours containing dioxin which has been associated with cancer, defects in reproductive and fetal development, neurotoxicity, hormonal and immune disorders. (4)

Sharps: Most dentists use sharps, lancets, needles and syringes generated from normal treatment of patients. Improper handling and disposal can lead to needlestick injuries or spread of disease not only for those using the health care products but for anyone finding them including children, janitorial staff and garbage collectors. Needle sticks can result in diseases such as HIV, hepatitis. (5)

Best management practices: Needles should be mutilated by a needle destroyer or cutter before disposing of syringes. Mutilation should be strictly practised, it is recommended for disposable needles and other sharp wastes. Mutilated needles and other sharp wastes may be kept in a puncture-proof container with 1% sodium hypochlorite solution for primary disinfection and the solution should be changed once every 2 days. Eliminate the unnecessary use of sharps by implementing changes in practice and by providing medical devices incorporating safety engineering protection mechanisms.

Chemicals, Disinfectants and Sterilizing Agents

Halogenated sterilants have a detrimental effect on the environment. Ignitable sterilants should not be put down the drain as they have a potency to explode. Directly pouring of sterilant into a septic system can significantly disrupt the bacteria which normally break down wastes. (3)

Best management practices: Staff should be trained in workplace hazardous materials information system for the handling of materials. Steam or dry heat can be used to sterilize dental instruments, whenever it is possible. Non-chlorinated plastic containers should be preferred to decrease environmental impacts and placed in the solid waste stream. HCHO sterilants should also not be disposed of down the drain.

Biomedical Waste: Biomedical waste and contaminated materials capable of causing diseases or suspected of harbouring pathogenic organisms, it includes blood-soaked gauze tissues and syringes, although not extracted teeth. Gauze soaked in blood is considered a non-anatomic waste. While excised tissues, organs, tumours, extracted teeth are considered anatomic waste. (5)

Best management practice: These wastes can be managed by collecting the non-anatomical and anatomical waste separately in yellow biomedical waste bags followed by labelling it with a biohazard symbol. [figure 1] These bags should be sealed and improve used to prevent leakage of the contained items. They are to be stored in an appropriate place until collection and incineration.

Figure 1: Cytotoxic hazard symbols

Steps in the management of biomedical waste include:

a. Generation

b. Segregation

c. Collection

d. Storage

e. Treatment

f. Transport

g. Disposal

Salient features of BMW Management Rules, 2016 along with Bio-Medical Waste Management (Amendment) Rules, 2018 [6]

1. The scope of the rules has been expanded to include vaccination camps, blood donation camps, surgical camps or any other healthcare activity.
2. Phase-out the use of chlorinated plastic bags, gloves and blood bags within two years of notification of BMW management 2016 rules i.e. by 27th March 2018. But as per the Bio-Medical Waste Management (Amendment) Rules, 2018, use of chlorinated plastic bags (excluding blood bags) and gloves has to be phased out by the 27th March 2019.
3. Pre-treatment of the laboratory waste, microbiological waste, blood samples and blood bags through disinfection sterilization on-site in the manner as prescribed by WHO or NACO.
4. Provide training to all its health care workers and immunize all health workers regularly against diseases like tetanus and Hepatitis B.
5. Establish a Bar-Code System for bags or containers containing bio- medical waste for disposal within one year of notification of rules i.e. 27th March 2017. But as per the Bio-Medical Waste Management (Amendment) Rules, 2018, bar-code System has to be established in accordance with the guidelines issued by the Central Pollution Control Board by 27th March 2019.
6. Report major accidents like needle stick injuries, broken mercury thermometer, accidents caused by fire, blasts during handling of bio- medical waste and the remedial action taken and record the same in Form I.
7. Procedure to get authorization is simplified.
8. The new rules prescribe more stringent standards for the incinerator to reduce the emission of pollutants in the environment.
9. No hospital/healthcare facility (occupier) shall establish on-site treatment and disposal facility, if a service of "common bio-medical waste treatment facility" (CBMWTF) is available at seventy-five kilometres.
10. The operator of common bio-medical waste treatment and disposal facility to ensure the timely collection of bio-medical waste from the healthcare facility and assist the healthcare facility in conducting training.

Colour Coding: It is essential to segregate clinical and dental waste at the point of production following the Safe Management of Healthcare Waste Guidance issued by the department of health. By using the national colour coding system detailed one can easily identify and segregate the waste and help to drive waste minimization and best practices within the industry. [6][figure 2,3]

Conclusion

Dental waste from dental clinics and offices has become an imperative environmental and public safety problem. As producers of hazardous waste, dentists have a responsibility and the duty of care for the correct management of waste within their practice. As health practitioners, we should be concerned with promoting not only human health and well-being but also that of the environment. A proactive approach will allow our profession to succeed in an era of increased public environmental concern and environmental protection legislation. It is not only a legal obligation to provide dental services that benefit the public at minimal expense to the environment, but also our moral and ethical obligation. Dental wastes are regulated under medical waste control regulations in most countries. Even though the quantity of hazardous waste in dental solid waste is a small proportion, there is still cross-infection risk and potential danger for the environment associated with mismanaged waste. For this reason, knowledge of waste composition and development of proper management alternative are necessary. It is very important to establish a medical and dental waste management system that would implement the existing legislation in all waste management cycles from waste production to treatment and final disposal.

Category	Type of bag / container used	Type of waste	Treatment/ disposal options
	Non-chlorinated plastic bags Separate collection system leading to effluent treatment system	a) Human Anatomical Waste b) Animal Anatomical Waste c) Soiled Waste d) Expired or Discarded Medicines & Cytotoxic drugs along with glass or plastic ampoules, vials etc. e) Chemical Waste f) Micro, Bio-t and other clinical lab waste g) Chemical Liquid Waste h) Discarded linen, mattresses, beddings contaminated with blood or body fluids. **Also routine mask & gown as per BMW rules, 2018.**	Incineration or Plasma pyrolysis or deep burial*

Figure 2: List of items to be disposed in yellow coded bins

	Non chlorinated plastic bags or containers	**Contaminated Waste (Recyclable)** Vacutainers, tubing, bottles, intravenous tubes and sets, catheters, urine bags, syringes (without needles) and gloves	Autoclaving/ microwaving/ hydroclaving and then sent for recycling, not sent to landfill
	(Translucent) Puncture, Leak, tamper proof containers	**Waste sharps including Metal sharps**-Needles, Syringes with fixed needles, Needles from needle tip cutter/burner, Scalpels, Blades	Auto or Dry Heat Sterilization followed by shredding or mutilation or encapsulation
	Cardboard boxes with blue colored Marking. **Puncture proof and leak proof boxes or containers with blue colored marking, as per BMW rules, 2018**	**Broken/ discarded glass**-Medicine vials & ampoules except those contaminated with cytotoxic wastes. **Metallic Body Implants**	Disinfection or autoclaving, microwaving, hydroclaving and then sent for recycling

Applications of Cone Beam Computed Tomography in Endodontics—A Review

Suresh Mitthra[1], Sekar Sangeetha[2], Ragupathy Shakila[2], Tirpuravaram Vinay Kumar Reddy[3]

[1]Reader, [2]Undergraduate Student, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayanapuram, Pallikaranai, Chennai; [3]Reader, Department of Conservative Dentistry and Endodontics, SRM Kattankulathur Dental college & Hospital, SRM University of Science and Technology, Potheri, SRM Nagar, Kattankulathur, Tamilnadu

ABSTRACT

Cone Beam Computed Tomography (CBCT) specifically designed for imaging of the dento facial region is a true shift from 2D to 3D imaging. It produces high resolution 3D images in thin, thick or curved slices in axial, saggital and coronal planes. CBCT is a valuable tool for endodontic diagnosis and treatment planning as well as for assessing apical periodontitis, resorption, root fractures, root canal anatomy, perforations and the nature of the alveolar bone around the teeth.

Keywords: *Cone Beam Computed Tomography, Endodontic diagnosis, Endodontic applications.*

Introduction

Cone Beam Computed Tomography (CBCT) is a new technology to dentistry that produces three dimensional images of the maxillofacial region in thin, thick or curved slices in axial, sagittal and coronal planes. The word tomography is derived from the Greek words tomos(slices) and graphien(write). CBCT is a divergent pyramidal or cone shaped sources of ionizing radiation directed through the area of interest that is used to acquire individual image slices of the Field of View(FOV) and then the slices are stacked to obtain a 3D representation.(1)

CBCT was developed as an alternative to conventional CT to provide rapid acquisition of data of the entire FOV and there is comparatively less radiation exposure. Intraoral and extraoral radiographs are 2D images captured on plain films and digital sensors. CBCT is superior as it produces 3D imaging of the maxillofacial structures.(1)

Historical background:

- 1875 – discovery of x-rays emanating from Crookes tubes by Johann Hittorf.
- 1887 – Nikola Tesla- Bremsstrahlung emission.
- 1895 – Wilhelm Roentgen- discovery of x-rays.
- 1896 – Edmond Kells-1st diagnostic dental x-ray.
- 1904 – John Ambrose Fleming invented the thermo-ionic diode valve (vacuum tube)
- 1920 – replacement of the cold cathode x-ray tubes by Coolidge tubes.
- 1928 – Major John Hall-Edwards-use of x-rays for medical purposes.
- 1972 – Sir Godfrey Hounsefield – CT scanner.
- 1974 – SIRETOM – first CT system developed by a medical equipment manufacturer.
- 1979 – G.N.Hounsefield and A.M.Cormack were awarded the noble prize in medicine.

- 1987 – SOMATOM plus- continuous rotation of the tube and detector, selection of five slices thickness (1 to 10mm).
- 1989 – first spiral CT scanner in routine operation, continuous volume measurement with high resolution 2mm- SOMATOM AR. Solid state imaging using indirect exposure of CCD became commercially available in Europe.
- 1992 – Integrated CT- angiography.
- 1994 – SOMATOM plus 4 (0.75 sec scan time for 360^0 rotation).
- 1998 & 1999 – SOMATOM volume zoom with Syngosoftware(fastest rotation time 0.5 sec), AAMOR- 19th principle developed by Feb 2009.
- 2000 – SOMATOM smile (dose modulation and reduced radiation).
- 2002 – SOMATOM sensation 16 (multi-slice scanning with 16 slices/rotation. Resolution upto 0.6mm. (16 X 0.75 mm submillimetre slices). (2)

Parts of the CBCT machine:

1. The scanning unit – gantry with tube and detector system.
2. The patient chair or table.
3. The image processor for image reconstruction. (3)

Principles of CBCT: The basic principle is tomography (movement of the x-ray source and detector during the exposure). Unlike the conventional CT which have fan shaped beam of x-ray, while CBCT projects a cone shaped x-ray beam. Patient positioning varies during imaging, it can be standing, sitting or supine. CBCT units can be divided into two types – one type of unit has charged coupled device (CCD) and the other utilizes flat panel imager (FPD). Basically, the x-ray sources and the scanner make a full rotation (360^0) or half rotation (180^0) around the patient head. The rotation occurs within 30secs to 1min. While doing so, a field of view is captured. This data is then analysed by sophisticated software to display images in various planes. Hard copies of the images can be obtained. These images can be transferred to aportable memory devices and also be mailed toclinicians for purposes of diagnosis and treatment plan.(4)

Effective Radiation Dose: The major advantage of CBCT is a low effective radiation dose. The operator should stand at least 8m away from the machine. The effective dose of CBCT may vary, but it almost as low as than the conventional panoramic dental x-ray.(5) The dose depends upon the regions to be scanned, the exposure settings of CBCT scanner, size of the FOV, the exposure time(S), the tube current(mA) and the energy or potential (KV).(6) The radiation dose can be reduced using a smaller FOV, fewer projections (180 degree) and a bigger voxel size. For endodontic applications, the FOV should be limited to region of interest; which is the most effective way to reduce the radiation dose. The radiation dose of a small volume CBCT is comparable to that of 2 to 7 standard periapical radiographs, whereas the radiation dose of a large volume scanner is similar to that of a full mouth series of periapical radiographs.(5)

The effective dose for–

1. Full FOV CBCT – 29 to 477 µSv.
2. Spiral CT – 474 to 1160 µSv.
3. Panoramic radiographs –3 to 24 µSv.(7)

Accuracy of CBCT: CBCT is more accurate than radiography in imaging anatomic as well as pathologic dento-maxillofacial structures. CBCT can be accurate in detecting vertical root fracture, apical periodontitis, resorptive defects. When compared to radiography, CBCT provides a better view of root and pulp canal anatomy. For example, buccolingual curvature in a root is most often missed by radiographs, but it can be easily detected in CBCT image. Most radiographs provide little or no information about the presence of additional canals, their shape and curvature, whereas CBCT imaging reveals the same findings with high accuracy.(4)

Applications

Apical periodontitis: Periapical lesion is defined as periapical radiolucency connected to the root at the apical part that exceeds at least twice the width of the periodontal ligament space. Bender and Shelter; Schwarz and Roster showed that periapical radiographs we underestimate the size of the periapical lesion.

CBCT detects the radiolucent endodontic lesions before the lingual or buccal plate is demineralised. It eliminates the superimposition of anatomical structures and is useful in identifying pathological changes

occurring within the cancellous bone. Both in vitro and vivo studies have shown that periapical lesions are more effectively detected in CBCT than periapical radiographs. [5]

Assessment of root canal anatomy and morphology: Conventional radiographs frequently failed to detect the number of canals in teeth undergoing non-surgical endodontic treatment.Failure to identity and treat accessory canals can negatively influence the treatment outcome using an ex vivo human model was demonstrated by Matherne at al 2008. Hence the superiority of CBCTover conventional radiography in detecting the presence of supplemental canals was confirmed.Conventional radiographs failed to identity at least one root canal in 4 out of 10 of the examined teeth.[8]

The detection of presence or absence of supplemental canals and root prior to the treatment will lead to higher detection rate in the former and more conservative access cavity preparations in the latter.

If the canal morphology is undetermined, it increases the possibility of peri-operatives mishaps such as ledge formation, canal transportation or even perforation, potentially compromising the outcome of the treatment. CBCT is a reliable tool to accurately assess the degree of curvaturesassociated with the roots of teeth with normal anatomical forms.

CBCT, in addition is useful in assessment of anatomical and morphological anomalies, such as dens invaginates and fused teeth that require endodontic treatment.[9]

Surgical Endodontics: CBCT is an extremely useful tool in planning of surgical endodontic treatment. The spatial relationship of the specific roots undergoing the surgical procedure can be related to the adjacent anatomical structures such as maxillary sinuses, the inferior alveolar nerve canal and the mental foramen. With this information, clinicians can assess the appropriate size of the lesion in individual cases for treatment planning. Identifying and excluding unsuitable cases for surgical treatment can reduce themorbidity rate. [9]Surgical endodontics without 3D- CBCT – there is an increased risk of iatrogenic damage.

Dental trauma: The exact extent of the injuries to the teeth and the alveolar bone can be accurately assessed by eliminating anatomical noise and image compression, thereby the treatment can be confidently implemented. The degree and direction of displacement associated with luxation injuries is evaluated easily by CBCT.

Failure to identity the presence of root fracture can result in poor prognosis.Periapical radiographs have low sensitivity for detection of minimal tooth displacements, root and alveolar fractures. Small volume CBCT scanners, is used for the assessment of endodontic problems, that capture all teeth and surrounding anatomy in 4cmX4cm.

Patient comfort is enhanced during the imaging process, with the use of CBCT extra orally. This is particularly pertinent in the assessment of dental trauma were the patient as difficulty in accommodating bulky film holders and image receptors for conventional imaging is exacerbated by potentially mobile teeth and painful intraoral tissues. [10]

Root resorption: The true extent of inflammatory and external cervical root resorption (ECR) in the early stages, cannot be determined by conventional radiographs. CBCT is a useful diagnostic tool for early detection and management of root resorption.

Kamburoglu et al., assessed the ability of the examiner to identify and differentiate between simulated internal root resorption (IRR) and simulated ECR of the root canal at the cervical region, using CBCT, conventional and periapical radiographs. It was concluded that CBCT was statistically better than the periapical radiographs in the detection of simulated resorption cavities. [11]

Vertical root fracture: Identifying the vertical root fractures (VRF) is an endodontic challenge. A deep, isolated, thin periodontal pocket is suggestive of VRF, whereas difficulty in aligning the periodontal probe across the periodontal defects sometimes means this sign is missed.

Radiographically VRF appears as a J shaped orhalo shaped radiolucency, which does not appear until significant bone destruction has occurred.

The 2D nature of periapical radiographs obscures the visibility of the fracture line due to superimposition artefact. 3D nature of CBCT visualizes the fracture line from multiple angulations and different orientations in thin slices at high contrast. [12]

Endodontic retreatment: Friedman considered that post – treatment endodontic disease (treatment failure) is commonly associated with root canal intra-radicular infection than the extra-radicular infection. [13] In such cases endodontic treatment is the best option, if there is persistent extra-radicular infection-apical surgery is considered.

CBCT demonstrates the location of inaccessible, unfilled, calcified canals and invagination areas of complex canal morphology.

Intra-Operative Considerations: CBCT is a useful diagnostic tool for:

1. Implant placement
2. Impacted third molar removal
3. Accessing the palatal root of maxillary molars using a vestibular or trans-antral approach root end surgery.

Advantages:

- CBCT units reconstruct the projection data to provide interrelation images in three orthogonal planes (axial, sagittal and coronal).
- The presence of collimation of the primary x-ray beam in CBCT reduces the radiation dose at the area of interest. [14]
- It determines the extent of non-endodontic lesion and its effect on surrounding structures.
- It is useful for diagnosis of the periapical pathosis in patients who are having no specific clinical signs and symptoms, poorly localised symptoms associated with an untreated or previously endodontically treated tooth with no evidence of pathosis identified by conventional imaging. [14]
- It is accurate, non invasive, reliable to detect osseous lesion size and volume.
- Beam limitation – focussed on the FOV – increased information content.

Limitations:

- CBCT is expensive when compared to conventional radiographs.
- CBCT is not suitable for soft tissue assessment.
- Scanner related artifacts.
- Endodontic sealers also produce artifacts that mimic fracture line. [4]
- Images quality is affected by scatter and beam hardening, that are caused by metal posts and restorations.
- The scan time of CBCT devices (1- 20 min) which is significantly longer compared to intraoral radiographs. Therefore, during the scan, the slight change in the movement of the patient may render the resulting reconstructed images of minimal diagnostic use. So, this poses a problem with children, elder patients and patients with neurological disturbances for example Parkinson disease. [15]

Conclusion

CBCT is a three-dimensional imaging technique which overcomes the limitations of conventional radiography and is a beneficial adjunct to the endodontists armamentarium. CBCT is a key tool for the diagnosis and management of endodontic disease. It helps in improved decision making thus improving the outcome of endodontic treatment.

Management of Medically Compromised Patients in Endodontic Practice—A Review

Venkatachalam Prakash[1], Ravindranath Megha[2], Suresh Mitthra[3], Alagarsamy Venkatesh[1]

[1]Professor, [2]Post Graduate Student, [3]Reader, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayanapuram, Pallikaranai,Chennai, Tamilnadu, India

ABSTRACT

Medical conditions of a patient play an important role in the planning of dental treatment. A thorough knowledge on the medically compromised conditions is required in endodontics for successful outcome of the treatment. This review throws light on some very important and frequently encountered medically compromised conditions and their management in endodontics

Keywords: *medical, endodontics, compromised, condition, management.*

Introduction

An endodontic emergency is a source of inconvenience and discomfort or pain for the patient. The dentist has a moral obligation to give immediate relief from pain even for the medically compromised patients.

The prime obligation of both the physician and the dentist is to relieve pain and restore to health any diseased organ. While pain elsewhere in the body may be tolerated for long periods of time, pain in the head or in a tooth is usually severe because they are contained by an unyielding structure[(1)] that produces severe inflammations because of an increase in fluid content.

In addition, pain is related to medical condition,emotional status, ethnic background and personal tolerance.

Importance of a Medical History: Medical history is taken so that the patient could be treated in a manner most harmonious with maintenance of general health. It is important to know the medical background of the patient before prescribing the medications. Medications already being taken by the patient should be considered to prevent undesirable drug interactions. At this time the dentist must consider not only the treatment modalities on the patient's existing conditions, but also the potential impact on the patient's health.

Virtually no medical contraindications exist to routine endodontic treatment. However, multiple situations might arise in which the patient's medical condition,past history, or regimen of medications may have implications that could alter the usual course of treatment.

Rheumatic Fever: Any patient with a history of rheumatic fever has the potential of suffering an attack of subacute bacterial endocarditis (SBE) after any bacteraemia[(2)]. Since almost every dental procedure, whether a simple prophylaxis, the extraction of a tooth or an endodontic treatment, causes some degree of bacteraemia[(3)]. Definite measures must be taken to avoid the possibility of SBE.

The pulp extirpation and extrusion of debris beyond the apex did produce a bacteraemia, which dissipated after 10 minutes[(3)]. Even the placement of a rubber dam

causes bacteraemia[2].Therefore it is best to ensure the standard prophylactic procedures before any endodontic appointment, whenever a periapical lesion is present and before any surgical appointment.Dental procedures for which antibiotic coverage is not recommended include treatment not likely to induce bleeding, such as adjustment completely supragingival and not requiring the use of matrix retainer.

The standard regimen for patients is 2g amoxicillin 1 hour before the dental procedure and then 1.5g 6 hours later[4,6]. For patients with allergy to amoxicillin or penicillin, 800 mg erythromycin ethyl succinate or 1.5 g erythromycin stearate taken orally 2 hours before the procedure and the half that dose 6 hours later[5]. Clindamycin may also be used with allergic patients, taking 300 mg (two 150 mg tablets) 1 hour before the procedure and then one 150 mg tablet 6 hrs later[5,7]. For children, amoxicillin may be taken as syrup, using 50mg/kg weight or, for those sensitive to amoxicillin, erythromycin at 20 mg/kg or clindamycin at 10 mg/kg[5]. The total child's dose should not exceed the adult dose.

Artificial Heart Valves: Insertion of an artificial valve in the heart to replace a valve damaged by congenital, systemic or local disease is no longer a rare surgical procedure. Artificial valves currently used are composed highly of Teflon or Teflon-like materials to diminish the possibility of adhesions. The danger of clumps of bacterial colonies collected in these valves increase greatly after bacteremia[8,9].Therefore any patient with artificial heart valve should receive the same prophylactic antibiotic administration like a patient with a history of rheumatic fever.

Coronary Artery Disease: The tremendous increase in life expectancy has caused more people of advanced age to require dental treatment. Coronary occlusion and other cardiovascular diseases are most common past 50 years,although they may be seen frequently in the 40s as well. Associated factors may include hypertension, angina pectoris, arteriosclerosis, stressful occupations, and smoking. Patients exhibiting these conditions may be suspected of tendency towards cardiovascular disease and should be treated accordingly.

Cardiovascular disease does not contraindicate endodontic therapy, but certain precautions should be observed when treating patients with a history of coronary occlusion who is receiving anticoagulant therapy. Nonsurgical endodontic treatment, requires no alteration in the administration of anticoagulants, if surgery becomes mandatory the patient's physician should be consulted. It is the physician and not the dentist to alter the administration of the drug to secure a blood level compatible with the clotting required for surgical procedure.

If the patient complains of substernal pain during an appointment, a dressing should be placed and the treatment terminated for that day.

Medication: The pain moreover subsides with rest and/or the administration of 0.4-0.8mg of sublingual nitroglycerin. The patient should be sent to the physician for further investigation.

Hypertension: High blood pressure may occur either as a separate disease entity or in conjunction with cardiovascular, renal disease or arteriosclerosis. Among the causative factors are an occupation causing tension and worry, familial tendency, overweight, unbalanced diet and abnormal stimulation of the sympathetic nervous system, often an emotional basis. Symptoms include shortness of breath, frequent and persistent headaches, poor vision, ringing ears, nose bleeds, and dizziness. Some patients, however, have no symptoms at all. Treatment is based on reduction of the symptoms by means of various drugs to lower the blood pressure.

For many years, physicians advised dentists who were treating patients with hypertension to avoid the use of epinephrine in local anaesthetic administration. Unfortunately, the local anaesthetics without vasoconstrictors have a less profound effect and shorter duration of action than those that contain epinephrine. Great depth of anaesthesia is required in endodontics for pulp extirpation and surgery. Any pain felt by the patient would produce much more epinephrine within the individual's own system than would ever be included in the anaesthetic solution. For that reason the epinephrine content of 1:10,000 available in many anaesthetic solutions is considered safe[10,6].These solutions should be injected extremely slowly, at a rate no faster 0.3 ml/sec[11] with frequent aspiration to avoid blood vessel.

Diabetics: Regardless of the type of maintenance therapy necessary for control of blood glucose level, for all diabetic patients, healing is usually retarded, which should be considered when evaluating periodic postoperative recheck radiographs.

Since diabetic patients are susceptible to infections and slow healing, antibiotics should be employed. Penicillin is the drug of choice, 1000 mg before treatment and then doses of 500 mg four times a day for 4 days[6]. Erythromycin is used for those patients with a history of penicillin sensitivity at 600mg before 1 hour.

Increase in blood glucose level as a result of an acute infection during and after a surgical procedure is common finding among diabetic patients. In these circumstances the patient should be referred to his physician for any adjustment in medication or diet necessary to combat the change. The choice of anaesthetics for diabetic patients differs from that of other patients. As pointed out by Burket, epinephrine should not be used in the local anaesthetic solution, since it increases the blood glucose level by stimulating the sympathetic nervous system[12]. Additionally, since diabetic patients often suffer from capillary ischemia due to arteriosclerosis, the increased ischemia produced by the epinephrine may cause tissue sloughs after a surgical procedure. If a vasoconstrictor is desired, levonordefrin (Neocobefrin) may be used, since it does not cause sympathetic stimulation although it does-elevate the blood pressure.

Mepivacaine And lidocaine are available without a vasoconstrictor and for surgical procedures either mepivacaine with levonordefrin (92% carbocaine HC1 with Neo-cobefrin) or a combination of propoxyphene (novocaine), procaine (novocaine), and lavarterenolbitatrate (norepinephrine bitartrate; Leophed) is an excellent anesthetic solution for use with diabetic patients[13].

Hepatitis: The microorganisms responsible for hepatitis are highly resistant to the sterilization procedures normally used in endodontics. Additionally, these microorganisms may remain in the affected patient's blood for a considerable time after the active phase. The incubation period of hepatitis A is about 3-5 weeks, with an average of 28 days. Therefore when a patient gives history of hepatitis, all intracanal instruments, which may have picked up causative agents should be discarded after use. Any files, reamers, broaches, probes or other such instruments that do pick up potentially dangerous microorganisms, even though subsequently sterilized by dry heat or steam, might cause cross-contamination if used on another patient.History of hepatitis, jaundice, or other liver disease may indicate less than normal liver function. Any drugs that are detoxified by the liver should be avoided. Drugs typically used in dentistry and falling into this category include erythromycin and halothane (Fluothane), a non-exclusive general anesthetic agent.

Epilepsy: Increased caries prevalence is seen in epileptic patients. They should be prescribed with fluoride toothpaste accompanied by the placement of pit and fissure sealants in indicated areas. Atraumatic restorative treatment should be favoured over electrically driven instruments wherever possible[14].

A few of the important seizure first aid in dental office are[15]:

1. Clear all instruments away from the patient.
2. Place the dental chair in a supine position near to the floor.
3. Turn the patient to one side (to decrease the chance of aspiration of secretions or dental materials in the patient's mouth).
4. Call for emergency if the patient becomes cyanotic from the onset. Administer oxygen at a rate of 6-8 L/minute.
5. If the seizure lasts longer than 1 minute, administer a 10mg dose of diazepam intramuscularly (IM) or intravenously (IV), or 2 mg of ativan, IV or IM, or 5 mg of midazolam, IM or IV[16,17].

Blood Diseases: Among the greatest hazards involved in treating hemophilia patient is the chance of internal bleeding caused by the injection of a local anaesthetic particularly for mandibular block. If the tooth to be treated is necrotic, no injection is needed. However, if a vital pulp is involved, extirpation becomes too painful without an anaesthetic. To accomplish pulp removal without the possibility of severe intimal bleeding caused by an injection, the dentist can gain access to the cavity by using a high speed instrument with a very sharp bur water spray, and a brush stroke with least pressure. When pulp exposure been gained, a cotton pellet dampened with formocresol is placed as a dressing and sealed with zinc oxide-eugenol (ZOE), and the patient is scheduled to return approximately a week later. The formocresol acts as a fixative on the pulpal issue and aids in gaining a satisfactory clot by its caustic action. At the second appointment, the dressing is opened and any fixed pulpal tissue removed by sharp spoon excavators and broaches with relatively little pain.

There are many disease states in which oral bleeding is symptom. Among the diseases characterized by gingival haemorrhage are aplastic anaemia, cyclic neutropenia, thrombocytopenia, leukemia, purpura, and macroglobulinemia. Two Other Blood diseases, anemia and sprue are accompanied by burning tongue.

If gingival bleeding is not relieved by periodontal therapy, referral to a physician is mandatory to investigate for the possible presence of a systemic conditions.

Prosthesis for Total Replacement of Joints: According to Mulligan, patients who have had total replacement of joints with prosthesis are also very susceptible to infections[18].The most common joints to be replaced are the hips, butt, knees, elbows and shoulder. Dental treatment without antibiotics may lead to failure of the prosthesis. Therefore Mulligan, suggests that when such patients are being treated, antibiotic coverage is indicated before endodontic treatment.

Patients who have already had a total joint arthroplasty should be advised to maintain effective daily oral hygiene procedures to remove plaque and to establish and maintain good oral health[3]. The risk of bacteremia is far more substantial in a mouth with ongoing inflammation than in one that is healthy[3,6]. Bacteremia can cause hematogenous seeding of total joint implants, both in the early post-operative period and for many years following implantation.

Other Diseases: Some infrequently present but often debilitating diseases (e.g. malignancy, nephritis,and pemphigus) will indicate that treatment may take longer than usual to gain a desirable result; the delay is due to the alteration of local response by the systemic condition.

HIV, Syphilis and Other Sexually Transmitted Diseases: HIV is a lento virus, or slow virus, indicating a long incubation period and slow progression of the disease. The mean incubation period from first contact to initial signs and clinical symptomatology, is approximately 10 years, but this time is extremely variable.

Because HIV progressively incapacitates the immune system, any disease that thrives in this immunologically depressed atmosphere will fulminate in these patients. Because of the long period of latency initially no deviation from normal may be noted by the patient or during examination by a health professional. Eventually, however opportunistic infections (persistent candidiasis, herpes simplex, or zoster, Mycobacterium infection, pneumonia, Salmonella infections) or neoplasms (Kaposi's sarcoma, several types of lymphoma) eventually cause death. The symptoms of several types of these diseases may be revealed after examination or consultation with a dentist.

It would appear that performing endodontic treatment, even for those at high risk for HIV, can be made acceptably safe. The virus seems to be killed easily by 5% sodium hypochlorite, the irrigant used during therapy. Contact with the patient's blood is very minimal, since most therapy is performed without surgery with a rubber dam. The instruments used to extirpate the pulp and enlarge the canal are disposed of according to those involved with possibly blood borne pathogens[19].

With the advent of antibiotics, syphilis cases are very significantly decreased, but now again are on the increase[20,21,22]. Oral syphilitic lesions may resemble a chronic draining sinus tract (fistulas tract), poorly healed apicoectomy or periodontal surgery scar, fibroma, or draining periodontal pocket. As a result of decreased resistance, HIV patients may succumb to Kaposi's sarcoma, which demonstrates oral lesions in approximately half its occurrences.

Drug and Medication Therapy: The medical history must include information concerning the patient's past and present drug medication. This information is important in clarifying any questions about a patient's physical condition and the possible effects expected from any medications that might be needed for the present dental problem. This segment of the history must also include any adverse reactions that the patient has had to any drugs particularly to those used in connection with dental therapy. Examples are those allergic to penicillin, sulfonamides, aspirin, tranquilizers, etc.

Drug Therapy in Endodontic Emergencies: Patients receiving endodontic therapy may need the prescription of drugs. The pain from a pulpitis or apical periodontitis that requires the need for endodontic therapy may be unbearable without analgesics. Also a similar degree of pain may follow appointments in which the apical constriction is violated or following a surgical procedure.

Analgesics may be necessary before an emergency appointment. When accurate measurements radiographs are taken and the canal preparations are done upto the working length, only minimal postoperative pain results.

In case of periapical infection, medically compromised patients or when the resistance of the host is low,requires antibiotic administration.Exacerbations are most frequent when extra appointments must be scheduled because of inability to gain the desired objectives at regularly scheduled visits or when visits are scheduled excessively far apart.

Analgesics: Relief of pain is a basic objective of any phase of dental treatment. The pain is responsible for the patient's presence in the office or may occur in the future unless definitive treatment is provided. In endodontics many patients requiring therapy have a great deal of chronic inflammation present in either the pulp or the periapical tissues. Even if pain is not a factor initially, the change in environment produced by any treatment may result in an acute reaction. The resultant need for analgesics is an almost constant requirement in endodontic therapy for enabling the patient to overcome the usually short but often present postoperative discomfort.

Usually the clinicians prescribe analgesic according to the degree of trauma induced. Since most analgesics have greater effectiveness when they are taken prior to development of pain and suitable prescriptions should be given to the patient at the conclusion of the appointment if postoperative pain is anticipated. The analgesic then can be taken either while the local anesthetic is still effective or if no anesthesia was used as soon as possible after the treatment. When a local anesthetic is used and an analgesic is prescribed, the dentist must calculate the anticipated duration of remaining anesthesia effectiveness. The analgesic should be ingested 30 to 60 minutes prior to the wearing off of the anaesthetic so that the drug will be effective. The dentist must remember that highly nervous patients may metabolize rapidly and thus the anesthesia lasts for less than the anticipated duration.

Sedatives and Tranquilizers: Sedatives and tranquilizers are drugs that are central nervous system depressants that decrease cortical excitability. Both have similar actions reducing abnormal excessive response to environmental situations that produce agitation, tension and anxiety.

Sedation drugs can be administered through various routes such as oral, inhalational, nasal, intramuscular, subcutaneous, and intravenous routes.

Midazolam is an anxiolytic agent having a short duration of action that limits its utilization to short dental treatment only. The intramuscular prescribed amount (used for premedication) is 0.07 to 0.08 mg/kg; the intravenous measured quantity for tranquility is 0.07 to 0.1 mg/kg, titrated according to response; the oral amount for tranquility/drowsiness is 0.2 mg/kg.

Midazolam is used (Sasada and Smith, 1997):

1. For induction of anesthesia,
2. For procedures performed under local anesthesia.
3. As a hypnotic agent,
4. As a premedication before general anesthesia,
5. For treating chronic pain, including differentiation syndromes.

Ketamine provides excellent amnesia and analgesia. It maintains muscle tone and it ensures breathing reflexes and facilitates spontaneous respiration. The intramuscular dose is 10 mg/kg; the onset of action is 2-8 min and the duration of action is 10-20 min. The corresponding IV dose is 1.5-2 mg/kg delivered over a period of 60 s: the onset of action occurs within 30 s and the duration of action is 5-10 min. Infusion of ketamine is done intravenously at the rate of 50 mcg/kg/min. The drug is equally effective when administered orally, extradural (in an adult dose of 10 mg) or intrathecally.

Ketamine is used (Sasada and Smith, 1997):

1. It is indicated in hypotensive or asthmatic patients to induce general anesthesia,
2. For short procedures like intra-visual examinations, burn dressing, radiological and radiotherapy procedures in children,
3. For analgesia both post-operatively and intensive care patients.
4. For chronic pain relief
5. For the reversal of severe unresponsive asthma

Nitrous Oxide: Nitrous oxide is small inorganic chemical molecule. It is also known as dinitrogen oxide or dinitrogen monoxide. It is colorless and non-flammable gas with a slightly sweet odor.Nitrous oxide is administered by inhalation, absorbed by diffusion through the alveoli, and eliminated via respiration. The elimination half-life of nitrous oxide is approximately 5

minutes[23]. It is excreted essentially unchanged (i.e. non metabolized) via the lungs; less than 0.004% is actually metabolized in humans.

Nitrous oxide is a weak general anesthetic and is generally used in combinations with other substances. It may be used in a 70% concentration in combination with 30% oxygen or as a carrier gas with more potent general anesthetic agents. It has a blood:gas partition coefficient of 0.46 and a minimum alveolar concentration (MAC) of 105%. It is used as an anesthetic because of its ability to initiate a timely and brisk emergence from anesthesia (generally <3 min)[23]. Nitrogen gas is known to assist in prevention of atelectasis[24].

Conclusion

The medically compromised conditions has direct implication in endodontics, and when the medical history is taken, patients should be asked specifically about them. Except for emergency treatment endodontic therapy should not be instituted until the systemic condition is diagnosed and treated. It is better to get the Medical fitness Certificate from the concerned physician who is treating the medically compromised patient before the endodontic treatment.

ABSTRACT

Dental caries is an infectious microbiologic disease causing localized dissolution and destruction of the calcified tissue. It is caused by host, agent, and environmental factors. The development and progression of dental caries mainly depends on time factor. The main pathogenic species involved in the initiation and development of dental caries are S. mutans, Lactobacillus acidophilus and Actinomyces viscosus. The prevention and control of dental caries plays a major role in the status of public health. Caries vaccines have been developed to prevent and protect against dental caries. Various types of vaccines are being developed at research centres, with some kind of caries vaccines being considered to diminish or prevent dental caries among the children and adults.

Keywords: *Dental caries, Caries vaccine, Glucosyltransferase, mutans streptococci*

Introduction

Dental caries is an infectious microbiologic disease of the teeth that results in localized dissolution and destruction of the calcified tissue [(1)]. Dental caries results from the interaction between the host, the host's diet, and the microflora on the tooth surface bounded by the time factor [(2)]. A wide group of microorganisms are detected from carious lesions of which Streptococcus mutans. Lactobacillus acidophilus, and Actinomyces viscosus are the important pathogenic species involved in the initiation and development of dental caries [(3)]. S. mutans has been the most implicated causative organism of dental caries. The prevention of dental caries have been implicated by various measures like immunization of the population against the disease. Many researches have been conducted on the development of an effective caries vaccine to prevent the dental caries. Vaccines are prepared from live modified organisms, inactivated or killed organisms, extracted cellular fractions, toxoids [(4)]. Vaccines are an immuno-biological substance designed to produce specific protection against a given disease. It stimulates the production of a protective antibody and other immune mechanisms.

Caries Vaccine: The protein components such as glucosyltransferase (GTF), adhesins, dextranases and glucan binding protein (GBP) present on streptococcus mutans has anticariogenic properties which are the key constituents for vaccine preparation. Adhesin, the proteins mainly the antigens acquired from Streptococcus mutans and sobrinus are individual polypeptide segments comprises roughly 1600 residues within it. Antigens I and II exhibits an enhanced activity due to the centrally placed proline and alanine that is located at the N - terminal third. Various researches on various animal models suggested that administering vaccine with undamaged proteins namely the Antigens I and II or passively administering monoclonal or transgenic proteins present in the salivary component can prevent curiosity [(5,6)].

Glucosyltransferase: S. mutans which are incapable to produce GTF have minimal potency to harm animal models. Isoforms of glucosyl transferase the GTF 1, GTFS-1, GTF-S that correspond to GTF-B, GTF-C and GTF-D respectively are present in S.mutans. The clinical trials on animal models like rodents were used to prove that GTFs in the gram positive anaerobes have analogous series at its functional realms that can protect other species by immunization [7].

Mode of Action: The main immunoglobulin constituent in the saliva is IgA along with IgM and IgG. They are liberated into the saliva from the gingival crevicular fluid along with inflammatory cells such as lymphocytes, macrophages and neutrophils. The various possible modes of action of antibodies are, 1. The specific agglutinin activity of salivary immunoglobulin communicates with the superficial receptors on the bacilli that causes hindrance to its array and resists caries. 2. Immunising the gut associated lymphoid tissue (GALT) directly can cause production of secretary IgA by salivary glands that prevents the adhesion of streptococcus mutans on the enamel. 3. The cellular and humoral elements of the immune system detected at the gingival crevices may exhibit its activity on the tooth surface. Following subcutaneous immunization with streptococcus mutans, the macrophages phagocytose and process the antigen. The B and T lymphocytes are sensitized by the macrophages, following blockade of human leucocyte antigen Class II complex and discharging IL1. The CD4 helper and CD8 cytotoxic suppressor response is activated with stimulated activity of IL2 receptors and liberation of IL2. The interplay between the cells is crucial in harmonising the formation of IgA, IgG, IgM and B lymphocytes [8,9,10,11,12].

Routes of Adminstration

Oral Route: Earlier studies, exhibited protective salivary IgA antibody reaction by oral administration of the soluble protein or combined with liposomes, gastric intubation and the like. Clinical trials were performed on animal models, by preference on germfree rats and monkeys. A significant reduction in caries was related to an increased level of salivary IgA antibodies to S. mutans, as the serum antibody titer was minimal. Administering aqueous media comprising of killed Streptococcus mutans caused decline of caries and elevated level of salivary protein IgA antibodies. However, oral administration caused detrimental effect on antigen due to stomach acidity [13].

Tonsillar Route: Tonsills can induce secretory IgA responses despite the predominance of IgG [14]. Palatine and nasopharyngeal tonsils are scheduled to provide messenger cells to regions of salivary glands by identifying the mucosal effector sites.

Intranasal Route: The nasal associated lymphoid tissue (NALT) by nasal inhalation, has been used to induce immunity to many bacterial antigens including those associated with mutans Streptococcal colonization and accumulation. Protective immunity after infection with cariogenic mutans streptococci could be induced in rats by the intranasal route with many S. mutans antigens [14].

Minor Salivary Gland: The minor salivary glands are suggested to be potential routes for mucosal induction of salivary immune responses.Glucosyltransferase (GTF) was topically administered onto the lower lips of young adults have suggested that this route may have potential for dental caries vaccine delivery [14].

Rectal Route: The colo-rectal region in humans is suggested to be the site of highest concentration of lymphoid follicles. sStudies have denoted that this route could also be used to induce salivary IgA responses to mutans streptococcal antigens such as GTF [14].

Systemic Route of Administration: The subcutaneous administration of antigens leads to the production of IgG, IgM, and IgA antibodies. The antibodies enters the oral cavity through gingival crevicular fluid and provides protection against dental caries.

Limitations of Caries Vaccine: Potentials risks are involved during manufacturing and administration of vaccines. The most dangerous was the patients with rheumatic fever who showed serological cross-reactivity between heart tissue antigens and certain antigens from hemolytic Streptococci [15]. The human IgG cross-reactive region is also present in other mutans streptococci such as Streptococcus sobrinus as well as in non mutans streptococci [16].

Conclusion

S. mutans and S. Sobrinus are in very association with dental caries. Desspite of many preventive measures such as topical or systemic use of fluorides, fissure sealants, and dietary control have been developed to prevent dental caries, the efficacy of these methods is not enough to eradicate dental caries in humans and it is

particularly distressing that many of those suffering will be among the least likely to obtain satisfactory treatment. Hence, studies on caries vaccine particularly clinical trials that could enhance the immune response safely in humans to be conducted in an advent to effectively prevent dental caries.

Root Canal Obturation- An Update of Materials and Methods: A Review

Alagarsamy Venkatesh[1], Arumugam Karthick[2], Rajendran Devakar[3], Dhakshinamoorthy Malarvizhi[2]

[1]Professor, [2]Associate Professor, [3]M.D.S, Second Year PG Student, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayanapuram, Pallikaranai,Chennai, Tamilnadu, India

ABSTRACT

A successful root canal treatment is based on diagnosis, treatment planning, knowledge of tooth anatomy, and concepts of debridement, sterilization, and obturation. Several techniques of obturation are available for root canal treatment. The choice depends on the anatomy of the canal and unique objectives of treatment in each case. The two common obturation procedures are lateral compaction and warm vertical condensation.

Keywords: *Obturation techniques, DownPak, Activ GP, Obtura II, Elements B*

Introduction

Successful root canal treatment is mostly based on diagnosis, treatment planning, knowledge of tooth anatomy, and the basic concepts of debridement, sterilization, and obturation.[1] An adequate access and a straight-line path to the root canal system allows complete irrigation, cleaning and shaping, and quality obturation.[2] Root canal treatment can be successful with careful cleaning and shaping of the root canal system, three-dimensional obturation, and a well-fitting coronal seal.

During the cleaning and shaping process, the organic and inorganic debris gets accumulate on the wall of the canal, resulting in an amorphous, irregular smear layer, which interferes with adhesion as well as penetration into dentinal tubules of certain intracanal medicament or root canal sealer during obturation process.[3]Prior to the obturation, removal of the smear layer should be done and the dentin interface should be thoroughly dried.

In 1941, silver cone was introduced by Jasper.[4] Rigidity of silver cones made them easy to place; but their inability to fill the irregularly shaped root canal system caused leakage. Silver points were found to corrode, and the corrosion products were found to be cytotoxic[5] and thus silver cones are no longer used for obturation. For many years, gutta-percha has proven to be the material of choice for a successful obturation when used with a root canal sealer, which is in turn necessary to seal the space between the obturating core interface and the dentinal wall. Sealers fill the root canal irregularities and voids, accessory and lateral canals, spaces between gutta-percha points used in lateral compaction.[6] Sealers are essential for all techniques. Some of the new materials used for obturation are based on dentin-adhesion technologies, to seal the root canal system more effectively and to strengthen the root.

Most popular core material used for obturation is Gutta-percha. It is made to flow using solvents, such as chloroform or eucalyptus or heat. They are available in standardized sizes. The conventional nomenclature refers to the tip and body dimensions (ADA-ANSI No. 26), e.g., a fine-medium cone has a medium body and a fine tip. Standardized cones are manufactured to match the taper of nickel-titanium and stainless steel instruments.

Alternative to gutta-percha is Resin-based oburation system has been used recently. Resilon is a high-performance polyurethane, used for endodontic use. It

has a close resemblance with gutta-percha and can be manipulated in the same way. It consists of a resin core material, which is available in standardized cones or pellets, and a resin sealer. Resilon is biocompatible, non toxic and non mutagenic

Obturation Techniques: There are several obturation techniques available for root canal treatment. The choice of the technique depends on the anatomy of the canal and the objectives of treatment in each case. Lateral compaction and warm vertical condensation of gutta-percha are the techniques that have been commonly used. Some of the newer methods include the use of injectable, thermoplasticized gutta-percha systems; carriers coated with an alpha phase gutta-percha; cold, flowable obturation materials which combine gutta-percha and sealer in one product; and glass ionomer embedded in gutta-percha cones. The two common and basic procedures of obturation are lateral compaction and warm vertical condensation. The methods usually vary by the direction of the compaction (lateral or vertical).

Lateral Cold Condensation: This technique has been considered the "gold standard" compared to other techniques. Lateral cold condensation has an advantage over the other techniques of being accomplished with any of the acceptable sealers and an excellent length control.[7,8] The working length determined with the larger file with a diameter consistent, a standardized gutta-percha cone is selected.Standardized cones (0.02) have less taper than those of the conventional cones, and permit deeper penetration of the spreader. Alternatively, a tapered conventional cone is adapted by cutting small increments from the tip. "Master cone" is measured by grasping with a forceps from the forceps to the cone tip is equal to the prepared length.The cone is placed in the root canal, and if an appropriate size has been selected, there will be a "tug back."

The master cone placement is confirmed with the help of a periapical radiograph. The sealer is then applied to the canal walls via the last-sized file used at working length. The spreader is selected that matches the taper of the canal. The accessory points are selected according to the spreader taper. Finger spreaders has shown to be less likely in inducing fractures in the root when compared with the traditional D-11T hand spreader and they provide better tactile sensation.[9] There appears to be a correlation between penetration of spreader and the establishment of a seal.[10,11] The spreader should fit within 1 to 2 mm of prepared length, and when introduced into the root canal along with the master cone, it should be within 2 mm of the working length. After placement, spreader is slowly removed by rotating it back and forth as it is withdrawn. The accessory cone is placed in the space which is made by the instrument and the process is repeated till the spreader does not penetrate beyond the coronal third of the canal.(Figure 1)

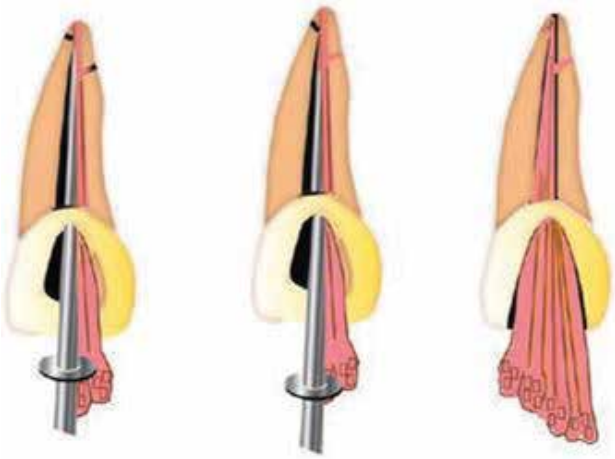

Figure 1: Cold Lateral condensation

Warm vertical condensation: Warm Vertical condensation forms the basis for many techniques, such as the thermoplasticized techniques, master-cone sectional and warm gutta-percha techniques, [12]

A master cone is fitted short of the corrected working length (0.5 to 2 mm) with resistance to displacement. This ensures that the prepared canal smaller than the core diameter. The canal taper are closely replicate the Conventional cones they permit the development of hydraulic pressure during compaction. Following its adaptation, the master cone is removed and the sealer is applied.

After cone is placed into the canal and the coronal portion sealed by applying heat with a spreader or plugger that also softens the remaining material in the canal. A plugger is inserted into the canal and the gutta-percha condenses, forcing the plasticized material apically.

The coronal canal space is back-filled using small segments of gutta-percha by placing into the root 3- to 4-mm sections approximately the size of the canal, applying heat, and condensing the gutta-percha with a plugger. In comparing cold lateral and warm vertical condensation techniques, it has been found that a higher percentage of the canal area is filled with

gutta-percha in oval canals using the warm vertical condensation technique.[13] In addition, it has been found that the gutta-percha adaptation is improved with deeper heat application.[14] Advantages of the warm vertical compaction technique include filling of accessory canals and canal irregularities. Disadvantages include the risk of vertical root fracture because of compaction forces, as well as less length control than in lateral compaction, with the potential for extrusion of material into the periradicular tissues.

Temperature Control: The DownPak Cordless obturation device (EI, a Hu-Friedy Company, Chicago, IL), as well as the System B, and Touch 'n Heat (SybronEndo) devices, are alternatives to applying heat with a flame-heated instrument because they permit temperature control. (Figure 2)

Figure 2: Devices permitting temperature control

A variation of warm vertical compaction is ***Continuous Wave Compaction Technique***. It employs the System B unit and stainless-steel pluggers—each tip of 0.5 mm diameter. The gutta-percha cones mimic the tapered preparation, permitting application of greater hydraulic force during compaction with appropriately tapered pluggers. After sealed with the master cone, a plugger are sized to fit within 5 to 7 mm of the canal length.

The point of plugger binding should be noted, as once the instrument reaches this point, the hydraulic forces on the gutta-percha will decrease and forces on the root increase. There appears to be a correlation between the depth of the heated plugger being at the working length, and the quality of obturation.[15]

The DownPak—3D Obturation with heat and vibration: The DownPak is a device which is recently introduced to the U.S. market and allows three-dimensional obturation with heat and vibration. Used in Europe under the name EndoTwinn, it recently gained Food and Drug Administration clearance in the United States. The DownPak is cordless and designed with a multifunctional, endodontic heating and vibrating spreader device, and can be used for both warm vertical and lateral compaction techniques. It is suitable for use with gutta-percha, Resilon, and hybrid resin filling materials. The clinician can choose to work with or without tip vibration or condensation techniques, making this device versatile.

The DownPak technique adapts a master cone in the same manner as that of lateral compaction. A 0.04 taper gutta-percha cone is fitted in the root canal to the working length. The 0.02 taper spreader of the battery-powered DownPak is activated and heated for 2 seconds in vibration mode and placed between the master cone and the dentin. It is advanced, when tip reaches within 2 mm of working length. In order to condense the filling material, spreader are removed and a D11T spreader is placed to within 1 mm of the working length. A fine-medium (FM) accessory gutta-percha point is placed. This procedure is repeated until no more than 2 mm of the spreader can be entered into the canal. Traces of gutta-percha and sealer were removed from the chamber with alcohol.

DownPak offers wide selection of tips in nickel-titanium and Ultrasoft stainless steel. The heat-carrying tips are designed with geometries that are consistent with tapered root canal preparations. The XF tip with ISO 0.030 diameter and 0.02 taper allows for deeper condensation, in narrow canals.

Plastic-Injection Techniques: The ***Obtura II*** system comprises of a hand-held "gun" with a chamber into which pellets of gutta-percha are loaded, along with silver needles of varying gauges used for delivering the thermoplasticized material to the canal. The temperature, and the viscosity, of the gutta-percha can be adjusted. A study found that at 6 mm from the apex, the highest internal temperature of the Obtura II was 27°C.[16] Hybrid technique is often employed by filling the canal to approximately 4 to 5 mm from the apex using the lateral compaction technique before filling the coronal portion with the thermoplasticized gutta-percha (Figure 3). The needle backs out of the canal as it is filled, and pluggers were dipped in alcohol and are used to compact the gutta-percha. Compaction should be done until the gutta-percha cools and solidifies to compensate for the shrinkage or contraction that occurs upon cooling.

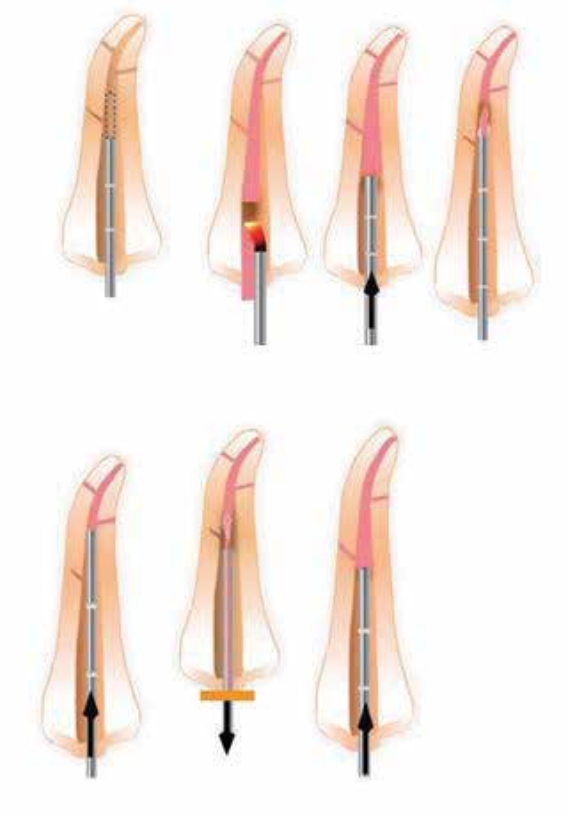

Figure 3: Combination of vertical condensation and warm injectable

The ***Calamus Flow Obturation Delivery System*** (Dentsply-Tulsa Dental, Tulsa, OK) has a handpiece and activation cuff to enable control of the flow and temperature of the gutta-percha into the canal. The activation cuff is released to stop the flow. The gutta-percha is packed in disposable, single-use cartridges, and a filling material indicator gets you monitor the remaining filling material (Figure 4) [17].

Figure 4: Calamus device

The ***Elements Obturation Unit*** (SybronEndo) comprises of a System B device and a gutta-percha extruder in a handpiece which is motorized (Figure 5). The extruder tips are 20-, 23-, and 25-gauge size and are pre-bent. The disposable cartridges of gutta-percha are heated quickly and the unit is shut off automatically to prevent overheating of the material [18].

Figure 5: Elements B obturation unit

Single Cone Technique: The ***Activ GP™ Precision Obturation System*** utilizes glass-ionomer technology, extends the working time of the glass ionomer sealer by modifying its particle size to nanoparticle level. The gutta-percha cones are usually coated with glass ionomer particles at thickness of 2 µm. The cones can be bent till 180° without showing any signs of delamination of the coating, and they are matched in size to the preparations created by the files. Matching of the primary cone to the preparation is important with any single cone technique, because the accurate fit of the cone to the preparation help reduce the amount of sealer used, as well as minimizing any potential shrinkage [19].

Conclusion

The most important goal of dental professions is to maintain the health as well as integrity of patients' dentitions. They must recognize that a particular obturation method will not satisfy each and every case that requires endodontic therapy. The method of obturation selected, whether a traditional or a contemporary one, and must be consistent with the principles of clinical practice, and to provide the best treatment for patients [20].

Endodontic Treatment Failures and its Management—A Review

Balasubramaniam Anuradha[1], Raja Sharumathi[2], Alagarsamy Venkatesh[3], Seenivasan Niveditha[4]

[1]Reader, [2]Undergraduate Student, [3]Professor, 4B.D.S, Undergraduate Student, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayanapuram, Pallikaranai, Chennai, Tamilnadu, India

ABSTRACT

Root canal treatment is a therapeutic process performed to remove inflamed or infected pulp tissue within the tooth and to prevent apical periodontitis. The ultimate goal of endodontic treatment is removal of the pathologic pulp, cleaning and shaping of the root canal system and the three dimensional obturation to prevent re-infection. The cause of endodontic failures can be due to inappropriate debridement, presence of extra root canals or lateral canals, persistence of bacteria in the canal or apex, under or over extension of filling material, coronal leakage are some of the common causes for failures. This article review general description of root canal treatment, causes of failures of root canal treatment and how to manage failed RCT.

Keywords: *Root Canal Treatment, re-RCT, failed RCT.*

Introduction

The main goal of root canal treatment is healing of periapical tissues and eliminate necrotic or infected pulp from the root canal and to fill the space with a permanent restoration in order to prevent secondary infection or periradicular tissue leakage into the canal [(1)] The chance of root canal treatment failure is more common in posterior teeth than anterior teeth and mostly right mandibular molars has greater incidence than maxillary molars[(2)]

Cause of Failure of Root Canal Treatment: The failure of root canal treatment is broadly categorized under three sub heading:

1. Preoperative cause
2. Operative cause
3. Postoperative cause

Email: anuradha_ind@yahoo.com

1. Preoperative Cause:

A. Incorrect Diagnosis: Failure to establish the nature, source and cause of the infection will lead to incorrect treatment resulting in non resolution of the initial complaint and perhaps creating additional problems. It may be due to poor case selection, poor prognosis, any misinterpretation, lack of information either by clinically or radiographically[(3)]

B. Altered Canal Space: Calcification may occur due to inflammatory response to caries in a root canal.[(4)] Decalcification can be done using chemicals such as EDTA followed retreatment will lead to success.

C. Traumatic Injuries: The rate of teeth requiring endodontic treatment after traumatic injury is higher than that of teeth with pulpal problems of the other origin. Root resorption that occurs as a result of the trauma results in failure. [(4)].

D. Anatomic Variation: Favorable prognosis can be prevented by presence of lateral canals, inaccessiable accessory canals, extremely curved canals, and complex internal anatomy. [(4)]

E. Internal Resorption: Over extension of filling, lack of adequate density and compaction of the obturation disrupts the prognosis of root canal treatment as the unobturated areas serves as a niche for the deposition of bacteria. [(5)]

F. **Radiographic Intrepretation:** When placing x-ray film with rubberdammay cause incorrect positioning of x-ray film leading to difficulties during root canal access and instrumentation due to mis judgement of the canal location. It can also be caused by incorrect use of the film positioner.[5]

G. **Systemic Diseases:** Systemic diseases which intervene with bone regeneration include hyper parathyrodism, Paget's disease, hyper thyroidism and osteoporosis. Other factors like nutrition, age, hormones, vitamins, stress, chronic diseases and dehydration also have an impact on periapical repair.[4]

2. Intraoperative Causes:

a. **Tooth Isolation:** Rubber dam is one of the most ideal isolation method for endodontic treatment, as it prevents salivary contamination, accidental instrument aspiration and allows prior proper access and visibility. [5]

b. **Access Preparation:** Access opening can be done to remove old restoration, infected dentin and pulp, deroofing of pulp and to expose root canals. Incorrect access opening leads to perforation of floor, walls, incomplete removal of pulp chamber, missed canal etc which can lead to serious consequences[5].

c. **Technical Difficulties:** The mechanical and biological objective of endodontic therapy is obtained through cleaning and shaping of root canal, hence poor cleaning and shaping of root canal would cause failure which ultimately leads to retreatment.[4]

d. **Infection:** Improper removal of necrotic and infected pulp tissue inside the pulp chamber acts as chronic irritant and causes failure of root canal treatment. Spaces in the canal after restorations create a nidus for accumulation of the microorganisms which exaggerate the infection. [4]

e. **Altered Canal Space:** Chronic inflammatory response of pulp results in calcification of canal space and prevent the proper and completed negotiation of canals leading to failure [5]. To prevent this adequate use of chelators and lubricants should be followed.

f. **Missed Canal:** Persistance of pain and inflammation even after the treatment maybe due to missed lateral canal. The reason for missed out canal is due to improper access and poor visibility, lack of knowledge of the anatomy or not improper examination of extra canals which may lead to post treatment disease[5].

g. **Poor Debridement:** Proper irrigation and agitation techniques can considerably reduce the bacteria content Poor debridement results in post treatment failure[5].

h. **Excessive Haemorrhages:** Small hemorrhages during endodontic procedure are repaired without incident. But, excessive hemorrhage when occurring due to extirpation of an inflamed pulp along with instrumentation extending beyond the apex of the tooth, results in mild inflammation due to formation of hematoma by local accumulation of blood. If not resorbed by macrophages, repair is delayed in the presence of infection of the blood acts as a nidus for bacterial growth (Seltzer et al 1988).

i. **Broken Instruments:** The presence of denticles in the root canal complicates endodontic therapy. When situated in apical third of root canal, denticles enhances the possibility of breakage of barbed broach especially if there is a defect in the metal. Consequently barbed broach should neither be introduced into tight canal, not should they be used for enlargement of canal but merely to engage the pulp tissue for removal. Commercially available retrieval kits can also be used for broken instrument removal.

j. **Mid -Treatment Flare Up:** The prompt & effective treatment of mid treatment flare ups of all types is essential & forms an integral part of endodontic therapy. The right management of these flare –ups enhances a positive attitude amongst patient towards endodontic treatment. Otherwise, patient may lose interest in continuing the treatment which ultimately returns in failure.

k. **Mechanical and Chemical Irritants:** When instrument has been confined to root canal

& presumably instrument tip has damaged the apical pulp stump, chances for repair are enhanced. (Strindberg 1956). There was lower frequency of failure when the canal could not be reamed through apex as compared to the situations where instrumentation was carried out to or beyond the apex. Grahnen&Hansson (1961) &Frosteu (1963) even found that failure frequency was greatest in single rooted teeth when the canal is apparently easiest to file & ream. During endodontic treatment, various medications are used as dressings in the root canal. Their functions are to eliminate or reduce microbial flora, prevent or lessen pain, reduce inflammation or stimulate repair. Torreck (1961), Schilder and Amesterdam (1956) have demonstrated irritating potential of many root canal medicament. Successful endodontic therapy does not require use of drugs (Matsumiya & Kitamar 1960).

l. **Under Extended Filling:** Under extension can be seen on radiograph and in such cases retreatment is the first consideration. Solvents like xylene can be used to remove gutta-percha, but care must be taken that such products should not force themselves into the periapical area during the gutta-percha removal procedure. If required surgical approach might become necessary to correct the underfillings.

m. **Over Extented Filling:** Over extension of root canal filling, gutta – percha and sliver point delays periapical heating. Selzar et-al (1972) performed some of the sliver cone studies which revealed that the corrosion of the sliver cone was associated with sulphur. Chemical product formed predominantly was a sliver amine sulfate amide, and all cells body contained sulphur primarily. Numerous studies have shown that highest success rates were obtained when root canal terminates 1-3 mm from the radiograph open (Strindberg 1956). Radiographically, the overfilling can usually be discerned as the filling material seeming to expand, curve or be lacking in the symmetry. According to Crump (1979), it is not necessary to treat overfilling unless clinical symptoms develop. It can be operated on to obtain radiographically pleasing result. Overfilling which is shown in the radiograph must be avoided for the successful of the root canal therapy.

Causes of overfilling: (1) Failure in determining the exact location of the apical foramen an absence of apical stop or constriction in mature teeth. (2) Incorrect selecting of master cone. (3) open apices.

n. **Improper Obturation:** Failure also occurs, when gutta-percha appears to fill the canal up to the apical foramen, but does not obliterate the canal space laterally. If master cone binds tightly in the middle third or coronal third of the canal, but fails to the apical third the tug-back resistance originates in the wrong area, because accessory cones fail to pass apical third of the canal after lateral condensation.

3. Post–Operative Causes

a. **Failure Following Retreatment:** Once endodontic treatment has failed, the chances for second failure after non surgical retreatment were enhanced (Bergenholtz et al 1979).

b. **Failure Following Surgical Retreatment:** Failure of endodontic treatment may occur following apiectomy, apical curettage. As per the block etc (1978) success rate after surgical retreatment is 67%, 3% failure outcome of 40% was uncertain.

Retreatment Techniques: Numerous techniques have been suggested for retreatment of root canals. They are discussed below according to the root filling materials that are proposed for retreatment.

1. Retreatment of Paste and Cements

i. **Soft –Setting Pastes:** Normally soft-setting pastes do not interfere with the negotiation of the root canal. Therefore, their removal does not require specific techniques. In such cases, instrumentation of the root canal with the use copious irrigation suffices to remove the paste.

ii. **Hard –Setting Cements:** If possible, hard-setting cements should be dissolved. When this is not possible, their removal may be attempted by either of the following two techniques,

a. **Dispersion of Ultrasonic Vibration:** Endosonic files are placed in the orifice of the

obturated canal and activated with light apical pressure. The ultrasonic vibration pulverizes the cement, while the continuous irrigation flushes out the dispersed particles. This procedure is gradually continued apically, until the entire obturation is removed.

b. **Drilling with Rotatory Instruments:** Hard cements may be drilled out by rotary endodontic instruments, such as Beutel-rock or engine reamers or by using bur.

i. Retreatment of Gutta Percha:

Techniques for Dissolving Gutta Percha

i. **Solvants of Gutta Percha:** Gutta-percha is soluble in chloroform, methylchloroform, carbon disulfide, carbon tetrachloride, benzene, xylene, eucalyptol oil, halothane and rectified white turpentine.

ii. **Hand Instrumentation:** This is the most commonly practiced technique, although it is time-consuming and occasionally yields limited results. By the use of solvent, the canal is negotiated with files or reamers to the desired working length estimated from the preoperative radiograph.

ii. **Automated Instrumentation:** This technique is fast and safe and short-filled curved canals may be negotiated beyond the obturation. Thus, a radiograph may be obtained at an early stage, without the need to first instrument the canal extensively to remove the bulk of the material from it. The Canal Finder system also has a built in apex locator that may be used as an aid in preventing overinstrumentation with this technique.

iv. **Ulrasonic Instrumentation:** Ultrasonic instrumentation following softening with chloroform does not facilitate the removal of gutta-percha from the root canal, even when continuous irrigation with a solvent is used.

Solid Gutta Percha Technique:

i. **Pulling Out Gutta Percha:** Reamers or Kfiles are used to bypass the obturation, and Hedstrom files are engaged into the loosely condensed gutta-percha cones, which are then retrieved in one piece by pulling back the instrument.

ii. **Rotatory Removal of Gutta Percha:** Removal of gutta-percha with rotary instruments is safe only in straight canals.

1. Retreatment of Solid Objects:

a. **Bypassing with Hand Instruments:** Reamers and files may be used to bypass an obstructing object in the root canal, and solvents can be used to soften its cementation.

b. **Bypassing with Automated and Ultrasonic Intruments:** Silver cones that cannot be bypassed with hand files may be bypassed and subsequently retrieved by the Canal Finder.

c. **Special Grasping Devices:**

d. **Masserann and Alternative Extractors:** The Masserann kit consists of an extractor into which the object to be retrieved is locked.

e. **Wire Loop Technique:** A thin steel wire is inserted into a 25-gauge hypodermic needle. On the sharp side of the needle a loop is formed and on its other side, the freeends of the wires arc pulled to tighten the loop. The needle is placed in the canal so that the loop contacts the broken instrument, and then the loop is tightened and the instrument may be retrieved by pulling the needleback.

Conclusion

Endodontic failure still occur despite technological advancements in the field of dental instrumentation and materials. Endodontic procedural errors are not the direct cause of treatment failure. The technological boom in endodontics has provided the methods and instruments that allow successful treatment of teeth with calcified chambers, calcified canals, severe root curvature, ledging, resorptive defects, perforations and canal blockage due to separated instruments. With enhanced magnification by operating microscope, direct lighting, use of ultrasonics, NiTi instruments, multiple delivery systems for obturation, almost all procedural errors during endodontic therapy can be minimized or prevented/successfully treated with predictable prognosis.

ABSTRACT

The complexity of the root canal system morphology presents a continuous challenge to endodontic diagnosis and therapeutics. Root canal morphology is limitless in its variability and clinicians must be aware that anatomic variations constitute a big challenge to the endodontic success rate. A proper diagnosis using radiographs play an important role in the successful treatment of such variations. This case report presents relatively rare cases of mandibular first and second molars with single roots and a single root canals.

Keywords: *Single canal mandibular molar,single root*

Introduction

Successful root canal therapy requires a thorough understanding of the tooth anatomy and root canal morphology.[1]The variation of root canal morphology is a constant challenge for diagnosis and successful endodontic therapy. Having complete knowledge of the root canal anatomy and its most frequent changes is essential to prevent endodontic failure. The dental pulp presents with various configurations and shapes throughout the human dentition. Thorough knowledge of tooth morphology, careful interpretation of radiographic documentation and adequate access to the exploration of the pulp space is prerequisites for all root canal procedures whether surgical or nonsurgical.

Periapical radiographs play a significant role in assessing the number, length, curvature, and aberration of the canal system of the tooth. Radiovisiography (R.V.G)system is a valuable adjunct for radiographic documentation. [2]It offers a lot of advantages compared to conventional radiographs, especially the ability to manipulate the captured image. The drawbacks of radiographic techniques are they only provide a 2-dimensional image of a 3-dimensional object.Other sophisticated techniques such as microtomography, computerized tomography scan, etc are not practical for a clinical setup.

Often, the mandibular first molars require endodontic treatment as they are the first permanent posterior teeth to erupt and are commonly affected by caries.[3] Typically, the mandibular first molar has 2 well-defined roots: a mesial root with two canals and a distal root with one or two canals. Variations in the form, configuration, and several root canals in mandibular molars have been discussed extensively in endodontic literature.[4] These include mandibular first molar with five, sixand seven root canals [5], middle mesial canal [6], middle distal canal [7], four canals in mesial root [8], four canals in distal root [9], radix entomolaris[10] and "C-" shaped canal. [11] These reports predominantly include cases with more number of canals than normal, but the clinician should also be aware of the possibility of the existence of a lesser number of roots or canals. Gopikrishna et al., published a case report of a single root with a single

canal in a maxillary first molar. [12]Krithikadatta et al., have reported a case of a mandibular first molar with two roots and two root canals.[13]Generally, the anatomical configuration of mandibular second molar is two roots, mesial and distal, which can also get fused to a single conical root with varying internal anatomy and often have a c-shaped canal configuration.

The purpose of this paper is to report the uncommon anatomy of mandibular first and second molar with a single root and single canal.

Case Report

In this article, we report 2 cases of endodontic management of a mandibular second molar and a mandibular first molar with a single conical root and a single canal.

Case I

Case I: A 36-year-old male patient reported to the department of conservative dentistry & endodontics with the chief complaint of pain in the lower left back tooth region for the past 3 months. History revealed dull aching pain which aggravates on chewing & relieved by medication. Extra-oral examination revealed no palpable lymph nodes and no facial asymmetry. Intraoral examination showed dental caries in 37whichwastenderon percussion. There was no relevant medical or dental history. Intraoral periapical radiograph revealed dental caries involving enamel,dentin and pulp with a fused conical root. Based on clinical and radiographic examination it was diagnosed aschronic irreversible pulpitis in 37 with symptomatic apical periodontitis (Fig 1-A) and root canal treatment was indicated in 37.

Figure 1-A)Pre operative radiograph B)Working length determination C)Obturation radiograph

Case II: A 23-year-old male patient reported to the department of conservative dentistry & endodontics with the Chief complaint of pain in the lower right back tooth region for the past 1 month. History revealed dull aching pain which aggravates on chewing & relieved by medication. Extra-oral examination showed no palpable lymph nodes and no asymmetry was evident. In the Intraoral examination, there was decay in 46 with tenderness on percussion. Intraoral periapical radiograph revealed dental caries in 46 involving enamel,dentin, pulp and periapical region with a fused conical root.Based on clinical and radiographic examination it was diagnosed as Chronic irreversible pulpitis in 46 with symptomatic apical periodontitis (Fig 2-A) androot canal treatment was indicated in 46.

Case II

Figure2-A)Preoperative radiograph B)Working length determination C)Obturation radiograph

Methodology

Localanesthesia was given using 1.8 mL 2% lidocaine with 1 : 200,000 epinephrine (Xylocaine; AstraZeneca Pharma India Ltd., Bangalore, India). Isolation was done using rubber dam and conventional endodontic access cavity opening was established with an Endo Access bur (Dentsply Tulsa, Tulsa, OK) in both the mandibular first and second molars and a single large canal was present at the center of the pulp chamber in both the cases. Most often single-rooted mandibular molars could be associated with the C-shaped canal but in these cases, a "C-" shaped orifice/canal was not identified. Smaller files were used to check the presence of extra canals in both buccal and lingual directions. ISO 20 K file was used for glide path. The canal patency was established with a suitable ISO 40 K file in mandibular first molar(46)(Fig 2-B) and ISO 50 K file in mandibular second molar (37) (Fig 1-B) respectively. The working length was determined with the help of an electronic apex locator (Root ZX,Morita) and confirmed using radiographs. Instrumentation of the canals were performed using a crown down preparation with K files up to 60 K for mandibular first molar(46) and up to 80 K for mandibular second molar(37) respectively. Canal irrigation was performed using 2.5 % NaOCl and 17% EDTA.Final irrigation was done using saline and 2% chlorhexidine. The canals were dried with sterile absorbent paper points and then coated with AH Plus sealer and obturated with gutta-percha using cold lateral compaction technique.(Figs 1&2 – C)

Discussion

The occurrence of abnormal anatomy depends on various factors like age, sex, and ethnicity that play a role in determining the pattern of the root canal. A radiographic examination is an essential component in endodontic treatment.Radiographs in multiple angulations aid in the diagnosis of canal abnormalities. Multiple preoperative radiographs and an additional radiographic view from a 20-degree mesial or distal projection increases the chances of detecting unusual root canal morphology.[14]

The mandibular first molars erupt at the age of 6-7 years with apical closure is completed by the age of 8-9 years. Completion of canal differentiation commences at about 3–6 years after root completion.[13] Any disturbances in this differentiation could have resulted in this type of single canal anatomy.

In the Systematic review of the literature on canal morphology of the mandibular first molar by Valencia De Pablo et al. [15] and Ballulaya et al.,[16],the occurrence of the single canal has not been documented. But this type of morphological variation has been documented in an in vitro study done by Reuben et al. [17] where out of 125 samples of mandibular first molars studied from an Indian population, only one sample had a single root and single canal.

Kottoor et al.,[18] and La et al.,[19] have suggested the use of CBCT to determining the root canal morphology in cases with aberrations. In both cases, the root canal was located at the center of the pulpal floor and the dentinal map was not evident therefore searching for an extra canal in such cases could lead to excessive removal of dentin and even perforation. Since the single canal was large circumferential filing technique was used.

The mandibular second molar erupts at the age of 11 to 13 years. The pulp chamber of the mandibular second molar is smaller than that of the mandibular first molar. Usually, the mandibular second molars have two mesial canals (MB and ML) and one distal canal similar to the mandibular first molars.[20]The two mesial orifices are located closer together.

Fava et al., [21]reported the presence of one single root and one root canal in all second molars of the same patient. Panciera& Milano studied 102 extracted human mandibular second molars and described six teeth (5.88%) possessing one root and one root canal.A study by Cimilli *et al*.,[22]in 2005 reported 1.3% of mandibular second molars had single canal configuration.

In the case of the occurrence of one root, the root canal system may have only a single broad root canal or two canals that may or may not join or a C-shaped canal. Sabala et al., [23]stated that the rarer the aberration, the more probable that it was bilateral. But bilateral presence of single rooted molarswere absent in both the cases reported here. One of the common iatrogenic errors during access opening is caused during the search for the missing or extra canals. Such iatrogenic errors can be prevented if the clinician has a thorough knowledge of the general location and dimensions of the pulp chamber. Even though extra canals are more common, the clinician should be aware of the fact that there is a possibility for fewer canals too.

Conclusion

The anomalies in the root canal morphology need not always be extra canals but it can also be in the form of fused or fewer canals. Whenever an unusual anatomic form is encountered, multiple angled radiographs of the tooth in concern will reveal more details of the anatomy of the root canal system thereby helping in a successful endodontic treatment.

ABSTRACT

Root perforation is an artificial communication between the root canal system and the supporting structures in the external root surfaces which may causes serious implications that can even lead to extraction, however if diagnosed early and with appropriate treatment plan of the perforation will lead to long term survival of the tooth. Successful outcome of the treatment depends mainly on proper diagnosis and immediate sealing of the perforation to eliminate risk of infection. A classification of root perforations is described in the review to assist the clinician in making a proper choice of treatment protocol.

Keywords*: root perforation, causes, diagnosis, materials, management*

Introduction

The American Association of Endodontists (AAE) Glossary of Endodontic Terms defines root perforations as mechanical or pathological communications between the root canal system and the external tooth surface[(1)]. Perforation is considered as an artificial opening between the root canal system and the surrounding tissues of teeth, which are either created by the clinician during entry into the root canal system and during cavity preparation or by a biological event such as resorption or caries, resulting in communication between root canal and periodontal tissues. According to Fuss and trope root perforation is defined as an artificial communication between root canal systems to the supporting tissues of teeth or to the oral cavity[(2)]. The etiology of perforation can be attributed as iatrogenic and non-iatrogenic[(3)].Iatrogenic perforation occurs due to lack of proper knowledge about the internal anatomy of tooth and in the failure of determining the possible variations in root canal system. Iatrogenic perforation can occur in any level during endodontic treatment. During access cavity preparation, due to misaligned use of rotary burs without appreciating the angulation of the tooth and search for other root canal orifices, root perforations can occur. It occurs most oftenly at coronal level of the tooth. During negotiating the calcified and curved canals, the lateral extension of the canal preparation is called strip perforation, and during post-space preparation, over instrumentation of rotary instruments leads to apical or crestal perforations of root canal wall, which is also called as strip perforation[(3)]. During cleaning and shaping of root canal system, the perforation may occur in coronal, middle, or apical third of the root. Non-iatrogenic perforation can occur due to internal or external resorption,[(3)] trauma, and caries mostly involving the furcal area.

Classification of root perforations: Considering the factors impacting the outcome of treatment mentioned above, the following classification of tooth root perforations, given by Fuss & Trope, [(4)] may assist the dentist to select a treatment strategy:

*Fresh perforat*ion – should be treated immediately or shortly after occurrence of under aseptic conditions, Good Prognosis.

Old perforation – previously not treated with likely bacterial infection, it has Questionable Prognosis.

Small perforation (smaller than #20 endodontic instrument) – mechanical damage to tissue in the root canal system is minimal with easy sealing opportunity, Good Prognosis.

Large perforation – done during post space preparation, with appreciable amount of tissue damage and marked difficulty in salivary contamination, providing an adequate seal, or coronal leakage along temporary restoration, it has Questionable Prognosis.

Coronal perforation – occurs coronal to the level of crestal bone and epithelial attachment with minimal damage to the supporting tissues and easy access, Good Prognosis.

Crestal perforation – occurs at the level of the epithelial attachment into the crestal bone, Questionable Prognosis.

Apical perforation – apical to the crestal bone and the epithelial attachment, it has Good Prognosis.

In multi-rooted teeth where the furcation is been perforated, the prognosis alters according to the factors described for single-rooted teeth.

Factors affecting the prognosis of perforation repair: Successful outcome of tooth root perforation treatment depends upon the whether bacterial contamination at the site of perforation can be prevented or eradicated [4]. Various factors that include time from the perforation to detection, size, and shape of the perforation and also its location have a great significance to control bacterial infection at the perforation site.

Time of perforation of tooth root: In a study conducted by Lantz and Persson making root perforations in dogs and treatment was initiated as soon as detected or after a small delay and on observation healing response were more clear when perforations were repaired immediately [5–7]. Seltzer et al. also has done a study [8] on 22 perforations on monkeys at time intervals from immediate observation to 10 months and they noticed that, the periodontium was collapsed in all most all teeth, however an increase in tissue damage was in the untreated root perforations and in those teeth where the sealing of perforation was been delayed. In the study Benenati et al. also [9] he noticed that a delay in sealing the perforations with amalgam did not affect the prognosis, with the assurance that the perforation site was kept aseptic. Healing response is more clearer when the perforation repair is done as soon as possible.

Size of perforation of tooth root: Himel et al. [10] conducted a study in which the mandibular teeth of the dogs to study the influence three materials that was used for healing the perforations of the pulpal floor and it was noticed that the larger teeth that has smaller perforations had greater chance of healing. Prognosis is marked as poor when there is a large perforation that occurs during post placement which leads to increased amount of tissue destruction and higher chances of microbial contamination from the oral cavity.

Location of perforation of tooth root: Location along the root surface is the most important parameter in determination of prognosis of root perforation. A perforation that appears nearer to the crestal bone and to the epithelial attachment is very important as there is more chance of microbial contamination from the oral environment through the gingival sulcus. Perforations, that occur coronal to the crestal bone, are easier to access and manage, and those teeth may be restored without periodontal involvement. Sufficient sound tooth structure for an adequate restoration is needed for good prognosis. Perforations that are apical to the crestal bone and epithelial attachment seem to have a good prognosis however prognosis depends upon cleaning, shaping and obturation[4]. In an in vitro study conducted by Seltzer et al. he found that furcal areas in molars are more troublesome as there is increased chance of periodontal involvement and tissue destruction [8].

Determination of the presence of root perforation and location of root perforation: As proper detection of root perforations and determination of location are very important to the treatment outcome, certain signs, and tools must be recognized in establishing the diagnosis. Sudden bleeding and pain during instrumentation of root canals or post space preparations in teeth are warning signals of a potential tooth root perforation. Blood appearing on paper points may also be indicative, but unreliable as bleeding may be from the apical foramen or from residues of vital pulp tissue. To aid in radiographic detection, it has been proposed to place a highly radiopaque calcium-hydroxide paste, by using barium sulfate, in the root canal [11]. However, caution should be exercised in crestal perforations as this can result

in extrusion of the material into the periodontal tissues and may lead to unnecessary mechanical and chemical irritation affecting the treatment prognosis. Radiographs taken at different angles with radiopaque instruments in the root canal are a more better choice and may confirm the presence of a perforation. However, when the perforation is located at the palatal or buccal aspects of the root, the diagnostic value of radiographs is limited. Anatomical structures, and also radiopaque materials superimposing on theroot image, may also obscure the perforation site. Electronic apex locators (EALs) can accurately determine the location of root perforations, and therefore it is more reliable than radiographs [12]. After root instrumentation, it is recommended that the working length to be determined and verified with EALs. Readings, that are significantly shorter than the original working length can be an indication of a perforation [11]. A dental operating microscope is another helpful aid [13,14]effective in detecting root perforations during orthograde root canal treatment and in surgical endodontic therapies. High magnification with proper illumination allows accurate detection and visualization of perforations along straight non-curved root canals.

Various materials used in perforation repair: An ideal materials used in the treatment of root perforation for root perforation material is still challenging. The repair material used in close contact with hard tissue and periodontal structures should be biocompatible as it can cause toxic reaction either by leaching of the material or by material itself. Earlier different material including Gutta-percha, Amalgam, Zinc oxide and glass ionomer cements, Calcium hydroxide, Composites were used. Newer developed materials like MTA, Biodentine, dentin chips, Bioceramics, Calcium enriched material, with and without the use of barrier could be used to repair the perforation.

Treatment aspects of root perforation

Prevention: Always care should be excerised during endodontic and operative procedures to prevent root perforation. Before accessing root canals the crown-root alignment should always be analysed and bony prominences noticed. Mostly, palpation is helpful to detect the direction of the root relative to the crown. Proper examination of radiographs is important to evaluate the depth and of the pulp chamber and width of the furcation floor. Indeed, proper amount of knowledge is required for the location and dimensions of the pulp chamber [15]. Root inclination, the long tooth axis, the number, shape and degree of root canal curvatures,calcifications, and type of previous restorations should be examined. Extra radiographs of good diagnostic quality should be taken in different angles if required [16].

During access preparation: The use of magnification as an aid is useful to observe canal orifices and the coronal alignment of the root canal. A rubber dam should not be placed before access cavity preparations in teeth with calcified or narrow pulp chambers [16,17], in re-treatments, and when accessing crowned teeth. In such cases, the pulp chamber may not easily been seen, as calcification processes induced by the previous treatment may have affected its normal anatomy. Krasner & Rankow [18] in his study found that the pulp chamber was always located centrally at the level of the cemento-enamel junction (CEJ). The CEJ was the consistent anatomic landmark. They proposed not to use the clinical crown contour as a guide in directing the access cavity preparation and instead use the CEJ. Radiographs taken during the access preparation with a bur was helpful. According to Kvinnsland et al. [19] in maxillary anterior teeth, all perforations were located at the labial root aspect due to the operator's underestimation of the palatal root inclination in the upper jaw.

During root canal preparation: Over use of rotary instruments can lead to apical or crestal perforations of the root canal wall, also called 'strip perforation' [20]. Hence, large tapered instruments and Gates–Glidden (GG) burs should therefore be used carefully [21]. Newer flexible nickel titanium instruments along with copious irrigation and effective lubrication were proposed for curved canals to prevent apical perforations [22,23].

During post preparation: Care should always be exercised during post space preparations so that canals are not overextended.A safe preparation is best achieved with the surgical microscope immediately after completion of a root canal filling. In a study Kuttler et al. [24]evaluated the effects of post space preparation with GG drills on residual dentin thickness in distal roots of mandibular molars in vitro and he found that such post space preparation has more risk of perforation. Kvinnsland et al. [19] according to his study stated that more than half of the perforations in their cases of root perforation occurred during post-preparation procedures.

Orthograde approach: In 1903, Peeso [25]stated that successful management of root perforations is

purely dependent on early diagnosis of the defect, choice of treatment, materials used, host response, and the experience of the practitioner. The rationale for orthograde treatment of root perforations is the same as that of conservative endodontic treatment, i.e. prevention and treatment of inflammation in the periradicular region. This may be achieved by control of infection of the perforation site, or if already infected, by using procedures that can disinfect the site and provide the best possible seal against penetration of bacterial elements.

Surgical approach: Indications for surgical approach are large perforations, perforations as a result of resorption, failure of healing after non-surgical repair [(26)], perforations inaccessible non-surgically, extensive coronal restorations [(27)], when concomitant management of the periodontium is indicated, and large overfilling of the defect [(28)]. The main purpose of surgical treatment is to achieve a tight and permanent seal that will prevent bacteria and their byproducts in the root canal system from entering the surrounding periodontium [(29)].

Intentional replantation: This may be considered when surgical and orthograde treatments are not possible, undesirable, or have failed already [(30)]. This procedure can be recommended instead of surgical treatment when the perforation defect is too large for repair and when the perforation is inaccessible without excessive bone removal [(31)].

Conclusion

Perforation repair requires adequate knowledge regarding the size, site, time and various materials that are used inorder to achieve a long term success of the perforated tooth. The materials used for perforation repair needs to be placed at the site to obtain a permanent seal between the peridontium and root canal system, however the operator skill play a vital important role in the success of root perforation repair. The prognosis of root perforation repair depends on how well the perforation has been sealed and also the cleaning, shaping and obturation techniques which cleans and seals root canal system three dimensionally.

Review on Platelet Rich Fibrin and Case Report on Management of Large Periapical Lesion

Nagarajan Geethapriya[1], Rajasekar Parthasarathy[2], Newbegin Selvakumar Gold Pearlin Mary[1], Alagarsamy Venkatesh[3]

[1]Reader, [2]Final Year PG Student, [3]Professor, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayanapuram, Pallikaranai, Chennai, Tamilnadu, India

ABSTRACT

Platelet Rich Fibrin consists of an autologous leukocyte-platelet-rich fibrin matrix, composed of a tetra molecular structure, with platelets, leukocytes and stem cells within it, which acts as a biodegradable scaffold that favors microvascularization and is able to guide epithelial cell migration to its surface. This case report describes about the management of large periapical lesions with surgical approach and PRF placement and a non-surgical approach.

Keywords: *Platelet Rich Fibrin, leukocytes, scaffold.*

Introduction

Bacterial infection in the dental pulp may lead to periapical pathology. If the infection gets contained within the canal, it will progress to the periapical region leading into excessive osteoclastic bone resorption circumscribing the root [(1)]. Most periapical lesions (>90%) can be classified as radicular cysts, abscesses or dental granulomas [(2)]. Incidence of dental cyst ranges from 6 to 55% [(3)].

The incidence of periapical abscesses is between 28.7 and 70.07% and periapical granulomas between 9.3 and 87.1% [(4)]. Some clinical evidence shows that as the periapical lesion increases in size, then the lesion may be radicular cysts. However, some large lesions have been shown to be granulomas [(5)]. The definitve diagnosis of a cyst can be made only by a histological examination.

A preliminary clinical diagnosis of a periapical cyst made based on the following:

(a) The periapical lesion is involved with one or more non-vital teeth,

(b) The lesion is greater than 200 mm^2 in size,

(c) The lesion is seen radiographically as a well circumscribed, radiolucent area bound by a thin radiopaque line

(d) It produces a straw-colored fluid upon aspiration.

The goal of endodontic treatment is to return the involved teeth to a healthy state and function without surgical intervention [(6)]. All inflammatory periapical lesions should be treated with conservative nonsurgical procedures initially. When this fails in resolving the periradicular pathosis alternative strategies like periapical surgery must be considered [(7)]. Various studies had shown the success rate of up to 85% after endodontic treatment of teeth with periapical lesions [(8)]. A high percentage of 94.4% of complete and partial healing of periapical lesions following nonsurgical endodontic therapy has also been reported [(9)]. In case of large lesions, as there is a chance for inadvertent undesirable consequences when surgical curettage is done, the procedures like Marsupialization or tube decompression are indicated [(10)]. In addition to elimination of pathologic

tissues, periapical surgery consists of resection of the apical root third (apicectomy), root end preparation and placement of a retro-filling material.

PRF consists of an autologous leukocyte-platelet-rich fibrin matrix [11], composed of a tetra molecular structure, with platelets, leukocytes and stem cells within it [12], which acts as a biodegradable scaffold [13] that favors microvascularization and is able to guide epithelial cell migration to its surface [12].

Methods for nonsurgical managment of periapical lesions:

- Bhaskar et al suggested that instrumenting 1 mm beyond the apical foramen when a periapical lesion is evident on a radiograph. This may cause transitory inflammation and ulceration of the epithelial lining resulting in resolution of the cyst [13].
- Weekly debridement and drying of the canals over a period of two to three weeks, followed by obturation has led to a complete resolution of lesions by 12 to 15 months [14].

Case Reports

Case 1-Surgical approach: A 36 year old male patient reported to the department of conservative dentistry and endodontics with a chief complaint of a recurrent palatal swelling for past few months. He gave a history of trauma 10 years back for which Root canal treatment was done in 11,12,13. He gave a history of swelling for approximately 3 years along with pus discharge from gums after root canal treatment. Clinically, there was diffuse palatal swelling extending from the right lateral incisor to the mesial aspect of 1st premolar, the swelling was fluctuant on palpation which indicated a loss of integrity of palatal bone, buccally there was a localized swelling and sinus tract in relation to 12. Periodontal examination revealed sulcus depths within normal limits [Fig.1 & 2].

Figure 1 & 2: Intra oral sinus in 12 and palatal swelling

An intraoral periapical radiograph of the 11,12,13 revealed a well defined periapical radiolucency was seen covering the root apex of 12 with radio opacity seen in root canal of 11,12 and 13 suggestive of root canal treated 11,12 and 13 [Fig. 3A]. From these above clinical findings it was provisionally diagnosed as infected radicular cyst in relation to 12.

Treatment plan: The treatment plan included Re-root canal treatment with respect to 12. Surgical management of the cyst was planned which included cyst enucleation and apicectomy in relation to 12.

Endodontic therapy: A multivisit endodontic therapy was planned with respect to 12. Acess opening followed by gutta percha removal was done in 12. Calcium hydroxide dressings was given in relation to 12 and closed dressing given. Patient recalled after 2 weeks. After 2 weeks, obturation was completed by cold lateral condensation [Fig.3B & C].

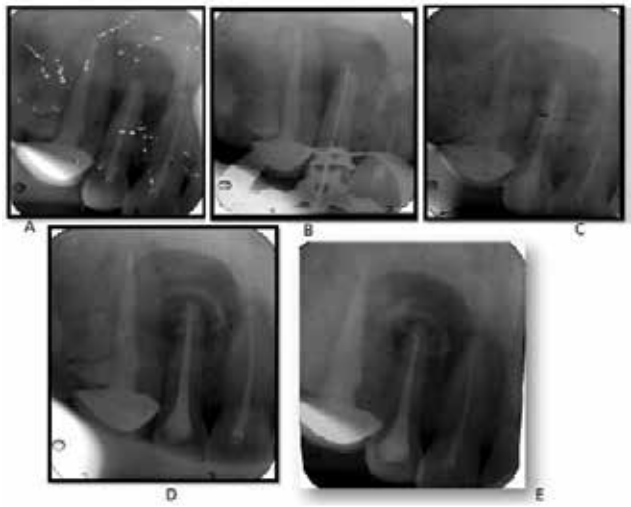

Figure 3: A. Pre op IOPA, B. Working length determination, C. Obturationin 12, D. 1month Post-OP, E. 6 months follow up

Surgical phase: For surgical enucleation of the cyst, a buccal approach was adopted and a full thickness flap was raised [Fig.4A & B]. Cyst enucleation was carried out in toto. Apicectomy was done in 12 followed by a retrograde MTA filling [Fig.4C]. Then PRF was prepared from patient's own blood sample and it was mixed with bone graft and placed into the cavity [Fig.4D]. Simple interrupted sutures were placed [Fig.4E]. Immediate post surgical & 6 months follow up radiographs were recorded [Fig. 3D & E].

Figure 4: A & B. Flap elevation and window preparation, C. Apicectomy, D. PRF and Bone graft placement, E, Suturing done

Case2-Non-Surgical Approach: A 20 year old female patient reported to the department of conservative dentistry and endodontics with a chief complaint of pain and swelling in upper front tooth region for past few weeks.

She gave a History of trauma to the teeth 5 years back. On intra oral examination a labial swelling was seen in association with 11 and 12 with mild tenderness on percussion. No sinus opening was present. The tooth 11 was previously crowned. Periodontal examination revealed sulcus depths within normal limits. Pulp sensibility tests showed a negative response in 12.

On radiographic examination a diffused radiolucency was seen in relation to the root apex of 11 and 12 [Fig. 5A]. Hence it was provisionally diagnosed as periapical abscess in relation to 11 & 12.

Treatment plan: Initially, Root Canal Treatment in 11 & 12 and periapical surgery if the lesion persists.

Endodontic treatment: Under local anesthesia, access opening was made through the crown in relation to 11 and 12 and the necrotic pulp tissue was extirpated. Working length was determined [Fig.5B] and the root canals were dried using paper points and filled with calcium hydroxide as intra canal medicament and the access cavity was sealed for a period of 2 weeks with an intermediate restorative material (IRM, Dentsply, USA). After 2 weeks, calcium hydroxide was flushed out, canals were dried using paper points and obturation was completed using gutta percha by cold lateral condensation [Fig.5C]. The access cavity was sealed with composite restoration. In 1 year follow-up, intra-oral radiograph shows healing of periapical lesion [Fig.5D].

Discussion

This case report has been presented to emphasize that all nonvital teeth with periapical lesion should be treated conservatively and surgical therapy is advised only when conventional treatment proves ineffective. Conservative approach is preferred over surgery as most of the periradicular lesions are the result of an inflammatory response due to bacterial infection within the root canal.

Nonsurgical root canal treatment involves cleaning and disinfecting the root canal system, thereby reducing the bacterial load and creating an environment in which periapical healing can occur.

Natkin et al. postulated that the larger the lesion, more possibilities for it to be a cyst [15]. Radicular cysts exist in two forms, such as Cavities enclosed completely by epithelium (periapical true cysts) and epitheliumlined cavities that are open to the root canals (periapical pocket cysts) [16].

The treatment of choice is determined by some factors such as the extension of the lesion, relation with adjacent structures, origin and characteristics of the lesion and systemic condition and co-operation of the patient.

Healing of pocket cyst occur through non surgical root canal due to communication with the canal. However, a true cyst is selfsustaining and is therefore unlikely to respond to the treatment. In these cases, a surgical approach would be required.

Calcium hydroxide is widely used as an intracanal endodontic material, due to its high alkalinity, tissue dissolving effect, causes induction of repair by hard tissue formation, has bactericidal effect [17] and substantivity. Its antibacterial actions are due to its action on bacterial cytoplasmic membranes, denaturation of protein, DNA lysis, carbon dioxide absorption, action on lipopolysaccharides and hygroscopic action. Study shows that placing Ca(OH)2 as intracanal medicament have a direct effect on inflamed periapical tissue by diffusion of hydroxyl ions (OH–) through the dentinal tubules and this favors periapical tissue healing and encourage osseous repair. In areas of root resorption, it also inhibits osteoclastic activity [18].

Çalişkan and Turkun have reported a case were apical closure and periapical healing occurred in a large cyst-like periapical lesion following non-surgical endodontic treatment with calcium hydroxide paste and a calcium hydroxide–containing root canal sealer [19]. Sjogren et al, (1991) founded that 1 week pushing of the calcium hydroxide in the canals kills the bacteria, so in the present two cases, calcium hydroxide was placed for 2 weeks. Since the periapical lesion was very large and could not be healed with calcium hydroxide, periapical surgery was planned for the case 1.

MTA was chosen as the retrofilling material because it is able to provide an excellent marginal sealing. According to Koh et al., the capacity of MTA to induce cell response is due to the calcium phosphate phase, which might cause a change in cell behavior, stimulating the adherence of osteoblasts to MTA.

Platelet-rich Fibrin(PRF) is an autogenous preparation that favors the increase in the number of platelets in a certain site, aiming at raising the concentration of growth factors, which consist of a group of biologic mediators that regulate important cell events involved in tissue healing.

Platelet-rich Fibrin is obtained from centrifuged anticoagulated blood. After centrifugation, 3 layers are obtained in the test tube. The top most layer consists of Platelet Poor Plasma, PRF clot in the middle and RBCs at the bottom of the test tube. The junction of PRF to the RBC layer is known to be rich in growth factors and therefore this region is preserved [20].

The PRF clot forms a strong natural fibrin matrix, which concentrates almost all the platelets and leucocytes of the blood harvest [21]. PRF could stimulate cell proliferation of osteoblasts, gingival fibroblasts, pulp cells and periodontal ligament cells, but suppress oral epithelial cell growth [22]. These cell-type-specific actions of PRF may be beneficial for tissue regeneration.

Clinical application of PRF[23]

- Socket preservation after extraction or avulsion of tooth.
- Filling of cystic cavity.
- In endo-perio lesion.
- In furcation defects.
- Regenerative procedure in treatment of osseous defects.
- Used in gingival recession coverage procedure.

Advantages of PRF[24]

- No need of addition of anticoagulant
- Slow natural polymerization leading to favorable healing.
- Simple and cost effective process.
- PRF helps in hemostasis.

Disadvantages

- Quantity of PRF produced is low because it is obtained from autologous blood sample.
- Clinically usable PRF clot is only obtained by its quick handling.
- PRF is totally specific to the donor because it contains circulating immune cells and all the highly antigenic plasmatic molecules.
- It cannot be stored for longer duration.

PRF can be used in conjunction with bone grafts. Besides promoting wound healing, bone growth & maturation, PRF with bone graft has advantages of graft stabilization, wound sealing, haemostasis and improved handling properties [25]. The success of spontaneous bone healing is directly related to the size of bony defects, the anatomical location, the patient's age and other parameters.

Conclusion

In modern endodontic treatment the indications for endodontic periapical surgery is decreasing. Still it accounts to 3 to 10% of the endodontic practice. So, non surgical endodontic treatment with intracanal calcium hydroxide is a viable approach for promoting periapical healing in non-vital teeth associated with periapical lesion.

But the periapical surgery is the only alternative when the tooth with periapical lesion fails to respond to intracanal calcium hydroxide.

Root-end Filling Materials: An Update on the Latest Materials: A Review

Dhakshinamoorthy Malarvizhi[1], Madan Niranjini[2], Jagadeesh Shuruthi[3], Balasubramaniam Anuradha[4]

[1]Associate Professor, [2]Private Practioner, [3]Second Year PG Student, [4]Reader, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayanapuram, Pallikaranai,Chennai, Tamilnadu, India

ABSTRACT

Root canal failures occur at a rate of 10 – 15% (Wong 2004). When teeth cannot be treated appropriately by root canal treatment or retreatment, endodontic surgery is usually the last option considered for saving the tooth. These procedures consist of periapical curettage, root-end resection, root-end preparation and root-end filling material being placed at the resected apex so as to act as a seal between the periodontium and root canal system. Harty et al. in 1970 reported that the apical seal was the single most important factor in achieving success in such surgery. So to achieve a perfect hermetic seal an ideal root-end material is required. A root-end material also requires other properties such as biocompatibility, easy handling, stability etc. This article is an overview on the newer root-end or retrograde materials that have been used so far in practice.

Keywords: *root-end filling material, retrograde filling, root-end resection, apicoectomy, hermetic seal, endodontic surgery.*

Introduction

Persistent radicular infections which cannot be treated by conventional orthograde endodontic therapy are recommended for endodontic surgery like root-end resection (apicoectomy/apicectomy). But resecting a portion of the root apex causes the root dentin and the orthograde filling material to be exposed. As orthograde gutta-percha alone is insufficient to support bone regeneration and healing in these cases. This is where a suitable retrograde material plays a pivotal role. These materials should also act as a physical seal to prevent bacterial leakage from the canal space into the periradicular tissues and vice-versa. The materials which have been used and also some newer experimental materials are listed (Table 1).

Latest Materials Being Used:

Mineral Trioxide Aggregate: Torabinejad developed MTA in Loma-Linda University in 1993. The major components of MTA are tricalcium silicate, tricalcium aluminate, tricalcium oxide, silicate oxide. It sets in the presence of moisture as hydrophilic particles in the powder on hydration form a colloidal gel that hardens and sets within 4 hours. The pH of the set cement is 12.5. Based on studies done by Torabinejad, evidence of healing in periapical tissues were noted with the use of MTA as a retrograde material. Most favourable characteristic tissue reaction of MTA was the presence of connective tissue after the first postoperative week. It induces cementogenesis and regeneration of periodontal tissues with minimal amount of inflammation. It shows no toxic effects on cells and osteoblasts show favourable response and new cementum was found laid over the material [(1)]. The major advantage of this material is its good sealing properties (superior to super EBA and not affected by blood contamination), biocompatibility, cell regenerative potential as compared to other materials. When mixed with 0.12% chlorhexidine it even shows antibacterial properties against E.faecalis, S. aureus, S.

aeruginosa, without compromising sealing ability [2]. The demerits are that it has difficult handling properties, long setting time, cost, may discolour, toxic elements in composition and absence of known solvent for removal. In another study the sealing ability of ProRoot MTA is superior to Biodentine and latter could be considered as an acceptable alternative to ProRoot MTA as root end filling material in peri-radicular surgeries[3].

In another study which compared and evaluated the sealing ability of four root end filling materials such as mineral trioxide aggregate (MTA)-Plus, Biodentine, MTA (MTA Angelus) and glass ionomer cement (GIC) using fluid filtration method and conluded that MTA Angelus showed better sealing ability as a retrograde filling material followed by Biodentine and MTA Plus[4].

Table 1: Retrograde Filling Materials Used Over the Years

Metals	gold-foil, silver points, titanium screws, tin posts, gallium alloy(rarely used now days) amalgam (with and without bonding agent)
Cements & Sealers	ZOE based cements (IRM, super EBA), cavit, zincpolycarboxylate, zinc phosphate, GIC, MTA, calcium phosphate cement,
Others	Diaket, Composite resin/dentin adhesive, Compomers, Gutta-percha.
Lesser Used Materials	laser, citric acid demineralization, ceramic inlay, teflon, mixture of powdered dentin &sulfathiazole and cyanoacrylates.
Newer Materials/Experimental Materials	
Biodentine, Bioaggregate, iRoot BP Plus bioceramic putty Ceramicrete, Endosequence, Cold Ceramic, Castor Oil Polymer (COP), Polymer nanocomposite (PNC) resin, Novel root end filling material (New Resin Cement, NRC), Novel root-end filling material using epoxy resin and Portland cement (EPC), Iron-free partially stabilized cement, Experimental Calcium aluminium-silicate based- Endobinder, Generex A, Capasio, Quick-Set,	

Biodentine: Introduced in 2010 and made available in 2011 (Septodont).Its indications are similar to MTA. Septodont claims that it features as an endodontic repair material that is far superior to MTA as it has better consistency, better handling and safety, and faster setting time. It is a calcium silicate based material used for crown and root dentin repair treatment, apexification, repair of perforations or resorptions and root-end fillings. It is also said to be a 'dentin replacement' wherever dentin is damaged. It consists of powder mainly containing tricalcium silicate, calcium carbonate, and dicalcium silicate, the principal components of MTA. The liquid potion consists of calcium chloride in aqueous solution with an admixture of polycarboxylate.

Bioaggregate: Bioaggregate seems to be a modified or synthetic version of original MTA. According to the manufacturer, it contains biocompatible pure white powder composed of ceramic nano-particles and deionized water. The powder is tricalcium silicate, dicalcium silicate, tantalum pentoxide, calcium phosphate monobasic and amorphous silicon oxide. According to the manufacturer, it is supposed to promote cementogenesis.

Ceramicrete: It is an impervious inorganic phosphate binder initially used to encapsulate hazardous waste. It is a versatile material which has a wide array of uses outside the dental and medical field. The dental based ceramicrete cement consists of a hydroxyapatite powder

with cerium oxide- radiopaque fillers which release calcium and phosphate ions. [5]

On immersion of set cement in phosphate containing fluid (PCF), there was formation of Dicalcium phosphate dihydrate (DPCD) or hydroxyapatite. Hence, it also shows bioactivity

A study to compare the sealing ability of ceramicrete, bioaggregate and white MTA showed both ceramicrete and bioaggregate had similar sealing ability to MTA, with ceramicrete performing better [6].

Endosequence (ERRM): It is a premixed bioceramic developed by Brassler USA, which consists of calcium silicates, monobasic calcium phosphate, and zirconium oxide. It is available as a syringable paste or putty. It is used for root perforation repair, apical surgery, apical plug, and pulp capping. It is considered bioactive and osteogenic because apatite crystals precipitated when set ERRM was exposed to saline buffered with phosphate [7]. It has negligible cytotoxicity and has a biocompatibility similar to both gray and white MTA [8,9].

Cold Ceramic: Recently introduced ceramic based root-end material with the main ingredient being calcium hydroxide. It is biocompatible and has an initial set of 10 mins and final set of 24hours. The sealing property is better than MTA even in blood contaminated condition and at least similar to MTA in other conditions [10] and the cytotoxicity is significantly lower when compared to IRM [11]. But more studies are required to fully test the properties of this material.

Castor Oil Polymer (COP): A relatively new material developed from a tropical plant (Riccinus Communis) has shown to have a good potential as root-end filling material. It has been widely used in medical field for making prostheses to replace bones. It is biocompatible, nontoxic and easy to manipulate. This biopolymer has high interaction capacity with human cells. It consist chain of fatty acids whose molecular structures are also present in lipid of human body. Therefore, COP is not recognised as a foreign body by the human cells [12]

A study comparing sealing ability of different materials showed that COP presented an efficient seal as a retrograde material showing even better results than MTA and GIC [13].

Polymer Nanocomposite (PNC) Resin: A polymeric nanocomposite is a generalised term for polymeric materials that are loaded with minimal amount of nanoparticles like clay and CNTs (carbon nanotubes). The dispersed state is at a nanoscale, they show superior quality to conventional composites. PNC resins like C-18 Amine montmorillonate (MMT) and vinylbenzyl octadecyldimethyl ammonium chloride (VODAC MMT) have been tested for their potential as root-end filling material Cytotoxic activity of the C-18 Amine MMT showed no difference from MTA and Geriostore. But VODAC MMT showed cytotoxic activity in almost all experiments [14]. Further testing is needed to evaluate its use as a root-end material.

Novel Root End Filling Material (NRC): New Resin Cement is introduced as a powder and liquid system where the liquid is composed of hydroxyethylmethacrylate, toluidine, benzoyl peroxide and toluenesulfinate and the powder consist of calcium oxide, calcium silicate, and triphenylbismuth carbonate. Cytotoxic studies done on NRC showed favourable results [15]. However, an in vivo study revealed that it showed a higher inflammation reaction than MTA [16]. The mineralisation of tissue maybe due to the calcium reservoir.

Novel Root-End Filling Material with Epoxy Resin and Portland Cement (EPC): EPC, is a novel composite derived from a mixture of epoxy resin and Portland cement, with low microleakage, appropriate radio-opacity, short setting time and clinically acceptable low cytotoxicity [1].

Iroot BP Plus Bioceramic Putty: iRoot BP Plus (Innovative BioCeramix Inc., Canada) a water-based bioceramic cement. It is convenient as it is a ready to-use white hydraulic premixed formula. An in vitro cytocompatibility study of iRoot BP Plus bioceramic putty concluded that iRoot had similar biocompatibility to MTA and did not have any cytotoxic effect. [18]

Ron-Free Partially Stabilized Cement (PSC): Portland cement-based PSC with Zinc was made by replacing Iron nitrate. It was developed to address some of the drawbacks of MTA. Cytotoxic testing has shown it to be non-toxic. The addition of increased weight percentages of Zn has decreased the setting time. [19]

Experimental Calcium Aluminium-Silicate Based Cements

***Endobinder:** EndoBinder (Binderware, Brazil), can be considered as a modified MTA which has been developed with the intention of preserving the properties and

clinical applications of MTA but eliminating its negative characteristics like darkening and expansion and staying biocompatible at the same time.In EndoBinder traces of free MgO and CaO were eliminated, which are responsible for the undesired expansion. Fe_2O_3 which is responsible for tooth darkening was also eliminated [20].

***Generex A:** Generex A (Dentsply, USA) is similar to ProRoot MTA but has to be mixed with unique gel instead of water like for MTA. It has excellent handling properties unlike MTA, it mixes to a dough-like consistency, making it easy to roll into a rope-like mass similar to IRM [21]. It is also the only new generation material other than MTA to have osteoblastic activity [22]. But further testing is required for finding its biocompatibility.

***Capasio:** Capasio (Primus Consulting, USA) is composed primarily of bismuth oxide, dental glass, and calcium alumino-silicate with a silica and polyvinyl acetate based gel. A recent study found that Capasio had bioactive capabilities as it promoted apatite deposition when exposed to synthetic tissue fluid and has a tendency to help mineralization [23]. The same study also showed that using it as a root-end filling material, Capasio is more likely to penetrate dentinal tubules.

***Quick Set:** A modified Capasio where the powder has been refined and surfactant removed from the liquid was produced which is renamed as Quick-Set (Primus Consulting). Surfactant was removed as it was interfering with cytocompatibilty [24]

Conclusion

Based on the review of literature, there is no shortage for root-end filling materials, be it calcium hydroxide or MTA, but the ideal root-end material is still elusive as it appears that no existing retrograde material possesses all the ideal characteristics. Apart from these properties, the dentist should also consider the long-term success of the materials. MTA remains to be the material of choice but newer material have shown comparable properties. The materials already present in the market require further biological and clinical evaluations and newer materials require more in vivo testing and clinical follow-up.

Radix: The Third Root In Mandibular Molars—A Case Series

Arunajatesan Subbiya[1], Wesly Sophreniaa[2], Ramachandran Tamilselvi[3], Newbegin Selvakumar Gold Pearlin Mary[3]

[1]Professor & Head, [2]Final Year PG Student, [3]Reader, Department of conservative dentistry and Endodontics SreeBalaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayanapuram, Pallikaranai, Chennai, Tamilnadu, India

ABSTRACT

The Endodontic treatment of a mandibular molar with third root can be diagnostically and technically challenging. The location of the extra canal and the curvature in its course to the apex can pose difficulty in the management of radices. This case report discusses endodontic treatment of three mandibular first molars with radix. Awareness of unusual root canal morphology and the modifications in the management protocol can contribute to the successful outcome of endodontic treatment.

Keywords *: Radix entomolaris, Radix paramolaris, mandibular molar.*

Introduction

The success of endodontic treatment depends on the eradication of microbes from the root-canal system and prevention of re-infection[(1)]. It is known that the mandibular first molar can display several anatomical variations; endodontic therapy of mandibular molars has always been an endodontic dilemma[(2)]. Carabelli[(3)] in 1844 first mentioned a major anatomical variant of the two rooted mandibular first molar; a tooth with a third root that is a distolingual root named as the Radix Entomolaris (RE)[(4)]. If this root is placed buccally then it is called Radix Paramolaris[(5)(6)]which is even a rarer entity described by Bolk[(4)]. When detected, the diagnosis and treatment are very much similar to any other canals[(5)]. This article describes the diagnosis and management of three cases with the extra third root; two Radix Entomolaris and one Radix Paramolaris.

Case 1: A 43 year-old female patient was referred to the Department of Conservative Dentistry and Endodontics complaining of pain in the lower right back tooth region for past 3 days. Pain was sharp and intermittent. Sensitivity to hot and cold items was present. Clinical examination revealed a carious lesion of the right permanent first mandibular molar. The involved tooth showed a delayed response upon thermal testing that persisted for 3 min after the removal of stimuli. Radiographic examination revealed coronal radiolucency involving the enamel, dentin and pulp with the loss of lamina dura and a periapical radiolucency involving the distal root of 46. The multiple angle radiographs also revealed an indistinct root outline in between the mesial and distal root. The condition was diagnosed to be dental caries with symptomatic irreversible pulpitis with symptomatic apical periodontitis. (Figure 1A)

Inferior alveolar nerve block anesthesia (2% Lignocaine with 1:200000 epinephrine) was given and access cavity preparation was done withendoaccess bur (Dentsply, USA) and canal orifices were found with a DG 16 endodontic explorer. The access cavity which was triangular in shape was modified into a more trapezoidal cavity in order to locate the orifice distolingually (Shamrock preparation). Initial negotiation of the root canals was confirmed with ISO size #10 file. Farther away from distal root canal orifice a fourth distolingual canal orifice was found (Figure 1B). The canal lengths were

determined radio-graphically with K file ISO size #15 (Figure 1C) and electronically with Root ZX, (J. Morita, Kyoto USA).3% Sodium hypochlorite (Neelkanth healthcare Private Limited, India) along with EDTA (Glide, Dentsply, USA) was used to clean the canals. Shaping was done with ProTaper Gold (Dentsply, USA) rotary system until a size of F2 after which a dressing of calcium hydroxide paste was placed and the patient was recalled after 14 days. The patient was asymptomatic in the subsequent visit. Proper fitting of cones was evaluated by the master cone radiograph (Figure 1D). Canals were thoroughly dried with paper points (DiaDent, BC, Canada) and obturation (using single cone technique) was done using zinc oxide eugenol sealer.(Figure 1 E).

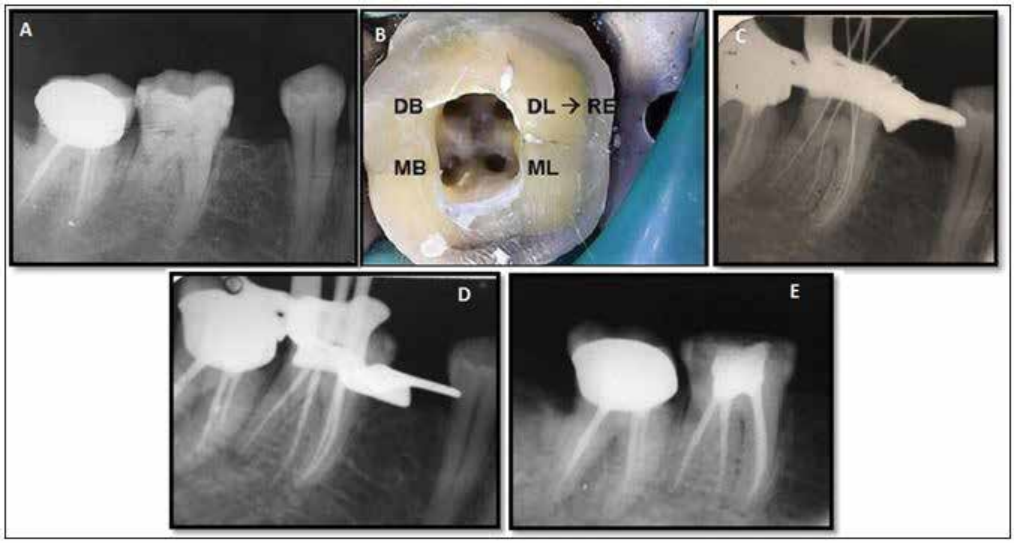

Figure 1: Case 1 of Radix entomolaris. A) Pre-operative IOPA B) Access cavity picture C) Working Length D) Master cone E) Obturation

Case 2: A 47 year old male patient, with the complaint of pain in the lower left back tooth region for 3 months which was intermittent and aggravated on mastication. On clinical examination, dental caries in 36 with tender on percussion was present. The involved tooth showed delayed response to thermal testing with persistent pain even after removal of stimuli. Radiograph showed a coronalradiolucent area involving the pulp with ill-defined radiolucency at the periapex of mesial, distal and the third root, radix of 36. Based on these findings, the tooth was diagnosed as dental caries with symptomatic irreversible pulpitis with symptomatic apical periodontitis.

Endodontic management was planned for the involved tooth and was carried out in a similar manner explained for case 1. (Figure 2A, 2B and 2C)

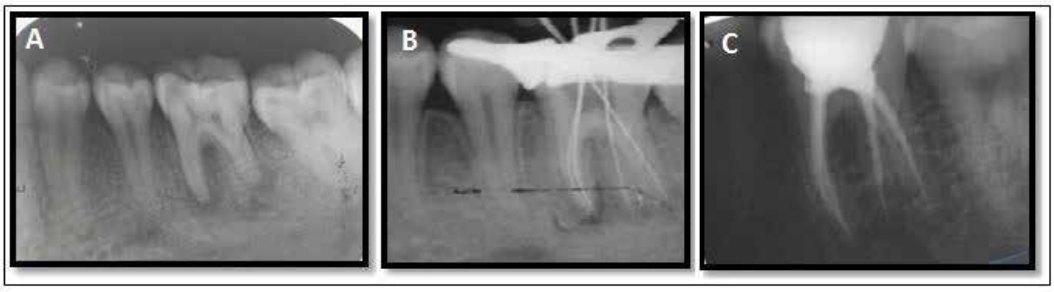

Figure 2: Case 2 of radix entomolaris in 36. A)Per-operative B) Working length C) Post- operative

Case 3: A 26 year old female patient, with the complaint of pain in the lower right back tooth region for one week which was sharp and pricking in nature and aggravated on taking hot and cold substances reported to the department. On clinical examination, dental caries in 46 with tenderness on percussionwas elicited. The involved tooth showed delayed response to thermal testing with persistent pain even after removal of stimuli. Radiograph

showed a coronal radiolucent area involving the pulp with ill-defined radiolucency at the periapexwith a faint outline of the third root was evident. Based on these findings, the tooth was diagnosed as dental caries with symptomatic irreversible pulpitis with symptomatic apical periodontitis.

Endodontic management was planned for the involved tooth and was carried out in a similar manner explained for case 1. (Figure 3 A, 3B and 3C)

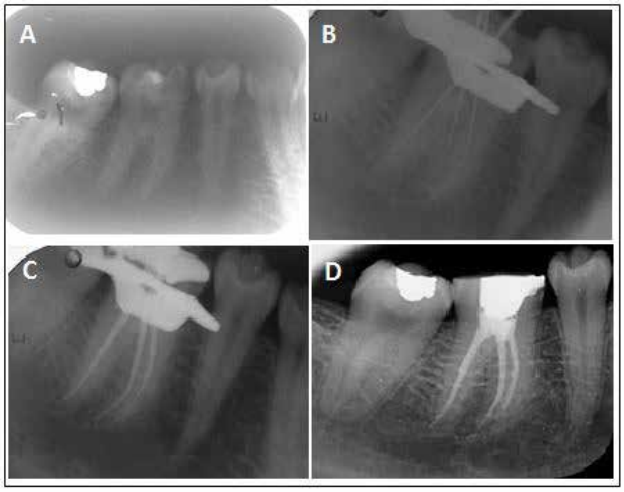

Figure 3: Case 3 of Radix paramolaris in 46. A) Pre-operative B) Working length C) Master cone D) Obturation

Discussion

The aetiology of radix is still uncertain; which can be due to external factors during tooth formation or be attributed to atavistic gene or polygenic system[7,8]. The Radix entomolaris is found with high prevelance of 30% in both pure Eskimo and Eskimo/Caucasian mixes[7,9]. Tratman in 1938 reported an incidence of 0.2% in Indian population[10]. However a study by Chandra et al in 2011 reported a high incidence of 13.3% in South Indian population[11] making it a morphological variant. The radix entomolaris may also be present in first, second and third molar; being less prevalent in second molar[7]. Bilateral occurrence of radix entomolaris has also been reported[12,13]. The relationship between radix entomolaris (RE), gender predilection and side distribution is not clear. Few studies have reported more of male predilection for RE while others reported no significant difference between gender and RE[14]. Similarly, no significant difference was reported for side distribution, despite few studies reporting it to be more on left side while others on right side[14]. Bilateral occurrence for RE have been reported to range from 37.14 - 67% [6,14–17]

Classification: Based on the location of the cervical part, Carlsen and Alexandersenin 1990 classified it into four different types[6]:Type A: RE is located lingually to the distal root complex which has two cone-shaped macrostructures.Type B: RE is located lingually to the distal root complex which has one cone-shaped macrostructures. Type C: RE is located lingually to the mesial root complex. Type AC: RE is located lingually between the mesial and distal root complexes.

De Moor et al. (2004) classified radix entomolaris based on the curvature of the root or root canal[9]:Type 1: straight root canal or root.Type 2: curved only in coronal third and becomes straighter in the middle and apical third.Type 3: initial curve in the coronal third which then orientsbuccally in the middle or apical third.

Morphologically a tooth with radix may present with a more bulbous crown, an additional cusp, a prominent distolingual lobe or cervical prominence. Radiographically, third root is visible in 90% of cases[18], occasionally being missed due to its slender dimension or overlapping with distal root. Additional radiographs taken using tube shift method with 20 degree from mesial ordistal projections is usually sufficient to reveal the basic information about the anatomy of additional root[19,20]. Lately, cone-beam computed tomography (CBCT) has emerged as a usefulaid in thediagnosis of teeth with complex root anatomies. However, it has to be used judiciously[21,22].

Radix paramolaris is very rare and occurs less frequently than radix entomolaris[4]. Visser reported the prevalence of radix paramolaris to be 0% for mandibular first molars, 0.5% for second molars and 2% for third molars[23].

Classification: Carlsen andAlexandersen (1991) classified radix paramolarisinto two different types[6]:Type A: cervical part on the mesial root complex. Type B: cervical part is centrally, between the mesial and distal root complexes.

Clinical Implications: A tooth with radix entomolaris has endodontic implications. Accurate diagnosis clinically and radiographically can avoid failure of root canal treatment because of missed canal. Most important basic principle for successful root canal treatment is the principle of 'straight-line access'[2]. Ultimate objective is to provide access to the apical foramen. The orifice

of radix entomolaris is present distolingually,hence the shape of access cavity should be modified from classical triangular form to trapezoidal or rectangular form. Thelaws of symmetry that the canal orifices are equidistant from a line drawn in a mesiodistal direction through the pulpal floor and lie perpendicular to this mesiodistal line across the centre, helps in easily locating the radix entomolaris[14,24,25]. Straight line access is mandatory as all are curved once or even twice. Excessive removal of dentin or gauging during access cavity preparation, may weaken the tooth structure and has to be avoided.

Conclusion

During molar endodontic treatment, it is essential to find all the canals as there may be a third root present. Radiographstaken in more than one angulation and careful interpretation helps to identify theinternal root canal anatomy and the variations present. The access cavity preparation for the management of radix is modified from the conventional triangular access cavity opening to a trapezoidal form to properly locate the canal orifice of the extra rootwhich is located distolingually. Due to the high incidence of severely cured canals seen in radices the straight-line access and glide path must be given further notice.

ABSTRACT

A Comparative evaluation of surface wear and distortion of ProTaper, RaCe and K3 nickel-titanium rotary instruments was done using resin blocks with 20 degrees curvature. Three groups of four samples were evaluated for spiral distortion and surface wear after instrumentation. The deformation and fracture of F1 of ProTaper, 0.06 tapers RaCe and were photographically recorded SEM 250X using magnification. It was evident from the scores obtained and SEM pictures analysed that ProTaper instruments exhibited significantly higher degree of spiral distortion and surface wear compared to both RaCe and K3, with no statistical variation between the latter two systems

Keywords: *surface wear, distortion and cyclic fatigue*

Introduction

The advent of nickel titanium (NiTi) rotary instruments has revolutionized endodontic therapy by minimizing the procedural errors encountered with hand instrumentation and reducing operator fatigue. Ever since its introduction, the technological improvement of endodontic instruments has been a perennial desire for manufacturers, researchers and clinicians. These improvements have led to the dramatic increase in the number of NiTi rotary systems that have been marketed by various manufacturers with enhancements pertaining to safety, quality, efficiency and efficacy. Flexural fatigue and torsional fracture are the two main properties that cause separation of these NiTi instruments. NiTi rotary files has specific limited torque, thus increased the risk of intra-canal fracture [(1)]. ProTaper generated lower torque between canal geometry and physical parameter during shaping [(2)].

Torsional failure, on the other hand, is usually accompanied with distortion or unwinding of the flutes adjacent to the fractured end. Such surface defects and distortion could be very subtle and inconspicuous that they could not be visually detected. If file diameter increased, the force of fracture also increased [(3)].Hence, visible inspection does not seem to be a very reliable and safe method of evaluating NiTi instruments.

In a quest to minimize the factors that lead to deformation and fracture of NiTi rotary instruments, several manufacturers have developed various systems with perceptible changes in the instrument design. These variations can be manifested in the type of cutting blade, body taper, flute design, rake angle, radial land and configuration of the file tip, which influences the outcome of the preparation to a large extent. The purpose of this study is to analyse the surface wear and distortion exhibited by RaCe, ProTaper and K3 NiTi rotary systems using scanning election microscopy.

Materials and Method Selection of the Samples

Forty eight simulated canals made of acrylic resin were used for the study. The resin blocks were of uniform dimension. The simulated canals were 25mm long and their initial diameter was equivalent to a size 10 instrument. Resin blocks with 20 degree curvature were selected. Nickel-titanium (NiTi) instruments from three different systems were used. They are ProTaper system (DENTSPLY maillefer); RaCe system (FKG Dentaire) and K3 system (Sybron Endo).

Grouping of the selected sample: A total of 48 resin blocks were divided into three groups (n=16) as follows:

Group A Pro Taper systems

Group B - RaCe systems

Group C - K3 systems

Four sets of instruments were used to prepare four simulated canals for every system (4x4=16). Before use all the NiTi rotary instruments were subjected to autoclave at121 C for 20 minutes. Following autoclaving the instruments were analysed with SEM and pictures were taken as control.

The microscope used Phillips 20(Philips, was Netherlands). The instruments evaluated by SEM were confined to size 25 0.06 taper of RaCe and K3 and F1 of ProTaper systems as this was the instrument that predictably touched the canal walls at full length.

Canal preparation: The resin blocks prepared by the NiTi were instruments as per manufacturer sequence using crown downpressure less technique. A torque control motor TCM -XSMART was employed at a predetermined torque and 350 RPM for each system per manufacturer recommendations. Each instrument was used in a gently pecking motion by the same operator. The technical sequences followed ProTaper, RaCe and K3 systems were shown below.

Results

Comparison of surface wear between different study groups (Table : 1)The mean surface wear demonstrated significant high values for ProTaper (Group A) compared to RaCe (Group B) and K3 (Group C). However, there is no significant difference in surface wear between RaCe and K3. (P>0.05)One fractured ProTaper instruments was noticed during the study.

Discussion

Ever since the introduction Ni-Ti rotary instruments in 1988 by Walia, a variety of instrument designs and types have been developed by manufacturers to satisfy the primary objective of shaping the root canal system. Despite their undeniably favourable qualities like super elasticity and shape memory, the potential risk of separation within the canal during instrumentation is an unconquered. Inadvertent fear still unconquered. In our study simulated canals made of acrylic resin were used. Compared to extracted teeth, the resin blocks reduced the variation in the instrumentation and allow comparisons between instrument types and sequences under identical conditions. Hence, the use of simulated canals provides the opportunity to standardize and research method exclude the parameters that could influence the preparation outcome, although, the use of simulated canals in resin blocks do not always reflect the action of instruments in canals of natural teeth. These

facts were in agreement with the procedures followed in other studies (Thompson &Dummer 1997, Yared& Kulkarni 2003, Yared 2004) [4-6].

Further, according to Franklin S. Weine [7] when canal curvature reaches 30 degrees or more the complexity of case increases markedly, and techniques that render good results in the simpler cases may or may not be successful. Hence, acrylic resin blocks of 20 degrees canal curvature were chosen for the study. The number of uses for all the 3 systems evaluated was four times. Susan Wolcott et al [8] performed a large cohort clinical study of 4,652 root canals performed over months to evaluate the separation a period of 17 incidences of a NiTi rotary system (Pro Taper). The results of this study indicate that ProTaper files may be safely reused at least four times". Moreover, the manufacturer of another NiTi rotary system (RaCe) suggested that following use in canals with simple curvatures (radius of curvature over 25mm) 2 petals out of 8 on the safety memory disc should be removed. Based on this fact it could be suggested that most of the canals had mild degree of curvature and the instrument could be safely was used four times. Hence, the number of uses was standardized to four times in our study.

The rotations per minute (rpm) fixed in our study for all the systems was 350rpm. Although most manufacturers advocate an rpm range of 150 to 600 for instrumentation, this range appeared to be too wide for precise evaluation. Darrell W. Daugherty et al [9] compared the efficiency of NiTi rotary instruments at 150 and 350 rpm. They observed that 350 rpm exhibited nearly double efficiency and half the deformation rate as compared to instruments used at 150 rpm. Accordingly 350 rpm was set as a standard in the present study. The instruments evaluated by SEM for 3 systems were confined to size 25, 0.06 taper for both RaCe and K3 and finishing file F1 for ProTaper. These instruments were specifically chosen to be analysed as these instruments predictably touch the canal walls at the full length and were used to complete the preparation at the apical stop. In addition these instruments were used in all the extension of root canal and therefore are subjected to maximal amounts of torsional and flexural loads This was in accordance with Troian et al, Raspisarda et al (2001), Li et al (2002) and Pessoa et al (2003) [10-12]. From the results obtained and the SEM pictures analysed it was clearly evident that ProTaper rotary systems demonstrated significantly higher amounts of surface wear and distortion compared to both RaCe and K3 rotary NiTi systems with no statistical variation between the latter two systems. ProTaper is an instrument with multiple tapers Incorporated within one file. Due to progressively increasing tapers in ProTaper instruments, the rate of increase in the diameter of the tip is higher when compared to both RaCe and K3 which results in a thicker instrument especially in finishing files. This inherent thickness reduces the flexibility enhancing the contact area with the canal wall which may result in higher surface wear further, the taper size of shaper file S2 is 0.04 at the tip and finishing file Fl is 0.07 at the tip. This jump in taper size from S2 to F1 is non-linear compared to both RaCe and K3 which have a gradual increase in taper size. Moreover, the finishing files used in RaCe and K3 had a taper size of 50% 125 size, 0.06 taper compared to a 7% taper for ProTaper. Considering these fact-findings, the file F1 may encounter greater frictional resistance from the canal walls resulting in a high degree of surface wear and distortion as evident from figures. It can be clearly visualized from that ProTaperdemonstrated canal straightening and transportation towards the outer aspect of the curvature. These observations were in accordance with Elasaad et al and Peters et al who showed similar findings [13].

The fact that some canal transportation towards the outer aspect of the canal was evident with ProTaper files may be because of the variable tapers along the cutting surface of these files in combination with the sharp cutting edges owing to their cross sectional design. RaCe demonstrated the least surface wear and distortion compared to other systems although the difference was not statistically significant with K3. The alternating cutting edges along the shaft of the RaCe instrument might be a main advantage compared to helical tapered active files of Pro Taper which may show a tendency to screw. The helix angle continuously changes from larger to smaller to arguer values along the working length virtually eliminates screwing in forces and decreases the area of engagement. This unique design of RaCe significantly reduces the frictional resistance with the canal wall thus preventing the threading or blocking effect Also, compared with ProTaper, RaCe instruments for end point preparation do not have the stiffness of thick ProTaper finishing files and therefore flexible because increasing thickness are more decreases flexibility Further, the manufacturers statement that RaCe instrument have an extremely low operating torque and an improved efficiency using fewer instruments

with sharp cutting edges might be a further advantage. Moreover, the RaCe instruments are subjected to an electrochemical treatment in order to increase the resistance to torsion and to metal fatigue and retain cutting efficiency electro polishing. Electro polishing is another method used by some manufacturers to improve the strength of rotary NiTi instruments. The event follows the alloy (acting as the anode) being submerged into an electrolytic solution (usually a combination of acids) containing a negatively charged cathode. A low current is passed through the solution, causing selective removal of protruding surface defects for NiTi alloys at a rate of 21 to 3.5 um/min.

It is also evident from that RaCe demonstrated uniform centred preparation in simulated canals and maintained the original curvature of the canals in resin blocks. This finding is in agreement with Elasaad et al, Baumann et al [(14)], who all showed uniform, centred preparation with RaCe instruments The K3 rotary system demonstrated surface wear and distortion comparable to that of RaCe but Significantly lesser than ProTaper systems. K3 features an asymmetrical cross-section with wide radial lands and a constant taper. The strength of the file comes from the inner core of the instrument, rather than the peripheral area near the cutting blade, which is referred to as the radial land. The less blade support (the amount of metal behind the cutting edge) the less resistant the instrument is to torsional stress. According to Yoshimine et al [(15)] the cross-sectional area of 0.04 tapered K3 file was nearly twice the size of that of RaCe files with same tip size and taper, indicating that K3 files were less flexible compared to RaCe.It is reasonable to hypothesize that greater the diameter, cross-sectional area or taper of the instruments the higher would be the bending stiffness of the instruments. Accordingly, K3 instruments with largest cross-sectional area were the Stiffest. These facts are attributed to the differences observed with respect to surface wear and distortion as compared to RaCe (although no statistical variation). However, constant taper of K3 as compared to variable taper of ProTaper yielded better results owing to less engagement and linear increase in instrument taper It can be observed from figure that K3 resulted in a well centered uniform preparation comparable to RaCe in resin blocks. As demonstrated by Bergmens et al[(16)]

Within the limitations of this study, variable tapered instruments (ProTaper) demonstrated greater surface wear and distortion compared to instruments with constant taper (RaCe and K3). The alternating cutting edges of RaCe attributed to its enhanced flexibility resulting in minimal surface wear and distortion compared to both a systems, although not statistically significant with K3.

Conclusion

Under the conditions of this study it was concluded

1. The rate surface wear and distortion was significantly greater with ProTaper as compared to RaCe and K3.
2. Despite large cross-section and stiffness K3 instruments exhibited less wear and distortion due to its constant taper, radial relief and helical design.
3. RaCe significantly exhibited least surface wear and distortion which may be attributed to its alternative cutting design, constant taper and electro polishing. Hence, it may be considered safer for canal preparation amongst the rotary systems.

Scope of Ultrasonics in Endodontics—A Review

Alagarsamy Venkatesh[1], Ravindranath Megha[2], Dhakshinamoorthy Malarvizhi[3], Balasubramanium Anuradha[4]

[1]Professor, [2]Final Yr Post Graduate Student, [3]Associate Professor, [4]Reader, Department of Conservative Dentistry and Endodontics, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research, Narayanapuram, Pallikaranai,Chennai, Tamilnadu, India

ABSTRACT

The dental operating microscope and the ultrasonics have found many important applications in dentistry. Ultrasonics is undoubtedly imperative for improving the quality of the treatment and for handling difficult cases in endodontics. It is useful in procedures such as gaining access to canal openings, cleaning and shaping, obturation of root canals, retrieval of separated instruments, removal of intracanal medicaments and blockages and endodontic surgery.This review throws some insight on the applications of ultrasonics in endodontics today.

Keywords: *ultrasonics, cleaning, shaping, cavitation, instrument retrieval*

Introduction

The ultrasonics to dentistry was first introduced for cavity preparations but it could not compete with the convenient high speed handpiece. In 1955, Zinner used the ultrasonics for removal of hard deposits from the tooth surface(1). Later the ultrasonic scaler became the standard tool for removal of dental calculus and plaque. The term endosonics was introduced by Martin and Cunningham(2,3). It is defined as the ultrasonic and synergistic system of root canal instrumentation and disinfection.

Ultrasound is sound energy which has a frequency above the range of human hearing, which is 20 KHz. Though originally having high frequencies, recently low frequency ultrasonic handpieces of 1 to 8 KHz are being used. They produce low shear stresses and thus causing less alteration to the tooth surface.

There are two methods of producing ultrasounds. They are magnetostriction and piezoelectric principle. Magnetostriction converts electromagnetic energy into mechanical energy whereas piezoelectric uses deformation of a crystal by electric charge to produce mechanical oscillations.

Applications

The introduction of ultrasonics has greatly reduced the risks of perforations and separation of instruments in root canal therapy. In conventional access procedures, they are useful for refining the access, locating the extra canals, removing calcifications and attached pulp stones. These are done by either diamond coated tips, stainless steel tips or zirconium nitride-coated tips. The diamond coated tips have more cutting efficiency than the other two because of their ability to transmit the oscillations of the ultrasonic unit into the dentin more effectively.

Clinicians frequently encounter obstructions such as hard impenetrable pastes, separated instruments, silver points or posts in their roots. In failed cases, these obstructions have to be removed for retreatment. Ultrasonics is one effective adjunct. The ultrasonic tips and the endosonic files can be used deep in the root canal

system. Their use is not restricted by the position of the fragment in the root canal system. Some fragments cannot be removed because of the limited access, inspite of use of ultrasonic tips. Straight line access and magnification are essential for maximum visibility of the metallic fragment.

The three orthograde approaches for the management of separated instrument are 1) Removal of the instrument 2) Bypassing the instrument or 3)prepare and obturate to the fractured segment [4]. Many techniques have been suggested for retrieval of the broken instrument but all of them result in excess loss of root canal dentin, ledging, perforation or apical transportation of the fragment [5]. Ruddle [6] proposed a technique using Gates-Glidden drills to prepare a cirumferential 'staging platform' at the coronal aspect of the obstruction.

Ultrasonics has been a useful option for removal of the posts with minimum loss of tooth structure and damage. Removal of fibre reinforced composite posts has been a challenge. The disruption of composite structure by ultrasonic vibration seems to be the most effective technique in fibre post removal. It is important to remove the entire composite material used in the luting procedure. If the ultrasonic tip leaves behind gray streakes, it is an indication that composite is still present. The conductance of the vibration forces is directly proportional to the square root of modulus of elasticity of the post material[7]. Because of low modulus of elasticity of the composite posts, the effectiveness of ultrasonics as an aid in post removal is decreased.

Ultrasonics is initially used to remove the restorative material and the luting cement of the post followed by placement of ultrasonic tip to the post. The energy is transferred to cement through the post until the cement breaks down and the post loosens [8]. This method minimises the loss of tooth structure and tooth damage.

Ultrasonics can be used for retrieval of silver cones. The method is to start by troughing around the silver point with an ultrasonic spreader tip to eliminate the dentin carefully. The space created around the silver cones will loosen the silver point which can then be removed.

The effectiveness of irrigation lies in mechanical flushing action and the chemical ability of the irrigants to dissolve the tissue [9,10]. Syringe irrigation is relatively weak and depends on many factors such as diameter of the needle, depth of placement and anatomy of the canal [9,11,12]. Ultrasonics is a useful option for cleaning of difficult anatomic features like fins and webs. Ultrasonic vibration generates a continuous movement of the irrigant which is directly proportional to the effectiveness of cleaning of the canal[13-17]. Higher velocity and more volume of irrigant flow is created in the canal during ultrasonic irrigation [10].It has been concluded that ultrasonic also brings about significant bacterial reduction from the root canals than the other methods of irrigant activation and conventional needle irrigation [18].

Acoustic streaming by ultrasonics described by Ahmad et al produces enough shear forces to dislodge the debris in the canal [16]. US creates cavitation and acoustic streaming. The cavitation is minimal and is restricted to the tip. The acoustic streaming effect, however, is important. The irrigant is activated by the ultrasonic energy generated from the energized instruments, giving out acoustic streaming and eddies [16,17]. There is a synergistic effect of NaOcl and US [19]. The ability of NaOCl to dissolve collagen is enhanced by the heat from Ultrasonics [20].

One more application of ultrasonics is in obturation by warm lateral condensation technique using thermoplastisized gutta percha. The technique is easy to master. The heat is generated only during activation and the plugger cools down rapidly once the activation is stopped. The gutta percha does not stick to the ultrasonic file and has less volumetric changes upon cooling [21]. Moreover the placement of sealers with ultrasonically activated file showed a better sealing of the canal walls and better filling of the accessory canals than with hand instruments [22,23]. In a study on penetration depth of sealers using ultrasonics, AH-plus showed greater penetration compared to aeroseal and endorez sealers [24].

The ultrasonics also aid in the placement of Mineral Trioxide Aggregate (MTA). MTA placement in open apices with ultrasonic vibration and an endodontic condenser improved the flow settling and compaction of MTA [25]. The ultrasonic energy generates a wave like motion, which adapts the cement to the canal walls. This can also be put to use in root end cavities and perforations.

Coming to surgical endodontics, ultrasonics was a boon to root end cavity preparation. The first root end cavity preparation using ultrasonic inserts was done by

Bernard et al [26]. They give proper access to the root ends in a limited working space. Similar to the ortho grade obturation, ultrasonically activated condenser tips are used for placement of retrograde filling materials. Ultrasonic tips are also used to polish root end materials, apical surfaces and refinement of external radicular surface to eliminate the extraradicular bacteria.

Ultrasonics has had its mark in almost all the procedures of endodontic treatment. They enhance the quality of the treatment requiring less time and operator efficiency. Research in going on on all the aspects of application of ultrasonics in endodontics and they will occupy an indispensible place in clinical practice.

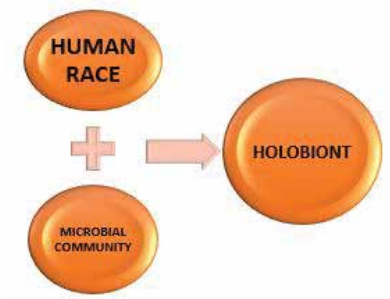
Oral Dysbiosis–Balancing Role of Oral Physicians

Shruthi Parthasarathy[1], Amudhan A[2]

[1]Post Graduate, [2]Reader, Department of Oral Medicine and Radiology, Sree Balaji Dental College and Hospital, BIHER, Chennai, Tamil Nadu, India

ABSTRACT

Since evolution, the oral cavity has served as a natural housing for numerous species of microbial colonies, which includes both beneficial and harmful organisms. They have developed various defensive mechanisms over time, and have known to survive hand in hand within the various human organs. An ecological balance is always maintained between these beneficial and harmful bacteria, which inturn keeps the hosts' organ systems in harmony. A plethora of deleterious effects may occur in the host when this harmony is disrupted. This article explains briefly about the harmful effects of oral dysbiosis and the role of oral physicians in controlling it.



Keywords: *dysbiosis, microbes, oral physicians*

Introduction

Oral cavity is the first and primary communication between the external environment and our internal organ systems. According to the Human Oral Microbiome Database (HOMD), around 150 genera and 700 species of microorganisms are known to flourish in various habitats or niches of the oral cavity like the teeth, tongue, mucosa, saliva, etc., inspite of constant removal of these microbes and their nutrition through various forces like swallowing and oral hygiene measures[1].

Microbiota in the oral cavity is personalized for each individual and also vary across different habitat and time. The co-existence of different species of microbes in the oral cavity is called microbial symbiosis. These species are known to exhibit a relationship with the host, which is very crucial in maintaining the oral and systemic health.Together with the symbiotic microbes, we are considered as a single unit and are called the HOLOBIONT[2], which is represented in Fig1.

Symbiosis is established as the host provides nutrition and suitable habitat to the microbiota, which in turn favors the host in many ways. They act as a barrier to various exogenic bacteria and protect the beneficial microbes from unwanted inflammatory reactions. Some residents convert dietary nitrates into nitrites in the saliva which is known to play a role in maintaining normal blood pressure. Further when nitrites are ingested, it is converted into acidified nitric oxide, which is antimicrobial in nature and stimulates gastric mucous secretions. This healthy relationship is balanced through various factors which include proper oral hygiene, healthy diet and good host defenses.

When drastic changes occur in the oral environment due to poor plaque control, low salivary flow, hormonal imbalance or antibiotics, deleterious shifts occur in the normal micro-community which is termed as dysbiosis. This is the key pathway for various dental and systemic diseases.

Role in Oral and Systemic Diseases: Dental caries which is the most prevalent dental disease is caused mainly due to a shift in the normal ecosystem of the mouth. Biofilm formation is the first step in the pathogenesis of periodontal diseases. This includes a sequence of events like primary colonization,establishment of a matrix and reinforcement of the primary matrix structure[1,2].

Oral mucosal lesions like oral leukoplakia, lichen planus have also become more prevalent with lifestyle changes, where dysbiosis plays quite a role in such lesions[1].

While bacteria like Peptostreptococcus, Streptococcus salivarius, Streptococcus gordonii, Gemmellamorbillosum, Enterococcus and parvimonas were found in tissue samples of oral squamous cell carcinoma[1,3] patients. These organisms does not directly initiate or cause oral cancer, but adds fuel to the flame through various mechanisms. Certain species like Streptococcus help in the breakdown of alcohol into its primary metabolite acetaldehyde which is a potential carcinogen. The microorganisms provoke chronic inflammatory reactions which releases pro-inflammatory mediators, some of which might trigger mutagenesis or oncogene activation. Also, secretion of bacterial effector proteins could alter the cell proliferation and inhibit apoptosis

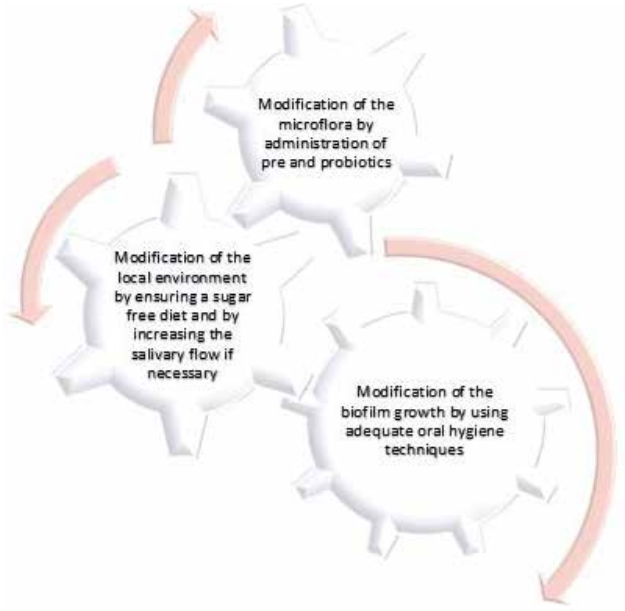
Dysregulation of the oral microbial flora is also known to play a role in the pathogenesis of various systemic diseases like diabetes mellitus, gastro-intestinal disorders like Inflammatory bowel disease, Crohn's disease, liver cirrhosis, rheumatoid arthritis, Alzheimer's disease, artherosclerosis leading to cardiovascular disorders, HIV infection, etc[1].

Factors Affecting the Persistance of Oral Dysbiosis[4]:

Complex anatomic factors:

1. Pits and fissures in teeth
2. Malocclusion
3. Papilla of tongue
4. Gingival crevice

Dental factors:



1. Overhanging restorations
2. Prosthetic surfaces
3. Orthodontic appliances

Subjective factors:

1. Ageing
2. Poor oral hygiene
3. Erratic dietary habits
4. Smoking
5. Alcohol consumption
6. Chronic use of antibiotics
7. Reduced salivary flow rate

Management Approaches: The main aim of clinicians is to prevent this imbalance and to re-establish homeostasis. Patient education is an important factor that would alter the imbalance that has occurred. Patients should be encouraged to modify their lifestyle by changing their dietary habits and other habits like smoking and alcohol consumption. Education about disproportionate and overuse of antibiotics should be given which might lead to bacterial resistance.

Once the imbalance have occurred, three main modifications can be done to treat oral dysbiosis[5] which is represented in Fig 2:

According to International Scientific association, Probiotics are live microorganisms when administered in adequate amounts confer health benefits on the host.

They mainly act through the following mechanisms: Compete with other pathogens for nutrition; Produce

Bacteriocins and other enzymes to inhibit potential pathogens; modulate cellular proliferation and apoptosis. The oral probiotics also have a tendency to attach itself to the dental hard tissues and to become an integral part of the biofilm.[6]

Prebiotics are fibers which act as nutrition for the beneficial bacterial colonies or probiotic bacteria. They stimulate the growth and activity of probiotics. [6]Both prebiotic and probiotic supplements are known to control dental caries, periodontitis and other oral diseases by manipulating the oral bacteria. They also prevent various gastrointestinal diseases and other systemic diseases like diabetes.

Urbanisationhas led to increased consumption of processed food and refined sugar, which exaggerates the existing condition. Patients should be advised to have afiber rich diet and to avoid cariogenic and acidic foods. Acidic environment may also be caused by reduced salivary flow due to old age, certain medications, radiotherapy or other systemic diseases. Increasing the salivary flow through sialagogues and artificial saliva will help neutralize the oral pH.

Reinforcement on oral hygiene measures like proper brushing and flossing techniques should be insisted to the patient. Importance of professional scaling should also be emphasized to disrupt the existing colonies in plaque and calculus[7].Dentrifices and Mouthwashes are widely being used as potent antiplaque agents. However it isinadvisable to recommend long term use of alcohol containing mouthwashes as it has been proved to increase the susceptibility to oral cancer[8].Moreover mouthwashes containing triclosan which is a broad spectrum antibiotic is known to reduce the total bacterial count in saliva which includes both good and bad bacteria.[9]Hence, prolonged use is contraindicated and is to be monitored.

Conclusion

Role of oral microbiome in maintaining homeostasis of mouth is crucial. Any imbalance paves path for disease occurrence due to altered oral hygiene. Prescription of mouth washes and medicated toothpastes must be strictly supervised. Antibiotic misuse is posing a great danger in medical field. Over the counter usage of these medications can deplete its usefulness during disease stages. Awareness about maintaining the oral microbiome and advise on oral hygiene aids among general public and general dentists should be initiated and widespread.

Oral Field Cancerisation–Note to General Dentists

Bhargavi R[1], Amudhan A[2]

[1]Post Graduate, [2]Reader, Department of Oral Medicine and Radiology, Sree Balaji Dental College and Hospital, BIHER, Chennai, Tamil Nadu, India

ABSTRACT

Oral cancer is a dreadful disease affecting the quality of life of patients and their concerned family. The concept of field cancerisation influences the disease progression and treatment prognosis to a greater extent, that recurrence becomes inevitable. Purpose of the article is to emphasize on the theory of field cancerisation among the general dentists who can therefore, approach their patients with tobacco- related oral habits in a proper manner and ensure early diagnosis of the disease to aid in prompt treatment.

Keywords: *Oral cancer, field cancer, general dentist, field tumour*

Introduction

Cancer of head and neck is sixth most common malignancy.[1] Despite extensive research on early diagnosis and constant improvisation in treatment aspects, Head and Neck Squamous Cell Carcinomas (HNSCC) pose a plenty of challenges to both, clinicians and patients. Key to success in treating these cases relies on early diagnosis and prompt treatment.[2] But, general lack of proper understanding of the genetic alterations and molecular aspects of this disease among the oral physician jeopardises the patient's health. Resultant cellular changes of genomic and metabolic abnormalities that go undetected under a microscope influence the disease progression, oblivious to the treating clinician.

Slaughter's concept: Albeit Slaughter in 1953 observed the presence of histologically altered cells around a squamous cell carcinoma lesion in his study. He then proposed that "cancer does not arise as an isolated cellular phenomenon, but rather as an anaplastic tendency involving many cells at once".[3]

This was further explored as field-effect/field cancerization that has been demonstrated in various epithelial tumours in other organs such as oropharynx, larynx, lung, oesophagus, vulva, cervix, colon, breast, bladder, and skin.[4] The current definition of field cancer states that "The presence of one or more areas consisting of epithelial cells that have genetic alterations. A field lesion (or shortly 'field') has a monoclonal origin, and does not show invasive growth and metastatic behaviour, the hallmark criteria of cancer."[5]

Field effect: Prolonged exposure to carcinogenic substances pre-condition the oral mucosal tissues, potentiating them for further the malignant progression. This transformation of clinically appearing normal tissue to a potentially malignant lesion can occur at any point of time. The susceptibility of multifocal carcinogenesis in HNSCC may occur due to independent cell alteration or migration of affected cells within the tissue bed.[6]

Hence, the following theories were proposed to explain the possible course of development of field-effect in epithelial tissues:

1. **Monoclonal theory**: Also known as Lateral cancerisation theory that suggests a progressive transformation of cells adjacent to the mutated cell and therefore expanding the tumour nidus in the lateral aspect.
2. **Polyclonal theory/Classic theory:** Continuous carcinogenic exposure to the soft tissue structuresin the oral cavity induces multiple areas

of genetically altered cells that exhibit abnormal molecular changes leading to altered cellular events. Such abetments lead to formation of multiple tumour sites of diverse clonality.

3. **Alternate theory:** A single genetically altered cell develops to form a tumour nidus through migration of its progeny cells resulting in multiple areas of tumour potential with the same clonality.
   i. Micro metastasis by Saliva.
   ii. Intraepithelial migration. [7,8]

Clinical consequences: Understanding the concept of field cancerisation is of utmost importance in treating a patient with the premalignant disease. Lesions such as leukoplakia, erythroplakia exhibit a localised presentation in the oral cavity. Whereas, Oral Submucous fibrosis, Plummer Vinson syndrome, Erosive Oral lichen planus, Graft- vs- Host disease and lesions alike present with generalised involvement of Oral and even pharyngeal tissues.Among the various pathways of carcinogenesis, long standing inflammation is considered to be a potential factor. Oral mucosal conditions including oral lichen planus that subject the tissues to persistent inflammation can induce tumours over the field area.[9] Formation of new tumours in the anatomical region of already resected tumours can be explained by two cause: Incomplete resection of the primary tumour or presence of genetically altered cells in the region which gives rise to second primary tumours.[10] The latter explains recurrence of tumour in radically resected carcinoma cases.[11-12]

Occurrence of second primary tumour can be synchronous, i.e., occurring within 6 months of time or metachronous i.e., occur after 6 months or any time later. The diagnostic criteria for double primary malignancies was given my Warren and gates in 1932 that states,

1. Histological confirmation of malignancy in both the index and secondary tumours.
2. There should be at least 2 cm of normal mucosa between the tumours. If the tumours are in the same location, then they should be separated in time by at least five years.
3. Probability of one being the metastasis of the other must be excluded.[13]

Schwartz et al, in 1994 conducted an analysis that suggested that high rate of second primary tumours in patients with initial head and neck malignancies. They also concluded that the development of a second malignancy is almost always fatal. The following table summarises the study report by Schwartz et al[14]

Table 1: Incidence of Multiple Primaries in Head and Neck Cancer

Year	Reference	No. of patients	Site of 2nd Cancer	Follow – up	2nd primaries (overall) (%)
1961	Moertel	732	Oral cavity		16.3
1983	Black	577	Head and neck	>5yr (1972 – 1978)	20.9
1984	Vikram	114	Head and neck	>5yr	14.0
1985	Shons	405	Head and neck	>5yr (1965 – 1980)	13.0
1987	Rousy	1146	Head and neck	>5yr (1978 – 1985)	14.5
1990	Hong	51	Head and neck	5yr	36.0
1991	Fijuth	600	Oral cavity and oropharynx	35mo	19.0
1992	Hirokawa	535	Oral cavity	10yr	11.4

The current treatment aspects of the premalignant diseases assure utmost care to the lesion-specific areas in the oral cavity, whereas the patient is under the danger of developing carcinogenic transformation in any part of the mouth. When knowledge of field cancerization is been considered, the clinicians can demonstrate a better approach to treatment planning in such patients. Few articles in the literature provide evidence for multiple site biopsies in cases of Oral submucous fibrosis suggesting a better view of the histological alteration of the tissue. Such investigational methods endow more information about the tissue progression into malignancy.[15]

Due to lack of good RCT studies, there hasn't been a proper protocol derived for management of oral potentially malignant lesions.[16] Enormous variations in tumour pathway exhibiting heterogenicity complicates a universal protocol in managing these patients. A patient having strong habitual history of tobacco usage logically lacks the knowledge of importance in regularly visiting an oral physician. Such patients miss out on the benefits of early diagnosis and prompt treatment.[17]

Note to general dental practitioner:

1. Emphasis on tobacco cessation and regular patient follow up.
2. Conducting frequent screening camps and awareness program towards patient education.
3. Knowledge on various Potentially malignant disorders and predicting their progression.
4. Responsibility in referring patients to higher centre for their management.
5. Consulting Oral physician specialists as and when needed rather than proceeding a case with pre conclusion of lesions.
6. Complete examination of a patient at every consultation.[18]

Conclusion

A clinically usual tissue appearance gives an absolute display of normalcy. This convinces general clinicians to ignore any possible genetic or molecular transformation of cells beneath it. Any such transformation that can be potentially managed still goes unnoticed beneath our nose. This puts the patient under a treacherous situation due to a cognitive error of the treating physician. Once developed a carcinogenic lesion, the whole approach in treating a patient is altered to a vigorous mode. Treating the pre malignant lesions in such tissue-specific manner doesn't guarantee a progression-free survival in such patients. Associated morbidity and mortality of the disease depends on the prognostic factors of HNSCC that include the tumour size, nodal involvement and presence of metastatic lesions. These factors are hugely influenced by new tumour formation either in the field area of existing tumour or at a site distant from the existing tumour. Recurrent lesions on a previously treated site further complicate the clinical scenario. To avoid such complications, clinicians must cultivate the habit of treating a patient as a whole rather than a lesion specific management.

Proton Therapy in Head and Neck Cancer—A Review

Jemima Judith M[1], Manigandan T[2]

[1]Post Graduate Student, [2]Professor, Department of Oral Medicine and Radiology, Sree Balaji Dental College and Hospital, BIHER, Tamil Nadu, Chennai, India

ABSTRACT

Conventional radiation therapy is one of the most common methods of cancer treatment. Because of conventional therapy's early and late toxicity,it is of great interest to find a modality that has low side effects to the normal tissues. This has led to the invention of proton therapy. Proton therapy is believed to have better results than conventional radiotherapy. Proton beam therapy is a recent modality that is more tumour conservative than photon beam therapy. The physical property of protons spares the normal surrounding tissues. More clinical trials and prospective studies are required for the inclusion of proton therapy in treating carcinomas of the head and neck.

Keywords: *Radiation, Photon therapy, Computed tomography.*

Introduction

Head and neck cancer is a range of malignancies with different causative factors. However, due to the tumour's proximity to vital structures and anatomical location, some of the tumors are difficult to treat. Anatomic locations of tumor within the head and neck range from the oral cavity, maxillary sinus, paranasal sinus, minor and major salivary glands, nasopharynx, oropharynx, and larynx. [1] Among cancer, head and neck cancer is accounted for 30% in India. Oral cancer is ranked eleven among all other types of cancer in 2013.The Indian subcontinent is responsible for one-third of the world's oral cancer burden [2, 3] For head and neck cancer the most common modality of treatment has been chemotherapy and/with radiotherapy. With surgery being the mainstay of management although often associated with morbidity and mortality. Recent advances of chemotherapeutic and radiotherapeutic modalities have emerged to treat these challenging tumours.[1]Among them, proton therapy is one of the radiotherapeutics advances that have less toxicity on surrounding tissues. A form of external beam radiotherapy is proton therapy it uses protons instead of x-rays to irradiate the tumorous tissues.

Dosimetric advantage of proton therapy: Clinical studies and also at the molecular level there are differences between the traditional photon therapy and the proton therapy. Clinical studies have also demonstrated the benefit of proton and the potential advantages and disadvantages when compared to traditional photon therapy. In contrast with photons, protons have a heavier mass that prompts to a relatively decreased scattering angle and subsequently sharper dose distribution within a finite, defined range**.** [4]

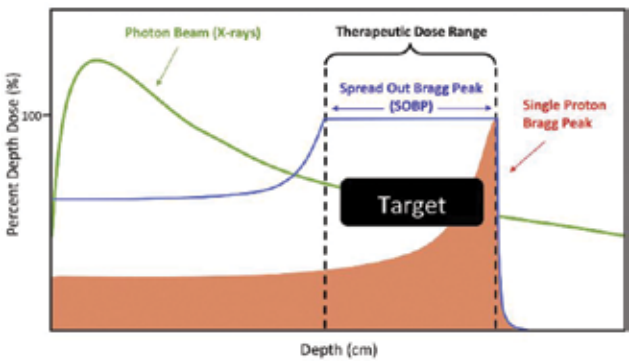

Figure 1: Spread-out Bragg peak (SOBP)

Furthermore, the dose depth distribution for proton beam therapy is characterized by a sharp increase in dose deposited at depth, delivered by a monoenergetic pencil proton beam and an abrupt distal dose fall off (Bragg

peak). A monoenergetic proton beam has a finite range and a well-defined peak in the depth-dose curve. This peak has a narrow width and a sharp distal falloff, which enables tissue sparing beyond the proton range. Because the proton particles halt in the tissue immediately after the Bragg peak, no exit dose is deposited beyond the target. For proton therapy to be clinically useful, it is necessary to superimpose several beams with distinct energies to produce a spread-out Bragg peak (SOBP) (Figure 1) to cover the target. SOBP formation takes place at the cost of entrance or skin dose as the SOBP width increases. However, the absence of an exit dose is the main dosimetric benefit compared to x-rays. [5]

Proton delivery system: The Proton is delivered in a pencil shaped beam system to the target tissue. Pencil beam scanning uses protons ' monoenergetic "spots," these spots are delivered in various energy layers so that the dose is distally and proximally conformed to the target. The pencil beam may be modified by scattering beam technique to form SOBP. Scattering beam technique is when the beam is spread out laterally using double scatterer and compensator and its depth is modulated by range compensators. In scanning beam technique electromagnetic field is used to expand and shape the lateral beam relying on the magnetic property of the protons. The energy of the generated proton beam is varied to read the tumour's distinct layers, and magnets are used to deflect and conform the beam to the volume of the target. So Intensity Modulated Proton Therapy (IMPT) is when the proton beam intensity is modulated as it moves through the field guided by magnets to paint the target with the dose that allows the capacity for the intensity modulation of the beam.[6, 7]

Treatment plan: The main treatment plan is to choose the shortest and the most reproducible path through the tissue to reach the target. Proton penetration may encounter worse tissue inhomogeneity issues due to artifacts, such as dental or surgical hardware, can lead to uncertainty in the tumour distance and localization of the Bragg peak and the accurate calculation of the radiation dose in the tissue. Computed tomography (CT) are used to plan and to consequently deliver the suboptimal treatment with the potential for normal tissue irradiation. Therefore, it is important to avoid choosing a beam path reaching the area of interest through hollow areas such as the mouth, hollow organs, and critical structures (e.g., spinal cord, pharyngeal constrictors, salivary glands). Treatment plans can be further complicated by fluctuations in a patient's anatomy, such as changes in tumor size, patient weight. In the head and neck, the complex anatomic geometry and irregularity in the shape of the target often require more complex and advanced proton techniques. Also, consideration should be given to techniques and plans for minimizing skin toxicity, such as using three-dimensional conformal passive scanning as the dose of the entrance beam is determined by the depth of the target density along the beam direction. [4, 1]

G- Grade, G-tube – gastrostomy tube, OS- Overall Survival, PFS- Progressive Free Survival, LC- Local Control, LRC-Local Regional Control, LFFS-Locoregional failure-free survival, DFS- Disease Free Survival DMFS-distant metastasis-free survival, PBT-Proton Beam Therapy, IMRT- Intensity Modulated (Photon) Radiation Therapy, PSPT- Passive Scattered Proton Therapy, NPC- nasopharynx carcinoma, RBE-Relative Biological Effectiveness, OPC- Oropharynx Carcinoma

Limitations: In terms of treatment planning, proton beam therapy is highly sensitive to fluctuations and uncertainties in particle range patient positioning and anatomical changes. The high sensitivity of IMPT is due to changes in the radiologic density as a result of setup errors or anatomic changes may be due to interfraction variations in positioning the patient, intrafractional organ motion, or changes in target volume throughout the treatment (i.e. tumor regression or patient weight loss) during or in between fractions are the greatest limitations.

For IMPT, Improvement on the methods of robust optimization and to use CT imaging frequently throughout the treatment to verify and/or to trigger adaptive planning during the treatment. Scanning-spot optimization algorithms, switching time and the RBE uncertainties of the proton therapy that affect the precision of IMPT planning are the limitations being actively investigated. Patient-specific quality assurance protocols should be established and standardised in the clinics**.** To understand the risks and benefits of proton beam therapy prospective, randomized controlled studies are needed.[4, 7]

Future directions: Further development of clinical evidence is needed to guide the proton therapy application for various malignancies of the head and neck.Additional insights into the advantages of proton

therapy would ideally be obtained from big, multicenter randomized clinical trials that directly compare proton therapy with photon-based therapy for the treatment of head and neck malignancies as they have the ability to reduce dose escalation toxicity relative to photon therapy; However, such studies may demonstrate to be impractical, partly because it would require big multi-institutional database registries to be developed. Oropharyngeal cancer, for instance, would be included in randomized studies comparing protons with IMRT. Further studies may be directed towards the relationship between proton beam therapy and other treatment methods, such as immunotherapy as proton beam therapy becomes more popular. Future research may explain the outcomes of proton radiation therapy on the immune response to antitumor and immunogenic cells destruction. One potential sector of future studies is to investigate techniques at the distal end of the Bragg peak to exploit proton-specific distinctive radiobiological characteristics such as a potentially higher comparative biological efficacy (RBE). Some disadvantage due to the uncertainty of the range and the potential for greater RBE at the distal Bragg peak, proton fields are not aimed at critical buildings, restricting some beam arrangements. In the future, a plan could be envisaged where the higher RBE edge is deliberately located within the tumour's most radioresistant part. Many comparative dosimetric planning studies have shown that proton therapy offers a favourable dose distribution to at-risk organs relative to IMRT, indicating that proton therapy can also lead to clinically significant decreases in acute and long-term toxic impacts caused by radiation. Other methods aim to use the normal probability of tissue complication (NTCP) models to define patients for whom proton therapy is likely to give a clinically significant benefit. Models have been developed to determine the NTCP value decrease from proton therapy versus IMRT and are being implemented prospectively. It is hoped that this strategy will lead to the detection by some threshold value of particular subsets of patients for whom proton treatment would exceed the anticipated advantage in reducing the NTCP value, such as 10%. Researchers assessing the advantages of proton therapy for other disease locations used cost-effectiveness analyses as a means to demonstrate the importance of PBR. To date, in patients with head and neck cancer, these models have not been used to assess PBR. However, as more data becomes accessible on the results of control, survival, and toxicity with PBR, cost-effectiveness analyses can become viable and informative. [1, 4, 5]

Conclusion

Proton therapy is a standard of care for skull tumor base as per National Comprehensive Cancer Network rules and is an alternative for periorbital tumors. Proton therapy use is also rising for other tumor regions in the head and neck. The possibilities of proton therapy will be further enhanced by new types of proton therapy such as IMPT and technical improvements in dose modelling, patient configuration, picture guidance, and radiobiology. Additional prospective studies are needed to quantify IMPT's clinical advantage over IMRT or PSPT and provide strong input on enhancing present techniques of planning and treating IMPT patients. Therefore, to identify and improve the indications for which proton radiation should be regarded, continuing and future attempts should produce forward-looking, comparative proof, ideally in the setting up of a clinical study.

Oral Psoriasis- Report of 2 Cases with Review of Literature

Aarthi Nisha V[1], Sujatha S[2], R. Sankar Narayanan[3]

[1]PhD Research Scholar & Assistant Professor, Sree Balaji Dental College And Hospital, Biher & Department of Oral Medicine and Radiology, Tamilnadu Govt Dental College & Hospital, Chennai; [2]Professor & Head of the Department, Department of Oral Medicine and Radiology, M.S.Ramaiah Dental College & Hospital, Bangalore; [3]Senior Lecturer, Department of Oral Medicine and Radiology, Sree Balaji Dental College and Hospital, BIHER, Chennai

ABSTRACT

Psoriasis is a genetically determined, inflammatory disease of the skin. It can occur at any age but, usually develops during young adult life and may persist throughout a person's lifetime with periods of exacerbations and remissions. It was earlier thought that oral psoriasis does not exist, however it is now believed that oral lesions of psoriasis do exist although the incidence is very low. Herein we report two cases of psoriasis with oral manifestations and one case of TMJ psoriatic arthritis.

Keywords: *Oral psoriasis, geographic tongue, lichen planus, granular gingival lesions.*

Introduction

Psoriasis is a chronic, remitting and relapsing inflammatory skin disorder with a strong genetic predisposition. It is a genetically complex disease with a multifactorial etiology[1]. A genome-wide linkage analysis of eight kindred localized a gene involved in psoriasis to the distal end of human chromosome 17q[2]. Infection, trauma, metabolic disturbances and endocrine dysfunction have been considered as triggering factors in the initiation of psoriasis. There are different forms of psoriasis namely, psoriasis vulgaris, psoriasis inversa and pustular psoriasis[1].

A review of the medical literature from 1903 to 1986 revealed only 33 cases of intraoral psoriasis. The reported frequencies of various oral psoriasis signs and symptoms are geographic tongue, fissured tongue, granular gingival lesions, lichen planus, other keratotic lesions and TMJ arthritis[3,4]. Conclusive data on the incidence of true psoriatic oral lesions is not available[4]. There is an increase in the prevalence of ectopic geographic tongue (5-10.3%) and fissured tongue (6-14.3%) in patients with psoriasis with a female predilection[5]. It has been suggested that geographic tongue, fissured tongue, and generalized pustular psoriasis have a genetic linkage[6]. Psoriatic lesions may be found on the gingiva, upper and lower lip, hard and soft palate, edentulous maxillary ridge, buccal mucosa and floor of the mouth[7-10]. One of the complications of psoriasis is psoriatic arthritis.

Involvement of the TMJ has been reported in patients with psoriasis varying from 31% - 63% and crepitus is the most characteristic TMJ sound in these patients[11]. Crepitus may persist even after all other signs and symptoms including pain have disappeared. There is a tendency for the arthritis to improve as cutaneous lesions resolve[12].

Pindborg recognizes four clinical presentations of intraoral psoriasis: small, whitish, oval to round lesions that can be scraped off leaving a bleeding surface; whitish plaques with red areas that parallel the cutaneous eruptions; fiery red areas: and geographic tongue. Oral lesions are uncommon in psoriasis vulgaris. However in pustular psoriasis, lesions clinically resembling geographic tongue are common[13].

Case Reports:

Case 1: A 50 year old male reported with the complaint of pain and burning sensation of the gums with discomfort and partial inability to open the mouth since two months.

He was a known psoriatic with extensive erythematous plaque like lesions on the skin covered with silvery scales. Auspitz sign was positive. He was on medication for the same but had discontinued it since 6 months. He was a known hypertensive and hyperthyroid on medication for the past 5 years. Family and personal history were non contributory. Physical examination revealed exophthalmia of eyes (fig 1); right thumb and index finger interphalangeal joint arthritis (fig 2) and lower lips were dry with shiny adherent scales. TMJ examination showed bilateral tenderness and clicking on opening the mouth and crepitus was present. Analysis of mandibular excursions showed limited mouth opening was limited to 25mm and limited lateral and protrusive movements. Intraorally there was generalized edema and erythema of the marginal and interproximal gingiva with generalized areas of erosion on the attached gingiva (fig 2). Oral hygiene was fair. Dorsum of the tongue showed patchy loss of filiform papilla resulting in erythematous flat areas. The margins were irregular, slightly raised and yellowish white in color. Oral manifestations like geographic tongue, psoriatic lesions of the gingiva and TMJ arthritis were considered under provisional diagnosis.

Right hand wrist radiograph revealed erosion of the metacarpal joint of the right thumb (fig 2). Panoramic radiograph showed no alveolar bone loss and TMJ appeared normal. Following biochemical investigations were done which revealed,

Table 1: Biochemical investigations with their results of case 1

Investigations	Observed value	Reference interval
S.uric acid	3.3mg/dL	3.6mg-8.6mg/dL
RA factor	Negative	-
Hb%	11.0gm/dL	12-14gm/dL
Random blood sugar	110mg/dL	<140mg/dL
HIV I & II tests	Negative	-
Blood pressure	160/120mmHg.	120/80mmHg
Thyroid profile		
T3	3.5ng/ml	0.8-2.0 ng/ml
T4	14µg/dl	4.6-12.0 µg/dL
TSH	0.05µU/ml	0.3-3.0µU/ml

Gingival biopsy followed by haematoxylin and eosin staining showed hyperplasia, acanthosis, neighbouring rete ridges seemed to coalesce at their base with elongation, edema and dilated tortuous capillaries surrounded by dense inflammatory infiltrate (Fig 2).

Treatment included oral prophylaxis and topical anesthetics with topical steroids to relieve the pain of the gingival erosive lesions. Patient was advised to discontinue the smoking and alcohol habit as they are exacerbating factors. Clobetasol propionate gel and psoralene UV-A therapy for twice weekly for four weeks was advised for the skin lesions. 25 mg of etanercept subcutaneously, twice a week, monthly with follow-up was advised for TMJ psoriatic arthritis. Following treatment, the intensity of the lesions reduced. On follow up after 6 weeks, the crepitus had disappeared and the mouth opening had improved to 31mm.

Case 2: A 40 year old female reported with the complain of pain and burning sensation of the mouth since 6 months which increased on taking spicy food. She was a known psoriatic patient on medication since a year. Physical examination revealed papulosquamous lesions with shiny scales over the trunk, abdomen, back and the extremities which were pruritic (fig 1). She also had severe arthritis that had limited the movements of her upper and lower arms. Intraoral examination revealed white, keratotic, unscrapable, smooth radiating striae associated with erythema on the buccal mucosa bilaterally measuring about 2X2 cm (fig 3). Dorsum of the tongue showed diffuse areas of atrophy of filiform papillae (fig 3). Lichen planus of buccal mucosa bilaterally and geographic tongue was observed in this psoriatic patient.

Following biochemical investigations were done which revealed,

Table 2: Biochemical investigations with their results of case 2

Investigations	Observed value	Reference interval
S.uric acid	2.6 mg/dL	3.6-8.6mg/dL
RA factor	Negative	-
Hb%	9.0gm/dL	13.0-15.0gm/dL
Random blood sugar	90 mg/dL	<140mg/dL
HIV I & II tests	Negative	-
Blood pressure	**130/100mmHg.**	120/80mmHg

Exopthalmos of eyes

Deformity of the right index and thumb

Papulosquamous eruptions over feet

Papulosquamous eruption over the elbow.

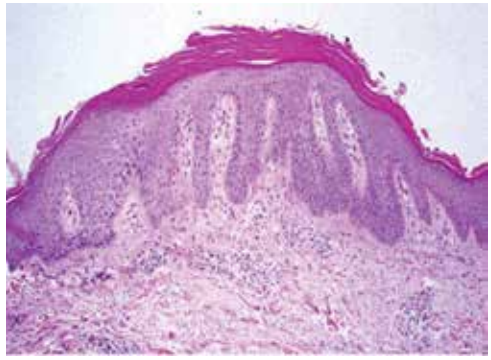

Figure 1: Shows Keratotic Eruptions of Hand and Feet

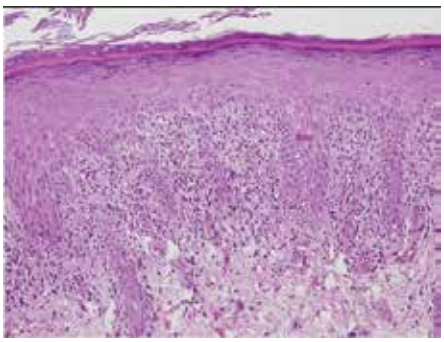
Gingival inflammation with erosion

Erosion of metacarpal joint in right thumb

Micro abscess of monro within parakeratotic layer

Papulosquamous lesions and shiny scales over the trunk, abdomen, back and the extremities.

Figure 2: Shows Oral Erosions and Joint Erosions



White radiating striae with erythema over the left buccal mucosa

White radiating striae with erythema over the right buccal mucosa

Tongue showing diffuse areas of atrophy

Micro abscess of monro within parakeratotic layer of filiform papillae.

Figure 3: Shows Oral Lesions

Histopathological features of the left buccal mucosa showed saw tooth rete ridges with dense inflammatory infiltrate suggestive of lichen planus. Civatte bodies were also found. The tongue biopsy revealed hyperkeratosis, elongation, clubbing and edema of the rete ridges, thinning of the suprapapillary epithelium, chronic inflammatory infiltrate with capillary dilatation and edema.

Treatment included oral prophylaxis and topical steroids for lichen planus lesions. Clobetasol propionate gel and psoralene UV-A therapy twice weekly for four weeks was advised for skin lesions. Patient's skin lesions and oral lichen planus lesions had reduced on consecutive follow up visits.

Discussion

Oral psoriasis is rare given the prevalence of cutaneous disease, one explanation is that oral lesions are asymptomatic and do not come to the clinician's attention[5].Oppenheim, in 1903 was the first to substantiate oral psoriasis with biopsy[7]. Psoriatic lesions are not premalignant, but dystrophic changes may occur secondary to treatment with arsenicals or radiation[8]. The frequency of geographic tongue, fissured tongue, gingival and mucosal lesions among psoriatic patients was more compared to the general population. Various studied on psoriatic patients have reported different incidence of geographic tongue and fissured tongue, Geographic stomatitis, glossal, and/or extraglossal lesions have been observed to appear and disappear with the cutaneous lesions of psoriasis[9]. Both our patients had geographic tongue and gingival lesions. One with erosive type of lesions and other with lichen planus like lesion. A strong association between psoriasis and HIV infections has been shown thus restricting the clinician to elicit Auspitz sign in the patient[2].

Inflammatory joint diseases may affect the temporomandibular joint (TMJ). Crepitus is the most characteristic TMJ sound in psoriatic patients which may persist after all other signs and symptoms including pain have disappeared. The onset of TMJ symptoms for this disease entity usually occurs by the fourth decade of life, most commonly expressed as pain and limitation of jaw range of motion. When the TMJ in these patients becomes involved, it is difficult to distinguish between various forms of arthritis such as rheumatoid or osteoarthritis. Usually, radiographic findings are not

specific, and diagnosis is based on the arthritis occurring in a patient who has psoriasis and a negative rheumatoid factor. There is a tendency for the arthritis to improve as cutaneous psoriasis resolves. Although oral psoriasis usually occurs in the presence of cutaneous diseases, Wooten et al did find a case of oral psoriasis of the maxillary ridge in the absence of cutaneous involvement.

Differential diagnosis of oral psoriasis include lichen planus, eczema, lupus erythematoses, syphilis, desquamative gingivitis, Reiter's syndrome, stomatitis medicamentosa, candidiasis, leukoplakia and squamous cell carcinoma.

The primary target in the management of TMJ psoriatic arthritis is pain relief. Initial therapy should include counseling and reassurance on the benign nature of the disease. Physiotherapy may improve pain reduction and joint range of motion. The pharmacologic management of psoriatic arthritis should initially include non-steroidal anti-inflammatory drugs (NSAIDs), and steroids administered systemically and intra-articularly[13]. Psoriasis can be managed successfully using coal tar, anthralin, salicylic acid and other keratolytic agents supplemented with calcipotriene and cautious use of corticosteroids. Patients with severe, refractory lesions should be referred to ultraviolet light B (UVB) or oral psoralene with ultraviolet A therapy (PUVA). Systemic therapy with retinoids, cyclosporine or cytotoxic drugs should be administered under supervision[11]. The cutaneous lesions in both our patients had resolved. The first patient's TMJ pain and discomfort had considerably reduced. Dental treatment strategy should emphasize oral hygiene and removal of local irritants. Patients should be reinforced frequently in oral hygiene performance. In cases with associated glossodynia, potentially initiating factors such as spicy or acidic foods and smoking should be eliminated. Symptomatic treatment may include frequent mouth rinsing with lukewarm saline, topical anesthetics. antihistamines, steroids, or a light application of liquid nitrogen or solid carbon dioxide[12].

Conclusion

The major findings of oral psoriasis are tongue changes which include geographic tongue, fissured tongue and ectopic geographic tongue (5-1 4.3%); gingival involvement (erythematous patches or grayish white crescent-shaped lesions) and TMJ inflammation are less common. To support the diagnosis of oral psoriasis. a concurrence of systemic psoriatic lesions should be present. Confirmation by biopsy is mandatory. Multiple supportive treatment regimens are presently used to relieve symptoms; future investigation into the etiologies may yield new strategies for possible cure.

ABSRACT

Successful management of impacted maxillary canines requires precise localization of these teeth which is usually achieved using a combination of clinical and radiographic examination. Various techniques have been employed in radiology to locate the impacted canines each of it with its own advantages and limitations. This article will emphasize on modified vertex occlusal view which is an extra oral view that images the maxillary arch in the superoinferior projection that was employed in our patient to accurately locate the position of the impacted tooth.

Keywords: *Impacted maxillary canines, localization, True/vertex occlusal view, Modified vertex occlusal view*

Introduction

Maxillary canines are the second most common teeth to be impacted after the mandibular third molars[1]. The prevalence of ectopic maxillary canines (EMCs) is approximately 1%. Determining the relative position of pathological lesions in the horizontal plane is essential for adequate diagnosis and treatment planning. Clinical examination in cases with EMCs may reveal the absence of a labial canine bulge on palpation, with prolonged retention of the primary canine. In the absence of the bulge, the tooth may be located palatally or superiorly within the arch. In these circumstances radiology plays a vital role in their localization[1].

In 70% of cases, an impacted tooth can be located by inspection and palpation. The other 30%, radiography is the only method to determine position of the impacted tooth[2].

Corresponding Author:
Dr. R. Sankar Narayanan, Mds, Senior Lecturer,
Department of Oral Medicine and Radiology,
Sree Balaji Dental College & Hospital, BIHER, Chennai

The following four methods for localizing these teeth are the tube shift/parallax method, orthogonal views, stereoradiography and the vertex/true occlusal view.[2,3]

Among these four methods the most commonly followed one is the true/vertex occlusal view. This requires an occlusal film to be inserted in the mouth and X-ray exposure is made through the vertex of the head[4&5] The disadvantages of the vertex occlusal view are long exposure time; poor image contrast due to non usage of grid, primary radiation beam is directed towards the thyroid gland and the gonads which should be harmful to the patient[2]. As an alternative, we had used modified projection technique to the maxillary arch which overcomes the disadvantages of the vertex occlusal view, produced an image with good details and image quality to locate the exact location of bilaterally impacted maxillary canines. We present this technique as it is revisited after long years and aptly this technique can be suggested as an unexplored treasure due to its easy availability and cost[3].

Case Report: A 14 year old female reported with chief complaint of missing teeth in the upper front region of the jaw since her childhood. After the exfoliation of the deciduous canines the permanent canines failed to erupt. The patient did not experience any symptoms in the alveolus of the missing teeth. Intraoral examination revealed missing maxillary canines 13, 23 with increased spacing between the upper anteriors. On palpation there was no bulge buccally to indicate the position of the teeth.

To rule out the presence of impacted maxillary canines, an intra oral periapical radiograph was taken which showed Clark's tube shift method was performed for both the right and left maxillary canines. The right maxillary canine was impacted and was situated between the root apices of the first and second premolars. On shifting the tube mesially in reference to the first radiograph the impacted tooth showed no significant movement in relation to the reference point of roots of premolars (Fig 1), which showed that the tooth was neither buccally nor palatally placed. The left maxillary canine was horizontally impacted and was situated over the root apices of the premolars associated with resorption of maxillary right first premolar root. On shifting the tube mesially in reference to the first radiograph the crown of the impacted tooth moved in the opposite direction (Fig 1), which showed that the tooth was palatally placed. This was followed by a panoramic radiograph (Fig 2) which revealed that both the canines bilaterally were neither magnified or diminished in comparison with the adjacent teeth which also suggested that that the impacted teeth were placed within the arch above the roots of the erupted teeth. The maxillary true occlusal view (Fig 3) showed the crowns of the canines were palatally placed between the crowns of premolars. But the exact positioning of the tooth cannot be determined by this view as the primary beam of radiation does not exactly pass through the roots of the anteriors along its long axis.

Figure 1: Localization of impacted canines using Clark's tube shift technique

Figure 2: Cropped Panoramic radiograph showing canines bilaterally with neither magnified nor diminished in comparison with the adjacent teeth

Figure 3: Maxillary true occlusal view showing crowns of the canines placed palatally between the crowns of premolars.

In this situation, a modified vertex/true occlusal view is preferred as the path of the central beam of X-ray passes exactly through the long axis of the maxillary anterior teeth. It can be performed using a cephalometric X-ray setup and extraoral cassette with rare earth intensifying screen and a green sensitive double emulsion film. The exposure was done by placing the patient erect against the cassette with the chest against the machine and neck fully extended. Now the patient was asked to open the mouth as widely as possible and the head was adjusted so that the maxillary occlusal plane is parallel to the floor and chin resting on the cassette (Fig 4). The film cassette was placed centrally in front of the maxilla and the X-ray beam was directed perpendicular to the occlusal plane and through the level of maxillary canines. The impacted teeth could not be visualized in the resultant radiograph (Fig 5) which suggested that the impacted teeth were neither placed buccally or palatally but with the arch above the roots of the first and second premolars bilaterally.

Figure 4: Patient positioned flat against the cassette with neck fully extended and mouth wide open for modified vertex occlusal projection

Figure 5: Resultant radiograph revealing bilaterally impacted teeth placed within the arch

Based on the radiographic appearances of the impacted teeth on the modified maxillary occlusal view, the surgeon had explored the region just above the roots of erupted teeth equidistant from both buccally and palatally and removed the impacted canines.

Discussion

The discrete organs of the head in the path of the primary beam will be exposed in imaging maxillary canines, hence a reduction in radiation dose will give a corresponding reduction in absorbed dose to these organs.[6] Compared to the true/vertex occlusal view, here the primary X-ray beam is directed away from the thyroid and gonadal organs[4&6]. It is really difficult to perform a vertex/true occlusal view in our routine intraoral X-ray unit. But comparatively, it is relatively much easier to perform the modified vertex occlusal projection in the cephalometric machine. Also the as the grid/screen film combination is used, the resultant image has an excellent contrast when compared the vertex/true occlusal radiograph[7]. The technique is reproducible and also has good infection control as we do not place the film inside the mouth for possible contamination from saliva[7]. In our case, with the help of modified vertex occlusal technique, the exact position of the impacted teeth was located thus guiding the surgeon the exact position of the teeth and the direction of approach ie.,buccally or palatally which had avoided excessive bone removal and also unnecessary trauma to the patient. There are also some pitfalls in this technique as it cannot be carried out in patients with cervical problems and also the magnification factor for this radiograph is high which produces image distortion of the molars.[8] Radiograph obtained by this method may be minimally magnified by the factor between 1.10-1.20, due to increased object film distance.[8]

Conclusion

The modified occlusal view, though a very old technique and only very few literature is available on this, should be reconsidered, as the technique produces accurate information for a successful management on impacted maxillary canines with a marked reduction of radiation and many more advantages discussed above.

ABSTRACT

Tuberculosis has recently resurged as a worldwide public health concern in spite of their recent advances in its diagnosis and management. It is estimated that approximately 8 million people develop TB each year & 3 million people die of complications associated with disease. Tuberculosis is an infectious disease caused by Mycobacterium tuberculosis, an acid-fast bacillus that is transmitted primarily through the respiratory tract and undergoes lymphohematogenous dissemination. Tuberculosis can involve any organ system in the body. While pulmonary tuberculosis is the most common presentation, extrapulmonary tuberculosis (EPTB) is also an important clinical problem. The term EPTB has been used to describe isolated occurrence of tuberculosis at body sites other than the lung. Extrapulmonary tuberculosis has increased in number. It has been said that the percentage of smear-positive re-treatment cases is high in India due to many causes. In this article we have presented three cases of tuberculosis.

Keywords: *TB, Lymphadenitis, Extrapulmonary TB*

Introduction

Tuberculosis has recently resurged as a worldwide public health concern in spite of the recent advances in its diagnosis and management. Every year about 8 million people develop TB & according to WHO 2 million people die out of this disease. The region with the highest incidence rates are the Indian subcontinent, Southeast Asia & Africa. Tuberculosis is a systemic disease usually caused by Mycobacterium Tuberculosis & also M.avium, M.kansasii & M.scrofulaceum. Tuberculosis chiefly affects the pulmonary system but it can also involve extrapulmonary sites such as lymph nodes, bone, kidneys. Lymph node tuberculosis (LNT) also known as tuberculous lymphadenitis, is commonly seen in underdeveloped countries, and with the spread of AIDS, tuberculous lymphadenitis is now frequently encountered in developed countries accounting for about 4–5% of all tuberculosis cases and 20–50% of extrapulmonary tuberculosis. These frequently involve the head & neck, with most common presentation as swelling in the neck region.

Cervical lymph nodes are the commonly affected lymph nodes by this disease which is classically termed as “scrofula”. Latin word SCROFA, means a broad sow due to likeness of cluster of nodes to piglets feeding from sow[1]. They are more common in women than in men[2,3,4,5]. The diagnosis of extrapulmonary TB is difficult due to restriction in diagnostic tests [6].

In India, under the Revised National Tuberculosis Control Program (RNTCP), the percentage of smear-positive re-treatment cases is high. The causes of re-treatment include relapse of the disease after successful completion of treatment, treatment failure and default in treatment[7]. *Relapse* is defined as a TB patient who was declared cured or treatment completed by a physician, but who reports back to the health service and is now found to be sputum smear positive. *Failure*, by definition, is any TB patient who is smear positive at 5 months or more after starting treatment. Failure also includes a patient who was treated with Category III regimen but who becomes smear positive during treatment. *Treatment after default* is a TB patient who

Sree Balaji Dental College & Hospital, BIHER, Chennai

received anti-tuberculosis treatment for 1 month or more from any source and returns to treatment after having defaulted, i.e., not taken anti-TB drugs consecutively for 2 months or more, and is found to be sputum smear positive[8]. In this article we have discussed about 3 rare cases of Tuberculosis.

Case 1: A 19 year old female patient reported to the Outpatient Department of Oral Medicine and Radiology with the chief complaint of painful swelling in the right side of neck that was present since a month and it gradually increased in size. The pain was of moderate intensity and dull during swallowing. Patient had gone to a private hospital and was given analgesics & antibiotics but the swelling did not respond to the medications. She also had persistent cough but there was no history of persistent fever, night sweats or weight loss. Patient was moderately built & nourished.

Extra-oral examination (Fig 1) revealed a solitary swelling 3x2cm in size in the region of the floor of the mouth just below the chin. The skin over the swelling and its colour were normal. The surface was smooth. It was oval in shape and margins were ill defined. The swelling was situated in the midline and anteriorly it extended about 3cms from the inferior border of the mandible. On palpation all the inspectory findings were confirmed and the submental lymph nodes were matted. It was non tender, firm and the temperature was normal.

Figure 1: Swelling just below the chin

Intra Orally there was no tenderness on percussion in any of the teeth and the floor of the mouth was also normal.

Occlusal radiograph (Fig 2) did not reveal any pathology. The Orthopantomograph was also normal.

Figure 2: Occlusal radiograph of Mandible

The Haemoglobin level of the patient was noted be 10.2gm/dl and ESR level was raised which showed 54mm/hr. Mantoux test was positive (12mm). Smear from the aspirate showed lymphocytes in singles & clusters, plenty of macrophages with phagocytosed particles, macrophages, few plasma cells occasional epitheloid cells in singles & in clusters & strands of fibrous tissue suggestive of tuberculous lymphadenitis. Chest x ray showed increased bronchovascular markings (Fig 3) and Ultrasound revealed multiple significant enlarged lymph nodes of varying sizes noted in right carotid, submandibular, upper deep cervical and posterior triangle of neck regions, largest measuring 3.5 x 1.0 cm in size and few similar nodes seen on the left side. Suggestive of bilateral lymphadenopathy.

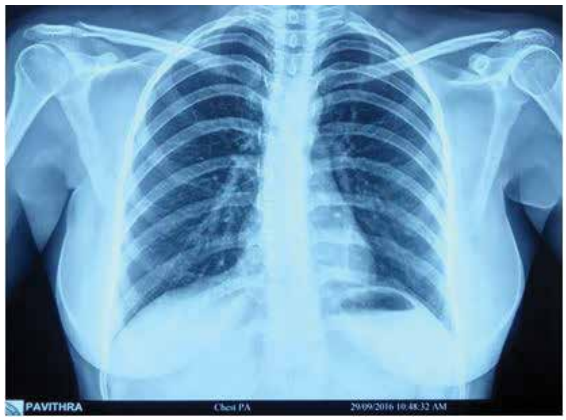

Figure 3: Chest X ray showing increased bronchovascular markings

The case was diagnosed as Tuberculous Lymphadenitis and was treated with Anti Tuberculous medications (ATT). Patient was reviewed for six months and the swelling subsided completely.

Case 2: A 56 year female patient who was moderately built and nourished, reported to the hospital with complaint of pain in the right side of neck present since three months that started spontaneously as a

mild intermittent pain three months ago and gradually increased while eating. The pain subsided to a certain extent while taking analgesics. Patient also had mild discomfort in the right & left jaw while chewing hard food for the past 1 month. Her medical history revealed that she was treated for tuberculosis thirty years ago and that she is suffering from evening rise in temperature, cough & weight loss for the past 2 months.

On examination the mouth opening was normal. There was mild deviation while opening the mouth towards the left with a click which was elicited along with tenderness on palpation in the right TMJ region. Single submandibular lymph node was palpable in both right & left submandibular region which measured approx.0.5 x 0.5cm in size. It was oval in shape, firm, non-tender & mobile.

Provisional diagnosis was given as Internal derangement of TMJ. Orthopantomograph revealed the presence of linear chain of calcifications on the left side (Fig 4). Chest X ray showed a supraclavicular and mediastinal node calcification (Fig 5). Patient was referred to the general physician and was treated for relapse of tuberculosis. The Internal Derangement of TMJ was managed by temporary soft splints, analgesics and anti inflammatory drugs.

Figure 4: OPG showing linear chains of calcification

Figure 5: Chest X ray showing a supraclavicular and mediastinal node calcification

Case 3: 67 year old female patient reported to the Department of OMDR with chief complaints of swelling in the right side of neck since 6 months (Fig 6) that started spontaneously and was smaller in size initially and gradually increased to attain the present size. Patient did not have pain or any other discomfort due to the swelling. Medical history was non contributory

Extraoral examination revealed a solitary swelling on the right side of the neck behind the sternocleidomastoid muscle region measuring about 2 X 1.5 cms in diameter & extended anteriorly 10 cm away from the midline of the neck, 5 cm above the supraclavicular region. The skin over the swelling appeared to be normal & the margins were well defined. No visible pulsation was noticed. On palpation it was soft in consistency, non tender, compressible and the skin over the swelling was pinchable. (Fig 6).

Figure 6: Solitary swelling seen on the right side of the neck

The case was provisionally diagnosed as Lymphadenitis in upper deep Cervical Lymphnode and further investigations were done.

Complete blood count was normal but Mantoux was positive (10 to 15mm). Smear from the aspirate showed lymphocytes in singles & clusters, plenty of macrophages with phagocytosed particles, macrophages, few plasma

cells occasional epitheloid cells in singles & in clusters & strands of fibrous tissue suggestive of tuberculous lymphadenitis. The case was diagnosed as Tuberculous Lymphadenitis and was treated with Anti Tuberculous medications (ATT) immediately.

Discussion

The classic term SCROFULA derived from the Latin word glandular swelling scrofuloderma is also known as tuberculosis cutis colliquativa, a skin condition caused by tuberculous involvement of skin by direct extension usually from underlying tubercular lymphadenitis[9]. Hippocrates mentioned scrofulous tumours in his writing. The European kings of the middle ages imparted the royal touch to cure 'King's Evil' to which mycobacterial lymphadenitis referred. In second half of 20th century, scrofula became a less common disease in adults but remained common in children. The risk increases further during pregnancy [10]. Clinically it presents with chronic, painless mass in the neck, which is persistent and usually grows with time and is usually accompanied by fever, chills, malaise and weight loss[11].

Tuberculous lymphadenitis most frequently involves the cervical lymphnodes followed by frequency in mediastinal, axillary, mesenteric, hepatic portal, perihepatic and inguinal lymph nodes. While in primary scrofulodermalymph nodes involved are either preauricular or submandibular. They present as a unilateral single or multiple painless growing masses. Jones and Campbell have classified peripheral tuberculous lymph nodes into following 5 stages[12]:

Stage1: Enlarged, firm, mobile and discrete nodes showing nonspecific reactive hyperplasia.

Stage2: Large rubbery nodes fixed to surrounding tissue owing to periadenitis.

Stage 3: Central sofetening due to abscess formation

Stage 4: Collar – stud abscess formation

Stage 5: Sinus tract formation.

In our first case patient complained of a neck swelling with mild pain on deglutition and cough but there was no history of fever, night sweats & weight loss. Lab investigations were positive for TB. In the second case patient reported with pain in TMJ. Patient was treated for TB thirty years ago and at the time of presentation she had evening rise of temperature, night sweats, weight loss. OPG showed a chain of calcified lymph nodes and in the third case patient complained of a solitary swelling in the neck and the investigations showed that it was Scrofula. All the three patients were started with Anti Tuberculous Therapy (ATT) and the patients showed improvement.

Drug resistance Tuberculosis has become widely prevalent these days. In 2016, 41% of laboratory confirmed TB patients notified globally were tested for MDR/RR-TB, up from 11% in 2012. In many countries a steady increase has occurred in recent years, driven by the continued expansion in the use of rapid molecular tests. In spite of increased testing, the number of MDR/RR-TB cases detected in 2016 only reached 153 000, a slight increase from the 132 000 cases reported in 2015. In 2016, 8000 cases of XDR-TB were reported worldwide. To date, 121 countries have reported at least one XDR-TB case[13].

Table 1: Antituberculosis agents for treatment of drug-susceptible and drug-resistant tuberculosis[14]

Group	Drugs
Group 1	First-line oral agents – isoniazid, rifampicin, ethambutol, and pyrazinamide New generation rifamycins – rifabutin and rifapentine
Group 2	Injectable agents – kanamycin, amikacin, capreomycin, and streptomycin
Group 3	Fluoroquinolones – moxifloxacin, gatifloxacin, levofloxacin, and ofloxacin
Group 4	Oral bacteriostatic second-line agents – thioamides (ethionamide and prothionamide), cycloserine, terizidone, and p-aminosalicylic acid
Group 5	Agents with unclear efficacy (not recommended by WHO for routine use in MDR-TB patients) – clofazimine, linezolid, amoxicillin/clavulanate, thioacetazone, imipenem/cilastatin, high-dose isoniazida, and clarithromycin

Conclusion

Tuberculosis is an atypical infection. Correct diagnosis is the key to cure the infection in the initial stage. The above discussed cases emphasized the

importance of proper history taking and also showed that periodic checkup should be done in case of tuberculosis to reduce its recurrence.

Conflict of Interest: There is no conflict of interest by other the authors in publication.

ABSTRACT

Neuralgia is the disorder produced by change in neurological structure or function. These neuralgias produces symptoms which affect the physical as well as mental health of the patient. There are several neuralgias that occur in maxillofacial regions, they are trigeminal neurlagia, glossopharyngeal neuralgia, postherpetic neuralgia, nervous intermedius neuralgia and occipital neuralgia. Out of all these, trigeminal neuralgia is the most common cause for occurrence of or facial pain. Neuralgic pain is characterized by mostly unilateral, superficial, short, shock like pain with recurrence attacks. They also have trigger points which can arise pain on appropriate stimuli. The aim of this article is to discuss various types of neuralgias and their recent advancements in treatment.

Keywords: *Neuralgia, Pain, Aneurysm.*

Introduction

Neuralgia is the pain that occurs in nerve pathways[1]. Neuralgic pain is caused by alteration in neurological unit rather than the excitation that causes nociceptive pain[2]. Neuralgia appears as a symptom of disorder and not a sickness. Pain in the maxillofacial region originates from tooth pulp, cornea, oral mucosa, nasal mucosa etc. This pain showing numerous unique physiological features associated with spinal nociceptive system[3]. Neuropathic pain have high occurrence rate with production of negative impact mentally and thereby influence the quality of life. Different neuralgias are trigeminal neuralgia, glossopharyngeal neuralgia, geniculate neuralgia, post herpetic neuralgia, occipital neuralgia. Trigeminal neuralgia is the most common neuralgia in head and neck region and is a major cause of orofacial pain[4]. Even there is more advancement in treatment of neuralgias had come, but the physician have a challenge over the diagnosis of specific type of neuralgia[1].

Trigeminal Neuralgia: Trigeminal neuralgia or tic douloureux is defined as paroxysmal, recurrent attack of pain, lasting from few seconds to few minutes, involving one or more divisions of trigeminal nerve[5]. It is the most frequent cause for facial pain. It is more common in older adults of more than 50 years of age with slight female predilection. Pain is short, sudden, severe, stabbing, lancinating type, shock like and almost unilateral. It is of two types, primary having no clear cause while secondary is of having underlying cause such as tumor, infarction and multiple sclerosis. Compression of nerve root by small blood vessels occur in trigeminal neuralgia. This compressed nerve produces pain by hyperexcitability of demyelinated nerve fiber, cross excitation between secondary channels, ectopic impulse discharge, impaired segmental inhibition and emphatic transmission[6]. Pain may be stimulated by external stimulus such as cold air, laughing, swallowing, chewing, talking, washing the face etc.

Glossopharyngeal Neuralgia: It is also called vagoglossopharyngeal neuralgia[2]. It is the pain occurs in the nerve supplying regions of glossopharyngeal neuralgia such as tongue, pharynx, tonsil, larynx, ear etc.It is rare when compared to trigeminal neuralgia. It is more common in male and older age adults. Pain is of short and shock type. Pain is triggered by chewing, yawning, swallowing, talking, lateral movement of jaw,

cleaning of throat, touching periodontium, touching external surface of ear, tinnitus[1]. It is more common in left side whereas trigeminal neuralgia is common in right side[7]. The proposed classification of IHS is 1.classical(occasional) and 2.symptom(constant) glossopharyngeal neuralgia. It is caused by nerve compression by pulsating artery and lesion includes trauma, infection, surgery, Eagle syndrome, vascular malformation etc. In Eagle syndrome, elongation of styloid process and calcification or ossification in stylohyoid ligament are seen.

Post Herpetic Neuralgia: It is caused by reactivated Varicella Zoster Virus(VZV) which previously caused herpes zoster infection. Reactivated VZV causes acute, stabbing, radiating pain, confined to dermatome. It produce erythema on cutaneous surface, where vesicle form and rupture whereas in oromucosal surface doesn't rupture. VZV acts on epithelial cells producing mucocutaneous lesion and on nerve cells producing pain. During rupture of vesicles, severe neuropathic pain including burning sensation, allodynia, hyperalgesia[9]. It is common in older age adults more than 60 years. Fatigue, anorexia, weight loss,insomnia, reduced physical activity, depression, anxiety, decrease in social contacts are also seen[10].

Occipital Neuralgia: It is a neuropathic pain condition caused by entrapment of occipital nerves in trapezius and semi spinalis capitis muscle at the attachment of occipital bone caused by injuries of neck, tumor infiltration, infection, aneurysms or following neurosurgery[11]. Pain is stabbing, shooting type in sub occipital region. It is mostly unilateral,but it is difficult to diagnose it from other headaches. Pain on palpation present in sub occipital region. Photophobia, phonophobia, radiation of pain to face are other symptoms. Marked pressure over scalp region producing typical pain is the confirmatory diagnostic test to occipital neuralgia.

Nervus Intermedius Neuralgia: It is rare one producing pain in commonly ear and also in anterior two third of tongue and uvula. Occasionally pain may be triggered by given stimuli to triggered zone of ipsilateral distribution of facial nerve. Pain is not sharp and non intense as severe in other neuralgia. Herpes Zoster of geniculate ganglion and nervus intermedius of facial nerve causes geniculate neuralgia, referred to as Ramsay Hunt Syndrome[2]. Viral vesicles may observed in ear canal and tympanic membrane[12].

Treatment and Updates: In trigeminal neuralgia, pharmacological therapy favours best results in 80% of patients. When drugs no longer offer pain relief, surgical intervention is preferred. Most common choice of drug is carbamazepine(200-1200mg/day) followed by oxcarbazepine.These drugs can also be given in combination for synergistic effect thereby reducing the symptom.Its effect may relate to the blockade of voltage-sensitive sodium channels resulting in the stabilization of hyperexcited neural membranes, inhibition of repetitive firing or reduction of propagation of synaptic impulses[21]. Pain in some patients may resolve on as little as 100 mg two to three times a day. If the pain is not subsided, the daily dose should be increased by 100 mg every other day until adequate pain relief is established. The dosage range from 200 to 1200 mg/day should be divided into two to three daily doses. Common initial side effects include drowsiness, nausea, dizziness, diplopia, ataxia, elevation of transaminases and hyponatremia. Potentially serious but uncommon side effects are allergic rash, myelosuppression, hepatotoxicity, lymphadenopathy, systemic lupus erythematosus, Stevens–Johnson syndrome and aplastic anaemia[21]. Oxcarbazepine is keto analogue of carbamazepine and converted into pharmacologically active form and induces hepatic enzymes. Oxcarbazepine is an acceptable alternative to CBZ and is initiated at 150 mg twice daily and increased as tolerated by 300 mg every 3 days until pain relief is accomplished. Maintenance doses range between 300 and 600 mg twice daily[21]. The dosage of baclofen is 40-80mg/day and it depresses excitary neurotransmission. The side effects of baclofen include lassitude, drowsiness, dizziness and gastrointestinal discomfort.Lamotrigine acts at voltage-sensitive sodium channels, stabilizes neural membranes and inhibits the release of excitatory neurotransmitter. It causes side effects such as nausea, dizziness, blurred vision, ataxia and skin rash resulting in desquamation in severe cases.Other drugs used for trigeminal neuralgia are phenytoin, clonazepam, gabapentin, pregabalin, topiramate, levetiracetam, valproate and tocainide.

Recently gabapentin with ropivacaine into trigger zone reduces the pain by blocking the trigger points which is followed by pregabalin for one year follow up[13].Gabapentin is initiated at 300 mg daily and may be gradually increased by 300 mg each 2–3 days as tolerated[21]. Gabapentin has low drug interaction and show minimal side effects. Hu et al systematically

reviewed therapeutic efficacy of injection of botulinum toxin type A(BTX-A), which reduces pain in higher level[14]. The dosage of botulinum toxin type A(BTX-A) is 3.22 units/cm2 and it should be administered directly into the affected region subcutaneously[21]. Tizanidine also used in reducing pain but it is less efficacious than carbamazepine.There is a problem in TN is the treatment of the acute crisis, where local anesthesia, such as ropivacaine, injected into a trigger area, an 8% spray of lidocaine, and the intravenous infusion of fosphenytoin can provide temporary pain relief [22].

Surgery is the secondary option when pain doesn't subsided by pharmacological agents. The aim of surgery is to free up the trigeminal nerve from squeezing or injuring by blood vessel. It includes Micro Vascular Decompression(MVD), neurectomy, percutaneous radiofrequency thermal rhizotomy, percutaneous ablation, cryotherapy, Gamma Knife Radio Surgery(GKRS), physical compression, injection of alcohol and injection botulinum toxin injection.There is an assumption that a compression of trigeminal nerve by an abnormal vascular loop is the direct cause of TN.MVD has become one of the most common treatments for TN providing long pain relief by decompressing the nerve. The reported pain-free duration without medication after MVD ranges from 0.6 years to 10 years [23].The complications after this procedure are infections, facial palsy, facial numbness, cerebrospinal fluid leak, and hearing deficit with a mortality of 0.1% [24]. In contrast, rhizotomy cause sensory loss, keratitis, eating difficulties and thereby reducing the satisfaction in the treatment. Recently, some authors reported the use of endoscope as a significant aid in patients with a bony ridge obscuring the view of the fifth nerve, with a very distal vascular compression, or if a combination of both occurs[25].

Percutaneous balloon compression (PBC) was introduced by Mullan et al and has been extensively used in the treatment of TN [26]. The advantages of this procedure are low cost, simplicity, and only the percutaneous procedure performed with the patient under general anesthesia. PBC offers a good rate of immediate postoperative pain relief ranging from 80% to 90% and a pain-free time without medication that ranges from 2 years to 3 years[27].Complications can include numbness, dysesthesia, masseter weakness; meningitis and cranial nerve deficits are less common. There are no standardized criteria concerning the compression time and the compression pressure. The long time compression may increase the risk of occurrence of complications. Moreover, higher balloon pressures have been associated with higher rates of dysesthesia,severe numbness, and masseter weakness. The size of the Meckel's cave has been an important influencing factor in this proceudure, based on the size of the cave different cannulas are used[17].

In glycerol rhizhotomy, glycerol is injected into the trigeminal cistern which relieves the pain in patients with trigeminal neuralgia. It acts by demyelination and axonal fragmentation. Initial pain relief given by this procedure, reported in patients is of about 90% treated by this procedure.Postoperatively sensory loos is the major complication of glycerol rhizhotomy. Patients may also experience facial pain during glycerol injection. The other complications are dysesthesias, corneal numbness, masseter weakness, and herpes labialis[17]. Recently, Goodwin et al performed a MVD with injection of glycerol to the inferior third cisternal portion of the nerve, anterior to the root entry-zone, in 14 patients without neurovascular conflict on pre-operative MRI, reporting an 80% of good response at 3 months follow-up[28].

Radiofrequency thermocoagulation is the procedure in which the trigeminal nerve and Gasserian ganglion rootletsare electrocoagulated. The common side effects are masticatory weakness, dysesthesia, and corneal numbness. Pulsed radiofrequency have been introduced for minimising the side effects.

Gamma Knife Radio Surgery is the alternative treatment option for the patients who were not opt for microvascular decompression and invasive surgery. The target zone in this procedure is root entry zone of trigeminal nerve. In many clinical target volume definitions, the root entry-zone of the trigeminal nerve situated at 2–3 mm from the brainstem surface is chosen[29].The target closer to the brainstem produce extensive pain relieffor prolonged duration. The common side effects are facial numbness, permanent dysesthesias and anesthesia dolorosa. The other alternative targets are trigeminal nucei in brainstem and centromedian nucleus of thalamus[30]. The higher dose is very efficacy in treating the pain but it also produce increased risk of side effects. Little et alreported that 75% of patients with no previous surgery achieved long-term pain relief at 7 years compared with only 10% of patients with

previous surgery[31]. GKRS requires a delay before pain relief occurs. For this reason, some authors suggest that patients with extreme pain in need of fast relief should undergo other procedures[32].

Ultrasound guided intervention of blocking of branches of trigeminal nerve such as supra orbital, infra orbital, auriculo temporal, maxillary and mandibular nerve are recently emerging advances[15]. Laser and acupuncture are also treatment modalities for trigeminal neuralgia. Neuromodulation by Motor Cortex Stimulation(MCS) and Deep Brain Stimulation(DBS) are used as refractory to other surgical treatments[17].

In glossopharyngeal neuralgia, first line of choice of drug is carbamazepine, followed by pregabalin, gabapentin, baclofen, dextromethorphan. Combination of two or more drugs can be given for effective therapy. Nerve block of glossopharyngeal nerve can be given with lignocaine(2%) and bupivacaine(0.5%). Thus can be given by both intra oral and extra oral approach. Paralysis of vocal cords may arise in case of bilateral nerve blocks. Surgically, MVD of vascular roots and rhizotomy of nerve roots are best options. Pulsed radiofrequency neurolysis, gamma knife radio surgery and stereotactic radiosurgery also have beneficial effects[1].

In Post Herpetic Neuralgia, Patients having history of Herpes Zoster should be vaccinated, suitable anti viral agents should be given within 72 hours of appearance of rash and pain control should be given. These are the preventive treatment for postherpetic neuralgia[10]. NSAIDs and opioids can be given in combination for effective pain control. Commonly used anti viral drugs are famciclovir, acyclovir, valaciclovir and these are all inhibit the replication of VZV[18]. Anti convulsants and anti depressants can also be given in severe uncurable cases. Relaxation, psychological intervention, social support, nerve block, acupuncture, cryotherapy, biofeedback and Trans Electrical Neural Stimulation(TENS)[19].

In occipital neuralgia, patients can be treated with analgesics, anti depressants and anti convulsants. If drugs fail to reduce pain, occipital nerve block can be performed using local anaesthetics and steroids. Chemical neurolysis with alcohol, radiofrequency ablation or cryoablation, occipital nerve stimulation, rhizotomy are also performed[20]. Meditation, hypnosis, acupuncture and herbal nutritional therapy reduces pain in some patients.

Conclusion

Neuralgia is difficult to diagnose for the physician, as it does not show abnormality on physical examination. Hence care must be taken regarding the appropriate diagnosis of specific neuralgia. Physician should also have knowledge about the various modalities and recent advancements in treatment and thereby improving the health of the patient.

ABSTRACT

Human mouth consists of diverse micro-organisms which includes bacteria, viruses, fungi and protozoan. Oral microbiome is unique because of the constant contact of oral cavity with the external environment. Diets, Temperature, pH of saliva are important factors that contribute to the establishment of oral microbiome. The oral microbiome is imperative to health as it causes both oral and systemic diseases. A dysbiotic microflora influences the development of oral diseases like dental caries, periodontal diseases (gingivitis and periodontitis). Promoting a balanced microbiome is the key to maintain or reestablish oral health. Technological advances Iin the recent times have started to unwind the mysteries and complexities of the oral microbiome helping us to gain insights into its role in health and disease states.

Keywords: *Microbiome, Microorganism, Disease, Health.*

Introduction

Oral Microbiome is the collective genome of microorganisms that reside in the oral cavity. This ecological community includes symbiotic, commensal and pathogenic microorganisms. Oral microbiome was first identified by Anton Von Leewenhoek and the term "Microbiome " coined by Joshua Lederberg. Oral cavity is the second largest microbial community in humanbeings, the first being the gut.[1] Microbes are extremely well regulated both structurally and functionally with interspecies collaborations and antagonisms that contribute to ecologic solidity. [2] The bacteria in the oral cavity can colonize the hard and soft tissues of the teeth and the oral mucosa. The temperature of the oral cavity (37^{o}C) and the stable pH of the saliva, the availability of epithelial debris as nutrients create a favourable environment for the microbes to survive.[3] The human microbiome is classified into a core microbiome and variable microbiome. The core microbiome comprises of predominant species which is shared among all individuals that exists at different sites of the body in health. The variable microbiome is unique to an individual and evolves in response to one's lifestyle, phenotype and genotype. Oral microbiome is vital to bodies overall to the health. Microbiome research aids in disease diagnostics and therapeutics.[4]

Composition of Oral Microbiome: Oral habitats form a highly heterogeneous ecological system that supports the growth of significantly different microbial communities. Several distinct oral habitats for microbial colonization includes teeth, gingival sulcus, attached gingiva, tongue, cheek, lip, and hard and soft palate.[5]The normal microbiome is formed by bacteria, viruses, fungi, protozoa and arachea. The viruses found in mouth are primarily associated with disease states. It includes Mumps and Rabies virus, Herpes simplex virus and Human papilloma virus. Hepatitis virus and Human Immuno-Deficiency virus can also enter the mouth via gingival crevicular fluid. *Candida* species is the most prevalent fungi in the oral cavity. A culture dependent studies on twenty healthy hosts reported 85 fungal genera. The main species observed belongs to Candida, Cladosporium, Aureobasidium, Saccharomycetales, Aspergillus, Fusarium and Cryptococcus.[6] *Entameobagingivalis* and *Trichomonaxtenax* are two main protozoan species found as a part of the normal microbiome. Arachea make up a small component of oral microbiome and is restricted to methanogens.[1,7,8] Elevated counts of methanogens are seen in subjects with periodontitis.[9,10]

The bacterial community of mouth constitutes *Firmicutes, Bacteroidetes, Proteobacteria, Actinobacteria, Spirochaetes*and *Fusobacteria* which

accounts 96% of the species.[11]The oral cavity taxon is highly personalized. The oral habitats are dominated by *Streptococcus* followed by *Hemophilus* in the buccal mucosa, *Actinomyces* in the supragingival plaque and *Prevotella* in the subgingival plaque.[12] The key features of the predominant bacterial taxa have been described and are available from Human Oral Microbiome Database (HOMD) website www.homd.org.[11]

Role of Oral Microbiome in Health: The microbiome plays an important role in oral and systemic health. Microbe-derived factors are essential in maintaining oral health.[3] Saliva and gingival crevicular fluid provide nutrients for microbial growth.[5]Salivary components such as secretory immunoglobulins A, lactoferrin, lactoperoxidase, lysozymes, statherins and histatins help to maintain a balanced microbiota. Nitrites in Saliva can inhibit cariogenic bacteria and protect against dental caries. *Streptococcus salivarius* have been shown to be antagonist to oral pathogens.[3] Saliva also aids to control build up of plaque biofilm. [2] The surfaces of the mouth are colonized by commensals limiting the binding sites for pathogens and further colonization, a phenomenon referred to as colonization resistance.[3] Microorganisms can also hinder a pathogen's abilities to multiply and degrade a pathogen's virulence factors.[4] S. gordanii had a role in reducing dental plaques due to its ability to produce hydrogen peroxide which is lethal for growth of invading bacteria.[5]

The oral microbiome relates to nitrate metabolism and cardiovascular health. The ingested nitrate is returned to the mouth via entero-salivary circuit. Oral bacteria reduce nitrate to nitrite which is taken up into the blood stream via gastric absorption and converted into nitric oxide. Nitric oxide has an anti-hypertensive effect by significantly influencing vascular health, keeping the blood vessels supple.[3]

Oral Microbiome in Oral Diseases: The once beneficial microorganisms initiate disease within the oral cavity when there is 1) a change in the relationships between the microbes and with the hosts 2) an increase in relative abundance and 3) acquisition of virulence factors.[13] If the diversity and relative proportions of species within the microbiota is disturbed it is referred to as a dysbiotic microbiome. [2] The chief factors responsible for causing an ecological shift includes poor oral hygiene, compromised immune system and genetics. Poor oral hygiene causes an accumulation of bacteria within biofilms. This may favour more of pathogenic bacteria. Immune system disorder can also cause an ecological shift in the microbiome. A compromised immune system disrupts commensal relationship facilitating growth of pathogenic species.[14]Genetic factors contribute to oral disease indirectly. Each individual has a specific genetic makeup that encodes for a permanent immune system disorder, which affects the microbiome. Compromised immune system inhibits proper flow of saliva thereby allowing buildup of dental plaque.[4]

The oral microbiome related diseases includes dental caries, endodontic infections, periodontal diseases (gingivitis, periodontitis) and oral cancer. Dental caries is the destruction and dissolution of tooth structure by acids which is produced by fermentation of dietary carbohydrates.[3]Aciduric species of oral microbiota predominates the most common ones including *Streptococcus mutans*, *Streptococcus Sorbinus* and *Lactobacillus acidophilus*. Bifidobacterium, Proponibacterium family and sacrdovia have been found to be associated with dental caries. [6]

Periodontitis is considered a polymicrobial inflammatory disorder of periodontium. Periodontal diseases results from subgingival plaque accumulation leading to shift in microflora from healthy state to diseased state. Gingivitis is the mildest, reversible form of periodontal diseases whereas periodontitis is severe and irreversible affecting soft tissues and bones that supports the periodontium. The most commonly involved pathogen in gingivitis includes *Fusobacterium, Treponema* and members of the *phylum synergistetes.* The most predominant pathogen involved in periodontitis are *Porphyromonasgingivalis, Aggregatibacteractinomycetecomitans, Prevotella intermedia, Fusobacterium intermedium, Treponema denticola, Tannerella forsythia*.[3,4] The core microbes in healthy patients were diferent signifcantly from those in patients with periodontitis.[11] Periodontitis is difficult to treat because causative pathogens lie deep within the pockets Periodontal pathogens develop virulent factors like encapsulation become nearly impossible to target with antimicrobial solutions.making resistant to antibiotics to control the disease.[4]Periodontitis can also affect systemic health by increasing the risk of atherosclerosis, adverse pregnancy outcomes, rheumatoid arthritis, aspiration pneumonia, and cancer.

Oral cancer exhibits multifactorial etiology with tobacco and alcohol being implicated as the primary risk factors. Certain pathogenic strains of oral microorganisms tend to increase genotoxic metabolite acetaldehyde concentration in saliva when metabolizing ethanol and tobacco smoke. [15] Acetaldehyde has been classified as a group I carcinogen to humans by the International Agency for the Research on cancer. Inflammation is the first symptom of compromised oral health and gets worse as health regresses. Poor oral hygiene is being encountered in oral cancer patients. A significant increase of *Porphyromonas gingivalis, Tannerella Forsythia* and *Candida albicans* was observed in patients with than in healthy controls.[13] OSCC surfaces show significantly raised levels of *Porphyromonas* and *Fusobacterium* as compared to the healthy mucosa.[14] Microbiome can produce toxic metabolites or carcinogenic products directly as cancer-transforming agents or play an indirect role by promoting cancer through induction of inflammation or immunosuppression.[12]

Identification of Microbiome: There are various methodologies for detection and evaluation of microbiomes. Use of conventional microbiological techniques to culture the abundant micro flora in the oral environment is limited. The surfacing of newer technologies has unraveled the mysteries of the oral microbiome. The newer techniques aim at studying the DNA, RNA, proteins or metabolites of the whole microbial population.[1]Metagenomics provides an insight of the total DNA of microbial system is obtained and studied. The oral microbiome alo is well studied through techniques like 16S rRNA sequencing and Next generation sequencing methods. HOMD is based on curated 16SrRNA sequencing and has body site-specific comprehensive database for the more than 600 prokaryote species that are present in the human oral cavity.[9,16] This also provides online tool for bacterial identification and characterization. Human oral microbiome identification microarray (HOMIM) is also used in characterization of oral microbiome. This 16S r-RNA based microarray contains more than 400 probes for the detection of variety of oral bacterial species. Moreover with the use of CRISPR, an advanced sequencing technologies it is revelaed that bacteriophages play a major role in altering and deciding the bacterial communities of the oral cavity.[5]

Conclusion

The microbiome are key determinants of oral health and disease. The oral microbial ecosystem is crucial for maintaining oral and overall health. When the homeostasis of the oral microbiome is altered or disturbed it can propagate the pathogenic activity leading to disease states. Analysis of oral microbiome at an early stage of oral diseases will aid in early diagnostics and therapeutics. The main emphasis is also to maintain good oral hygiene for a balanced microbiome. Understanding the role of the microbiome and host–microbiome interactions in health and various disease states is very fundamental for all oral health care professionals.

Oral Submucous Fibrosis: A Review on Etiopathogenesis and Recent Trends in Management

Sudha Jimson[1], Nishanth G.[2], S. Leena Sankari[3], K. M. K. Masthan[4], N. Aravindha Babu[5]

[1]Reader, [2]Post Graduate student, [3]Professor, [4]Professor and Head of the Dept, 5Professor Sree Balaji Dental College and Hospital, Bharat Institute of Higher Education (BIHER) Chennai

ABSTRACT

Oral submucous fibrosis is an incidious, chronic disease stirring any part of oral cavity and sometimes the pharynx. South east Asian counties are proven to be high prevent zones.for oral sub mucous fibrosis.. Areca quid related oral mucosal lesions are potential hazard to an outsized e population worldwide. Commercially freeze dried products such as pan masala, guthka and mawa have high concentration of areca nut per chew and appear to cause osmf more rapidly than by self prepared betel quid that contain smaller amounts of areca nut. These chemicals appear to interact with the molecular processes of deposition and or degradation of extracellular matrix molecules such as collagen causing imbalance in the regular process. Various studies done in the past include osmf as potentially malignant disorder. Understanding the etiopathogenesis of osmf may be beneficial to revert the risk factors thereby minimizing the progress of the disease which is included as the priority in the prevention of disease.

Keywords: *OSMF, areca nut, Betel quid*

Introduction

Oral sub mucous fibrosis is a ceaseless weakening illness which was first portrayed by Pindborg and Sirsat[1]. It contains juxta epithelial hyalinization which is pursued by fibro elastic changes in the lamina propria [1]. It causes limitation in mouth opening, paving way to trismus and patient are deprived of nourishment, trouble in keeping up oral health care and furthermore speech impairment [1, 2]. In the past decades Sushruta coined a term for the condition called VIDARI under infections of mouth and throat. Lal and Joshi in 1953 presented the term oral sub mucous fibrosis.[3] The etiological variables for OSMF have been categorized as areca nut, capsaicin in chilies, and micronutrient inadequacy of iron, zinc and basic nutrients[4]. The marked-up prevalence is because of industrially produced areca nut and tobacco products like gutka, paan masala, seasoned supari and so on [5,6]. The malignant transformation rate of oral submucous fibrosis was recognized as 7.6% [6]. The reason behind the limited mouth opening is due to the deposition of dense fibrous bands under the connective tissue [2].

Discussion

Epidemiology: The epidemiological investigations demonstrate Indian populace has the most astounding rate of frequency as the time advances [5]. Reports from north western India gives a rate of 2.6 and 8.5 per 100000 every year for both males and females respectively [3, 5]. No relationship to any network or religious gathering has been recommended, however an ethnic premise is demonstrated in light of the fact that OSMF is found generally in Asians or Asians settled in other countries. Recent information proposes that prevalence of OSMF in India has inflated from 0.03% to 6.42%.

Table 1: Epidemiology of oral sub mucous fibrosis: A review Madhushree das[3]

Zonal prevalence in India	Percentage
Northern Zonal Council	30%
North-Central Zonal Council	6.3%
North Eastern Zonal Council	No studies
Eastern Zonal Council	2.7%
Western Zonal Council	0.03%
Southern Zonal Council	0.55%

Etiopathogenesis: Various epidemiological reviews, case series reports, huge measured cross-sectional studies, case-control studies, accomplice and mediation studies give over whelming proof that areca nut is the principle etiological factor [7]. Every day use was given more priority in the role of etiology than the time. An ongoing contextual analysis demonstrates more youthful people built up the symptoms of OSMF in 3.5 years while elderly people in 6.5 years from the beginning of propensity.

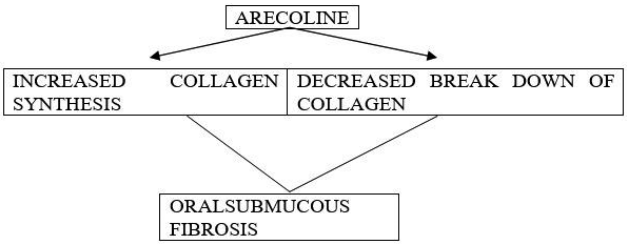

Chart 1: Pathogenesis of oral sub mucous fibrosis: Arecoline[2]

Chemical constituents and alkaloids from arecanut have the most significant role in pathogenesis of oral submucous fibrosis. Arecoline, Arecaidine, Guvacine, Guvacoline are the real alkaloids present in arecanut [7]. It is obvious that fibrosis and hyalinization of sub epithelial tissue represents most clinical highlights experienced in this condition. Later it was demonstrated by the finding that slaked lime $Ca(OH)_2$ causes this impact [8]. The flavonoids, tannins and catechins can cause increased fibrosis by forming insoluble and stable collagen filaments by inhibiting the formation of collagenase compound [4]. The alkaloids and flavonoids from the BQ and aid indigestion. These constituents and their metabolites are perpetual stimulants to oral tissues

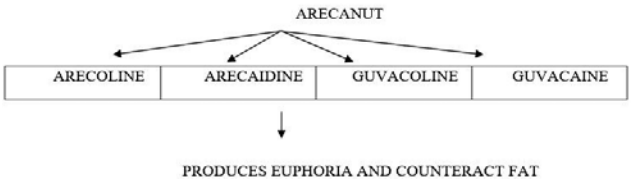

Chart 2: Effects of areca nut[2]

TGF-beta: It supports the origin of collagen generation. The qualities COL1A2, COL3A1, COL6A1, COL6A3, and COL7A1 have been recognized as clear TGF-β targets. These are early promoting genes in fibroblasts. The increased expression of pro-collagen genes is responsible for the increased collagen levels in OSMF for which the TGF-β -production acts as a mediator for the increased expression of procollagen genes[9].TGF-ß may assume a significant job in the pathogenesis and malignant transformation of OSMF [10].

Lysl oxidase (LOX): The LOX is a fundamental chemical for conclusive handling of collagen strands into a settled covalently cross-connected develop fibrillar structure that is impervious to proteolysis. The LOX movement is significant for arrangement of insoluble collagen because of cross-linking[11]. The declaration of LOX is directed by different elements, among which TGF-β is viewed as a significant factor.

Tannins: Diminish collagen corruption by tannin assumes a noteworthy job in pathogenesis of oral sub mucous fibrosis. Huge amounts of tannin present in areca nut diminished collagen corruption by repressing collagenases and proposed the reason for fibrosis as the joined impact of tannin and arecoline by decreasing debasement and expanded generation of collagen separately.

Copper: The catalyst lysyl oxidase is a copper stimulated chemical enzyme for collagen cross linking and association of ECM. The fibroblasts in OSF have expanded lysyl oxidase exercises as well as explicit as well as explicit development attributes.

Genetic factors: Hereditary qualities take partas an etiological factor. Connective tissue development factor (CTGF/CCN2) is related with numerous human fibrotic issues and was found to overexpress in OSMF. Micro trauma could prompt the liberation of thrombin. Thrombin created by micro trauma may add to the pathogenesis of OSMF by up regulating CCN2 articulation.

Raised estimations of human leukocyte antigen (HLA) in OSMF patients contrasted with typical people is seen [2]. Sirsat exhibited that capsaicin in chilies animates far reaching palatal fibrosis in rodents [11]. Betel quid influences safe framework and the degree of changing development factor-β and interferon are lower in mononuclear cells among old patients [3]. Lack of iron, nutrient B-complex, minerals and malnutrients are considered as etiological factors that stifles the fix of aggravated oral mucosa, hence resultant scarring and fibrosis [6]. Abnormal iron metabolism additionally assumes a noteworthy job in OSMF. Microcytic hypochromic along with serum iron has been accounted in oral sub mucous fibrosis [3].

Biopsies role in pathogenesis of osmf[4]. By radioimmuneassayendothelinandTGF-β-1wereheightened in OSMF fibroblasts [11]. As indicated by an examination there is decrease in the phagocytosis due to decreased cell mediated immunity which suppresses T cell activity

by aericoline[12]. Expanded and continuous deposition of extracellular matrix may take place because of disturbance of the balance between matrix metalloproteinase and tissue inhibitors of matrix metalloproteinase [8]

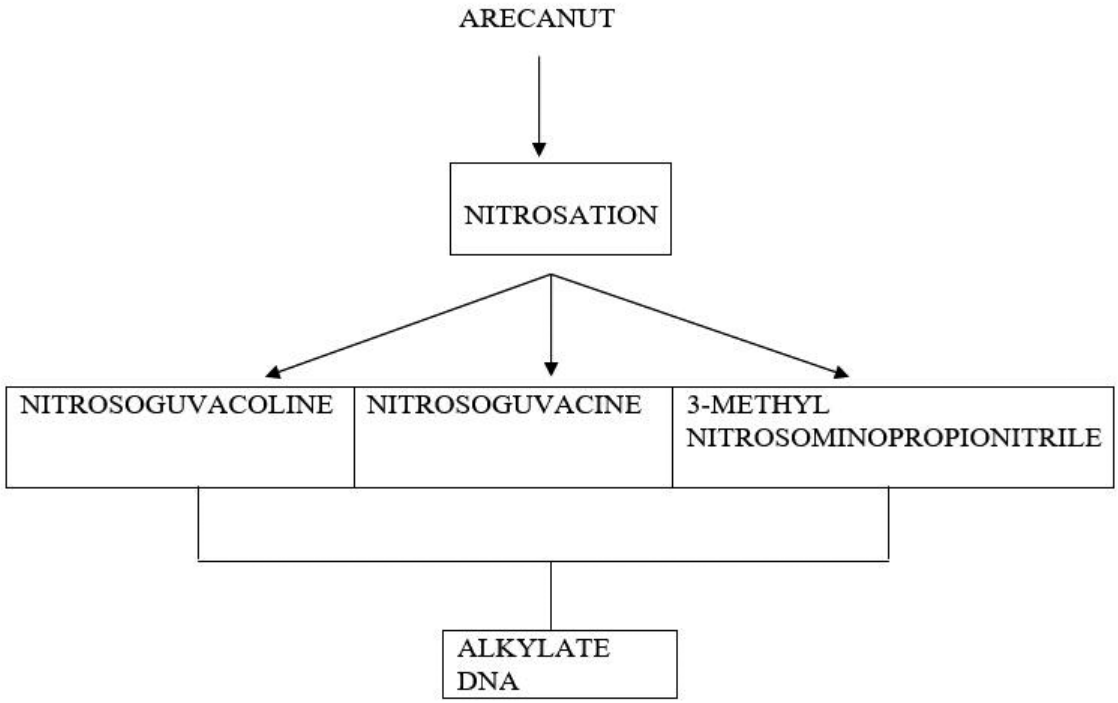

Chart 3: Nitrosation of Arecoline[2]

Classification System: Kerr et al[13]:

GRADE I	**MILD**	Any highlights of the infections group of three for osmf (Depapillation,consuming, whitening or weathered mucosa) might be accounted for and between incisal opening >35mm.
GRADE II	**MODERATE**	Above highlights of osmf and between incisal confinement of mouth opening between 20-35mm.
GRADE III	**SEVERE**	Above highlights of osmf and between incisal opening <20mm.
GRADE IV A		Above highlights of osmf with conceivably harmful issue on clinical examination
GRADE IV B		Above highlights of osmf with any evaluation of oral epithelial dysplasia on biopsy
GRADE V		Above highlights of osmf with oral squamous cell carcinoma.

More et al[14] characterized dependent on clinical and utilitarian parameters.

Clinical Staging:

1. **Stage I:** Stomatitis and additionally whitening of oral mucosa.
2. **Stage II:** Discernable stringy groups in buccal mucosa or potentially oropharynx, with/without stomatitis.
3. **Stage III:** Nearness of discernable stringy groups in buccal mucosa or potentially oropharynx, and in some other pieces of oral depression, with/ without stomatitis.
4. **Stage IV:**

A: Any of the above stage alongside other possibly dangerous issue, e.g.; oral leukoplakia and oralerythroplakia.

B: Any of the above stage alongside squamous cell carcinoma.

Functional Staging:

1. M 1: Between incisal mouth opening up to or> 35mm.
2. M 2: Between incisal mouth opening between 25 to 35mm.

3. M 3: Between incisal mouth opening between 15 to 25mm.
4. M 4: Between incisal mouth opening < 15mm.

Patil and Maheshwari [15] recommended new characterization dependent on adaptability of cheek. Typical cheek adaptability watched was 35-45mm for males and 30-40mm for females.

1. **Grade 1: (Early):** cheek adaptability of 30mm or more.
2. **Grade 2: (Gentle):** cheek adaptability between 20 to 30mm.
3. **Grade 3: (Moderate):** cheek adaptability under 20mm.
4. **Grade 4 : (Extreme):** above conditions without simultaneous nearness of potential threatening sores.
5. **Grade 5 : (Progressed):** Above condition with simultaneous nearness of oral carcinoma.

Malignant Transformmation and Precancerous Nature of Oral Submucous Fibrosis: In 1956, paymaster watched squamous cell carcinoma in 33% of patients with oral sub mucous fibrosis [12]. Pindborg et al revealed malignanttransformation rate of 4.5% in 66 instances of OSMF in 4-15 years. In Taiwan it is 3.27-8.63% [13]. An examination by Patel and Maheswari in 2014 it is 4.6% [14].

Management: Oral sub mucous fibrosis is notable for its retention and constant nature. Being a premalignant condition, there is no treatment modality that delivers complete cure. Legitimate treatment begins with the instruction of the patient about the condition. Patient ought to be educated about the idea of illness regardless of stopping the propensity.

Gupta et al, whotreated 6 patients of osmf with nutrients containing A palmitate 2500IU nutrient E, beta carotene 50mg, nutrient C, zinc, copper and manganese[16].

Lycopene is the real carotenoid present in tomatoes which are regarded as cancer prevention agent and chemopreventive properties against potentially malignant disorders.Blend with intralesional steroids and hyaluronidase is exceedingly effective in diminishing mouth opening [17].

A number of glucocorticoids are utilized in the administration of osmf. Short acting (hydrocortisone), intermediate acting (triamcinolone) and long acting (betamethasone and dexamethasone). A mix of chymotrypsin (500IU), hyaluronidase (1500IU) and dexamethasone (4mg) twice week a week sub mucosal infusion for 10 weeks [18].

Pentoxifylline 400 mg multiple3 times daily for 7 months was utilized as adjuvant therapy for Osmf [19].

Curcuma is generally known as Haldi, turmeric or Indian saffron is a notable for its calming and against oxidant nature. Das in an investigation found that combination with turmeric oil was fundamentally useful non-intervention herbal treatment[19, 20].

Li and tang discovered that tea shades assume a noteworthyrole in diminishing blood consistency [21]. Aloe Veraplays a major role in wound healing and is topically applied at the initial stage of lesion [22].

Microalgae which contains beta carotene, tocopherols and phenolic acid has anticancer properties. Shetty et al, in an investigation utilized 500mg spirulina twice every day as adjuvant treatment [23].

Surgical intervention for the management of osmf is decided based on clinical stages Oral stent can likewise be utilized as an adjuvant to avoid relapse.[24].

Conclusion

Oral sub mucous fibrosis is for the most part an ailment of Indian sub-mainland where areca nut biting is rampant.Thus, there is anurgent need to start general wellbeing instruction measures to teach individuals about the weakening, oral harmful condition before it is past the point of no return. Till date, no authoritative and broadly expected treatment is at present accessible. Being a chronic debilitating disease there is a need of herbal prescription to be utilized for longer periods as they have lesser symptoms.

Giant Cells and Assosiated Lesions of the Oral Cavity—A Mini Review

Sudha Jimson[1], Parasakthi M.[2], S. Leena Sankari[3], K. M. K. Masthan[4], N. Aravindha Babu[5]

[1]Reader, [2]Post Graduate Student, [3]Professor, [4]Professor and Head of the Dept, [5]Professor, Sree Balaji Dental College and Hospital, Bharat institute of higher education(BIHER) Chennai

ABSTRACT

Giant cells are often seen in many conditions. Their presence in microscope is of great interest and play a vital role in histopathological diagnosis. They can be classified into several types by various authors. Their formation in physiological and pathological conditions is based on several mechanisms. The physiological giant cells seen in our body are synctiotrophoblasts in placenta, megakaryocytes in bone marrow and osteoclasts in bone. This article attempts to review on the basic mechanisms of formation and histopathology of giant cell associated lesions.

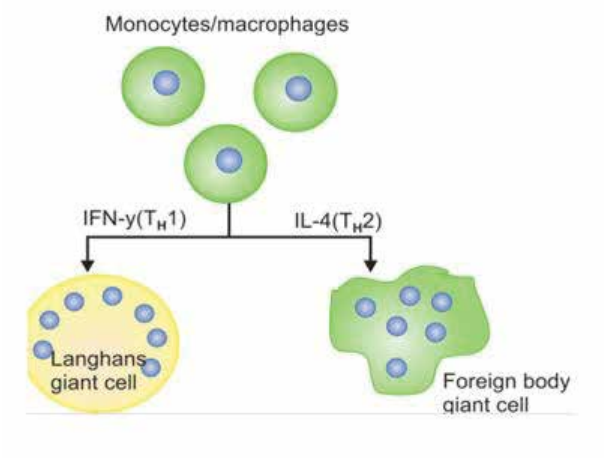
Keywords: *Giant cell, Langhans cell, Touton, osteoclast*

Introduction

A giant cell is a huge cell in contrast to normal cells that are found in the body. These cells are formed as either mononucleated or multinucleated based on the mechanism of origin. Understanding the histogenesis of these cells pave way for the diagnosis. These cells take part in both physiological and pathological processes.[1]The phenotype of giant cells varies based on the process of exposure to chemical factors and their response.[2] The size of giant cells may vary from 40 to 120 micrometers and are formed from monocyte macrophage precursors.

Mechanism of Formation: The theories in mechanism of formation are

1. Amitotic division of single nucleus where there is no cellular division.
2. Non replicating monocyte adhesion.



Corresponding Author:

Bharat Institute of Higher Education and Research,
(BIHER), Chennai

According to Forkner (1980) the type of rosette encircled by nuclei in the periphery is the epithelioid or Langhans giant cell formed by nuclear division.The next category of cells with haphazard arrangement of nuclei were the foreign body giant cell formed due to monocytes fusion.[3]But radiolabeling studies proved that both arise due to monocyte fusion[4]Cell surface alterations are brought about by cell fusion which creates a close approximation with the opposed lipid bilayers[5]

Immune related phenomenon suggests that lymphokines are responsible for the fusion of macrophages to form giant cells. Inflammatory process too helps in formation of giant cell by producing antigenicity to foreign material.E.g.Glass. Second theory states that young and old macrophages fuse with each other since the old macrophages were exported to the granulomatous environment for prolonged period which acquired chromosomal abnormalities and alterations in macrophage surface. The young cells are the structures for cell fusion by recognizing the altered and abnormal surfaces[6]

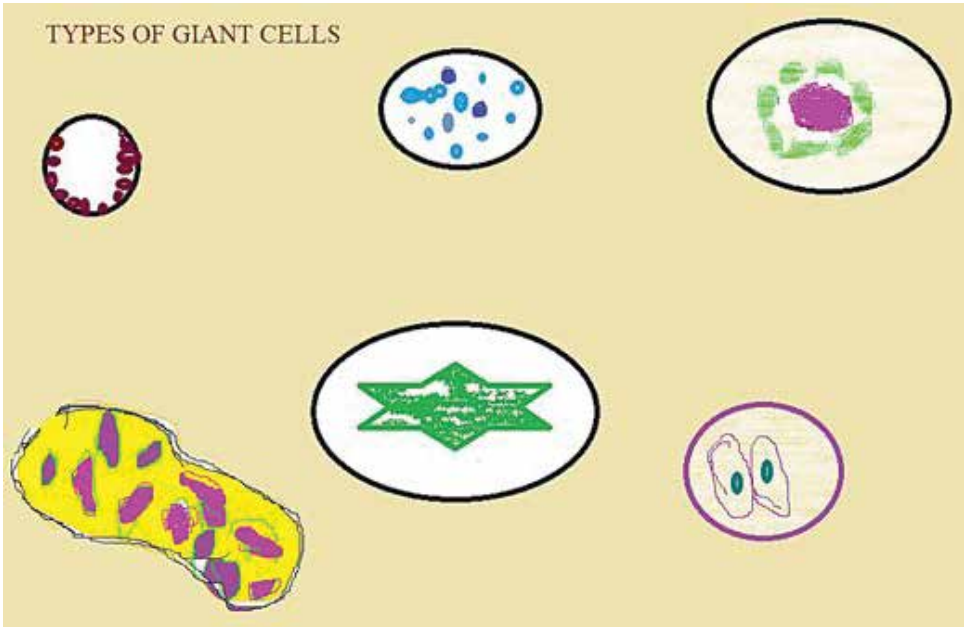
The third mechanism suggests that ingestion of some particles into two or more macrophages where phagocytosis takes place simultaneously where the endosomal margins form multinucleated giant cells.[7]Viral etiology explains that multinucleated giant cells are formed either in altered virus or infective virus. The thickness of cell coat is reduced by a of viral

envelope which makes feel core easier. Live virus enters the cell and fuse giving the appearance of virally encoded proteins. Expansion of fusion leads to syncytium.[4]

Classification of giant cell lesions:

1. Based on etiopathogenesis Chattopadhyay, 1995[8]

A. Where giant cells are present in the concerned background and are path gnomic:



1. Hodgkin's disease
2. Peripheral giant cell granuloma
3. Giant cell fibroma

B. Where giant cells are characteristic, but not pathognomic:

1. Tuberculosis
2. Herpes simplex virus infection
3. Measles
4. Xanthoma

C. Diseases associated with the presence of giant cells:

1. Orofacial granulomatosis
2. Fungal infection foreign body reactions
3. Neoplasms
4. Syphilis
5. Leprosy
6. Fibrous dysplasia.

Antishow cells: Large macrophages which participate in formation of Aschoff's nodule are known as Antishow cell. The difference between macrophage and the anitshows cell is that the macrophages have a finger like extensions in the peripheral cytoplasm. Nuclei contain clumped chromatin that give caterpillar appearance in longitudinal sections and owl eyed in cross sections.[9]The nuclei take a form of elliptical shape with uneven indentations with Feulgen positive reaction of chromatin. These features of multiple Aschoff nodules produce giant Aschoff nodules[10].

Langhans giant cells: They are formed by the fusion of epithelioid cells in response to chronic inflammation. It contains 20 or more small nuclei around the periphery in horseshoe/ring form or clustered at two poles. Nucleus is normal and same as macrophage and epithelioid cells.

Foreign body giant cells: They are seen prolonged exposure to exogenous or endogenous substances. They show haphazard arrangement around foreign material.

Examples: suture materials, implants, asbestos, silica, beryllium.

Touton giant cells: These are seen as ring of nuclei separating the outer foamy cytoplasm.

Reed Sternberg cells: They are seen in Hodgkin's disease. Popcorn cells are lymphocyte rich variant.

Warthin Finkeldey giant cells: These are seen in measles.

Tumor giant cells: These are the dividing nuclei of neoplastic cells. Single or polymorphic nuclei with hyperchromatism showing other features of malignancy.

Differential Diagnosis

Brown Tumor: Browns tumor is a reactive lesion which complicates to hyperparathyroidism. They affect in the 3rd and 4th decades of life and females are more common than males. Radiographically appears as an expansile lytic lesion with intralesional trabeculations which is considered in the differential diagnosis between metastatic tumor and multiple myeloma.

Histologically they are lobulated with fibrous septae containing trabeculae of woven bone. The lobules are composed of plump fibroblasts, hemosiderin laden macrophages, and osteoclast like giant cells.Brown tumours have a much more lobulated architectural growth pattern than giant cell reparative granuloma which helps in the differential diagnosis. In the giant cell tumour, the mononuclear cells are not much spindled as those in fibroblasts seen in brown tumor, and the nuclei are similar to that of osteoclasts which is not a finding in browns tumor.

Giant Cell Tumor: The histological marked feature of giant cell tumours is the incalculable multinucleated osteoclast-like giant cells that are dispersed evenly throughout the tumor. The number of nuclei in any individual cell is fluctuating but may be as many as 50 or more. The round or oval mononuclear stromal cells are the diagnostic and neoplastic component of the tumor. These cells appear to grow in a syncytium and have little cytoplasm and ill-defined cell borders.

Histopathological DD include central giant cell granuloma, Brown tumor of hyperparathyroidism and aneurysmal bone cyst.

Aneurysmal bone cyst: pathologic differentiation is often necessary, particularly when fluid-fluid levels are seen; cystic component tends to be larger than solid component; posterior mandible is more commonly involved.(American neuro radiology)

Osteoblastoma: Numerous osteoclasts like giant cells containing more than 100 nuclei scattered in the stroma.Differential diagnosis includes Brown tumour, Aneurysmal bone cyst, chondroblastoma.In the above-mentioned lesions, the giant cells are irregularly distributed.

Bacterial Lesions: In tuberculosis and leprosy langhans giant cells are present which can be differentiated by special stains like Ziehl-Neelsen staining or by immunofluorescence using auramine-rhodamine.[13] Mycobacterial culture and detection of mycobacterial deoxyribonucleic acid (DNA) using PCR are other diagnostic test for tuberculosis and usingFite stain and a positive lepromin test for lerosy[14]

In sarcoidosis the granulomas are noncaseating with langhans giant cells and other giant cells surrounded by lymphocytes. Elevated levels of angiotensin converting enzymeand labial biopsy are use in diagnosing the disease.Serum calcium levels are elevated which also aids in diagnosis.Kveim skin test can also be done along with gallium scintiscanning.[15]

Sarcoid granulomas are noncaseating, contain Langhans and other giant cells and are surrounded by lymphocytes[8] Other histologic features include stellate inclusions called asteroid bodies and concentric lamellar calcifications called Schaumann bodies[9,14] Labial gland biopsy and elevated levels of angiotensin converting enzyme (ACE) are used in diagnosing the disease.[8] Elevated serum calcium levels and adenosine deaminase levels for macrophage activity in granulomas are other diagnostic tests. Kveim skin test can also be done along with gallium scintiscanning.[9] Polaroscopy reveals little crystalline refractile things (LCRT) within the granuloma.[11] Recently a latent infection of *Propionibacterium acnes* has been postulated to be the cause of sarcoidosis.

Conclusion

Presence of multinucleated giant cells among the oral lesions is an easily identifiable histological feature. Proper histopathological and radiographic examination are much essential in establishing an accuratediagnosis[11]Recent advances in the understanding of pathogenesis are necessary to develop new treatments for the diseases.

Geriatric Dentistry—A Review

N. Anitha[1], K. M. K. Masthan[2], L. Malathi[1], Sangeetha Priya P.[3], N. Aravindha Babu[4]

[1]Reader, [2]Professor and Head, [3]Post Graduate Student, [4]Professor, Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital, BIHER

ABSTRACT

Geriatrics, is a specialty that focuses on health care of elderly people. It aims to promote health by preventing and treating diseases and disabilities in older adults. The World Health Organization (WHO) has set 55 as the beginning of old age. Living a long life can be attributed to a number of factors, such as improvements in the standard of living, better sanitation, nutrition, and healthier lifestyles. This review discusses on the importance of evaluating the oral health of the geriatric population in a detailed manner, beyond simple clinical assessments to look for, understand and diagnose possible signs and symptoms or oral pathoses in the elderly.

Keywords: *Geriatric dentistry, old age, Aging*

Introduction

Aging is a natural process. Old age should be regarded as a normal, inevitable biological phenomenon. In humans, ageing represents the accumulation of changes in a human being over time, encompassing biological, physiological, social and behavioral [1]. Aging not only affects the overall health, but the effect of aging on oral health can also be seen that includes effect on oral hard and soft tissues. As these structures had been on constant function, over the phase of aging process there is hypo-functioning of these structures and reduced activity can be seen that may compromise patient's mastication, swallowing, and pain leading to anxiety and depression.[2]

Biological and physiological characteristics of aging: The aging process is mediated by genes and physiological changes[3].The age related physiologic changes include changes to cellular homeostasis, which includes regulation of body temperature,blood and extracellular fluid volumes, decrease in organ mass, and decline in reserves of body system functional[4]. This progressive constriction start in the 3rd decade of life. This state is usually asymptomatic and has little impact on activities of daily living regardless of age[3]. Physical changes include decreased quality and quantity of bone and muscle mass[5].

Hard tissue changes associated with aging: The most common age change is the attrition or wear of the tooth surface due to constant wear of the enamel surface[6]. Enamel wears, dependent on diet pattern and masticatory habits. This is clinically evident as loss of vertical dimension of the crown and flattening of the proximal contour[7]. The patterns of tooth wear vary with each patient and are progressive because the enamel is not capable of repair and regeneration. The wear can range from minimal faceting to extreme loss of tooth substance sometimes even to the level of gingiva. The enamel tends to become more brittle and susceptible to chipping, cracking and fracture[8]. Also as result of age changes in the organic portion of enamel, the teeth become darker, and their resistance to decay may be increased, fluid permeability of older teeth is reduced.[9]

Geriatric patients are more prone to *dental plaque and dental caries.* Dental plaque is the primary source of micro-organisms (e.g streptococcus mutans and lactobacilli) causing coronal and root surface caries

Corresponding Author:
Dr. N. Anitha, M.D.S,

in elderly people. Older individuals form plaque more rapidly than do younger people[3].

The reparative indices of dentin produce transparent or sclerotic dentin that are observed in the teeth of elderly people. Sclerosis reduces the permeability of the dentin and may help prolong pulp vitality [10]. Although in general, there is high prevalence of tooth loss due to caries, as many of the old aged patients psychologically feel there is no much need in saving or treating the infected teeth and rather prefer extracting the tooth[11].

The pulp shows various changes due to aging. The continual dentin deposition results in decreasing volume of pulp canal and the pulp chamber. Pulp stones are nodular, calcified masses appearing in either the pulp organ. But more frequently seen in coronal pulp. They are usually asymptomatic. The incidence and size of pulp stone increases with age[3].

Age related gingival recession leads to exposure of cementum causing root caries. These lesions appears as well defined and discoloured defects on cementum or at cemento-enamel junction.[13]

Mobility of teeth is common complaint of geriatric patients. Age related progressive loss of soft tissue attachment, with the combined effect of systemic and medications which also contribute the adverse effect on periodontal health leading to exposure of the root and loosening of the teeth within their bony sockets[14]. A compromised periodontal status and bone resorption leads to tooth loss and edentulism. Edentulism can be divided as partial or complete edentulism, depending on number of teeth absent from oral cavity. Resorption exceeds deposition in elderly people, resulting in a net loss of bone[15]. Problems, such as reduced vertical dimension, increased alveolar ridge loss also result due to loss of teeth. Also, the patients are unable to take food adequately, thereby nutritional deficiencies take place and manifestations, such as vitamin and iron deficiencies can be seen[16].

Age related soft-tissue changes

Oral Mucosa: The clinical appearance of the oral mucosa in older patients is often indistinguishable from that of younger patients. However, changes over time including mucosal trauma, mucosal diseases, and salivary gland hypofunction can alter the clinical appearance and character of the oral tissues in older patients[17]. Elderly patients may develop vesiculobullous, desquamative, ulcerative, lichenoid and infectious lesions of the oral cavity. In addition, oral cancer is primarily a disease of ageing and associated cell irregulation. It is estimated that more than 90% of all oral cancers in developed countries occur in individuals older than 50 years, with a mean onset during the sixth decade of life. [18]

Denture stomatitis: The mechanical trauma caused by ill-fitting dentures along with mucosal changes and superadded infections, a condition may be developed which is known as denture stomatitis or denture sore mouth. This condition is characterized by various degrees of erythema, and also may be associated with petechial hemorrhage which is localized to the maxillary denture bearing areas (palate). Whether it is an actual infection by Candida albicans or host tissue response remains controversial.[19]

Angular cheilitis: It typically occurs in older persons with reduced vertical dimension of occlusion and accentuated folds in the corner. There is increased pooling of saliva in these areas which keeps it moist and thus, favors a fungal infection. It is characterized by erythema, fissuring, and scaling.Contributing factors also include iron and riboflavin deficiency. This condition is primarily seen along with denture stomatitis.[20]

Burning mouth syndrome: Burning mouth syndrome (BMS) is a disabling, spontaneous, continuous, and often intense burning sensation that occurs primarily in postmenopausal women. This condition is characterized by a sensation described by the patient as stinging, burning that primarily affects the oral mucosa, when no clinical or laboratory signs are present to justify these symptoms. [21]

Salivary gland: With age a generalized loss of salivary gland parenchyma tissue occurs. The lost salivary cells often are replaced by adipose tissue. Although decreased production of saliva often is observed in older persons, whether this is related directly to the reduction in parenchymal tissue is not clear.[3]

Xerostomia: Xerostomia is defined as dry mouth resulting from reduced or absent salivary flow. According to a study 30% of the affected patients are above the age of 65 years. It can also affect nutrition as well as psychological health. Individuals with xerostomia complain of dry mouth and problems with eating,

speaking, and swallowing along with oral burning or soreness and a sensation loss or altered taste which is known as dysguesia. [22]

Temporomandibular joint: In the temporomandibular joint it is difficult to distinguish changes due to ageing from those related to osteoarthrosis. Patient with osteoarthritis of other joints may complain of clicking and snapping in the TMJ, also complain of difficulty in opening the mouth associated with pain. But however pain is not necessarily a feature of osteoarthritis alone.[3] Excluding those changes due to osteoarthrosis, the main age changes are related to remodelling of the articular surfaces and disc in response to functional changes following tooth loss. These changes may include fibrillation(separation of collagen bundles) of the fibrous covering of the articulating surface of the disk[3]. Remodelling may result in disc displacement, particularly anterior displacement.[23]

Oral consideration in geriatric patients with regards to systemic conditions: Although systemic diseases can occur at any age of a person, they are more common in elderly patients. Many conditions and medications can influence oral health and dental care in patients. The systemic diseases can impact upon oral care or can have oral manifestations. These changes may have an effect on medication absorption and metabolism or an individual's sensitivity to certain medications, in some patients chronic intake of certain medications for systemic illness could develop changes in the oral mucosa.[3]

Gastrointestinal diseases

Gastroesophageal reflux disease(GERD): Patients who experience GERD complain of dysgeusia (foul taste), dental sensitivity, erosion, and/or pulpitis. Dental sensitivity is due to erosion of enamel by gastric acid. Erosion leads to dentin sensitivity and at times irreversible pulp involvement

Peptic ulcer/gastric ulcer: Dental erosion in the palatal aspect of the maxillary teeth is seen due to persistent regurgitation of gastric acid.
Vascular malformation of the lip have been reported and range from a very small macule to a large venous pool.[3]

Respiratory Diseases

Asthma: Oral manifestation include candidiasis, decreased salivary flow, increased calculus, increased gingivitis and periodontal diseases, and increase incidence of caries. Prolonged use of BETA2 agonists may cause reduced salivary flow, with resulting increase in cariogenic bacteria, dental caries and increased incidence of candidiasis.

Chronic obstructive pulmonary disease (COPD): Periodontal pathogens have shown to be the causative pathogen of exacerbation in 4% of individuals with COPD. On prospective study suggested that oral colonization with respiratory pathogens in patients residing in chronic care facility was significantly associated with COPD.

Pulmonary embolism: The main concern in the provision of dental care for individuals with pulmonary embolism in the patient who is being managed with oral anticoagulants.[3]

Cardiovascular Diseases

Hypertension: The common findings encountered in hypertention are changes caused by hypertensive medications for example:

Diuetics	Oral dryness
Adrenergic inhibitors	Oral ulceration and dryness
Direct vasodilators	Gingival overgrowth
Calcium antagonists	Lichenoid reactions of the oral mucosa
ACE inhibitors	Loss of taste

Renal diseases

Chronic renal failure: As renal failure develops,one of the early symptoms may be a bad taste and odor in the mouth, particularly in the morning. With impaired renal function a decreased glomerular filteration rate (GFT) and accumulation and retention of various products of renal failure, the oral cavity may show a variety of changes as the body progresses through an uremic state. Some of the presenting signs were an ammonia-like taste and smell, stomatitis, decreased salivary flow, xerostromia, and perotitis. An acute rise in the Blood Urea Nitrogen (BUN) level may result in uremic stomatitis, which may appear as an erythropultaceous form characterized by red mucosa covered with a thick exudates and a pseudomembrane or as an ulcerative form characterized by frank ulceration. White plaques called 'uremic frost' can rarely be found intraorally

Hematological diseases:

Anemia: The major oral sign of iron deficiency anemia is pallor of the mucosa. In addition,the oral epithelium cells become atropic. The tongue may become smooth due to atrophy of the filiform and fungi form papillae an glossodynia can be a presenting or associated symptoms. In long standing cases esophageal strictures or web can develop resulting in dysphagia

Leukemia: Oral complications are common throughout the clinical course of the disease,dental management is complex. Oral sings and symptoms include cervical lymphadenopathy, oral bleeding, gingival infiltrates, infection and oral ulcers. Thrombocytopenia and anemia caused by marrow suppression from disease and chemotherapy results in pallor of the mucosa, petechiae and ecchymoses. Oral mucosal ulcers are common findings in leukemic patients. Oral infection is a serious potentially fatal complication in neutropenic leukemic patients. Candidiasis is common oral fungal infection.[3]

Immunologic diseases

Scleroderma: It is a multisystem connective tissue disease that involves hardening of the skin and mucosa, smooth muscle atrophy. Oral manifestation of scleroderma include:

- The lip become rigid and the oral aperture narrows considerably
- Tongue can also become hard and rigid, making speaking and swallowing difficult.
- Oral telangiectasia is commonly observed on the hard palate and lips.
- When the soft tissue around the TMJ are affected, they restrict movements of the mandible causing pseudoankylosis.

Rheumatoid arthritis: The treatment for rheumatoid arthritis can cause oral manifestations. The long term use of methotrexate and other antiheumatic angents such as D-penicillamine and NSAIDs can cause stomatitis, periodontal disease, including bone and teeth, and cyclosporine may cause gingival overgrowth.[3]

Infectious Diseases

Tuberculosis: It appears most likely that the organisms are carried in the sputum and enter the mucosal tissue through a small break in the surface. Tongue is most commonly affected, followed by the palate, lips, buccal mucosa, gingival and frenula. Ulcer is irregular, superficial or deep, painful ulcer which tends to increase slowly in size.

Candidiasis: Candidiasis is the most common opportunistic infection of the mouth caused by overgrowth of a species of the fungus Candida. The species most frequently implicated in oral infections is C. albicans. The change commonly occurs when there is a reduction in host resistance caused by bacterial and viral infection, systemic disease or medications. Oral candidiasis generally presents in one of three distinct clinical forms: acute pseudomembranous candidiasis (thrush), acute atrophic candidiasis (antibiotic sore mouth), or chronic atrophic candidiasis (denture sore mouth). The lesions of acute pseudomembranous candidiasis consist of either multifocal or diffuse, white, superficial curd like plaques occurring anywhere in the oral cavity. The infection is called pseudomembranous because the plaques can be scraped off easily, leaving an erythematous base. Most other white mucosal lesions cannot be rubbed off. Acute atrophic candidiasis often follows prolonged antibiotic or steroid therapy and results clinically in a painful erythematous mucosa particularly involving the tongue. The problem usually resolves with cessation of the medications, but antifungal therapy will hasten recovery. Chronic atrophic candidiasis presents as a slightly granular or irregularly eroded erythematous mucosa under dentures. Any of these types of candidiasis can be accompanied by angular cheilitis. [3]

Conclusion

In summary, variety of oral changes may be observed in elderly patients. These changes can be attributed to a variety of physiological and pathological processes which have developed over a lifetime. Clinically, it is important to recognize these changes and provide appropriate treatment. As the number of geriatric population and their associated oral and general health problems are considerably increasing with time, there is a need for clear understanding of correlation of systemic health with oral health and providing support and treatment for the same.

Abstract

Palliative care is the care given to terminally ill patients to improve the quality of life. Oral cancer is the sixth most common cancer in the world with higher annual incidence. These oral cancer patients are not only compromised on general health but also on oral health, alleviation of pain, reducing the suffering, providing relief, treatment of any other complication which occur during treatment or post treatment are taken care in palliative care. The major concerns in these patients include mucositis, xerostomia, candidiasis, pain, dysphagia, dyspnoea, depression, anxiety and nutritional deficiencies.

Keywords: *Oral cancer, Pain, Dysphagia, Dyspnoea*

Introduction

Palliative care is the care given to terminally ill patients to improve the quality of life and giving relief from their sufferings for the rest of the life[1].According to WHO, palliative care is "the study and management of patients with active,progressive, far advanced disease in whom the oral cavity has been compromised either by disease directly or by its treatment, the focus of care is quality of life"[2].In other words, Palliative care is the supportive care with principal curative treatment of cancer. Palliative care is the multidisciplinary team work given by doctors of various specialities, nurses and social workers. Oral cancer is the sixth most common cancer in world with annual incidence of 2,75,000 for oral and 1,30,000 for pharyngeal cancer[3].Inspite of various modalities in treatment of oral cancer, more than half patients lost their life as disease progresses and in the end of their life they are shifted to palliative care for reducing their symptoms not curing and also gives psychosocial spiritual support to patients.

Surgical Palliation: Patients undergone surgery for the treatment of cancer, postsurgicallythey develop symptoms such as pain and bleeding at surgical site, dysphagia, dyspnoea. In these cases palliative surgery may be indicated to relieve their symptoms. This palliative surgery includes removal of the recurred tumor and endovascular techniques such as embolisation and vessel stenting controls bleeding. Secondary haemorrhage from carotid vessel due to erosion results in critical complication such as dying state. This can be managed by swift surgical intervention and attempts to reduce flow of blood with direct pressure[1].

Control of Pain: Pain is the most " An unpleasant sensory and emotional experience associated with actual or potential tissue damage, or described in terms of such damage" as given by International Association for Study of Pain[4].Patients of oral cancer persists with pain throughout the lifetime, both before and after the treatment. Pain that encountered are of three types. They are somatic, visceral and neuropathic pain[1]. Pain can be best managed with analgesics. The WHO proposed the analgesic ladder for treating cancer pain based on the severity of pain and strength of analgesics, given in table 1[5]. Among all other opioids, morphine is the first choice for somatic pain. Morphine can be given alone or in combination with other co analgesics. Care must be taken regarding appropriate dosage of drug and switching of oral form to patch on the skin[6].Oral form includes

sustained release preparation followed by immediate release doses for breakthrough at a sixth of 24 hour sustained release dosage.In case of adverse effects such as vomiting, morphine can be given as subcutaneous preparations.Diamorphine is mostly preferred for subcutaneous preparation. If there is morphine tolerance and in renal failure patients, transdermal preparation of Fentanyl can be given[1].

Table 1: WHO analgesic ladder for treating cancer pain

Step1(mild pain)-Non opioids and adjuvant.
Example is paracetamol 500mg to 1g 6 hourly.
If pain is not controlled in 24 hrs, proceed to step 2.
Step 2(mild to moderate pain)-weak opioids with step 1 medication.
A combination of paracetamol, dextropropoxyphene, codeine or tramadol.
If step 2 medications are not adequate in 24hrs,proceed to step 3.
Step3(moderate to severe pain)-Strong opioids with step 1 medication.
Morphine 5mg four hourly, a maximum daily dose of 30 mg is required.

Local application of Fentanyl through buccal, sublingual and intranasal routecan also be given. Some patients develop dysphoria due to morphine intake, in these cases, oxycodone may be used as an alternative to morphine[1].Hydromorphoneand methadone are given as an alternative to morphine.

Due to radiation, neuropathic pain may usually results. Neuropathic pain can be best managed with anti depressants, anti convulsants such as gabapentin and pregabalin, sedatives such as carbamazepine [1].The combination of both antidepressants and anticonvulsants should be given for intolerable pain. Corticosteroids may also be used as first line for neuropathic pain but it produce the adverse effect of appetite stimulation if the patient persists with dysphagia. Clonazepam, methadone and ketamine are occasionally used.Mucosal pain around the lesion region arise due to infection or tumor. Topical application of local anaesthetics such as lignocaine preparations favours the best result for mucosal pain. Other topical agents such as sucralfate, steroids,chlorhexidine can also be used.Dexamethasone can be given for visceral pain[1].

Palliation of Dysphagia: Dysphagiaor difficulty swallowing is a disturbing symptom that occurs in the majority of patients with oral cancer in the initial as well as life limiting stage. Difficulty swallowing can impact the quality of life of the patient as well as of caregivers.

Dysphagia can be a cause of result of dying. Muscle wasting, cachexia, and asthenia affect the coordination and muscle strength needed for swallowing, which in turn, can lead to poor appetite and inefficient oral intake. Speech-language pathologists (SLPs) play a critical role in the multidisciplinary team by providing careful assessment to determine swallowing potential, prognostication to assist in decision making, and guidance in safe and appropriate feeding methods[7].More than 40% of oral cancer patients experience dysphagia. It may be due to mechanical and functional obstruction of oropharyngeal structure and also due to adverse effects of drugs.Aspiration is most common for about 40% to 60% oral cancer patients. Functional Endoscopic Evaluation of Swallowing (FEES) is the procedure to detect the presence, assessment of ability and etiology of aspiration[1].These patients can be managed with use of thickened fluids thereby maintaining their oral intake. Patient must also be educated about the risk of aspiration pneumonia. Through the nasogastric tube, hydration, nutrition and medication can be maintained in these patients. When the nasogastric tube feeding is delivering the nutrition for more than two weeks then gastrotomy is performed[1]. Surgical debulking of obstruction and use of stents are also performed in severe cases.

Palliation of Airway: Dyspnoea is a frequent symptom in advanced cancer patients and symptoms increasing in the terminal phase (up to 80%). Dyspnoea may be present as suffocating, choking or tightness of breath, effort of breathing and air hunger[8]. This is managed non pharmacologically with cooling the face, opening windows, using small ventilators, adequate positioning (e.g. coachman's seat, elevation of the upper part of the body), respiratory training, the use of a walking frame or a walker[9]. Pharmacologically, it is managed with the help of opioids, benzodiazepine, neuroleptics, anti depressants and steroids. Tracheostomy is the final choice for the airway palliation. However, tracheostomy may be avoided when there is a chance of surgical debulking. It depends on local expertise and equipment[10]. But patient

having repeated surgical debulkingnot to be opted for tracheostomy and they are managed with drugs for reduction of secretion, palliative sedation. In dying patient on dyspnoea, pharmacological intervention include reduction of artificial hydration, adding antisecretory drugs such as atropine, hyoscine or glycopyrronium bromide and optimise positioning of the dying.

Palliation of Other Symptoms: Mucositis and stomatitis are common in patients who undergone chemotherapy and radiotherapy. In Chemotherapy, high rate of mitosis of cells takes place and mucositis occurs. It is estimated that 40% of chemotherapy patients suffer from mucositis[11]. Methotrexate and 5-Fluorouracil are the potent chemotherapeutic agents which causes mucositis. Usually mucositis occurs in the first week after chemotherapy. Mucositis manifest with pain, bleeding, reduced intake of foods leading to nutritional deficiencies, infection and compromised masticatory function. In later stages ulceration occurs which act as a site for microbial invasion. Xylocaine and dyclonine are topical anesthetics used for mucositis and stomatitis but must be used with caution as they will block the gag reflex and increase the risk of aspiration. The use of diphenhydramine hydrochloride 5% and loperamide are used as a rinse to relieve pain has been used for herpetic stomatitis. Milk of Magnesia causes dryness of the mouth, hence it should not be given as substitute[11]. Benzydamine, a nonsteroidal analgesic with anti- inflammatory properties palliate radiation induced stomatitis. Patient is also advised for the use of saline solution followed by a 0.2% morphine solution can be used topically to relieve the discomfort associated with mucositis and also be advised to avoid spicy foods, smoking and alcohol[11].

Xerostomia occurs due to side effects of drugs and radiotherapy. Radiotherapy causes destruction of the salivary gland tissues within the treatment zone[11]. It causes decrease in lubrication and the protective agents in saliva render the tissues more susceptible to dryness and pathogenic invasion. Xerostomia affects nutrition, communication and oral tissues. Xerostomia manifest with ulcerated, erythemic, taste alteration, dysphagia, nutritional deficiencies, radiation caries etc [12]. Water soluble lubricants, alcohol free mouth rinses and saliva substitutes are used for treating xerostomia. Drugs used for xerostomia are pilocarpineand cevimeline. Malic acid, vitamin C and citric acids are also used to stimulate saliva secretion.

Nausea and vomitingin palliative care patients areoccurred due to obstruction in gastro intestinal tract, gastro intestinal infiltration, pancreatitis,azotemia, hypercalcemia, electrolyte imbalance, emotional reaction, after radiotherapy and chemotherapy. These are managed with anti emetics and prokinetic drugs such as metoclopramide and domperidone. Haloperidol and metoclopramide causes tardive dyskinesia, while hyoscine butylbromide, promethazine causes xerostomia. Tardive dyskinesia occurs in long time dosage of drugs and interferes with the denture wear.

Constipation may develop due to adverse effects of anti cholinergics and opioids. Laxatives and softeners are used to treat constipation, most commonly used are laxido and movicol. Manual evacuation with enemas may be needed in severe cases.

Cachexia characterized by progressive weight loss, persistent erosion of host cells in response to malignant growth. Anorexia is also a component of cachexia. Cachexia results in reduce in ability of patient to fight against cancer[5].

Candidiasis occurs almost 80% of the patients under palliative care. It occurs due to xerostomia, poor oral hygiene, use of corticosteroids, use of broad spectrum antibiotics, poor nutritional status, diabetes, denture wearing and immunosuppressive drugs[11]. Candida albicans is the most common infectious organism causing candidiasis. Candidiasis manifest as pseudomembranous, erythematous or hyperplastic candidiasis or angular cheilitis. Pseudomembranous candidiasis (thrush) is characterized by small white or yellow plaques with surrounding erythemic areas. These lesions can be rubbed off, revealing raw mucosa. Erythemous (atrophic) candidiasis appears as red lesions, frequently on the hard palate and dorsal surface of the tongue. Hyperplastic candidiasis is similar to pseudomembranous; however, the plaques do not wipe off. Angular cheilitis appears as white and red fissures arising from the corners of the mouth having both bacterial and fungal component [13]. Xerostomia is the major cause for candidiasis. The species level of candida are higher in denture wearing patients than dentate patients.Denture wearing patients use soaking agents such as as bleach and water benzalkonium chloride,chlorhexidine, and also microwaving the denture to get rid of the candida species and prevent from candidiasis.Topical agents used in the treatment of

candidiasis are nystatin and clotrimazole and sysytemic agents used are ketoconazole, fluconazole, itraconazole, amphotericin BCandidiasis may be treated efficiently by a combination of topical and systemic applications. Nystatin is the most common antifungal agent which can be administered throughdifferent methods and it can produce adverse effects such as nausea, vomiting and diarrhoea. Clotrimazole usage may increase the risk of occurrence of caries as it contains sucrose content. Systemic medications should be reserved forcases in which topical agents are ineffective and these agents have renal or hepatic toxicity. Ketoconazole decreases the absorption of antacids and increases the half-life of benzodiazepines[11]. Fluconazole,ketoconazole and itraconazole may interact with anticoagulants such as coumadin. Itraconazole decreases the pharmocological effect of oral contraceptives and increases plasma levels of benzodiazepines. Amphotericin B is the final choice of drug for candidiasis[11].

Chemotherapy or radiotherapy in oral cancer patients may developdysgeusia.It is treated with zinc supplementation and monosodium glutamate.

Psychotherapy: Patients commonly experience anxiety, confusion, delirium, agitation etc., as a result of opioid intake, alcohol withdrawal and fear of dying. These are pharmacologically managed with sedatives such as benzodiazepines. In critical stage of dying patient, benzodiazepines and anti psychotics are given in combination[1]. Psychological support can be given by cognitive behaviour therapy, positive affirmations, hypnosis, therapist support, relaxation etc[5]. Hypnosis reduces oral pain experienced by patients due to mucositis [14].

Radiotherapy: Radiotherapy uses high energy X-rays or particles to destroy cancer cells or reduce its rate of growth. It is effective in reducing the symptoms such as pain, bleeding, dysphagia, bony metastatic pain of patients in palliative care. Most commonly External Beam Radiation Therapy(EBRT) technique is used, in which machine is focused from outside the body targeting on the tumor site. It should be usually given for 5 days a week for 6 to 7 weeks[15]. There is a debate continues around the use of hypofractionated schedules or short course radiotherapy for local pain control[1]. Bisphosphonates and monoclonal drugs such as denosumab are used in bony pain control[1].

Chemotherapy: It uses anti cancer drugs for reducing the symptoms in advanced cancer patients.It also used as an alternative to surgery, where tumoris difficult to remove surgically, as it attempts to shrink the larger tumor and also slow down the growth rate of cancer cells. This can also be used as an adjuvant to radiation and surgery. Most commonly used chemotherapeutic drugs are cisplatin, carboplatin, 5-fluorouracil, paclitaxel, docetaxel and less commonly used are methotrexate, bleomycin and capecitabine[16]. These drugs can also be given in combination of two or more drugs.Adverse effects caused by these drugs are hair loss, mouth sores, diarrhoea, neuropathy, renal damage etc. Intravenous fluid may be given before and after each dose to reduce the occurrence of renal damage[16]. In addition to cancer cells, these drugs can also produce damage on other normal cells such as bone marrow cells thereby causing risk of infection, bleeding disorders etc.

Social Well Being in Palliative Care: Patient's family members play a important role in palliative care as care giver and care recipient. They are called 'hidden patients' and need to be psychologically well treated for the mental support for the patient[5]. Health care professionals must view patient's family as a unit of care for patient and support them.

Conclusion

The WHO reports estimates that around three fourth of cancer patients are in end stage. Global approach towards palliative care also has taken as positive outlook especially in last two decades[15]. Palliative care in oral cancer patient is the multidisciplinary approach includes specialist of various fields, nurses and social workers. Thus the health care professionals must take some active participation in enhancing the quality of life by minimising their symptoms. Psychological support and motivation by psychotherapist to patient and their families makes their rest of life better.

Xerostomia-Causes, Diagnosis and Management—A Review

S. Satheesh Babu[1], E. Rajesh[2], L. Malathi[2], N. Aravindha Babu[3], K. M. K. Masthan[4]

[1]Reader, Sri Venkateshwaraa Dental College, Ariyur, Puduchery; [2]Reader, [3]Professor, [4]Professor and Head of the Dept, Sree Balaji Dental College and Hospital, Bharat Institute of Higher Education, Chennai

ABSTRACT

Xerostomia is the subjective feeling of dryness of mouth which is often associated with hypofunction of the salivary gland. Xerostomia can also have a major impact on a patient's oral health and quality of life. Patients with xerostomia complaints of problems with mastication, phonetics, deglutition and wearing dentures. Treatment of this condition always depends on the cause. Oral physicians should be able to diagnose this condition and able to give proper treatment to provide comfort to their patients. This article reviews the causes of xerostomia and its management.

Keywords: *Drymouth, saliva, salivary flow, xerostomia*

Introduction

Saliva is a complex fluid, which is composed of 99% of water and only 1% of non organic and organic substances[1] [Table 1]. These constituents are within the gland and transported from the blood[2]. The major role of these components present in the saliva are to provide prophylactic, therapeutic and diagnostic properties to saliva. The compounds which are present in the saliva are also present in the blood[3]. Saliva plays an important role in maintaining good oral and general health. People become aware of its importance only when the salivary flow reduces. It causes reduction of person's quality of life[4].

Functions of Saliva:

- Digestion
- Masticatory function
- Swallowing
- Speech
- Improves taste
- LubricatIion
- Free movements of oral tissues
- Maintaining mucosal integrity.
- Irrigation and cleansing of teeth
- Protect teeth from demineralization
- Anti microbialaction.
- Immunological protection against infections.
- Retention and comfort of denture
- Saliva as a diagnostic tool

Dry Mouth (Xerostomia): Dry mouth (xerostomia) is a common complaint of salivary problem and is the subjective sense of dryness which may be due to:

- Reduced salivary flow (hyposalivation) and/or
- Changes in composition of saliva.

Patients who have chronically decreased salivary flow (hyposalivation) suffer from lack of oral lubrication, affecting many functions and they may complain of dryness (xerostomia), and can develop dental caries and other infections (candidiasis, or acute bacterial sialadenitis) as a consequence of the reduced defences.

Causes: There are also physiological causes of hyposalivation. Thus a dry mouth is common during periods of

- anxiety,
- due to sympathetic activity
- mouthbreathers may also have a dry mouth and advancing age is associated with dry mouth probably because of a reduction of salivary acini[5], with a fall in salivary secretory reserve.

Table 1

Causes of dry mouth
Iatrogenic
Drugs
Irradiation
Graft versus host disease
Disease
Dehydration
Psychogenic
Salivary gland disease
Sjögren's syndrome
Sarcoidosis
Salivary aplasia

Drugs: In older people[6] complaining of xerostomia is due to drugs. Indeed, the main causes of dry mouth are iatrogenic. There is usually a close relation between starting the drug treatment or increasing the dose, and experiencing the dry mouth[7]. However, the reason for which the drug is being taken may also be important.

For example, patients with anxiety or depressive conditions may complain of dry mouth even in the absence of drug therapy (or evidence of reduced salivary flow). Drugs recognised as causes of reduced salivation include mainly those with anticholinergic, or sympathomimetic, or diuretic activity.

These include those shown in Table 2.

Drugs associated with dry mouth
Drugs which directly damage the salivary glands
Cytotoxic drugs
Drugs with anticholinergic activity
Anticholinergic agents such as atropine, atropinics and
hyoscine
Antireflux agents eg proton-pump inhibitors (such as
omeprazole)
Psychoactive agents with anticholinergic activities such as:
Antidepressants, including tricyclic (eg amitriptyline,
nortriptyline, clomipramine and dothiepin [dosulepin]),
selective serotonin re-uptake inhibitors (eg fluoxetine),
lithium and others.
Phenothiazines
Benzodiazepines
Opioids

Irradiation: Radiation theraphyfor malignant tumours in the head and neck region, such as oral cancer, can produce xerostomia. Other sources of irradiation such as radioactive iodine (131I) used for treating thyroid disease, may also damage the salivary glands, which take up the radioactive iodine.

Dehydration: As in diabetes mellitus, chronic renal failure, hyperparathyroidism, any fever or diabetes insipidus [8] can cause xerostomia.

Diseases of salivary glands can also cause salivary dysfunction. These are mainly:

- Sjögren'ssyndrome[9] (a multisystem auto-immune condition).
- sarcoidosis; HIV disease; hepatitis C virus infection; liver
- diseases
- cystic fibrosis (mucoviscidosis)

It is also important to also recognise that some patients complaining of a dry mouth have no evidence of a reduced salivary flow or a salivary disorder (ie they have xerostomia but not hyposalivation), and in these there may be a psychogenic reason for the complaint.

Clinical features: The patient with hyposalivation may have difficulty in:

- Swallowing — especially dry foods (the cracker sign)
- Controlling dentures
- Speaking, as the tongue tends to stick to the palate — leading to 'clicking' speech.

- Patients may also complain of unpleasant taste or loss of sense of taste, or halitosis.
- The patient with hyposalivation may complain of a dry mouth or these sequelae alone, or also complain of dryness of the eyes and other mucosae (nasal, laryngeal, genital). Those with eye complaints have blurring, light intolerance,
- burning, itching or grittiness, and sometimes an inability to cry.
- Systemic features (such as joint pains) may be suggestive of Sjögren'ssyndrome[9].

Examination

- **Examination** may reveal that the lips adhere one to another and an examining dental mirror may stick to the mucosa because of the reduced lubrication.
- Food debris may be seen sticking to the teeth or soft tissues, and the usual pooling of saliva in the floor of the mouth may be absent.
- Thin lines of frothy saliva may formalong lines of contact of the oral soft tissues, on the tongue, or in the vestibule.
- Saliva may not beexpressible from the parotid ducts. The tongue is dry and may become characteristically lobulated and usually red, with partial or complete depapillation.

Complications of hyposalivation can include:

- **Dental caries** — which tends to involve smooth surfaces and areas otherwise not very prone to caries — such as the lower incisor region and roots. Hyposalivation may explain patients with uncontrollable recurrent caries, who are apparently complying with dietary advice.
- **Candidiasis** — which may cause a burning sensation or mucosal erythema, lingual filiform papillae atrophy, and angular stomatitis (angular cheilitis)
- Halitosis
- Ascending (suppurative) sialadenitis — which presents with pain and swelling of a major salivary gland, and sometimes purulent discharge from the duct.

Diagnosis: Hyposalivation is a clinical diagnosis which can be made by the history and examination. It can be helpful to document salivary function by salivary function studies such as salivary flow rates (sialometry). Collection of whole saliva (oral fluid) is currently the routine technique for sialometry used by many clinicians, despite the fact that it is rather inaccurate and non-specific.

It is usually carried out by allowing the patient to sit quietly and dribble into a measuring container over 15 minutes; in a normal person, such an unstimulated whole saliva flow rate exceeds 1.5 ml/15 min (0.1 ml/min).

The specialist may be needed to:

- Study and document the degree of salivary dysfunction
- Determine the cause.

Investigations may be indicated to exclude systemic disease, particularly to exclude:

- Sjögren's syndrome and connective tissuedisorders
- Diabetes
- Sarcoidosis
- Viral infections (hepatitis C; HIV).

Commonly used investigations may thus include:

- Blood tests (mainly to exclude diabetes, Sjögren's syndrome, sarcoidosis, hepatitis and other infections)
- Eye tests (egSchirmer test mainly to exclude Sjögren's syndrome)
- Salivary gland biopsy (if there is suspicion of organic disease such as Sjögren'ssyndrome)
- Imaging (mainly to exclude Sjögren's syndrome, sarcoidosis or neoplasia).

It is important to remember, as stated above, that in someelderly[10] patients complaining of a dry mouth no evidence of a reduced salivary flow or a salivary disorder can be found. There may then be a psychogenic reason for the complaint.

Table 3:

Diagnosis is clinical but investigations may be indicated, including:

- Blood tests (ESR and SS-A and SSB antibodies; see below)
- Eye tests (Schirmer; see below)
- Urinalysis
- Salivary flow rate tests (sialometry)
- Salivary gland biopsy (labial gland biopsy)
- Imaging
- Chest radiograph
- Sialography
- Scintiscanning
- Ultrasound

Management of Hyposalivation

- Any underlying cause of xerostomia should if possible be rectified.

  Eg: xerostomiaproducing drugs may be changed for an alternative, and causes such as diabetes should be treated. Patients should be educated into efforts toavoid factors that may increase dryness, and to keep the mouth moist

- Salivary substitutes may help symptomatically.

  A variety are available including:

  - Water or ice chips; frequent sips of water are generally effective
  - Synthetic salivary substitutes.

- As patients with objective xerostomia are at increased risk of developing caries it is important that they take a non-cariogenic diet and maintain a high standard of oral hygiene. The regular use of topical fluoride agents forms animportant component of their long-term care.
- Salivation may be stimulated by using diabetic sweets or chewing gums (containing sorbitol or xylitol, not sucrose).
- Cholinergic drugs that stimulate salivation (sialogogues), such as pilocarpine, or cevimeline should be used only by a specialist. Oral complications should be prevented and treated.

Microwave Tissue Processing

F. RyhanathGulshan[1], Aravindha Babu N.[2], JayasriKrupaa[3], K. M. K. Masthan[4]

[1]Post Graduate Student, [2]Professor, [3]Reader, [4]Professor and Head of the Department, Department of Oral Pathology and Microbiology, SreeBalaji Dental College and Hospital, Bharath Institute of Higher Education and Research.

ABSTRACT

Conventional tissue fixation and processing is as old as 100 years and still remains the gold standard in which all new technologies and methods are need to be assessed. Tissue processing is one of the important steps for obtaining good thin sections without artifacts. Though conventional tissue-processing methods are most commonly followed, they are well-known as very laborious and tedious procedures. Microwaves is a form of electromagnetic wave-induced heat, when applied in histotechnology, reproducibly yields histolologic material of similar or superior quality than conventional processing methods, making it popular in the recent years. Microwave irradiation of tissue during fixation and subsequent histochemical staining procedures significantly reduces the time required for incubation in fixation and staining solutions.

Keywords: *Tissue processing, Microwave, Staining*

Introduction

Microwaves were invented by Percy Spencer in 1945. It iswidely used in food processing, chemical, pharmaceutical, and other industries for many years[1]. The concept of fixation of tissues using microwaves was first advocated by Meyers in1970. It can penetrate tissues to a greater extent than heat waves.[2]Microwave irradiation during tissue processing reduces the time required for fixation, decalcification, staining with chemical reagents. It also induces rapid oscillation of water molecules (2.45 GHz) and thus increases tissue temperature. Conventional microwave devices irradiate tissues both rapidly and uniformly, and microwave irradiation protocols differ with specific microwave devices used. Microwave irradiation is routinely applied for special staining, fixation and subsequent staining procedures, such as enzyme-based staining and immunofluorescence staining.[3]

Microwaves in Processing of Tissues: Tissue processing performed permits sectioning of tissue into thin sections so it can be visualized microscopically. It consists of a series of steps in which the tissues pass through various reagents, which will finally permit sectioning.[4]Microwave histoprocessing relies on the principle of using microwave energy to speed up the process of the diffusion of liquids into and out of the specimens. Conventional tissue processors involves a graded series of alcohols, a clearing agent, usually xylene and paraffin wax in an overnight process whereas microwave histoprocessing employs just three reagents as mentioned below in four step processinvolving single change in ethyl alcohol andisopropanol and two changes in paraffin.[5]

1. 100% ethyl alcohol for dehydration
2. Isopropanol for the intermedium
3. Liquid paraffin for infiltration

The alcohol can be used several times and the paraffin can be reused many times, possibly for months. Paraffin should be added to the microwave in liquid form as microwave energy will not melt paraffin pellets. Theuse of microwave tissue processing enhanced safety by eliminating formalin and xylene from the procedure. The approximate time taken for processing is [6]

1. Short Schedule-15 min and
2. Long Schedule-60 min

Microwave Instaining: Obtaining good histological images for successful interpretation is made possible by good sample preparation and staining. Staining of tissue sections and cell preparation is based on diffusion of dye into the tissue and its binding to the substrate. Microwave irradiation can be applied for accelerating routine, special, metallic, as well as immunofluorescent stains. Staining methods which takes minutes can be done in a microwave oven in seconds; those that take hours, in minutes; and those that take days or even weeks can be completed in hours using microwave techniques. The optimum temperature for most non-metallic stains is between 55° and 60° C and for metallic stains between 75° C and 95° C

The microwave processed tissue sections had better cytoplasmic and nuclear details with good erythrocyte integrity and lymphocyte appearance than the conventional method. The effect of microwaves on the different types of tissue such as epithelium, fibrous, and glandular, showed no statistically significant variation

Advantages of Microwave[7]

For the pathologist

- Microwave-processed slides enable the pathologist to deliver same-day diagnosis of lesions
- Same-day diagnosis will enhance the pathologist's role in management of the cancer patient

For the lab administrator

- Improved work environment for laboratory personnel
- Reduced cost for reagents storage and disposal

For the clinician

- Within hours, oncologists and clinicians can advise patients on the base of definitive diagnosis and Treatment can be initiated immediately

For the patient

- Elimination of needless stress while waiting for a diagnosis
- More timely start of needed treatment

Disadvantages of Microwave[7]

- Microwaving tissue in formalin releases large amounts of dangerous vapors
- Expensive
- Requires proper use of calibration and monitoring

Conclusion

Rapid processing of histopathologic material is increasingly desirable to fulfill the needs of clinicians treating acutely ill patients. Moreover, this will be a boon for the technical personnel whose work practices and lifestyles would change for the better, and this is something which defies statistical analysis. It is encouraging to see the growth of this technology in our field. When used properly, it can decrease the time and reagent costs tremendously. Most important of all is the diminished wait by patients for their diagnosis which makes microwave technology an important in today's laboratory.

Saliva as a Biomarker for Sysytemic Diseases

Hariharan R.[1], Aravindha Babu N.[2], N. Anitha[3], K. M. K. Masthan[4]

[1]Post Graduate Student, [2]Professor, [3]Reader, [4]Professor and Head of the Department, Department of Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

Human whole mouth saliva (WMS) is secreted by salivary glands, namely parotid, submandibular/sublingual and other minor glands of the oral cavity. The human saliva consists of various proteins and peptides which serve as diagnostic aids in detection of various contagious and organ related diseases. Saliva can be used to detect various systemic and oral diseases. In any disease early diagnosis helps in proper treatment planning and better prognosis. Saliva has a great potential as a diagnostic fluid and offers advantage over serum and other biological fluids by an economic and non- invasive collection method for monitoring of systemic health and disease progression.This review examines the diagnostic application of saliva for systemic diseases

Keywords: *Saliva, Diagnostic fluid, Biomarker, Systemic disease.*

Introduction

Saliva is a clear, slightly acidic and complex biological fluid. It contains secretions from the major salivary glands like parotid, submandibular and sublingual glands as well as minor salivary glands like buccal, lingual and palatal glands[1].The advantages of saliva is a diagnostic tool are surveillance of disease, diagnosis of the disease, prognosis and research purposes[1].Similiar to blood, saliva is composed of a variety of hormones, antibodies, antimicrobial constituents and growth factors[1]. Through the spaces present between the cells saliva enters the blood by transcellular and paracellular routes[1].

Diagnosis of diseases like cancer cardiovascular, metabolic, and neurological diseaseswhich have a great global impact have become challenging day by day[2].Therefore newer laboratory testing procedures and diagnosing techniques are required along with supplemental clinical evaluation. Salivary diagnostics holds great promise as an effective modality for the early diagnosis, prognostication, and monitoring posttherapy status[2].Whole saliva is a mixture of the secretions of the major and minor salivary glands, mucosal transudations, gingival crevicular fluid, serum and blood derivatives from oral wounds, desquamated epithelial cells, expectorated bronchial and nasal secretions, bacteria and bacterial products, viruses and fungi, other cellular components, and food debris. It is a complex fluid containing an entire library of hormones,proteins,enzymes,antibodies, antimicrobial constituents, and cytokines[2].

Use of saliva as a diagnostic aid has various advantages like being non-invasive, safe, cost effective, can be used in mass screening and time saving[3]. The salivary tumor markers and their role in diagnosis of various tumors are briefed in this article[3].

Biomarkers: Biomarkers referto a quantifiable biological parameter that is measured and evaluated as an indicator of normal biological, pathogenic, or pharmacologic responses to a therapeutic intervention, according to the National Institutes of Health (NIH)[5]. Biomarkers can be classified as: Genomic biomarkers (analysis from DNA), Transcriptomic biomarkers (analysis from RNA), Proteomic or Protein biomarkers (analysis from protein profile), Metabolomic biomarkers (as inter mediates and products of metabolism)[5].

Department of Oral pathology and Microbiology
Sree Balaji Dental College and Hospital
Bharath Institute of Higher Education and Research (BIHER), Chennai

Saliva Vs Serum: For the diagnosis of systemic diseases whole saliva is most frequently used as it has the advantage of being easily collected andit containsmostoftheserumconstituents[2]. While cells, tissues, stool, and other alternatives are routinely pursued, blood serum or plasma is traditionally and most frequently the source of measurable biomarkers[6]. Although lifesaving in many instances, the blood collecting procedures have disadvantage of being expensive, problematic, and invasive[6]. Saliva carries many advantages over blood, including the following:

1. Collection is undemanding[6]. Saliva can be self collected while blood sample collection requires trained professional[6].
2. The procedure is noninvasive.In patients who are reluctant for repeated blood drawings and biopsies saliva sample procurement is advantageous. It is painless and does not cause any discomfort while encourages others to participate in timely medical evaluations and screenings[6].
3. Samples are safer to handle. Salivary secretions contain factors that inhibit the infectivity of HIV, resulting in extremely low or negligible rates of oral transmission[6].
4. salivary samples can be easily store and transported. Saliva does not clot and requires less manipulation than blood[6].
5. The procedure is economical. The easier method of collection and storage decreases overall costs for patients and health care providers[6].

Collection Methods of Saliva: There are various methods for the collection of saliva. It is classified depending on whether the saliva is stimulated or unstimulated. Stimulated saliva involves use of chewing gums to increase masticatory action and the saliva is collected by increasing the salivary flow [1]. This method is used only in patients who are unable to produce adequate quantities of saliva as collection of saliva through this method causes a change in the quantity as well as the pH of the saliva [1]. Unstimulated saliva is collected without exogenous facilitation, and its flow rate is mostly affected by the degree of hydration. Draining, spitting and suctioning are the three common methods of approach to collect unstimulated saliva. The oral cavity of the subject is cleaned and rinsed thoroughly before collection of saliva to ensure that any contamination is avoided [1].

Autoimmune Disorder: Sjogren syndrome is a chronic autoimmune disorder characterized by salivary and lacrimal gland dysfunction, serological abnormalities and multiple organ system changes[1].According to the studies and researches conducted an significant increase in levels of salivary IL-2 and IL-6 concentrations are elevated in sjogren syndrome patient[1]. Also an alteration in cytokine profiles is seen which is useful both in diagnosis and prognosis of the disease[1].Salivary protein analysis demonstrated an increased level of lactoferrin, beta 2 microglobulin, lysozyme C, and cystatin C. However,a significant decrease in the levels of salivary amylase and carbonic anhydrase were observed[2]. Rapid concentrations of NaCl, Ig A, Ig G, lactoferrin, inflammatory mediators such as PGE2, TXB2, Interleukin-6 were also observed in saliva of patients with Sjogren syndrome[4].

Multiple sclerosis(MS) is an inflammatory disease characterized by loss of myelin and scarring caused due to destruction/failure of myelin producing cells by the immune system[2]. In patients suffering from multiple sclerosis there is an increased production of IgA in the saliva secreted. There is no other significant change observed in salivary diagnostics[2].

Sarcoidosis is an inflammatory disease of the lymph nodes, lungs, liver, eyes, skin, or other tissues. Salivary diagnostics demonstrates a decrease in the secretion[2]. In these patients the activity of the enzyme alpha- amylase is reduced in addition to the volume of saliva secreted. However, there was no correlation between the decrease in the enzyme activity and the secretion volume[2].

Cardiovascular System: Cardiovascular disease is one of the major causes of death world wide[1]. The levels of total serum amylase and salivary amylase have been determined before cardiovascular surgery[1]. In ruptured aortic aneurysm salivary alpha amylase level is increased[1]. Salivary markers like C-reactiveprotein (CRP), myoglobin (MYO), creatininekinasemyocardialband (CKMB), cardiac troponins (cTn), and myeloperoxidase, which, when used in combination with an ECG, shows a positive correlation with myocardial infarct patients[2]. Significantly higher salivary MYO levels are seen within 48hr of onset of chest pain in Acute myocardial infarction patients[2].Salivary concentrations of CRP, TNF-α, and MMP-9 were significantly higher in patients with acute myocardial infarction and the salivary concentrations correlated positively with the serum concentrations[2].

Elevated levels of MMP-8, Lysozyme seen in IMT[6]. Elevated levels of MMP-8 seen in patient who had undergone heart surgery[6].

Endocrinology: The levels of cortisol, dehydroepiandrosterone, estradiol, estriol, and testosterone can be assessed accurately using salivary sample currently as can be assessed using saliva currently. The evaluations of mood and cognitive emotional behaviour, study of child health and development, in considerations of premenstrual depression, screening of cushing's syndrome can be done from the salivary assay. Also to assess ovarian function, to monitor full-term and pre-term neonates and also to evaluate risk for preterm labour and delivery the salivary sample can be used. Measurement of elevated late-night salivary cortisolusually at 2300 to 2400 hours for diagnosis of cushing syndrome can be a very reliable diagnostic tool[2]. However, salivary cortisol measurements for diagnosis of adrenal insufficiency have notyet been established[2]. Also, in diabetes mellitus increased level of Ig A, salivary peroxidase, glucose content, potassium, saliva total protein and amylase are seen[4].

Infectious Diseases:

Viral Disease: Testing for the human immunodeficiency virus is an excellent example of the potential usefulness of saliva in infectious disease diagnosis[1].

In cases of HIV infection Ig A antibodies in saliva are seen [4]. There are also confirmatory tests like western blot technique/polymerase chain reaction which is usually done using saliva for detection of p24 antigens and antibodies which is present against both HIV 1 and HIV 2[4]. Furthermore, in cases of acute hepatitis A and B infection presence of Ig M antibodies in saliva is seen and can be used as diagnostic tool[4].

Bacterial Infection: Helicobacter pylori is a critical pathogen that is seen in patients with peptic ulcer. Saliva can be effectively used to detect this pathogen thereby helping in diagnosis of the bacterial infection[1]. H. Pylori antibodies in saliva may be valuable for predicting risk for gastric adenocarcinoma[1]..H.pylori binds to salivary mucins MUC-4B and MUC 6 secreted by the mucous and serous acinar cells of these mucous salivary glands, respectively[2]. Higher levels of salivary MUC-4B and MUC6 could be used as an indicator for infection with H.pylori[2].

Fungal Infection: Salivary diagnostics can also be used for the detection of oral fungi. The salivary fungal count analysis provides valuable information in cases of oral candidiasis[2]. The alterations in the salivary proteins, like immunoglobulins, Hsp60, calprotectin, histatins, mucins, basic proline rich proteins and peroxidases also have important diagnostic value in these cases[2].

Nephrology: Creatinine concentrations in saliva show a high sensitivity and specificity for determining the presence of renal disease[1].Cortisol, nitrite, uric acid, sodium, chloride, amylase and lactoferrin are the salivary biomarkers which are usually associated with renal diseases [4]. These biomarkers are usually seen at the end stage of renal diseases[4]. The salivary phosphate levels are higher in patients undergoing hemodialysis and chronic renal failure as compared to normal healthy individuals[4].salivary phosphate levels serve as a better tool in diagnosis of chronic renal failure and hemodialysis than serum phosphate level[4].

Oncology: Allelic loss on chromosome 9p has been observed in Oral squamous cell carcinoma[1].Mitochondrial DNA mutations have also been useful targets to detect exfoliated oral squamous cell carcinoma cells in saliva[1]. Using plaque hybridization, tumor specific p43 mutation are identified from patient with head and neck cancer[1]. In patients with poor prognosis in OSCC Cyclin D1 gene amplification has been found to be associated [1].In patients with small cell lung cancer Microsatellite alterations of DNA were also observed in the saliva [1]. The presence of HPV (human papilloma virus) and Epstein Barr virus genomic sequences have been identified as possible DNA molecular markers in detecting OSCC and tumor progression[1].Interleukin -8 was detected at higher concentrations in saliva[1]. Higher levels of Salivary kallikrein is seen in malignant tumors when comparedtoa patient diagnosed with benign tumor[1].

Early detection is the key to good prognosis in almost all types of cancer. Saliva has been used as a diagnostic medium for oral squamous cell carcinoma (OSCC), and salivary analytes such as proteins, mRNA, and DNA have been used in their diagnosis[2].CA14-3 tumor marker was found in the saliva of women diagnosed with breast cancer[2].Inpatients with oral,breast, and ovarian tumors CA124 is a tumor associated antigen which is found to be elevated in the serum and saliva [2].Fibroblast growth factor 2 (FGF2) and fibroblast growth factorreceptor1 (FGFR1) concentrations in saliva are significantly

elevated in patients with salivary gland tumors making it a potential biomarker in the early detection of salivary gland tumors. Prostate specific antigen is a marker for prostate adenocarcinoma[2]. p43 antibody which can be detected in oral squamous cell carcinoma, high level of salivary kallikrein in oral malignant tumors and Ca-124, a glycoprotein for ovarian cancer[3].

Dental Caries and Periodontal Disease: The levels of oral bacteria in saliva can be used to detect periodontal diseases. The increased numbers of Streptococcus mutans and lactobacilli in saliva have been associated with increased caries prevalence and root caries. Increased levels of aspartate aminotransferase (AST) and alkaline phosphatase (ALP) have been associated with periodontal diseases. Salivary AST can be used as a marker for monitoring periodontal disease. Lower levels of uric acid and albumin in the saliva were associated with periodontitis and diabetes. This could be attributed to the oxidative stress present in the oral cavity during these conditions [2].

Conclusion

The different biomarkers which are present in the saliva thus help the health professional to diagnose not only oral diseases but also systemic diseases and conditions at an earlier stage. Saliva gives an alternative to serum as a biological fluid that can be analysed. This review suggest that certain diagnostic uses of saliva hold considerable promise in future.

Child Abuse-Dentist Perspective

Nishanth G.[1], Aravindha Babu N[2], E. Rajesh[3], K. M. K. Masthan[4]

[1]Post Graduate Student, [2]Professor, [3]Reader, [4]Professor and Head of the Department, Department of Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

Child abuse is characterized as those demonstrations or oversights of consideration that deny a kid from the chance to completely build up his or her one of a kind possibilities as an individual either physically, socially or emotionally. The overall incidence of child abuse is not so clear. Measurable information don't demonstrate the genuine rate due to the unreported cases. Physicians has minimal training in oral health, dental injury and disease and thus may not detect dental aspects of abuse or neglect as readily as they do child abuse and neglect involving other areas of the body. Therefore, physicians and dentists should collaborate to increase the prevention, detection, and treatment of these conditions. Dentists with expertise in child abuse will strengthen their ability to prevent and detect child abuse and neglect and enhance the ability to care for and protect children.

Keywords: *Child abuse, Injuries, Dentist, Neglect*

Introduction

Child abuse is characterized as those demonstrations or oversights of consideration that deny a kid from the chance to completely build up his or her one of a kind possibilities as an individual either physically, socially or emotionally [1]. As per the definition given by The Child Abuse Prevention and Treatment Act (CAPTA), violence can be physical and mental abuse and injury, neglect or negligent treatment, exploitation and sexual abuse Violence may take place in homes, schools, orphanages, residential care facilities, on the streets, in the workplace, in prisons and in places of detention. Such violence can affect the normal development of a child impairing their mental, physical and social being. In extreme cases abuse of a child can result in death [2].

Problems- India and Worldwide: In India largest number of children (375 million) in the world, nearly 40% of its population. 69% of Indian children are victims of physical, emotional, or sexual abuse (or read it as every 2 out of 3). New Delhi, the Nation's capital, has an over 83% abuse rate. 89% of the crimes are perpetrated by family members. Boys face more abuse (>72%) than girls (65%). More than 70% of cases go unreported and unshared even with parents/family [3]. Nearly five children die every day in America from abuse and neglect [4]. In 2010, an estimated 1,560 children died from abuse and neglect in the United States [5]. Children's Advocacy Centre around the country served over 266,000 child victims of abuse, providing victim advocacy and support to these children and their families in the same year. In 2011, this number was over 279,000 [6].

Causes: There are many interacting causes of child abuse and neglect. It can depends upon characteristics or circumstances of the abuser, the child, and the family may all contribute. Probably in many cases the abuser himself/herself was abused. The key factor in a growing number of cases is because of substance abuse. In many cases abusers do not have the knowledge and skills needed to raise a child, thus increasing of abuse, and providing inadequate parental role models for the

child. Children who are low birth weight, ill, disabled, or otherwise perceived as different are more likely to be the targets of abuse[3]

Types and Dental Aspects:

Physical Abuse: Physical abuse is a physical injury experienced by children, which is not caused by accidents [7]. Intraoral examination on oropharynx include examination on frenulum, gingival, soft and hard palate, tongue, sublingual region, buccal mucosa and posterior pharynx to notice every signs of trauma. Physical abuse such as trauma caused by tableware, hand, fingers, blunt instruments or caustic substance. The violent activities can caused contusion, laceration and bruise on the tongue, buccal mucosa, palate, gingival mucosa or frenulum, dental or avulsion fracture, facial and jaw fracture, burn, and other kinds of injuries. Besides, trauma in oral cavity, tongue, palate and frenulum, blunt trauma on the teeth and facial bone and jaw bone fracture can be caused by repetitive trauma [8]. Wound, bleeding, erythema, or swollen outer ear canal, broken lips, unstable teeth or fractured teeth, tongue laceration and blue eyes without trauma on the nose indicates physical abuse [9].

Sexual Abuse: Sexual abuse means every sexual act between older person and the child. The acts can be called sexual abuse if the child's caregiver, family members, father, mother, nanny, or teacher, either at home or outside the child's house. If others participated in that kind of action, the action is called sexual assault [7]. Oral cavity is one of the areas of sexual maltreatment frequently found in kids. The presence of gonorrhea or syphilis in the oral or perioral areas in prepubertal youngsters is one of the indications of sexual maltreatment. Bond recognition in the kid's oral depression can be performed in a couple of days time span after the maltreatment. Along these lines, during an examination towards a youngster who is associated as an injured individual with sexual maltreatment, cotton swab ought to be performed to get the buccal mucosa and tongue smear. Erythema or petechiae palatum, particularly in the intersection among delicate and hard sense of taste can turn into a proof of constrained oral sex activity. Another oral injury can be found as condylomata acuminate [10]. Bite marks are important in one of several visual expressions of active child abuse [8]. The spacing in human nibbles is regularly 2.5 to 4 cm, which is the separation between the upper canines. In the event that the intercanines separation is under 2.5 cm, the opportunity of the age is that the nibble is brought about by youngsters. In the event that the separation is 2.5 to 3 cm, the nibble is brought about by a youngster, and if it's in excess of 3 cm, it is brought about by a grown-up chomp [10].

Emotional Abuse: Emotional maltreatment is characterized as each demeanor or practices that can bother emotional wellness or social improvement of a Child. Different names for psychological mistreatment are verbal maltreatment, mental maltreatment, or mental abuse. Psychological mistreatment quite often happens together with different types of maltreatment [11]. Psychological maltreatment does not leave injury signs on the tyke's body, however it leaves mental injury on the kid. The youngsters become terrified of everything, impassive discouraged, experience fixation issue, or uprisings. On the off chance that this circumstance props up on, it can make genuine conduct issue, intellectual issue, enthusiastic or mental issue for the kids. Dental specialist ought to have the option to perceive signs in youngsters who is the casualty of psychological mistreatment and apply suitable new approaches [11].

Neglect: Neglect is a ignorance towards the youngster either through sustaining, regulating, care, and training that can caused ruinous impact on the tyke's physical condition and his/her mental improvement [12]. There are 3 kinds of neglect; physically neglect, educational neglect, and emotional neglect[11]. In the dentistry territory, a dental negelct is additionally perceived as a piece of physically neglect [10].

Dental neglect, as characterized by American Academy of Pediatric Dentistry, is deliberate disregard by the guardians or parental figure towards the kid's oral depression and dental wellbeing or a disregard that forestall the tyke to get dental and oral treatment required by the youngster so as to accomplish oral wellbeing level required for satisfactory capacity [10]. Dental disregard can be viewed as the presence of caries, periodontal sickness, and other oral cavity ailments [10,13]. Caries, periodontal sicknesses and other oral condition, if not treated, can prompt torment, disease, and loss of oral capacity that can influence correspondence, nourishment, learning exercises and other youngsters exercises required for typical development and improvement. Inability to get great dental treatment can be brought about by different factors, for example, family seclusion, poor money related status, parent's disregard

and absence of thankfulness towards oral wellbeing esteem. The time when to consider a parent careless and to start intercession happens after the parent has been appropriately alarmed by a human services proficient about the nature and degree of the youngster's condition, the particular treatment required, and the instrument of getting to that treatment [10]. The dental specialist ought to be sure that the parental figures comprehend the clarification of the illness and its suggestions and, when obstructions to the required consideration exist, endeavor to help the families in discovering monetary guide, transportation, or open offices for required administration. Parent is ought to be consoled that suitable pain relieving and sedative methodology will be utilized to guarantee the tyke's solace during dental systems. On the off chance that, notwithstanding these endeavors the parent is neglect to get treatment, the case ought to be accounted for to proper kid defensive administrations [14].

Prevention: Children are a country's people to come. Along these lines, it ought to be avoided on the grounds that it can influence the long life procedure of a child [12]. In Indonesia, dental specialist's power to report child abuse has not been directed in a law or guideline. Notwithstanding, counteractive action and the executives of maltreatment and brutality towards youngsters is a genuine issue that should to be followed up on quickly by every single related gathering, including the guardians, teachers, law power, security power, broad communications and wellbeing administration [12]. They are required to report it to social administration or law authorization organizations [15]. Doctors get negligible preparing in oral wellbeing and dental damage and dental ailment, along these lines may not identify dental parts of kid maltreatment as different territories of the body. Hence, doctors and dental specialists has to work together to build the counteractive action, discovery, and treatment of this conditions [16,17,18]. In Indonesia, there is no such activity yet. The dental specialist learning and aptitude in overseeing tyke misuse has not been completely picked up. Along these lines, youngster misuse and scientific dentistry educational plan ought to get a spot in the instruction program. Child abuse comprises of every awful treatment followed up on a kid by the guardians, parental figures or other individual/s who ought to give care and security for the kids. This can be found in every single social class and can be brought about by different triggers. The long haul impacts of incessant presentation to abusive behavior at home and it might influence a youngster's general improvement. Social, psychological, and enthusiastic improvement might be adversely affected.

Conclusion

The investigation recommend that dentists has a role in recognizing, overseeing, helping and treating these exploited people since the wounds are regularly found in the oral and facial zones. Other than overseeing such cases, dental specialist likewise has a role in anticipating child abuse since it can influence the future existence of the kids. Such abilities will upgrade the capacity to mind and secure youngsters.

Comparison of Cystic Content of Odontogenic Cysts

Nishanth G.[1], Aravindha Babu N[2], N. Anitha[3], K. M. K. Masthan[4]

[1]Post Graduate Student, [2]Professor, [3]Reader, [4]Professor and Head of the Department, Department of Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

The cystic lesions that affect the oral and maxillofacial region are predominantly odontogenic in origin. The odontogenic cell rests entangled within tissue of the jaws such as cell rests of Malassez, cell rests of serre, and enamel organ leads to its formation. The factors leading to the enlargement of these jaw cysts are increased the permeability of cyst wall, increased the protein content of the cyst fluid, and when the intracystic fluid pressure on the jaw bone is increased. This review is an attempt to analyze and compare the components of cystic fluids such as albumin, prealbumin, globulin, and total protein content among various odontogenic cysts.

Keywords: *Odontogenic cysts, Rushton bodies, Keratin*

Introduction

The odontogenic cystic lesions incorporate inflammatory cyst such as, radicular cyst, developmental cyst for example, dentigerous cyst and, benign tumors like odontogenic keratocyst. Clinical and radiologic files are frequently lacking to separate dependably among these conceivable outcomes. Most of these growths are distinguished unexpectedly when radiologic imaging is performed for unrelated indications. Examination of substance of cystic liquids may help in a precise determination at whatever point a growth is recognized before careful extraction or conservative management. This survey is an endeavor to give a review of different odontogenic cysts and to discuss the values of protein which is present.

Review of Literature: The odontogenic keratocyst (OKC) was first presented as a different pathologic element by Philipsen in 1956. Different examinations have revealed that 11.25% of all odontogenic cysts are OKC and are viewed as formative in origin.[1,2] Their pathognomonic microscopic features, conceivably forceful clinical conduct, and high repeat rate make them a remarkable substance among odontogenic sores. The WHO (2005) renamed the lesions as a tumor and included it in the gathering of benign odontogenic tumors got from odontogenic epithelium with mature fibrous stroma without odontogenic ectomesenchyme. [2] The immunohistochemical articulation of P53, Ki 67, multiplying cell atomic antigen is higher in keratocystic odontogenic tumors than in different sorts of odontogenic cysts.[1,2] The cystic covering is contained the parakeratinized stratified squamous epithelium. In certain sores, folded surface epithelium can be seen.

The most widely recognized developmental odontogenic cyst is the dentigerous cyst. The growth encases the crown of an unerupted tooth by the extension of its follicle because of a gathering of cystic liquid. The definite pathogenesis of dentigerous cyst is unknown and most authors favours developmental origin. It possesses the crown of an unerupted or supernumerary tooth by the extension of its follicle and is appended to its neck. Infinitesimally, the dentigerous cyst covering looks like reduced enamel epithelium and comprises of flat, cuboidal cells 3-5 cell layer thickness. Mucous-secreting cells might be available in the epithelium.[3]

The most widely recognized odontogenic cyst is the radicular cyst. Radicular cyst make around 52-68% of all cysts affecting the human jaws.[1,4] The cystic coating of radicular cyst is contained non-keratinized stratified squamous epithelium which of a few layers in thickness. The epithelial linings might multiply and indicate arcading pattern with an intense inflammatory cell infiltrate. The inflammatory cell infiltrate in the proliferating epithelial linings is predominantly polymorphonuclear neutrophils leukocytes, whereas adjacent fibrous capsule is infiltrated mainly chronic inflammatory cell infiltrate. Rushton bodies are portrayed by a shiny pink (hyalinized appearance) in around 10% of the radicular growths. These hyaline bodies are accepted to be because of the past discharge inside the aroused blister wall.[4]

Biochemical Investigation: The cystic content in radicular cyst is typically dark in color. The presence of cholesterol crystals gives a shining gold or straw shading. Yellow mural nodules of cholesterols may extend into the cavity. Complete protein substance is ordinarily somewhere in the range of 5 and 11 g/100 ml.[9,13] The cystic liquid of dentigerous cyst is straw colored liquid. The content in the dentigerous cyst is normally 4-8 g/100 ml.[3] Dirty white cheesy material was found on aspiration in every one of the instances of OKC. Keratin squames are generally found in the aspirated cystic liquid. Electrophoretic investigation uncovered that the proportion of dissolvable protein to add up to protein substance was lower than that in serum. Absolute protein substance is <5 g/100 ml.[6-8]

Discourse: The substance of odontogenic cyst are variable from clear yellow fluid to a semisolid cheese like mass.[8-10] The odontogenic cyst fluid can be read for their shading, consistency, nearness of cholesterol precious stones, keratin specks, and various protein parts.[11] Electrophoresis isolates proteins dependent on their physical properties. The movement of charged particles through an electrolyte subjected to an electric field is called electrophoresis. The surface charge for various plasma proteins vary. They migrate at different rates from the point of application of the protein mixture to the other end of the cellulose acetate membrane (CAM) strip.[14,15] Scanning of the stained CAM strips by densitometer or elution can be done for the quantitative estimation of protein fractions. Phosphomolybdate methodology can be used for determining inorganic phosphorus level, and total protein estimation can be done by Biuret method. Centrifuge the cystic content at 2000 rev/min for 5 min to remove cell debris and deposits. The supernatant cystic fluid thus collected can be analyzed for their protein contents by CAM electrophoresis. The protein content and different fractions can be quantitated by scanning the CAM strips in a densitometer at 590 mm (green filter) and the relative percentage, and absolute value. Toller has suggested that these proteins are transported to the cystic fluid by immunoglobulin (Ig) producing cells. Syringe aspiration is positive for almost all odontogenic cysts Fine-needle aspiration cytology is the technique commonly used for pre-operative diagnosis which is mandatory in diagnosis. The aspirates taken from cystic lesions are less cellular.[16] Smith et al. in their study showed that most cysts contains higher molecular weight proteins and the passage of lactoferrin into the cystic lumen is by increased epithelial permeability together with discontinuities in the epithelial lining and intraepithelial channels.[17]

Conclusion

In this review, we have discussed the composition and components of various odontogenic cyst fluids including OKC, dentigerous cyst, and radicular cyst. Diagnosing them before surgery will lead us to determine surgical procedures and conservative for preventing the recurrence of the cyst. In OKC, the total soluble protein content notably lower compared to dentigerous and radicular cyst. Thus, we conclude that it is mandatory to evaluate the clinical, radiological, and biochemical findings with histopathological features of cystic lesions for proper diagnosis and management.

A Review on Effects of Alcohol in Oral Diseases

E. Rajesh[1], Sangeetha Priya P[2], N. Aravindha Babu[3], K. M. K. Masthan[4]

[1]Reader, [2]Post Graduate Student, [3]Professor, [4]Professor and Head of the Department, Department of Oral Pathology and Microbiology Sree Balaji Dental College and Hospital Bharath Institute of Higher Education and Research

ABSTRACT

These days, consuming alcohol is a common feature among all regional population irrespective of age and gender. However, the drinking alcohol is associated with a risk of adverse health and social effects, consumption of alcohol inevitably affects the oral cavity, oral mucosa and teeth. Literature indicates that alcohol dependents may have increased risk of dental caries, probing pocket depth and mucosal lesions related to its intoxicating, toxic and dependence-producing properties. Hence, a short review has been attempted to evaluate the effect of alcohol on oral health.

Keywords: *Alcohol, Diseases, Periodontitis*

Introduction

The World Health Organization (WHO) estimates that excessive alcohol consumption is the third largest life style risk factor in the developed world. Chronic alcohol abuse produces toxic effects on several organs and apparatus, including mouth and dental system. [1,2]. They are at high risk of developing dental caries, gingival diseases and may suffer from oro-pharyngeal cancers. The risk of oral cancer further increases when alcohol is consumed along with cigarette.

Effect of Alcohol on Saliva and Associated Dental Hard Tissue Changes: The Ethanol diffuses rapidly into saliva during alcohol consumption. Within 30 minutes, salivary ethanol concentration balances with that of the plasma level, thus suggesting that ethanol easily penetrates the whole body, including oral cavity tissue and salivary gland. Salivary glands, more commonly parotid glands, become affected in long term alcohol drinkers. Resulting in sialadenosis and it is also associated with ethanol induced peripheral neuropathy which causes disturbances in the metabolism and excretion of saliva from the salivary glands [3].

Dental caries as a cause of Alcohol consumption: Reduced salivary secretion along with diminished buffering capacity, acidic nature, less attention to oral hygiene and intake of sugared drinks,carbohydrate rich food and cariogenic food leads to decrease in salivary pH below critical level there by causing increased risk of dental caries.[4] Alcohol consumption also increases the Blood Lead Levels (BLLs) in humans and BLLs have been correlated with dental caries. These patients had a permanent tooth loss three times higher than the national average for corresponding ages. Another study conducted by Marc Niquille et al. on alcoholic and non-alcoholic subjects showed positive association between alcoholism and dental caries (crude odds ratio, 2.24; 95% CI, 1.15-4.31) [5].

Dental Erosion: Regular and prolonged consumption of acidic drinks such as alcohol, wine makes oral cavity as well as the teeth surface acidic in nature which increases the risk of developing dental erosion. This is because alcohol consumption has the potential for high degradation rate mechanisms and by the direct and indirect ethanol effects in the organic systems. This acidification dissolves surface enamel and makes teeth surfaces more vulnerable to mechanical damage due to

Email: rajeshomfp@gmail.com

tooth-brushing, teeth clenching, etc. Most commonly affected tooth surfaces due to erosion are palatal surfaces of upper teeth followed by occlusal surfaces of posterior teeth. The lower teeth and buccal surfaces of the upper teeth are least affected by erosion.[6]

Effcts of Alcohol on Oral Soft Tissue and Mucosa: Damage to the oral tissues seems to be ascribed mostly to the action of acetaldehyde, although some acute effects depend on a direct action of ethanol and formation of reactive oxygen(ROS) and fatty acid ethyl esters(FAEEs). It is know that the oral mucosal surface is the home of numerous normal flora microorganisms and is the portal of entry for the majority of pathogens.

Periondontal conditions: Alcoholics have severe risk of developing chronic generalized periodontitis associated with gingival inflammation, blunting of the interdental papillae and deep pockets with related bone loss. Alcoholic patient more frequently suffer from horizontal bone loss and calculus deposition compared to non-alcoholics.

Changes in tongue: Besides direct harmful effects on oral health, alcoholics suffer from a number of indirect effects which manifest as a result of lack of adequate nutrition. The most common effects are tongue inflammation (glossitis), inflammation of corner of mouth (angular cheilitis). Early stages of glossitis show painful and smooth tongue, but sometimes show swollen fungiform papillae. Alcoholics taking disulfiram may have changed taste sensation, most commonly a metallic taste. In later stages, tongue suffers from burning sensation and becomes intensely red followed by atrophy of filiform and fungiform papillae. Angular cheilitis results in development of painful cracks at the corners of the mouth.[7]

Mucosal Changes: Dehydrating effect of alcohol on cell walls enhances mucosal permeability to other toxins and carcinogens which leads to various malignant and premalignant lesions. Change in mucosal morphology with a reduction in epithelial thickness are evident among patients who are chronic alcoholic. The metabolism of ethanol produces acetaldehyde which causes damages to DNA of oral epithelial cells and oncogene expression of oral keratinocytes which increases the risk of Oral Carcinomas along with other causative factors. And as mentioned before, ethanol disrupts salivary gland function by reducing secretion of epidermal growth factor which protects oral mucosa from injuries caused due to acids which results in increase in the risk of oral mucosal ulcerations. Nutritional deficiencies associated with heavy drinking can lower the body's natural ability to use antioxidants to prevent the formation of Oral lesions.[8]

Conclusion

High consumption of alcohol manifests in severe impact on oral health. However there is a proven fact alcohol drinking provides synergistic interaction along with tobacco for the increased risk of cancer, the role of Chronic alcoholism in the development of oral cancer has equal impact. Some of the systemic diseases associated with alcohol consumption may indirectly affect the oral health. There are cases of missing teeth due periodontitis associated with alcohol consumption, tooth erosion due to gastric reflux, stomatitis caused by deficiency of several micro-nutrients, etc. Harmful impact of alcohol on oral cavity includes formation of dental caries, oral cancer, etc. The high concentration of organic and inorganic acids in alcohol and the practice of keeping the alcohol in the mouth can result in chronic inflammations of the soft tissues and can increase the negative side effects from metals of crowns, bridges, orthodontic devises and various metal restorations.

Grossing—A Review on Stepwise Procedures

L. Malathi[1], N. Aravindha Babu[2], Sangeetha Priya P.[3], K. M. K. Masthan[4]

[1]Reader, [2]Professor, [3]Post Graduate Student, [4]Professor and Head of the Department, Department of Oral Pathology and Microbiology Sree Balaji Dental College and Hospital Bharath Institute of Higher Education and Research

ABSTRACT

The initial dissection and preparation of any specimen for histological or microscopic analysis involves more than simply the transcribed macroscopic description and sampling of the specimen. Grossing is a gross examination of surgical specimens in which pathologists inspect the excised specimen with the bare eye to obtain diagnostic information. Grossing of surgical pathology specimens isthe first and an important step in tissue processing, leading to diagnosis. It forms a connecting link between the patient and the pathologist. A correct grossing procedure helps in minimizing the processing errors while at the same time providing useful information about the specimen helping in the achievement of correct diagnosis. The purpose of this short review is to provide adequate insight about the grossing procedure of the pathologic specimens of the head and neck region and to emphasize the importance of grossing in diagnostic oral pathology and provide guidelines to carry out the procedure in a sequential order.

Keywords: *Grossing, Fixative, Specimen, Diagnosis*

Introduction

This dissection/blocking/cut-up are the other terms used for grossing.[1] "Grossing"—the word refers to the detailed examination and the systematic dissection of surgical specimens in order to obtain tissue sections, which facilitate microscopic examination. An accurate diagnosis from this tissue is dependent upon correct identification, handling, and processing of the specimen. It is the first step and it is generally performed by any trained person. The gross room is the area where pathology specimens are transferred for pathological review and analysis. [2]

Procedures to be Followed During Grossing:

1. Identification and Labelling the specimen
2. Requisition form to be filled with complete data
3. Fixation of the specimen
4. Specimen photography and radiography
5. Grossing description to be noted
6. Examination of the specimen
7. Sectioning of the specimen
8. Description on sectioning details to be noted
9. Inking
10. Labelling of the cassettes.

Identification and Labelling the Specimen: Specimen identification and labeling are important steps before proceeding with the grossing procedures. The basic identification of the specimen include the type of biopsy and the type of the specimen. After the initial identification each patient and tissue is labelled with unique accession numbers which is usually specific for different institutions and laboratories. [3] The labelling procedure should include the specimen's unique number

along with the date and time of the specimen being received. These labels must be consistent and should be on the container so that the labels cannot be separated from the specimen.[4]

Requisition Form to be Filled with Complete Data: The requisition form is probably the most important bit of document in the preanalytical phase of surgical pathology reporting, and there are serious risks of errors being made in this document. Each specimen container should include the patient's name with age (birth date) and a medical record number along with matching paperwork that is a surgical request form. The surgical request form provides the actual request for pathological services and the required relevant clinical history of the patient. Any discrepancies in specimen identification/ labeling (e.g., a medical record number that does not match the patient name or a surgical request form which does not match the specimen) must be resolved with the clinician/surgeon before processing any specimen, and the discrepancy should be noted on the request form. Misidentification of any specimen can result in failure to make a proper diagnosis on one or more patients, incorrect treatment, and possibly legal action.[5,6]

Fixation of the Specimen: Specimen being received most often may not be be stored in a proper fixative medium, this has to be checked at the time of receiving the specimen and to be transferred immediately into 10% neutral buffered formalin which is the most common fixative used for tissues submitted for routine examination including tooth specimen. However, mineralized samples such as bone or tooth may require decalcification before it can be processed.[7] To facilitate uniform penetration of fixative, it is important to fix small volumes of tissues (5 mm to 1 cm). The volume of the fixative should be in excess of 20 times the volume of the tissue. In practice, it is assumed that these processes require at least 1 hour per mm of tissue thickness, but routinely the tissues are fixed for 24 to 48 hours. It may be necessary to replace the fixative with fresh solution when the specimen contains high percentage of blood. Covering large specimens with fixative soaked gauze or cloth may help penetration and reduces surface drying.[8,9]

Specimen Photography and Radiography: Photographs of fresh or fixed anatomic pathology specimens are obtained to aid in the documenting of pathologic lesions. They can be used in teaching, conference presentations, and publishing. Before photographing, the tissue must be prepared by washing to remove blood, blood clots and fat, opening the ducts and vessels, and removing other unnecessary tissues around the lesion. The background should be spotlessly clean with no texture and should be well illuminated. A clean ruler with metric system should be used for obtaining a reference to size. The specimen should be properly oriented in the anatomical position and centered. Radiographic examination of surgical specimens sometimes provides important information. Specimens suitable for this type of examination include bone lesions, calcified soft-tissue masses, and lesions with embedded tooth radiopaque foreign bodies such as metal clip.[10,11,12]

Grossing Description to be Noted: The gross description is an important integral part of macroscopic surgical pathology. The reader should be able to correlate the patient, the specimen, and the structures present with this description. After a generic description of the specimen, characteristics, such as size, number, color, shape, consistency, and weight of the specimen should be recorded correctly.[2] For an appropriate description of the grossing specimen, required measuring instruments are to be used such as a metal scale with clear markings, a divider, vernier calliper, digital weighing scale, and a magnifying glass to look for detailed specifications such as the surface texture of the specimen. These grossing description are to be noted as a attached copy along with the specimen's requisition form. This is a very important piece of information, which communicates to the diagnosing pathologist each slide in perspective to its actual location in the gross specimen.

Examination of the Specimen: The specimen has to visually and manually examined before it to be sliced. On palpating the specimen, the colour is noted visually and the consistency of it is felt which provides differential diagnosis regarding the interpretation.

Sectioning of the Specimen: This step include sectioning/slicing of the specimen using a sharp blade or knife[13]

Parallel cut	Longitudinal section
Perpendicular cut	Cross section
Cut at any angle between these two planes	Oblique section
Procedure to only graze the surface	Grazing section / tangential section

In some cases, the internal microscopic structure of parts of the body is so complicated that it can only be understood by mounting photographic enlargements of serial (consecutive) sections on the material of appropriate thickness and assembling them in a proper order to constitute large reconstruction.

Description OS the Sectioning Details: The original image of the specimen should be diagrammatically represented beside the grossing description and once the sectioning of the specimen is done, the angle at which the specimen was sliced has to marked over the diagrammatic picture. This is done in order to know the sectioning pattern at the time of microscopic evaluation of the slide of that particular specimen.

The second detail to be noted is the number of tissue bits that have been retained or embedded. This help in having an idea regarding the number of tissue bits retained so as to process the retained tissue if in case the first embedded tissue have some issues at the time of processing, sectioning of the embedded tissue or while staining.

Inking: Inking is most commonly used to indicate or mark the margins of an excision. Alternatively, it can also be used for indication of areas of interest and also to aid in orientation of the specimen during embedding. Usually, the unstained area is placed down in an embedding mold.[14,15]

Labelling of the Cassettes: This this the final step of Grossing, once sectioned specimen is inked, it is been placed with the cassettes for next procedure called as the tissue processing. There are various sizes of cassettes available which are chose according to the size of the cut specimen. Before the cut specimen is placed within the cassette, the specific specimen number/the biopsy number mentioned on the specimen bottle or the requisition form to be transferred on to the cassette. This is done to avoid confusions on processing different patient's biopsy specimens.

Conclusion

Like all skills, grossing is a skill that will develop in individuals over a period of time; however, skills cannot be gained in the absence of knowledge and efforts. Simple steps, such as observation of as many grossing procedures as possible, and bringing about a correlation between macroscopy and microscopy will help accelerate the learning. Gross examination of pathology tissue specimens forms an important part in reaching at a correct diagnosis. Accurate gross description and observation of the pathology specimen can give many clues to aid in final diagnosis. The final report must include macroscopic and microscopic findings along with the final diagnosis. Thus, it is imperative for the pathologist to undertake this step meticulously.

Oral Mucoadhesive Drug Administration—A Short Review

Sangeetha Priya P.[1], N. Aravindha Babu[2], Sangeetha Priya P.[3], N. Anitha[4], K. M. K. Masthan[5]

[1]Post Graduate Student, [2]Professor, [3]Post Graduate Student, [4]Reader, [5]Professor and Head of the Department, Department of Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

On focus with route of drug administration, the oral cavity is an attractive and the safest site for the delivery of drugs. As an advantage it can overcome acidic environment thereby causing instability of the drug, extensive first pass metabolism and low bioavailability of drug results an inadequate absorption. The buccal mucosa is rich in blood supply and relatively permeable. Buccal cavity was found to be most accessible site for both local and systemic delivery of drug. This review presents a brief description of advantages and limitations of oral mucosal drug delivery, mechanisms of drug permeation followed by current developments in this drug delivery systems.

Keywords: *Drug, Buccal, Sublingual.*

Introduction

The oral route of drug administration is the most common(90% of drugs used) and preferred method to produce systemic pharmacological effect among various other routes. Oral route in which the drug is swallowed and enters the systemic circulation primarily through the membrane of the small intestine. The main advantage of this system is the self– administration of medication. Absorption of drugs after oral administration may occur at the various body sites between the mouth and rectum. A drug taken orally must withstand large fluctuation in pH as it travels along the gastrointestinal tract, as well as resist the enzymes that digest food and metabolism by micro flora of the digestive tract. [1]

It is estimated that 25% of the population finds it difficult to swallow tablets and capsules and therefore do not take their medication as prescribed by their doctor resulting in high incidence of non-compliance and ineffective therapy. Difficulty is experienced in particular by pediatrics and geriatric patients, to people who are ill bedridden and to those active working patient who are busy or travelling, especially those who have no access to water to consume the drugs orally.[2] In these cases oral mucosal drug delivery is most preferred. It has been known for centuries that buccal and sublingual administration drug are rapidly absorbed.

Buccal/sublingual administration drug

↓

Absorbed into the reticular vein

↓

Transported through the facial vein

↓

Then via the internal jugular vein and braciocephatic vein

↓

Finally drains into the systemic circulation [2,3]

Therefore the buccal and sublingual routes of administration can be utilized to bypass the hepatic first-pass elimination of drugs. The buccal region offers

an attractive route of administration for systemic drug delivery as they have a rich blood supply and it is relatively permeable and have fast onset of action.

Oral Mucous Membrane: The Oral cavity lined with mucous membranes which includes the floor of mouth (sublingual), the buccal mucosa (cheeks), the gums (gingiva), the palatal mucosa and the lining of the lips. The oral mucosal tissues consist of a multi- layered epithelium enclosed with mucus. The epithelial layers are

Stratum basale

Stratum spinosum

Stratum granulosum

Stratum corneum

The basal lamina attaches the epithelium to a connective tissue layer (lamina propria).The oral mucosa protects the body from external influences. The epithelium of the human oral mucosa shows several distinct patterns of maturation, related to the functional demands of the tissue. Keratinized epithelium (dehydrated, mechanically tough and chemically resistant) is found in the less flexible masticatory mucosa of the gingiva and part of the hard palate. [5,6]Non- keratinized epithelium (flexible) forms the surface of the distensible lining mucosa of the soft palate, floor of mouth, lips and cheek. The oral mucosa mainly composed of three layers. The outermost is stratified squamous epithelium act as barrier which protects underlying tissues; intermediate lamina propria serves mechanical support and followed by innermost layer submucosa. The epithelium of the buccal mucosa is about 40-50 cell layers thick, when compared with sublingual epithelium. The turnover period for the buccal epithelium has been found at 5-6 days, and this is representative of the oral mucosa as a whole.

The oral mucosa in general is a somewhat leaky epithelium intermediate between that of the epidermis and intestinal mucosa, whose estimated permeability is 4–4000 times greater than that of the skin. In general, the permeability of the oral mucosa decreases in the order of sublingual greater than buccal, and buccal greater than palatal. [7]

Mucoadhesion: Mucoadhesion or bioadhesion is defined as the attachment of synthetic or biological macromolecules to biological tissue. When it is applied to mucosal epithelium bioadhesive interaction occurs primarily with mucus layer and this is called as mucoadhesion.

Oral Mucosal Route of Drug Absorption: The cellular structure of the oral mucosa suggests that there are two permeability barriers. Since the intercellular spaces and cytoplasm are hydrophilic in character, lipophilic compounds would have low solubility in this environment. On the other hand, the cell membrane is rather lipophilic in nature and hydrophilic solutes will have difficulty permeating the cell membrane due to a low partition coefficient. Therefore, the intercellular spaces act as the major barrier to permeation of lipophilic compounds and the cell membrane acts as the major transport barrier for hydrophilic compounds. Considering the coexistence of the hydrophilic and lipophilic regions in the oral mucosa, drug transport may involve a combination of the paracellular and the transcellular routes. All compounds can use these two routes simultaneously, except that one route is usually preferred over the other depending on the physicochemical properties of the diffusant. [8,9]

Within the oral mucosal cavity, drug delivery is classified into three categories:

1. Sublingual delivery, which is systemic delivery of drugs through the mucosal membranes lining the floor of the mouth
2. Buccal delivery, which is drug administration through the mucosal membranes lining the cheeks (buccal mucosa), and
3. Local delivery, which is drug delivery into the oral cavity. [10]

The selection of one category over another is mainly based on anatomical and permeability differences that exist among the various oral mucosal sites. The sublingual mucosa is relatively permeable, giving rapid absorption and acceptable bioavailability of many drugs, and is convenient, accessible, and generally well accepted. The buccal mucosa is considerably less permeable than the sublingual area, and is generally not able to provide the rapid absorption and good bioavailability seen with sublingual administration. Local delivery to tissues of the oral cavity has a number of applications, including the treatment of toothaches, bacterial and fungal infections, aphthae and dental stomatitis, and the facilitation of tooth movement with the use of prostaglandins. Moreover, there is intra-periodontal pocket drug delivery, which is a special category of local delivery where the drug delivery happens in a specific site, within the periodontal pocket.

Adhesive Tablets: In order to improve the bioavailability of administrated drug in the oral cavity, several bioadhesive tablet systems have been developed in recent years. Adhesive buccal tablets can be applied to different sites in the oral cavity, i.e., the palate, mucosa of the cheek, and between the upper lip and gum. The tablet softens and adheres to the substrate and is retained in position until dissolution and/or release is complete. After a short time the presence of tablet is reported to be no longer noticeable to the patient. The tablet should not be moved about the mouth once in position, since this causes more rapid drug release. The position of successive tablets can be alternated on either side of the mouth. Patients wearing dentures may place the tablet in any comfortable position between the lip and gum. The location of the tablet in the mouth appears to have a great impact on the tolerance and the retention time. Depending on the location, either palatal or gingival, retention times varied from 4–6 h to 7–12 h, respectively. Usually, it is important that excipients of buccal tablets do not cause or stimulate salivation, since in this case a larger fraction of drug may be swallowed rather than becoming bioavailable or being absorbed. Few examples of available adhesive tablets in the market are Nicorette1 (nicotine), Suscard1 (glyceryl trinitrate), and Striant1 (testosterone) [11]

Adhesive Patches: The oral cavity mucosa is an ideal surface for the placement of retentive delivery systems such as patches, since it contains a large expanse of smooth and immobile tissue. Mucoadhesive patches for administration to the mucosa of the oral cavity may have a number of different designs, depending on various considerations, such as the therapeutic aim and the physicochemical and pharmacokinetic properties of the active ingredient. Regarding the therapeutic aim, two different rationales for developing mucosal patches may be considered:

- patches can be intended to deliver a drug to the systemic circulation in a way that is superior to other routes of administration, or
- their purpose may be local therapy of the oral mucosa.

As alternatives for both classes of patches, more conventional dosage forms are available. In the case of locally acting patches, the alternatives most often used today are oral gels, oral liquids, and lozenges. For systemic action, there are a number of dosage forms, including sustained- or controlled-release oral technologies, transdermal patches, and injectable depot formulations. It is necessary for a successful mucosal patch to have clearly defined advantages over alternative products.[12] Oral mucosal patches can be applied directly to the affected mucosal region and have the potential to supply the site of action with effective drug levels and to sustain these levels over a prolonged period of time. In contrast, conventional therapy exposes the affected tissues to the dose for a very short period of time. Thus, the first step in the development of a patch is the selection and characterization of a polymer with appropriate bioadhesive properties and drug release control or of combined polymers in order to obtain both of these properties [13] A suitable oral bioadhesive drug delivery system should be flexible, elastic, soft, adequately strong to withstand breakage due to stress from mouth activities, and possess good bioadhesive properties, so that it can be retained in the oral cavity for the desired duration. Patches should be able to meet these requirements and swell to a certain extent when placed in aqueous medium. [14,15]

Medicated Chewing Gums: Medicated chewing gum is an other alternative for drug delivery system with several advantages including convenience for administration, individually controlled release of active substance and effective buccal drug administration for the treatment of local oral disease and systemic action. Mainly chewing gum is used to promising controlled release drug delivery system. Medicated chewing gums are currently available for pain relief, smoking cessation, travel illness and freshening of breath. A hydrophobic gum was used for the formulation of chewing gum. A new chewing gum device in the form of a three layer tablet has been also developed. In vitro release study of chewing gum requires special apparatus and instrumental setting. [16,17]

Conclusion

The oral mucosa possesses a range of permeabilities and properties. Oral bioadhesive dosage forms have many

advantages over traditional oral dosage forms. Adhesive tablets, unlike conventional tablets, allow drinking and speaking without major discomfort. Drugs with short biological half-lives, requiring a sustained effect and/ or exhibiting sensitivity to enzymatic degradation in the intestinal tract, may be successfully delivered via oral bioadhesive delivery systems. Optimizing systemic treatment of disease via transmucosal drug delivery from the oral cavity continues to be investigated using a variety of dosage forms containing novel bioadhesive polymers.

Geriatric Oral Health—A Comprehensive Review

A. M. Sherene Christina Roshini[1], Aravindha Babu N.[2], E. Rajesh[3], K. M. K. Masthan[4]

[1]Post Graduate Student, [2]Professor, [3]Reader, [4]Professor and Head of the Department, Department of Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

Ageing causes certain abnormal conditions in periodontium which consists of gingiva, periodontal ligament, cementum and alveolar bone. Since there is a compromised immunity among older individuals, oral cavity is the prime focus for infection. Dentists should be educated to differentiate between the physiological and pathological changes in the oral cavity. According to which treatment plan can be framed. Maintenance of oral hygiene should be instructed to ageing person by the dental care professionals.

Keywords: *Oral mucosa, Keratinisation, Xerostomia*

Introduction

Tooth tissues such as gingiva, periodontal ligament, cementum and alveolar bone are supported by periodontal tissue. Often age advancement may influence the periodontal and mucosal diseases. Indeed, it is challenging to distinguish between physiologic aging and the cumulative effects of diseases. Aging means restricted natural function, a dissolution of the equalised control and organization that describes a young adult**.**There are also evidences of connection between oral health and poor general health where they continue to develop an association between severe periodontal disease and diabetes mellitus, ischaemic heart disease and chronic respiratory disease.[1]Combination of physiological age changes with superimposed pathological and iatrogenic effects are evident in the oral and dental tissues. Hence this review article discusses about the changes in oral health due to advancement of age since it is important for the dentist to differentiate between physiologicaging and diseases.

Bharath Institute of Higher Education and Research (BIHER), Chennai

Gingiva: The alveolar processes of the jaws and neck of the teeth are covered by a part of oral mucosa called gingiva. Certain changes in gingiva with aging were expressed by Carranza, they are declined keratinisation, reduction or unaltered bulk of stippling; excessive diameter of attached gingiva with mucogingival junction at its consistent area all over adult's life;diminished connective tissue cellularity; an increased sum of intercellular substance and decreased oxygen consumption. They also noticed an additional alterationof the mitotic index in gingival epithelium in elder individuals.[2]

Periodontal Ligament: Periodontal ligament, a specialised connective tissue with 0.2 mm width is located between the tooth and the alveolar bone and its primary role is to link the tooth and the jaw. Daniel and Rolf Lappalainen et al discovered a relative reduction in suspensory fibres and cellular content of periodontal tissues and deep periodontal pockets in older individuals respectively [3].Due to aging, there is reduced vascularity, increase in number of elastic fibers, collagen fibers, a mucopolysaccharides and arteriosclerotic changes, mitotic activity and fibroplasias in periodontal ligament. In addition, changes in diameter of the ligament was also observed with aging [2].

Teeth: Age changes in teeth include physiological wear with superimposed changes in morphology associated with pathology, including attrition and changes in the structure and composition of the dental hard tissues.

Enamel: Enamel has susceptibility to chip, crack and fracture and it also has a tendency to become brittle. In addition, it reflects the exchanging of ions with oral environment and also exhibitspermeability with age.

Dentino-pulpal complex: Due toage advancement, there are two important dentinal changes : formation of secondary dentine which results in decreased size, obliteration of the pulp chamber in some cases and dentinal sclerosis combined with persistent production of peritubular dentin. Caries and tooth wear are also correlated with these two processes. Sclerosis of radicular dentin has a tendency to create brittleness to roots and may result in diminished injury response and healing potential due to decreased vascularity, cellularity and increased fibrotic content. Reduction in nerve supply and increased thickness of dentin makes vitality testing more difficult. Due to the presence of tougher tissue, it is difficult to penetrate them with files. Thus resulting in compaction of pulp tissue to form a dense collagenous plug which is as impregnable as any calcified deposit. Hence for elderly patients, pulp is removed with barbed broaches and lubricants are used to permit the instrument to glide through tissue instead of compaction. [4]

Cementum: Cementum formation occurs in the apical half of the root resulting in progressive increase in thickness compensating for interproximal and occlusal attrition and in response to trauma, caries and periodontal disease. Deposition of secondary cementum at the tooth apex helps in estimating the radiographic working length in endodontics and for estimating age in forensic dentistry. Hence, additional bulk of cementum combined with secondary and reparative dentin decreases tooth sensitivity and perception to painful stimuli.[5]

Alveolar Bone: Gradual reduction in bone mass (osteoporosis) is mainly due to age changes[3]**.**In edentulous patients, age related osteoporosis plays a role in alveolar atrophy and basal bone even though the relationship has not been clearly established. Tooth loss is commonly connected to alveolar atrophy. Upwards and forwards posturing of the mandible occurs when there is a loss of facial height. Mandibular alveolar bone loss is more extensive than maxillary alveolar bone. Cyclo-oxygenase 2 (COX 2) enzyme levels has a vital role in bone repair but due to ageing, the function of this enzyme is reduced. This explains the delayed bone healing in elder patients. In order to stimulate the activity of the COX 2 enzyme and subsequent bone healing researches are conducted. [6]Fermin & Carranza reported that alveolar bone changes mimics the changes in the skeletal system. Osteoporosis, decreased cellularity and a reduction in metabolic rate and healing capacity are the age changing complications in older patients. Increase or decrease in bone density and bone resorption depends upon the individual and location. Gingival recession, tooth attrition and decreased bone height in elder individuals are not due to the physiologic changes instead they are due to oral diseases. Because of reduced immune response with aging accumulation of plaque with gingival recession is more rapid. Interproximal alveolar bone loss and clinical attachment loss has been related to bone mineral density according to Tezal. He also implicated that in postmenopausal caucasian women, periodontal disease is indicated by postmenopausal osteopenia.[7]

Salivary Gland: Commonest complains of older individuals are dry mouth (xerostomia) and diminished salivary output. Xerostomia is also accompanied by oral and pharyngeal consequences[8]Salivary output from major salivary gland does not undergo clinically significant decrements in healthy older people. Hence dentists should not attribute complaints of a dry mouth in an elder population to their age instead proper diagnosis is required. Salivary disorders is caused due to the intake of prescribed and non prescribed medicines. This is due to the fact that older people are more likely to take medications and are more vulnerable to their side-effects and medication-induced xerostomia. Anticholinergic drugs causes decreased salivary flow and dry mouth. Permanent salivary hypofunction is caused by the external beam radiation which was given as a treatment for head and neck cancers. Thus resulting in permanent complaints of xerostomia by the patients. [9]Systemic medical conditions, such as Sjögren's syndrome; Diabetes mellitus; Alzheimer's disease; and Dehydration can cause or promote salivary gland diseases. Patients with primary sjogren's syndrome have less production of saliva. Oral and pharyngeal complications due to salivary hypofunction are dental caries, dry lips,dry mouth, dysphagia,gingivitis,halitosis, problems with mastication, mucositis,oropharyngeal candidiasis,difficulty with removable prostheses, difficulty sleeping anddifficulty with speech[8]**.**

Oral Mucosa: Clinically oral mucosa of elder patients cannot be differentiated with the oral mucosa of younger patients. However, certain changes such as mucosal trauma, mucosal diseases, and salivary gland

hypofunction can change the clinical appearance and characteristics of oral tissues in elder populations.[10]Due to ageadvancement, the stratified squamous epithelium becomes thinner, loss of elasticity and atrophies are observed. Infection and trauma are caused due to the declined immunity. Oral mucosal disorders in elderly persons are caused due to the increased incidence of oral and systemic disorders, along with increased use of medications. Oral cancer is a disease of ageing and it has a high rate of morbidity and it is most commonly occurs above 50 years of age. Elder people may also develop vesiculobullous, desquamative, ulcerative, lichenoid and infectious lesions of the oral cavity. [11,12]

Conclusion

Oral changes are common in ageing individuals. Dentist should have knowledge to distinguish between physiologic and pathologic process After diagnosing the pathologic condition, treatment delivery and preventive regimes should be given. Periodical check up, brushing with fluoridated tooth paste, using floss should be done by the patients to maintain oral hygiene. In order to improve overall health good diet, less sugar content in diet, probiotic formulations, intake of fruits and vegetables enhances good health and also fights oral health and ageing problems.

ABSTRACT

Dentistry is a high-risk occupation due to the frequency of exposure to blood and body fluids. Similarly patients are also at risk of acquiring infection from the dental field if proper infection control measures are not followed strictly. According to the routes of disease transmission, we can classify the diseases into three: bloodborne, airborne and also through fomites. Public health consequences of morbidity and mortality is due to emergence of newer diseases within these classification. Disease control measures must be implemented in clinics by the health care provider and dentists. Dentists should understand the impact of diseases and provide certain steps to control the spread of disease within the dental field. Bloodborne diseases, such as hepatitis A, E, B, C, D and G, HIV; respiratory diseases such as tuberculosis, influenza, severe acute respiratory syndrome (SARS), AH1N1 influenza and immunizable childhood diseases are the commonest diseases in society. Aside from infection control measures, immunisation against diseases and postexposure disease control measures should be implemented by the public health care professionals.

Keywords: *Bloodborne diseases, Respiratory diseases, Immunizable childhood diseases, Public health measures.*

Introduction

Differentvirusescausing hepatitis, HIV and AIDS, and tuberculosis (TB) are the commonly spreading infectious diseases in community.[1]Transmission of hepatitis B, C, D and G viruses through bloodborne route whereas hepatitis A and E viruses through fecal-oral route.Improper and unhygienicfood and water are combined with fecal-oral route of transmission for hepatitis A and E. The transmission of hepatitis occurs to a lesser extent in world whereas common conditions such as HIV infection and tuberculosisare present in many regions of the world.[2] Major concern in tuberculosis are multidrug-resistant tuberculosis (MDR-TB) and extremely drug resistant tuberculosis.[3]Epidemics of respiratory diseases and infections have been observed in past decade[4]. Herpetic infections, influenza and bacterial infections are the other common infectious diseases where clinician may provide additional care if they are infected.

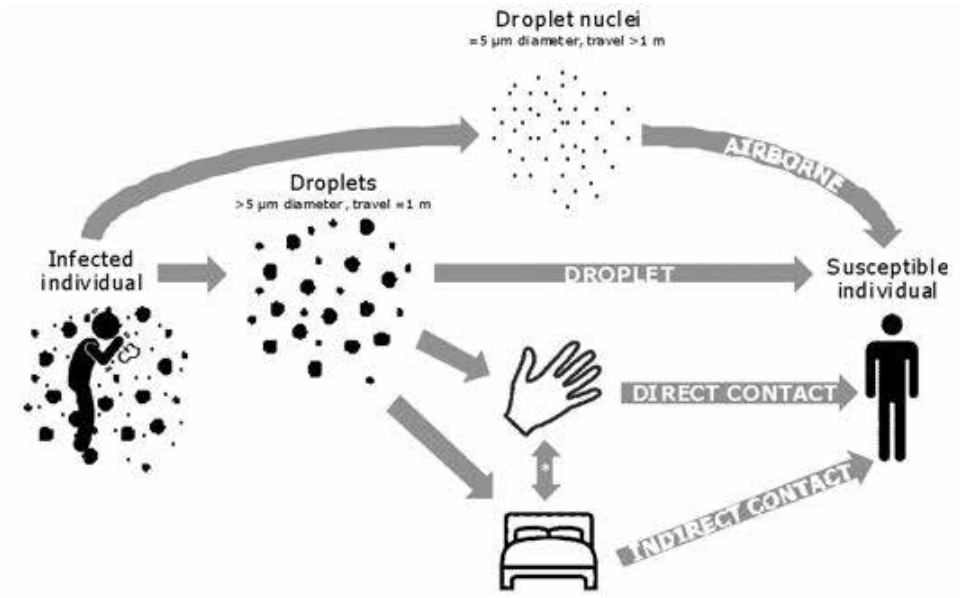
Hepatitis: Hepatitis A virus (HAV) are grouped under Hepatovirus genus and Picornaviridae family and is an RNA virus.[5] It causes acute inflammation of liver, jaundice where it shows only mild to severe signs and symptoms but it rarely leads to death. Death rate of this infection is about one in 1,000. If the patient is normally asymptomatic, the incubation period is 4 to 6 weeks or about 15 to 50 days but shedding of virus is observed in the stool. It is compulsory for all the dental students to get immunised for life-long immunity.

Hepatitis E virus (HEV)[6]is an RNA virus and it spreaded through fecal-oral route. Hepatitis E and HAV infection are similar in nature except for the increased rate of infectionin the third trimester among pregnant women (20% infection rate). There is no availability of vaccine against hepatitis E virus till date.

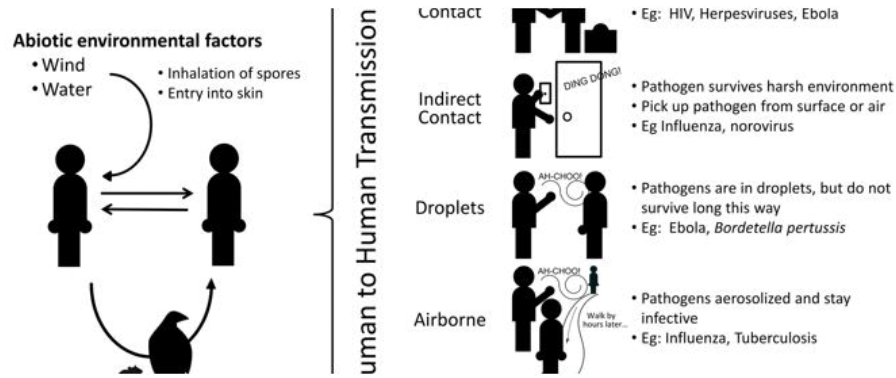
Hepatitis B viral (HBV) infection is caused by hepadnavirus (DNA virus). Clinical identification ofHBV infections cannot be identified in most patients[7].It is also called "chronic hepatitis infection" where the incubation period lasts from 45 to 160 days.Since Hepatitis B is very contagious, it is acquired by dentistsoccupationally in the past.



Outcomes of HBV infection are: About 90% of the infected patients will become healthy again; about 9 to 10% is asymptomatic carriers where patient suffer from chronic, persistent hepatitis promoting hepatocellular carcinoma and death and about 1% of patients develops fulminant disease after infection and die.Currently, dental students and faculty arerequired to complete a series of vaccinations in most dental institutions in India as a protection against this disease. It is also important to make vaccination mandatory for all oral health professionalsif they are not immunised before because it is the first and the best line of defense.

Hepatitis D virusesalways depens on the persistence of hepatitis B viral infection in the patient (piggyback virus). It occurs as an additional infection with HBV or after being infected by HBV. It has similar mode of transmission i.e., through blood and other body fluid contact.[8]

Hepatitis G viral infection is identified in most recent years and it is a bloodborne disease. Moreover it is the most insidious infections occurring among susceptible patients. Adequate barrier techniques should be used by the dentists to avoid contact with blood and other body fluids of patients by adopting safer practices for waste disposal to avoid cross-infection among other patients.[2] In addition, immunization for this infection is necessary if the vaccines are availableas the first line of defense.



Human Immunodeficiency Virus: Transmission of human immunodeficiency virus (HIV) occurs through contact with blood and other body fluids. It is most commonlyseen among homosexual individuals initially and later it is observed among heterosexuals, females and children. Initially progression of HIV is more severe and debilitating condition combined with AIDS or acquired immunodeficiency syndrome. AIDS are grouped under certain classifications such as the Center for Disease Control's surveillance definition, the Walter Reed's classification or the WHO's classification.HIV infection may not be noticeable at initial stages and symptoms, such as weakness, arthralgias are accompanied with this infection or even be totally asymptomatic.HIV infection and AIDS are associated with some oral lesions such as hairy leukoplakia, Kaposi's sarcoma and candidiasis. Dentists should have knowledge about the clinical appearance of these oral lesions as well as the systemic conditions, such as protozoal infections, fungal infections, other viral infections and mycobacterial infections.There is no chances of occupational exposures causing HIV infection of the dentist or dental auxiliaries during dental treatment. In order to prevent the HIV infection postexposure protocols must be followed and antiviral drugs must be taken immediately after treating HIV infected patient within 2 hours after exposure to infected blood.[9].

Tuberculosis: Tuberculosis is the oldest infectious diseases caused by mycobacterium tuberculosis commonly affecting lungs. Many respiratory conditions are imitated by Tuberculosis, therefore when dentists identifies a patient with cough for more than 3 weeks of duration and blood tinged sputum should be referred for a TB skin test and if it is positive treatment should be started. [10] To prevent the spread of this infection dental treatments are equipped to deal with the limit of cross-contamination or occupational exposure. Dentists and staff should undergo testing for the disease on regular intervals, especially if they are residing in endemic areas where there is a highprevalence i.e., within 6 months in high endemic areas and once in a yearin moderate endemic areas.Multidrug-resistant TB [MDR-TB] is increasing in India than TB. [11]Dentistsand other oral healthpersonnel in India must undergo annual TB testing and if it is positive, BCG vaccine should be given to the affected dentist and treatment should be given to them until it is non-infectious. MDR-TB is defined as "resistance to Isoniazid and Rifampicin with or without resistance to other anti-TB drugs".[12]Severe acute respiratory syndrome is a coronavirus which is associated with respiratory infection and it is referred as SARS-CoV.The signs and symptoms of this syndrome are body temperature of > 100.4°F, headache, bodyache with mild respiratory discomfort followed by moderate to severe respiratory distress, dry cough and many developing pneumonia. Transmission of SARS is through close contact, fomites through droplet infection (droplets can travel up to 3 feet) and through aerosolization.

Controlling methods of SARS in a dental clinic are patient are not allowed to sit in waiting room if they are not feeling well instead the appointment should be given on another day when they are feeling better. The face should be covered with disposable tissue or the sleeve of your shirt/coat while sneezing. Hands should be frequently and regularly washed oralcohol based hand gels can be used or hand sprays and wipe with disposable hand wipes if there is no possibility of washing hands. Facemasks must be worn regularly to control inhalation of droplets

Mode of Transmission of Disease

Childhood diseases: Commonly encountered diseases are chickenpox, measles, mumps, rubella, diphtheria, pertussis, tetanus, rubeola, meningitis and poliomyelitis. Vaccines are available in market for all these diseases and hence it is mandatory for all health professionals including dentalstudents to be vaccinated. It is mandatory to show the proof of immunization by the applicants before getting admitted.[13]

Conclusion

Developing immunization of health care professionals and students who are in the careers in health professions is mandatory in India. This is done by the working staffs in dental schools, the dental council and other public health organizations. Similarly all residents who are residing at residential institutions should be immunized against communicable diseases. Hence communicable or infectious disease can be controlled by having a basic knowledge about disease and also about the immunization since they are the first line of defense. Health care professionals, dentists, dental staff must be immunized and should also have a knowledge out the condition to educate the society.

Oral and Dental Aspects in Child Abuse and Neglect

A. M. Sherene Christina Roshini[1], Aravindha Babu N.[2], K. M. K. Masthan[3], N. Anitha[4]

[1]Post Graduate Student, [2]Professor, [3]Professor and Head of the Department, [4]Reader, Department of Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

Suspected cases of abuse and neglect should be reported by the health and dental care providers to parents, society and law enforcement agencies. This review reports the oral and dental aspects of physical and sexual abuse and dental neglect in children and pediatric and dental care provider's role in evaluating such conditions. Perioral and intraoral injuries which raise suspicion for child abuse or neglect are evaluated through bite marks. Multiple kinds of maltreatment have been exposed to children nowadays. Hence health and dental care professionals should be aware and educated about these concerns. Oral health problems can also be noticed in bullying and human trafficking victims. These are noticed by the dentist during physical examination or else children or young adults may reveal these facts about experiencing abuse or neglect. It is mandatory for all dental and health care professionals to know about the signs and symptoms of child abuse and neglect and in addition they should also know how to respond to those conditions.

Keywords: *Oral health, Tongue, Lips, Oral mucosa*

Introduction

Dental and health care providers should be aware of the different kinds of maltreatment that have been exposed to children. Maltreatment includes physical and sexual abuse, bite mark evidences and dental neglect. Other serious long term effects are bullying and human trafficking of children. The above mentioned problems are observed during physical examination, or else children or young adults may reveal these facts about experiencing abuse or neglect. Alterations in social values promotes the recognition of child abuse as a boundless medico-social issue publicly or universally. So, it is mandatory for the health and dental care providers to be aware and educated about the signs and symptoms of child abuse and neglect. Dentists should not only diagnose the problem instead they should also report, treat and prevent additional complexity**.**

Oral Signs in Physical Abuse: Oral cavity is the prime focus for physical abuse [1],and their characteristic lesions are described anatomically. Theoro-facial manifestations are bruising, abrasions or lacerations of tongue, lips, oral mucosa, hard and soft palate, gingiva, alveolar mucosa, frenum; fractures of maxilla and mandible, dental dislocations, fractures, avulsions.[2]. Haematoma, lacerations, scars of previous trauma, burns due to cigarettes or torrid food items are found in lips, since it isthe most common site for inflicted oral injuries. As a result of gags applied to oral cavity bruises, lichenification, or scarring are observed at the corners of the mouth [3]. In the labial or lingual frenum, gingiva, tongue, palate, floor of the mouth, lacerations and abrasions are found because of assault or pressure feeding of food or handling with blazingtableware and it shouldbe recorded as other correlating manifestations [4]. In case of earlier injuries, fracture of maxilla and mandible can be identified and it is confined to the condyles, ascending ramus, symphysis, other disorders such as pulpal necrosis due to discoloured teeth anddental malocclusions may also be apparent[5]. During oral examination, multiple residual roots can be observed by the dentist which helps them to detect the developments of the traumatic incident[6].The healing stages of injuries should provoke a suspicion of

abuse [7] because oral lesions may be imposed with tools such as utensils or a baby bottle during forced feedings, hands, fingers, scalding liquids or caustic substances [8]. Usually, Battered Child Syndrome is done through blunt force trauma of varied morphology, voluntarily inflicted according to different procedures. Apart from oral cavity, it is mandatory to focus other traumatized body parts such as retinal and subconjunctival haemorrhage,, dislocated lens, detached retina, optic atrophy, ptosis, periorbital hematoma, contusions and nasal fracture, injury in the tympanic membrane and auricular hematomas [9].

Oral Signs in Sexual Abuse: Involvement of a child in sexual activities with an adult is known as sexual abuse where the child is not allowed to know the actual meaning of action [10]. Oral cavity is frequent site for this type of abuse in children but on oral examination, injuries and infections are rare.[11]Significant indications of sexual abuse are erythema, ulcer, vesicle with purulent drainage or pseudomembranus and condylomatous lesions of lips, tongue, palate and nose-pharynx [6]. Laboratory culture for sexually transmitted diseases (Gonorrhea, Human Papilloma Virus, Chlamydia, Syphilis, HIV) should be conducted as per guidelines for the evaluation of sexual abuse of children, if there is any suspicion of an oro-genital contact. This guideline can also be used in vertical transmission i.e., from mother to child [12]. Most commonest sexually transmitted diseases found in child abuse victims isGonorrhea[13]. On clinical examination a child with gonorrhoea shows erythema, ulcer and papular-vescicobollous lesions and pseudomembranous in certain parts of lips, tongue, palate and nose-pharynx. Human Papilloma Virus infection can be transmitted through oro- genital contact. Infective agents of HPV causes Condyloma acuminatewhich is a unique lesion resembling a cabbage. Presence of this lesion can prove child abuse [14]. In case of presence of syphilis, papule is observed in the lip. As well as in this case, laboratory test should be carried out to detect the presence of Treponema Pallidum. If the result is positive, then it is highly suggestive of sexual abuse. In forced oral sex, erythema and petechiae are observed at the junction of hard and soft palate or at the floor of the mouth. [15]In these circumstances dentists should know to differentiate signs of sexual abuse with traumatic lesions, hemorrhagic lesions, violent cough or vomit, bleeding diatheses, antithrombotic or anticoagulant pharmacological therapy [16]

Bite Marks: Indication of abuse are acute or healed bite marks. For evaluating and detecting the bite marks related to physical and sexual abuse, dentists are trained as forensic odontologists[17].Presenceof ecchymoses, abrasions, or lacerations with elliptical, horseshoe shaped, or ovoid pattern should create a suspicion of bite marks to the health and dental care professionals. Ecchymoses (contusions) caused by

- Positive pressure from the closing of the teeth with disruption of small vessels
- Negative pressure caused by suction and tongue thrusting

Human bites tend to produce abrasions, contusions, and lacerations but rarely avulsions of tissue. Human bite marks can be identified by the intercanine distance (i.e., the linear distance between the central point of the cuspid tips) measuring more than 3.0 cm [18]. Evaluation of the pattern, size, contour, and color of a bite mark can be done by a forensic odontologist. In his or her absence, a forensic pathologist can be consulted. If there is no specialist available, an experienced medical or dental provider can be consulted. In absence of both forensic odontologists and pathologists, medical or dental provider must observe and document the characteristics of bite mark photographically. Photograph should be captured by placing camera lens directly over the bite and in the same plane to avoid distortion**.** In addition to photography, Polyvinyl siloxane impression is done soon after swabbing of the bite mark for secretions containing DNA. Saliva is also collected and documented by double-swab technique.[19]

Bullying: Children who have orofacial or dental issues (including malocclusion) are frequently subjected to bullying as a result of which they suffer from psychological complications such as depression and suicidal ideation.[20] Poor oral health are observed in children who have reported physical abuse, intimate partner violence, forced sex, and bullying. Anti bullying programme should be conducted in in schools and other community settings by the health and dental care professionals to prevent bullying [21].

Human Trafficking: Human trafficking is a child health problems involving medical and dental ramifications. It is defined as the recruitment, harboring, transportation, provision, or obtaining of a person for labor or services through the use of force, fraud, or coercion for the purpose of subjection to involuntary servitude, peonage, debt bondage, or slavery. Most of the children experience sex trafficking such as inducing the child forcefully to indulge in sex before attaining 18 years of age. [22] Sex

trafficking is considered "commercial sexual exploitation of children" as a survival sex i.e., for food, shelter and money, children are forced to exchange sexual activity.[23] Children with 12 years of age are commonly exploited sexually. Children who have psychosocial and physical challenges are the victims of trafficking since they do not have a sound mind to respond to that kind of action. These victims has higher risk of dental issues since they usually suffer from malnutrition causing poor growth of teeth, dental caries, infections and tooth loss [24]. Human trafficking does not have sex predilection because boys are more affected than girls as per surveys.

Dental Neglect: Accoding to American Academy of Pediatrics Dentistry, Dental neglect is defined as "willful failure of parent or guardian to seek and follow through with treatment necessary to ensure a level of oral health essential for adequate function and freedom from pain and infection" [25]. Pain, infection, and loss of physiological functions are caused due to the untreated dental caries, periodontal disease, and other oral conditions. Theunacceptable effect of these conditions can cause adverse effects on learning, communication, nutrition and other activities which are necessary for normal growth and development [26]. Dentists can carry out an early diagnosis of dental neglect because of several considerations. They are uncertain answers from the parent regarding child's physical and psychological growth stages [27]. Lack of general hygiene, poor nutrition and frequent respiratory system diseases are the physical signs that proves the significant neglect of the parents or the care givers. [28] Poor oral hygiene and halitosis are the easily identified oral signs of neglect. Complications of nutritional deficiencies are due to certain signs such as Early Childhood Caries (ECC), or untreated dental caries, odontogenous infections), periodontal disease etc.,[27]

Recommendations

- Health & dental care providers are required to report injuries in abused and neglected child to child protective services (state & legal requirements).
- Sexual abuse -mouth, even without overt signs, and thus, health &dental care providers should know how to collect a history to elicit this information as well as how to appropriately collect laboratory tests to support forensic investigations.
- Ask their patients about bullying and advocate for antibullying prevention programs in schools and other community settings.
- Safely connect the patients to resources, and advocate for anti-trafficking efforts.
- If parents fail to obtain therapy after barriers to care have been addressed, the case should be reported to the appropriate child protective services agency as concerning for dental neglect.

Conclusion

Hence the health & dental care providers should be aware of the physical and sexual abuse, which may result in oral and dental problems, when and how to document suspicious injuries and how to obtain laboratory evidence, photo documentation, and/or consultation with experts when appropriate. Pediatric dentists and oral and maxillofacial surgeon should conduct an advanced education programs including mandated child abuse curriculum. This provides a valuable information and assistance to other health care providers about oral and dental aspects of child abuse and neglect.

ABSTRACT

Probiotics are used to control periodontal diseases, dental caries and halitosis (oral malodour. It also has a potentiality to manage multifactorial diseases such as the periodontal diseases and caries. Conventional treatment cannot restore homeostasis. Studies about the use of probiotics in dentistry are held, where certain studies had a negative result and some had a positive result. Probiotics are used to modulate and regulate the immune system of an individual.

Keywords: *Homeostasis, Dental caries, Gingivitis and Periodontitis.*

Introduction

Probiotics are viable microorganisms which is administered in adequate amounts to provide a health benefit to the host. This is successful to control intestinal diseases where it act through colonisation to resist and modulate the immune system. Probiotics have the potential to investigate and to prevent or treat diseases of the oral cavity, such as dental caries and the periodontal diseases[1]. Suitable probiotic species is selected when the normal oral habitat and association with health should be considered. Certain gastrointestinal bacteria, such as Lactobacillus and Bifidobacterium spp., has the capacity to control the growth of oral microorganisms (cariogenic streptococci) [2]. Antimicrobial compounds are produced by probiotics to stop activity of other oral bacteria. A range of antimicrobial agents such as organic acids, hydrogen peroxide, peptides, bacteriocins and anti-adhesion molecules are produced by the lactic acid bacteria[2].Probiotics acts indirectly within the oral cavity by modulating innate and adaptive immune function. Some probiotics has a capacity to enable mucin production and barrier function, upregulate host defence peptide, induce angiogenesis and wound healing [3].

Role of Probiotics in Dental Caries: Although dental caries is preventable it remains one of the most prevalent oral diseases in children and adults worldwide. Consumption of sugar-rich diet promotes carious lesions.[4] Tooth decay can be prevented by targeting S. mutans and limiting sugar intake for inhibiting disease progression. An alternative preventive measure such as bacteriotherapy which target oral biofilm composition towards healthier microbial community[5] Lactobacillus rhamnosus GG [LGG] has caries preventive effect which can be due to enhanced salivary buffering capacity and decreased levels of S. mutans counts.[6] Withthe time of administration caries preventive effect of probiotics is correlated. A probiotic tablet containing L. salivarius has a property to increase salivary buffering capacity and probiotic administration promotes resistance to caries risk factors.[7]

Role of Probiotics in Periodontal Diseases: Gingivitis and periodontitis are included under periodontal diseases, where it originate in the presence of susceptible pathogens in oral biofilm. Bleeding on probing, swelling, color changes, pain, and tooth mobility is the leading symptom in advanced stages are the clinical manifestations. Primary treatment strategies are scaling and root planing and deep pocket debridement

Bharath Institute of Higher Education and Research

allowing to reduce aggressive perio pathogens. For efficient treatment, probiotics or beneficial microbes are essential for tailoring treatment after routine periodontal treatment. After administration of probiotic lactobacilli, there is reduction of periodontal pathogens in supra- and subgingival biofilm. [8] Thenumber of periodontal pathogens after administration of L. reuteri is reduced and it also contributes to improved gingival health. [9] L. reuteri is the commonly used probiotic species in chronic periodontitis patients and it act as an adjunct to scaling and root planing when it is given as a lozenge once or twice daily. Observed treatment outcomes are lowering plaque index, gingival index, probing pocket depth and bleeding. [10] Mechanism ofprobiotic activity are combined with less number of periodontal pathogens including Porphyromonasgingivalis, and reduced concentrations of TNF-α, IL-1β and IL-17 in gingival crevicular fluid.[11]Inperi-implantitis and peri-implant mucositis, there is no clinical evidence to justify the probiotic use supplements in addition to mechanical debridement and oral hygiene reinforcement.[12]Generallyconnection between peri-implantitis and probiotics is still weak.

Probiotics and Oral Candida Infections: In chronic Candia infections of the soft tissues in the mouthprobiotics application is essential. Commonly isolated Candida species are C. albicans, C. glabrata, C. krusei, C. parapsilosis and C. tropicalis. Various inhibitory activity against oral Candida by probiotic lactobacilli, with strongest inhibitory effect is observed with LGG [13] In yoghurt drink, Lactobacillus casei and Bifidobacterium breve affects secretory IgA levels in saliva and there is a reduction of Candida and non-Candida species in the oral cavity of older patients. [14]Combination of probiotic and Propionibacterfreudenreichii, LGG in cheese decreases the high risk for salivary Candida counts by 75% comparatively with placebo cheese in a study on the older population. [15]

Probiotics in Halitosis: Halitosis is known to be combined with periodontitis and putrefactive activity of the tongue microbiota plays a major role in volatile malodour production in both physiological and pathological halitosis [16]. To maintain a healthy tongue, tongue cleaning has to be done. Difficult areas to reach in tongue the dorsal posterior surface to the circumvallate papillae, where there will be a more amount of gram-negative bacterial species combined with malodour [17]. Lactobacilli exposes positive effects on treating periodontitis and producing good oral health to reduce malodour. Reuterin-like compounds reduces volatile sulfur compound VSC production by periodontopathic bacteria such as F. nucleatumand P. gingivalis, downregulation of the enzyme (methionine γ lyase) responsible for VSC methanethiol production later. [18]. L. brevis CD2 lozenges are given to patients with persistent malodour to observe some improvement in them but unfortunately there is no improvement in organoleptic scores or breath VSC concentrations [19]. Consumption of Lactobacillus casei Shirota milk also shoes no improvement. Hence in vivo studies shows that there is a limited ability to control oral malodour. Moreover indigenous oral strains could be screened for probiotic activity to help in colonising and maintaining healthy tongue ecology.

Conclusion

Probiotics has a major role in the clinical treatment of dental caries and the periodontal diseases and halitosis even though there is less convincing regards. Establishment of safety of probiotics and long-term efficacy in preventative or treatment contexts is necessary to produce safeclinicalrecommendations. In order to increase the role of probiotics in treatment innovative access of using oral microbiome transplants is helpful. Further studies should be carried on to determine strain specific and synergistic effects of strains.

Teledentistry: Future Perspective in Dentistry

A. M. Sherene Christina Roshini[1], N. Aravindha Babu[2], Karthika Nagarajan[3], K. M. K. Masthan[4]

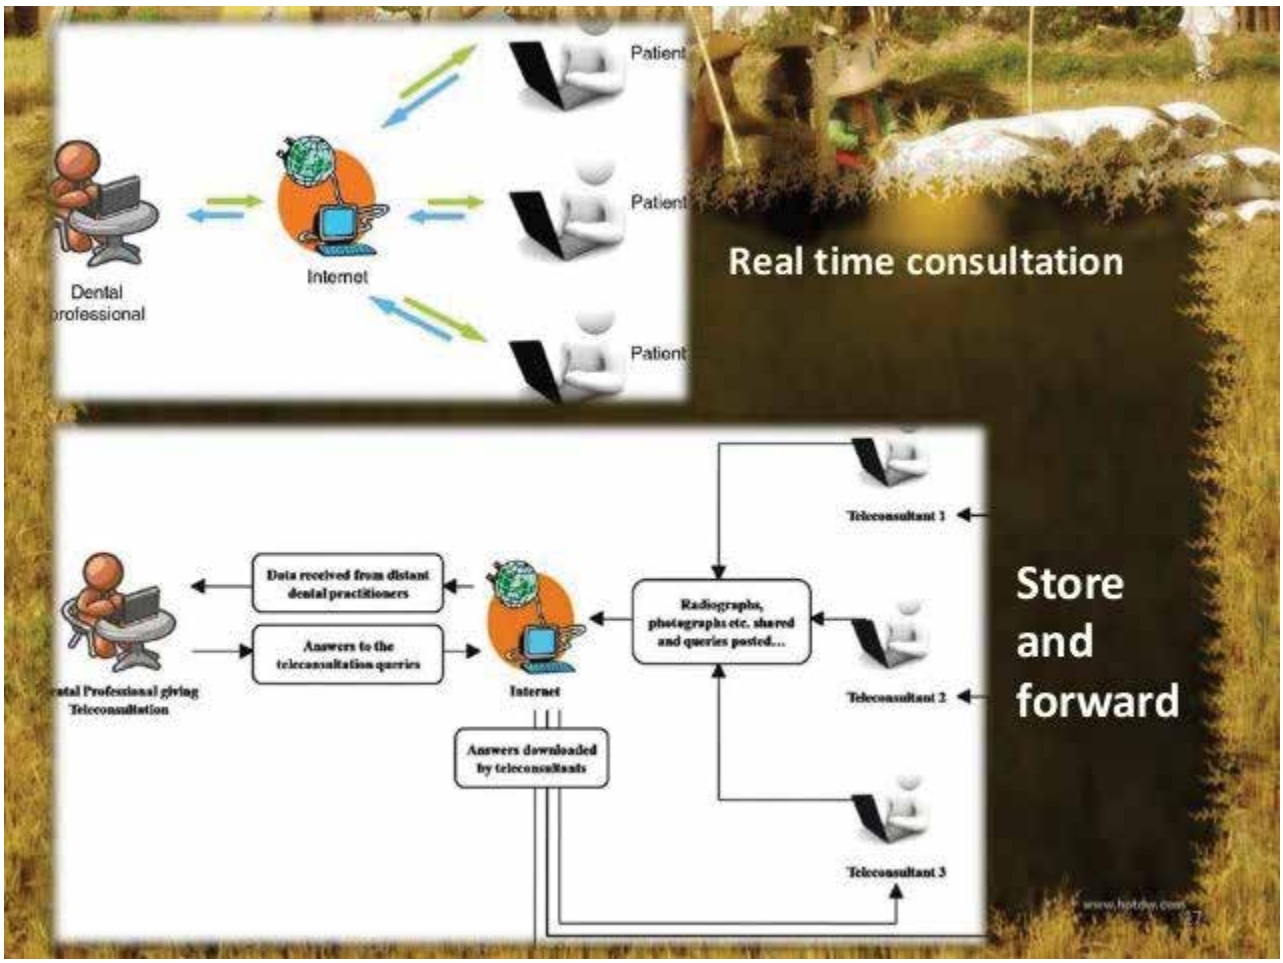
[1]Post Graduate Student, [2]Professor, [3]Reader, [4]Professor and Head of the Department, Department of Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

Combination of telecommunications and dentistry such as exchanging clinical information and images over remote areas for dental consultation and treatment planning is known as Teledentistry. It has the capacity of improving the access and delivery of oral health care at lower price. It has a potentiality to eradicate the discrepancy in oral health care between rural and urban areas. This review article discusses about the scope, origin, requirements of teledentistry along with ethical and legal issues. This article also reviews about the teleconsultation methods and applications of teledentistry in rural and urban areas.

Keywords: *Teledentistry, Telemedicine, Microphone, Headset or External speaker*

Introduction



Information-based technologies and communications systems are used to provide healthcare beyond geographic extent (telemedicine).[1]Telemedicine uses electronic information for technological communication and to contribute healthcare when there is an separation between the participants.[2]It is also a piece of an expansive method or series of care which can be improved by intensifying the characteristics and effectiveness of health care.[3] Currently telemedicine benefits educational medical centers, public hospitals, health insurance companies, georgic hospitals, and to link providers in developing countries internationally to hospitals in developed countries. Extensive technologic innovations in recent years has been observed by dentistry. Certain advancement have been created while using computers, telecommunication technology, digital diagnostic imaging services, devices and software for analysis and follow-up. [4]The possibility of quality management of dental patients and incomplete or complete treatment at thousand kilometres interval beyond healthcare centers or qualified dental practitioner has been improved by new information technology. This complete action of networking, distributing digital information, distant opinion, workup, and analysis is handled by a part of the science of telemedicine which is concerned with dentistry is known as "Teledentistry".[5]

Origin: In 1989, basic idea of teledentistry is a piece of pattern for dental informatics and in 1994, teledentistry is created as a part of telemedicine. United States Army created a military project addressing the improvement of patient care, dental education, implementing the communication between dentists and dental laboratories. This project exhibited the advantage of teledentistry as there is a reduction in total patient care price and extension of dental care to distant and rural areas [5]. It may also help in offering new opportunities to improve the patient care level and the current business models can be reshaped. [6]

Teleconsultation Method: Teleconsultation has following ways through teledentistry, they are – "Real-Time Consultation" and "Store-and Forward Method" where Real-Time Consultation describes the videoconference when dental practitioners and their patients are at different areas. Through this method they can see, hear, and communicate with one another[7].

Whereas exchange of clinical information and static images which was collected and stored by the dental professionals, who forwards them for consultation and treatment planning [8]

Advantage is that patient information, radiographs, graphical representations of periodontal tissues, applied therapies, lab results, tests, remarks, photographs, and other information can be shared by dentist. For patients who are in need of specialist consultation are benefitted by sharing data[5]. Remote Monitoring Method is the third method where patients are monitered at a distant area and can either be hospital-based or home-based.[9]

Scope: Ability of teledentistry is that the access to oral health care and the delivery of oral healthcare at lower price can be improved. By considering the uses of teledentistry such as lower cost, faster communication between rural-urban health it has a great scope in near future [10]. For instant, if there is a shortages of dentists in the next decade teledentistry helps the rural and urban people [11]. It also contribute an opportunity for dental students and dentists and to supplement traditional teaching methods in dental education [12]

Requirements of Teledentistry: Certain hardware, software and network connection are required forpractise in teledentistry. Essential requirements are desktop or laptop computer with substantial hard drive memory, a significant amount of RAM, and a speedy processor. A digital camera, video camera, and intraoral camera, and a panoramic digital X-ray unit, preferably portable, is needed to enable the dentists to consultwith maximum clinical valueimages.[13]For PCbasedvideo-conferencing Microphone, headset or external speaker, and a webcam are necessary.

Teledentistry and its Use in Rural Areas: Geographical remoteness, poor or no transportation, poverty and complications due to enhancement ofa quality dental carecompromise are the barriers for rural Indian to approach a speciality dental care[14]**.** Teledentistryhas the ability to increase the accessibility of the specialists to provide dental needs to underserved areas[15]

Teledentistry and its Benefits in Dental Education: Self-instruction and interactive video-conferencing are the two categories where teledentistry plays a major role in education. Self-instruction educational system contains developed and stored information before the user accesses the program.[16] The main use of this system is that the pace of the learning can be controlled by the user and they can also review the material for infinite times as per their wish.[17]

Teledentistry and its Use in Postgraduate Education and Dental Practice: Teledentistryis a good instrument to educate postgraduate students and it also providesrecent updates for the dental practitioners. Evaluation of patient's information is done first either in presence or in absence of the patient in interactive video-conferencing method. This helps in interaction and collecting feedback between the educator and the students. Students and dentists gains enthusiasm and a new learning opportunities by discussing the case details without the presence of patient, after collecting adequate information about the case through transmitted datas.[18]

Teledentistry and its Role in Schools and Child Care Centres: Optimum oral health of the children are ensured in schools and child care centre through:-[19]

- Oral screening for dental issues prior to emergency situations.
- Educating children about chronic ill treatment.
- Children and their families are connected to the needed health and social services
- Providing emergency care.

Ethical and Legal Problems:

Confidentiality: From the transfer of medical histories and records including the general security issues of electronic information, concern about the confidentiality is raised. Teledentistry practitioners must take care to make sure that patient privacy is not compromised by unauthorised individuals. Before that, it is mandatory to inform the patient that their data are transmitted electronically and other possibilities existing to intercept the data, despite of maintaining security. In addition, it is important to inform the patient about actual risk of inaccurate diagnosis and/or treatment because of technological problems.[10]

Medico legal and copyright issues: This is an important issue to be considered in teledentistry.Due to absence of specific standards these issues are raised. Legal issues such as licensure, jurisdiction, and malpractice have not yet been decided by legislative or juridical branches of various governments.[20] In 2002, 20 states in US implemented restrictive licensure laws ensuring teledentistry practitioners to obtain full license to practise.[10]

Feasibility in India: Since India is developing country certainbasic amenities of daily routine life and primary health education services are absent. Knowledge and awarenessin our country are changed due to the development of modern telecommunication and information technology.Modern telehealth and teledentistry are equipped in primary health center and community health center to provide education and essential services to the society. Importance and functioning of telehealth in connection to higher center and experts are educated and trained to school and college teacher and students and social workers from gram panchayat. Government should take some steps to emphazisethe importance and benefits of teledentistry in the society. There are certain disadvantages too. They are patient compliance, unreliability in internet connectivity, computer hardware and software problems which should be taken into consideration by the trained dentists.[21]

Conclusion

In the field of teledentistry, technological developments are taking place. Dental practitioners may eventually create a connection between virtual dental health clinics and new era of dentistry in near future. In situations like long-term unavailability of dental care in future,distant telemedical control of robotized instruments might be seen i.e., during space flights, on transoceanic ships, and in various rural areas. The results are very encouraging and they are creating a pathway for future investigations. However, certain things should be addressed before teledentistry reaches its peak. Few drawbacks and constant efforts has a hopeful future and long way to go. Hence more participants are required to substantiate various aspects of teledental applications.

Stress among Dentists—A Short Review

E. P. Sridevi Anjuga[1], N. Aravindha Babu[2], E. Rajesh[3], K. M. K. Masthan[4]

[1]Post Graduate Student, [2]Professor, [3]Reader, [4]Professor and Head of the Department, Department of Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

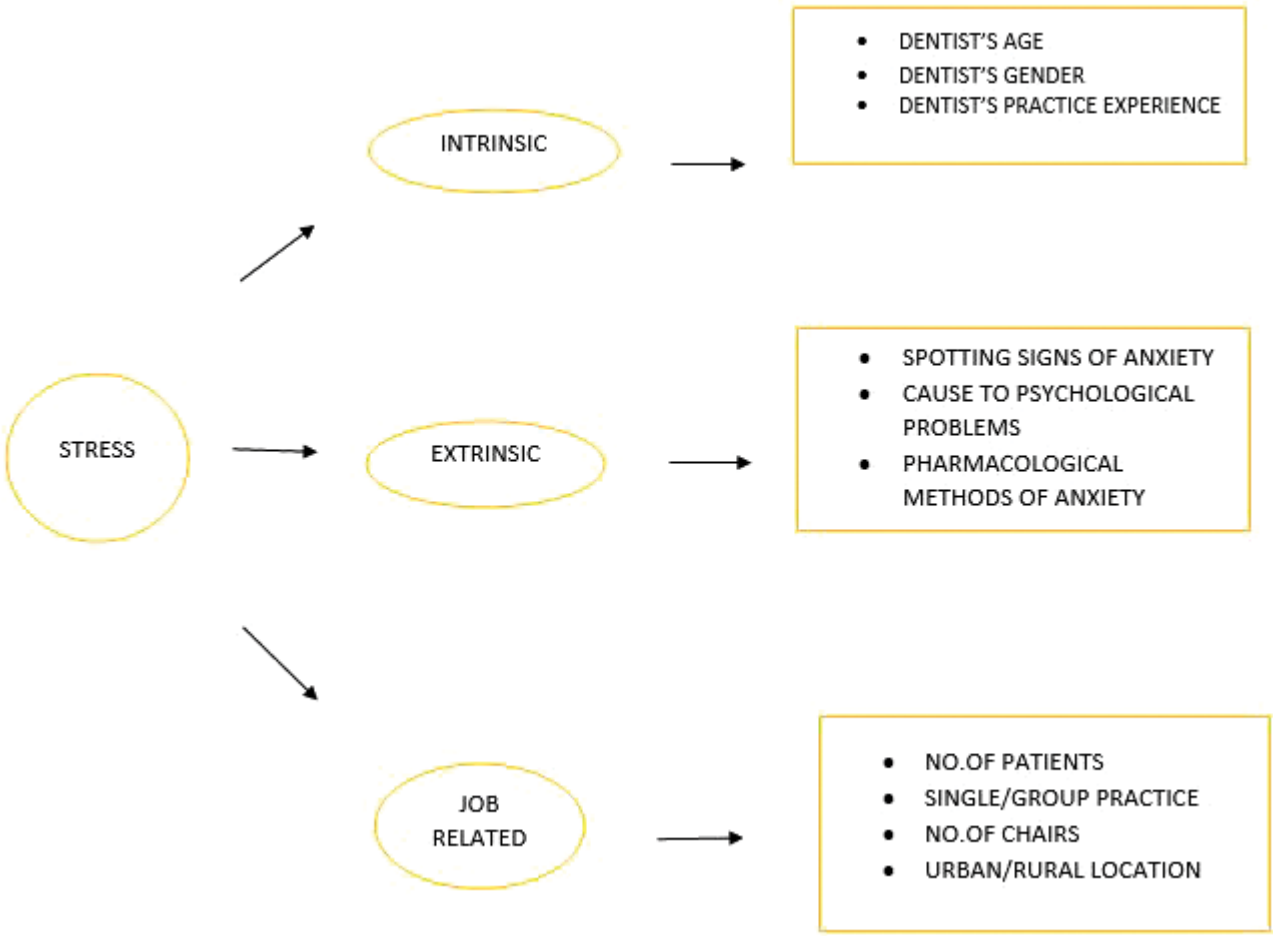
ABSTRACT

Dentist experience a range of physical, economic and emotional stress – related issues. Dentists must apply techniques that assist them de-stress by decreasing the amount of stressors and improving the ability to deal with stress. Narratives such as stress resistance, time management advantages, and the selection of realistic objectives are encouraged. This is used to reduce stress to manageable concentration. It can be daunting as with any shift from being an the work place. This applies particularly to medical professionals, since they are accountable for their patients well being. The consequences of stress management inclusion into dental education, offer additional practical suggestions for stress reduction and alleviation. This article gives an overview of such techniques and encourage dentist's general wellness by highlighting the significance of well- balanced living.

Keywords: *Dentist, Stress, Techniques, Financial issues.*

Introduction

Dentists are often believed to have a serenity profession, but it's a meagre known fact that if you are a dentist, there's a lot to worry about[1]. Dentist may find wide range of pressure frequently develop when entering clinical practice. It may include problems in handling frightened children in dental office or coping with obsessive, hard or uncompliant adults[2]. Stress can also come in the form of personal insult if dentist are considered incompetent in comparison with their colleagues, or if they are considered disrespectful, inconsiderate and inferior to physician[2]. A chronic source of stress is trying to remain on schedule in a busy dental practice[2]. Not receiving adequate payment for their services, anxiety about upcoming years and lengthy working hours can also function as stressors[2]. These problems may have a major impact on their physical, mental and overall health and wellness for some dentists[3].There may be clinical illnesses like burnout, anxiety and depression[3]. These illnesses may adversely affect private relationships, professional relationships, health and wellness of dentists[3].



Some stressors can be seen as typically excellent stresses that focus our energies on edifying situations that can happen through increased motivation, greater educational levels and excitement about that we are attempting to achieve[2].

Key Stressors in Dentistry:

- Running after implementation[2].
- It causes pain (musculoskeletal pain)[2].
- Heavy work pressure[2].
- Handling of unco-operative patients[2].
- Patient demands[5].
- High concentration and focus level[5].
- combining work and private life[5].
- highly efficient organization of work[6].

- patient reservations scheduled weeks ahead[6].
- long working hours[6].
- working without assistant[6].
- lack of leisure time[6].
- lack of support by practice management[6].
- doubts about one's own capabilities[6].

Types:

- Physical stress[1].
- Psychological stress[1].
- Financial stress[1].

Physical Stress:

1. Working as a dentist needs a mixture of strength, stamina, flexibility and coordination alongside many other abilities[1].
2. Engage yourself by eating well- balanced, nutritionally intensive meals and getting enough sleep to assist your mind revitalize and rejuvenate[1].
3. In addition to offering mental and emotional benefits, exercise helps maintain your body at its highest rate of performance. in order to avoid musculoskeletal disorders, weekly activities should include preventive aerobic and relaxation exercises[1].

Psychological Stress:

1. In order to ensure early identification and intervention in psychological circumstance students and teachers should be trained on the physical and psychological symptoms ofanxiety and depression[1].
2. We should be the first physicians to acknowledge the need for excellent mental health[1].
3. One often attempts to fix one's own problems as a medical professional[1].
4. In reality, it is totally and normal to seek assistance to improve mental health[1]. We should be the first

physicians to acknowledge the need for excellent mental health[1].

5. Exercise with relaxation techniques such as deep breathing and muscle relaxation exercise decrease stress[1].
6. Improve the clinic's operating atmosphere and try to speak to other dentists and work together to understand and master the abilities of effective practice management[1].
7. Discuss techniques for managing patient anxiety efficiently.You should handle your time with sensitivity and leisurely take off[1].

Financial Stress:

1. Your financial and economic abilities are incorporated in a good and stress free dental practice[1].
2. In return for a small management fee, you can employ a financial advisor to handle the financial aspect of your practice[1]. This can save time and free trouble[1].

Stress Level Influence:

- Many of the characteristics of a healthy dentist's personality may also predispose dentists to depression[4].
- There has been a substantial distinction in the manner personal professionals think about their job satisfaction because it has to do with stress and dentists identify themselves as staff[6].
- professionals who slept less than seven hours a night revealed more than twice as much jobpressure as those who who slept more than seven hours[6].
- Dentists with severe stress levels worked 39.7 hours a week on average[6].

Stress Related Issues:

- Depression[5]:
  - Depressed mood
  - Frequent insomnia or hypersomnia
  - Loss of energy or fatigue
  - Recurrent thoughts of death or suicide ideation
  - Lack of interest
  - Weight loss or weight gain
- Burn out[6]:
  - Negative attitude towards patients or staffs
  - Dissatisfaction with work
  - Drained emotionally or mentally.
  - Suicide[6].
  - Physical pains
  - Musculoskeletal pain
  - Back pain
- Consumption of alcohol[6].

How to overcome:

- Time management training[6].
- Adequate sleep[6].
- Exercise, Sports or any physical activity[6].
- Help – reading books, websites, organizations and professionals[6].
- Be confident

Prevention:

Improve the working atmosphere

Avoid isolation and sharing issues with fellow practitioners

Work sensitive hours and create time for leisurely break everyday

Learn how to handle uncooperative patients

Enhance communication skills.

Conclusion

As a health care professional, we are all vulnerable to stress.In the end, yes, we got a tremendously stressful profession, but we have to take measures to strangle your stress levels wherever we can.It's what we do with the stress that ultimately determines our results.If we can recognize our reliable sources of stress, we can begin looking for patterns in your everyday lives that can assist us to prevent stressors as much as possible.

ABSTRACT

Domestic violence or intimate partner violence as it sometimes called is a world wide problem. Women are much more likely to be injured by a family members or by someone knownto them. Domestic violence is a wide spread problem, its actual extent is difficult. Domestic violence refers to violence against women not only in homes but also in work place. In recent survey it shows that 27% of women have experienced domestic violence since the age of 15 in India. The violence tends to escalate often the first to detect the domestic violence victim since usual site of injuries are in head and neck region. The dentists can play a vital role in preventing violence against women and children by helping and providing necessary treatment and care.

Keywords: *Domestic violence, injury, women, dentist.*

Introduction

Violence against women is widespread throughout the world[1]. Violence against women and girls constitutes a severe infringement of their right to dignity and to a life without discrimination[1]. Violence against women is also known as gender- based violence which leads to long term mental and physical effects, sometimes causing women and girls to die and become disabled[1]. In our community, many women are treated violently by their intimate partner while they suffer in silence[2]. Gender based violence including rape, internal violence, murder and abuse are major global health issue for women[3]. It exists across caste, culture, class, education, income, ethnicity and age boundaries in every country. But the worst manifestations are seen in south asia. Violence against women is widespread in India, primarily because of the long lasting gender inequality that has existed for centuries. TheNCRB's (National Crime Record Bureau) last annual report published in august 2018 stated a rise in violence against Indian women.

Overall, 35% of women between the ages of 15 to 49 years have encountered physical or sexual abuse in India. violence against women occurs from pre-birth, infancy, adolescence to senescence throughout the cycle[4].

Gender based violence throughout the lifecycle at various phases[1];

Prenatal:

- Forceful abortion of female child
- Physical violence during pregnancy

Infancy:

- Female infanticide
- Lack of access to care, nutrition, healthcare.

Childhood:

- Child marriage
- Child labour

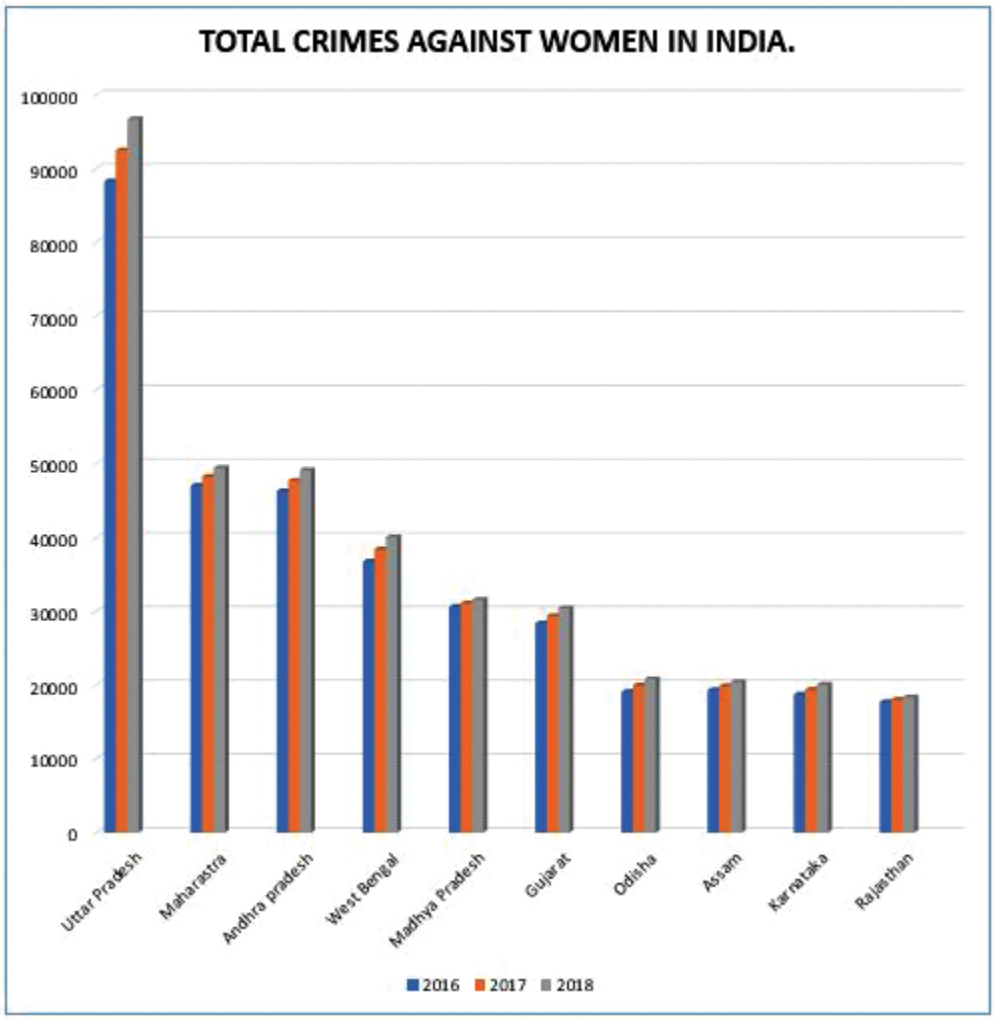
- Child sexual abuse
- Kidnapping
- Lack of access to care, nutrition, healthcare, education

Adolescence:

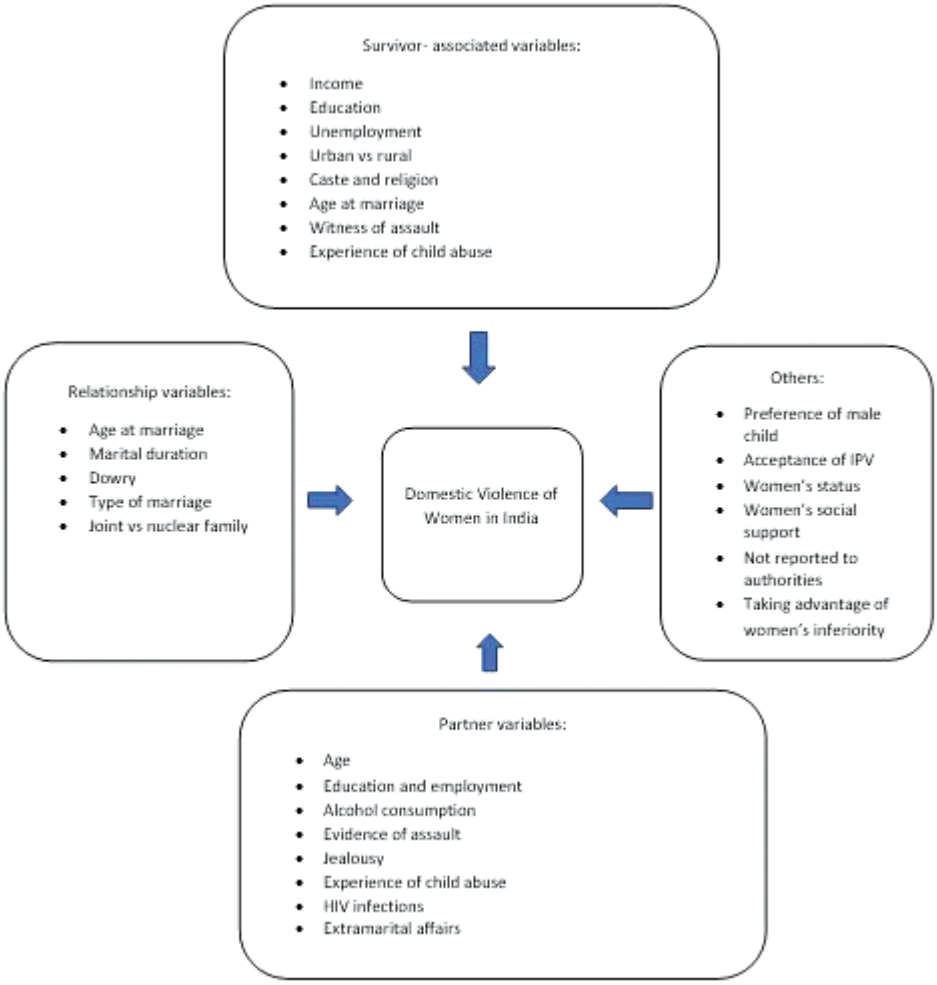
- Rape
- Molestation
- Sexual harassment in work place
- Forced prostitution
- Kidnapping and abduction



Youth and adulthood:

- Domestic violence
- Dowry related issues
- Homicide
- Sexual harassment in work place
- Rape
- Molestation

Old age:



- Psychological abuse
- Lack of access to care, nutritionand medical facilities.

Prevalence:

Source: A crime map of India in R – Crimes against women. – Tinniam V Ganesh.

Causes of IPV:

Woman's Place in Society: Indian society has always provides safety and care to women. Historically, the role of Indian females has been inconsistent[4]. A woman's strength is evoked in ensuring that women effectively perform their traditional roles as daughters, mother, wife and daughter-in-laws[4]. On the other side, the "weak and helpless woman" stereotype is promoted to guarantee full reliance or masculine sex[4].

According to 2011 census the gender ratio between male and female shows 940:1000[7]. The gender ratio is worst in Punjab, Rajasthan and Haryana's northwestern state[6]. The primary reason for this missing number is sex-selective abortions, infanticide and possible neglect of young girls during childhood, which indicates a strong preference for male children rather than female children[7].

Indian women face internal violence, dowry and its related violence, dowry death, rape, abduction, sexual harassment in work place, molestation, homicide and husband and in laws cruelty[7]. Statistics from NCRB (National Crime Record Bureau) show that an Indian women in her marriage home is most dangerous with 43.6% of all offenses against women being "cruelties" inflicted by her husband and relatives[7].

Why Violence Against Women is so Common: Women and girls in India are susceptible throughout their lives to various forms of violence[1].

i. Physically weak

ii. Gender inequality and discrimination

iii. Low level of education

iv. Male control over decision making and assets.

v. Lack of safe space for women and girls

vi. No one has stopped them or reported them to authorities.

vii. Lack of awareness about human rights.

Forms and Manifestations of Domestic Violence: These are all types of violence faced by women in her life.

Physical Abuse: Slapping, hitting, burning, choking, kicking, punching, fractures, head injuries, lacerations, using of injury causing physical items, acid attack, pulling her hair, bruises, control of reproductive freedoms and health[1].

Psychological Abuse: Threats, dictating what a girl or woman can and cannot do, isolating her, shouting, verbally abusing, spitting on her, humiliating the woman or her relatives, leaving the home or visiting her native home[1]. Victim may experience depression, anxiety and have increased risk of suicide. Post-Traumatic Stars Disorder is the most commonly seen psychological effect in victim[2].

Sexual Abuse: Rape, unwanted sexual activity, refusal to practice safe sex, trafficking, forced sex[1].

Economic Abuse: Stealing or destroying her private property, demanding cash, depriving the female of fundamental necessities such as food and clothing, not allowing her to work[1].

Pre-Birth Elimination of Females: Pre-birth elimination of female is one of the worst type of violence in the family[1]. Society in India is Patriarchal, Patrilineal and Patrilocal. In addition to religious consideration, economic, social and emotional wishes favour males as parents expect financial assistance from children but not daughter particularly in their old age[1].

Infanticide: Thousands of newborn baby girls are dying of opium overdoses. They are forsaken or thrown to death in waterways or dustbin. Major reasons are extreme poverty, dowry system in India, unwanted children, such as those conceived after rape, deformed children, relationship difficulties.

Dowry: Wife abuse has been found to be higher if a spouse and/or family thinks that dowry payment is not sufficient. It is a age-old practice has continued and has caused many females to commit suicide. Crimes like dowry murder, death, cruelty done by husband or in laws.

Effects of Domestic Violence: Effects seen in domestic violence are[6]:

- Depression
- Anxiety
- Pain
- Malnutrition
- Induced abortions
- Suicide attempts
- Sleep disorders
- Sexual dysfunction
- Panic attacks
- Death
- Inability to adequately respond to the needs of their children.
- High risk of Sexually transmitted diseases.
- Sexual assaults can lead to unwanted pregnancies.

Forensic Response: Domestic violence not only leaves the individual with physical and emotional injuries, it also has an impact on all family members. The local emergency center or emergency department is often the first to be involved with a victim of domestic violence[7]. The patient may have a broad variety of medical conditions, including abdominal pain, headaches, body aches, pain, bruising[7]. Injuries may appear minor or major based on the type of violence caused. Ideally, a nurse or doctor speaks privately to the patient and with patience and concern[7]. If patients are often unwilling to share the information publicly, they are taken to another private room and given privacy, they are more likely to respond honestly[7]. If a patient reports a history of domestic violence, it is important to identify a patient's risk or hazard[7].

Forensic Documentation: The word "forensic" implies the law.

Therefore, health records containing forensic documentation such as cases of internal violence injury are likely to be referred to the criminal and/or civil court as evidence[8]. Forensic evidence may be substantial, such as photographs or drawing of wound, written word[8].

Forensic document of IPV patients[8]:

1. Name.
2. What happened before, during and following the assault(including earlier assaults and severity)
3. Number of times the patient was hit and how the injury was inflicted, including an item or weapon used.

4. Parts of the targeted body as well as parts of the affected body.
5. Time of assault and the location of the attack.
6. Name of the witness of the assault.
7. Whether children witnessed the assault.
8. Whether threats were made by the abuser during the attack or before or after the assault.

Documentation should include not only care given, but references to other members of the health team.

Role of Odontologist: Forensic dentists have a major role in researching violent and abusive offences. They also help detect abuse as most wounds happen in the region of the head, face, neck and mouth[9]. Domestic violence, child abuse, spousal and elderly negligence can be investigated by the dentist with the help of police[9]. As a dentist we should[9]:

1. The obligation to report
2. Underreported abuse
3. Detect signs and symptoms
4. Reporting

Signs and Symptoms:

- Cranial and facial bone fracture
- Traumatic hair pulling
- Bruises
- Cut
- Choking
- Direct dental injuries like fractured tooth or avulsed tooth
- Subconjunctival haemorrhage
- Improperly healed wounds
- Multiple injuries with various stages of healing

Recommendations

The recommendations highlighting the roles/ services of different segments to reduce the incidence and prevalence of domestic violence are outlined below:

NGOs

1. A number of support facilities have been set up by women's organisation and NGO's for victims of intimate partner violence[1].
2. Several women's organizations have worked to educate the public on gender based violence through campaigns and ongoing education and awareness- raising in schools, universities and youth groups[1].
3. Information on all national violence organizations should be made accessible for reference to all health care organizations, leading in the provision of services as and when necessary[2].

Government:

1. Medical, paramedical professionals and all NGO to be sensitised to raise awareness among public about domestic violence[3].
2. Efforts should be produced to enforce current women's legislation properly and effectively[3].

Police:

1. All crimes against females should be handled by female police officers[3].
2. Police should be given special training in instances of domestic violence[3].

Government of Tamilnadu:

1. The Government of Tamilnadu instructed to install CCTV in public places- 2012
2. Tamilnadu is the first state in India to set up "ALL WOMEN POLICE STATION" to deal with crimes against women.

Judiciary:

1. Strict enforcement of Drug addiction legislation should be implemented to reduce the incidence of domestic violence[3].
2. Measures should be taken to treat alcoholics who perpetuate intimate partner violence[3].
3. Cases of intimate partner violence should be dealt with quickly and without delay, avoiding excessive strain and stress[3].

Domestic Legal Remedies in India:

Crimes Heads under the Indian Penal code(IPC)[10]:

1. SECTION 376 IPC - Rape
2. SECTION 376/511 IPC - Attempt to commit Rape
3. SECTION 363 IPC - Kidnapping and Abduction of women

4. SECTION 364 IPC - Kidnapping and Abduction in order to Murder.
5. SECTION 364A IPC - Kidnapping and Abduction for Ransom
6. SECTION 365 IPC - Kidnapping and Abduction of Women to compel her to marriage
7. SECTION 366 to 369 IPC - Kidnapping and Abduction for Other Purposes.
8. SECTION 304B IPC - Dowry deaths
9. SECTION 354A IPC - Sexual harassment
10. SECTION 354C IPC - Assault on Woman with Intent to outrage her Modesty
11. SECTION 354D IPC - Voyeurism
12. SECTION 509 IPC - Insult to the Modesty of women
13. SECTION 498A IPC - Cruelty by husband or his relatives
14. SECTION 366B IPC - Importation of Girl from Foreign country
15. SECTION 306 IPC - Abetment of Suicide of Women.

Crimes Heads under the Special and Local laws:

16. The Dowry Prohibition Act – 1961
17. The Indecent Representation of women (Prohibition) Act – 1986
18. The Protection of women from Domestic Violence Act – 2005
19. The Immoral Traffic(Prevention) Act - 1956

Health Care Support:

1. Health professionals should refer the victim to counselors and psychotherapists after physical therapy[2].
2. Women seeking medical assistance should be given unique care following an episode of violence[3].

Counselling:

1. Intending couples to handle their marriage relationship should be provided comprehensive and extensive premarital counselling[2].
2. Counselling centres should be started at urban/ rural areas focusing more on intimate partner violence[3].
3. Mobile counseling should be implemented as an efficient approach to comfort victims of domestic violence[3].

Helpline:

1. The Government of India launched 24X7 helpline number – 181.
2. The Government also suggested a center to amend current laws to make death and chemical castration heavy penalities for perpetrators.

Conclusion

Violence against women is a biot on the nation and society as well. As long as the Indian women are subjected to violence the international image of India also going to suffer. Long term measures are needed to empower women and educate men to curb this menace. Taking the issue only as a public health problem will be futile attempt unless a multifaceted approach using legal, social sciences and mental health is employed to check it.

Lichen Planus Vs Lichenoid Reaction: A Comprehensive Review

E. P. Sridevi Anjuga[1], N. Aravindha Babu[2], N. Anitha[3], K. M. K. Masthan[4]

[1]Post Graduate Student, [2]Professor, [3]Reader, [4]Professor and Head of the Department, Department of Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

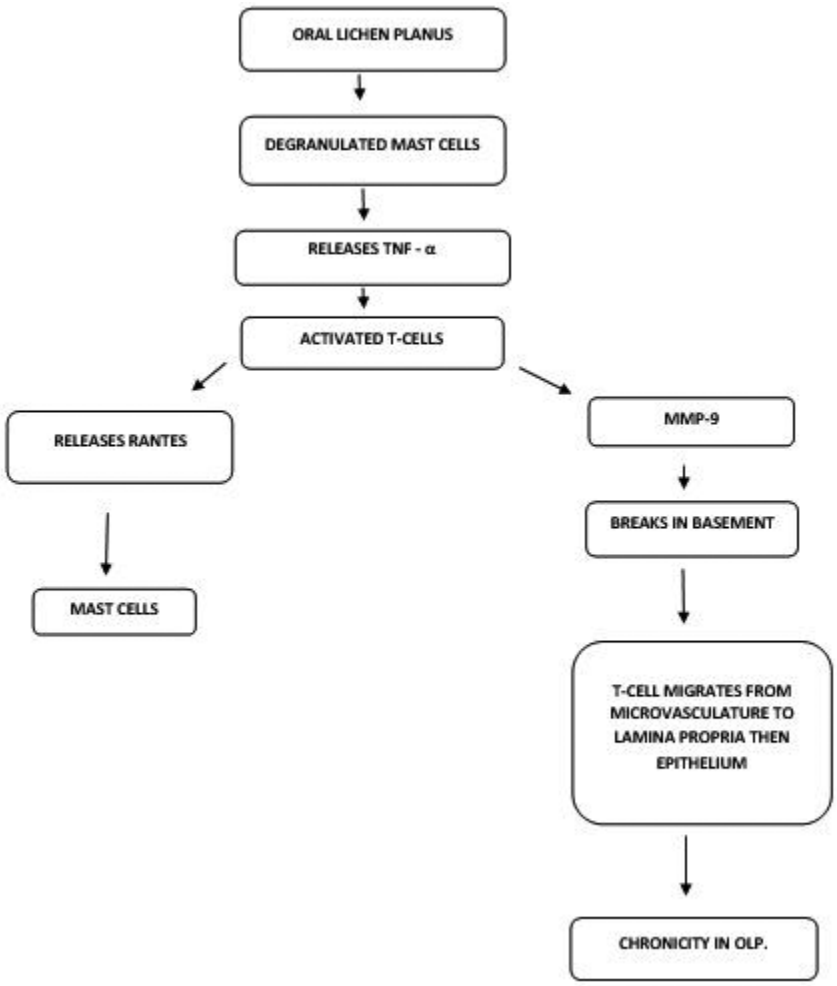
ABSTRACT

Lichen planus (OLP) is relatively common, chronic dermatologic disease that frequently affects oral mucosa besides skin, genital mucosa, scalp and nails. Oral lichenoid reaction (OLR) represent a prevalent endpoints for extrinsic agents (allergens, medicines, dental materials) modified self antigens or superantigens. In lichen planus, an immune mediated pathogenesis is acknowledged although the correct causative agent is unknown. Despite comparable clinicopathological characteristics: etiology, diagnosis and prognosis between OLP and OLR. Diagnosis of OLP is established either by clinical or by clinical and histopathologic confirmation. Histopathologic features of OLP and OLR are similar with suggestions of certain discriminatory features by some authors.The significant role played in the diagnostic process by the inclusion of the clinician and the oral pathologist. In this article, etiopathogenesis, diagnosis, management, malignant transformation of OLP and OLR is reviewed.

Keywords: *Lichen planus, Lichenoid reaction, Dermatologic disease, Oral pathologist.*

Introduction

Erasmus Wilson in 1869 described the disease and coined the term 'lichen planus"[1]. Lichens are primitive plants composed of symbiotic algae and fungi, the term planus is Latin for flat[1]. Lichen planus is a chronic mucocutaneous disease of unknown cause[1]. Usually involves the oral mucosa along with or preceded by lesions on skin and genital mucous membrane[1]. Even though the term lichen planus suggests a flat, fungal condition, current evidence indicates that this is an immunological mediated mucocutaneous disorder.



Lichenoid reactions and lichen planus are of different etiology yet show similar clinical and histopathologic features. Lichenoid reactions are inflammatory lesions with a variety of etiology, along with immune mediated illness, systemic and dental responses. Such agents are believe to expose the specific antigen on keratinocytes.

PATHOGENESIS: (3 and 4):

Lichen Planus Vs Lichenoid Reaction:

Etiology:

Lichen planus: Autoimmune[1].

Lichenoid reaction: Drug induced immune disease[1].

Trigger:

Lichen planus: chronic liver disease, Hepatitis C, Stress, Genetic factorsand Tobacco chewing[4].

Lichenoid reaction:

Drugs – Beta blockers, antimalarials, ACE inhibitors, NSAID, thiazide diuretics, pencillamine, sulfonamides.

Dental materials – amalgam restoration.

Flavouring agents – Peppermint oil, cinnamon flavoured mouthrinses.

Heavy metals – mercury and graft versus host disease[4].

Latent Period:

Lichen planus:absent or unknown[2].

Lichenoid reaction: a few weeks to months, average latency of 12 months[2].

Clinical Findings:

Lichen planus: Flat papules, papulosquamous eruptions[6].

Lichenoid reactions: scaly or eczematous, psoriasiform or violaceous plaques[2].

Wickham's Striae:

Lichen planus: present

Lichenoid reaction: uncommon.

Distribution

Lichen planus: Flexural with involvement of wrists, forearms, lower legs, genitals.

Lichenoid reaction: Generalized distribution, frequently spares the classic sites of lichen planus.

Pruritus:

Lichen planus: usually present

Lichenoid reaction: present

Mucosal Involvement:

Lichen planus: present

Lichenoid reaction: usually absent.

Nail Involvement:

Lichen planus: present

Lichenoid reaction: Absent

Scalp Involvement:

Lichen planus: common

Lichenoid reaction: Uncommon

Koebnerization:

Lichen planus: common

Lichenoid reaction: not a well- defined finding

Types:

Lichen planus[5]:

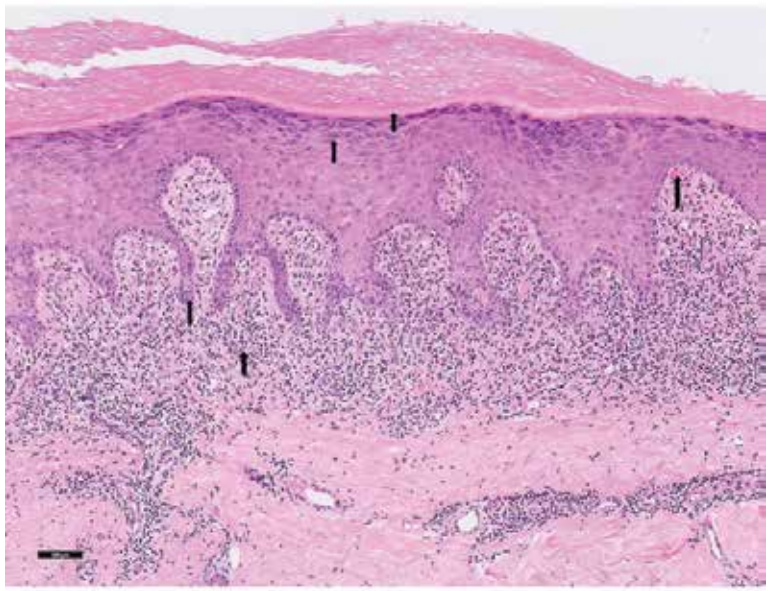
- Reticular lichen planus,
- Erosive lichen planus,
- Plaque like,
- Papular,
- Ulcerative and bullous.

Histopathologic Feature:

Histopathologic Features:

Lichen planus: Saw tooth rete ridges[2], vacuolar degeneration of basal cell layer[2], band like infiltrate of lymphocytes[1], degenerating keratinocytes[1], colloid, cytoid, hyaline or civatte bodies[1], no signification degree of epithelial dysplasia[1], hypergranulosis[6], hyperorthokeratosis[6].

Lichenoid reaction: Multiple colloid bodies[2], eosinophils, plasma cells, neutrophils, infiltrate of lymphocytes[2], focal spongiosis and infiltrate around blood vessels[2], focal parakeratosis[2], focal disruption of granular layer[2], colloid bodies in *s.corneum* and granular layer[2].



Course And Prognosis:

Lichen planus: self- remitting course, subside with post inflammatory pigmentation.

Lichenoid reaction: chronic relapsing course, it takes months to subside with post inflammatory pigmentation

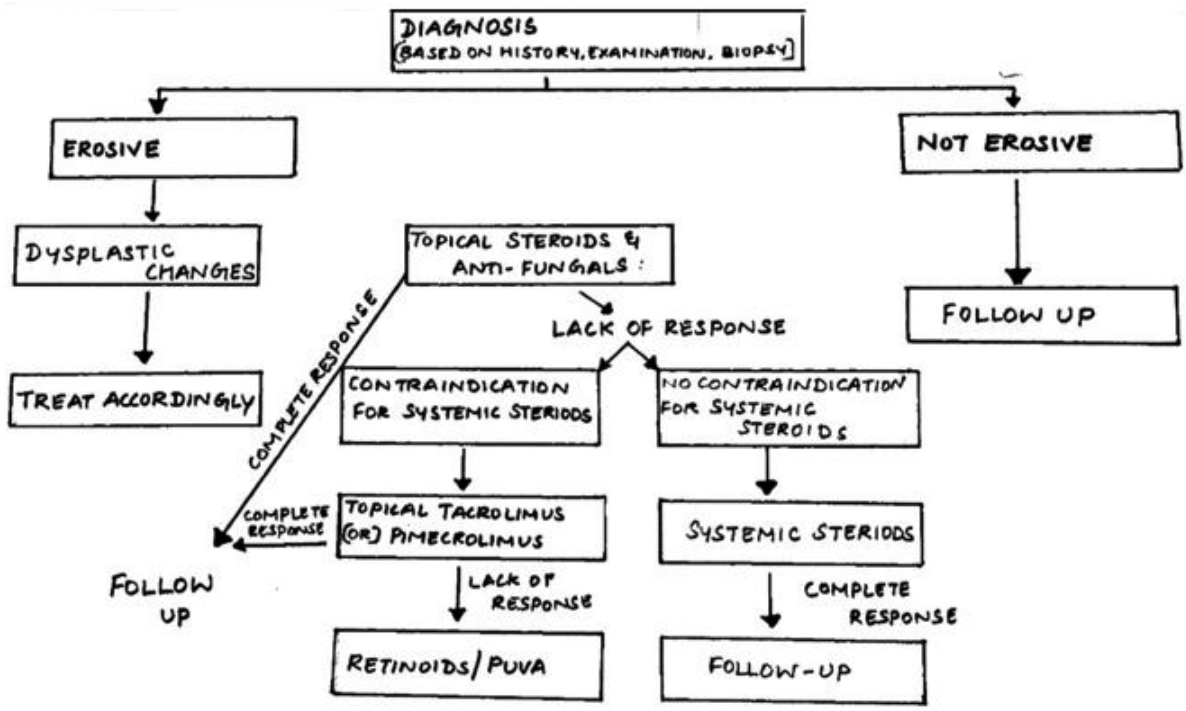
Malignant:

Lichen planus: Increased risk of malignant transformation[7].

Histopatholgical picture of lichen planus

(From left to right)

A. Saw tooth rete- ridge,



B. Subepithelial band of chronic inflammatory infiltrate,

C. Hypergranulosis,

D. Hyperorthokeratosis,

E. Civatte bodies.

Treatment:

(source: www.jomfp.in)

Conclusion

Attention should be given to the difficulty in determining the differential diagnosis by doctors unaware of the two diseases or who do not follow their patients for the period required for their differentiation as well as if the microscopic diagnosis of LR can not be achieved owing to absence of indication of a cause effect connection. In addition to specific diagnosting testing, a thorough history and full mucocutaneous examinational is crucial. OLP Presents both the patient and physician with a therapeutic challenge, and due to the potential for malignant transformation, long-term monitoring of OLP patients should be carried out.

Nanotechnology in Detection of Oral Cancer

N. Aravindha Babu[1], E. P. Sridevi Anjuga[2], Karthiga Nagarajan[3], K. M. K. Masthan[4]

[1]Professor, [2]Post Graduate Student, [3]Reader, [4]Professor and Head of the Department, Department of Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

Oral cancer is a widespread and aggressive cancer with a greater rate of morbidity, mortalityand recurrence worldwide. Early diagnosis is of utmost significance for the prevention and management of cancer. Nanotechnology is a broad field that has pioneered the sectorand set modern trends in oral cancer management. Tissue biopsy is usually the fundamental basis for the diagnosis of oral cancer, but it is invasive and can cause discomfort to patient. Nano detection devices are recognized as recent emerging non-invasive approaches to nano scale biomarker sensitivity detection. Nanotechnology can help with less harmful substance to have a better diagnosis. Nanotechnology next- generation technology have many benefits in treating cancer patients during oral malignancy stages from diagnosis to therapy and monitoring disease.

Keywords: *Cancer, Diagnosis, Nanotechnology, Non-invasive.*

Introduction

Oral squamous cell carcinoma (OSCC) is a devastating disease and is globally pervasive[1]. While most lesions are preceded by potentially malignant lesion, only about 5% of these lesion are progressing1. Potentially malignant lesion appear on the oral mucosa as white or red patches and there is no clear indication for cancer1. Oral cancer is the sixth most prevalent cancer in the world and has a survival rate of about 50% for 5 years2. The significant form of malignancy is OSCC, representing over 90% of all oral cancer2. They can invade tongue, mucosa, floor of mouth, alveolar and hard palate and it is reported that the tongue is the most subsite with poor prognosis[2]. Typically,unresolved lesions will undergo scapel biopsy and histopathological assessment for signs of epithelial dysplasia[3]. Because most of these lesions are benign, this method is unduly invasive and leads to other problem3. Chemotherapy, Radiotherapy and surgery are the most common treatment for oral cancer4. Limitations in the therapy of oral cancer consequence from present challenges in cancer therapies, including inability of early detection of disease, non-specific systemic distribution, insufficient tumor concentration of drugs and failure to monitor therapeutic reactions[4].

Richard P Feynman developed the concept of nanotechnology in 19595. Nanotechnology is revolutionizing biomedical engineering by enabling new types of drug delivery, tissue module synthesis, biomaterial growth and enhanced surface of medical devices5. Nanotechnology provides a wide variety of technologies and improvements in oral cancer prevention, diagnosis and therapy[5].

Generations of Nanotechnology

Nanomaterials: Due to its distinctive size (1 -100 nm) and huge surface-to-volume ratio, nanotechnology has the ability to give alternatives to current barriers in cancer therapies4. Increased permeation and retention effects are known to accumulate nanoparticle with a size of 200nm at the solid tumor site4. Nanomaterials in one dimension

are called sheets, nanowires, nanotubes and three dimensional quantity points in two dimensions[5]. Because of the gain in surface region and quantum impacts their characteristics differ from other fabrics5. Nanomaterials have much higher surface area per unit mass compared to larger particles owing to their tiny size[5].

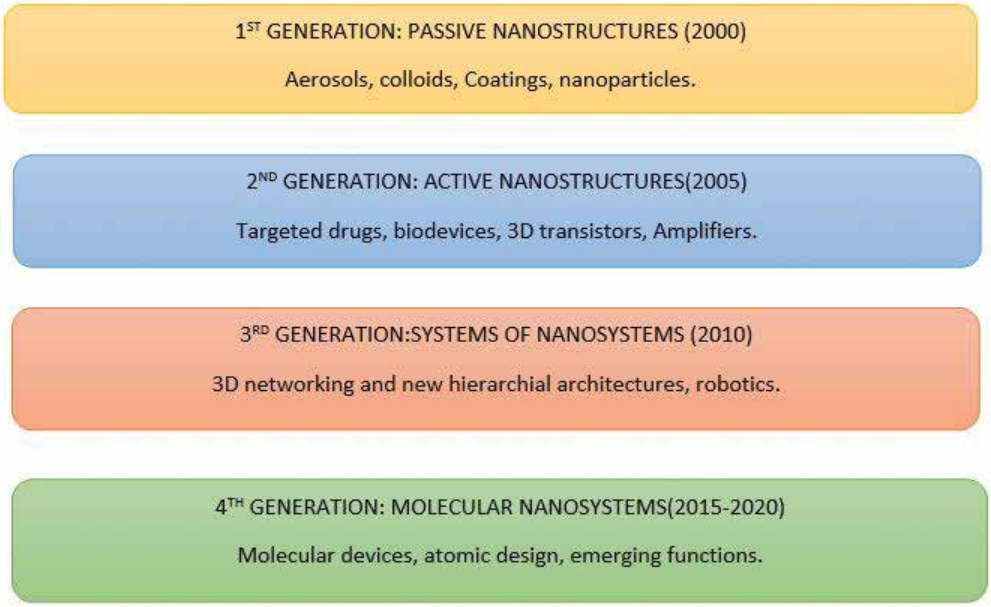

Fig. 1: (Source: overview and implications of nanotechnology – mike roco)

Nanotechnology: Numerous autofluorescence adjunctive, chemiluminescence, or tissue staining dye -based method assist to visualize potentially malignant lesions[3]. However, as their sensitivity and specificity are inadequate for diagnostic use, clinicians usually opt for biopsy evalution[3]. Cytological assessment, on the other hand is regularly used to diagnose a variety of other malignancies[3].

Quantum dots, carbon nanotubes, paramagnetic nanoparticles, liposomes and gold nanoparticles are the most well studied nanoparticles[4]. QDs are used to conduct cell motility assays and to study migration related cell signalling occurences and to distinguish between invasive and non-invasive cancer cell lines[4]. The Optical detection method is the most widely used method for detecting the existence of cancer and image cancer tissue with the help of biomarker or functionalized nanomaterials, where nanoparticles either fluroresce oralter their optical properties when binding to tissue affected by cancer[4]. By incorporating novel-functional on novel shaped nanomaterials and biomolecular markers, Bio-MEMS was used as a diagnostic instrument in cancer treatment[4].This allows studying the studying the basic biological mechanism that dictate health and disease[4]. Bioconjugated particles and equipment are also being developed in body fluids such as serum and blood for early identification of cancer[4]. These nanoscale devices work on cancer cells or target protein selectively captured[4]. The sensors are covered with a cancer-specific antibody or other receptors of bio recognition so that the capture of a cancer cell or target protein results in electricity[4]. Uses of nanoparticles in blood or serum specimens to detect and analyze circulatingtumor cells and biomarkers[4]. By combining magnetic nanoparticles and semiconductor QDs, it is feasible to improve the capacity to capture and assess these rare circulating cancer cells[4].

Nanotechnology has reshaped the detection and therapy of cancer5. It has the ability to detect even a single cancer cell in vitro and to offer extremely toxic drugs directly to cancer cells[5]. Nanoshells, carbontubes, Quantum dots, supermagnetic NPs, nanowires, nanodiamonds,dendrimers and lately synthesized nanosponges are some of the tools used to detect cancer[5]. NPs can selectively target cancer biomarkers and cancer cells, enabling for more delicate diagnosis; early detection requiring a minimal quantity of tissue; tracking of treatment advancement and tumor burden over time; and the destruction of cancer cells alone[5]. Plasmonic NPs combines with nuclear targeting peptides in cancer cells

trigger DNA damage and apoptotic population[5]. NPs can be used to detect tumor cells qualitatively or quantitively in vitro5. Probably, nanotechnology is the only technique that can be used for site-specific action without the killing of ordinary cells causing side effects5. The recent trend in cancer therapy is cancer nanotechnology[5]. It is a good hope for enhancing cancer treatments by acting atleast on two primary levels : giving a pharmaceutical agent fresh characteristics (enhanced stability, altered pharmacokinetics) and directly targeting the agent to the tumor[5].

Conclusion

Despite incredible progress in cancer therapy, there are still many science, technological andclinical difficulties that require a extremely interdisciplinary and cooperative approach to cancer management.There is no doubt that nanotechnology has the ability to be the most effective and advantageous type of future cancer treatment and diagnosis. Nanotechnology will make a more profound transformation of dentistry, health care and human life than many other advances in the past.

Sports Dentistry—A Current Update

N. Aravindha Babu[1], E. P. Sridevi Anjuga[2], Jayasrikrupaa[3], K. M. K. Masthan[4]

[1]Professor, [2]Post Graduate Student, [3]Reader, [4]Professor and Head of the Department, Department of Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

Sports Dentistry is one of the latest and developing field in dentistry. It engages in the prevention, maintenance and therapy of oral and facial illnesses,as a well as in the gathering and dissemination of details on dental trauma, beyond study stimulus. Dental injury is the most common type of orofacial injury that occurs during participation in sports. Oral injuries can trigger disfigurement of the sufferer after healing, which may influence the quality of life of athlete. Many athletes are unaware of the health consequences of a traumatic injury to the mouth or the potential for severe head and orofacial injuries while playing. The dentist can play an important role in conveying athletes about the importance of preventing dental and facial injuries in sports. The purpose of this article is to raise professional consciousness and interest in sports dentistry orientation.

Keywords: *Sports, injuries, dentistry, athlete.*

Introduction

Dental injury in sports is the biggest link between sports and dentistry[1]. In perspective, of the enhanced popularity of contact sports and encouragement of early participation, the role of dental profession in the prevention of dental and other orofacial sport accident has become more crucial[3]. Sports dentistry originated in the 1980s, but sport -related injuries are increasing prevalent; this could be due to the dentists lack of any specific training[6]. Soft tissue injury and hard tissue injuries like tooth intrusion, luxation, crown and/or root fracture, avulsion, dental and facial fracture, abrasions, contusion, laceration are the most common orofacial injuries in sports[6]. The effects of orofacial trauma on children and their families are substantial due to potential for pain, psychological effects and economic consequences[6]. Sports Dentistry is designed to prevent oral/facial atheletic injuries and associated oral illness and manifestations[1].

It has two main parts:

1. The treatment of orofacial injuries related to sports[1].
2. The avoidance of orofacial injuries related to sports[1].

Mouth guards were made compulsory in many sports during the 1960s and 1970s, including football, lacrosse, hockey, boxing, racquetball, shot placing, skateboarding, skydiving, soccer, squash, volleyball, polo and wrestling[9]. Currently, to prevent sport related orofacial injuries 3 shielding devices can be used, mouth guards, facemask and helmet[9]. Athletes, coaches, people involved in sports and dental community members should be conscious of how people involved in sports operations are at high danger of dental/orofacial trauma[10].

Incidence: Face, is the body's most susceptible region and is generally the least protected area[3]. Most often these injuries are due to direct hits with contacts with a ball or player to player[3].Studies have shown that 13-

Email: Dr.aravindhmsdc@yahoo.co.in

39% of all dental injuries were linked to sport and 11-18% of all sport incidents were maxillofacial injuries[7]. Nose, zygoma and mandible are the most prevalent forms of sport facial trauma[7]. These injuries frequently occur together[7].Males are more commonly affected than females.In dental injury, upper lip, maxilla, maxillary incisors are commonly affected[7].

Evaluation: The assessment of facial injuries should follow the principles of trauma assessment and should begin with ABCDE Airways, Breathing, Circulation, Disability, Exposed control of surroundings[3]. The facial examination is then performed after the final evaluation and stability[7]. A systematic method is followed to effectively determines the magnitude of injury and properly diagnose injury to teeth, periodontium and related structure[7]. Assessment involves a comprehensive details of medical and dental history[7]. Clinical and radiographic examination and additional test such as palpation, percussion, mobility evaluation as person[7].

Intra-oral radiography is helpful for the assessment of dento-alveolar trauma. Extra-oral imaging may be indicated if the region of concern extends beyond the dentoalveolar complex[7].

Factors: (1)

Various Sports Related Injuries:

1. Eye injuries[4]:
   - Sudden loss of field of vision
   - Foreign body sensation
   - Laceration of eyelid
   - Sub-conjunctival haemorrhage
   - Broken contact lens
   - Shattered eyeglasses.
   - Red and inflamed eye.
2. TMJ Injuries[5]: In temporomandibular joint injuries, we can see;
   - Pre- auricular pain
   - TMJ dysfunction
   - TMJ dislocation
   - Pain during mastication
   - Restricted mouth opening
   - Deviation
   - Crepitus.
3. Intrusion[8].
4. Extrusion[8].
5. Crown and root fracture[8].
6. Avulsion[8].
7. Soft tissue injuries[8]:

   Abrasion

   Contusion

   Laceration

Involved sites: eyebrows, cheeck, chin and lip (most commonly)

8. Fractures[8]:

Zygoma

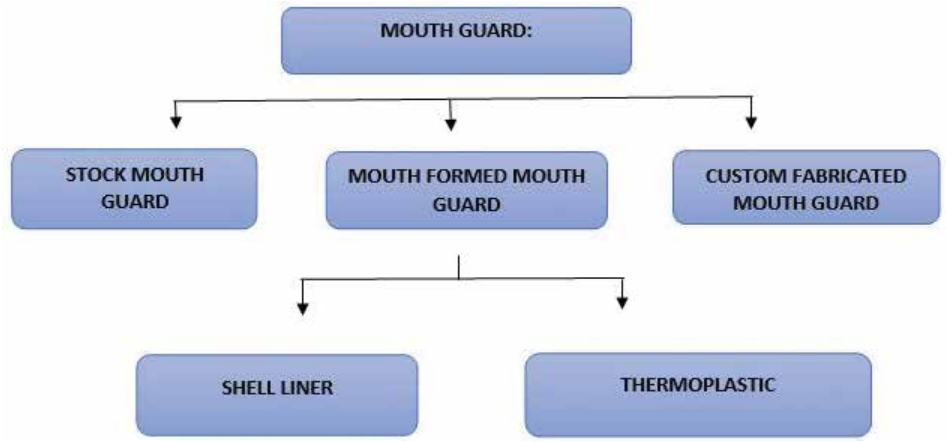
Nose

Mandible

Tooth or alveolar bone fracture

Floor of orbit

Prevention of Sports Related Traumatic Orofacial Injuries: All preventive services provided by the private physician should be made accessible to athletes and others whoprone to trauma associated with sports[1]. It is essential to provide specific guidance on trauma prevention, correction of mal-aligned teeth, extraction of affected teeth, use of mouth protectors, and treatment of any pathological anomaly and prevention[1].



Proper training, emergency management is very important.

Pre-Operative Protocols[10]:

1. Extraction of affected tooth which is untreatable[10].
2. Maintenance of proper oral hygiene[10].
3. Teeth replacement[10].
4. Restoration of decayed tooth[10].
5. Special care for children[10].
6. Making of shielding devices to prevent dental injuries[10].

Devices:

1. Helmet[2]
2. Face masks[2]
3. Mouth guard[2]

Dental Emergency Kit[8]: (Sports)

- Gloves
- Mouth mirror
- Pen torch
- Tongue depressor
- Scissors
- Sterile wire cutters
- Rope wax
- Intermediate restorative material
- Spatula
- Mixing pad
- Sterile gauze – 2X2 and 4X4 size.
- Mouth guard
- Tooth preserving solution.

Conclusion

Sports dentistry covers a broad variety of oral/ facial athletic injuries and associated oral illnesses and their manifestations, including preventive and therapy modalities. Safe participation in sport should be the objective of any program of sport. It is the dentist's responsibility as a health care professional to become and remain educated and pass this education on to the community on issues relating to sport dentistry and specifically the prevention of oral and maxillofacial

accidents related to sports. A mouth guard should be the essential equipment for every athlete to prevent these types of injuries.So play smart, wear mouth guard and protect your smile.

Complications of Bisphosphonate Therapy in Dentistry

Sudakshina Mukherjee[1], N. Aravindha Babu[2], E. Rajesh[3], K. M. K. Masthan[4]

[1]Post Graduate Student, [2]Professor, [3]Reader, [4]Professor and Head of the Department, Department of Oral pathology and Microbiology, Sree Balaji Dental College and Hospital and Research, Bharath Institute of Higher Education

ABSTRACT

Bisphosphonates are group of drugs that inhibit bone resorption thus used in the treatment certain disorders like Paget's disease, Osteoporosis, Multiple Myeloma and metastasis associated with breast or prostate cancer. The most common complication faced by any dental surgeon is Osteonecrosis of Jaw which can occur after any surgical procedures. Since proper effective treatment of Bisphosphonate induced osteonecrosis is not known prevention is very important in high risk individuals.

Keywords: *bisphosphonates, osteonecrosis of jaw, osteoporosis*

Introduction

Reports regarding bisphosphonate induced osteonecrosis of jaw first came into being in the year 2003[1,2] where IV Bisphosphonate like zoledronic acid and panidronate taking patients got affected. Its not limited to IV administration only, patients were also reported with cases of Osteonecrosis of jaw with orally administered bisphosphate as per case reports in 2006 [3-5]. **BRONJ** (Bisphosphonate Related Osteonecrosis Of Jaw) generally affects the quality of life. Thus strategies for managing these kind of patients with or at risk for BRONJ was done by American Association Of Oral & Maxillofacial Surgeons (AAOMS) an approved by Board Of Trustees in Sep 2006[6].

Types: Generally two types based on **mode of administration**-

1. Intravenous
2. Oral

Corresponding Author:
Dr. N. Aravindha Babu MDS
Professor,
Department of Oral pathology and Microbiology,
Sree Balaji Dental College and Hospital,
Bharath Institute of Higher Education and Research

Based On Generations- Three generations are there.

Indications

Intravenous: Effective in treatment of cancer related condition like

1. Hypercalcemia of malignancy
2. Breast cancer
3. Prostrate Cancer
4. Lung cancer
5. Management of cystic lesion in the sitting of multiple myeloma [7,9].

Oral: Osteoporosis, sometimes it is used to treat Osteopenia as well [46]. Certain condition like Paget's disease, Osteogenesis imperfecta of childhood [10,11].

Mechanism of Action: Generally four mechanism of action can be noted in bisphosphonate-

A. **Inhibition of calcification:** For this mechanism of action bisphosphonate was earlier proposed for treatment of ectopic calcification like calcification of soft tissues. But it was later found out that it can inhibit the mineralisation of normal calcified tissues such as bone, cartilage, enamel, dentin,and cementum [12]

B. **Inhibition of Bone Resorption:** It has direct action on osteoclastic differentiation, reducing their activity, and inducing osteoclast apoptosis [13].

C. **Anti-tumor Effects**: Nitrogen containing Bisphosphonate especially Zolendronic acid exhibit anti tumor effects. They exhibit proliferation and also enhance apoptosis in cultured cancer cells to the bone matrix and thus inhibit cell migration and inhibition.

D. **Anti-angiogenic effect**: Bisphosphonate like Zolendronic acid has anti angiogenic properties mediated by inhibition of growth factors like FGF and VEGF B4[14].

Clinical Appearance of Osteoradionecrosis of Jaw: ONJ clinically appears as an intraoral lesions with areas of exposed yellow-white hard bone having smooth or ragged borders sometimes can associated with smooth or ragged extra-intraoral sinus tracts lasting more than eight weeks [15,16-18]. Presence of painful ulcers also can be noticed in the soft tissues adjacent to bone Patients considered to have BRONJ if following these characteristics are present

1. Current or Previous treatment with a bisphosphonate
2. Exposed bone in maxillofacial region that has persisted for more than 8 weeks
3. No history of radiation therapy taken to jaws.

Stages: staging was done to correctly specify the patients according to their symptoms.

Stage-0: NO clinical evidence of necrotic bone but some non-specific symptoms or clinical and radiological findings can be seen.

Symptoms: Like unexplained toothache, dull aching bone pain in the body of the mandible, which may radiate to temporomandibular joint region, sinus pain which may be associated with inflammation and thickening of the maxillary sinus wall can be seen.

Clinical Findings: Loosening of teeth without any periodontal disease or sometimes periapical fistula can be seen not associated with pulpal necrosis.

Stage-1: Exposed and necrotic bone in asymptomatic patients without any evidence of infection.

Stage-2: Exposed and necrotic bone in patients with pain and infection.

Stage-3: Exposed and necrotic bone in patients with pain and clinical evidence of infection with any one of the following manifestations like pathologic fracture, extraoral fistula, oral antral or oral communication, osteolysis infiltrating to inferior border of mandible or sinus floor.

Risk Factors:

1. Risk of developing osteonecrosis with intake of bisphosphonate largely depends upon bisphosphonate potency, mode of administration and dosage. When we compare IV and oral route of administration and their respective potency, IV is more potent. Among various IV administered bisphosphonate, Zolendronate is the most potent bisphosphonate since it has high mineral binding affinity [19-22].
2. History of any Dental Treatment: a history of dental disease followed by any invasive dental treatment which induced trauma like extraction and impaction, also periodontal disease are sometimes considered to be risk factors for development of ONJ in association with bisphosphonate. [21,23-24]
3. ONJ occurs twice as frequently in mandible than in maxilla and in areas with thin mucosa such as torus mandibularis and mylohyoid ridge.[25,20,26]
4. Malignancy: Type and duration of malignant disease, duration of bone metastasis may pose an increased risk of ONJ development [23]. ONJ mostly seen in Breast Cancer, Multiple Myeloma and Prostrate cancer [27].
5. Concomitant treatment: Patients receiving chemotherapy and corticosteroid are at high risk.
6. Age & Sex: Old and female patients are at increased risk of developing ONJ.
7. SMOKING also pose as threat to incident of ONJ.
8. Comorbid Conditions: Conditions like low hemoglobin level [26], Low serum calcium level and secondary hyperparathyroidism [28], renal dialysis[27], diabetes[29], Obesity[30]-possible risk factors for ONJ. Other conditions like Hypertension, Hyperlipidemia, Hypercholestrolaemia, Rheumatoid Arthritis and diabetic contribute also to risk of developing ONJ in patients receiving bisphosphonate for non cancer indications [31].

Radiological Features: In symptomatic patients, OPG is usually first screening examination. Though Computed Tomography (CT) or Magnetic Resonance Imaging (MRI) are methods of choice for evaluating bisphosphonate-associated jaw bone osteonecrosis since they correlate with histopathologic examination [32]. Recently Cone Beam Computed Tomography (CBCT) gained popularity since it offers access to 3D image of bone structure. In CBCT destruction of trabeculae structure of cancellous bone is vivid and erosion of cortical bone with increases severity of BRONJ bone sequestration and formation of new periosteal bone can also be detected[33]. Evaluation of sockets for 4-6 months should be initiated and if the socket is persisting even without clinical signs of a follow up should be done [33].

Radiographic Finding on Stage 0: Patients with no clinical evidence of necrotic bone, but present with non-specific symptoms or clinical and radiographical findings, such as, alveolar bone loss or resorption not attribute to chronic periodontal disease, dense woven bone and persistence of unremodeled bone in extraction sockets. Thickening and obscuring of periodontal ligament, inferior alveolar canal narrowing. These are non specifying findings can be seen in patients with a history of Stage 1,2 or 3 disease who have healed and no clinically exposed bone.

Management and Prevention of Bronj: Thorough oral check up to the patients before they undergo monthly IV bisphosphonate. Non restorable teeth or poor prognostic teeth if any should be extracted and all invasive procedures should be competed and optimal periodontal health should be achieved B1. As per three studies reported, the preventive dental treatment decreased BRONJ risk among patients with malignancy treated with Bisphosphonate [19,34,35]. Though risk of BRONJ with oral Bisphosphonate Therapy is less in number but it is not nil. Sometimes in presence of chronic corticosteroids use this condition is aggravated. If the systemic conditions permits, discontinuation of oral bisphosphonate or drug holiday can be considered, though there are limited data available to support the evidence of benefits of discontinuing Bisphosphonate Therapy [37]. For asymptomatic patients if systemic condition persists on oral bisphosphonate for more than 4 years, a drug holiday of 2 months prior to and 3 months following extraction can be implemented. [36].

Treatment Protocols[25,20,38-40]

1. **Patients who are about to undergo bisphosphonate treatment:** Since majority of these kind of patient develop osteonecrosis while undergoing dental surgery [21,41,42] Therefore if systemic condition persists bisphosphonate therapy should be delayed until oral and dental health is optimized. Atleast a gap of 14-21 days should be given from dental surgery to initialize the therapy to promote enough osseous healing.
2. **Asymptomatic patient already under intravenous Bisphosphonate:** Good oral and dental hygiene maintainance should be of utmost importance. Avoiding any invasive dental procedures like intra and trans alveolar extraction should be avoided. Generally the risk of develping BRONJ associate with oral bisphosphonates increased when duration of therapy exceeded three years. Although sound recommendations based on strong clinical research designs are still lacking for these patients. [43,38-44].
3. **Patients with BRONJ:**

   Treatment objectives: elimination of pain, control of infection of soft and hard tissues, minimize the progression or occurrence of bone necrosis.

   Treatment Accrding Stages: Stage 1 - these patients benefit from the use of oral antimicrobial rinses such as chlorhexidine 0.12%. No surgical treatment is indicated.

   Stage 2: these patients get relief from using oral antimicrobial rinses in combination with antibiotic therapy. Most of the isolated microbes have been sensitive to penicillin group of antibiotics. Quinolones, etronidazole, clindamycin, doxycycline and erthromycin have been used with success in those patients who are allergic to penicillin.

   Stage 3: These patients benefit from debridement including resection in combination with antibiotic therapy, which may offer long-term palliation with resolution of acute infection and pain.

Biochemical Marker: No specific proper studies are there for using markers of bone turnover to diagnose BAONJ in patients treated with bisphosphonate or

to identify those who are at risk [44,45] of developing BAONJ. Still handful of patients as per some authors have suggested that lower level of biochemical markers of bone turnover like serum C-telopeptide or N-telopeptide could identify those who are at risk of developing BAONJ.

Conclusion

High risk individuals to ONJ should be sorted out while treating patients. So, case history and moreover drug history is to be taken carefully due to the seriousness of this condition and to provide necessary preventive measures. But more researches are necessary in order to find and clarify the risk factors that lead to development of BRONJ.

Long Term Effects on Adult Survivors of Child Maltreatment

Sudakshina Mukherjee[1], N. Aravindha Babu[2], Karthika Nagarajan[3], K. M. K. Masthan[4]

[1]Post Graduate Student, [2]Professor, [3]Reader, [4]Professor and Head of the Department, Department of Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

The physical injuries seen in children though can be quantified, the psychological long term impacts in response to child maltreatment I.e child abuse and neglect can have life long negative impacts. Somehow in later life indirectly it hampers the society as a whole. These consequences can be independent of each other, but sometimes they are interrelated also.

Keywords: *child maltreatment, abuse, psychological consequences*

Introduction

Child maltreatment can be of various forms be it physical, verbal, sexual which leads to ultimate psychological abuse. However, consequences of child maltreatment can be devastating and it varies widely. Effect are usually depends upon type, frequency, duration, severity of maltreatment and also the relationship between child and perpetrator. According to WHO every year about 41,000 children under 15 years are victims of homicide. More deaths from child maltreatment go unreported-since they are incorrectly documented due to other causes. The consequences can also last a lifetime. Adults who were abused or neglected as children have a higher risk of-being a perpetrator or victim of violence, can be under prolonged depression, probability of obesity are seen more in these victims, they often fall prey of substance abuse, high risk sexual behaviour or unintended pregnancy as reported.

Bharath Institute of Higher Education and Research

Physical Health Related Consequences: Often physical abuse which mainly includes hitting, beating (battered baby syndrome),shaking(shaken baby syndrome) may lead to some immediate physical effect like brain damage by head trauma, retinal hemorrhage etc. On the contrary some takes years to manifest. It has been seen that higher risk of certain diseases like diabetes, lung disease, malnutrition, vision problems, functional limitations, heart attack, arthritis, back problems, high blood pressure, brain damage, migrains, chronic bronchitis, chronic obstructive pulmonary disease, cancer, stroke, bowel disease, chronic fatigue syndrome- are in direct relation to child maltreatment[1]. Child abuse and neglect can cause hindered growth in both form & functions of certain areas of brain. It can also affect the volume and overall size of the brain[2]- According to studies certain areas of central nervous system are hampered like - amygdala, the key to processing emotions, the hippocampus,the centre of learning and memory, the orbitofrontal cortex, responsible for reinforcement-based decision making and emotion regulation, cerebellum the centre of motor coordination behaviour and executive functioning, corpus callosum, which is responsible for left or right brain communication and other processes like arousal emotion, higher cognitive abilities.

Psychological Consequences: 80% of Adults reporting child abuse have atleast 1 Psychological disorder 50% of Child abuse victims have more than 3 Psychological disorders. Mental illness is the only disease that deny its own existence, certainly that the brain can deny its

own existence is a frightening thought. Disrupted brain development as are result of maltreatment can cause impairments to the brain's executive functions like working memory, self control, and cognitive flexibility [2] So certain conditions manifest itself like:

- **Anxiety Disorder:** Difficult to control or interferes with normal functioning Mental disorders like Panic attack, frightening physical symptoms, Flashback of traumatic events, Nightmares, Obsessive thoughts or even housebounds.
- **Mood Disorders:** These are outside the bounds of normal fluctuations from sadness to elation.

  In the workplace, major/clinical depression is a leading cause of absenteeism and diminished productivity. Disorders include: clinical or major depression, dysthymia and bipolar disorder.
- **Psychotic Disorders:** Often suffers from SCHIZOPHRENIA. **SCHIZOPHRENIA** is serious brain disorder affecting the most fundamental human attributes such as LANGUAGE, THOUGHT, PERCEPTION, affect SENSE OF SELF.

Psychotic Manifestation: Hearing internal voices, hallucination, delusions, withdrawal, and incoherent speech and impaired reasoning. Often in superstitious country this is considered as demonic possession and that individual is totally isolated and tortured rigorously under this false harmful beliefs, medical attention becomes a far fetched thing for that individual and ultimately his life is totally destroyed.

- **Dementias:** Characterized by a disturbance of consciousness and a change in cognition, (including memory loss and a decline of intellectual and physical functioning)

Disorders include Alzheimer's, vascular dementia, dementia due to medical conditions, (e.g., HIV, Parkinson's disease)

Substance-Induced: Dementia (drug abuse, alcohol abuse, inhalants), toxin exposure like mercury and lead. Dementia can be due to a combination of multiple factors.

- **Eating Disorders:** Eating disorders are serious, sometimes life-threatening, conditions that tend to be chronic. Onset usually occurs in adolescence and tends to predominately affect females. It is present when a person experiences severe disturbances in eating behavior such as extreme reduction of food intake or extreme overeating or feelings of extreme distress or concern about body weight or shape.

Three major eating disorders are **Anorexia Nervosa, Bulimia Nervosa, Binge Eating Disorder**. Persons with eating disorders may also have other mental illnesses such as: depression, anxiety, obsessive-compulsive disorder (OCD), personality or substance abuse disorder

Post-Traumatic Stress: Children who experienced any abuse and neglect can develop post-traumatic stress disorder (PTSD), characterized by persistent re-experiencing the traumatic events related to abuse, avoiding people, places, and events that could be associated with their past maltreatment. Feeling of fear, horror, anger, guilt, or shame, startling easily and exhibiting hypervigilance, irritability, mood changes [3]. PTSD in children can lead to depression, suicidal behaviour, substance use and defiant behaviour continued to adulthood.

Long Term Effects of Sexual Abuse: Adult survivors of child sexual abuse may face following concerns which are specific to their experience

- **Guilt, shame, and blame:** guilty about not able to stop the abuse,or they then blame themselves. A feeling of shame and blame followed by that which most of the time are enforced by society or even parents.
- **Low self esteem:** sexual abuse victims often become low on their self esteem. Usually it is the aftermath of guilt, shame, and blame that has been burdened on her/him by the society. They have a feeling of worthlessness and avoid others because they believe themselves impure and they have nothing to offer[6]. This affects their different future aspects of life like relationship, career, even their health.
- Often **hatred towards a particular gender** becomes prevalent. They dissociate to protect themselves from experiencing the sexual abuse. As adults they may still use this coping mechanism when they feel unsafe or threatened[4].
- Denial and repression of sexual abuse is believed by some to be a long term effect of childhood sexual

abuse. Symptoms include experiencing amnesia concerning parts of their childhood, negating the effects and impact of sexual abuse, and feeling that they should forget about the abuse[7].

- **Establishing Relationship:** Survivors of sexual abuse may experience difficulty in establishing interpersonal relationships. Symptoms correlated with childhood sexual abuse may hinder the development and growth of relationships. Common relationship difficulties that survivors may experience are difficulties with trust, fear of intimacy, fear of being different or weird, difficulty establishing interpersonal boundaries, passive behaviors, and getting involved in abusive relationships[7].
- Many survivors experience sexual difficulties. The long-term effects of the abuse that the survivor experiences,affect the survivors sexual functioning. Author Maltz[5] gives a list of the top ten sexual symptoms that often result from experiences of sexual abuse: "avoiding, fearing, or lacking interest in sex; approaching sex as an obligation; experiencing negative feelings such as anger, disgust, or guilt with touch; having difficulty becoming aroused or feeling sensation; feeling emotionally distant or not present during sex; experiencing intrusive or disturbing sexual thoughts and images; engaging in compulsive or inappropriate sexual behaviors; experiencing difficulty establishing or maintaining an intimate relationship; experiencing vaginal pain or orgasmic difficulties (women); and experiencing erectile, ejaculatory, or orgasmic difficulties (men). A study done on the prevalence and predictors of sexual dysfunction in the Untied States which found that male victims of childhood sexual abuse were more likely to experience erectile dysfunction, premature ejaculation, and low sexual desire, and they found that women were more likely to have arousal disorders [8].

Recommendations

1. Proper IMPLEMENTATION & ENFORCEMENT of laws such as laws banning violent punishments given by parents, teachers or any caregivers.
2. Parents should let their kids know about what is sexual abuse especially what is wanted or unwanted touch and how to handle when someone approaches.
3. If a child that would be an adult someday is physically and psychologically strong at peace then he would productively participate in the development of society.
4. Protection of a mistreated child must be our main concern. Abused children and children who witness violence between parents are at an increased risk of growing up to be abusers themselves. Thus, every time we prevent an individual from being abused, we may be protecting future victims as well.
5. Communities can ensure that public and private agencies have the tools-such as assessments, evidence-informed interventions, and properly trained staff- to provide children and their families with timely, appropiate care to prevent child maltreatment and alleviate its effects.

Who Recommended Steps That Should Be Taken By Health Sectors:

1. Awareness should be raisedabout long term negative health effects and social burden of child maltreatment- both in health sectors and other sectors.
2. Data about prevalence, risk factors,health consequences of child maltreatment should be collected and communicated.
3. Evidence-based interventions should be developed and tested to prevent child maltreatment-like home visits with nurses and parenting programmes held in provider's office or health facilities.
4. Support and services should be provided to victims of child maltreatment including mental health and psychosocial health services.
5. Other sectors should also be collaborated to address child maltreatment, especially social welfare protection, education, criminal justice sectors.

Conclusions

Tens and thousands of children each year become the victim of child abuse and neglect. Though it is a complex societal issue, little is known about the consequences of adult outcome which this review article tried to shade

light on it. Doctors and health care professionals play a key role in detecting such inhuman atrocities but unfortunately most of the time fail to do so due to lack of understanding and protecting these vulnerable groups. So this review article discussed about various outcomes of child maltreatment and its traumatic impact on victims, family, society.

Physiotherapy in Dentistry

N. Aravindha Babu[1], Sudakshina Mukherjee[2], L. Malathi[3], K. M. K. Masthan[4]

[1]Professor, [2]Post Graduate Student, [3]Reader, [4]Professor and Head of the Department, Department of Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

Physiotherapy can be the alternative line of treatment for orofacial pain. It can be considered and well tolerated by the patients since it is painless, but by now also the concept is quite unclear to many so implementation in dental practice is far fetched. So dental professionals should be aware of the positive benefits regarding this line of treatment and try to incorporate in the challenging cases of various orofacial pain.

Keywords: *physiotherapy, orofacial pain, dentists*

Introduction

Orofacial pain is one of the most common problems that dentist faces in his clinical practice. These are complex, chronic disorders of multifactorial origin, the diagnosis and management is a real challenge to dentists. An understanding doctor, a well informed patients reasonably adequate communication between both, devoted compliance to treatment and a consistently mental attitude are essential to alleviate even the most intractable orofacial pain. Orofacial pain can vary from occasional nags to suicidal pain which can affect the quality of life and well being of human beings. Primary treatment aim should always priortize in giving relief from pain to patients and return the particular individual to his normal life.

The concept and benefit of physiotherapy have been a foreign idea to lot of people in past and up until now, people usually suffering from the orofacial pain conditions consult doctors and demand drugs to get relief but this only deals with the symptoms rather than the cause of the pain and have addictive side effects too. So, alternatives like field of physiotherapy can play here a major role as it is a non-pharmacological treatment, based on the traditions established in the field of orthopedics concerned with care, management and rehabilitation without any side effects as do in oral medications.[1]

Dentists Awareness: As day passes on the field of Physiotherapy are coming into light. They have been incorporated in certain orofacial conditions and results are also satisfactory. But still there are dental professionals who are not so aware of the positive outcomes of this branch or how it could be implemented in their practices. According to a study conducted in Florida, a large percentage of dentists who completed the survey were not aware of benefits of physiotherapy in treating TMDs, where TMD is a very common disorder a dentist faces in his daily practice. [2]

Treatment Modalities in Physiotherapy

Physical Therapy[3]: Mainly **indicated** on muscle spasm, migraines, myositis, revascularization.

Physical Therapies are **contraindicated** in - Acute infectious conditions, Cancers, Skin infections, Abscess, Synovitis.

Types[4,5]:

1. **Massage:** Flexibility is restored and stimulates parasympathetic activity.

Corresponding Author:
Dr. Sudakshina Mukherjee
Post Graduate Student
Department of Oral pathology and Microbiology
Sree Balaji Dental College and Hospital
Bharath Institute of Higher Education and Research (BIHER), Chennai

A. **Deep Massage:** Assist in mobilizing tissue and increase in blood flow thus eliminating triggering point

Mechanisms of Physical Therapy:

A. **Biomechanical Effect:** It produces mechanical pressure on tissues. It decreases tissue adhesion, Increase muscle compliance and range of joint motion. Decrease passive and active stiffness.

B. **Physiological Effect:** It produces changes in tissues or organs, like increasing muscle blood flow and skin blood circulation. It increases parasympathetic activities, cause increased in relaxation of hormones and decreases stress hormones.

C. **Pschological Effect:** Increases relationship between body and mind by promoting relaxation and decreasing anxiety.

D. **Neurological Effect:** promotes reflex stimulation, neuromuscular excitability thus decreasing pain and muscle tension or spasm.[3]

2. **Spray And Stretch Technique:** Mixture of flurocarbons as vapocoolant are used since it decreases the pain so that manipulation becomes comfortable.

3. **Physical Activity:**

Indication: Myofacial pain due to active trigger point, musculoskeletal dysfunction, to increase range of motion of various joints.

A. **Soft Tissue Mobilization:** Also called Myofacial release. Similar to deep massage. It also alleviates the trigger point and enhance blood flow and mobility.

B. **Joint Mobilization:** Not indicated in inflammatory joint disorders.

C. **Muscle Conditioning:** Compilation of exercises that help to restore normal function and movement of orofacial structures. These are - I)Passive Muscle Stretching ii)Assisted Muscle Stretching iii)Resistance Exercises Iv) Postural training. POSTURAL TRAINING is mainly done with patient of TMD having a forward head posture to keep the head in a more normal relationship with shoulders which in turn can help in reducing the TMD symptoms. Further Exercises like facial strengthening exercise which includes puckering of lips and moving from one side to other, smiling by showing teeth and gums, puffing of cheeks, "O" Exercises (pursuing the lips in an O shape hiding the teeth under lips), Lower lips lifting, lip holding (by putting stick or tongue blade) between lips and holding with two lips only) T2,1. TONGUE EXERCISES like straight tongue stretch side tongue stretch, up & down stretch, tongue sweep, Pushing the tongue against the cheek[4].

Electrotherapy: Frequently used now in clinical physical therapy for pain relief and tissue regeneration. It has a bioelectric effect on human cells. It stimulates sensory nerve to treat pain. Photomodulation of LASER activates the components of the mitochondrial respiratory chain resulting in starting of cascade of cellular events. Release of Histamine, Serotonin, Bradikinin and Prostaglandins which are the substances all related to pain takes place once LASER radiation gets absorbed in tissues.

Contraindications: pregnancy, infections, malignancy

Significance of Low Level Laser Therapy(LLLT):[6] Beneficial aspect off LLLT has been found in swelling, oedema in acute phase injury and in accelerating healing of surgical wounds. **Analgesic & Anti-inflammatory effects** of LLLT seen effective in ulcer, burns, herpes infectins, scar tissue, keloid, scleroderma, neurodermitis, lichen planus, psoriasis,hematoma. Neurological Diseases like Carpal Tunnel syndrome, Trigeminal Neuralgia, facial palsy, headache, Post Herpetic Neuralgia, peripheral nerve Injury are treated by LLLT.

TENS (Transcutaneous Electric Nerve Stimulation): It is stimulating device which delivers electric currents across intact surface of skin.

Indications: Produce an analgesic effect in acute pain of dental procedures, chronic pain conditions like post herpetic neuralgia, trigeminal neuralgia, causalgia, peripheral nerve injuries, angina pectoris, facial pain. Non analgesic effect like as an antiemetic, thus improving blood flow which is useful in reduction of symptoms with Reynauds disease and diabetic neuropathy. It also plays important role in healing wounds and ulcers.[12]

Thermal Therapies: Human Tissues are easily affected by heat and cold in form of beneficial thermal therapy. In cryotherapy intramuscular temperature reduced to 3-7 degree centigrade which in turn helps

in reduction of inflammation and thus pain. Ice, cold packs, compression devices, vapocoolant sprays used to deliver cold tmperature to relief pain, reduction in hemorrhage, swelling and oedema, muscle relaxation [7]. Heat therapies using hot water bottles, electric heating pads, hot packs, at lamps, in circulating fluid hot pack, hydrotherapy, paraffin baths, sedative, antispasmodic, analgesic and decongestive effects are carried out. Heat application are useful in relieving pain, providing warmth, to promote healing, to decrease muscle tone and to soften exudates. [7]

Indications: Diseases like Malignancies, Painful muscle spasms, abdominal cramps, Menstrual Cramps, Superficial thrombophlebitis [8].

Role of Physiotherapy in Some Common Orofacial Conditions

1. **Trismus: lock jaw** OR reduced opening of jaw. Treatment Modalities like a) Tongue blades, b) Yawning exercise and c) Therabite jaw motion rehabilitation system [11]

2. **Temporomandibular Disorders (TMD):** Various steps are used to treat this disorders. Physical activities like soft tissue mobilization, by practicing various stress reduction exercises. Advice to the patients like regularly eating soft food, chewing on back of teeth from both sides simultaneously. Eating small bites. Avoiding habits like involving in excessive jaw use like yawning, grinding, clenching and chewing gum, long dental appointments should be avoided and cradling telephone for very long time between head and shoulder.

   Acupuncture, Thermotherapy,TENS, can also be used to alleviate the pain from TMDs.

3. **MPDS:** Several Physiotherapy techniques are used in treating MPDS are as follows:- **Thermaltherapy:** superficial heat (warm-wet), deep heat (ultrasound), Cryotherapy (ice packs, vapocoolant spray) and **TENS** (electrotherapy) used. These modalities help in reduction of muscle tension, decrease inflammation and inactive muscle trigger points [13]

   Exercises relieving muscle pain like a) Various exercises like opening the mouth with a hinge movement.b) Exercising the jaw by closing the mouth on the back of teeth.c) Putting the tip of tongue on the palate behind front teeth.d) Moving the tongue across the palate as far as it will go by keeping the tongue in this position with teeth closed for 10n seconds and opening the mouth the mouth slowly until tongue starts to leave the palate- This usually helps in relieving the pain of TMJ. This exercise is repeated three times daily for minutes[10].

4. **OSMF:** Oral Submucous Fibrosis usually at severe conditions end up in restricted mouth opening in patients. In those cases- Oral physical exercises like cheek, tongue and lip exercises, diathermy and ultrasound therapy generally add benefits to patients [1]

5. **Bell's Palsy:** Greatly disrupts the quality of life of patient. Thus certain physiotherapy treatment modalities like different facial exercises, exercises to close the eye and sometimes acupuncture can provide some relief to patients and also return them to their normal life [1]

6. **Hypermobility of Mandible:** Muscle Conditioning exercises like rhythmic stabilization exercises and progressive isometric strengthening are useful in treating this condition.

Discussions

It is important to implement physiotherapy according to the clinical condition of each patient. So appropiate diagnosis and treatment plan is very crucial to make the patient symptom free. Thus a clear understanding about the detailed physiotherapy applications as needed along with their benefits is needed. The dentists should be careful in choosing the physical therapy as treatment option for orofacial pain. So more collaborations between dentists and Physiotherapists for management of orofacial pain conditions is needed to improve the result. But as we can see lack of knowledge about physiotherapy is prevalent and it is preventing this field to get fully involved with dental profession. In future this novel method of treatment should be promoted as it show a promising result in non invasive way cost effectiveness of this field also make it easy acceptable to patients. But still now compliances of patients towards this way of treatment is low since it is time consuming. So, much awareness has to be made o council the patients about its wide range benefits enhancing the quality of life of patients.

Conclusion

Future studies needed to investigate whether collaborations between dentists and Physiotherapists have increased and treatment benefits from those collaborations should be assessed. From the past studies though it is limited in number, it has been assessed that a multidisciplinary approach using combination of pharamacology and physiotherapy giving out best possible outcomes in management of various orofacial pain disorders.

Role of Oral Pathologists in Regular Practice

Sudakshina Mukherjee[1], K. M. K. Masthan[2], R. Jayasri Krupaa[3], N. Aravindha Babu[4]

[1]Post Graduate Student, [2]Professor and Head of the Department, [3]Reader, [4]Professor, Department of Oral Pathology and Microbiology, Sree Balaji Dental College and Hospital, Bharath Institute of Higher Education and Research

ABSTRACT

It is this branch of dentistry where research meets practice, and thus unique and rare in its own way. This science investigates the causes, processes, and effects of the disease affecting oral and maxillofacial region. It is the backbone of dental science and bridge between dental and medical sciences. So Oral pathologists can be called as an epitome of research in dentistry, given the large area available for researches and vast area of issue to be explored regarding the pathophysiology of diseases related. They also play a vital role in diagnosis and treatment planning sometimes guiding the oral and maxillofacial surgeons in their surgical procedures since they have the distinction of meeting patients, observing the clinical presentation of the disease process, investigating the cause of the pathology and determining the final histological diagnosis based on clinico-radiologic-pathologic correlation.

Keywords: *Oral pathology, Diagnosis, Oral mucosa.*

Introduction

Recognition of the importance of this speciality in the minds of Indian dental fraternity is quite behind. Though lots of research scopes are there, it becomes negated due to lack of infrastructure and funding for research in the dental institutions across the country. The uniqueness of this field should be made understood in the budding dentists since oral pathologists not only are capable in diagnosing various diseases and oral cancers, their unique training and experiences are capable of providing specialized services that cannot be found anywhere else in the dental health care system. As rightly said by Sir Williams Osler, a Canadian physician "As is our pathology, so is our practice". Though it is impossible to learn all the oral lesions and conditions, a fundamental knowledge of oral pathology is essential to become a successful practitioner[1]. So this is high time when Dental Council Of India should encourage & initiate to create centers of oral pathology in each dental institution with adequate infrastructure and material for quality dental research.

Significance of Oral Pathologists in Diagnosis: The most undeniable significant role of oral pathologists in daily dental practice seen in diagnosing a premalignant lesion from malignant. If it is diagnosed as one, then determining the right grade is very crucial since that denotes the varying treatment plan on which the quality of life of that particular patient depends upon.

Systematic Diagnostic Approach of Oral Pathologists: Arriving on a proper diagnosis is not an easy task. It requires a systematic approach to get to the right answer.

1. **Collection:** Thorough history taking for collection of proper information is crucial. History regarding the onset, frequency, duration of their chief complaints plays a very vital role in determining a preliminary diagnosis or get a rough idea about the disease. Medical history should be properly taken to prevent any contraindications in upcoming dental treatment and also to find out any drug related clinical or pathological changes [2].

Corresponding Author:
Dr. K. M. K. Masthan MDS,
Professor and Head of the Department,
Department of Oral pathology and Microbiology
Sree Balaji Dental College and Hospital
Bharath Institute of Higher Education and Research

2. **Classification:** Now in this crucial part of diagnosis of any lesion, clinician once come across a particular lesion he/she tries to fit according to the following categories- Generally most of the oral lesions are categorized into either change of colour, or loss of integrity of mucous membrane like erosion fissure, ulcer, which could be primary or secondary, It can be growth or swelling. Lesions may involve tooth or bone either alone or in combination with soft tissues or it could be a part of syndrome[1].

3. **Comparison:** Once the lesion has been sorted and classified to one comes the next step of comparison. In this stage the oral pathologists ensure a greater advantage than rest of the dental specialities since their wide range of knowledge relating a particular lesion and their unique training makes its advantageous than the rest. Coming to a more appropiate conclusion clinically becomes evident for them than rest. Mainly here clinician try to see the size of the lesion, whether they are single or multiple or whether well circumscribed or not and then is correlated with patients' history, depending on this only the differential diagnosis is made. For example a macule cannot be compared with papilloma. A comprehensive evaluation of the possible etiology of the condition while taking history may sometimes give a clue to the diagnosis. This is especially seen in hereditary disorders and developmental lesions. Palpation denotes the nature of the lesion I.e whether it is cystic or neoplastic. Habit history also gives vital points in denoting and diagnosing disease. For example if whitish homgeneous patch unscrapable noticed with chronic history of tobacco leukopakia could be the provisional diagnosis of the patient. Non healing ulcer for than 2 weeks in oral cavity with history of tobacco chewing can easily got suspected to squamous cell carcinoma. Intrabony lesions like ameloblastoma, odontogenic keratocyst, pindborg tumor, gorlin cyst generally require radiographs for primary investigation. Some lesions have typical radiographic appearance that gives a definite diagnosis however dental physician should never give a diagnosis based only on radiographic features since sometimes it can be misleading like cotton wool appearance in radiograph can be seen in Paget's disease and also sometimes in condensing osteitis.

4. **Clinical Impression:** Based on all presenting features, that is, history, age, gender, clinical characteristics (appearance, site, location, signs and symptoms), radiological appearance (where applicable), and possible causes, the clinician should correlate all these with each other before venturing to give an opinion.

5. **Confirmation:** When one methodically approaches the patient with an oral lesion, the clinical diagnosis is, usually, not difficult and does not require any further investigations. However, many diseases of the mucosa, other soft tissue and bone require additional information to make a precise diagnosis. This information in many instances may be provided by biopsy and submission of tissue for histopathologic examination. The indications for oral biopsy and other allied techniques and the procedures that will help ensure accurate diagnosis.

Biopsy soft tissue Indications[4]: Soft Tissue Lesions For any unknown lesion or condition of the oral mucosa, a scalpel biopsy is the gold standard for diagnosis. When recognizing tissue abnormalities, the clinician must first attempt to determine the etiology.Clinician may choose to provide treatment and to monitor the lesion that are suspected from traumatic injury or any infections for a period of 1-2 weeks for resolution,if not then it should undergo biopsy. Leukoplakia, erythroplakia and persistent or widespread ulcerations necessitate biopsy. Persistent changes in color or any new growth noted on examination should also be considered for biopsy.No matter how confident the clinician may be with their clinical diagnosis, any tissue removed from a patient should be submitted for histopathologic examination and this is where the sole role of oral pathologists come into being.

Biopsy Hard Tissue Indications[4]: Few bony abnormalities can be accurately diagnosed based on their radiographic features.Most bony lesions cannot be diagnosed exclusively based on their radiographic appearance. Confirmatory diagnosis requires a biopsy and microscopic examination. Periapical inflammatory lesions and intrabony cysts and tumors show radiographic changes that are indefinite beyond a presumptive clinical diagnosis. Given the differences in treatment and prognosis for many of these entities, identification of these lesions mandates biopsy.Rapid

bone loss, irregular widening of the periodontal ligament, spiking root resorption and tooth mobility in the absence of trauma or an identifiable source of inflammation is often an ominous sign and should be evaluated carefully. Expansion, pain and paraesthesia are some other features of hard tissue lesions that would warrant biopsy and histopathologic examination.

Final Confirmatory Diagnosis: After getting the histological clarification and diagnosis of the given specimen from oral pathologists clinician can come into conclusions confidently about the lesion and plan treatment accordingly. One mistake in oral pathologists part and whole scenario is changed so is the life of that patient.

Limitations and Recommendations: Generating demand for oral pathology services is the prime requirement to sustain the growth of the profession. There is a need to create awareness about the significance of utilization of the profession in clinical practice. Histopathological examination of every tissues should be made mandatory, so that all dentists should realize their responsibility to utilize post extraction soft tissues and other tissues removed from oral cavity[5].

Oral pathologists need to come in direct contact with the patients for diagnostic evaluation with active participation in direct patient care within both the hospital environment and dental school setting, and play and active role in cancer screening by performing biopsy and cytological procedures themselves. Addition of imunohistochemistry and gene sequencing has strengthened diagnostic pathology in recent years[3]

Conclusion

Management of oral and maxillofacial diseases and conditions by the oral and maxillofacial pathologists must also assume a greater level of importance, not just in dentistry but within the health care delivery system as well. Oral pathologists need to take lead role in researches in dental institutions which include clinical and basic research in areas of cell and molecular biology, stem cell research, immunology, genetic studies for various oral diseases [5]. Diagnostic and investigative labs have a good scope in India curriculum needs to be modified to train oral pathologists to be able to establish, manage microbiology, hematology, biochemical and oral pathology single handedly. Lastly to conclude one must remove barriers that serve to isolate oral pathologists fro other components of health care system, while reinforcing the importance of oral and maxillofacial pathology to members of their own profession. Oral and maxillofacial pathology is in a position to lead our profession, but educational programs must be redesigned to allow innovative growth and developmental skill in graduates that will be valued by the research community on one hand and the health care delivery in 21st century.

Radicular Cyst of Jaw: A Review

Sudha Jimson[1], S. Jimson[2], S. Leena Sankari[3], Lokesh Bhanumurthy[4], A. Julius[5]

[1]Professor, Department of Oral Pathology, Sree Balaji Dental College & Hospital, Chennai; [2]Professor & Head, Department of Oral & Maxillofacial Surgery, Tagore Dental College & Hospital, Chennai; [3]Professor, Department of Oral Pathology, Sree Balaji Dentalcollege & Hospital,Chennai; [4]Reader, Department of Oral & Maxillofacial Surgery, Tagore Dental College & Hospital, Chennai; [5]Professor & Head, Department of Biochemistry, Sree Balaji Dental College & Hospital, Chennai

ABSTRACT

Radicular cyst is the common odontogenic inflammatory cyst which arises from the cell rest of malassez. It is asymptomatic and swelling proceeds solely indicating cortical plate expansion radicular cyst is the consequence of pulpal necrosis. The management of radicular cyst is aided by clinical, FNAC and radiographic examination. Diagnosis is confirmed by histopathological examination. Treatment options are based on the extent of the lesion, structure, origin and clinical/systemic condition of the patient. Untreated cyst may expand causing local tissue destruction and further pathological deformity. Management includes non-surgical endodontics and surgical methods like endodontic surgery, decompression, marsupialization or enucleation. This article briefly discusses the clinical features, etiopathogenesis and treatment options for management of radicular cysts.

Keywords: *Cyst, MTA, pathogenesis, periapical*

Introduction

Radicular cyst (*also known as periapical cyst, apical periodontal cysts,root end cyst& inflammatory dental cyst*) is an inflammatory cyst of odontogenic origin. It is the most common odontogenic lesion of the jaws. WHO defines that Radicular cyst is an odontogenic cyst of inflammatory origin associated with non-vital teeth; a residual cyst is a radicular cyst that remains in the jaws following extraction of the affected tooth.[1]Kramer defined cyst as a pathological cavity that may or not be lined by an epithelium and with filled with fluid, semi-fluid or a gaseous substance. A radicular cyst pathologically arises as a sequel to pulpal necrosis following dental caries or maxillofacial trauma. The lining epithelium of the cyst has its origin from the epithelium rest of malessez in periodontal ligament; inflammatory stimulus causing proliferation of a pre-existing peri-apical granuloma may result in a radicular cyst.[2]

Radicular cyst is the most common (55%) odontogenic lesions of the jaw with a wide patient age-range. Peak incidence seen in the 4th and 5th decade of life with slight male predilection. Most commonly seen in the maxillary jaw representing a periapical well defined radiolucency, very often seen in the apex of the root. Sometimes may be associated with lateral root canal as well. Conventionally, radicular cysts are managed by conservative and surgical management. Extraction of the tooth or apicectomy with enucleation of the cystic cavity may be done; root canal treatment may be opted as a non-surgical management. [1]

Although literature has discussed in detail about radicular cyst, this article highlights recent findings in the pathology and treatment of radicular cysts.

Discussion

Radicular cyst is an inflammatory odontogenic cyst caused due to pathological inflammatory stimulation

Corresponding Author:
Dr. K. M. K. Masthan MDS,
Professor and Head of the Department,
Department of Oral pathology and Microbiology
Sree Balaji Dental College and Hospital
Bharath Institute of Higher Education and Research

of the cell rests of malassez found in the periodontal membrane. These are remnants of the hertwigs epithelial root sheath. Pathogenesis of radicular cyst is briefly described in **Chart 1.**A cystic cavity is formed and enlarges with hydrostatic pressure and also resulting in bone resorption.

Chart 1: Summary of Pathogenesis of Radicular cyst Formation: *Clinically,* radicular cysts don't show any symptom and are often diagnosed on incidental radiological examination of a carious or non-vital tooth. The growth of the cysts results in further expansion of the cyst in the jaw. *Radiographically,* it is seen as a well-defined, well demarcated unilocular radiolucency which is round or oval in shape and found commonly in the apex of the root. Radicular cysts may be seen in 1-2cm diameter, larger cystic lesions have also been reported in the literature. [1,3]*Histopathological features* shows radicular cysts with a wall composed of inflammatory fibrous or granulation tissue lined by a non-keratinized stratified squamous epithelium. The epithelium is proliferative and has elongated long rete pegs that usually form the characteristic arcading pattern. Long standing mature or residual cyst mature may show comparatively minimal inflammatory component with a regular thin epithelium. The inflammatory component is often mixed, may also contain prominent foamy histiocytes, cholesterol crystal deposits, foreign body giant cells etc. Hyaline and Rushton bodies are characteristic findings of radicular cysts but may not be always seen. Metaplastic changes may also been observed. [4]

Treatment option depends on the size, localization of the lesion, bone integrity in relation to the lesion and the proximity of the lesions to vital structures. Patient cooperation and systemic condition should also be taken into consideration. [5,6]

Non-Surgical Management includes endodontic therapy in small lesions, not commonly done in larger lesions. Endodontists prefer conventional Root Canal treatment for successful management of radicular cysts of small sizes. Conservative approach here includes thorough endodontic therapy, Baker had suggested an over-instrumentation of 1mm beyond apex to disrupt the lining epithelium and enable better healing by converting the cyst to a granuloma. Bender further added that this technique helped in establishing proper drainage of the cystic lesion. Eventhough the technique is found to be effective in cases, undue or excessive trauma beyond the apex may even be eventful. Proper biomechanical preparation, drainage of cyst intracanal medication and follow up plays an important in such cases.[7-11]

Calcium hydroxide is the commonly used intra-canal medicament, it has an alkaline and bactericidal effect that helps to initiate repair mechanism and stimulate hard tissue formation. Placement of Calcium hydroxide is the best known alternative to over-instrumentation. Souza et al suggested the following effects of calcium hydroxide as an intra-canal medicament: anti-inflammation action, neutralization of acidic products, activation of alkaline phosphatase and anti-bacterial activity. Endodontic therapy may be following by apicectomy and retrograde fillings. MTA (Mineral Trioxide Aggregate) is the commonly used retrograde filling following an apicectomy, this avoids further inflammation and aids in healing. Literature not only shows that MTA is a useful in endodontic surgery (apicectomy and retrograde filling) but aids in sealing pulp chamber perforations, internal resorptions, lacerations and apical transportation. MTA is also known to produce predictable and better results than calcium hydroxide. [12-15]

Surgical Management is often indicated in larger lesions where endodontic treatment may not be effective. Surgical management includes decompression, marsupialization or enucleation of cyst or combination of techniques. Surgical approach depends on the size and location of the lesion. Enucleation is preferred treatment of choice of odontogenic cysts when it is possible to completely remove the cyst without damage to vital structure. Enucleation involves complete removal of the cystic sac followed by primary closure. Marsupialization may be done when the lesions are large with vital structure nearby and has increased risk of fracture. Marsupialization with decompression may be done to first reduce the size of the lesions. In any scenario, long term follow up is essential to appreciate osseous regeneration of the site. [16-19]***Decompression*** is a conservative approach used to progressively reduce the size of the lesion, thereby eliminating the reason for surgical enucleation. This technique involves the surgical exposure of the cyst wall and insertion of a drain tube to enable draining and decompression of cyst. Decompression aids in disruption of the lesional wall which results in reduction of internal osmotic pressure and followed by osseous regeneration. Decompression in not indicated in lesions without any cystic fluid, like

in cases of large dental granulomas or solid cellular lesions. Similarly, aspiration or irrigation shall not be done when there is no aspiration of fluid from lesions in adjacent tissue space or sinus cavities nearby.[7, 21, 22]Marsupialization is done in cases of large cysts where it may be associated with vital structures. The technique is favored due to its low morbidity; healing and bone regeneration takes place with shrinking size of the lesion. However, this management require longer post-operative management and long term follow up is essential.[23]

Conclusion

Multidisciplinary approach is the key in management of radicular cyst depending the associated factors like size and proximity of lesions. Whenever possible size of the lesion should be reduced or decompression before attempting a surgical curettage of the cyst. Regular follow-ups with radiographs is essential even when only endodontic therapy is involved, long term follow up becomes essential when endodontic surgery with or without surgical management is involved.

ABSTRACT

Alternative medicine is the term that describes medical treatment which helps to attain the healing effects of medicine, it includes a group of medical and health care system and practices but lacks in evidence-based information, safety and drug interactions. The healing methods of alternative medicine includes both natural and spiritual ways. Since ancient time the alternative medicines have come into our practice and till today it is being practiced all over the world.Alternative medicine has gained more popularity all over the world and in recent times alternative medicines are included in many fields including dentistry. This article reviews about impact of alternative medicine in treating oral diseases.

Keywords: *Alternative medicine, dentistry, yoga, oral diseases.*

Introduction

Oral disease is one of the major health problem all over the world. It may seem to affect limited area of oral cavity but there are possibilities that it may affect the body as a whole. Even in 21st century with advancement in dentistry, oral disease are considered to be the greatest health issue. In recent times, alternative medicine is more popular because ofcost efficiency, safety, better treatment options and have more successful results. Alternative medicines are used in many countries even though they have their own health care system. Complementary medicine, integrated medicine, holistic medicine, fringe medicine, unconventional medicine are the other names for alternative medicine. Some of the alternative medication used in dentistry are Siddha, Ayurveda, Yoga, Acupuncture, Herbal therapy, Unani. These alternative medicines are not only used to treat medical and dental diseases, but also it helps in weight loss, relaxation, also aids to treat physical and mental illness. It also aids in leading ahealthy and balanced life style.

Role of Ayurveda: Ayurveda is the ancient health care system followed in india[1]. It is a holistic medicinewhich treats not only the illness,it also gives wellness for body, mental health and spirit. It is believed that ayurvedic treatments are based on the balancing of three constitutions - vata, pitta, kapha[2]. Ayurveda and Traditional Chinese are medicine based on plant-based drugs for the management of specific diseases[3]. Symptoms of sickness may be observed if these constitutions are imbalanced[3]. Ayurvedic preparations contain plant based medicines, animal products and minerals like gold, copper, Sulphur, arsenic[4].

It helps to treat gingivitis, periodontal diseases, ulcers, dental pain, halitosis[2]

Tulsi leaves (*Ocimum sanctum*) prevents plaque formation, gingivitis and halitosis[2.] Eucalyptus (*eucalyptus globules*)[5], olive oil (*oleaeuropaea*)[5], Mustard oil (*Brassianigra*)[5]are used to treat periodontal diseases[2,5].Honey *(Apis Mellifera*) is used to treat ulcers[5]. Garlic (Allium sativum) is used to treat tooth pain. Turmeric (*Curcuma longa*) is used to treat tooth pain, periodontal diseases, and also used to treat potentially malignant disorders of oral lesions. Pomegranate *(Punicagranatum*)[5]is used to treat bleeding gums and periodontitis[5].Jasmine (*Jasminum*)[5] is used to treat tooth pain, ulcers, periodontal disease, lesions of skin[5]. Aloe vera(*Aloe barbadensis*) is used to treat inflammatory diseases[5].

Clove oil, honey, tulsi has anti bacterial property[5]. Jasmine and pomegranate has anti-oxidant property[5]. Jasmine and honey has anti-inflammatory and anti-ulcerogenic property[5].

Ayurvedic preparation i.e plants and natural products are being used for the management of various oral diseases for their therapeutic properties[4]. These are cost effective and easily available remedies. So, traditional methods of Ayurveda can be incorporated with dental practice and to treat oral disease.

Role of Acupuncture: Acupuncture first originated in China, it is used to treat the disease by stimulating certain points with the help of inserting thin needles to human body at varying depth[6]. Mechanism of action of acupuncture is changing the way of pain signals in nervous system and releasing serotonin and endorphins[7].

In dentistry, acupuncture can be used to manage some disorders like tooth pain, temporomandibular joint disorders, muscle spasm, head aches, drymouth, paresthesia of oral structures, neuralgia[7].

In dental pain, acupuncture serves as a supplement in achieving pain relief, by stimulating the nerves which leads to release of endorphins[7]. Because of structural anomalies acupuncture is not helpful in Temperomandibular joint disorders, but it may help to relieve discomfort and pain in muscles[6]. In facial pain, it triggers the nervous system which leads to release of neurochemical messenger molecules, these changes promotes physical and emotional well being of patients[7]. Acupuncture also helps to treat xerostromia by releasing neuropolypeptide and it increases saliva secretion by activating parasympathetic nervesand salivary nuclei in pons and salivary glands[7].

Acupuncture is traditional technique which plays a promising role in other treatment modalities. It is safe, non- toxic and show very low adverse reactions[7].

Role of Herbal Therapy: Herbal therapies are used to treat medical and dental diseases all over the world. In dentistry, herbal therapy is used to treat inflammation, sores and relieve tooth pain[8].

Toothpastes, chewing sticks and mouth washes from Salvadorapersica, acacia gum, sanguinaria, azadirachtaindica has antiplaque, antibacterial and anticarcinogenic properties[9].

Role of Yoga: Yoga comprises the physical, mental and spiritual wellness of body. It originated in india, which helps to unite mind, body and spirit[10]. It reduces stress and enhances health and mental wellness[11]. It helps to treat the occupational hazards of dentists like cervical spondolysis, tendonitis, varicose veins, stress related disorders in mouth such as Temperomandibular jointdisorders, xerostromia, bruxism[12].

Bhujangasan rejuvenates and revitalizes spinal cord, *padmasana*for healthy and flexible spine, *vajrasana*to treat varicose vein, *sirshasana* to produce increased blood circulation[12].*Shitali*and *sheetkariprayanama* for proper alignment of teeth[12].

Compared to all physical activites, Yoga is considered to be the most effective, which helps to reduce psychological stress and promotes good and healthy life style.

Role of Siddha: Siddha a traditional medicine commonly practised in India. It originated in tamilnadu, which belongs to southern part of India[13]. Siddhi is a Sanskrit noun which means perfection.It is not used more frequently in dentistry, but dentist should know about the safety, interactions, use, effectiveness, and adverse reactions[13]. Using of siddha is very rare in dentistry but as per literature, siddha is helps to cure various orofacial diseases.

Karpamooligaigal are used to prevent and treat chronic infections which are existing already[13]. Herbs which are recommended in siddha possess anti-plaque, antibacterial, analgesic, anti-fungal, anti-stress, anti-cariogenic, inhibits the growth of tumor and has high rate of healing properties[13].

Manjal poo chedi (*spilanthesacmella*Murr) is used to treat tooth pain, Thottasinungi (*mimosa pudica*Linn) is effective against gram negative bacteria. Thottasinungiand Chukuti chedi (*solanum nigrum* Linn) are used to treat ulcers in oral cavity[13].Vata (Ficusbengalensis Linn) has anti-inflammatory property and is used to treat oral swellings[13].Karuoomathai (*datura metel*Linn) is used to treat Temperomandibular joint swellings[13]. Kundamani (*Abrusprecatorius* Linn) is used to strengthen the gums and teeth, it can also be used as dentrifice[13].Mahila (*Mimusopselengi*Linn) has anti-inflammatory property and is used to treat inflammation, ulcers, periodontitis and abscess[13]. Sitaphalam *(Annona squamosa)*has antimicrobial, antibacterial anti-neoplastic activities and is used to treat periodontal abscess, squamous cell carcinoma, malignant tumors,bleeding gums[13]. Sivakaranthai (*sphaeranthusamaranthiodesburm) is* used to treat conditions like leukoplakia, erythroplakia[13].

Herbs in siddha show more benefits because of its holistic properties, which prevents bacterial and fungal infections, plaque formation, ulcers and dental caries. It can be used to treat few dental disease but not frequently.

Role of Unani: Unani a Greek medicine, which has higher rate of healing. It is not only used to treat disease, it treats the person as a whole (body, mind and soul). Unani medicine follows the principle of Hippocratic theory of 4 humors i.e blood,phlegm, yellow bile, black bile[14]. Unani medicine preparation i.e herbs and other ingredients show anti-inflammatory, antimicrobial, antiulcer, antioxidant and wound healing properties[14].

Miswak (*Salvadora Persica*), Haldi (*Curcuma longa*), Anar *(Punicagranatum*), Aqarqarha (*Anacyclus pyrethrum*), Suddab*(Rutagraveolens),*Amla (*Emblica Officinalis*), Aqaqia*(Acacia nilotica*), Lehsun (*allium sativum*), Aspaghol (*PlantagoovataForsk*), Babuna (*Matricariachamomilla* Linn), Clove (*syzygiumaromaticum*) are used for the management of orofacial diseases[14].

Unani has gained more popularity in recent years and is being practiced in more than 20 countries around the world[14].

Conclusion

This article has covered various alternative medicines and therapies such as Ayurveda, Acupuncture, Unani, Siddha, Yoga and Herbal therapy. Centuries old alternative medicines are still in practice. In additionto that numerous economical and scientific barriers are faced by alternative practioners that leads to their minimal acceptance in mainstream of medicine. When compared to conventional medicine, alternative medicine is cost efficience, so it will be beneficial for the people with low socio-economic status. The alternative medicines which are safe and cost effective can be included in conventional medicine and dentistry.

Hidradenoma—A Case Report

Vinesh E.[1], Janani S.[2], Sathish Kumar M.[3], Aravindha Babu N.[4], Rajesh E.[5]

[1]Reader, [2]Senior Lecturer, [3]Professor and Head of the Dept, Karpaga Vinayaga Institute of Dental Sciences, Chennai; [4]Professor, [5]Reader, Sree Balaji Dental College and Hospital, Bharat Institute of Higher Education (BIHER) Chennai

ABSTRACT

Hidradenoma refers to a benign adnexal tumor of apical sweat gland. It is often cutaneous, benign tumor of sweat glands. Other names of it are nodular hidradenoma, eccrine acrospiroma, and solid cystic hidradenoma. Lesions are commonly seen on the head, face, extremities and are rarely seen in oral cavity. Clinical appearance of hidradenoma is not specific, but can be diagnosed histopathologically, after complete removal of the lesion. Histopathologically, it has a striking resemblance to salivary gland pathology. A 75 Year old male patient reported with an extra oral swelling near the lip region. Clinical diagnosis was found to be different when compared to the histopathological diagnosis. Management includes wide local excision.

Keywords: *Hidradenoma, Hemangioma, papilloma, Myoepithelial cells*

Introduction

Hidradenoma is often a cutaneous, benign tumor of sweat glands. Also known as solid cystic hidradenoma, nodular hidradenoma and eccrine acrospiroma. Lesions are commonly seen on head, face, extremities and are rarely seen orally. Clinically it appears as solitary, intradermal nodule.[1,2] Histopathological examination show stratified squamous epithelium with underlying connective tissue stroma. Underlying dermis show circumscribed lobules composed of polyhedral cells with moderate eosinophilic to clear vacuolated cytoplasm and centrally placed nuclei. Tumor nests are surrounded by hyalinised fibrovascular stroma showing lymphoplasmacytic infiltrate. One should also take care to check for any rapid growth or ulceration clinically which denotes the malignant change. In this case report, we describe a 85 Year old male patient presented with the chief complaint of bleeding from the swelling on the right side of face near the lips

Case Report: An 85 year old male patient presented with the chief complaint of bleeding from the swelling in the right side of face near the lip region. On examination, a well defined extra oral swelling was present which was oval in shape measuring approx. 3 X 3.5 cms present over the right side of face near the commissure of lip. Surface over the swelling was not even, found pigmented with reddish and bluish hue(Fig 1a). Swelling was firm in consistency and is non tender on palpation. (Fig.1b)

Differential diagnosis of Hemangioma and papilloma was considered. Local excision was done. Macroscopic specimen of skin was received with globular mass measuring 3x2x1 cms, cut surface was grayish white. Firm in consistency.

Fig 1a: Swelling found pigmented with red and blue color

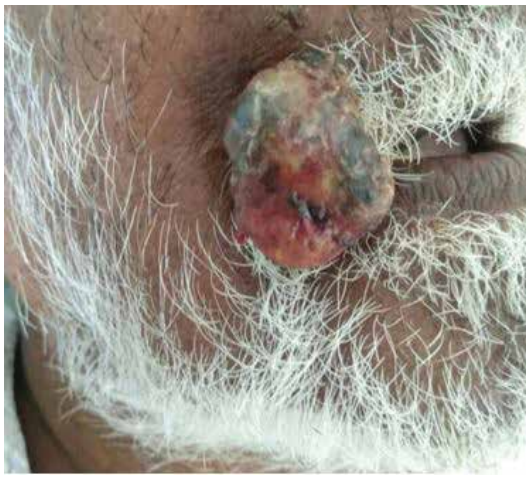

Fig 1b: Firm swelling on the lip

Haematoxylin and Eosin stained histopathological sections of the given specimen show stratified squamous epithelium with underlying dermis. (fig.2a) Dermis show circumscribed lobules composed of polyhedral cells with moderate eosinophilic to clear vacuolated cytoplasm, centrally placed nuclei.(fig.2b) Lobules are separated by hyalinised fibro vascular stroma showing lymphoplasmacytic infiltrate.

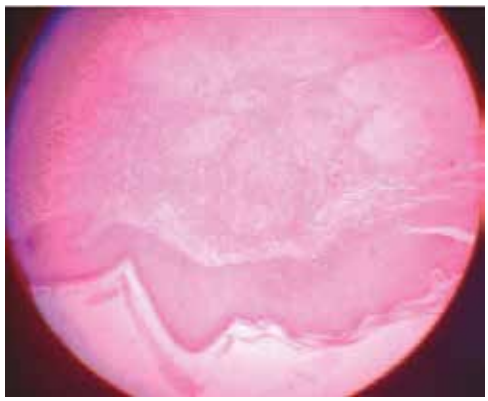

Fig. 2a: Squamous epithelium with underlying dermis.

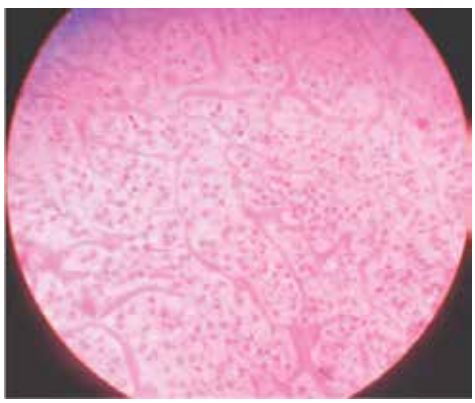

Fig 2b: Lobules composed of polyhedral cells with eosinophilic cytoplasm, centrally placed nuclei.

Discussion

There are two types of sweat glands namely eccrine and apocrine glands. Eccrine sweat glands are found everywhere on the skin except on vermilion zone of lip and nail bed.[3] Apocrine sweat glands are found only on the armpits and ano-genital region. The primary germ cells arising from embryonic stratum germinativum give rise to formation of hair, sebaceous, eccrine and apocrine glands. At 12-13 weeks of embryonic life, eccrine glands first develop.[4] Later at 16 weeks, both intra epidermal and intra dermal tubular lamina begins. Finally a double layer of epithelial cells are seen in Secretory and ductal components. The functional component of sweat glands is Secretory epithelial cells and Myoepithelial cells. Clear cells in the eccrine glands are PAS positive and diastase resistant. They are rich in neutral mucoploysaccharides.[5]

Hidradenoma is the benign tumor of skin appendages arising from the distal excretory duct of eccrine sweat glands. Mostly seen on the face, head and upper extremities. Liu in 1949, coined term eccrine acrospiroma. The term spiroma means adenoma of sweat glands and acro meaning topmost or the end.[8] other names of this are nodular hidradenoma, solid/ cystic hidradenoma. They occur at any age. But more commonly seen in 4th to 8th decades of life. Twice more common in females.[6] but this case it is male patient. Mostly asymptomatic. Solitary growth intra dermal nodule that is slightly elevated above the surrounding skin. Lesions sometimes show aggressive clinical behavior with rapid growth, ulceration and pigmentation.

Histopathology reveals an encapsulated tumor with solid and cystic components. Cystic components may or may not be seen. Solid components mainly consist of two types of cell population. They are epidermoid cell and clear cell. Epidermoid cell are the predominant type. They are eosinophilic with granular cytoplasm and round to oval nucleus. Clear cells are pale with round nucleus. Clear cells are PAS positive and diastase resistant.

Secretory and Myoepithelial components of sweat glands and salivary glands are similar. However tumors arising from eccrine glands show area of apocrine decapitation Secretory activity, primitive hair follicles and melanin pigmentation. These features help in signifying cutaneous origin rather than salivary gland origin.

Sometimes Melanocytes are seen in tumors of sweat gland origin since Melanocytes are component of sweat duct germs in early stage of embryogenesis.

Malignant transformation is rare. And if at all clinically there will be ulceration with rapid growth. Histologically there will be nuclear atypia, increased number of mitotic figures with infiltration [6, 7]

Routine hematoxylin and eosin stained sections are sufficient for final diagnosis. But in case of diagnostic difficulties IHC can be suggested. Biernat et al showed cytokeratin expression in hidradenoma. Most expressions are CK 6/18, CK 7 and CK 8/18. [9]

Conclusion

Diagnosis of hidradenoma can be done histopathologically. They can be treated by simple surgical excision and recurrence is rare.

Columellar Lengthening in Cleft Nasal Defects

Author: Prabu NP[1], Shanmugapriyan D[2], Rakesh Mohan M[3], Vigil Dev Asir[4], Wasim Ahamed S.G.[5]

Sree Balaji Dental College and Hospital, BIHER, Chennai

ABSTRACT

Introduction: A correction of cleft lip/palate associated rhinoplasty using abbe flap is performed in this study. The outcome and perception of the abbe flap for cleft rhinoplasty at patient, surgeons, and patients caregiver evaluation questionnaire.

Materials and Method: A retrospective analysis of preoperative satisfaction and prospective analysis of postoperative satisfaction of patients who underwent cleft rhinoplasty were carried out using questionnaire.

Results: Six case of bilateral cleft lip and palate who had earlier undergone cleft rhinoplasty and lip revision with abbe's flap formed the study group. The mean age of 6 subjects was 23.00+/-3.8years. there were 2 males and 4 female forming the study group.the mean presurgical questionnaire score was 22.8+/- 10.6 while the postsurgical score was 83.5+/-26.2. This difference was statistically significant (p=0.001). the difference in score between the time period was 60.7%.

Discussion: From the questionnaire and other qualitative parameters, it is possible to demonstrate the impact of abbe flap of cleft rhinoplasty and its impact on the quality of life of patient. most of the patient and caregivers believed that this approach achieved agood or excellent postoperative results

Keywords: *abbe flap, revision rhinoplasty*

Introduction

In cases of patients with cleft lip and palate (CLP), often the columella, owing to deficiency of columella height, the nasal tip is depressed, alar bases flared and altered nasolabial angle in the profile. The degree of deformity is different between unilateral and bilateral cases. In most instances of the complete unilateral CLP cases, the deformity is often tilted to the involved side while in the complete bilateral CLP (BCLP) cases the entire columella is deformed.[1] In complete CLP rehabilitation, such a deformed, "crooked nose" poses a significant challenge.[2] In cases of deficiency, the columellar lengthening procedure (COLP) is the most viable treatment procedure. However, the type of COLP needs to be chosen on the degree of nasolabial deformity. It has been always a challenge to recreate an ideal and a natural columella. This could be due to the reconstructed columella which often becomes thick and retracted. Addition of autogenous cartilage would solve the issue in most of the instances. Moreover, it would help to design proper nasal tip, contour.[3,4]

The "Abbe flap" introduced by Robbert Abbe as "lip switch" flap in 1898 for the secondary correction of a cleft lip deformity is still most widely used flap. Still this pedicled flap is used to recreate the philtral subunit which is usually deficient in BCLP.[3,5,6]

Materials and Method

The present study is a retrospective who had undergone rhinoplasties with BCLP correction in our center during 2016-2018. The study included a retrospective analysis of preoperative satisfaction and a prospective one concerning the postoperative satisfaction. The patients who were turning up for clinical review. A specifically formulated rhinoplasty

outcome evaluation questionnaire based on previous publication was used for this specific purpose.

The questionnaire contained the following questions:

1. How much do you like the appearance of your nose?
2. How much can you breathe through your nose?
3. How much do you think your friends and those close to you like your nose?
4. Do you think the appearance of your nose limits your social or professional activities?
5. How safe are you that your nose has the best possible appearance?
6. Would you like to surgically change the appearance or function of your nose?

Each question in the questionnaire was answered with a score between 0 and 6. zero was used for the least score and six for the most positive score. The total score was then added, divided by 24 (maximum possible score) and multiplied by 100 to be expressed as a percentage as described previously.[7]

The questionnaire was administered twice during the visit and the patient's satisfaction was measured pre- and post-surgery. To aid the patients, their profile photographs from the records were shown. The postsurgical experience did not required any aid.

Besides the 2 questionnaire scores, age and gender of the patients were noted down. The qualitative assessment of the postrhinoplasty success as perceived by the patient was also taken down. Postrhinoplasty, the deforming malposition, distortion, asymmetry or scar of the lip vermilion, columellar lengthening, the axis of the nose, and its deviation from the midline, tip projection, and dorsal augmentation of the nose were asked for. The choices were categorized as unnoticeable (to be recognized by patients), obvious (noticed by patients but not by attendants), and deforming (noticed both by patients and attendants). This procedure was also followed in previous, pertinent literature.[3]

Surgical Procedure: The preoperative assessment of patients was those that are used for a standard BCLP and rhinoplasty, the factors that were given specific reconsideration for reconstruction included symmetry of the alar bases and nostril shape, length of the columella, any deformations or deficiencies of the nasal lining, associated lip deformity due to a lack of correct muscle realignment at primary surgery. All patients had undergone various degree of presurgical orthodontics and would require further postsurgical orthodontics for refinement of the technique.[2-7]

Presurgical counseling about the procedure was done. Informed consent was obtained from patients as well as their attendants. They were detailed about the two staged procedure, especially the need to raise the flap from the central (mental) part of the lower lip. The need to temporarily join the upper and lower lip for a limited period and its potential, brief impact on quality of the life was explained with the help of diagrams. The need for procuring grafts for rhinoplasty was explained.[2-7]

The first stage of the procedure was performed under general anesthesia with orotracheal intubation. Local epinephrine injection was avoided in the labial region to prevent possible immediate swelling and thus distortions. The surgical margins were outlined and marked. Fistulas, if any were eliminated and the lateral lip segments were mobilized by incisions onto the nostril floor. The release incision of the oral mucosa and muscle form the premaxilla and pyriform margin allowed the medial advancement of the lateral lip segments without tension.[2-7]

The standard open rhinoplasty was performed with incision being placed along the lower border of the alar cartilages. The nasal columella was slightly raised from its nasal base through a small, strategically placed lateral incisions, just behind the columella that was extended upward and into the nostrils. To perform nasal tip modifications, subcutaneous dissection of the nasal skin envelope was performed. In this process, hemostasis was achieved at every stage. Previously harvested, preshaped (to prevent warping) cartilage grafts were employed for supporting the medial crus of elongation. At this stage, nasal tip morphology was also corrected if needed. The nasal skin was checked and lateral margins of the lip flap were approximated to the columella base. Alar cinch sutures were placed to keep the redesigned nostril width and height.

As per previous work up, the Abbe flap design was marked. Care was taken to rise only minimal, narrow portion of graft and utilized to stimulate the missing philtrum. The flap at tis end was forked to a classic W

shape to match the columellar base incision. While rising an abbe flap by blood pressure blade 11, a full thickness graft with a cuff of tissue on one side was allowed back to facilitate donor site closure. It was ensured that the flap contained sufficient amount of mucosa, muscle, and arterial supply (from an inferior labial branch of facial artery). The flap was then carefully rotated upward to the recipient site without any vascular distortion. The flap was then closed with approximation at the recipient site. The edges were trimmed and donor site carefully closed in layers to prevent scar formation. Standard postoperative medicines and care instructions were given. The Abbe flap was dissected under local anesthesia on postoperative 10-14 days. During the postoperative period or the perioperative circumstances, no complications such as airway obstruction, bleeding, infection, would disruption, or flap necrosis were encountered as observed in the case records. No instances of warping was encountered. None of the patients required surgical revision of the scar or any functional compromise.

Discussion

The BCLP intrinsically involves an alteration in the formation and bulk of the premaxillary structures, noticeably the philtral areas. This results in the deficiency of the tissues along the philtral column and partly nasal structures. In addition, this deficiency reflects on the nasal width, prominence, malformed nasolabial fold. These, in addition to deformed nasal structures, compromise the nasal form, function and esthetics. Surgical correction of BCLP, which at certain instances, requires correction of the basal architecture too.[4,5,8]

The versatility of Abbe flap to correct the BCLP, especially the philtral area has been carried out successfully. Combining this with cosmetic cleft rhinoplasty offers a simple solution to midfacial deformity. The flap is based on the principle that it employs the extra local tissue, namely the lower tissues to correct the deformity the lips to help the transfer of tissue. As the flap is a local flap, ideal color, tissue type matching is possible as accurate as possible. [3-6]

The timing of revision of BCLP and nasal deformities has often been deferred till functional growth ceases for the following reasons as cited by various authors including Bardach and Sayler.[3,9-11]

- To facilitate the orthodontic intervention
- To permit the maturation of the lower nasal cartilage maturation – strong, stable, support for redesigned nasal tip
- To facilitate completion of cleft palate correction
- The current technique is often reserved for a patient who shows a nasal and upper labial deformity in spite of early intervention.[1]The results of the simultaneous correction show the effectiveness of this technique. However, in well-executed cases of early cleft lip repairs, this approach may not be required.

As in this modified method, the entire philtral subunit is redesigned; it gives a well desired esthetic appeal. The patient of their immediate attendants often do not observer the residual deformities or scar. This is evident from the results given in Table 1.

Table 1: Qualitative difference in perception of postoperative rhinoplasty outcome measures

	Malposition	Distortion	Asymmetry	Scar
Unnoticeable	5	4	2	1
Obvious	1	2	1	1
Deforming	Nil	Nil	Nil	Nil

The patients perception of their deformity before the surgery as reflected by the questionnaire score, indicate the psychological, social and physiological impact of nasal deformity. The postsurgical questionnaire score indicates that nearly all patients were completely satisfied to the highest order.

This approach for understanding the success of rhinoplasty has been previously studied, published, and accepted. [2,3]To the best of our knowledge, this study is the first of its kind, which appreciates the outcome of rhinoplasty of BCLP patients. Few other studies have been in this approach, [2,3,7] but none of them employed the questionnaire kind of approach. The effective lengthening of columella with Abbe flap serves many purposes:[5,6,8]

1. Helps to correct the redundant lowerlip
2. Helps to correct the deficient upper lip, particularly the philtral area
3. Corrects the nasal base, tip, columella length, and tissue deformities in the area
4. In case of males, facial hair is found in both the donor and recipient sit. In this regard, with the Abbe flap, the issue of facial hair is negated.

Lo et al., [5] Mokal and Juneja, [3] and kumar et al.[2] have shown that the Abbe flap with simultaneous reconstructive rhinoplasty is a safe and effective procedure without any significant surgical morbidity and airway obstruction. Similar to Mokal et al.[3] authors did not encounter any airway obstruction, but kumar et al.[2] reported two such instances in their cohort. Probable, the nature of the study, patient factors, and difference in approaches contributed to this effect.

The late labial correction often aggrevates nasal deformity owing to complex muscle and loco-regional interactions of the peri-oral and peri-nasal musculature. In this regard, the simultaneous correction of the base of nose, columella, and the upper lip yields a better result than the separately reconstructed ones.[3] In addition, the patient's perception of their postoperative results, the attendant's version are crucial as they have living with the stigma over the years. In this, it was identified that the scar was a major problem. Atleast 1 of the 4 patients reported that they were conscious of the resultant scars in the lips, while none of the patient's attendants noted the same. Malpositioning of nose, distortion of tip, and asymmetry of nares were not noticeable in atleast 86% of the study subjects, postoperatively. This part of the study could carry an inherent time-related bias. However, to compensate for this bias, we did show the archival images that probably helped them to revive their memories. This type of study approach has been used previously.

Mokal and Juneja: Secondary bilateral cleft lip-nose deformity correction by rhinoplasty with simultaneous abbe flap

Figure 1: Twenty-two year old male who after correction of occlusion with orthodontics underwent simultaneous correction of the lip and nose. Comparison of preoperative (a, c) and postoperative status (b, d)

Figure2: Eighteen-year old female had normal occlusion most likely due to unrepaired cleft palate. Patient underwent cleft palate repair and later correction of the lip and nose. Figures a,c showing preoperative status and figures b, d showing postoperative results. Fig e, f, are intra op

Conclusion

Abbe flap with reconstruction rhinoplasty is a reliable, safe procedure, and much effective in corrective of secondary or residual deformities that are especially found at the time after cessation of growth with no complications. The present study presently evaluated the outcome of the procedures and found to have a high degree of satisfaction, postoperatively.

Evalutation of Maxilla Stability in Cleft Patients with Le Fort 1 Maxillary Advancement

Rakesh Mohan M[1], Prabu N. P.[1], Shanmugapriyan D.[1], Wasim Ahamed S. G.[1], Vigil Dev Asir[1]

[1]Reader, Sree Balaji Dental College and Hospital, BIHER, Chennai

ABSTRACT

Context: le fort 1 maxillary osteotomy in operated patients of cleft lip and palate (CLCP). AIMS: to study stability of le fort 1 maxillary osteotomy in operated patients of CLCP by two -dimensional evaluation using cephalometric analysis.

Setting and Design: Prospective study conducted at Sree Balaji dental collage and Hospital from 2016-2018

Materials and Method: Subjects included 3 consecutively operated patients of CLCP with maxillary hypoplasia. Maxillary advancement be le fort 1 maxillary step osteotomy was performed. There was two males and one females with an age of range of 18 to 20 years and follow up range was 6 to 24 months. presurgical and postsurgical changes were compared usingcephalometricsfor orthognathic surgery (cogs) system to determine stability of maxillary movements and quantify relapse at 21days and 18 months.

Statistical Analysis: Student t-test.

Result: Mean linear horizontal advancement achieved along nasion (N) to anterior nasal spine (ANS) with reference to true vertical plane at 21 days and 18 months was 4.17 and 2.91mm,respectively. The mean relapse in anteroposterior dimension was 20.63%. the mean vertical displacement observed along nasion and ANS with reference to true horizontal plane at 21 days and 18 months was 4.21mm and 2.3, respectively with a resultant relapse of 38.54%.

Conclusion: Based on clinical and COGS analysis, it is evident that le fort 1 advancement in operated cases of CLCP has inherent potential for relapse

Keywords: *Le fort 1 maxillary step osteotomy, maxillary hypoplasia*

Introduction

General sequel of CLCP ranges from a mild maxillary hypoplasia to disfiguring midface deficiency collapsed alveolar arches, unerupting/missing teeth and occlusal discrepancies. Secondary alveolar grafting provides a good support to alar base and path for eruption of teeth into alveolar cleft defect. However, midface deficiency is more or less persistent in all cases in varying intensities.

Hussain suggested indications for distraction osteogenesis against conventional orthognathic surgery in CLCP as (a) patients who have not attained skeletal maturity, (b) patients requiring advancement of more than 7mm of maxilla alone, (c) patients with severe fibrosis of lip and palate following multiple attempts at palate repair, and (d) those who have had a pharyngeal flap for velopharyngeal insufficiency (VPI) correction. [6] In the present study, patients who did not require distraction osteogenesis were taken up for evaluation of conventional orthognathic surgery in CLCP with functionally stable fixation.

Materials and Method

A prospective study was conducted at Sree Balaji Dental College and Hospital, Chennai, from 2016-

2018 on 3 consecutive operated patients of CLCP. Individuals requiring single jaw surgery, that is, maxillary advancement of less than 6mm were included in the study. The study group compromised of 2 males and 1 females in an age range of 16-18 years. Follow-up range was 6-24 months. 2 patients had unilateral CLCP (repaired) and 1 had bilateral CLCP (repaired) associated with maxillary hypoplasia. All patients had undergone prior secondary alveolar grafting. Patients analysed had not undergone any orthognathic procedure earlier and complied for a follow-up for a period of atleast 6 months.

Presurgical preparation involved study model evaluation and lateral cephalometric analysis using cephalometric for orthognathic surgery (COGS) analysis. To avoid excessive radiation by cone beam tomography or other techniques such as computed tomography (CT), standard lateral cephalogram was taken as an aid. Standardized lateral cephalogram (same voltage-Kvp, current-mA, and exposure time) was taken for all patients by a single machine and a single technician. Also the image were calibrated to avoid problems such as magnification.

All patients underwent Le fort 1 maxillary high-step osteotomy with downfracture under general anesthesia. Step osteotomy was performed with goal of addressing a wider area of midface deficiency. Occlusal splints were used as a guide for optimum occlusion and following advancement, the fragments were fixed using miniplates. Intraoperatively occlusion was reassessed for stability. Patients were not kept under intermaxillary fixation initially, but were placed on interdental elastics after 24 h of surgery once the airway was secure.

Patients underwent definitive postoperative orthodontic treatment for settling of minor occlusal discrepancies. Follow-up period ranges from 6-24 months. Lateral COGS was performed at 21 days and 6 months postoperatively. Landmarks studied for horizontal advancement was change in nasion (N) to anterior nasal spine (ANS) distance with reference to true vertical plane. Vertical displacement was assessed by change in distance between nasion and ANS with reference to true horizontal plane. Comparison of presurgical and postsurgical changes at 21 days and 6 months interval was carried out to determine stability of maxillary advancement and quantify the relapse.

Results

Postoperative records including lateral cephalograms were analysed at 21 days and 18 months with preoperative records [Figures 1-8]. All patients (n=3) were satisfied with postoperative results due to marked improvement in facial aesthetics. Mean linear horizontal advancement achieved along nasion (N) to anterior nasal spine (ANS) with reference to true vertical plane at 21 days and 18 months was 4.17 and 2.91mm, respectively [Tables 1]. The mean relapse in anteroposterior dimension was 20.63 % at 18 months. The mean vertical displacement achieved along nasion and ANS with reference to true horizontal plane at 21 days and 12 months was 5.21 and 3.2mm, respectively with a resultant relapse of 4.54% at end of 12 months. In a patient of bilateral CLCP, fragmentation of maxilla was encountered intraoperatively which was managed using surgical splint. No other significant intraoperative or postoperative complication was observed.

Figure 5: Postoperative view of case 2, a)Frontal b) Profile

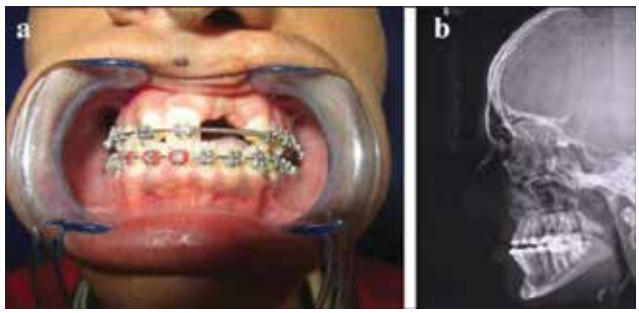

Figure 6: a) Preoperative occlusion, b) Preoperative lateral cephalogram

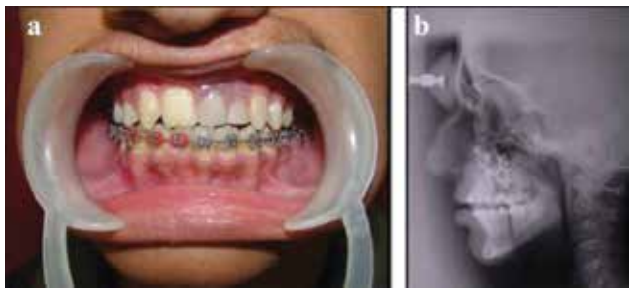

Figure 7: a) Postoperative occlusion b) Postoperative lateral cephalogram

Figure 8: Post operative view, a) Frontal b) Profile

Table 1: Mean values of horizontal advancement and vertical displacement

Mean values	21 days	12months	Relapse	Relapse %
Horizontal advancement (mm)	5.17	3.91	1.26	21.63
Vertical displacement (mm)	5.21	3.91	1.26	41.54

Discussion

Scarred tissues from earlier surgical repair which are often accompanied by presence of a pharyngeal flap can impede horizontal growth and restrict advancement of maxilla during a Le fort I procedure. These forces combined with normal masticatory movements have led to a marked tendency for skeletal and dental relapse after maxillary advancement. Many authors have recommended overcorrection of upto 100% to compensate for this problem.[1] In our study, in view of above few also opted for overcorrection by about 80-90% in all cases.

In 1977 Freihofer[7] stated that maxillary advancement should be delayed until permanent dentition. He documented high incidence of "pseudorelapse" secondary to mandibular growth in adolescent patients. This was later confirmed by Ross.[1] In the present series, we performed Le fort I advancement in adolescent patients in permanent dentition stage.

Araujo et al.,[8] in their series of maxillary advancement stabilized the fragment using stienmann pins and performed bone grafting in 5/8 patients. They found significant decrease in relapse, particularly when grafting was done between maxillary tuberosity and pterygoid plates as also suggested by obwegeser. However, in present study bone fixation was done using miniplates and no grafts were employed. D

Willmar showed that all statistically significant relapses occurred during first year which was later confirmed by posnick and ewing.[9] Most authors agree that vertical relapse is significantly higher than horizontal relapse and tends to occur predominantly during the period of intermaxillary fixation (IMF). Willmar proposed several reasons for a higher tendency for vertical relapse, that is forces exerted by the muscles of mastication, influence of lower jaw position, effects of IMF, pull exerted by suspension wires if they were used. We also got similar results of higher relapse in vertical dimension (41.54%) than along horizontal plane (21.63%)

Houston and James[10] and Posnick and Ewing[9] noted that relapse did not correlate with magnitude of surgical advancement in either horizontal or vertical dimension. Posnick and Ewing also reported that relapse increased in case of pharyngeal flaps, relapse was more in nonrigid type of fixation, and bimaxillary surgery did not affect relapse.

Both the patients in our study group with bilateral CLCP had maximum linera horizontal relapse with 30.4 and 29.16. Tvhus, our findings are also concurrent with Hirano and Suzuki[11] who stated that relapse was more likely to occur in patients with bilateral cleft. They also advocated that jaw surgery should be performed twice in cases of severe maxillary hypoplasia.

In 2001 Heliovaara et al.,[12,13] reported a mean maxillary horizontal relapse of 20.5% and mean vertical relapse of 22.2% within first year following Le fort I advancement and fixation using miniplates in operated cases of CLCP. One year later, the same group of authors showed decrease in relapse in both the dimensions following use of autogenous bone grafts in pterygoid region. The mean relapse was 8.5% (0.4mm) horizontally and 16.7%(0.6mm) vertically in this study. Autogenous bone grafts in pterygoid region has been used by many authors as an alternative to overcorrection. However, it carries the risk of bone resorption and dislodgement with additional donor site morbidity. Our results are similar to that of Willmar, Posnick and Ewing and Heliovaara et al., with a mean horizontal relapse of 21.63% and vertical relapse of 41.54%.

Gateno et al.,[14] and Hussain [6] suggested that advancement of >6mm of maxilla in operated cases of cleft palate require distraction for more stable results. In the present series of cases, patients requiring a composite advancement, that is, with overcorrection to manage postoperative relapse, of <6mm were only included in the study.

It is evident that vertical relapse and horizontal relapse are some of the inherent limitations of Le fort 1 maxillary osteotomy and advancement in operated

patients of CLCP even with autogenous bone grafting. In this study, we assessed functionally stable fixation using miniplates (2mm thickness titanium miniplates) with overcorrection by 80-90% and providing a stable occlusion intraoperatively as a promisabletechnique to achieve satisfactory results. Also, the role of postoperative orthodontics cannot be overemphasized.

Conclsion

In the present study, three operated patients of CLCP with maxillary hypoplasia were prospectively studied after Le fort 1 maxillary advancement. Operated cases of CLCP have inherent limitation for relapse to advancement procedures. Though the present study has a limitation of a smaller sample size; it ascertains that orthognathic surgery with use of rigid fixation of segments though reduces, but does not eliminate the risk of relapse.

Lymphangioma of Tongue—A Case Report

Vigneswaran T[1], Visalakshikaleeswaran[2], Kirthika R[3]

[1]Professor, Department of Oral and Maxillofacial Surgery, Sree Balaji Dental College and Hospital, BIHER, Chennai, Tamilnadu, India

ABSTRACT

Lymphangioma is a hamartomous benign tumour[1]that is characterized by the proliferation of lymphatic vessels due to the congenital malformation of the lymphatic system. This benign tumour can occur anywhere in the body but head and neck being the common site of occurrence. However intraoral lymphangiomas are rare, if occurs it is more common on the dorsal surface of the tongue and the lateral border,and rarely occur in palatal mucosa, buccal mucosa, gingiva and lips[2]. Lymphangiomas of tongue can be associated with difficulty in speech, mastication, chewing and maxillofacial deformities.

Surgical treatment is aimed at providing symptomatic relief ; surgical excision remains the treatment of choice. However other treatment modalities like cryosurgery, electrocautery, sclerotherapy, radiation therapy, laser and tissue ablation can also be used[3]. We hereby present a case of 41 year old male with lymphangioma on the ventrum of the lateral surface of the tongue treated with surgical excision.

Keywords: *Lymphangioma, Cryosurgery, tongue*

Introduction

A 41 year old male reported to the department of oral and maxillofacial surgery, sreeBalaji dental college and hospital with a chief complaint of a growth in his tongue for the past 15 days. The patients history was taken. On intraoral examination a swelling of about 1.5*1 cm in size was present in right ventrolateral border of tongue. On palpation the lesion was soft and tender. There was no bleeding on probing and no restriction in tongue movements.

The treatment done was surgical excision followed by excisional biopsy including 2mm margin under LA. Under LA a suture was placed on the tip of the tongue for the purpose of retraction. Incision was all around the elevated mass and it was then further deepened to excise the lesion completely followed by approximation using silk 3-0 suture.Healing was normal postoperatively. Excisional biopsy confirmed the diagnosis -Lymphagioma.

Differential Diagnosis:

The differential diagnosis includes

- Hemangioma
- Congenital hypothyroidism
- Amyloidosis
- Neurofibromatosis
- Primary muscular hypertrophy[4]

Conclusion

Occurrencea of lymphagiomas are quite rare in the oral cavity however early recognition and treatment helps in preventing complications and continous follow up is necessary to check for any future recurrence.

Nasal Floor Reconstruction in Cleft Patient

T. Vigneswaran[1], Prabu N. P.[1], Rakesh Mohan M.[1], Wasim Ahamed S. G.[1], Vigil Dev Asir[1]

Sree Balaji Dental College and Hospital, BIHER, Chennai

ABSTRACT

Introduction: Widening of alar base width is often required in the lip/palate rehabilitation.the aims of this study is to evaluate such a procedure.

Materials and Method: This is a retrospective study. All cleft case requiring alar base widening were analysed, and the outcome presented at end of 4thand 8th month. This study was typical superomedially placed nasolabial full thickness flap to correct the alar base width simultaneously replaced the nasal lining.

Result: A total of three cleft patient underwent the procedure. Qualitative observation of the outcomes and postoperative changes with the resultant nasal alar base width are presented.

Discussion: The efficacy of this type of nasolabial flap for the alar basal widening and of nasal lining reconstruction is presented. The essential, functional and anatomical consideration in such a flap design is presented in this study.

Keywords: *Alar base reconstruction, Rhinoplasty*

Introduction

Alar base defects could be due to several causes including trauma and developmental aspects.[1,2] In the latter condition, postrhinoplasty, there is a restricted alar base being created by the stress created by the surgical repositioning of the orbicularis oris and the circumoral musculature.

This unique condition poses a tough challenge to the maxillofacial surgeon. Besides the aesthetic requirement, need for considering nasal lining mucosa and provision to accommodate and serve as a base for strong, curvy alar margin is required.[8] In addition to these requirements, recreation of a base that resembles the contralateral alar base is the most daunting challenge. Often such cases would have undergone multiple previous surgeries, and their expectations are varied. The nasal alar base widening is performed as the last step at completion of nasal reconstruction.

Like other openings of the facial cavities, the alar base mucosa has an innate tendency to rescar and contract in spite of the best of the surgical flap designs and postoperative follow-up. In addition, a defective lobule-ala-columella complex, loss of healthy vestibular lining, defective ala, circumferential scarring of the alar base aid the distortion of the alar base. Often the medial aspect, one nearer to columella are resistant to distorting forces as they are held in place by the medial crura and the insertion of the connective tissues (that form the floor of the nares) into the septal region. In addition, the reduced opening of the nares leads to the development of negative pressure caused by the inspiratory actions cause further reduction of the space.[2]

Several strategies have been reported in the literature to correct this deformity. When there is a scar tissue, the dictum is to remove the scar tissue and replace with new healthy lining.[8] When there is no scar as in cleft cases, substitution of the defect with new tissues and lining mucosa would be the norm. There are several types of flaps and designs to rehabilitate the condition.[9]

Material and Method

This retrospective study was conducted in the period between 2014 and 2018. All cases treated for isolated

nasal alar defect with the superiorly directed nasolabial flap with at least 8 months follow-up were included for this study. Only cases with adequate records were included for the study. In total, three cases fulfilling the criteria were retrieved.

Surgical Method: The surgery is done under general anaesthesia. The entire area involved is infiltrated with an adequate amount of lignocaine with vasoconstrictor adrenaline(1:80,000) to achieve minimal bleeding at the site of surgery.

Flap Design: From the base of the involved alar, along the dome, a 'wedge and sill type' of release incision[10] is placed to release the flare from the nasal floor. This will allow the repositioning of the alar base and this incision serves to prepare the recipient site. A peri-alar flap, superiorly (to alae) and medial to the nasolabial fold is raised. The flap is made as thin and long as required but with a wide base. The flap is checked for the length and flexibility. This flap is then transposed into the floor of the nostril. If the flap is bulkier, the flap is rendered thin by preserving the subdermal plexus and removal of unnecessary adnexial structure without compromising the vasculature. This would help in the future to reduce the bulk of the future nasal floor. Care is taken to ensure the preservation of skin adnexial structures. This full-thickness skin graft will cause two benefits: (i) It recreates the vestibular lining, and (ii)Causes lateralizing of the preexisting contracted alar base. This also ensure the proper curvature of the naris, which is often repositioned during the cleft rhinoplasty or during the closure of the orbicularis oris[Figure 1-5].

When the flap is placed in a position along the floor of the nose, it is secured by sutures. The dog ears are cut, and appropriate approximations performed. The now free tip of the released dome ala is approximated with the distal most incision placed for the flap while the mesial part is approximated with the inner part of the nasal flare. The ends are approximated and secured tightly. prescribed as required.

Measurments: Presurgically, the internasal width along the floor was measured thrice with a Vernier caliper. The average value of this was taken as the length of the nasal floor (PN) for the normal side and PA0 for the affected side. At the immediate peri-operative period, it was PA1. After 4 months, in the involved side, the length was measured as PA4and PA8at the end of 8-month period. The difference was expressed as a ratio of the PN and expressed in percentage.

Results

There were one male and two females with age ranging from 22 to 30 years (mean 25.23years). All three cases were unilateral cleft lip and palates cases.In all cases, the grafts were adequately tolerated resulting in complete flap survival. There was no complication with the donor site survival too.

At the baseline, the mean ratio of the PN -the [PA0/Pn] *100 was 86.23+_5.37%. The same after surgery, the [PA1/PN] *100 was 92.27+_ 2.29% and at the [PA4/PN] *100 and the [PA8/PN] *100 were 96.82+_ 1.25% and 90.98+_ 1.05% respectively.

Discussion

The goal of any nasal correction would be to (1) Restore an ideal symmetrical nasal contour suited to the patient's face. (2) The defective nasal part is reconstructed in its three-dimensional form layer by layer. (3) Scars at the donor site should by minimal or could be camouflaged. (4) Modify the nasal aesthetic unit without affecting the function. (5) Use appropriate subcutaneous tissue modulation to refine the result.[11]

The history of alar base correction reveals several diverse surgical designs catering to several types of clinical situations and condition.[9-11] There are simple designs that require only soft tissue correction to complex grafts that might require skin, subcutaneous tissues and even cartilages. The most prominent difficulty encountered in such maneuver is ear notching deformity.[10,12] The place of incision is a crucial factor in the occurrence of this deformity. This designoffers the best result with little complications as this is a salvage surgery that corrects residual defects and produces predictable results with simple maneuvers.

The technique mentioned herein, as per experience of peck et al.,[12] is resistant for such dog ear formation. [12] The involvement of triangle of tissue along the cutaneous part of the nasal base, postsurgically results in an intranasal 'dog ear', however accurately planned. This extraneous tissue, remodels and flattens over time, leaving a nasal closure that is resistant to notching. The depth of the muscle modulation also could contribute to notching.[10] As this technique does not involve muscle manipulation per se, inherently this technique could minimize the notching. This is vital in cases of cleft lip/palate as the alar cinch process, which is often used in cleft closure involves deep circum oral muscle manipulations.

The present technique remotely resembles the 'sill excision and an alar bunching technique' as reported by kridel and castellano.[10] Placing the skin incision for the nasolabial flap about 1mm anterior to the alar-facial groove involving dense concentration of sebaceous glands and the visibility, often creates aesthetical disharmony with the normal side. For this purpose, the careful placement of the early sill incision and proper eversion of the alar margins is needed. The natural alar groove remains as a large portion of the lateral ala is unaffected by this surgery and in the process is shifted laterally too.[10]

Frequent measurement (preoperative and intraoperative) often helps to minimize the asymmetry. But the care must be borne that exact symmetry is always not possible. This is reflected by the mean

[PA1/PN] *100 score of 92.27+_2.29% in the present study. Deep sutures could minimize the same but could cause notching after healing. Hence, a delicate balance is needed. An additional benefit of this surgery is the lateralization of the base of the ala, caused by the closure of the donor site.

Usually, all surgery is subject to several complications. In nasal floor reconstruction, partial necrosis of intranasal lining flaps is often the complication.[9,11]The success of this flap rests on its blood supply. The Superior labial artery is a major arterial supply to this nasolabial flap. No interference with flap circulation was noted with the thinning, clinically. Thinning of the flap may have an impact on the vascularity of the flap, but this could not be measure. However, several studies have claimed its efficient application and graft survival which is consistent with the present observation.

Widening of the alar base is an essential and probably the last part of the cleft rhinoplasty. This is essential as the constricted alar base in this situation causes, reduced inspiratory volume, poses a difficulty in cleaning of the nostrils besides reduction in other physiological functions of the nares. By this surgery, the alar base is widened, the nares and nasal floor morphology is symmetrically matched with that of the normal side. In addition, the resultant defective area is covered with a lining that is adjacent and is a local flap. As the flap is supplied by the labial artery and its branches, the supply is always ensured. The increase in postoperative alar floor length ratio and the maintenance of the same reflects that the results of such a surgery attempt is permanent and lasts for long.

Conclusion

A simple way to widen the alar base in cleft lip/ palate patients with reconstruction of the defect using a local flap is described. Its success and long term results have been reported.

Dental Implants a New Treatment Modality for Replacement of Missing Teeth in Adolescent Patients

Vijay Ebenezer[1], Balakrishnan Ramalingam[2], M. Elumalai[3]

[1]Professor and Head, [2]Professor, Oral and Maxillofacial Surgery Sree Balaji Dental College and Hospital, BIHER; [3]Department of Advanced Zoology and Biotechnology, Govt Arts and Science College, Nandhanam, Chennai

ABSTRACT

The use of implants in replacement of missing teeth is usually minimal in patients with completed craniofacial growth. This literature review is to give an insight about the use of dental implants in growing patients and in patients with ectodermal dysplasia and the effect of maxillary and mandibular skeletal and dental growth on the strength of these implants. It is advisable that on deciding the optimal individual for implant placement, the time point of implant insertion, the status of skeletal growth, the degree of hypodontia, and extension of related psychological stress should be taken into consideration, in addition to the status of existing dentition and dental compliance of a pediatric patient.

Keywords: *Children, dental implants, ectodermal dysplasia, growth.*

Introduction

The most frequently encountered problem in pediatric patients is congenital partial anodontia and traumatic tooth loss. In these cases, oral rehabilitation is required even before skeletal and dental maturation has occurred. Removable partial denture is the treatment of choice in these patients, but it has certain drawbacks like increased caries rate, periodontal complications, and increased residual alveolar resorption. Many studies have discussed the use of implants in children. The use of dental implants for children are a new treatment modality. The two major concerns are: (i) First, if implants are present during several years of facial growth, there is a danger of these implants becoming embedded, relocated, or displaced as the jaw grows. (ii) Secondly the effect of prosthesis on growth. To compensate for growth changes in these cases design changes must be incorporated into such prosthesis.[1] From a physiologic stand point, the conservation of bone may be considered for use of dental implant in a growing patient. The availability of alveolar bone is very less in congenital partial anodontia and placement of dental implant changes the load mechanism on bone and retards its resorption[2].

Growth Determination: It plays an important role in planning implant placement in children and adolescents. To determine the cessation of growth, although a good quality method is the use of serial cephalometric radiograph taken 6 months apart with superimposed orthodontic tracings. If no changes occur over a period of 1 year, one may assume that growth is complete[3]. Oral findings of ectodermal dysplasia Clinically these patients presents with, multiple tooth abnormalities such as anodontia, hypodontia, and tapered, malformed, and widely spaced teeth, abnormal alveolar ridge development. Other physical signs can involve the sweat glands, scalp, hair, nails, skin pigmentation, and craniofacial structures (e.g. cleft lip and cleft palate). Children with Ectodermal Dysplasia do not have normal patterns of growth, and a risk and benefit analysis must be made to assess the value of implant placement, especially in anterior mandible where lateral growth is usually completed by 3 years of age.[4,5,6]

Suggestions for implant placement in unaffected patients

At most care must be taken while placing implants in children because of growth changes in jaw and the dentition.

1. Whenever possible, implant placement must be delayed until the age of 15 years for girls and 18 years for boys.[3]
2. Adequate follow-up is essential in growing patient treated with dental implant [3]
3. Further research is needed in the areas of implants in growing children.[3]
4. Implant location, the sex of the patient, and the skeletal maturation level are the most important factors in the final decision of when to place implant.[7,8]
5. It is still recommended to wait for the completion of dental and skeletal growth, except for severe cases of Ectodermal Dysplasia.[7]

Recommendation for implant placement by quadrant: Maxillary anterior quadrant is an important area for consideration due to traumatic tooth loss and frequent congenital tooth absence. Vertical and anteroposterior growth changes in this area are substantial, the vertical growth of the jaw exceeds all different dimensions of the expansion during this quadrant. The premature implant placement may end up within the repetitive have to be compelled to lengthen the transmucosal implant association that ends up in poor implant-to-prosthesis ratios and also the potential to load magnification[4]. According to Krant,[9] the position of implants within the anterior jaw quadrant before the age of fifteen in feminine patients and seventeen in male patients is good to attain distinctive treatment planning goals and with explicit stress on the sole determination of skeletal age, informed consent, and the possibility of future implant replacement.

Maxillary posterior quadrant is subject to same general growth factors delineate for the jaw anteroposterior space. An additional protein is crosswise jaw growth at midpalatal suture, which produces rotational growth that anteriorizes the position of the maxillary molars. Placement of osseointegrated dental implants within the jaw posterior quadrant is best delayed till the age of fifteen years in females and seventeen years in males[4].

Mandibular associate degreeterior quadrant is that the best website for the location of an osseointegrated implant before skeletal maturation. Mandibular anterior quadrant presents fewer growth variables. The closure of the inframaxillarysymphyseal suture happens throughout the primary two years of life. Prosthesis supported by dental implants within the anterior mandibular bone ought to be of a recoverable style to permit for a median increase of dental height of 5–6 millimeter moreover as the anteroposterior growth(22).

Mandibular Posterior Quadrant: The dynamic growth and development of the posterior mandibular bone within the crosswise and anteroposterior dimensions not to mention its move growth presents multiple treatment considerations. Placement of osseointegrated implants within the posterior inframaxillary quadrant is best delayed till skeletal maturation[7].

Discussion

The benefits of implant use in growing patients are as necessary because the considerations for his or her premature use. Reports were published by Cronin et al. and Smith et al.[10] documenting the placement of endosseous implants in the anterior mandibular region as early as 5 years of age with positive treatment results. Prachar and Vaneek[11] present the results of a 5-year study on the use cylindrical or screw implants in adolescents of age 15–19 years. Prosthesis remodeling, as stated by Smith et al., Brugnolo et al.,Guckes et al., and Kearns et al.,[15] is an undesirable condition due to the repetitive need to lengthen the transmucosal implant-to-prosthesis ratios and also the potential load magnification. According to Dietschi and Schatz[16] and Mackie and Quayle,[17] implant placement in children younger than 16–18 years must be avoided.According to Guckes et al.,[18] bone volume in children may not be sufficient for the placement of implants in ideal positions for prosthesis support. In the totally anodontic patient, the vertical and anteroposterior changes in alveolar development may not be as important as in the partially anodontic patient in whom considerable dental changes can be expected with growth. Bergendal et al.[19] stated that implants must be placed when growth is almost complete, except for rare cases of total aplasia as in ED. Elsewhere, it had been counseled that treatment with

implants should be delayed till the age of thirteen years, since an implant placed at the age of 7 or 8 may not be in a favorable position at the age of 16 years.

Congenital anodontia may be a rare condition and is seen principally as a feature in transmissible syndromes. Anodontia of the mandible is most commonly found in ED. It is rare. Small children with no teeth the least bit within the lower jawbone gift special treatment challenges within the effort to normalizing the looks and performance throughout the years of growing up. Implants in the mandibular anterior region can be placed to support an overdenture, from the age of around 6 years, when the median sutures of the mandible is closed[21,22,23]. According to the 1988 National Institute of Health accord Development Conference on Dental Implants at Bethesda, paediatric patients with disfunction may benefit from the employment of dental implants[23].

Following the presented case and review of literature by Kramer et al,[25] in their article, they recommended the insertion of implants in those pediatric patients who suffer from extended syndromalhypodontia, such as seen in ED. The most appropriate website for insertion appears to be the anterior mandible; insertions within the upper jaw ought to be avoided or a minimum of mustn't cross the sheet. Ryda[26,27] established that all clinical judgment and treatment for children should be performed according to the United Nations Convention on the Rights of the Child. Respect the child's development physically as well as psychologically.

From 1995, many case reports on youngsters with ED are printed on the putting the implants within the canine region of the associate degreeodontic articulator to support an overdenture from the age of 3 to 6 years[4,13,22]. The youngest child reported was a French boy who had implants placed at the age of 1.5 years[29]. Placement of dental implants cannot be recommended before the age of 6 years, since it is well established that children can and should take part in decisions on elective surgery from the age of around 5 years[28].The first published case of placing implants in a boy with hypohydrotic ED and anodontia of the mandible was treated at the Institute of Jonkoping and has been followed for more than 20 years. Overdenture served well until the patient was 19 years old, when two additional implants were placed and the patient was provided with a mandibular fixed implant supported prosthesis[30]. The timing of implant placement in growing patients was discussed at a Scandinavian Consensus Conference in Sonkoping, Sweden,[31] where there was a general agreement that implant placement should be postponed until skeletal growth is completed or nearly completed in normal adolescents. In the individual with genetic disease or anodontia, however, earlier intervention could be indicated, especially in the mandible.

Anodontia and severe genetic disease were mentioned as exceptions to the rule.

Conclusion

Studies on the use of dental implants in young patients are as yet very limited; long-term clinical studies are necessary for sound conclusions. If the goals of treatment planning favor implant use before skeletal maturation, parents of the child need to be informed about the benefits and possible complications of its use. More emphasis has to be given during prosthesis planning. Still, some children are treated with implants, and there are a few in whom the therapy may result in a better quality of life. However, the treatment can only be justified when the anticipated positive effects are greater than the drawbacks of the procedure. Furthermore, when utilizing techniques that are still not fully evaluated for the purpose intended, as clinicians and scientists, we have a greater responsibility of follow-up and monitoring the outcome.

Graft Used in Direct Sinus Lift Technique Followed by Dental Implant

Vijay Ebenezer[1], Balakrishnan Ramalingam[2], M. Elumalai[3]

[1]Professor and Head, [2]Professor, Oral and Maxillofacial Surgery Sree Balaji Dental College and Hospital, BIHER; [3]Department of Advanced Zoology and Biotechnology, Govt Arts and Science College, Nandhanam, Chennai

ABSTRACT

Implant is the best alternative option nowadays for missing tooth replacement. Lack of bone height poses a significant obstacle for its placement. Bone augmentation is an option to counter this problem. To treat the local physiological as well as anatomical limitation, maxillary sinus floor elevation has become an important pre-placement procedure in maxilla. With the advent of Various methodologies to increase the thickness of maxillary sinus floor, One of the techniques involve minimal elevation of maxillary sinus membrane, Schneiderian membrane, while other include placement of various type of grafts including allografts, autografts, bone morphogenetic proteins, and hydroxyapatite crystals. The bone substitutes used in sinus lift is reviewed in this article.

Keywords: *dentalImplant, Schneiderianmembrane, sinus lift, bone graft.*

Introduction

Patients suffering from tooth loss in the posterior maxilla are often subject to esthetic, functional, and psychological complications. Maxillary sinus[1] augmentation (also known as sinus lift) procedures have become increasingly popular procedures prior to placement of dental implants in posterior maxillae that have suffered severe bone loss due to sinus pneumatization, alveolar bone atrophy, or trauma. This article will highlight different sinus augmentation technique, including elevation procedures, regenerative materials, possible complications and postoperative instructions will also be reviewed[2].

Direct Sinus Augmentation Technique (DSAT): Cases with residual alveolar bone (RAB) height 5 mm or below was considered for the direct technique. Autogenous bone grafts was harvested by shaving the mandibular bone from external oblique ridge area or chin area[3]. A bone mill was used to grind the bone shaving into fine particles. After adequate local anesthesia and preparation, a surgical incision was placed on the crest of the RAB at most appropriate area, with vertical releasing curvilinear incisions flaring into the vestibule. Flaps that were raised, reflected full-thickness, subperiosteal labial, and palatal flaps. The base of flap was made sure it was broad as well as adequate buccal and palatal tissue for closure. After elevation, the anterolateral wall of maxillary sinus was visualized. Care was taken to identify and protect infraorbital nerve, if encountered[4]. The dimension of osteotomy was determined based on clinical and radiographic examinations as well as the extent of edentulous span. Using a postage stamp method a buccal bone window was made on exposed wall of maxillary sinus. A gentle manipulation of the bony wall was done with sinus membrane elevators without damaging Schneiderian membrane. The previously obtained graft material was then placed and packed. The implant was placed on same day with guidance of a stent which was positioned, then removed, and the site was checked for appropriate faciolingual and mesiodistalpositioning.

Any obvious abnormal crestal defects required slight modification of the position[5].

Indirect Sinus Augmentation Technique (ISAT): Indirect sinus augmentation is performed on those cases wherein the RAB height was 6-8 mm. The RAB to receive the implant was given local anesthesia and perforated using a small rounded drill. A pilot drill was the initial drilll in order the mark the implant site to establish the axis of implant recipient site. Following the pilot drill, subsequently sequential drills of increasing diameter were used to enlarge implant recipient site till the desired diameter corresponding to implant diameter was reached. The height of drill was 2 mm short of sinus floor which was maintained. The sinus floor was fractured and elevated upby insertion of correct caliber osteotome and working up through successively greater instrument diameters. The sinus floor was fractured with at most care, separated from the Schneiderian membrane avoiding damage to membrane using a surgical mallet with controlled force. Autogenous graft material was used if required and was placed within the socket. The material was displaced apically with help of larger-diameter instruments, thereby lifting the membrane and condensing graft material between the latter and sinus floor. The implant placement was carried out immediately in the prepared site. Wound closure was done with 3-0 Vicryl. Patients were prescribed with Antibiotic, pain killers, and nasal decongestants for 5 days. The patients were monitored on a periodic basis both clinically and radiologically[6].

Sinus Elevation Procedure: The elevation of the sinus floor is an internal augmentation of the maxillary sinus, intended to increase the vertical bony dimension of the lateral maxilla to allow placement of dental implants in sites with insufficient alveolar bone height. The classic sinus lift procedure consists of the preparation of a window in the lateral maxillary sinus wall. This window is then luxated inward and upward with the schneiderian membrane to a horizontal position, thus forming a new sinus floor. The space underneath the membrane is filled with different graft materials according to the specific case. When bone height is sufficient to achieve primary stability (approximately 4 mm), implants can be inserted simultaneously[6]. However, if the grafted bone has to remodel, implants should be inserted in a subsequent procedure. There are 2 main approaches for maxillary sinus floor elevation: the lateral antrostomy approach and the crestal approach.

Crestal Approach: This technique begins with a crestal incision. A full-thickness flap is then raised to expose the alveolar ridge. Next, an osteotomy is performed, starting with an osteotome of the smallest size, which is tapped in place in the bone with a mallet or drill. More osteotomes of gradually increasing size are then used to expand the alveolus and compress the bone[7]. Once the largest osteotome has been placed, prepared bone grafting material is added to the osteotomy so that it presses on the sinus membrane. This additional pressure causes the elevation of the membrane. Additional grafting material may be used to achieve the desired amount of elevation. An implant—slightly larger in diameter than the osteotomy—is then inserted in the site[12,10].The crestal approach technique is a less invasive procedure, improves the density of the maxillary bone, and has the potential to allow the use of less autogenous grafting material. The major disadvantage of this approach is an increased risk of misalignment of the long axis of the osteotome during the sequential osteotomy[12].

Surgical Procedure and Flap Design: The flap should be designed in such a way that there isminimimal disturbance of the blood supply, and the surgical site needs to be securely covered[4]. As previously mentioned, the incision is usually made midcrestally or paracrestally through the keratinized, attached mucosa. The infraorbital foramen should be avoided; precautions should be taken not to injure the neurovascular bundle during the preparation of the door and retraction of the flap[3]. Ideally, the shape of the door should follow the inner shape of the maxillary sinus, which usually is curved. Radiographic and clinical evaluations of the extent of the maxillary sinus can be used to plan the shape. Incase the lateral sinus wall consists of thick bone, the whole lateral sinus wall should be thinned out. It has been suggested that rounded corners be approached with a wide cranial hinge base in order to reduce the risk of damaging the membrane[1]. The door luxation is done with finger pressure so that the surgeon can feel resistance and avoid the use of a sharp instrument.

Augmentation Materials: Various grafting materials have been used for sinus elevation procedures. Based on their source, grafting materials can be categorized as autograft, xenograft, allograft, or alloplastic. These types may be used alone or in any combination for sinus augmentation. The biological rationale for using bone grafts is based on 3 different healing mechanisms:

osteogenesis, the capacity of the graft to bring new bone-forming vital cells into the defect; the capacity of the graft to serve as a scaffold for bone formation;osteoconduction and osteoinduction, the capacity of the graft contents to induce an osteoblastic differentiation of the host's undifferentiated cells[5]. Osteoconductivity is an essential mechanism in any grafting material, as it provides biomechanical support and stabilization to the coagulum in the first healing phase and a scaffold for the new bone that will form in the later phase.45 Autogenous bone (also known as autologous bone or autograft) is considered the gold standard graft material for sinus augmentation, because it has osteogenetic, osteoinductive, and osteoconductive properties in addition to its high biocompatibility. The main drawback of this bone type is the need for a second surgical site, which can cause donor site morbidity. Donor sites are either extraoral (such as the ilium, tibia, or cranium) or intraoral (such as the mandibular ramus, mandibular symphysis, and maxillary tuberosity)[3]. Complications at donor sites include pain, gait disturbance, hernia, paresthesia, infection, antral perforation, dental injury, and fracture of the site[2]. Allogeneic graft material can be obtained from tissue banks as either mineralized or demineralized bone.46 Mineralized bone is less commonly used in sinus elevation procedures because of its lengthy process of bone formation. Demineralized bone is more commonly used due to the presence of bone morphogenetic protein that stimulates osteoinduction in adjacent undifferentiated cells to form new bone tissue. However, the main concerns about use of this type of material include the high cost and the risk (albeit low) of disease transmission. Xenografts, especially deproteinized bovine bone (such as Bio-Oss, Geistlich Pharma North America, Inc.), are widely used and have been studied extensively both in vitro and in vivo. Deproteinized bovine bone possesses osteoconductivity and can be used alone or in combination with other grafting materials. Bio-Oss is a bovine bone derivative that undergoes a low-heat (300°C) chemical extraction process by which all organic components are removed while the natural architecture of bone is maintained[(6)].Alloplastic grafting materials are easy to use and relatively less expensive than the cost of bone harvesting[(7)]. The most common alloplastic grafting materials are those composed of some form of hydroxyapatite, mainly calcium phosphate ceramics[(8)]. Mesenchymal stem cells have recently been implemented in maxillary sinus augmentations with clinically promising results[(8)].Mangano et al evaluated the literature pertaining to the effectiveness of cell-based approaches in maxillary sinus augmentation in humans.

Postoperative Instructions: The patient should be provided with both printed and oral instructions postoperatively.These instructions should include application of ice and pressure to the site, elevation of the head, and rest for the patient[10]. Although smoking is not an absolute contraindication, it is recommended that the patient cease the habit before, during, and after sinus augmentation and implant insertion because it has the potential to affect healing; several studies have shown higher failure rates among smokers. Actions that create negative pressure (such as blowing the nose or sucking through a straw) must be avoided by the patient during the first week after surgery[(12)]. If the patient does sneeze, he or she must keep the mouth open, so pressure is not exerted within the sinus[(14)]. Also, the patient should be warned against pulling back the lips to observe the surgical site, which could open the surgical incision line[(16,17)]. The patient should be informed about which symptoms to expect shortly after surgery, including slight bleeding from the incision line the day of surgery and soreness, swelling, and bruising for several days postsurgery. The presence of small bone particles or granules in the mouth or from the nose (with some bleeding) is not unusual. In addition, the patient should be advised to take medications (such as anti-inflammatory drugs, antibiotics, and nasal decongestants) as prescribed by the surgeon[(17)].

Complications: Several complications may arise during or after sinus augmentation. The most frequently encountered surgical complication is perforation of the schneiderian membrane, which occurs in 7%-35% of sinus augmentation procedures[(18,19)]. Perforation of this membrane is most likely to happen at sharp edges and ridges, such as spines or maxillary sinus septa (also known as Underwood septa). However, when the perforation is small and located in an area where the elevated mucosa folds together when the door is lifted, there is no need for further management, although use of biological glues might be considered[(20,21)]. If the perforation is larger and located in an unfavorable area, the perforation must be closed and covered to prevent loss of the graft.1 This can be achieved by covering the defect with a resorbable membrane and a surgical adhesive (such as BioGlue, Cryolife, Inc.). In cases

where the membrane perforation is very large, further sinus lift should be abandoned and reentry might be considered. The second surgery should not be performed for 6 to 8 weeks.2 Hernandez-Alfaro et al studied the prevalence of surgical complications and sinus membrane perforations.62 They evaluated 338 patients who received 474 sinus augmentation procedures and a total of 1166 simultaneously placed dental implants. The researchers reported 104 (21.94%) perforations of the sinus membrane (19 bilateral). Of these cases, membrane perforations less than 5 mm were observed in 56 (53.85%), perforations between 5 and 10 mm were observed in 28 (26.92%), and membrane perforations more than 10 mm were observed in 20 (19.23%)[26]. If small vessels are found bleeding in the exposed membrane, it is best to let them stop spontaneously or to apply light gauze pressure.1 Due to the presence of arterial anastomoses of the alveolar antral artery, which branches from the posterior superior alveolar artery within the infraorbital artery on the lateral wall where an osteotomy will be performed, precaution must be taken to avoid massive bleeding. Rosano et al investigated the prevalence, location, size, and course of anastomoses on 30 maxillary sinuses from 15 human cadaver heads and on 100 CT scans from patients scheduled for sinus augmentation surgery[26].They found anastomoses in 100% of the cadaver maxillary sinuses by dissecting the sinus anterolateral wall. However, a well-defined bony canal was detected radiographically in 94 of 200 sinuses in the CT scans of the scheduled patients (47%). The mean vertical distance from the lowest point of this bony canal to the alveolar crest was 11.25 ± 2.99 mm in the CT scans. The canal diameter was less than 1 mm in 55.3% of the cases, 1-2 mm in 40.4%, and 2-3 mm in 4.3%. In 100% of the CT scan cases, the alveolar antral artery was found to be located between the schneiderian membrane and the lateral bony wall of the sinus, in the area selected for sinus elevation[29]. Careful treatment planning, patient selection, and the appropriate sinus augmentation technique are essential to minimize the risk of implant migration into the maxillary sinus. Implant migration may occur several days postimplantation, at abutment connection surgery, or years later. Once the displacement is diagnosed, the implant must be removed as soon as possible. Other complications are related to the presence of preexisting antral pathologies, such as rhinosinusitis, odontogenic sinus diseases, pseudocysts, retention cysts, and mucocele[27].

Conclusion

The techniques employed in this manuscript has facilitated implant placement in areas of limited bone height, improved primary stability, high implant success in posterior maxilla, simple, and minimally invasive surgery with increased success[31].

Since the introduction of dental implants, bone grafting has become an important procedure required for the treatment of patients with limited bone availability. Bone autograft, alone or together with other bone substitutes, has been the biomaterial of choice for clinicians worldwide. However different xenogenic, allogenic and synthetic biomaterials have shown promising results in many bone augmentation procedures[30]. The major part of success with implant placement lies in the treatment planning. It is utmost importance that the preoperative evaluations are done perfectly and the most suitable technique is decided accordingly for that particular situation, to improve the prognosis of that treatment[32.]Thus the bone substitute needed for each bone regeneration procedure must be selected based on the individuaĺs characteristics, and the surgical procedure itself. Factors such as the osteogenic potential of the host residual bone, systemic health of patients, and morphology of the defects, will delimit the ideal bone substitute for each situation[33].

A Comprehensive Review On Novel Approach

Vijay Ebenezer[1], Balakrishnan Ramalingam[2], M. Elumalai[3]

[1]Professor and Head, [2]Professor, Oral and Maxillofacial Surgery Sreebalaji Dental College and Hospital, BIHER; [3]Department of Advanced Zoology and Biotechnology, Govt Arts and Science College, Nandhanam, Chennai

ABSTRACT

Success of a dental implant depends on osseointegration which is the direct structural and functional connection between the dental implant and the alveolar bone. Successful osseointegration requires both primary stability (mechanical stability) between the implant and the bone and secondary stability (biological stability) which occurs during bone remodelling during healing.

Keywords: *osseodensification, osteotomy, bone density.*

Introduction

Traditional osteotomy is a subtractive technique in which the drills have a positive rake angle of 25 to 35 degrees to drill away small amount of bone with each sequential drilling which might result in few drawbacks like compromised stability and heat generated bone necrosis whereas a unique method called osseodensification is a non excavating method in which bone is not removed but is densified with each drill thereby enhancing primary stability by establishing immediate contact between the implant and the alveolar bone.

Various factors that contribute to the stability are

i. Implant design (thread type, geometry and surface coating) [1]

ii. Instrumentation (sequence of surgery, speed and technique)

iii. Bone density[2]

However factors like drill protocol sequence, velocity and design may aid in accelerated osseointegration.

OD is carried out with unique burs with tapered flutes with a negative rake angle (non cutting edge) in counter clockwise direction at a speed of 800 to 1200 rpm/ minute.Asthe osteotomy expands bone is densified[3,4,5] as a layer of dense and compact bone that surrounds the osteotomy wall is created which would increase the primary stability and bone mineral density.copious amount of irrigation is required to avoid overheating.

Materials and Method

A database search was carried out in PUBMED using keywords like osseodensification, OD, implant stability and osteotomy for articles upto the year 2018 the search was scrutinized for full text articles. clinical trials, in vivo studies, review articles were selected for this review.

Osseodensification and Bone Density: Stability of any dental implant depends on the bone mineral density.

According to trisi et al there is a significant correlation between the bone density in the peri implant region, insertion torque and micromotion[6].

Bone evaluation around the dental implants can be performed and visualized either in ground sections of methylmethacrylate materials or light microscopic examination of peri implant tissue at the cellular level.

In an animal experimental study carried out by Burri and wolter in 1977 it has been proved that the new bone formation occurs in the peripheral osteotomy site and also the amount of new bone formed was shown to be proportional to the degree of compression.

D3 and D4 type of bone has poor bone density making it difficult to achieve implant stability. Using osseodensification procedure a layer of increased bone mineral density has been shown by imaging around the periphery of osteotomies which has shown a good effect on the implant stability.

Conventional Drilling Vs Osseodensification: Conventional drilling with sequential drills facilitates implant placement by bone excavating thereby compromising the primary implant stability which inturn results in reduction of torque during insertion. some surgical techniques like undersizing the osteotomic implant site have been proposed to reduce bone sacrifice during implant placement procedure and to enhance primary implant stability and bone quality. An alternate to this procedure is the Osseodensification which has shown to increase required penetration force and torque. Moreover during osteotomy a zone of osteocyte death is produced by conventional drilling[7,8,9] ; despite the use of copious irrigation a peak temperature of ~80 °C was generated at the cut edge whereas with OD even without copious amount of irrigation the peak temperature remained within normal range well below the temperature known to cause osteocyte death (45°C[10].

OD retains osseous coagulum (trabecular bone chips, blood, and stroma) which have inherited osteogenic potential[11,12]. This coagulum serves as a nucleating surfaces to promote new bone formation around the implants and providing greater bone density and better stability.

Disscusion

Preservation of cell viability is the most important factor [13,14,15]for the success of any treatment. conventional drilling might compromise the viability by creating mechanical and thermal trauma[16,17]. A viable osteotomy site is very critical for enhanced osteogenesis.

OD has shown to increase the % of bone at the implant surface by increasing the Bone mineral density in the peri implant region which inturn is directly linked with increased bone-implant contact, improved bone healing and increase in primary stability.

OD is a slow incremental process carefully controlled by surgeon. The residual strain on the bone surface creates compressive forces that increases the implant stability.increased removal torque is a good indicator for primary implant stability.

Conclusion

Osseodensification is a promising alternative to conventional drills as it helps in maintaining ridge integrity with preservation of bone. This osseous coagulum shows excellent osteogenic potential that brings about robust formation of new bone in the osteotomy site and allows for the placement of dental implants with superior stability. It also helps to improve bone density and also BV and increased bone-to-implant contact, thereby improving implant stability. However more clinical studies are recommended in future to derive any concreate conclusions.

Comparative Evaluation of Periodontal Status & Il -6 Levels in Chronic Kidney Disease Patients and Healthy Individuals

Goutham Siriyala[1], Nithya Anand[2], Bagavad Gita[3], J Bhaskar[2], J. Bhuvaneswarri[4], S A. Keerthana[1]

[1]Post Graduate Student, [2]Professor, [3]Head of the Department, [4]Reader, Sree Balaji Dental College and Hospital, BIHER, Department of Periodontics and Implantology, Velachery Main Road, Pallikaranai, Chennai, Tamil Nadu, India

ABSTRACT

Background: Chronic kidney disease (CKD) is a veryreal and growing problem, as indicated by demographic trends. Presence of undiagnosed periodontitis may have significant effect on the medical management of CKD patient as its been found to contribute to systemic inflammatory burden.This study evaluate and compare the periodontal status and IL -6 levels among CKD, periodontitis and Healthy patients.

Materials and Method: Whole serum samples werecollected from 80 patients who were further divided into four groups; healthy(n=20), periodontitis(n=20), HD(n=20), PD(n=20). Serum IL -6 concentrations were determined by Standard enzyme -linked immunosorbent assay.

Results: Indicates the IL -6 levels in the studypopulation. The mean IL -6 value being highest in pre-dialysis (92.695) compared to dialysis(53.112), periodontitis (9.22) and healthy individuals (9.6).ANOVA results show a significant increase of IL -6 levels in the pre - dialysis group compared to alter groups.No significant change on PPD was appreciated.

Conclusion: Treatment of moderate to severeperiodontitis in ESRD populations will result in decreased IL-6 levels and, more importantly, decreased incidence of atherosclerotic complications awaits the result of interceptive clinical trials in this population

Keywords: *Chronic renal disease, Periodontitis, interleukin 6, End stage renal disease, dialysis, Periodontal status*

Introduction

Chronic kidney failure is associated with many kinds of metabolic changes caused by the kidney disease itself and also attributable to substances and dysregulation of metabolic pathways, decreased urinary excretion plays a crucial role and leads to retention of metabolites in the organism. Regular dialysis treatment partly decreases this accumulation but cannot avert the overall deficit. Changes in the oral cavity, such as periodontitis and other manifestations of poor oral health, are common in patients with chronic kidney disease(CKD)[1].The incidence of end-stage renal disease(ESRD)is increasing and patients receiving renal replacement therapy including hemodialysis[2][3], peritoneal dialysis or renal transplantation will comprise an enlarging segment of dental patient population[4]. Periodontitis has been found to contribute to systemic inflammatory burden including the elevation of c -reactive protein(CRP) in the general population. Consequently, periodontitis may be covert but treatable source of systemic inflammation in the ESRD population[5].

Materials and Method

Study was done in the Department of Periodontology & oral Implantology at SreeBalaji Dental College, and Department of Nephrology at SreeBalaji Medical College, ChennaiThe study was reviewed and approved by Ethical Committee of Bharath University of Chennai.

To evaluate and compare the periodontal status amongchronic kidney disease patients[6] (Dialysis & pre-dialysis),chronic periodontitis and healthy individuals and To estimate the serum IL -6 levels in the study population[7][8].

80 patients were divided into 4 groups. All participants were informed about the procedure and an informed consent was taken. Prior to examination, a thorough medical and dental history was taken.

Study Population: Study population comprises both male and female patients.

Total population –80, Age - 25-75 years, Selected patients were divided into four groups. Control group (n=20) -- systemically and periodontally healthy subjects.[fig 1]

CP group (n=20) -- subjects who were systemically healthyand clinically diagnosed with untreated chronic periodontitis [fig 2], HD group (n=20) -- Dialysis group [fig 3,4],clinically diagnosed with untreated chronic periodontitis.

Inclusion Criteria: Age group (above 25 years), Chronic kidney disease patients with chronic periodontitis[9], Periodontitis (localised chronic periodontitis with probing depth of >5mm and clinical attachment loss >3mm), Systemically and periodontally healthy for control group.

Exclusion Criteria: Individuals who underwent periodontal therapy in the past 6months, Individuals who received antibiotic therapy in the past 6months[10], Individuals with malignancy, HIV, Hepatitis, Upper respiratory tract infections[11], Completely edentulous, Smokers, Pregnant[12] and lactating women.

Sample collection: Medical history taken [13].Informed consent obtained and Clinical examinationdone using mouth mirror and probe.

Blood was collected approximately 3ml from each patient, into sterile tubes. Blood samples were placed on ice immediately and aliquoted prior to freezing at -80 c.samples were thawed and analyzed.Serum concentration of IL -6 was determined using an Enzyme linked immunosorbent assay (ELISA) by using Human Quantikine ELISA kit.

Results

Table 1: IL-6 levels in the study population (ANOVA)

	Group								Significance Tests	
	Pre-dialysis (n = 20)		Dialysis (n = 2 0)		Periodontitis (n = 20)		Healthy (n = 20)			
	Mean	SE	Mean	SE	Mean	SE	Mean	SE	Test & Value	Sig. (P Value)
IL-6	92.695	2.574	53.112	9.220	8.073	4.470	9.649	4.463	ANOVA: F Value: 49.530	0.000
PPD	4.888	0.210	4.925	0.171	.	.	.	.	t-test: Value: -0.138	0.891

Inference: The above table indicates the IL -6 levels in the study population. The mean IL -6 value being analysed in pre - dialysis(92.695) compared to dialysis(53.112), periodontitis (9.22) and healthy individuals(9.6).

ANOVA results show a significant increase of IL -6 levels in the pre -dialysis group compared to other groups. No significant change in probing depth was appreciated.

Table 2: Comparative evaluation of IL -6 values with reference to Age groups in the study population

	Age														
	30 Years or Less			31 - 40			41 - 50			51 - 60			More than 50		
	Mean	SE	n	Mean	SE	n	Mean	SE	n	Mean	SE	n	Mean	SE	n
Pre-dialysis	.	.	0	111.91	.	1	96.01	4.46	7	90.18	3.24	7	87.73	5.60	5
Dialysis	.	.	0	11.22	.	1	67.53	14.08	8	46.44	12.54	11	.	.	-
Periodontitis	3.73	.46	5	3.67	.25	12	32.93	30.00	3	.	.	-	.	.	-
Healthy	3.53	.54	3	5.96	1.62	12	22.18	17.55	5	.	.	-	.	.	-

The above table indicates that mean IL -6 levels is analysed for the Pre -dialysis patients in the age group of 31-40 years(111.91) and reduces in the older age groups.In all other groups IL -6 levels were higher in the 41 -50 age groups.

Table 3: Comparison of Inflammatory & periodontal status between pre-dialysis and dialysis group

	Group Statistics					Independent Samples t-test	
	Group	N	Mean	Std. Deviation	Std. Error Mean	t-Value	Sig.
IL-6	Pre-Dialysis	20	92.6955	11.51166	2.57409	4.135	0.000
	Dialysis	20	53.1125	41.23289	9.21996		
PPD	Pre-Dialysis	20	4.8875	.94059	.21032	-0.138	0.891
	Dialysis	20	4.9250	.76563	.17120		
Age	Pre-Dialysis	20	56.00	13.657	3.054	1.475	0.148
	Dialysis	20	51.20	5.022	1.123		

Inference: This table indicates significantly evaluated IL-6 level in pre-dialysis(0.000) compared to dialysis group but no change in probing pocket depth between the two groups(significance 0.891)

Table 4: Characteristics of dialysis cases:

	Mean	SD	SE
Years	2.78	1.83	.41
Frequency (weeks)	2.45	.60	.14
IL-6	53.11	41.23	9.22
PPD	4.93	.77	.17
Age	51.20	5.02	1.12

This table indicates that the average Number of years is 2.78 and frequency of dialysis in 2.5 per week with a mean PPD of 4.9 and IL -6 of 53.11.

Table 5: Correlation of probing pocket depth with years and frequency of dialysis:

		PPD	PPD
Years	Pearson Correlation	1	-.261
	Sig. (2-tailed)		.267
	N	20	20
Frequency (weeks)	Pearson Correlation	-.261	1
	Sig. (2-tailed)	.267	
	N	20	20

PPD increases with years of dialysis and decreases with the frequency of dialysis

Figure 1: Healthy Patient

Figure 2: Periodontitis Patient

Figure 3: Pre-Dialysis Patient

Figure 4: Dialysis Patient

Discussion

Periodontal diseases are a group of inflammatory diseases that affect the supporting tissues of the dentition. The formation of a periodontal pocket is a characteristic feature of periodontitis in primates. Recruited into the connective tissue adjacent to the periodontal pocket is an intense cellular infiltrate consisting of polymorphonuclear leucocytes, monocytes/macrophages, B and T cell lymphocytes. It has been estimated that,in an individual with moderate to severe periodontitis, the total surface area of the inflamed periodontal pockets can range from 8to20cm depending upon the number of teeth affected. Therefore, the large surface area of the aggregate periodontal lesion can potentially become a significant source of inflammation in individuals with moderate to severe periodontitis.

In our study we aimed to evaluate the periodontal status and IL-6 levels among chronic kidney disease patients (Dialysis& pre-dialysis)[14],Chronic periodontitis and Healthy individuals.We estimated that there was a statistically significant increase of IL -6 levels in pre-dialysis (92.695)compared to dialysis(53.112), periodontitis (9.22) and healthy individuals(9.6). Although No change in probing pocket depth between the groups was appreciated. A poignant finding was that probing pocket depth increases with years of dialysis and decreases with the frequency of dialysis.

The presence of elevated IL -6 levels in pre -dialysis compared to dialysis and periodontitis patients indicate, that there is a high level of inflammatory burden in chronic kidney diseasespatients[15], who have not started dialysis. Periodontitis increases with years of dialysis and reduces with increased frequency of dialysis could be due to the compromised nutritional status over the years and reduced inflammation, when more frequent dialysis is done[16].

Conclusion

Many sources of inflammation exist for ESRD patients on hemodialysis therapy but in view of the incidence of periodontitis in the general population and possible increased incidence and severity in the ESRD population, periodontitis may be one source of systemic inflammation that can be readily managed through effective periodontal therapy.

Moderate to severe periodontitis is prevalent in the general population and may be more prevalent in the ESRD population on haemodialysis maintenance therapy [17]. Periodontitis has been associated with increased markers of systemic inflammation [18], and limited studies in the general population suggest that effective periodontal therapy may decreases their levels. In our study, we conclude that IL -6 is significantly elevated in pre -dialysis individuals and periodontal inflammation increases with years of dialysis. Therefore, periodontitis in ESRD populations may be a covert source of systemic inflammation that can be managed through effective periodontal therapy. However, whether treatment of moderate to severe periodontitis in ESRD populations will result in decreased IL -6 levels and, more importantly, decreased incidence of atherosclerotic complications awaits the result of interceptive clinical trials in this population.

Personalised Periodontal Medicine—A Paradigm Shift

Ramya V.[1], Sajid T. Hussain[1], Preethe Padmanabhan[1], Harshitha Reddy T.[2]

[1]Reader, [2]Post Graduate Student, Department of Periodontics, Sree Balaji Dental College and Hospital, BIHER, Chennai

ABSTRACT

Personalized medicine in Periodontics is considered as a new paradigm shift of future health care. It is considered to provide great help in identification of etiological factors, evaluating the host risk in clinical and genetic point of view and prediction of response of to treatment. It of great support in development of diagnostic, prognostic and therapeutic approach in a personalized way. As an overview we throw light on the advantages of personalized periodontal medicine over the usual conventional symptoms- oriented disease diagnosis and treatment.

Keywords: *Pharmacogenomics, Microbiome, Periodontal disease*

Introduction

Personalized or Precision medicine is expected to become the future paradigm of future health care, owing to the substantial improvement of high-throughput technologies system approaches in the past two decades[4]. Conventional symptoms- oriented disease diagnosis and treatment have several significant limitations, for example, it focuses on only late/terminal symptoms and generally neglects preclinical pathophenotypes or risk factors; it generally, disregards the underlying mechanics of the symptoms ; the disease descriptions are often quite broad so that they may include multiple diseases with shared symptoms ; the reductionist approach to identify therapeutic targets in traditional medicine may over-simplify the complex nature of most diseases[2]. Advances in the ability to perform large-scale genetic and molecular profiling are expected t overcome these limitations by addressing individualized differences in diagnosis and treatment in unprecedented detail.

Personalized medicine approaches could be harnessed to:

i. Facilitate identification and analysis of etiological factors contributing to oral disease:
ii. Permit assessment of environmental impact on oral health and disease;
iii. Evaluate host risk from a clinical and genetic perspective;
iv. Predict response to treatment;
v. Support development of diagnostic, prognostic and therapeutic approaches for application on a personalized basis.

Genomics in Disease–Oriented Medicine: The revolution of omics profiling technologies significantly benefited disease-oriented studies and health care, especially in disease mechanism elucidation, molecular diagnosis and personalized treatment[5]. These new technologies greatly facilitated the development of genomics, transcriptomics, proteomics and metabolomics, which have become powerful tools for disease studies.

Whole genome sequencing (WGS) and whole exome sequencing (WES) have become more and more affordable for genomic studies and are rapidly replacing DNA microarrays. Single-base analysis of a genome/ exome is achieved, which allows scientists to investigate the genetic basis of health and disease in unprecedented

detail. Assigning variants to paternal and maternal chromosomes. One field that significantly benefitted from WGS technologies is cancer-related research.

Pharmacogenomics is another important application of genomic sequencing. It is known that the same drug may have different effect on different individuals due to their personal genomic background and living habits.

Integrative Omics in Preventive Medicine: The concept of personalized medicine emphasizes not only on personalized diagnosis and treatment, but also personalized disease susceptibility assessment, health monitoring and preventive medicine[5]. Because disease is easier to manage prior to its onset or when a disease is at its early stages, risk assessment and early detection will be transformative in personalized medicine. Systems biology has the potential to capture real-time molecular phenotypes of a biological system, which enables the detection of subtle network perturbations precluding the actual development of clinical symptoms.

Role of Oral Microbiome and its Potential Impact on Personalized Dental Medicine: Every human body contains a personalized set of foreign inhabitants essential in maintaining heath, yet also capable of eliciting disease. The number of microbial cells within a human body exceeds the total number of human cells in the body by nearly 10 times. The human body exceeds the total number of human cells in the bod by nearly 10 times[1]. The human microbiome ca be classified into a core microbiome and a variable microbiome. The core microbiome is shared among all individuals and is comprised of the predominant species tat exist under healthy conditions at different sites of the body. The variable microbiome is exclusive to the individual and has evolved in response to unique lifestyle, phenotypic and genotypic determinants. Microbiome research is becoming central to the advancement of disease diagnostics and therapeutic as well as the development of personalized medicine proper diagnostic methods and technologies should be developed to enable professionals to identify individual microbial profiles and treat specific microbes responsible for disease[1]. Microbiomics aims to understand how microorganisms' interplay with its host physiology and health by analyzing their functions and irrelationships.

Role of Oral–Systemic Personalized Medicine: Periodontal disease and diabetes, two disease that have achieved epidemic status share a bidirectional relationship driven by micro-inflammatory processes[2]. The present reviews frames the current understanding of the pathological processes that appear to link these diseases advances the hypothesis that reversal of the epidemic is possible through application of the interdisciplinary intervention and advancement of oral systemic personalized medicine.

Role of Biomarkers in Periodontal Personalized Medicine:

Table 1: Various salivary biomarkers of periodontal disease[7]

Dental Biofilm	Inflammatory	Collagen Breakdown	Bone Remodelling
Immunoglobulins (IgA, IgM, IgG)	β-glucuronidase	α2-macroglobulin	Alkaline phosphatase
Mucins	C-reactive protein	MMP-8	Osteoprotegerin
Lysozymes	II-1β	MMP-9	Osteocalcin
Lactoferrin	II-6	Aspartate aminotransferase	SPARC/Osteonectin
Histatin	MIP-1α	Alanine aminotransferase	RANKL
Peroxidase	Tumor necrosis factor-α	TIMPs	B C- terminal type I collagen telopeptide
			C- telopeptide pyridinoline cross-links of type I collagen.

Table 2: Various products and their uses for measuring salivary biomarkers[7]

Product Name	Purpose
MyPerioID	Identifies the type and concentration of the specific bacteria that cause periodontal diseases.
My PerioPath	Determines the cause of periodontal infections.
Oral Fluid NanoSensor Test	Simultaneous and precise detection of multiple salivary protein and nucleic acids.
Electronic Taste Chips	Detects multiple biomarkers for early diagnosis of periodontal disease.
OraQuick	An antibody test that provides results in 20 minutes, usually detects HIV 1 and HIV 2
Integrated Microfluidic Platform for Oral Diagnosis	Rapidly (3-10 min) measures the concentrations of MMP-8 and other biomarkers in small amounts (10ml) of saliva.

Point-of-Care Diagnostics: Investigators are continuously identifying and testing the complex periodontal disease 'signatures' that will allow for accurate chair-side diagnostics and enhance individualized care. Nature technologies are becoming available that can measure salivary biomarker panels for accurate periodontal disease diagnosis and treatment recommendations. The time is growing to a point where oral health-care providers will be able to utilize high-throughput biomarker validation tools for rapid chair-side testing[4]. The focus has been on the development of miniature-sized 'chemical processing units' that process fluids and provide information that is relevant to the inflammatory, connective tissue- degradation and bone-loss phases of periodontitis. As the specific biomarkers for periodontal disease and progression are determined through longitudinal analysis, it appears that the technology is prepared o meet the scientific discovery. Both will come together to allow oral health-care providers to improve prevention and treatment of periodontal disease through personalized medicine.

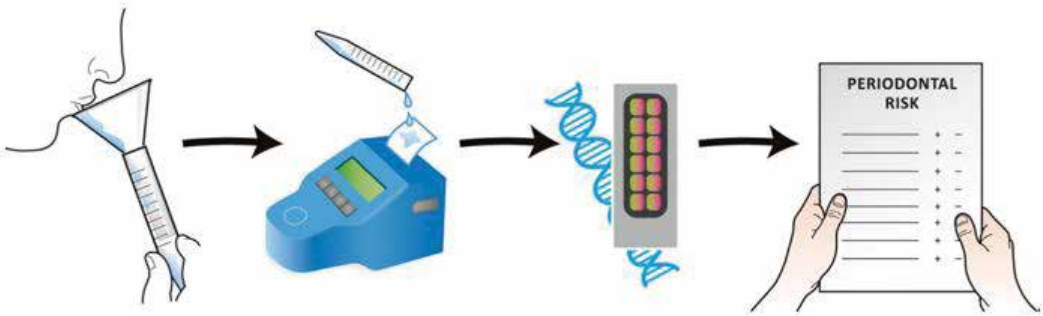

Fig.1

Summary and Conclusion

Hence personalized medicine has a role in bringing in individualized treatment to patients. It is used in

- Diagnosis and intervention
- Drug development and usage
- Respiratory proteomics
- Cancer genomics
- Population screening

As personalized medicine is practiced more widely, several challenges arise. The current approaches to intellectual property rights, reimbursement policies, patient privacy and confidentiality as well as regulatory oversight will have to be redefined and restructured to accommodate the changes personalized medicine will bring to healthcare.

Assessment of Salivary TBARS Level in Pregnant and Non-pregnant Women with Gingivitis before and after Scaling

Swetha Gadde[1], Judith Christina J.[2], Surendranath P.[2], Bagavad Gita[3], Mohan Valiathan[4], Anitha Balaji[4]

[1]Senior Lecturer, Department of Periodontics, Ragas Dental College, Chennai; [2]Post Graduate Student, [3]Head of the Department, [4]Professor, Department of Periodontics, Sree Balaji Dental College and Hospital, BIHER, Chennai

ABSTRACT

Background: The aim of the present study is to assess salivary Thiobarbituric Acid Reactive Substances(TBARS) levels in pregnant and non-pregnant women with gingivitis before and after scaling.

Materials and Method: Fifteen subjects (Non-pregnant) were selected out of the patients who attended the Department of Periodontics, Sree Balaji Dental College, Pallikaranai, Chennai. Fifteen subjects(Pregnant-second trimester)were selected out of the patients who attended Velachery K.S Hospital, Chennai. Periodontal examination is done and again evaluated after scaling(30 days). Collection of saliva and assessment of TBARS is done. Assessment of TBARS is done by TBARS assay using thiobarbituric acid as a reagent. Statistical analysis done using student T test.

Results: Results indicated that the level of salivary TBARS in non-pregnant individuals after scaling is reduced and is statistically significant and the level of salivaryTBARS in pregnant individuals after scaling also reduced but it is not statistically significant.

Conclusion: Gingivitis in pregnancy is not a contributing factor for the oxidative stress.

Keywords: *Oxidative Stress, Salivary TBARS, Pregnancy, Reactive Oxygen Species*

Introduction

Pregnancy is defined as a state that includes fertilization, implantation and embryonic and fetal growth that ends with the birth of a baby after 280 days or 40 weeks. During pregnancy, many changes take place in both systemic and local environments leading to a significant increase in the severity of gingivitis. Changes in female sex hormone levels during pregnancy are related to the enhanced susceptibility to gingival inflammation. This phenomenon, also named pregnancy-related gingivitis, typically occurs without a clear association with the amount of dental plaque, and develops more severe forms, in comparison to plaque-induced gingivitis in non-pregnant women[1]. Clinically, pregnant women present withmore inflammation and gingival bleeding than general population [2].

Oxidative stress is essentially an imbalance between the production of free radicals and the ability of the body to counteract or detoxify their harmful effects through neutralization by antioxidants[3].

Reactive Oxygen Species (ROS) is a collective term which includes Oxygen Derived Free Radicals(ODFR) such as Superoxide radical, Hydroxyl radical and the non-radical derivatives of oxygen, such as Hydrogen peroxide and Hypochlorous acid. Free radicals are defined as species containing one or more unpaired electron, and it is this incomplete electron shell that confers their high reactivity[4].

PMNS are recognized as a particularly rich source of ROS;in the absence of suitable antioxidants,ROS can lead to tissue damage.ROS cause tissue damage by different mechanisms: DNA damage,lipid peroxidation,protein damage and oxidation of important enzymes and by stimulation of pro-inflammatory cytokine release by monocytes and macrophages. Several ROS and lipid peroxidation products are produced in physiological

quantities in the human body, but it has been well established that overproduction of ROS occurs at sites of chronic inflammation[5].

Thiobarbituric acid reactive substances (TBARS) are formed as a byproduct of lipid peroxidation(i.e.degradation products of fats) which can be detected by the TBARS assay using thiobarbituric acid as a reagent[6].Because reactive oxygen species (ROS) have extremely short half-lives, they are difficult to measure directly. Instead, they can be measured as several products of the damage produced by oxidative stress, such as TBARS.

Materials and Method

Subject Selection

i. **Control group (Group A):** Fifteen subjects (Non-pregnant) were selected out of the patients who attended the Department of Periodontics, Sree Balaji Dental College, Pallikaranai, Chennai.

ii. **Study group (Group B):** Fifteen subjects(Pregnant- second trimester)were selected out of the patients who attended Velachery K.S Hospital, Chennai.

Inclusion Criteria

i. Age 20 - 45years

ii. Minimum of 20 teeth

Exclusion Criteria

i. Control group (Group A)

- Any known systemic disease i.e., Hypertension, Diabetes mellitus, Thyroid diseases.
- Patient who received antibiotic therapy in the past six weeks.
- Periodontal treatment within the last six months.

ii. Study group (Group B)

- Any known systemic disease i.e., Hypertension, Diabetes mellitus, Thyroid diseases.
- Gestational diabetes mellitus
- Preeclampsia
- Patient who received antibiotic therapy in the past six weeks.
- Periodontal treatment within the last six months.

A. Periodontal Examination: The clinical parameters- Oral Hygiene Index – Simplified (John C. Greene, Jack R. Vermillion, 1964) and Gingival Bleeding Index (Loe, H and Silness, 1963) were assessed at baseline and 30 days after scaling.

B. Collection and assessment of TBARS in saliva: Unstimulated whole saliva is collected using MahvasNavazesh technique[7] and the level of lipid peroxides was assayed by the method of Devasagayam and Tarachand[8]at baseline and 30 days after scaling.

Results

Comparison of the mean salivary TBARS between the two groups shows that salivary TBARS is higher in Pregnant group and is statistically significant with a p value of <0.001 (0.05).

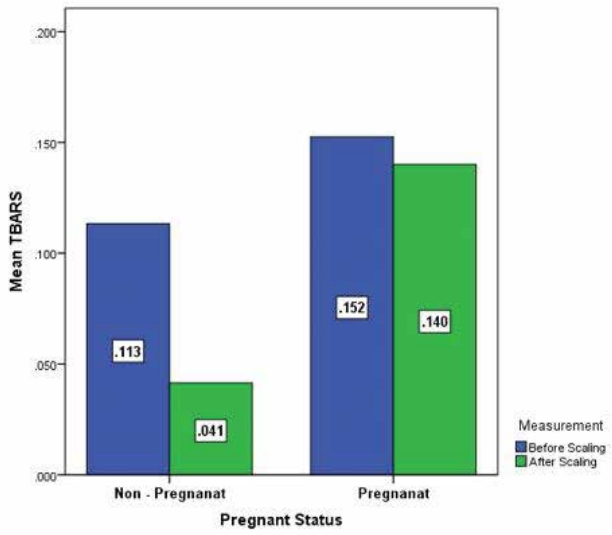

Fig. 1: Mean salivary TBARS

The comparison of the salivary TBARS between the two groups shows that mean difference of TBARSis higher in Pregnant group and is statistically significant with a p value of 0.025 (0.05).

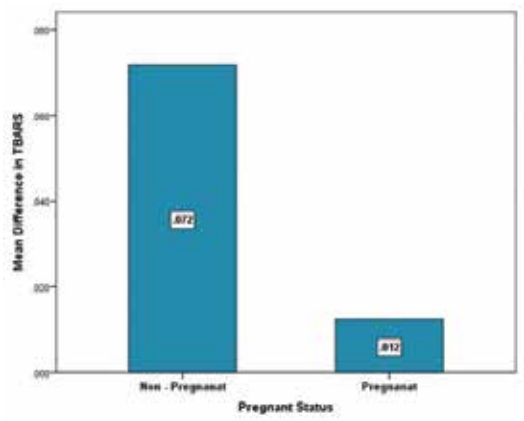

Fig. 2: Comparison of the TBARS

Comparison of the Mean Gingival Index between the two groups shows that GI is higher in Pregnant group and is statistically significant with a p value of <0.001(0.05).

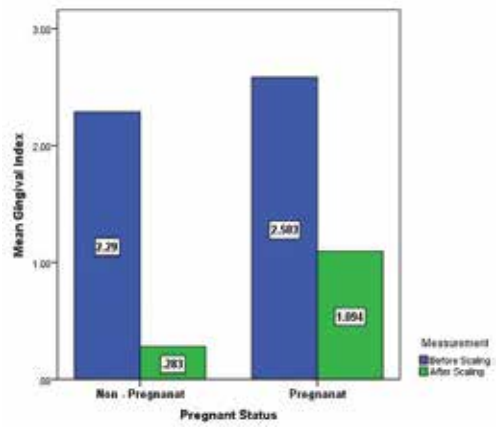

Fig. 3: Mean Gingival Index of Pregnant and Non-Pregnant Groups

The comparison of the GI between the two groups shows that GI is higher in pregnant group and is statistically significant with a p value of 0.048(0.05).

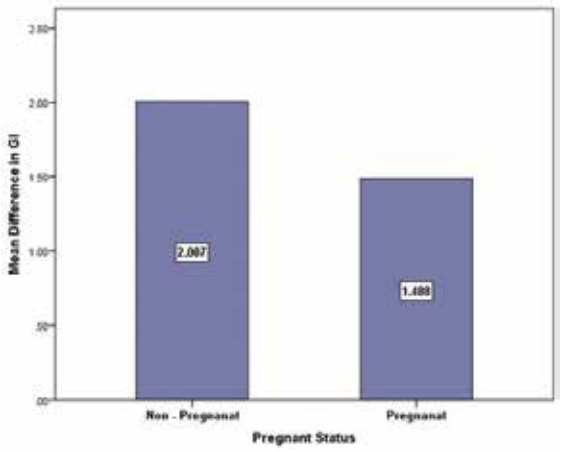

Fig. 4: Comparison of the GI

Comparison of the mean OHI-S between the two groups shows that OHI-S is higher in Non-Pregnant group and is statistically significant with a p value of 0.334 (0.05).

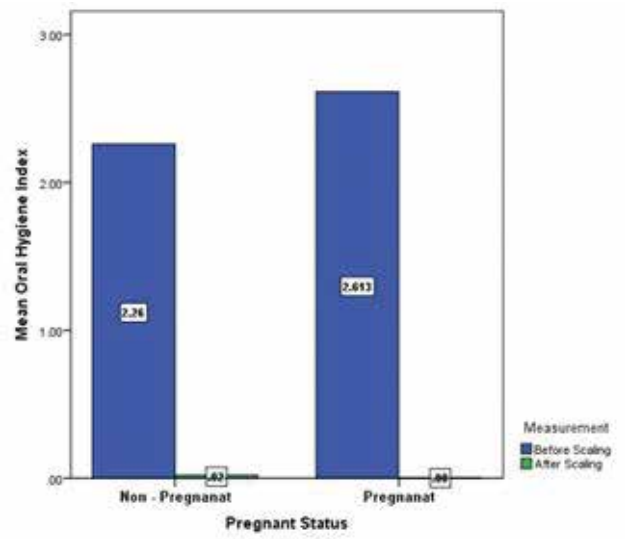

Fig. 5: Mean Oral Hygiene Index

The comparison of the OHI-S between the two groups shows that OHI-S is higher in pregnant group and is statistically significant with a p value of 0.044 (0.05).

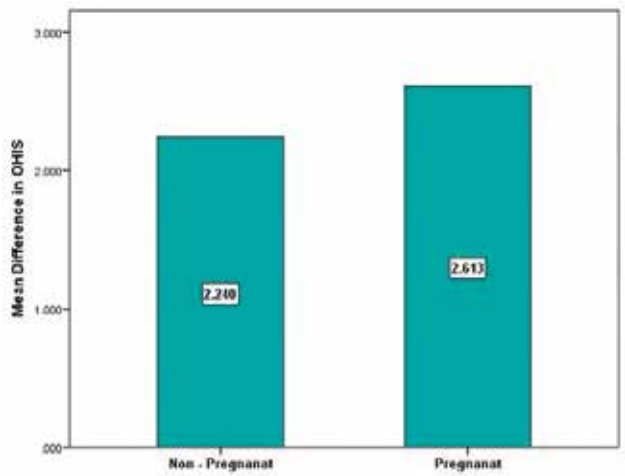

Fig. 6:Comparison of the OHI-S

Overall results indicated that the level of salivary TBARS in non-pregnant individuals after scaling is reduced and is statistically significant.And the level of salivary TBARS in pregnant individuals after scaling also reduced but it is not statistically significant.

Table 1: Comparisons Based on Mean Values

Measurement		Pregnant Status				Independent Samples t-test	
		Non-Pregnant		Pregnant			
		Mean	SD	Mean	SD	t-Value	Sig.
Before Scaling	Gingival Index	2.290	.317	2.583	.444	-2.077	.048
	Oral Hygiene Index	2.260	.410	2.613	.504	-2.106	.044
	TBARS	.113	.036	.152	.053	-2.375	.025
After Scaling	Gingival Index	.283	.320	1.094	.264	-7.572	.000
	Oral Hygiene Index	.020	.077	.000	.000	1.000	.326
	TBARS	.041	.025	.140	.030	-9.877	.000

After scaling there is a negative correlation between gingival index and salivary TBAR levels in pregnant individuals.

Discussion

The aim of the study is to assess salivary TBARS levels in pregnant and non-pregnant women with gingivitis before and after scaling.Fifteen subjects(Non pregnant) were selected out of the patient who attended the Department of Periodontics, Sree Balaji Dental College, Pallikaranai, Chennai were grouped into Group A. Fifteen subjects (Pregnant- second trimester)were selected out of the patient who attended Velachery K.S Hospital, Chennai were grouped into Group B. The clinical parameters used for case selection were Gingival index(Loe, H and Silness, 1963),Oral hygiene index – Simplified(John C. Greene, Jack R. Vermillion, 1964). Unstimulated whole saliva is collected using Mahvash Navazesh technique[7] and the level of lipid peroxides was assayed by the method of Devasagayam and Tarachand[8]. Thiobarbituric acid reactive substances (TBARS) are formed as a byproduct of lipid peroxidation(i.e. as degradation products of fats) which can be detected by the TBARS assay using thiobarbituric acid as a reagent.

Pregnancy is accompanied by an increase in the production of estrogen and progesterone. Two theories have been proposed for the actions of the hormones on the cells of the periodontal tissues: 1) a change in the

effectiveness of the epithelial barrier to bacterial insult and 2) an effect on collagen turnover[9]. Estrogen firstly decreases collagen production and keratinization of gingival epithelium and secondly induces proliferation of fibroblasts and decreases the collagen and blocks the turnover of the gingival tissue, thereby reducing the capacity of gingival tissue to repair. The result is an increase in the permeability of the epithelial barrier and an increased response to plaque bacteria. Estrogen regulates DNA synthesis in human gingival epithelial cells displaying strong estrogen beta immunoreactivity[10]. In addition, a decrease in the rate of collagen is mediated by ERbeta.The reactivity for progesterone receptors was observed in periodontal ligament cells at gene and protein levels[11]. Progesterone also has effects on the vascular system favoring an increase in gingival exudate and vascular permeability and proliferation; this is possibly due to progesterone receptors present in the gingival tissue[11].

Gingival inflammation associated with pregnancy has been initiated by dental plaque and exacerbated by endogenenous steroid hormones[12]. Between second to eight months of pregnancy, gingivitis ranges from redder looking gingival that bleed while brushing to severe swelling and bleeding of the gingival tissues.[13]. Alterations in the quantity and quality of biofilms at gingival margin is considered to play a role in the initiation and development of pregnancy related gingivitis[14]. There are many studies which demonstrated that these pregnant women's diseases affect a predisposed group of the population that presents an exacerbated inflammatory/ immune response to the pathogenic bacteria accumulated on the teeth and around the gingival tissue, which in turn lead to tissue damage. The exacerbated response characterized by hyper inflammation fails to remove the causative pathogens and generates prolonged release of proinflammatory mediators and Reactive Oxygen Species (ROS)[15].

Oxygen is an essential element of aerobic life and oxidative metabolism and represents a principal source of energy, but when partially reduced, it generates Reactive Oxygen Species (ROS)[16].ROS production is inevitable in all aerobic organisms including in the human body which possess a complex antioxidant defense system. There is a balance between ROS and antioxidants. Oxidative stress refers to the imbalance due to excess ROS or oxidants over the capability of the cell to mount an effective antioxidant response[17].

Oxidative stress condition directly damages cell structures and molecules, including lipids, proteins and DNA[18]. It may also be responsible for activating key nuclear transcription factors that initiate the synthesis of pro-inflammatory mediators[19.] Oxidative stress results in macromolecular damage and is implicated in various disease states such as artherosclerosis, diabetes, cancer, neurodegeneration and aging[17].Pregnancy, per se, is a state of oxidative stress arising from the increased metabolic activity in placental mitochondria and the reduced scavenging power of antioxidants[20].

Markers of oxidative stress represent promising tool for the research of oral diseases. Oxidative stress markers, which include glutathione peroxidase(GPX), which is an antioxidant, thiobarbituric acid reactive substances(TBARS),a measure of ROS damage and 8-hydroxy-2'deoxyguanosine(8-OHDG),a measure of DNA damage were studied in serum, saliva, GCF[6]. Lipid peroxidation is one of the major consequences of oxidative stress and could be evaluated by monitoring the levels of MDA[21].

Studies reveal a promising outlook for saliva as a key diagnostic medium for determining systemic diseases or health statuses of individuals. Because collecting saliva involves noninvasive methods and due to the fact that it is an abundant and easily accessible biofluid, saliva is attractive for diagnostic purposes greatly due to its highly enriched content of disease biomarkers that can be deciphered and analyzed[22]. Saliva is an ideal research tool and diagnostic medium and it is being employed as a novel means to study biomarkers for various oral and systemic diseases and conditions[23]. This was the first study evaluating TBARS in pregnant and non-pregnant gingivitis patients using saliva as a diagnostic medium.

In the present study, gingival index in pregnant women is more and is reduced after scaling which is statistically significant. Lieffet al[24] conducted a study on the oral conditions and periodontal status of a cohort of pregnant women and the results indicated that no significant change in the mean attachment loss, gingival index or bleeding scores is seen after scaling.

In this study, oral hygiene index in pregnant women after scaling is zero which shows a statistical significance. ManinderKaur et al[25]conducted a study on effect of intensive oral hygiene regimen during pregnancy on periodontal health, cytokine levels, and pregnancy

outcomes and concluded that intensive instructions and non-surgical periodontal therapy provided during 8 weeks at early pregnancy resulted in decreased gingival inflammation and a generalized improvement in periodontal health. Research on the epidemiology of periodontal disease has demonstrated a close correlation between periodontal disease and oral debris[26].

In the study TBARS, which is a measure of lipid peroxidation is higher in pregnant group, after scaling it reduced but not statistically significant. Salivary TBARS in non-pregnant group after scaling reduced which is statistically significant. No previous literature pertaining to lipid peroxidation in pregnancy gingivitis is present.

In the present study TBARS,a measure of ROS damage in saliva reduced in pregnant patients after phase I therapy(Scaling) which is not statistically significant. To conclude, gingivitis in pregnancy is not a contributing factor for the oxidative stress. The limitations of this study arethis was the first study evaluating TBARS in gingivitis patients. Larger samples are required to know the exact role played by TBARS in pregnant patients. Further research is needed to determine whether the treatment decreases maternal oxidative stress during pregnancy.

From the above discussion of the results, it can be concluded that oxidative stress in pregnant individuals is not correlated with periodontal status. However, future multi centric studies with a higher sample size can throw better light on this association.

ABSTRACT

Background: The Anaemia of chronic disease (ACD) is a prevalent, poorly understood condition that afflicts patients with a wide variety of diseases, including infections, malignancies and rheumatologic disorders.

Materials and Method: 40 patients 20-65 years of age with chronic periodontitis were assessed before and after periodontal therapy for Hb, ESR, Erythrocyte count, MCV, MCH, MCHC and PROHEPCIDIN (ELISA).

Results: A significant (p<.000) increase in RBC (4.581) and Hb (12.77) values were estimated after SRP compared to baseline. Prohepcidin levels decreased insignificantly after SRP. Tailed t test results shows significant correlation at the 0.01 level between RBC parameters but no significance between probing depth or prohepcidin values with RBC parameters.

Conclusion: The results conclude that reduction in periodontal inflammation by scaling and root planning improves RBC count and hemoglobin level significantly Prohepcidin levels decreases with periodontal treatment but rather insignificantly.

Keywords: *Chronic periodontitis, Prohepcidin, Scaling and root planning.*

Introduction

Anaemia of chronic disease (ACD) defined as the anaemia occurring in chronic infections and inflammatory conditions is not due to marrow deficiencies or other diseases and occurs in the presence of adequate iron stores and vitamins[(1)].It is characterized by blunted erythropoietin response by erythroid precursors, decreased red blood cell survival and a defect in iron absorption and macrophage iron retention,which interrupts iron delivery to erythroid precursor cells.

Periodontitis is an inflammatory disease of the supporting tissues of the tooth which is caused by specific micro-organisms in a susceptible host. The subgingival microbiota in patients with periodontitis poses a significant and persistent gram-negative bacterial challenge to the host.

Human hepcidin, a 25–amino acid peptide made by hepatocytes, may be a new mediator of innate immunity and the long-sought iron-regulatory hormone [(2)]. The synthesis of hepcidin is greatly stimulated by inflammation or by iron overload. In anaemia of inflammation, hepcidin production is increased up to 100-fold and this may account for the defining feature of this condition.

In the recent years, rapid progress has been made on periodontitis, ACD interlink by elucidation of the central role of hepcidin, an iron-regulatory hormone and a mediator of innate immunity.

Materials and Method

This study was reviewed by the Institutional Ethical Committee, Sree Balaji Dental College & Hospital, Bharath University and the study was approved to be conducted on the patients who fulfilled the following selection criteria (SBDCEM 106/14/11). A total of 40 patients were selected based on the inclusion criteria that they should be of age 20-65 years with chronic periodontitis, AAP 1999 with probing depth ≥ 5mm and clinical attachment loss ≥ 3mm(atleast 3 permanent teeth other than first molar and incisor).Patients with history of any systemic diseases, bleeding disorders and pregnant or lactating mothers were excludedThe subjects who met the above said criteria and agreed to participate in the study was informed about the procedure and a written consent was obtained.

Laboratory Investigations: The following RBC parameters were taken before and after periodontal therapy.**(Picture 1,2,3)**

- Haemoglobin.
- Erythrocyte sedimentation rate.
- Erythrocyte count.
- Mean Corpuscular Volume.
- Mean Corpuscular Haemoglobin.
- Mean Corpuscular Haemoglobin Concentration. (Above all parameters at Baseline, 30th and 90th day).
- PROHEPCIDIN (Baseline and 90th day by (**Elisa kit).**

Full mouth intra oral periodontal examination was done by two calibrated examiners (VD and AF) and the following clinical parameters like Gingival index, Probing depth and Clinical attachment level were measured.

Prohepcidin (ELISA) procedures: Bioassay Technology Laboratory (Picture 4)

Dilution of standard solution preparation: 120µl original concentration+120µl standard solution

Standard solution wells:(Picture 5) Add 50µl standard and streptavidin-HRP 50µl

Sample well: Add 40µl sample and then 10µl PRO-HEPC antibodies, 50µl streptavidin-HRP. then cover it with seal plate membrane. Shake gently to mix them up. Incubate 37˚c for 60 minutes.

Washing:

Prepare wash buffer: Remove the seal plate membrane carefully, drain the liquid and shake off the remaining liquid. Fill each well with washing solution. Drain the liquid after 30seconds standing. Then repeat this procedure five times and blot the plate.

Colour development: Add 50µl chromogen solution A firstly to each well and then add 50µl chromogen solution B to each well as well. Shake gently to mix them up. Incubate for 10minutes at 37˚c away from light for colour development.

Stop solution: Add 50µl stop solution to each well to stop the reaction. Reading at 450nm wavelength.

Results

The results showed that correction of periodontal inflammation resulted in a significant increase in haemoglobin levels and erythrocyte counts with a significant, but much lesser, improvement in MCV, MCH and MCHC values. In our study we inferred a significant ($p<.000$) increase in RBC (4.581) and Hb (12.77) values after SRP compared to baseline. All the other RBC parameters also showed a marginal insignificant increase after SRP. Prohepcidin levels decreased insignificantly after SRP (TABLE I).

A significant reduction ($p<.000$) in probing depth from baseline (6.075) to 90 days after SRP (3.250) (TABLE II) and gingival index ($p<.000$) at 90 days after SRP (.298) (TABLE III) compared to baseline values (1.733) was noted in our study which is conclusive of effective periodontal treatment. We elucidated significant correlation at the 0.01 level between Hb and other RBC parameters and significance at the 0.05 level between Prohepcidin and Hb, ESR levels as they are interrelated. Tailed t test results shows significant correlation at the 0.01 level between RBC parameters but no significance between probing depth or prohepcidin values with RBC parameters (TABLEIV,V,VI)

Table I: RBC Parameters at Baseline and 90 Days after SRP

	Baseline			90th Day			Paired Samples t-test	
	Mean	SD	SE	Mean	SD	SE	t-Value	Sig.
Prohepcidin	604940	192.318	30.408	894.635	1024.753	162.028	-1.834	.074
RBC Count	4.444	.548	.087	4.581	.539	.085	-3.747	.001
Hb	12.513	1.747	.276	12.770	1.780	.282	-4.743	.000
ESR	14.175	8.878	1.404	13.925	9.577	1.514	.613	.543
TC	8630.250	1575.633	249.129	8873.750	1488.340	235.327	-1.960	.057
MCV	86.685	7.099	1.122	86.900	7.059	1.116	-.568	.573
MCH	28.478	2.398	.379	28.750	2.250	.356	-1.251	.218
MCHC	31.925	1.023	.162	32.350	.864	.137	-2.888	.006

Inference: This table shows a significant (.000) increase in RBC (4.581) and Hb (12.77) values after SRP compared to baseline. All the other RBC parameters show a marginal insignificant increase after SRP. Prohepcidin levels decreased insignificantly after SRP

Table II: Probing Depth Reduction from Baseline to 90 Days after SRP

										Paired Samples t –tests		
	Baseline			30th Day			90th Day			Baseline – 30th Day	Baseline – 90th Day	30th Day – 90th Day

Discussion

Anaemia is one of the most common global public health problems in recent times. Globally, anaemia affects 1.62 billion people, which is 24.8% of the total population. Evidence indicates that ACD is seen in rheumatoid arthritis and chronic periodontitis, though the etiologic factors of both the diseases are different, stating that long-standing chronic inflammation can lead to anaemia. Various studies have found associations between ACD and periodontitis. The pro-inflammatory cytokines released in periodontitis interact with hepcidinthe iron regulating hormone and down regulate erythropoiesis. **Siegel et al** reported a depression in the number of erythrocytes secondary to periodontaldisease[3]. **Hutter et al** suggested that periodontitis also needs to be considered as a chronic disease which may cause lower number of erythrocytes andconsequently lower Hb levels[4].

Epidemiologic studies suggested that periodontal deterioration increases the risk of systemic problems such as cardiovascular diseases[5], atherosclerosis[6], diabetes mellitus[7], and preterm low birth weight of infants[8]. These associations suggest that periodontal diseases have systemic effects. In addition, some studies had found that periodontal infection elicits systemic blood chemistry changes[9].

Anaemia of chronic disease (ACD) seems to be one of the most common forms of anaemia observed in clinical medicine. ACD is defined as the anaemia occurring in chronic infections, chronic inflammatory processes or tumour formation that is not due to dysfunction of bone marrow cells or other diseases and occurring despite the presence of adequate iron stores and vitamins. A characteristic finding of the disorders associated with ACD was the increased production of the cytokines that mediate the immune or inflammatory response; such as tumour necrosis factor, interleukin-1, and the interferon. All the processes involved in the development of ACD can be attributed to these cytokines, including shortened

red cell survival, blunted erythropoietin response to anaemia, impaired erythroid colony formation in response to erythropoietin, and abnormal mobilization of reticuloendothelial iron stores[10]. These cytokines are also released by periodontal tissues in response to bacterial infection, which suggests that periodontitis like other chronic disease may cause ACD.

A few early reports in the literature have investigated the bidirectional relationship between anaemia and periodontitis**. Goldstein[11], Siegel[3], Lainson et al[12], and Chawalaet al[13]**were among the first to observe anaemia in periodontitis. Most of these authors believed that anaemia was one of the causes of periodontitis rather than being the consequences[11,12,13].

Various studies have tried to evaluate the relationship between periodontitis and haemoglobin**. Hutter et al[4] and Thomas et al[14]**found that periodontitis patients have lower haematocrit, lower numbers of erythrocytes, lower haemoglobin levels and higher erythrocyte sedimentation rates when compared to healthy controls. **Rai and Kharb[15]** found an increased in haemoglobin and RBC levels in patients with severe periodontitis after scaling and root planning. Also, **Agarwal et al [16]** demonstrated a significant improvement in haemoglobin value and erythrocyte count after periodontal treatment, including surgery in patient with generalized chronic periodontitis with anaemia. On the other hands, **Wakai et al [17]**failed to show any association between haemoglobin levels and periodontal status. Furthermore**, Havemose-Poulsen et al[18]**. failed to show any association between haemoglobin levels and periodontal status in patients with localized aggressive periodontitis, generalized aggressive periodontitis, juvenile idiopathic arthritis, and rheumatoid arthritis.

Conclusion

Reduction in periodontal inflammation by scaling and root planning improve RBC count and haemoglobin level significantly Prohepcidin levels decreases with periodontal treatment but rather insignificantly.

Peripheral Ossifying Fibroma in Young Patient—A Case Report

J. Bhuvaneswarri[1], Sindhuj A. S.[2], Bagavad Gita[3], Mohan Valiathan[1]

[1]Professor, [2]Post Graduate, [3]Professor and Head of the Department, Department of Periodontics, Sree Balaji Dental College And Hospital, BIHER, Chennai

ABSTRACT

Fibroma is a benign tumor in which fibroblasts proliferate to form neoplasia, resulting in an increase in collagen fibers. Many of the fibroma-like lesions seen in the oral mucosa represent reparative or reactive hyperplasia of fibrous tissue against chronic irritation, and true neoplastic lesions are considered rare. Peripheral ossifying fibroma (POF) is a non-neoplastic, reactive lesion of gingiva. The precise etiopathogenesis of POF is unclear. However, it is suggested to originate from the connective tissue of periodontal ligament. This lesion predominantly occurs in the maxillary anterior region. The treatment protocol involves surgical excision followed by the biopsy of lesion. The high recurrence rate of the lesion is due to its reactive nature and unpredictable course. Hence proper postoperative monitoring and follow-up of the lesion are necessary. The present case was surgically managed and did not show any sign of recurrence during the follow-up period of 7 months.

Keywords: *Peripheral Ossifying Fibroma, Fibroma, Non-Neoplastic Lesion, Inflammatory Growth.*

Introduction

Peripheral ossifying fibroma (POF) is an inflammatory, reactive lesion of gingiva which predominantly involves the maxillary anterior region. It is non-neoplastic in nature, originating from the periodontal ligament (PDL) as a response of periodontal tissues to chronic injurious agents such as dental calculus, plaque, orthodontic appliances, and ill-fitting restorations, etc. It is commonly observed in the second and third decades of life with females being affected more than males. About 60% of these tumors occur in the maxilla and more than 50% of the cases are found in the incisors and canine region.

Most of the POF lesions measures approximately <2 cm. Radiographically, no bony involvement is found in majority of the cases. However, some cases may report with superficial erosion of the bone. The management of POF includes the elimination of local irritating factors with surgical excision of overgrowth and strict plaque control.

Case Report: A 15 year old boy reported to the Department of Periodontology with a chief complaint of swelling in the upper front tooth region for past 6 months. [Fig 1] History of the present lesion revealed that initially the growth was small in size and it gradually increased over 6 months attaining the persistent size. There was no history of pain, sensitivity, bleeding on brushing.

Periodontal examination revealed that the growth was measuring approximately 2*1 cm in the palatal region of 11,12,13,21 and extended from the mesial aspect of 21 to the distal aspect of 13.[Fig 2] The overgrowth was movable, pedunculated and fibrotic in nature with well defined margins. The growth was firm and tender on palpation. The oral hygiene status of the patient was fair with presence of plaque and calculus. No mobility or attachment loss was found on examination. A provisional diagnosis of irritational fibroma and differential diagnosis of fibrous epulis were considered on the basis of anatomic location and clinical presentation.

Fig. 2: Pre operative picture

The treatment was explained comprehensively to the patient and patient's consent was got and hematologic investigations was done. Surgical excision of the lesion was done in 11,12,13,21 region and curettage was done. The wound was debrided. Excised tissue was fixed in 10% formalin and then sent for histopathological examnination. Histopathological examination revealed ulcerated epithelium and few hyperplastic areas.[Fig 3,4] The fibrous connective tissue shows increased cellularity with intervening plump fibroblasts and bony trabaculae. Numerous spherules of calcifications are noticed. Diffuse chronic and acute inflammatory cell infiltrate is noticed with moderate vascularity.[Fig 5,6] Based on these results a confirmatory diagnosis of peripheral ossifying fibroma was obtained. No recurrence of the tumor is seen at the site for past 7 months.

Discussion

The focal reactive lesions of gingiva are pyogenic granuloma (PG); peripheral ossifying fibroma(POF); fibrous hyperplasia; and peripheral giant-cell granuloma (PGCG). The prevalence of POF among reactive lesions is found to be 20.78%.[1,2,3] The first case of ossifying fibroma was reported by Menzel in 1872, however, the terminology was given by Montgomery in 1927.[4] Ossifying fibroma can be categorized into two categories – central and peripheral. The central type has its origin from endosteum and expands from medullary cavity of bone, whereas, the peripheral type is suggested to originate from PDL or from the soft-tissue overlying alveolar process (periosteum).

Usually, the size of POF is <2 cm; however in the

present case it was a 2*2 cm. Poon *et al*. have mentioned a case of giant POF measuring approximately 9cm. [5] Many studies have been conducted to understand the etiopathogenesis of POF, but the exact mechanism is still undefined. Few researchers have suggested that the chronic irritation caused by local factors results in inflammatory hyperplastic cellular response of PDL/ periosteum in the form of metaplastic changes in connective tissue.[3,6] Calcified metaplastic changes of the connective tissue may manifest in many histologic variants such as bone, cementum-like material, and dystrophic calcification. The occurrence of POF and PGCG was interrelated by some authors and they have mentioned that both the lesions are the progressive forms with the same spectrum of pathogenesis.[7] The reason behind the recurrence rate of POF is due to the remnants of the lesion, persistence of local irritants or repeated injury.[2] The basic microscopic pattern of the POF is fibrous proliferation associated with different types of mineralized components.[8]

Other group of researchers has suggested that one of the factors in the etiopathogenesis of POF is influence of hormones and considered it to be responsible for the higher prevalence in females[2] Regezi *et al*. found a large number of XIIIa + cells and a subset of monocyte/ macrophages in POF and in other oral fibrovascular reactive lesions. They hypothesized the role of dendrocytes in these lesions.[9]

Conclusion

There was no recurrence of the lesion over a period of 7 months follow up. Peripheral reactive lesions are a common group of lesions encountered during routine dental examinations. Early detection and treatment of reactive lesions by dentists can reduce more dentoalveolar complications. Hence knowledge of the frequency and distribution of these lesions is beneficial while establishing a diagnosis and a proper treatment plan in practice.

Consent

Written informed consent was obtained from the patient for publication of this case report and accompanying images.

Oral Hygiene Status, Periodontal Status and Treatment Needs among Psychiatric Outpatients in Chennai, India

Anita M.[1], U Vidhya Rekha[2], Sadhana.Kandavel[2]

[1]Reader, [2]Senior Lecturer, Dept. of Public Health Dentistry, Sree Balaji Dental College and Hospital, BIHER

ABSTRACT

Aim: To assess the oral hygiene status,periodontal status and treatment needs among psychiatric outpatients in Chennai.

Materials and Method: A cross – sectional descriptive study was carried out on patients receiving care at the Outpatient Wing of The Department of Psychiatry, Stanley Medical College and Hospital, Chennai. A cluster sampling technique was employed. The study sample consisted of 159 males and 145 females.

Oral Hygiene Index Simplified and Community Periodontal Index of Treatment Needs index were recorded. Data was analyzed using SPSS (Version 15) software. Chi – square test, Trend Chi – square test and Multiple linear regression analysis were employed.

Results: Among the male subjects; 6 (3.7%), 75(47.2%) and 75(47.2%) had good, fair and poor oral hygiene, respectively. Among the female subjects; 9(6.2%), 87(60%) and 49(33.8%) had good, fair and poor oral hygiene, respectively.

6 (2%) subjects had healthy periodontium, 3(1%) had bleeding on probing, 146(48.5%) had calculus, 115(38.2%) had shallow pocket and 34(11.2%) had deep pocket. Prevalence of periodontal disease among the study subjects was 98%.6(2%) did not require treatment, 298 (98%) needed oral hygiene instruction, 295(97%) needed scaling and oral hygiene instruction, 149(49%) needed complex periodontal therapy along with scaling and oral hygiene instruction.

Conclusion: The oral hygiene status and periodontal status of psychiatric outpatients is very poor and treatment needs are very high.

Keywords: *Oral hygiene status, Periodontal status, Psychiatric outpatients.*

Introduction

Illness, whether physical or mental may lead to deterioration in self care and have an adverse effect on the holistic wellbeing of the individual[1]. The term psychiatric illness is used to describe clinically recognizable patterns of psychological symptoms or behavior causing acute or chronic ill health, personal distress or distress to others[2].

Psychiatric illness is not a single condition. Rather, it is a continuum ranging from minor distress to severe disorder of the mind or behavior[3].

Lack of knowledge about the cause of oral disease, relatively high frequency of non-compliance with oral health practices, embarrassment regarding neglected oral care, low perception of dental treatment needs, unwillingness to accept treatment, high sugar content in diet and mistrust of dental health professionals contribute to oral neglect in psychiatric patients[4].

Maria Isabel et al (2009, Columbia)[5] conducted a study to determine the periodontal status of female psychiatric patients. Of 60 patients, 49.2% had a clinical attachment loss (CAL) of 7mm. CAL was higher in patients with more than 10 years of hospitalization.

In a study conducted on 220 psychiatric patients in Davangere by Manish Kumar et al (2006)[6], 98.1% had periodontal disease with bleeding on probing, calculus, shallow pocket and deep pocket being present in 10.5%, 40.6%, 35.3% and 7.8% participants respectively.

Routine dental health care for institutionalized psychiatric patients are provided within many of the large institutions, but only a small portion (2.35%) of psychiatric patients are users of mental health services[7]. These patients have to arrange their own dental care[8].

Among the states of India, Tamil Nadu has the maximum number of mental health institutions[9]. Yet, the population is so vast and diverse that majority of mentally ill patients are still treated as community dwelling outpatients[10].

Materials and Method

Study Design: A cross – sectional descriptive study

Study Area: Stanley Medical College and Hospitals

Inclusion Criteria:

- Subjects who had been diagnosed with psychiatric illness at least 5 years ago.
- The patient must be currently receiving treatment for the psychiatric illness.

Exclusion Criteria:

- Those who are not stable to give informed consent.
- Those who are not willing to participate in the study.

Approval and Informed Consent: Ethical approval was obtained from the Institutional Review Boards of Stanley Medical College and Hospital and Sree Balaji Dental College and Hospital.

Informed consent was obtained from all the participants and minors were examined only after obtaining consent from their parents or guardian.

Sampling Methodology: A cluster sampling technique was employed. A list of Government administrated psychiatric outpatient facilities in Chennai was obtained from the Department of Health and Family welfare, Government of Tamil Nadu. One hospital was selected from the aforementioned list by simple random sampling using lottery method.

Survey instrument: An operator administered pre-tested questionnaire was used. Demographic information, duration of illness and current medicationswere obtained. Oral hygiene index-simplified and periodontal status and treatment needs index were recorded.

Clinical examination: Dental examinations were conducted by a single trained examiner. Dental examinations were conducted in supine position under natural light by means of mouth mirror and a CPI probe.Only completely filled forms were considered for analysis. The intra examiner reliability was calculated using the data obtained by re-examination of first and eleventh subject of each day after scheduled number of subjects were examined for the day (K=0.81).

Statistical analysis: Data was entered in Microsoft Excel spreadsheet and analyzed using SPSS software.

Table 1 depicts the demographic distribution of study subjects. The study sample consisted of 304psychiatric out-patients. 159 (52.3%) of the respondents were males and 145 (47.7%) were females. The study subjects were between the age group of 18 and 71 years.

Figure 1 depicts distribution of study subjects based on type of psychiatric illness. Among males; 57 (36%), 12 (7%), 54 (34%) and 36 (23%) were diagnosed with schizophrenia, mood disorder, organic brain damage and others, respectively. Among females; 30 (21%), 66 (46%), 21 (14%) and 28 (19%) were diagnosed with schizophrenia, mood disorder, organic brain damage and others, respectively.

Figure 2 depicts the distribution of study subjects based on duration of psychiatric illness. Among the 304 study subjects, 78(26%), 120(39%) and 106 (35%) were diagnosed with psychiatric illness 5 years, 6 to 10 years and >10 years ago.

Table 2 describes the distribution of study subjects based on oral hygiene status. Among 159 male subjects; 6 (3.7%), 75(47.2%) and 75(47.2%) had good, fair and poor oral hygiene, respectively. 3(1.8%) male subjects were excluded. Out of 145 female subjects; 9(6.2%), 87(60%) and 49(33.8%) had good, fair and poor oral hygiene, respectively.

Among males, the maximum number of subjects having good, fair and poor oral hygiene were found in the 20-29, ≤ 19 and ≥ 50 years age group, respectively. Among females, the maximum number of subjects having good, fair and poor oral hygiene were found in the ≤ 19, 20-29 and ≥ 50 years age group, respectively.

Trend Chi-squaretest was performed to determine the pattern of OHI-S score variation across the age groups. It was found that as age increases, OHI-S score also increased [$X^2 = 5.352$, $p = 0.021$]. The association between age and OHI-S score was found to be statistically significant [$X^2 = 2.561$, $p = 0.015$].

Table 3 depicts subjectwise distribution of periodontal status. Among the study subjects, 6 (2%) had healthy periodontium, 3(1%) had bleeding on probing, 146(48.5%) had calculus, 115(38.2%) had shallow pocket and 34(11.2%) had deep pocket. The prevalence of periodontal disease increased as the age advances and this relationship was found to be statistically highly significant. Prevalence of periodontal disease among the study subjects (according to CPITN index) is 98%.

Table 4 depicts sextantwise distribution of periodontal conditions. Mean number of sextants coded healthy was maximum among the ≤19 yrs age group (3.4). Mean number of sextants coded for bleeding (3.3) and calculus (3.1) was maximum among the 20 – 29 yrs age group. Mean number of sextants coded for shallow pocket was maximum among the 40 – 49 yrs age group (3.3). Mean number of sextants coded for deep pocket was maximum among the ≥50 yrs age group (2.6).

ANOVA test was performed to test the association between age and periodontal condition among the study subjects, it was found to be statistically significant between the groups.

Table 5 depicts the distribution of study subjects according to treatment needs. Among the study subjects 6(2%) did not require treatment, 298 (98%) needed oral hygiene instruction, 295(97%) needed scaling and oral hygiene instruction, 149(49%) needed complex periodontal therapy. It was found that as the age increases more complex periodontal treatment was required in the study population. The relationship between age and treatment needs was found to be statistically highly significant.

Discussion

Age of the participants in this study ranged from 18 years to 71 years. Among the study subjects; 87, 78, 75 and 64 were diagnosed with schizophrenia, mood disorder, organic brain damage and other psychiatric illnesses respectively. In our study, the use of tooth brush and tooth paste as the preferred mode and material for cleaning teeth was maximum among the ≤ 19 years age group and minimum among ≥ 50 years old age group. This may be due to the increased awareness and increased willingness to adopt new lifestyle modifications among the younger generation. 11% of the participants in the present study cleaned their teeth with the help of an assistant. This is similar to studies conducted by Peter Horst G et al[17] in Netherlands and by Angelillo et al[18] in Italy.

In the present study, mean OHI-S score increased with increased duration of psychiatric illness. This is in accordance with previous studies conducted in Bangalore city (Rekha R et al, 2002)[24], Italy (Lucchese et al, 1998)[20] and Denmark (Hede B et al, 1995)[19]. Longer the patient has been psychiatrically ill, longer he/

she may not have been able to prioritize and effectively perform oral hygiene maintenance.

In this study, 1%, 48.5%, 38.2% and 10.3% of the study subjects had bleeding on probing, calculus, shallow pocket and deep pocket respectively. In a study by Angelillo et al[18] in Italy; 4.6%,10.1%,19.6% and 64.8% of the study subjects had bleeding on probing, calculus, shallow pocket and deep pocket respectively. Lucchese C et al[20](Bologna) reported that 29% of the subjects had bleeding and calculus and 66% had pathologic pockets. This vast variation in the distribution of periodontal conditions may be due to differences in lifestyle variations, level of care available and differences in dietary habits across these countries.

In the present study, there was no association between type of psychiatric illness and severity of periodontal diseases. Lucchese C et al[20] (Bologna) reported similar findings. However, Solis A C et al[25] and Persson K et al[9] reported that periodontal disease was significantly associated with Schzophrenia.

Thus, results of this study show that psychiatric patients have extensive dental diseases, many of them requiring complex treatment. However, prevention should be the main objective because patients with advanced psychiatric illness are often anxious and uncooperative for extensive curative therapy.

Relationship between Speaking Anxiety and Self-Efficacy among Elementary Students in Second Language Classrooms in Malaysia

Kee Jiar Yeo[1], Seok Lian Tiw[2]

[1]Professor, [2]Student, School of Education, Universiti Teknologi Malaysia (UTM), Johor, Malaysia.

Abstract

Learning English as a second language has been long implemented in Malaysia since post-independence in 1967. However, many research findings have established that language anxiety remains as an obstacle, which hinders students from mastering English in their second language classrooms. This paper presents the exploration on the relationship between English speaking anxiety and self-efficacy among 289 elementary school students from the population of 1080 students in the zone of Nusajaya, Johor, Malaysia. The results were compared across different academic achievers and genders. A modified version of FLCAS (Foreign Language Classroom Anxiety Scale) by Horwitzs and Cope (1986) and English Speaking Self Efficacy (ESSE) which was adapted and adopted from QESE by Wang (2013) were used as the research instruments. Questionnaires were distributed to the respondents to assess their self-perception on speaking anxiety and self-efficacy. The findings realized the existence of a significant moderate negative relationship between English language speaking anxiety and self-efficacy. No significant difference between genders in the level of speaking anxiety was found but there were significant differences among different academic achievers in the level of speaking anxiety

Keywords: *Speaking anxiety, Self-efficacy, Second Language.*

Introduction

English Language is a dominant language for employability, communication, business and research. In Malaysia, it is the most important second language in the school system. It is stipulated in the Malaysia Education Blueprint (2013-2025) to produce students who are proficient in both Bahasa Malaysia and English Language. Proficiency in using English is an advantage to the employees in Malaysia and in many countries. Global employability increases with the level of English competency1. However, the Malaysian Employer Federation (MEF) in the latest Salary Survey for Executives 2014 found that half of their newly recruited executives and non-executives did not reach the satisfactory level of English oral communication skills2.

Research findings have pointed to some problems faced by students in second language learning. The widespread use of mother tongue during English lessons for teacher-talk and peer interaction interferes the correct use of English gramar, syntax and morphology in spoken English proficiency 3,4. Besides, the extreme focus on national examinations like UPSR, PMR and SPM has limited the communicative use of English for real purposes 4.

Hiew5 in a recent study has revealed the existence of moderate anxiety among secondary students in the second language classroom due to their hesitation for communication. Their relunctancy to communicate using English was mainly out of their fear of being judged negatively. This impediment affects students' communication practice and the mastery of English competencies 5,6. The current emphasis on the development of communicative competence poses especially great challenges for the students of high anxiety (Horwitz et al)7. As such, second language anxiety is regarded as a significant issue which is

unavoidable in the progress towards a successful English education in primary schools.

According to Social Cognitive Theory, self-efficacy plays an important role in students' anxiety arousal. The notion of their incapability in managing threatening consequences such as test or to speak in front of others may induce greater levels of anxiety (Bandura, 1986)8. As their self-efficacy increases, their academic achievement will be upgraded too. However, their anxiety toward specific subject matter does not posses any relationship to their academic performance. Low level of self-efficacy in a student in certain subjects can arouse certain level of anxiety about the corresponding demands. The assessment of their sense of speaking in a second language would discover clear perception into the understanding of students' self-apprehension of their capabilities to manage and deal with their oral output.

The purpose of this study is to investigate the level of second language speaking anxiety among elementary students in English classrooms and examine how their speaking anxiety was related to second language speaking self-efficacy. Besides, the effects of gender difference and their English academic achievement was examined in relation to their level of self-efficacy and speaking anxiety.

Problem Statement

Anxiety and self-efficacy are considerably relevant and crucial in acquiring a second language. in Malaysia investigating English speaking anxiety among elementary school children in second language classrooms. A few studies about anxiety and self-efficacy in learning second language have been done in Malaysia but they all focused mainly on students of tertiary level or secondary level 9-12.

Method

The research is a quantitative and non-experimental study, which collects descriptive data using survey questionnaire as the main method of data collection. Before the main study, a pilot study was done to confirm the reliability of the modified version of Foreign Language Classroom Anxiety Scale (FLCAS) and Questionnaires of English Self-Efficacy (QESE). Using stratified random sampling method, the author selected a sample of 289 Primary 5 (10-11 years old) students out of the target population size of 1080 students from Chinese vernacular elementary schools in the zone of Nusajaya, Johor, Malaysia to participate in the survey. The study was planned to measure self-perceptions using Second Language Classroom Anxiety Scale (SLCAS) and English Speaking using Self-Efficacy (ESSE).

Results and Discussion

Findings in Table 1 showed the means and standard deviations of the variables speaking anxiety (ANX) and speaking self-efficacy (SE). The students show moderate level of total speaking anxiety (M= 2.16, SD= 0.64) during their second language learning. For self-efficacy assessment, the results revealed moderate sense of efficacy (M=3.06, SD=0.79) in students when they speak English in the classroom.

Independent-samples t-test was conducted to examine the difference in speaking anxiety and self-efficacy between two genders. Table 2 shows no significant difference in the level of anxiety for male (M=2.50, SD=0.69) and female (M=2.43, SD=0.59) students; t (287) = 0.946, p = 0.345. For self-efficacy, no significant difference was found in the level of self-efficacy for male (M=3.04, SD=0.82) and female (M=3.09, SD=0.75) students; t (287) = -0.623, p = 0. 534. These results indicate that genders do not have an effect on the level of speaking anxiety and self-efficacy. The results suggest that both male and female students experienced almost the same level of anxiety and self-efficacy while speaking in the second language classrooms.

A one-way ANOVA between subjects was run to compare the impact of academic achievements on levels of anxiety and self-efficacy in grades A, B, C, D and E. Table 3 shows a significant effect of different grades on levels of speaking anxiety (ANX) and self-efficacy (SE) at $p<.05$. Significant difference of academic achievement on level of ANX [$F(4, 284) = 9.22$, $p = 0.000$] and SE [$F(4, 284) = 12.44$, $p = 0.000$] was found.

Post hoc comparisons using the Tukey HSD test for ANX showed that the mean score for A graders ($M = 2.61$, $SD = 0.69$) was significantly different than D graders ($M = 2.16$, $SD = 0.46$) and E graders ($M = 2.11$, $SD = 0.79$). However, B graders ($M = 2.67$, $SD = 0.58$) and C graders ($M = 2.31$, $SD = 0.49$) did not significantly differ from A graders in the level of total speaking anxiety. Taken together, these results suggest that students with better academic achievement are less anxious to speak in the second language classroom. Specifically, our results suggest that students with lower academic achievement

experienced higher anxiety level and are more reluctant to use the language for communicative purpose.

For testing self-efficay, post hoc comparisons using the Tukey HSD indicated that the mean score for A graders (M = 3.16, SD = 0.81) and B graders (M = 3.42, SD = 0.70) were significantly different than C graders (M = 2.93, SD = 0.57), D graders (M = 2.83, SD = 0.69) and E graders (M = 2.32, SD = 0.83). In conclusion, these results suggest that students with better academic achievement have higher sense of self-efficacy to speak in the English classrooms. In contrary, student's especially E graders experienced lower sense of self-efficacy.

A Pearson product-moment correlation coefficient was analyzed to examine the relationship between the level of speaking anxiety and self-efficacy. Table 4 shows a strong and negative relationship between self-efficacy and speaking anxiety, r = -0.680, n = 289, p = 0.000. In particular, students who have low sense of speaking efficacy are significantly more anxious than those of relatively stronger English speaking self-efficacy. Increases in their sense of self-efficacy could lower the anxiety while speaking English in second language classrooms.

In summary, elementary students experienced moderate level of anxiety when they need to converse in second language classrooms. In addition, they have moderate level of self-efficacy to talk using the target language in the classroom. That is to say, they do believe in their capability in speaking English well even though they feel quite anxious in the classroom. The level of speaking anxiety could be further reduced by promoting their sense of self-efficacy in speaking English in the classroom. Male and female students appeared to have the same level of speaking anxiety and self-efficacy but students of different academic achievements show significant difference in the level of speaking anxiety and self-efficacy.

The reports on the level of speaking anxiety and self-efficacy were consistent with the other international studies 13-16 and local studies 10, 17-18 which utilized survey questionnaires to assess students' self-perception on language anxiety and self-efficacy. Anxiety can negatively affect language learning experience in various ways and thus it is vital for all stakeholders to take efficient measures to reduce anxiety to increase language acquisition, retention and learner's motivation. The strong and negative correlation between anxiety and self-efficacy was found to be consistent with other studies done on English Language 14,15, French (Nicole, 2006) 19 which revealed correlation coefficients ranging from -0.470 to -0.747.

Conclusion

To address the issue of decline in the English proficiency among Malaysian students, our government has implemented English Language Enhancement Program to promote English level among our students. Despite new and improved teaching pedagogies, students are still found to be deficient in acquiring English Language even they have learned in schools for many years 3,20. Therefore, it is crucial to look into the deterioration of English Language especially in the command of English based on psychological aspects. Previous studies have shown that anxiety is an obstacle that hinders language learning. This study has proven the existence of speaking anxiety and students especially of lower academic achievement are found to be reluctant to speak in the second language classrooms.

Bandura (1977, 1986) 8,21 stated that self-efficacy is important in regulating anxiety arousal and anxiety is also the main source of efficacy belief. That said, the increase of speaking self-efficacy could reduce the anxious feeling while speaking. The result of the study again revealed a strong negative relation between these two variables, which supports the above claim. More drastic measures could be designed to increase the sense of efficacy among primary students. Further research and development on interventions to promote speaking self-efficacy among primary students could be considered. If valid speaking performance could be measured, the effect of speaking anxiety and performance could be correlated. Last but not least, this research can be extended to students of national elementary schools and Tamil vernacular elementary schools.

Awareness of Workstation Ergonomics and Occurrence of Computer-Related Injuries

Lely Lubna Alaydrus[1], Dewi Nusraningrum[2]

[1]Master Candidate, Operations Management, Universitas Mercu Buana, Jakarta, Indonesia, [2]Associate Professor, Faculty of Economics and Business, Universitas Mercu Buana, Jakarta, Indonesia.

Abstract

The computer-related injuries (CRIs) is reported having a high incidence among office workers who works daily with a computer and do not practice good working habits or not aware of workstation ergonomics. The study's aim is to assess awareness of workstation ergonomics and occurrence of CRIs among office workers at a private university in Jakarta, Indonesia. This is a survey of 120 office workers selected with a simple random sampling method. The data were obtained using a validated self-administered questionnaire and analyzed using SPSS version 23. All participants are office workers who work with computer >5 hours daily (100%). More than half participants are women (50.8%), aged 20-30 years old (56.7%), with a bachelor's degree (73.3%), duration of occupation 1-5 years (68.3%), and never attended any ergonomics training (87.5%). Most of the participants had adequate awareness regarding workstation ergonomics (65%), however many of them still experienced CRIs e.g. eye strain (78.3%), blurred vision (41.7%), watery eyes (39.2%), headache (37.5%), tingling and numbness sensation of feet and hand (29.2% and 19.2% respectively). Assessment of body pain using Nordic Body Map showed that most of the participants experienced pain on the upper neck (44.2%), shoulder (40.8%), waist (40%) and lower neck (39.2%). Practice a good working habit is crucial and ergonomics training is highly recommended to all office workers in the university in order to reduce the occurrence of CRIs in the future.

Keywords*: Awareness; Ergonomics; Workstation; Computer-Related Injuries; Office Workers*

Introduction

Working with computer may cause computer-related injuries (CRIs) such as neck and shoulder pain, blurred vision, headache, and repetitive injury of the arms and hands.[1] It is predicted that 25% ofthe office workers are suffering from this type of injury.[2] Musculoskeletal disorders (MSDs), one type of CRIs, are the most disorders among the workers.[3] The prevalence of the neck and shoulders pain was reported quite high, leading to sickness absence and disability, decreasing work efficiency, and extensive costs upon the organizations.[3] Another example, computer vision syndrome (CVS) is a visual symptom occurred because of computer usage. More than 50 million people experience CVS in worldwide. This incidence may reduce the productivity and quality of life of the workers. Another research reported that CVS was experienced by almost 90% among the office workers.[4]

It is a certainty that a computer is an important instrument in many activities. But using a computer in a long period may increase the chances of developing CRIs. The inappropriate computer uses or unergonomic position may cause MSDs.[5]

The university office workers are a group of people who work almost daily with the computer. The occurrence of MSDs or CRIs is often among these people. On pre-survey observation that has been carried out by the researcher, there are few findings regarding this issue at UMB. Some office workers showed improper position while working with computers and some stated that they

Corresponding author:

felt muscle and joint pain, headache, blurred vision, watery eyes, and numbness of the feet. This phenomenon can cause serious injuries and illnesses among workers. Therefore, awareness regarding workstation ergonomics is important in order to reduce the incidence of CRIs and absenteeism of workers because of sicknesses or disability.

There was no research had been conducted regarding the awareness of workstation ergonomics among office workers and the occurrence of CRIs at UMB. Thus, this study's aim is to assess the awareness of workstation ergonomics and the occurrence of computer-related injuries among office workers at UMB, Jakarta.

Literature Review

Ergonomics derives from Greek words, 'ergon' means work and 'nomos' means natural law. This word was first used by Professor Wojciech Jastrzebowski in Poland in 1857. Then, Professor K.F.H. Murrell suggested official use of this word at an assembly of the British Admiralty in 1949, and later the word ergonomics officially accepted in 1950 by British researchers for the name of their society, Ergonomic Society.[6]

Ergonomics is a branch of knowledge that explores the interaction between human and their working environment and system in order to enhance workers' welfare and overall system performance.[7] Workstation ergonomics is a workstation that well-designed ergonomically. Awareness of workstation ergonomics is the ability to know and perceive or being conscious or knowledgeable about well-designed and comfortable workstation for the workers. This awareness is important for every worker because the unergonomic workstation may cause injuries to the workers. The ergonomic injuries do not occur immediately. Some of the ergonomic injuries are MSDs, CVS, and carpal tunnel syndrome (CTS). This type of injuries is termed computer-related injuries (CRIs).[7]

A good ergonomic workstation can help to avoid the occurrence of CRIs. The employers also need to be aware of this matter by choosing proper furniture, such as desks, chairs, computers and its accessories for their workers. On the other hand, practicing good posture and working habits are essential for every worker. This habit can be ingrained if the workers are aware of workstation ergonomic.[8]

Method

This quantitative study was conducted at Universitas Mercu Buana (UMB), Meruya campus, Jakarta, from January-February 2019. The inclusion criteria of the participant were office workers at UMB, that have been using the computer for their daily tasks for about one year and with a minimum of 5 hours daily. The exclusion criteria were office workers who are having musculoskeletal complaints because of acute trauma in the last 30 days or systemic diseases such as gout, hyperlipidemia, or eye diseases such as conjunctivitis.

The total number of participants selected with simple random sampling was 120 workers from a total of 500 office workers. The data was collected by using a validated self-administered questionnaire that includes questions on socio-demographic data and workstation ergonomics by using the Workstation Ergonomics Self-Assessment [5] and modified Nordic Body Map to assess the occurrence of CRIs.[9] The content and face validity were done by the researchers and the construct validity was done by using Pearson's Bivariate analysis. A pilot study was carried out by distributing a questionnaire to 30 non-sample participants, with Cronbach's alpha 0.7.

The SPSS version 23 was used to analyze the data with a significance level set at 0.05. The independent variable was the socio-demographic factor, that consist of gender, age, education level, and work duration, and ergonomic training. The dependent variables were awareness of workstation ergonomics and occurrence of CRIs (neck, shoulder, hand, wrist, elbow and back pain, visual problems, headache, and carpal tunnel syndrome).

Results

A total number of 170 questionnaires have been distributed among office workers of UMB, Jakarta, from 16-19 January 2019. Only 146 questionnaires have successfully been collected and 26 questionnaires were excluded to fulfill the inclusion criteria. Finally, 120 questionnaires were used for analysis.

The result showed that more than half participants are women (50.8%), aged 20-30 years old (56.7%), with a bachelor's degree (73.3%), duration of occupation 1-5 years (68.3%), and never attended any ergonomics training (87.5%). All participants are office workers and working with computer >5 hours daily (100%). Based on the assessment of workstation ergonomics, most of the participants had adequate awareness regarding

workstation ergonomics (65%), however many of them still experienced CRIs e.g. eye strain (78.3%), blurred vision (41.7%), watery eyes (39.2%), headache (37.5%), tingling and numbness sensation of feet and hand (29.2% and 19.2% respectively). Assessment using Nordic Body Map showed that most of the participants experienced pain on the upper neck (44.2%), back (40.8%), waist (40%) and lower neck (39.2%).

The binary logistic regression was carried out to assess factors associated with the awareness of workstation ergonomics. Six variables had *p*-value <0.25: gender ($p = 0.097$), education level (0.094), work duration ($p = 0.145$), blurred vision ($p=0.147$), watery eyes ($p = 0.089$), headache ($p = 0.051$) and tingling and numbness sensation of feet ($p = 0.182$). These six variables were proceeded to undergo the binary logistic regression using backward stepwise method.

All variables with p-value <.25 were selected to build the preliminary model. The variable gender, education level, work duration, blurred eyes, watery eyes, headache, and tingling and numbness of feet were selected for analysis. The backward LR method was used in this analysis. Four variables were significantly associated with the awareness of workstation ergonomics: gender, education level, work duration, and watery eyes.

From the analysis, workers with work duration > 5 years have increased odds of having adequate awareness of workstation ergonomics 2.4 times compared with workers with work duration ≤ 5 years. Female workers have increased odds of having adequate awareness 2 times than male workers.

The prediction model of awareness of workstation ergonomics among participants is as follows:

Logit (P) = 1.430 + [0.892*work duration] + [0.698*gender] –

[0.803*watery eyes] – [1.248*education level]

Discussion

Majority of the participants had adequate awareness regarding workstation ergonomics (65%), although they never attend any ergonomics training (87.5%). It seems that this awareness was not reflected in their daily practices. So, as a result, the majority of them experienced CRIs and on assessment with NBM showed that most of them experienced body pain.

Another reason, it might be from the chairs that are improper to each worker. The chair selection in UMB was not based on the body size of the workers but based on job position or hierarchy. A worker who has a high position in the office will get a good quality of chair compared to a worker who has a lower position. This policy is not correct. A chair selection needs to be adjusted to the body height and weight of a worker. Some workers may be taller than other workers or having excessive weight. The measurement of body weight and height are ideally required in the selection of a chair, so the workers will feel comfortable sitting for hours on the chairs. An ergonomic chair may prevent CRIs and reduce body pain.[10]

In this study, most of the participants felt pain on the neck (upper and lower neck) (44,2% and 29.2% respectively), back (40.8%), waist (40%) and shoulder (35%). It is like the studies conducted by Daneshmandi and Besharati in Iran, also Salem et al. in India. Daneshmandi carried out a study among Iranian office workers, found that the highest pain was on the neck and back (41.6% respectively) and shoulder (40.6%).[11] A study conducted by Besharati et al. also found a similar result that the highest pain was on the neck.[12] Another study conducted by Salem et al. among 500 software professionals in information technology (IT) reported that the common MSDs were on the neck, back, and shoulder.[13]

The two following studies also reported similar results. A study conducted by Loghmani among 101 Iranian office workers from a university, reported the most pain occurred on the neck (69.2%) and low back (58.2%).[14] An observational study conducted by Akrouf among 750 office workers in Kuwait showed that most cases were on the neck (53.5%), lower back (51.1%), and shoulders.[15]

Another study showed different results. A case study carried out by Moom among 50 office workers in Punjab, India, reported that some workers suffering from pain on the low-back (40.4%), upper back (39.5), neck (38.6%), and hand or wrist (36.8%).[16] A study conducted by Quemelo among 50 office workers in Brazil reported that 74% of them experienced MSDs on the back (81%) and upper limbs (70%).[17] Similar result was found in a study conducted by Noorozi among 392 office workers at Ahvaz Jundishapur University of Medical Sciences, Iran, reported the most of body part affected by MSDs were back region (51%), neck (36.7%), wrist (23%),

right shoulder (10.2%) and right elbow (3.8%).[18]

Some visual problems were also reported in this study. Most of the workers experienced eyestrains (78.3%), blurred vision (41.7%), watery eyes (39.2%) and headache (37.5%). It is parallel to a study conducted by Chiemeke regarding the evaluation of CVS among 103 computer users at the University of Benin, Nigeria, reported that participants experienced eyestrain, blurred vision and headache (42.7%, 45.7%, 28.2% respectively).[19] This study also found that visual problems begin to happen after one hour working with computer and increases if the workers spend more hours with a computer without interruption. Respondents that spend less than one hour on the computer daily recorded the lowest visual symptoms complaints.[19] Another study conducted by Shantakumari among 471 students in United Arab Emirate, showed that the most common CVS reported were headache (53%), burning sensation of the eyes (54.8%) and eyestrain (48%).[20] Chiemeke stated that CVS was common among workers who work with the computer more than 8 hours daily.[19]

In this study, male workers were reported to have increased odds of having adequate awareness 2 times than female workers. It is parallel to a study conducted by Saleem et al. that there was a statistically significant difference in terms of gender with the occurrence of MSDs.[13] Moreover, workers with years of employment >5 years have increased odds of having adequate awareness 2.4 times than workers with years of employment for ≤ 5 years. This report was different from a study by Saleem that reported no significant difference in terms of age and work duration. Habibi and Husein suggested ergonomic interventions such as computer workstation redesign, educate the users about ergonomic principles of computer and reduce working with computers to prevent the injuries.[21-22]

Conclusion

Most of the office workers in UMB had adequate awareness of workstation ergonomics. However, the majority still experienced pain especially on the neck, back, waist, and shoulder. It might be because they did not maintain good posture while working with a computer or sitting on chairs that improper to their body size. Hence, maintain a good posture is suggested and ergonomics training is highly recommended to all office workers at UMB. Moreover, the selection of chair for every worker is important and the organization also needs to implement routine ergonomics assessment to reduce the occurrence of CRIs in the future.

Suggestion for Future Research

Some ergonomics research had been done in Indonesia especially among factory workers, but very rare study among office workers. Hence, this study becomes additional literature for ergonomics research in Indonesia. Future research regarding ergonomics can be carried out in other universities or institutions in Indonesia.

Limitation of the Study: The study was conducted only in one university in Jakarta.

Acknowledgment: This research was funded by the Ministry of Research, Technology and Higher Education of Indonesia (Project no.71372111).

Ethical Clearance: Not required

Effect of Cation on Efficiency of Aspegillus flavus Bioflocculant Produced from Chicken Viscera Hydrolysate

Jibrin Ndejiko Mohammed[1, 2], Wan Rosmiza Zana Wan Dagang[2]

1PhD student, Faculty of Natural sciences, Department of Microbiology, Ibrahim Badamasi Babangida University, Lapai, Nigeria, 2 Senior Lecturer, Faculty of Science, Universiti Teknologi Malaysia, Johor Bahru, Malaysia

Abstract

The cations are needed as stimulants for effective flocculation by the negatively charged bioflocculants. In the present study, addition of all dose of both Ca2+ and Mg2+ stimulated the efficiency of the bioflocculant with optimum flocculation efficiency of 95% recorded with 5 mL of 1% Ca2+. While lower dose (1 – 2 mL) of Al3+ also stimulated the bioflocculant to about 94%, Na+ and Fe3+ inhibited flocculation at all doses tested. K+ slightly enhanced the flocculation at 4 - 10mL of 1%. The present cationic bioflocculant can be suggested as a substitute for chemical flocculants

Keywords: *cationization; bioflocculant; Aspergillus flavus; chicken viscera*

Introduction

Generally chemical flocculants are cost-effective and efficient in flocculation but are associated with secondary pollutants accumulation. To address this limitation, ongoing research efforts are focusing on extracellular polymers (bioflocculant) that have flocculation ability. These microbial based polymers can aggregate solid particles and cells from solutions. They are easily degradable to non-toxic residues that are not pollutant in nature 1. However, their application is hinder by high cost of production arising from cost of fermentation substrate and low efficiency (Mohammed and Dagang, 2019a).

Compositional characterization of biopolymer flocculants revealed existence of anionic functional moieties including uronic acids and proteins which contained mostly carboxylic functional groups with negative charges. Majority of the solid particles found in the wastewater are also negatively charged.

Cations play a significant role in stimulation of cation dependent bioflocculant through neutralization and stabilization of the lingering negative charges mainly of the active moieties of the bioflocculant. In this process, the cations lessen the distance between the particles and the biopolymer flocculants through increase in electrostatic attraction between the duo 2. The present study focuses on cationization of bioflocculant produced with chicken viscera hydrolysate to increase the flocculation efficiency of the bioflocculant.

Methodology/Materials

Bioflocculant production

The bioflocculant was produced by growing A. flavus in a liquid viscera hydrolysate. The culture conditions used included temperature 35°C, agitation 150 rpm, incubation time 72 h, inoculum 4% and pH 7 as optimized in our previous studies. Subsequently, the 72h culture broth was dispensed in to 50mL centrifuge tubes and spin at 10,000 rpm with the aid of a centrifuge (KUBOTA 5922) to remove the biomass. The bioflocculant rich culture supernatant was collected into sterile glass beaker and used as the crude bioflocculant in subsequent experiment.

Determination of flocculation efficiency and cationization

The bioflocculant efficiency was estimated in accordance with the methods demonstrated by Kurane

et al. (1994). Briefly, 4mL (optimum dose) crude bioflocculant was dispensed in to 100 mL suspended Kaolin clay (4g/L, pH 7) in 500 mL glass beaker. Different doses (1 – 10mL) of 1% of the cation of interest were added as the bioflocculant aid. The mixture was stirred in a flocculator tester (JLT6, VELP) at 200 rpm for 1 min, 80 rpm for 5 min, and then held motionless for 5 min. The optical density reading of clarified top solution at 550 nm estimated with T60 spectrophotometer was recorded. The efficiency was finally calculated using the following equation

$$\text{Flocculation efficiency} = [(A - B/A) \times 100\%] \quad \text{(Eqn 1)}$$

Where A is the optical density of the control and B the optical density of the sample at 550 nm. The control experiment in which no cation was added was carried out and calculated following the same procedure above.

Measurement of Zeta potential

The zeta potential studies were conducted with the aid of Zeta potential analyser, Zeecom (ZC-3000 series). Samples were prepared for zeta potential measurement by dissolving 5mg of the flocculated particles in10mL deionized water. The samples were loaded into a clean measurement cell and mounted to Zeecom main unit. All measurements were conducted for at least 200 particles using automatic tracking measurement and scattered light source

Results and Findings

Effect of N+ on the bioflocculant Efficiency

The effect of Na+ on the bioflocculant is presented in Figure 1. All the doses tested inhibited flocculation of the Kaolin suspension. The maximum flocculation efficiencies recorded were 54 and 53.4% at the cation dose of 1 and 2 mL 1% NaCl2 respectively as compared to the flocculation efficiency (60.3%) of the control in which no cation was added. Interestingly the inhibition of flocculation increases as the cation dose increases to the lowest flocculation efficiency of 26.5% at the cation dose of 10mL 1% NaCl2. The zeta potential of the flocculated particles at pH 7 also increases to the maximum of -29.3mV as the cation dose increases. The zeta potential value has a direct relationship with stability of suspended particles and is used to predict flocculation. Particles with ZP values of ±(0 –10mV) are extremely unstable, ± (10–20mV) is discreetly stable, ±(20–30mV) is moderately stable and more than 30mV is highly stable 3, 4. Thus, the closer the zeta potential of particles to zero, the higher their tendency to aggregate and vice versa.

The binding ability of the cations to the biopolymers has direct relationship with the ionic size and radius of the hydration shell. Increase in ionic size triggers decrease in the hydration shell radius. Therefore, cations that has high valency, size, and tinny hydration shell could move nearer to the negative charges of the biopolymers to form bonds 5. Though potassium and sodium possess same charge, the hydration radius of potassium (0.53 nm) is smaller than that of sodium (0.79 nm) 6. As such potassium can easily loses its hydration shell when it is in proximity with the functional groups of the bioflocculant while the water molecules around the sodium prevents it approach to the surface7.

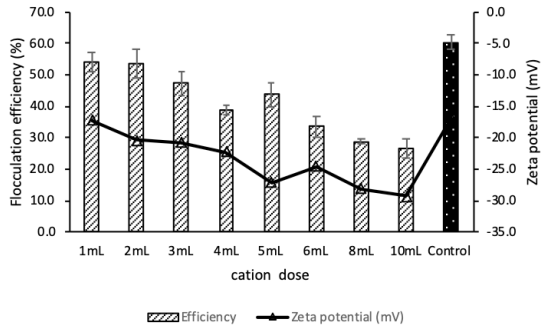

Figure 1: Effect of Na+ on bioflocculation efficiency of A. flavus bioflocculant produced from chicken viscera hydrolysate

Effect of K+ on the bioflocculant efficiency

The effect of K+ is as display in Figure 2. The maximum flocculation of about 77.6 % was achieved at the cation dose of 4 mL. As the cation dose increases beyond 5 mL, the efficiency dropped to minimum of 69.2% at 10mL. The minimum zeta potential recorded was -5.6mV at 4mL cation dose while the highest of 23.2 was recorded at 2 mL cation dose. K+, a monovalent cation has a lone valency on its exterior electron arrangement and thus can only form a single bond with the bioflocculant (Mohammed and Dagang, 2019b).

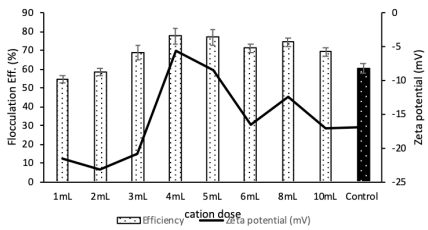

Figure 2: Effect of K+ on bioflocculation efficiency of A. flavus bioflocculant produced from chicken viscera hydrolysate

Effect of Ca2+ and Mg2+ on the bioflocculant

The stimulation activity of the Ca2+ on the bioflocculant is as shown on Figure 3. All the doses tested showed remarkable stimulation on the bioflocculant to maximum of 95% at 5mL. Meanwhile, the efficiency dropped to minimum of 76.2% at 10mL cation dose. Lowest efficiency of 84.9% was also recorded at the lowest dose of 1mL. Like the Ca2+, Mg2+ highly stimulated the bioflocculant at all doses tested (Figure 4) however maximum efficiency of about 91 – 93% was recorded with 3 – 5 mL MgCl2. The lowest efficiency of 75.9% was recorded at 10 mL of 1% MgCl2.

The divalent cations have valency of 2+ on its outer layers and can form two bonds between bioflocculant and suspended Kaolin particles. These bonds held the bioflocculant and the particles nearer and firmer together (8). Ca2+ has less stability. Its electron conformation and atomic radius is 4s2 and 197 pm respectively in comparison with Mg2+ with only an electron conformation and radius of 3s2 and 160 pm. Thus binding between Ca2+ and the carboxylate group in the biopolymer is easier (8).

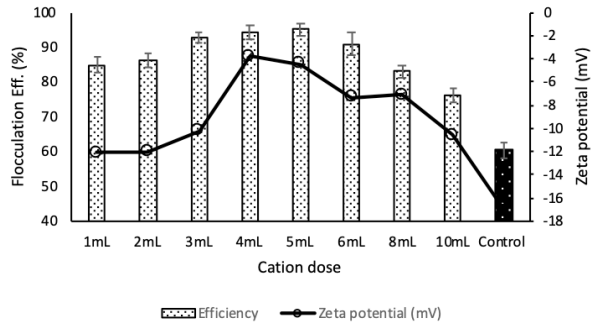

Figure 3: Effect of Ca2+ on bioflocculation efficiency of A. flavus bioflocculant produced from chicken viscera hydrolysate

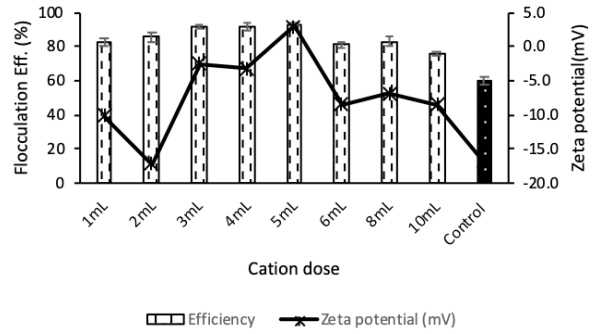

Figure 4: Effect of Mg2+ on bioflocculation efficiency of A. flavus bioflocculant produced from chicken viscera hydrolysate

Effect of Fe3+ on the bioflocculant

The Fe3+ has high inhibition effect on the bioflocculant at all the doses (Figure 5). The highest efficiency recorded was 45.5% at 2 mL of 1% FeCl3. The inhibition of the bioflocculation became more pronounced as the cation dose increases with only about 33% efficiency at 10 mL of 1% FeCl3. This inhibition is consolidated by the high zeta potential (-21 - -29.88 mV) recorded for all the cation doses. This results agrees with the work of Zheng, Ye (9) who demonstrated the inhibitory effect of Fe3+ on the ability of Bacillus sp. F19 bioflocculant to flocculate Kaolin, activated carbon and fly coal.

The inhibitory effect of Fe3+ is because addition of trivalent ion does not only add to the cationic concentration of the bioflocculant, but likewise increase the cationic thickness over the surface of the particles with its extra electron.

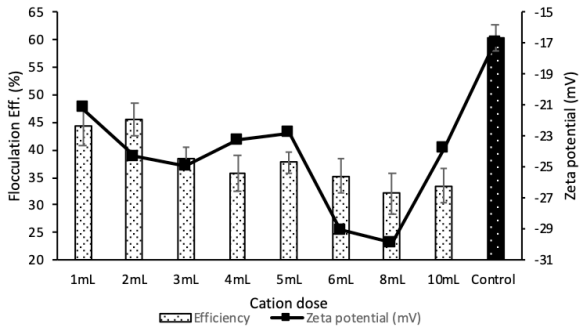

Figure 5: Effect of Fe3+ on bioflocculation efficiency of A. flavus bioflocculant produced from chicken viscera hydrolysate

Effect of Al3+ on the bioflocculant

The stimulatory effect of Al3+ on the bioflocculant is shown in Figure 6. Interestingly, significant stimulatory effect was recorded at lower doses of 1 – 3mL with highest efficiency of 94.6% at 1mL. No significant effect was observed as the cation dose increases to 4 – 10mL. This result indicated that the wide reported inhibition by the Al3+ is due to use of higher dose. Al3+ has been reported to stimulate the flocculation activity of pH and cation dependent bioflocculant produced by a Consortium of Halomonas sp. Okoh and Micrococcus sp. Leo (10)

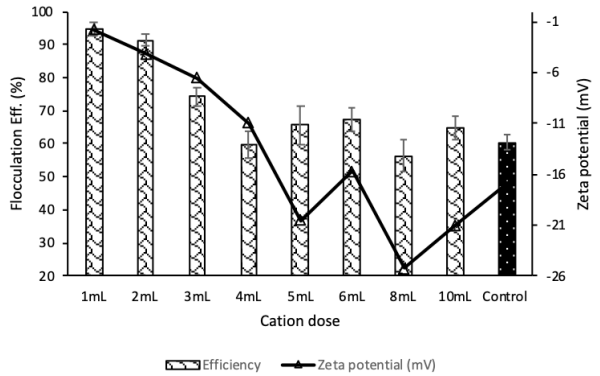

Figure 6: Effect of Al3+ on bioflocculation efficiency of A. flavus bioflocculant produced from chicken viscera hydrolysate

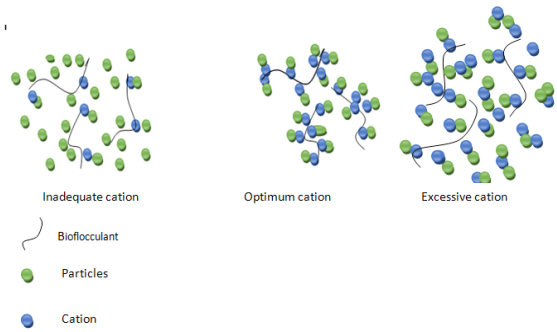

Figure 7: Schematic effect of cation dosage on bioflocculant stimulation

Mechanism of bioflocculant stimulation by the metal ions

Cation stimulated bioflocculation occurs through neutralization and stabilization of lingering negative charges found on the active sites of the bioflocculants thereby bridging between the particles and the bioflocculant. this subsequently improves the flocculation capacity of the bioflocculant (11). In the present study, the zeta potentials were generally low at higher flocculation efficiencies recorded with multivalent cations such as Ca2+, Mg2+ and Al3+ while higher zeta potential values were recorded at low flocculation efficiencies with cations such as Na+, Fe3+ and higher doses of Al3+. For example, when flocculation efficiency of 95% was achieved with 5mL 1% CaCl2, the zeta potential of only -4.5mV was recorded. When the flocculation efficiency (32.1%) was inhibited at 8mL 1% FeCl3, the zeta potential rises to -29.88mV. The lower zeta potentials recorded were due to the ability of the cations to neutralize and bridge between the bioflocculants and the particles while lack of neutralization and bridging resulted in low flocculation efficiencies and higher zeta potential values.

Conclusions

The present study achieved a bioflocculant production from a bioflocculant producing fungus; A. flavus using hydrolysed chicken viscera as medium. The flocculant secreted has good flocculating efficiency promoted by hybridization with divalent cations (Ca2+, Mg2+) and a trivalent cation Al3+ in Kaolin suspension. While K+ only slightly promoted the flocculation efficiency flocculation was inhibited by Na+ and Fe3+. The stimulatory effects of Ca2+, Mg2+ were visible at 1 – 10mL of 1% of both cations while Al3+ was at 1- 3mL of 1%. The zeta potentials of the flocculated particles were in most cases correspondent to the flocculation efficiencies. Overall, bridging mediated by the cations is suggested as the mechanism of bioflocculation for the present bioflocculant.

A Study on Anxiety among English Language Learners in School of Hospitality and Tourism, KYPJ

Syazwani Zakaria[1], Abdul Rahim Salam[2], Wan Zarina Wan Zakaria[3]

[1]Lecturer of English Department, Kolej Yayasan Pelajaran Johor, 81900 Kota Tinggi, Johor, [2]Assoc. Prof. of Language Academy, Faculty of Social Sciences and Humanities, Universiti Teknologi Malaysia, 81310 UTM Johor Baharu, Johor, [3]Senior Lecturer of Language Academy, Faculty of Social Sciences and Humanities, Universiti Teknologi Malaysia, 81310 UTM Johor Baharu, Johor

Abstract

The purpose of this study is to investigate the problem of language anxiety among English Language learners in the School of Hospitality and Tourism, Kolej Yayasan Pelajaran Johor. This study is conducted to investigate the level of anxiety as perceived by the Hospitality students majoring in Hotel Management and Culinary Arts. This study also aims to investigate the possible factors that contribute to the feeling of anxiety in ESL classroom among Hospitality students in terms of Communication Apprehension, Fear of Negative Evaluation and Test-taking Anxiety. Then, the study tried to find out THE students' attitudes and values toward learning English as a Second Language and, to find out ways to overcome speaking anxiety as perceived by the students. A total of 90 samples from hospitality courses' students of KYPJ were chosen as respondents for this study. The instrument used in this study was a set of questionnaires adapted from Foreign Language Class Anxiety Scale (FLCAS) designed by Horwitz, (1983) and a pilot study of interview for supporting the validity and reliability of the questionnaire given. The findings show the most influential factor for anxiety is the Communication Apprehension. The respondents also suggested that both learners and teachers play significant roles in overcoming language anxiety

Keywords: *Language Anxiety; Learners; Tertiary Level; Communication Apprehension; Test-Taking Anxiety; Fear of Negative Evaluation*

Introduction

The Malaysian English language learners, or second language acquisition (L2) learners are very familiar with English speaking anxiety due to the imbalance reaction in terms of fear, worry, and nervousness towards the L2 learning.1 Horwitz, Horwitz and Cope2 asserted that language anxiety (LA) could relate to "a distinct complex phenomenon of self-perception, beliefs, feelings and behaviors related to classroom language learning arising from the uniqueness of language learning process". This assertion means that the issue of LA is about how the language is exposed to Malaysian learners and how the teachers identify this problem among the students.

Corresponding Author:
Syazwani Zakaria
English Department, Kolej Yayasan Pelajaran Johor,
81900 Kota Tinggi, Johor
Email: syazwani_zakaria88@yahoo.com

Some researchers also discussed speaking anxiety when they reveal the learners' experience. Zhang and Zhong3 stated that the significant reason for anxiety is the learners had a negative perception of English language and think that they lack ability to learn a new language. This means some Malaysian learners could face the similar issue of speaking anxiety as Mansor et al4 stated. It is because the learners did not receive an authentic input during the lesson. Then, speaking anxiety can cause reduced performance in the language classroom because the learners are afraid of making mistakes due to received negative comments and feel scared to try new things, especially speaking.

The experience of language anxiety is also related to the grading system. When Malaysian students become anxious about their grades, it could lead to nervousness. Daley et al5 stated that the feeling of anxiety comes from trying to score a good grade. However, the reality of doing evaluation will continuously occur in daily life.

There are expectations from the industrial workplace or employers as they look forward to job scopes in the future. The employees are expected to handle the professional matters in English. These situations might cause emotional intensity among students. Therefore, Malaysian learners should learn how to acquire the L2 properly in the class.

Statement of the Problem

Currently, the English Language has become a significant influence on people's achievement especially when the learners enter the tertiary level. They are unable to use the language efficiently due to lack of exposure. LA can affect their performance because the learners are afraid to make mistakes and demotivated when receiving negative comments. This problem statement is supported by MacIntyre[6] when the learners reported that despite compulsive efforts in acquiring the new language, anxiety override their competence in communication.

LA could also be caused by the grading system as students become so anxious about their grades. In KYPJ, it is a requirement that English is one of the compulsory subjects that students need to master in order to graduate. Moreover, there are also professional expectations from the industries as they need Hospitality students who can handle the front desk efficiently. Hence, these situations may cause LA in their workplace.

Objectives

The following are the objectives of this study:

(i.) To investigate the level of anxiety as perceived by the Hospitality students majoring in Hotel Management and Culinary Arts.

(ii.) To investigate the factors that contribute to the feeling of anxiety in ESL classroom among Hospitality students in terms of Communication Apprehension, Test-taking Anxiety and Fear of Negative Evaluation.

(iii.) To find out the students' attitudes and values toward learning English as a Second Language.

(iv.) To find out the ways to overcome speaking anxiety as perceived by the students.

Literature Review

In order to improvise the research, the researcher synthesize views from other studies. Some of them were very clear in their findings, but some were not. Hence, further research should be conducted to gain more insight. One of the studies on Anxiety and Speaking English as a second language by Woodrow[7], is "why LA effect on the oral performance of speakers in L2". Recently, most articles talk about the relationship between the LA and the motivation or integrated language skills, especially on oral speaking. Speaking skills means talk spontaneously in front of the people. So, that is why some researchers came out with one of the research questions given; (i) Is a dual conceptualization of second LA according to in-class and out-of-class communication supported?[7] Consequently, the research includes the elements of the outsider influence for LA such as real context interaction among the learners.

However, the researcher agreed that the learners should communicate in L2 outside the classroom in order to see the real context. This point could help the students to visualize the communication process. The teachers should aid learners by minimizing the LA in classroom learning. Most students feel anxious once they met the native speaker outside the classroom. The teachers should assist them to minimize the anxiety. Critically, previous research suggests the alternative ways for handling the LA such as starting the conversation in L2 by using the relaxation techniques and positive talk.[8,9] This will help the students in dealing with the anxiety. In brief, the teachers should work together with the students but the learners themselves should know how to deal with L2 LA.

Methodology

The study focuses on the LA on the L2 among the hospitality students in Kolej Yayasan Pelajaran Johor (KYPJ). The researcher aims to measure the level of LA among the students. Both Hospitality courses which are the Hotel Management and Culinary Arts students will be the respondents of the study, and the researcher aims to investigate if the L2 learning will influence their career hunting once they have graduated.

Research Procedures

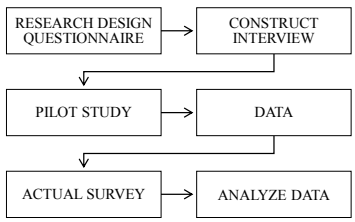

Figure 1. Research Procedures

Data Analysis

The data for this research is collected from the Hospitality students (Diploma in Hotel Management and Diploma in Culinary Arts). The questionnaires contain three (3) sections. Section A include the respondents' details such as race, gender and age together with the period of learning experience and English achievements. The result of the data in the first section leads to the significant differences between three (3) sections. Section B contains the questions for the contributing anxiety's factors, and Section C shows the values of L2 learning among Hospitality students. It has been analyzed with a descriptive statistic. The analysis to measure the means and percentage, and the weighted mean is used to describe the whole general anxiety factors among Hospitality students. Lastly, the standard deviation (SD) is to ensure the variability of the responses. Moreover, the levels of anxiety among the respondents were divided into two (2) groups, which are High Anxiety and Low Anxiety. The High anxiety is determined from 1.00 to 2.50, and Low Anxiety is determined from 2.51 to 4.00. The table below shows the level of anxiety and the range of mean:

Table 1. The Mean Value for Anxiety Level

No.	Level of Anxiety	Mean Value (Range)
1	High	From 1.00 – 2.50
2	Low	From 2.51 – 4.00

Results and Findings

The first part of this chapter presents the respondents' demography such as gender, race, age, English result for the Sijil Pelajaran Malaysia (SPM) and English result for their previous semester. Then, different factors that contribute to the feeling of anxiety among English language learners in School of Hospitality and Tourism, KYPJ are analyzed and discussed. Three factors analyzed are communication apprehension, test anxiety, fear of negative evaluation. By the end of this analysis, comprehensive view on factors of anxiety that contribute to the feeling of anxiety in L2 learning and level of anxiety is examined.

Level Analysis for Each Anxiety Factor

Table 3 describes the analysis of the level for each contributing factors of anxiety, which are Communication Apprehension, Test Anxiety and Fear of Negative Evaluation. The overall level of anxiety also will be presented in Table 2 below. With an overall view, all items showed a high level of anxiety among the respondents. Firstly, the first factor of anxiety is Communication Approach, which is the mean is 2.25, and the percentage of high anxiety is 65.1 per cent. Secondly, the next factor of anxiety is Test Anxiety also represents a high level of anxiety with the mean value of 2.26, and the percentage of high anxiety is 63.4 per cent. Thirdly, the other factor of anxiety will be Fear of Negative Evaluation, which the mean is 2.34 and shown as a high level of anxiety with the percentage of 60.3 per cent. Thus, the table clearly shown the most influenced factor for anxiety is the Communication Apprehension when this factor contributed the highest mean and percentage on the questionnaire.

Table 2. Analysis of the Level of Anxiety

Anxiety Factors	Total Mean Value
Communication Apprehension	2.25
Test Anxiety	2.26
Fear of Negative Evaluation	2.34

Table 3. Analysis of the Level of Anxiety (High and Low Anxiety)

Anxiety Factors	Communication Apprehension		Test Anxiety		Fear of Negative Evaluation	
	High	**Low**	**High**	**Low**	**High**	**Low**
Frequency	644	346	628	362	597	393
%	65.1	34.9	63.4	36.6	60.3	39.7

Interview

The researcher conducted a pilot study to ensure valid questions. The duration of the interview is less than 10 minutes and a recorder was used. The researcher only interviewed two respondents on the questions below:

Table 4. Feedback of Interviews

Interview Questions	Respondents	Feedbacks
1) What are the possible factors which caused you to feel anxious in your English classroom?	Student 1	• "Sometimes I feel my confident level is not there because when I looked at my friends more *kebolehan* rather than me."
	Student 2	•"I afraid to speak wrongly in my English classroom, so that will be make me feel anxious."
2) What have you done to overcome your language anxiety?	Student 1	• "…everyone should have their confident level when speak in front of others."
	Student 2	• "I think I can improve my problem by watching movies and sometimes, singing English song."
3) How efficient are your techniques in overcome of the language anxiety?	Student 1	• "I would like to listen to English song. They would make me feel like I want to know the vocabulary of the meaning."
	Student 2	• "Let say by watching movie, I watched the movie not only for one time. I will watch the movie many times, so with that I will remember the words."

Discussion

This chapter summarizes the three factors of anxiety, namely Communication Apprehension, Fear of Negative Evaluation, and Test Anxiety.

Research Question 1:

What is the anxiety level among the learners as perceived by Hospitality Students specializing in Hotel Management and Culinary Arts?

This section focuses on the anxiety level among English Language Learners in School of Hospitality and Tourism from Kolej Yayasan Pelajaran Johor. Overall the feeling of anxiety indicates Communication Approach, which the mean is 2.25, and the percentage of high anxiety is 65.1 per cent. Secondly, the next anxiety will be test anxiety, which the mean is 2.26 and shown as a high level of anxiety with the percentage of 63.4 per cent.

Thirdly, the other factor of anxiety is Fear of Negative Evaluation also represents a high level of anxiety with the mean value of 2.34, and the percentage of high anxiety is 60.3 per cent. Thus, it was clearly shown that the most influenced and highest contributing factor for anxiety will be the Communication Apprehension when this factor contributed the highest mean and percentage on the questionnaire.

Research Question 2:

What are the possible factors contributing to the feeling of anxiety in ESL classroom among Hospitality students in terms of Communication Apprehension, Fear of Negative Evaluation and Test-taking Anxiety?

The highest of anxiety level will be Communication apprehension, and it is characterized by an unwillingness to talk or shyness in communicating. As a result, the learners may feel anxious due to the lack of opportunities to speak English. Another study which is done by Aydin10 also show the same results. Then, other issue of anxiety is the role of the classmates in English class. In this case, most students feel less anxious when they have their supportive friends, but the motivation of students will be decreased due to peer evaluation in classroom learning such as stated by Lightbrown and Spada11 and Krashen12. They suggested that motivation is closely related to the anxiety level among learners.

Research Question 3:

What are the attitudes and values of students toward learning English as a Second Language?

Most of the students scored the mean between 2.51 to 4.00, which means the students were portrayed as low anxiety. In this section, the researcher focuses on the values of hospitality students to clarify the importance of English Language for the students' future workplace. Most of them are clear about the objective of the courses when only a few shown as high anxiety on the values part as mentioned by Krashen12 who said, when the learners are highly motivated in learning a language, their level of anxiety is low.

Research Question 4:

What are the ways to overcome speaking anxiety as perceived by the students?

The students were interviewed, and the responses indicate that most students know the importance of English and the need to overcome the anxiety. The students mentioned about memorizing words. This technique will help the students to reduce the anxiety. Krashen13 stated, the increase of confidence level indicates a lowering of language anxiety levels. This way was successful in lowering language anxiety levels among students, and the effort to communicate with peers and create meaningful interaction also could overcome all the LA matters.

Conclusion

In conclusion, the study discussed the use of L2 in language learning in Malaysia and how the speaking anxiety appeared in relation of teaching approach. The English subject becomes important gradually, and the education system in Malaysia has evolved rapidly and speaking skills should be taught from the beginning. The foundation of the learners must be excellent to ensure a sound output in the future.9,14 The suggested ways for handling the language anxiety such as starting the L2 learning by using the relaxation techniques and positive talk.

It has been explained how the relation of teaching approach could affect the learner's achievement. The students cannot forget the anxiety when speaking, but they can reduce the uncomfortable feeling. The assistance from the teachers by giving the motivation also could release the tense. In summary, every institution, teachers and learners should work together to solve the problem.

[2,3] Professor, Dep. of Sport Education, Program Pascasarjana Universitas Negeri Jakarta, Jakarta, Indonesia

Abstract

This study aims to determine the effect of training methods and functional movement on strokes technical skills on the backhand smash in the table tennis game. This research was conducted at table tennis athletes in the city of Makassar. The method used is an experiment using a 2x3 factorial design. The sample consisted of 60 athletes, divided into 6 groups, each consisting of 10 athletes. The data analysis technique used is the analysis of two-way variance (ANOVA) and continued with the t-Dunnet test at the level of significance α = 0.05. The results showed that: the distributed practice method has a higher effect than the massed practice method on backhand smash skills, the massed practice method is more effect than the mixed practice method for smash backhand skills, methods distributed practice has more effect than the mixed practice method on smash backhand skills, there is interaction between the massed practice method, distributed practice method, mixed practice method, and functional movement on backhand smash skills, massed practice method is higher than mixed method practice on smash backhand skills in high functional movement groups, distributed practice methods are higher than mixed practice methods of smash backhand skills in high functional movement groups, distributed practice methods are higher than massed practice methods of smash backhand skills in low functional movement groups, Mixed practice methods are higher than the massed practice method of low functional movement smash backhand skills. Multimedia technology comes using Kinovea, as a software that has been created specifically for sports professionals and their coaches.

Keyword: *Exercise Method, Functional movement, Smash Backhand, Kinovea*

Introduction

Obviously, to improve achievement is not an easy thing because it needs a variety of ways and efforts. As in Hartono's (2009: 205-206), he found that the discovery of various problems and challenges faced in the development of today's sports in general can be grouped into the main thing in relation to the field of sports physical education.

Lack of support for the standards of facilities and infrastructure as well as routine scheduled calendar events makes opportunity to accumulate playing experience is also lack. As a result, it has an impact on the development of very slow performance. Alam at al.[1] suggest that increasing sports performance is influenced by several factors; supporting factors such as consistent coaches, good quality athletes, private assistance, and sports events.

Table tennis game is one of the sport's branches having certain basic techniques including; techniques of push, drive, block, smash, and service. That basic technique must be mastered by an athlete or player to be able to play games with advanced or high skill levels in accordance with the characteristics of the table tennis game. As known that table tennis technique consists of various punches; service punch techniques, defensive punch techniques, and attacking techniques. Defensive

punch group techniques include push and block punches while attacking techniques include drive punches, smash blows, and spin punches.

In the game of table tennis, it is also known various types of games namely the type of defensive game (defensive), type of attack (offensive), and the type of combination (mixed). More types of defensive players use or utilize the ball spin from top to bottom (back spin), the type of attack player uses more or utilizes the round of the ball from the bottom up (top spin) resulting in the emergence of the term modern table tennis game that adheres to the type of attacking game. Saputra[2] states that to achieve achievements in table tennis, the level of accuracy of the punch plays influential role. Then, the level of punch accuracy can be obtained from consistent and programmed training[2].

Literature Review

Sumarno[3] says that, table tennis is a sports bet that is played by two people (for singles) and played by four people (for a double), sometimes people call it ping-pong. Table tennis has evolved from recreational sports to achievement sports, this sport is now widely favored by students and in society.

Table tennis is one sport where players must have basic strokes techniques which include; techniques of push, drive, block, smash, and service. That basic strokes technique must be mastered by an athlete or player to be able to play games with advanced or high skill levels in accordance with the characteristics of the table tennis game. The table tennis technique consists of various strokes, such as; serve strokes, defensive strokes, and attack shots. Defensive stroke technique groups include push strokes and block strokes, while attack stroke techniques include drive strokes, smash strokes, and spin strokes.

When athletes play or compete in table tennis rarely use a backhand smash, it is because the athlete prefers to return the ball using a forehand smash by shifting and reversing the body rather than directly hitting a backhand smash.

There are several general factors that must be considered in improving table tennis performance. Hadjarati[4] said that these factors were the development of young athletes, training methods, good facilities and infrastructure, good funding, professional trainers, good bureaucracy in the table tennis federation, and community support. In addition, in the study of Faridah[5] said that there are several special factors that must be considered, namely; physical and mental condition.

To improve the performance of table tennis, there is a need for treatment, especially on strokes technique skills, especially on improving the smash strokes technique skills needed in modern table tennis, especially the backhand smash technique that athletes rarely use when competing. In addition, people also tend to be more interested in researching forehand smash than backhand smash, as stated by Takeji and Yoichi[6] who say that: from some biomechanical research that has been done, generally only researching table tennis forehand strokes. However, it paid little attention to the biomechanics of backhand blows.

Hodges[7] says that smash blows are hitting the ball at maximum speed so that the opponent cannot return it. while Backhand is a type of strokes that is done by using a bet to the left of the elbow for the player using the right hand, and the opposite for the player who uses the left hand[2].

Cook[8] said that functional movement is a condition when the organs of a human body perform a pattern of movement, are in a functional position that is good or performs its functions well, because it is supported by good mobility and stability.

The strategy of passive and active play has the opposite effect on match activities and physiological responses. The effect is more on stroking activities and activity profiles than on walking activities and physiological responses can be seen through kinovea[9].

Burdick in Murray & Udermann[10] defines massed practice as practice that occurs without resting between experiments. Hale and McMorris[11] define the distributed practice method when work is interspersed with rest periods[11]. Whereas mixed practice is a training method that combines the method of solid or continuous practice and the method of interval training or distributed practice, where the rest time is filled by doing a free strokes to stretch the body so that the muscles, especially in the area arms, stomach and legs relax again.

This problem makes the writer feel it is important to do more in-depth research on how to improve the smash backhand technique skills in table tennis games that involve their functional factors, by applying three training methods, namely; massed practice methods,

distributed practice methods, and mixed practice methods. This experimental study aims to determine the effect of training methods and functional movements on the skill of smash backhand techniques in table tennis.

Methodology/Materials

As what was explained earlier that this research is an experimental research, Sudjana[12], said that the design of this study was 2x3 factorial. The design of this study can be seen in the following table:

Table: 1

Exercise Model (A) / Functional movement (B)	*Massed Practice* (A1)		*Distributed Practice* (A2)		*Mixed Practice* (A3)
1. High Functional movement (B1)	A1B1	>	A2B1	>	A3B1
2. Low Functional movement (B2)	A1B2	<	A2B2	<	A3B2

Regarding the population and sample, table tennis clubs that actively train table tennis athletes in the city of Makassar amount to 4 and the population to be taken for treatment in this study ranges from 40 athletes per club, so that the overall population is around 160 athletes, so samples that could be taken by randomization (group design) were 110 people.

Determination of the sample came from 160 athletes with a significant level of 5%, then obtained 110 athletes as stated by Sugiyono[13]. Of the 110 athletes or samples tested for functional movement, then 27% were taken, resulting in 29.7 and rounded up to 30 samples for high and low functional movements. to determine the height and low of functional movement based on determining ranking. Athletes in the order of 1-30 are referred to as samples with high functional movement while athletes in the order of 80-110 are referred to as samples with low functional movement.

Figure 1. Analysis of Smash Backhand Motion with Kinovea

Based on the target of functional movement, 30 athletes who have high functional movement and 30 athletes have low functional movement. then in a random manner, the researcher determined the athletes who entered the group who received treatment for the massed practice method, distributed practice methods, and mixed practice methods, to be subsequently formed into 6 training groups, each of which numbered 10 people as stated by Edwards14.

This research was conducted at the Table Tennis Sports Building in the sports science faculty of Makassar State University for approximately seven weeks. The implementation of this study consisted of three activities, namely: the initial test in the form of a functional movement test to group samples consisting of 5 test items, namely: deep squat test, hurdle test step, test in-line lunge, straight leg raise active test, test seated rotation.

Then the sample or testee is given treatment for 18 meetings or about 6 weeks, with a frequency of 3 meetings a week. The type of treatment given to testee in the form of smash backhand training by applying the 3 training methods, namely: the method of massed practice, distributed practice methods, and mixed practice methods.

After 18 treatments were given, the final test was a test of backhand smash strokes skills for all sample members. Data on smash backhand technique skills is a combination of the scores from the results of the backhand smash skill test and the process score of the smash backhand movement pattern based on the instrument grid consisting of several indicators. before being summed, the two data are first equated with the t-score formula which will then become the data (score) of the backhand smash strokes skill.

In this study the research is experimental research, the data is analyzed as stated by Hasan15, namely: by using a variance analysis technique (ANAVA) two ways with a significance level of $\alpha = 0.05$.

Results and Findings

A summary of the research data for each treatment can be seen in the following table:

Table 2: Table of Research Results Data Summary

Functional movement	subject	Exercise Mode		
		Massed	*Distributed*	*Mixed*
High	N =	10	10	10
	μ =	114,54	111,81	85,74
	sd =	11,18	10,90	13,40
	ΣX =	1145,41	1118,06	857,39
	ΣX^2 =	132320,4	126075,1	75128,7
Low	N =	10	10	10
	μ =	84,10	97,22	99,41
	sd =	13,64	14,33	13,76
	ΣX =	841,02	972,23	994,07
	ΣX^2 =	72405,5	96370,4	100521,8
Total	N =	20	20	20
	μ =	99,32	104,51	92,57
	sd =	19,78	14,47	14,97
	ΣX =	1986,43	2090,29	1851,46
	ΣX^2 =	204725,95	222445,50	175650,46

As for the summary analysis of variance can be seen in the table below:

Table 3: Table of Calculation Results Summary Anava 2x3

Source Variant	JK	db	RJK	$F_h = F_0$	F_{table} α=0,05	T_{table} α=0,05
1. Between A	1434,06	2	717,03	4,29	3,17	1,67
2. Between B	1638,46	1	1638,46	9,79	4,02	1,67
3. Interaction AB	4991,60	2	2495,80	14,92	3,17	1,67
4. In	9035,83	54	167,33			
Total (R)	17099,94	59				

The hypothesis that has been tested using the Dunnet t-test can be seen in the table as follows:

Table 4: Table of Hypothesis Advanced Test Results in each Anava Category 3x2 Summary

Contrast Value	(Se)	t_0	t_{table}	Result
1. $\bar{Y}_1 - \bar{Y}_2 = -103,86$	6,47	-25,39	1,67	Significant
2. $\bar{Y}_1 - \bar{Y}_3 = 134,97$	6,47	33,00	1,67	Significant
3. $\bar{Y}_2 - \bar{Y}_3 = 238,83$	6,47	58,39	1,67	Significant
4. $\bar{Y}_{11} - \bar{Y}_{21} = 2,73$	6,47	0,47	1,67	Not-Significant
5. $\bar{Y}_{11} - \bar{Y}_{31} = 28.80$	6,47	4,98	1,67	Significant
6. $\bar{Y}_{21} - \bar{Y}_{31} = 26,07$	6,47	4,51	1,67	Significant
7. $\bar{Y}_{12} - \bar{Y}_{22} = -13,12$	6,47	-2,27	1,67	Significant
8. $\bar{Y}_{12} - \bar{Y}_{32} = -15,31$	6,47	-2,65	1,67	Significant
9. $\bar{Y}_{22} - \bar{Y}_{32} = -2,18$	6,47	-0,38	1,67	Not-Significant

After analyzing the data with a two-way analysis of variance (Anava) approach, then proceed with the Dunnet t-test, the discussion of the research results is as follows:

Based on the results of the hypothesis advanced test calculations, if t is calculated compared to t table (0.05; 54), then obtained t 0> t table, thus H0 is rejected. So that it can be interpreted: there are significant differences in the results of backhand smash strokes skills in table tennis games significantly between groups A1 and A2, groups A1 with A3, groups A2 with A3, groups A1B1 with A3B1, group A2B1 with groups A3B1, groups A1B2 with A2B2, A1B2 group with A3B2.

Based on the results of the calculation of Fcount (AB) compared with Ftable (0.05), then obtained 14.92 > 3.17 so that H0 is rejected. So that it can be interpreted that there are differences in the results of backhand smash strokes skills in table tennis games significantly between groups of training methods and functional movement groups. The results of research data analysis for group A1 obtained an average score: 99.32, group A2 obtained an average score: 104.51, and group A3 obtained an average score: 92.57, while for group B1 obtained an average score average: 104.03 and group B2 obtained an average score: 93.58. So that it can be concluded, that: there is an interaction between those who are trained using a method with those who have functional movements, against the technical skills of backhand smash.

Overall there are differences in the average backhand smash skills between athletes who are trained in the massed practice method, distributed practice methods, and mixed practice methods. The results of these studies are in accordance with research16. The results of backhand smash strokes skills trained using the distributed practice method have a better effect than those trained by using the massed practice method. Likewise those who are trained using the distributed practice method have a better effect than those who are trained using the mixed practice method. The results of this study are in line with the results of research conducted by Leo17. In addition, there are interactions between those who are trained using these three methods and those who have functional moves towards the backhand smash technique skills.

Conclusion

Based on the analysis of research data, the conclusions of this study are, massed practice methods, distributed practice methods, and mixed practice methods and functional movement are variables that can effect the smash backhand technique skills in table tennis. For athletes who have high functional movement then trained using the massed practice method and distributed practice method, it turns out to have a better effect or there are significant differences in the results of their smash backhand strokes skills than those trained by using the mixed practice method. On the other hand, athletes who have low functional movement are then trained using mixed practice methods and distributed practice methods, which have a better effect or there are significant differences in the results of their smash backhand strokes skills than those trained using the massed practice method.

Based on the conclusions stated earlier, several suggestions can be made in this study, namely: in an effort to improve smash strokes skills and technical skills, especially in the backhand smash technique of table tennis athletes in the city of Makassar, physical

education teachers in high school are expected , coaches of table tennis clubs, and table tennis lecturers, to apply these three training methods according to the functional mobility of the athletes they train so that mastery of techniques can be more effective and efficient..

These three training methods can be introduced and applied as early as possible by the trainer to beginner athletes or at the level of cadets at the beginning of the training gradually, so that athletes can adapt if later given a similar training method based on an exercise program to improve their strokes technique skills. This research basically focuses on the effect of training methods and functional movements on improving smash backhand technical skills in table tennis. Thus, it is expected that the next researcher will expand or add to the research variable for the sake of increasing achievement in the table tennis sport in the city of Makassar.

Acknowledgement: The author would like to thank for the support of the family and would like to express his deepest gratitude and appreciation to the Chancellor of the Jakarta State University Prof. Dr. Intan Ahmad, Ph.d., and Director of the Postgraduate Program at Jakarta State University Prof. Dr. Ilza Mayuni, MA., Along with her staff both lecturers and administrative staff for providing teaching and services and have sought to improve the quality of education in the Physical Education Study Program.

Preschool Children's Emotional Intelligence: Using Module in Malaysian Context

Nor Aizal Akmal Binti Rohaizad[1], Jumadil Saputra[1], Azlina Binti Mohd Kosnin[2], Aqeel Khan[2], Norwaliza Binti Abdul Wahab[3]

[1] Lecturer, Faculty of Business, Economic and Social Development, University of Malaysia Terengganu (UMT), [2]Lecturer, Faculty of Education, Universiti Teknologi Malaysia (UTM), [3] Lecturer, Faculty of Human Development, Universiti Pendidikan Sultan Idris, Malaysia (UPSI)

Abstract

A preliminary study conducted by the researchers found that preschool teachers in Malaysia are having problems teaching the socio-emotional components due to the lack of specific teaching tools, guidance and structure. In this study, a teaching module was developed to help preschool teachers in pedagogy of emotional intelligence (EI) to enhance the preschool children's EI in Malaysia. This module was developed based on Gagne Information Processing Theory, Bandura's Social Learning Theory and The Zone of Proximal Development (ZPD) Theory by Vygotsky. The module includes ten topics which cover all elements of EI: indentifying emotion, understanding emotion, controlling emotion and using emotion. Activities were designed for each of these elements and in-service teachers were the ones who taught the children using the module. The effectiveness of this module was examined through an interview among the preschools teachers (experimental group) who using the module. Results show both preschools teacher in experimental group satisfy with the effectiveness's teaching and learning module to enhance preschool children's emotional intelligence. It is significant increase of children's emotional intelligence in the experimental group. These findings suggest that the module can be a useful tool for preschool teachers to help develop preschool children's emotional intelligence.

Keywords: *Socio emotional development, emotional intelligence (EI), module, preschool.*

Introduction

Many studies have found significant relationships between Emotional Intelligence (EI) and future success in education [5]. Children who are able to apply EI would have better academic achievements [9,10,12,13]. According to Denham, children who have higher EI are more apt to follow teacher instruction, pay attention, listen and solve problems with patience. Positive emotional skills instilled in children can allow them to develop EI and can shape behaviors which can assist children in learning and eventually to achieve better academic results [21]. Children with greater EI are better able to cope and control unexpected circumstance such as frustration, anger, sadness and so on [2,3,18, 23-25].

EI is important in a wide variety of contexts in any person's life as Jain [11], Gallagher and Vella-Brodrick [7] have noted that individuals who are successful in life (i.e. in carrier) use only 20 percent of intellectual intelligence compared to 80 percent of EI. Goleman [8] has also noted similar findings. In addition, individuals who have a higher level of emotional control are better able to lead good relationships with others through their social skills such as communication, building consensus and efficiency in influencing others [16].

Problem Statement

An early study was conducted by some of the present researchers at several preschools at Johor Bahru, Malaysia and it was found that preschool children are weak in mastering the elements of EI which is contained under the socio-emotional pillar of the national curriculum for preschoolers [15]. Apart from that, the results of interviews conducted with preschool teachers indicated that the elements of EI and other elements under the socio-emotional pillar (of the national curriculum) were not given

proper importance by the curriculum forming authorities and the said pillar has only been used as an ancillary pillar only to be combined with the others pillars which are considered important such as science and technology pillar, communication pillar and so on. Whereas EI is very important and its elements ought to be given importance as it helps construct an individual's life trajectory such as higher mental abilities and positive personality attributes and may drive them in the right way to life 2,4,20. On children context have found that proper development of emotions is important for children because it is a regulation skill which promotes social behavior and positive learning 14, thus creating a conducive learning environment of a preschool setting 20.

In addition to the above problem, another problem is that of limited teaching aids or teaching and learning specific modules to enhance EI elements that can be used as a guide or facilitator for preschool teachers to facilitate them in teaching and learning processes undertaken. This scarcity of resources is particularly high in Malaysian context. Due to this dearth of available resources, preschool teachers in Malaysia find it difficult to carry out the teaching and learning. Moreover, there are limited specific modules available that provide information or knowledge about planned and systematic use of instructions to emotionally support and facilitate preschoolers. The teachers added that most of the teaching and learning process of EI and other elements under the socio-emotional pillar are just run only by some talk and storytelling and this makes it difficult for the students to understand the information received and thus somehow reduces their interest in learning and attention in class. According to Ovelyn, Baharom, Dg. Norizah, Molod 17, a compilation of modules accordance to the syllabus content, will successfully make the process of teaching and learning become effective and also fun for students.

Theoretical Framework

Teaching and learning module to help develop preschoolers' EI was created involving a number of theories i.e. Gagne Information Processing Theory 6, Bandura's Social Learning Theory 1 and Theory Zone of proximal Development (ZPD) by Vygotsky 22.

The use of module in teaching and learning can encourage children to understand faster and the information can be transmitted through many different activities. Teaching and learning process will be more interesting with a variety of activities that can be included in the module. Figure 1 show the theories that have been used to produce the teaching and learning module to enhance preschoolers' EI.

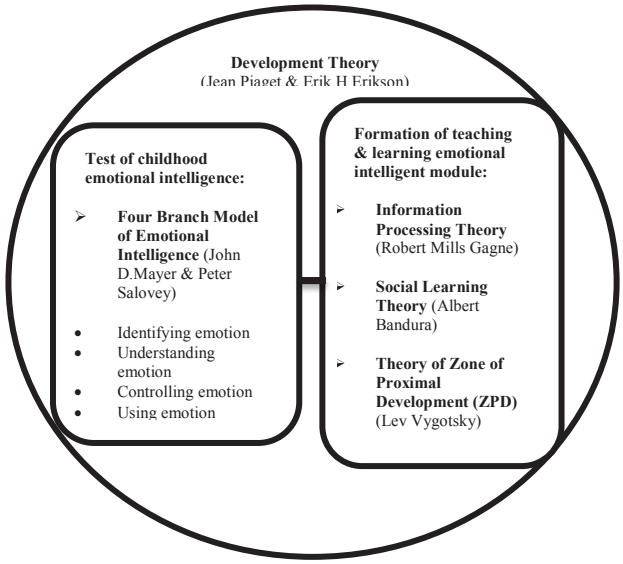

Figure 1: Theoretical Framework

The present research was conducted with children at the preschool level. According to Piaget's Theory of Development, children at this stage have an egocentric nature that will make it difficult for them to distinguish between delusions and reality. These children usually can only think of specific examples known as transductive. For them, every experience and all points of view of others are similar to what they themselves have.

Based on the Development of Erikson's Theory, the children at ages three to six years, will do things that are not fully aligned with their age due to the ongoing cognitive and physical development. If children feel criticized while experiencing curiosity, it will cause them to feel guilty and they will not take initiative in doing an activity again. Thus, the tug of war between the motivation to do new things and the prohibition to not try new things goes on. It is needed that adults promote well-meaning feelings in the children. Therefore, such children need the help of adults or peers who are better able to guide and an easily disclose the learned things. This method will involve the Zone of proximal Development (ZPD) theory by Lev Vygotsky 22 to support it.

According to Vygotsky 22, students who experience learning difficulties can be resolved when getting modeled help from an adult or collaboration partners. Student performance can also be expanded to higher

levels of potential. However, children also need an example to be imitated in order to facilitate the learning process. This process has been explained through social learning theory by Albert Bandura 1. Bandura suggested that indirectly children will learn a behavior change when observing the process and outcome of others' behavioral changes. This process is called modeling.

However, each stimulus received from the external environment which aims to simplify the process of learning, will depend also on the degree of information processing received in the nervous system through the human senses such as hearing, sight, touch, action and so on. We used the information processing theory by Gagne [9] to explain how this process occurs. According to Gagne [6], to facilitate new learning, people need old experiences that are stored in long-term memory which associate to the new experiences. Therefore, to facilitate the new learning process, we conduct an attractive activity which was contained in the module. With an activity being undertaken plus guidance from teachers and friends, teaching and learning process will be easier and will not boring. Children can see and apply the material learned in lessons. This will enhance their understanding through the teaching and learning process.

In addition to facilitating teachers in the teaching and learning processes, it was aimed by the present study to tap the level of preschool children's EI stages i.e. to know the level of EI before and after the teaching and learning modules run. Theory used to assess the children EI is through the Four Branch Model of EI by Mayer and Salovey. Through this model, Mayer and Salovey agree that individuals who are able to achieve the harmony of life are those who can master the four branches of EI namely identifying emotion, understanding emotion, controlling emotion and using emotion. Accordingly, all theories and models involved were used to create the module revolving around these four aspects. So in a way, Mayer and Salovey's model served as the spine of our teaching and learning module to promote the enhancement of preschool children's EI.

Result

Table 1 show the perception of preschool teachers on the effectiveness of teaching and learning modules in enhance preschools children's' emotional intelligence. Based on Table 1 show that in term of allocation of time for exercises to carry out an activity module, available time is feasible. Modules are concise. Easy to be referenced and easy to find specific parts when necessary. This is because the learning materials are contained in the module is structured and organized. Apart from that, both preschool teachers agreed that the activities are carried out in accordance with the level of pre-school children age. In addition, using the module can attract students' interest and attention to actively implement the activities provided. In terms of the elements of emotional intelligence which are applied to the module, according to the pre-school teachers, the preschool children are able to identify emotions himself and others, are able to understand the emotions, being able to understand the emotional changes, being able to control emotions and be able to use emotions towards a positive attitude when given an appropriate stimuli and activities available in the module. So as a brief, the teaching and learning module to enhance the preschool children's emotional intelligence is effectively implemented as successfully improving the preschool children's emotional intelligence.

Table 1. Preschool Teachers Perception on Teaching & Learning Module to Enhance Preschool Children's Emotional Intelligence

(n = 100)

Elements	Time Provided	Module Length	Suitability of Activity	User Friendly	Suitability of Module Content Meet to Malaysian National Education Curriculum
Teachers					

***Cont* .. Table 1. Preschool Teachers Perception on Teaching & Learning Module to Enhance Preschool Children's Emotional Intelligence**

Teacher 1	The time of 30 minute provided for each theme enough to implement all the activity which contained in the module. Even there have an activity which can finish early.	The module is not too thick. The instruction contained in the module concise and easy to understand. Easy to find specific parts when necessary. This is because the learning materials are arranged in a neat and organized. The information contained herein is concise.	Activities planned and implemented in accordance with the development of pre-school children. Every preschool children have equal opportunities in the experience of the learning process.	To attract students because there are certain images, as well as fun activities.	Activities that are carried out in the module help in building self-development preschool students. This is in line with the national educational philosophy that emphasizes the development of individual potential in a holistic and integrated to create a balanced and harmonious human.
Teacher 2	Most of the activity conducted can be finished within 30 minute that provided. However, it proposed that have one or two activities should be finish within 30 minute to 40 minute. So that students have enough time to complete the activity provided such as build character from the '*doh*' activity	The information contained herein is concise. Description of each activity undertaken concise. Teachers do not need to take a long time to understand the activities to be undertaken. Only a few minutes to read and activities have been implemented. In addition the module content is easy to pass on to students.	Activities can help teachers in the teaching to achieve the specified learning outcomes. There is emphasis on 'learning through play' in the teaching and learning activities performed. There are also activities that provide two options that encourage teachers to modify activities according to the level of student achievement, interests and themes that have been planned.	Activities and images contained within the module interesting and easy to understand preschool children. Apart from that, the activities require teachers and students to cooperate. This can strengthen the relationship of students and teachers as well as to provide an opportunity for teachers to get to know his students closer.	Content modules in line with the national education curriculum. This is because the activity in the modules is achieving the set objectives of the emotional and social aspects. For example, students can work alone as well as teamwork. Besides, they can also understand and respect the feelings and rights of others, and this can create a positive relationship between a classes.

Conclusion

It can be concluded that there are significant differences between the schools in the experimental groups before and after teaching and learning of EI module were conducted. It shows that preschool children's EI risen up from middle level to relatively higher level of EI. Meanwhile, the schools in the control group had no significant difference before and after the existing teaching and learning of EI were conducted. The level of preschool children's EI in this group is remained almost same at middle level. Therefore, teaching and learning of EI module was effectively implemented to increase the level of preschool children's EI. It has

been said because of on the result, it is to show that the experimental group which used the module was successful in increasing preschool children's EI. At the same time, with the module can help preschool teachers to teach EI to preschool children rather more systematically.

Abstract

Human consists two elements - physical and spiritual. In the context of science, studies of human events focus more on their physical or biological elements. There is still limited of research by scientists examines the spiritual elements, especially from Islamic perspective even when these two elements are widely mentioned in the Qur'an and studies by Islamic psychologists. Therefore, this article will discuss one of the spiritual elements of humanity namely emotional sadness. The study applied content analysis of the Qur'an and Hadith as well as Miskawayh and al-Kindi's perspectives on sadness. Miskawayh and al-Kindi's work is the focus of discussion. This article discusses the feeling of sadness from the perspective of Quran and Hadith, the impact of sadness, sad feeling from the perspectives of Miskawayh and al-Kindi and the method of treating sadness according to these two scholars. The findings show that sorrow and sadness is one of the forms of emotion caused by a number of factors. Extreme sadness can affect health physically and psychologically. Sadness can be solved through Islamic psychological methods that focus on human spiritual aspects.

Keywords: *sadness, health, treatment, Miskawayh, al-Kindi*

Introduction

From Western psychology's perspective, the study of sorrow or sad emotions is called psychological depression study. Study of sorrowness means the application of knowledge or psychological sciences in order to understand, assess and manage all forms of human behavioural reactions and mental processes resulting from significant loss.

Psychologists have given various definitions to explain the meaning of sorrowness. The most appropriate definition is the behavioural or emotional reaction to significant loss, both expected or not expected16. Zaini Said20 concludes that sorrowness is a heart breaking grief, agony, disappointment that is naturally occurred, facing distress and misfortune.

Sadness and sorrowness are one of the most common emotions experienced by every individual. The differences are in the degree of sorrowness and the ability to control the emotions. This is because humans are unable to escape from various trials and tribulation from Allah which ultimately brings sadness and sorrow to heart. Negligence of soul strength development will lead to spiritual development disorder. One of the consequences is the existence of extreme sadness and sorrow is depression as one of the mental illness that disturbs life and prevents someone from executing jobs and daily life task perfectly.

Corresponding Author:
Dr Siti Norlina Muhamad,
Associate Professor**.** Universiti Teknologi Malaysia, 81310, Skudai , Johor, Malaysia.
Email: norlina@utm.my

Islamic psychology's scholars have classified spiritual illness to some features. Among them are greedy (bakhil), fear of death, sadness / depress / sorrow, anger and anguish, extreme love for person, rank and treasure[11,5]. According to Mahadir Ahmad[10], the sorrowness experienced by an individual is assessed in terms of the type and level by formulating the results of the interviews and the standard tests on individuals with a different state. The type of sorrowness can be identified based on a report of the individual concerned.

Sorrowness and sadness from the Quranic and Hadith Perspective

In context of Islamic psychology scholars' studies such as al-Ghazali, Ibn Qayyim, Miskawayh, al-Kindi, sorrowness is viewed as a feeling that exist when one loses a loved one or loses something that is meaningful in his or her life or fails achieving something very important[14].

The Qur'an mentions depress or sorrowness as a state of very sad and in a very sorrowful condition or grieving. Sad or sorrow is one of human nature facing trials or misfortunes, but Allah SWT forbids human beings grieving beyond the limitation.

The Quran has taught human being to control the feeling of sadness. Individuals should not be in extreme sadness when being tested in any kind of trials or tribulations such as nature disasters, poverty, hunger or childless. This is because it is written in Luh Mahfuz, by Allah SWT before the occurrence. Expressing extreme sadness will not alter *qadr* Allah SWT. In contrast, the test is to train one's self to acquire high standard value such as patience, trust, good thought, humble, gain closeness to Allah SWT and to seek help from Allah SWT solely.

Referring to the previous study, sorrowness usually arises in response to loss including money, family and health. For example, death of beloved individual, break of significant relationship, loved ones suffer from chronic or life threatening illness, financial problem, jobless and significant negative changes[16]. According to Malaysia Mental Health Promotion Advisory Council Member, Tan Sri Lee Lam Thye, Malaysians who are expected to experience mental health problems due to increased workload and rising living cost are increasing. National Health and Morbidity Survey 2015 showed that 4.2 million Malaysians aged 16 and over or 29.2 percent of the country's population suffer from various mental problems. The number was alarming as it showed an increase of 11.2 percent compared to 2006. In addition, a study by World Health Organization (WHO) showed that mental health problem will likely to replace cardiovascular disease as a major determinant factor of one's capability to continue working.

Islam does not prohibit a person to express sad feelings. However, excessive crying is prevented, especially using strong voices, mourning and grief [13]. Rasulullah SAW taught his people to seek protection from Allah SWT from acquire sadness as he prayed;

"O Allah, surely I seek refuge in You from the pain and sorrow."

(Sahih Bukhari)

Impact on Physical and Spiritual (Psychological) Health

Human physiology acts on how one thinks, feels and behaves. Therefore, sorrowness can affect both individual's physical and psychological well-being. When a person is in sorrow, the body will react accordingly. He or she will experience stress, increasing chance of developing high blood pressure. Psychologically, symptoms of sorrowness and sadness are not only seen in the form of crying, complaining, anxiety and feelings of stress, but less work morale, difficulty sleeping, decrease appetite, loss of focus on daily tasks as well. This situation, if no addressed will cause depression, a mental health disorder[4].

Sad, sorrow and worry are normal feeling but prolonged and excessive sadness for more than two weeks is one of the symptoms of depression. Untreated depression can interfere with everyday life of the individual[7]. Most people with depression will experience insomnia and loss of appetite. Sudden loss of appetite in elderly can lead to a condition called anorexia geriatric[15].

Depression without treatment may lead to physical illness. Han Selye introduced a stress model in 1946, called General Adaptation Syndrome (GAS) for a better understanding on body's reaction to stress[17]. There are three levels of response, namely (1) alarm (danger sign), (2) resistance, and (3) exhaustion. According to Lyon[9] and Rice[17], human organs may stop functioning and death may occur at the third stage.

Sorrowness, sadness and depression due to stress or vice versa raise pressure hormones such as

catecholamines. Prolonged high catecholamine will have a damaging effect on liver. Stress also increase body oxygen, cause coronary blood vessel spasm and electrical instability in the heart flow system. Besides, chronic pressure has been shown to increase heart rate and blood pressure. Prolonged high blood pressure will lead to essential hypertension and other heart-related problems[6].

The Feeling of Sorrowness from Miskawayh's and Al-Kindi's Perspective

Miskawayh and al-Kindi are one of Islamic psychology and psychotherapy scholars. They have discussed about psychology of sadness and the management method from Islamic perspective. Miskawayh classified that extreme sorrowness as one of mental illnesses. The grief-related illness is the suffering of a soul who experienced losing something that is loved or missing sought-after thing[11]. Human deal with sorrowness in a various way and depending on their understanding and appreciation of religion. Islam has showed evidences on the power of faith in healing individual from various diseases, releasing the feeling of peace and eliminating sadness[20].

According to Miskawayh[12], the role of religion is very important in generating *akhlak* (good morale) because the main purpose of Islamic law is to educate human morality. According to Miskawayh[11], apart from the formal education, the power of spiritual and soul education should also be addressed. This can be done by empowering the rationality inside a person (*quwwah natiqah*). Morality of a person is heavily influenced by the power that controls him. With the power of being rational, humans are worthy of being called human beings and some individuals have the advantage and glory of having a good rationality.

Besides that, al-Kindi has defined grief, explained its causes and ways to resist sadness and sorrowness in his book, *Fi al-Hilah li Daf'i al-Ahzan*. He defined sorrowness as mental disorder that occurred because of the loss of loved and desirable things[1]. According to him, preventive measure should be taken seriously to protect individual soul.

In preventing the detriment of individual souls, Al-Kindi has expressed his own view. He divided sorrowness into two categories: sad feelings that occurred due to actions performed by himself or by others. Self-effacement can be cured by avoiding the act. While sadness by actions of others, one should not grieve before it happens. Once happened, he or she must try to shorten the period of sadness by managing the cause[1].

Sorrowness Treatment Method

Human's body will respond physiologically or biologically to pressure and stress. The stimulant caused various systems in the body to react. The autonomic nervous system and hypothalamus-pituitary-axis (HPA) are the two main systems of pressure and stress. There are many ways to reduce stress as well as reducing long-term complications of chronic stress such as heart disease, depression, anxiety, and type II diabetes[2]. However, the best treatment is to prevent it. Prevention methods are also often used as a part of a multidisciplinary treatment program.

In term of feeling of sorrowness, there also is no specific or exclusive preventive measure and treatment. However, if one is facing a difficulty in life and showing many signs of sorrowness, there are treatments that can help. These include face to face speaking, medications, Eco therapy, complementary and alternative therapies. In addition, treatment of the recovery of soul and spiritual strength is equivalently important to the treatment mentioned.

Sadenss, sorrowness or depression must be treated appropriately to the individual's situation. While this feeling is experienced by every individual but the strength and ability of a person to deal with it is different. Hence, Miskawayh and al-Kindi have put forward several appropriate methods that can be practiced by each individual.

Sorrowness Treatment Method According to Miskawayh

Miskawayh's recommended treatment methods are as follows:

(a) Eliminate greed and love for the world

One of the factors that causes sadness is a deep love of the world's pleasure and luxury. According to Miskawayh, a person feels sad, sorrow and depressed after losing something is because they consider their belonging as theirs forever. To get rid of the sorrowness, the individual need to realize that everything in this world is momentary and mortal. Second, recognizing that all desired matters may or may not be acquired and

owned. Such awareness will stop a person from greed in pursuing the worldly things. Hence, he or she will not be sad on losing beloved person or destruction of beloved property because he realizes he has no ownership[11].

(b) Establish a strong and true faith

According to Miskawayh[11], individuals need to establish faith (*iman*) to eliminate sadness. Miskawayh suggests that individuals who have firm and true faith will not be overwhelmed by grief and sorrow. Everything happened or missing from him does not affect his emotions and soul hence he will not feel sad.

Methods of Sorrowness Treatment According to al-Kindi

Apart from the treatment methods suggested by Miskawayh, al-Kindi also stated some measures to treat the symptoms, such as:

(a) Conducting healing of the soul gradually from disruption of sadness

Al-Kindi stated that healing of sorrowness needs to be done gradually. The first level is to familiarize easy and commendable act, then enhanced by disciplining the habits of commendable things in challenging situation. Lastly, it is to upgrade to more difficult and tough things. This level continues until it reaches a very difficult matter[1].

(b) Have patience on improvement

Al-Kindi also suggested that individuals should practice patience in treating sorrowness. Healing of souls does not require huge expenditure[1]. According to Al-Kindi[1], this healing process can only be done through the determination of people who want to improve themselves expenditure.

(c) Discipline oneself with the habit of doing good things

Healing of sorrowness can be done through habit of doing easy good act. If the implementation of the good thing has become a habit, an individual will be able to increase his ability to do good habits at a more difficult level. This is because the habit will make it easier for humans to achieve what is reflected in his mind and it also helps one to be patient facing various events of loss[1].

Muhammad Uthman Najati[14] emphasized that the idea of al-Kindi is preceded by the idea of modern psychologists on important fundamental principle of learning, a gradual principle on learning difficult habits. This principle has been used by modern behavioral psychologists in healing from bad habits as well as anxiety and depression.

In conclusions, the advice and suggestions used by al-Kindi in overcoming sorrowness is a method of deep understanding on the situation of grief, critically learning of its causes and wisely determined effective measure. Al-Kindi adheres to the concept of treating sorrowness and depression by generating awareness, explaining the meaning, and illustrating the nature of sorrowness as well as enhancing knowledge that can help to overcome the feelings.

Conclusion

In the era of globalization, the need for knowledge related to the development of identity and soul strength is crucial. Knowledge of Islamic psychology methods needs to be known and understood clearly as it can help people face persistent life problems. Faith and knowledge are dependent on the greatness of the trials that the believer's hearts and minds have successfully met. Human soul which has undergone the process of education through the tests and allegations of Allah SWT, will produce outstanding individuals from physical, mental and spiritual aspects. Islamic scholars have left valuable treasures as a result of their assessment of the contents of the Qur'an and hadith as guides to humanity.

Abstract

In nursing profession, it is quite challenging to achieve a good work-life balance. This resulted in nurses facing burnout issues constantly. This study aims to identify the influences of work-life balance on burnout among nurses. A quantitative research method was used in this study by using survey forms to collect the data. The population was consisting of 150 nurses from KPJ Johor Specialist Hospital. A total of 135 nurses participated in this study which gives a response rate of 90%. The respondents were chosen by using convenience sampling technique. Descriptive statistics and Structural Equation Modeling (SEM) had been used to analyze the data of this study. Descriptive analysis and SEM analysis were carried out by using SPSS and SmartPLS version 3 softwares respectively. The findings of this study indicated that there was a significant relationship between work-family enrichment with reduced personal achievement and between work-family conflict with emotional exhaustion, depersonalization and reduced personal achievement. The findings of this study contribute to the empirical study related to work-life balance and burnout especially among nurses in Malaysia. In terms of practical aspects, this study can serve as a guide for organizations and practitioners such as hospitals and human resource practitioners to develop policies or programs to improve work-life balance for workers and to reduce burnout levels.

Keywords*: Work-life balance, Burnout, Work-family conflict, Work-family enrichment, Nurses*

Introduction

Twenty first century organizations are characterized by persistent changes, uncertainties and excessive pressure to increase productivity. These changes disturb the balance in the lives of employees causing confusion and stress. This is also fuelled by extreme levels of competitiveness in the work sphere posing new challenges and problems to workers. Thus, this study arises from the need to enhance the work-life balance by reducing burnout among nurses.

Usually healthcare professionals are trained to put the needs of others before themselves and spend each working day exposed to the emotional strain of dealing with people who are sick or dying and who have extreme physical and emotional needs. This emotional strain, coupled with other stress factors inherent in the healthcare work environment, renders healthcare professionals especially vulnerable to burnout[1]. Nurses have been found to be the most vulnerable health care professions to burnout[2]. This is because, even in environments with limited resources and reduced supply of nurses and increased responsibility, the nurses are expected to deliver humane care, empathy, cultural sensitiveness, competent and moral care[3].

In nursing profession, burnout is one of the main problems faced by nurses[4]. Burnout negatively affects the performance of an individual[5]. For nurses, this is crucial information as this directly puts patients' well-being and lives in risk and also conflicting with the code of morals for nurses[6].

Literature Review

Work-Life Balance is divided by two parts, such as work-family conflict and work-family enrichment. Work-family conflict is a type of inter-role conflict in which the part weights from work and family areas are commonly inconsistent in some regard. That is, investment in the work (family) role is made more troublesome by ideals of investment in the family (work) role. Conflict amongst work and family has been observed to be bi-directional[7,8]. Whereas, work-family enrichment characterized as the degree to which encounters in one role enhance the quality of life in the other role[9].

Job burnout defined as a sense of reducing effectiveness, lack of motivation and dysfunctional attitudes toward their work[10]. There are three dimensions under burnout namely emotional exhaustion, depersonalization and reduced personal achievement. Emotional exhaustion refers to feelings of being emotionally overextended and depleted of one's emotional resources. Depersonalization refers to a negative, callous, or excessively detached response to other people, who are usually the recipients of one's service or care. Reduced personal achievement refers to a decline in one's feelings of competence and successful achievement in one's work.

A research studied the role of work-family conflict on burnout syndrome among medical workers in South West China[11]. The results of this study revealed that work-family conflict somewhat influence the level of burnout syndrome. In addition, females and those with lower technical titles and without administrative duties are more at risk to burnout syndrome than their counterparts.

It is clear that work-family conflict is seen as a predictor of burnout. Since, burnout has three dimensions thus the hypotheses deduced separately for each dimension. All the three dimensions, emotional exhaustion, depersonalization and reduced personal achievement can be deduced as giving positive relationship towards work-family conflict[12]. Based on the findings from the above studies, this study proposes to test the following hypotheses:

H1: Work-family conflict is positively related to emotional exhaustion.

H2: Work-family conflict is positively related to depersonalization.

H3:Work-family conflict is positively related to reduced personal achievement.

Another research studied whether work-family enrichment predicted burnout between sole and partnered working mothers[13]. In this study, a total of 107 sole working mothers and 516 partnered working mothers completed an online survey. The findings of the study showed that work-family enrichment negatively significant to burnout. Based on the previous studies, this study deduces the following hypothesis:

H4: Work-family enrichment is negatively related to emotional exhaustion.

H5: Work-family enrichment is negatively related to depersonalization.

H6: Work-family enrichment is negatively related to reduced personal achievement

Method

Participants

The population of this study consisted of nurses from all departments in KPJ Johor Specialist Hospital. Due to ethical issues in KPJ Johor Specialist Hospital, the researcher did not get permission to get the population size of nurses. Consequently, the researcher had to choose convenience sampling method to obtain samples because of the confidentiality issues from the hospital. Due to the restriction from KPJ Johor Specialist Hospital, they only allowed 150 nurses to participate in this study. The researcher managed to obtain 135 completed questionnaires from the hospital out of 150 questionnaires that were initially distributed. A total of 21 male and 114 female nurses participated in this study. 57 nurses are within the range of 20-29 age group. While 55 nurses and 12 nurses are in between 30-39 and 40-49 years old. 11 nurses are aged 50 and above. Majority of the nurses (N=123) have a Diploma as their highest education level followed by High certificate (N=2), degree (N=8) and Master (N=2). The marital status of the nurses are as follows: single (N=41); married (N=92); divorced (N=1) and widowed (N=1). Lastly, the working experience of the nurses was collected as well. Majority of the nurses (N=53) have 0 to 5 years of experience in working. There are 7 nurses with more than 30 years of working experience at KPJ Johor Specialist Hospital.

Instruments

Work-family conflict (WFC) assessed by adopting scales developed by Netemeyer et al. (1996)[14]. WFC is defined as a form of inter-role conflict in which the general demands of, time devoted to, and strain created by the job interfere with performing family- related responsibilities. The work-to-family conflict instrument comprises of five items. The items will be rated using a 5-point Likert scale ranging from (1) strongly disagree to (5) strongly agree. The participants need to indicate to what extent they agree with each conflict items. A sample item from WFC is "The demands of my work interfere with my home and family life". This instrument developed by Netemeyer et al. (1996) was used in this study because it has very strong reliability (Cronbach's alpha = .89)[14].

Work-family enrichment (WFE) was assessed by adopting scales developed by Carlson et al. (2006)[15]. WFE has nine items with three elements namely development, capital and affect. Each subscale has three items each. The example of item in development element is "My involvement in work helps me acquire skills and this helps me be a better family member". The example of second element capital is "My involvement in my work provides me with a sense of accomplishment and this helps me be a better family member". Lastly, the third element affect has item sounds like "My involvement in work makes me feel happy and this helps me be a better family member". The response rates are on a 5- point Likert scale. It is ranging from (1) strongly disagree to (5) strongly agree. This instrument was selected for this current study because it has very strong reliability which was Cronbach's alpha of 0.93[15].

Burnout assessed by using questionnaire items adopted from Maslach Burnout Inventory (MBI) developed by Maslach and Jackson (1986)[16]. The Maslach Burnout Inventory (MBI) was designed to assess three components of the burnout syndrome: emotional exhaustion, depersonalization and personal achievement. MBI consists of 22 items which divided into three subscales. The nine items in Emotional Exhaustion (EE) subscale measure feelings of being emotionally overextended and exhausted by one's work[17]. The five items in the Depersonalization (DP) subscale assess an unfeeling and impersonal response toward recipients of one's service, care, treatment or instruction[17]. The eight items in the reduced personal achievement (reduced PA) subscale measure feelings of competence and successful achievement in one's work with people[17]. All the 8 items in the reduced PA were reversely scored so that it standardized to the other two variables, EE and DP. Higher mean scores for both EE, DP and reduced PA subscales correspond to higher degrees of experienced burnout[17].

Results

The data of this study was analysed with Structural Equation Modeling using SmartPLS version 3.0. Table 1 shows the findings of this study.

Table 1: Relationship between WLB and Burnout

Hypothesis	Variables	β	T statistics	P values	Hypothesis
H1	WFC -> EE	0.420	6.372	0.000	**Accepted**
H2	WFC -> DP	0.468	6.769	0.000	**Accepted**
H3	WFC -> Reduced PA	0.218	3.903	0.000	**Accepted**
H4	WFE -> EE	0.044	0.463	0.644	Rejected
H5	WFE -> DP	-0.087	0.947	0.343	Rejected
H6	WFE -> Reduced PA	-0.524	9.376	0.000	**Accepted**

The results deduced that WFC has a significant relationship between all the three variables namely EE, DP and reduced PA. Therefore, the research hypotheses for WFC to burnout dimensions (H1, H2 and H3) were accepted. Whereas, WFE does not have a significant relationship between EE and DP which resulted in the rejection of the hypotheses H4 and H5. While there is a significant relationship between WFE and reduced PA ($p<0.05$). Thus, the hypothesis is accepted for H6.

Discussion and Conclusion

This study found that work-family conflict influences all the dimensions of burnout (i.e. emotional exhaustion, depersonalization and reduced personal achievement). These findings are consistent with the previous studies[8,18]. One of the most common effects of the work-family conflict is burnout[19,20]. Family variables were identified as the reasons for burnout[21]. Employees experience burnout because of issues or conflicts they are facing with their spouse or because of not spending adequate time at home or their families and also because of augmented requirements and responsibilities at work[18] Therefore, the level of burnout increases if the conflict between work and family arises among nurses.

Burnout is not a symptom of work stress, but it is the end result of unmanaged work stress[22,23]. Extended stress at workplace causing burnout among nurses because nurses are those who require frequent contact with people. In this profession, nurses are facing hardships in coping with demands and pressure from their jobs in terms of energy, time and resources on a daily basis. These are the reasons why nurses having difficulties in balancing their work and family lives. They are also more likely to exhaust emotionally, depersonalized and showing declines in personal achievements.

The next relationship that researcher examined was between work-family enrichment and burnout variables. There is no significant relationship between work-family enrichment and emotional exhaustion. Same goes for the relationship between work-family enrichment and depersonalization. However, this study indicated that there is a significant relationship between work-family enrichment and reduced personal achievement. This finding is in line with a study by[13] that argued work-family enrichment influence reduced personal achievement among the respondents.

There are several implications arose in this study. The theoretical implication was most of the studies on work-life balance and burnout were conducted in western countries. There are very limited studies being carried out in hospitals at Malaysia. Therefore, this study will be one of the pioneer studies in the health-care sector in Johor Bahru, Malaysia involving nurses.

In terms of practical aspects, the findings of this research provide empirical evidence on the influence of work-family conflict on all the dimensions of burnout. The findings of this study can be used by Hospital management in order to design intervention to reduce burnout among nurses.

In conclusion, this study proved that work-life balance influence burnout among nurses. Work-family conflict is more dominant affect burnout compared to work-family enrichment.

Problem-Solving Games on the Development of Pupils' Critical and Creative Mental Model: An Experimental Study

Roziana Shaari[1], Azlineer Sarip[2], Azizah Rajab[3], Nor Hasliza Binti Md Saad[4]

[1]Associate Professor, [2]Senior Lecturer, School of Human Resource Development and Psychology, Faculty of Social Sciences and Humanities, Universiti Teknologi Malaysia, [3]Associate Professor, Language Academy, Faculty of Social Sciences and Humanities, Universiti Teknologi Malaysia, [4]Senior Lecturer, School of Management, Universiti Sains Malaysia

Abstract

Problem-solving teaching technique is believed to contribute to critical and creative, pupil-centered learning environment. This article presents results from a study of problem-solving games and the development of pupils' mental model towards critical and creative thinking. An experimental study was carried out on 163 pupils aged 11 in one primary school in Kangkar Pulai, Johor Bahru district in Malaysia. Quantitative and qualitative results show that pupils' level critical and creative thinking changed after the intervention of problem-solving games.

Keywords: *problem-solving games; critical and creative thinking; mental model*

Background

Reforming curriculum in education into higher order thinking skills (HOTS) are critical in the 21st century that aimed to encourage active learning among learners. Beginning from primary schools, students are expected to demonstrate critical, logical, reflective, meta-cognitive and creative thinking when encountered with uncertainties, dilemmas or unfamiliar problems. A scaffolding teaching technique is a lesson plan that enable to generate students thinking skills when they model from desired thinking such as applied thinking – students are giving support at the beginning of a lesson and they need to operate independently later[1]. This implies that a problem-solving lesson should be integrated into teaching curriculum to rejoin content and application to support HOTS.

Solving problems require learner to form mental models based on situation they are manipulating even through know-what and know-how process[2]. The kind of mental model that students develop are greatly dependent on what problems they expect to solve. For example, in our study students are experiencing problem-solving through game. In Game A, students are in dilemmas when the game activity was presented in disorder and ambiguous manner that require them to solve it into ordering manner. They are required to write an action in complete, properly sequenced form, taking note of the ambiguous wording and how it could be interpreted. Disorder and ambiguity seem to be an excellent creative thinking and cognitive activity. Jansoon et al. supported that manipulating the mental model is a key step in problem-solving because learners need to predict the effects of various possible actions until they come closer to the solution[3].

Mental model as described by early works is a representations in the mind of real or imaginary situations. Based on new understanding gained from solving anticipated events, individuals form their cognitive structures to interpret new events[4]. In this paper, mental models help pupils throughout the problem-solving games based on several processes namely explain, predict, control action and thought,

diagnose, communicating among group members, and memorizing the games simulation. Iliopoulou in his observation supported that understanding mental model is so crucial for educators to allow children to construct mental models in order to generate solution for their environment, to predict and to reason[5]. That is the actual learning when children are able to control and modify their existing mental models to address environmental and real-world phenomena. The learning context should include events, tasks, problems, procedures or a concept so that when learners use mental models, they could reflect the structure of phenomena in solving the problems[4].

Material and Method

This study is to install and evaluate the critical and creative thinking skills through problem solving games. Two games were designed as problem-solving intervention for pupils to experience. The games involve critical and creative thinking that allow students to see that not only can problems have more than one solution, but sometimes the same solution works for more than one problem. Many students think that there has to be "just one right way" to solve a problem so this game can be an eye-opener for them. After playing this game, the moderator or instructor discuss how the more succinct, concise, and accurate the clue words, the easier it is to guess the key word. This draw students' attention to how this works when writing or stating a problem to be solved.

Participants of this study were 163 students aged 11 in a public school in Kangkar Pulai, Johor Bahru district in Malaysia. The experimental research that used the pre and post-test were adopted to measure the results on the critical skills of sorting, recalling, describing, problem-solving, predicting, and estimating which was adapted from Collier et al based on the suitability of the respondents[6]. This instrument was analyzed quantitatively by using mean and t-test. On the other hand, the element of creative thinking was adapted from the Torrance Tests of Creative Thinking (TTCT) which used figural test to evaluate how respondents complete a figure to create a story. The analysis is using qualitative method that based on drawing or figural results from pre and post-test.

The respondents were asked to answers both tests of questionnaire and figural test 2 weeks before they were taught and trained about creative and critical thinking through the games. During the games, the respondents were facilitated by mentors to play two games within 4 hours sessions. After six weeks, the respondents were given the similar tests. To analyze the data, the paired sample t-test was used to evaluate the difference between pre and post-test.

Findings

Critical Thinking in Solving Problem

The overall results on the critical thinking among respondents was shown in Table 1. The mean items were to interpret the results and categorized the mean into three levels namely high, medium/moderate and low. The level of critical thinking was observed as moderate for pre and post-test except Item 4 and 5, of which the critical thinking level during the pre-test was low.

Table 1: Overall Mean

No	Aspects	Pre (N=163)	Post (N=163)
1	Independent problem-solving	3.01 Moderate	2.97 Moderate
2	Asks for help	2.96 Moderate	3.20 Moderate
3	Alternate solutions	2.96 Moderate	2.94 Moderate
4	Create visuals	2.31 Low	2.37 Moderate
5	Retell directions	2.31 Low	2.47 Moderate
6	Recall information	2.86 Moderate	3.07 Moderate

Cont... **Table 1: Overall Mean**

7	Cooperate with others	3.28 Moderate	3.27 Moderate
8	Attentive listener	2.94 Moderate	3.07 Moderate
9	Inquisitive, curious	3.19 Moderate	3.19 Moderate
10	Describe ideas/events	3.45 Moderate	3.36 Moderate

The Difference of Critical Thinking Between Pre and Post Test

The overall value of mean difference between pre and post-test was shown in Table 2. Only two items were shown to have significant difference namely *asks for help* and *recall information*. Based on the t-test analysis, the *t*-value are (163) = -2.492, $p<0.05$ and (162) = -2.227, $p<0.05$ for *asks for help* and *recall information* respectively. The detailed results are depicted in Table 3.

Table 2 : Mean Difference

No	**Aspects**	**Pre (N=163)**	**Post (N=163)**	**Mean Difference**	**p- value (significance)**
1	Independent problem-solving	3.01	2.97	0.03	0.73
2	Asks for help	2.96	3.20	-0.20	***0.01***
3	Alternate solutions	2.96	2.94	0.01	0.90
4	Create visuals	2.31	2.37	-0.01	0.91
5	Retell directions	2.31	2.47	-0.16	0.12

Post	163	3.07	.757		

Creative Thinking in Solving Problem

Findings on creative thinking can be illustrated when participants are able to complete the figural test on 4 relevant pictures that have meaningful story about *My Holiday*. The figural test provide incomplete object for each of the 4 boxes and participants were given 20-30 minutes to complete and transform the object into meaningful picture according to the story title. They are required to imagine and complete the figural story according to the flow 1-4. The complete 1-4 pictures with relevant meaning were scored as 5 points each making a total of 20 points. From the 163 participants, only 57 (35%) of them completed the pictures.

Discussion

Problem-solving games that had been used for this study is part of a play that has significant changes on tacit level based on learning from experience. The games experienced by participants in this study had produced some significant changes in both critical and creative thinking. Level of asking and recalling changed after participants were trained and experienced throughout the games. Being able to recall directions and retell details, information and ideas from stories and past experiences are important skills for critical and problem-solving process. Previous studies agreed that play is critical factor for socialization and learning throughout life[7]. It has power and fantasy that enable participants in this study to think outside their ordinary thinking style. Even though only 35% of participants demonstrated the changes in creative thinking outcome, these results are considered as an imperative changes among pupils at age 11. By reflecting on the games, learners develop personal awareness and insight, and this is identified as debriefing stage in learning and is very important to encourage learners discover meaningful connections between game activity and their own lives[8].

Conclusion

In conclusion, problem solving teaching technique using game may overcome limitation of teaching lessons plan that failed to encourage pupils' ability to think at higher level. The design of learning instruction is critical to promote and stimulate critical inquiry and creative thinking. Unfamiliar scenario and dilemmas are able to encourage the development of new mental model based on what the pupils experience when they are solving puzzles in the game. In this study, curiosity and inquisitiveness are the character traits that can be gained after participating in the game. Teacher or instructor should create systematic learning instructions to promote pupil-centered environment that allow pupils to engage and be interactive in learning.

Abstract

Background: Lung volume reduction means reduction of part of the lung which is physiologically nonfunctional and has no role in the normal process of gas exchange between air in the alveoli and blood in the alveolar capillaries. This part of lung may also compress and affect the function of the normal functioning lung tissue adjacent to it. Many bronchoscopic lung volume reduction materials used to reduce lung volume in patients with emphysema such as one-way valves, coils plugs/occluders/blockers, and other biological lung volume reduction maneuvers.

Purpose: to evaluate feasibility, efficacy and safety of silver nitrate or Histoacryl in bronchoscopic lung volume reduction in COPD patients.

Materials and Method: The present study included 30 patients subjected to full history taking, full clinical examination, chest x-ray & HRCT chest, spirometry, lung volumes, 6- minute walk test, diaphragmatic excursion by chest ultrasound, Fiberoptic bronchoscopy and BLVR with application of silver nitrate or Histoacryl.

Results: In our study, lung volume reduction was associated with improvement after 3 months in FEV1 ((8.55±12.38 %) with Histoacryl VS (10.61±11.50 %) with silver nitrate), 6MWT (61.94±37.45 %) with Histoacryl VS (48.08±33.68 %) with silver nitrate), diaphragmatic excursion (48.03±29.12 %) with Histoacryl VS (61.31±26.15 %) with silver nitrate) , RV ((41.50±21.58 %) with Histoacryl VS (40.98±18.12 %) with silver nitrate), TLC ((37.12±16.17 %) with Histoacryl VS (37.37±18.74 %) with silver nitrate), MMRC ((22.78±9.69 %) with Histoacryl VS (27.78±8.72%) with silver nitrate) and CAT ((15.97±7.08 %) with Histoacryl VS (16.17±5.94 %) with silver nitrate).

Conclusion: Bronchoscopic Lung Volume Reduction With Silver Nitrate solution 0.5% or Histoacryl may be a safe, cheap and effective therapy in patients with advanced emphysema.

Key words: *COPD, BLVR, Histoacryl, silver nitrate.*

Introduction

COPD is a preventable and treatable disease. Smoking is the most important risk factor and about 90% of COPD ptientsare smokers1.

Corresponding Author:
Mohamed Abd El-Hakim Elnady
Chest Department, Faculty of Medicine, Kasr Alainy Medical School, Cairo University, Egypt.
E-mail: dark_angel20002020@yhoo.com

Medical management of COPD mainly depends on smoking cessation, bronchodilators, anti-inflammatory drugs, antibiotics, prophylactic vaccines, pulmonary rehabilitation and long term oxygen therapy, mucolytics, antioxidants, and good nutrition. Smoking cessation has disease modifying action that can slow down the decline in lung function and increase survival 2.

Despite proper medical therapy, many patients with advanced disease have been seen to deteriorate or minimal improvement may be achieved. Management of such patients includes a more interventional therapy

as lung transplantation and lung volume reduction procedures. Bronchoscopic lung volume reduction (BLVR) is one of the interventional procedures that may help in the treatment of patients with advanced COPD 3.

Lung volume reduction used to reducethe part of the lung which has no role in the normal process of gas exchange between air in the alveoli and blood in the alveolar capillaries and may affect the function of the adjacent functioning lung tissue4.

Many bronchoscopic lung volume reduction materials used to reduce lung volume in patients with emphysema such as one-way valves, coils and other biological maneuvers5.

Materials and Method

The present study was conducted in the Chest Department, Kasr Al-Ainy hospital in collaboration with Radiology Department, faculty 0f medicine, cairo university

Study Design:

The present study included 30 patients with heterogenous emphysema who fulfilled the selection criteria. The included patients were selected from the Chest Department inpatients, Kasr Al-Ainy Hospital. Bronchoscopic lung volume reduction was done using Histoacryl for 15 patients and silver nitrate for 15 patients.

Inclusion criteria:

Stable COPD patients with predominant emphysema with heterogeneous and upper lobe predominance emphysema admitted in Chest Department at Kasr al Ainy Hospital for BLVR.

All age groups regardless the gender.

FEV1 < 45% predicted.

PaO2 ≥ 60 mmHg on nasal prong ≤ 4 liter per minute.

PaCO2 < 60 mmHg

RV ≥ 200%

TLC ≥ 120%

Exclusion criteria:

Airflow limitation with FEV1 < 20%.

Patients not candidate for FOB:

Life threatening arrhythmia.

Severe hypoxemia.

Bleeding tendency that can't be corrected.

Assessments:

All patients were subjected to the following:

1) Full history taking.

2) Full clinical examination.

3) Laboratory tests including:

Complete blood count.

Arterial blood gases.

Bleeding profile.

4) ECG.

5) Chest X-ray (Postero-anterior view).

6) High resolution CT chest was done as it is more sensitive to detect emphysema using "MSCT (multi slice computed tomography) 16-channels" device. HRCT chest was useful in detection of type of emphysema, distribution of emphysema and absence of collateral ventilation when 80 % of fissures were seen.

7) Pre and 3 months post BLVR spirometery (FEV1%) and lung volumes were done using "Master screen Carefusion Germany 234GmbH LeibniZstrasse" device.

8) Pre and 3 months post BLVR evaluation of dyspnea grade according to Modified Medical Research Council Dyspnea Score (mMRC)

9) Pre and 3 months post BLVR 6 minute walk test.

10) Pre and 3 months post BLVR diaphragmatic excursion with chest ultrasound.

11) pre and 3 months post BLVR COPD assessment test (CAT)

12) BLVR procedure

Patients were prescribed antibiotic (levofloxacin) 5 days before and after the bronchoscope to prevent development post procedural infection which is the

commonest complication.

Fiber-optic bronchoscopy.

Patient preparation:

Patients fasting for at least 6 hours.

Intravenous access was ensured.

Premedication:

0.5-1 mg atropine sulphate was given intramuscular, half an hour before the procedure to reduce the bronchial secretions and suppress vagal overactivity.

Patient position:

The patients were lying semi-sitting.

Approach:

Fiberoptic bronchoscopy was performed via the nasal route from front of the patient.

Local anesthesia:

Lidocaine 2% was given as local anesthetic agent. The oropharynx was anesthetized with 2% lidocaine applied intranasally. The vocal cords as well as the bronchial tree were properly anesthetized by direct instillation of 2% lidocaine via the working channel of the bronchoscope to suppress the cough reflex.

Monitoring of the patient throughout the procedure:

The patient's oxygen saturation, heart rate and blood pressure were monitored to ensure adequate oxygenation and hemodynamic stability.

Steps of the procedure:

After insertion of FOB (PENTAX FB 18RX, Ashi optical. Japan) and visualization of vocal cords, systematic inspection of the tracheobronchial tree was done. The bronchoscope was advanced to reach the targeted segment of the bronchial tree that was recognized by chest X- ray and high resolution CT chest, and then the bronchoscope was wedged to the targeted segmental bronchi.

BLVR with Histoacryl:

A small catheter (19-gauge disposable injection needle) was introduced through the working channel of the bronchoscope.

1 ampoule (0.5 ml) Histoacryl blue, was injected through the catheter after mixing it with 0.6 ml lipidol which act as a lubricant to the catheter wall which facilitate transfer of histoacryl blue through it and it delays the coagulation of histoacryl blue glue until it reaches the target segment.

Manufactured by B. Braun, Histoacryl® consists of n-Butyl-2 Cyanoacrylate..Histoacryl® and Histoacryl® Blue polymerize in seconds upon being exposed to water or water containing substances like human tissue. Histoacryl® and Histoacryl® Blue are supplied in 0.6 ml single patient use plastic ampoules.

The injected adhesive material, histoacryl blue, led to obstruction of the targeted segment, shrinkage and collapse of the targeted segment (upper lobe segment in emphysematous patients).

BLVR with Silver Nitrate:

A small catheter with balloon (Swan Ganz, 110 cm, triple lumen, Edwards, USA) was introduced through the working channel of the bronchoscope and was wedged into the selected segment, then the balloon was inflated to prevent leakage of silver nitrate outside the selected segment, then the bronchoscope was dislodged slightly upward to protect it from coming in contact with silver nitrate during coughing.5 ml of the prepared silver nitrate (0.5%) was injected through the catheter.

The injected silver nitrate led to inflammation, fibrosis, and obstruction of the targeted segment, shrinkage and collapse of the targeted segment.

Patients were discharged out of the hospital at the same day after checking the vital signs.

We targeted upper lobes in COPD patients with heterogenous emphysema.

Statistical methods:

Data were coded and entered using the statistical package SPSS (Statistical Package for the Social Sciences) version 24. Data was summarized using mean, standard deviation, median, minimum and maximum in quantitative data and using frequency (count) and relative frequency (percentage) for categorical data. Comparisons between quantitative variables were done using the non-parametric Mann-Whitney test. For comparison of serial measurements within each patient the non-parametric Wilcoxon signed rank test was used

6. For comparing categorical data, Chi square (□2) test was performed. Exact test was used instead when the expected frequency is less than 5 7. P-values less than 0.05 were considered as statistically significant.

Results

30 males with hterogenous emphysema were subjected for BLVR with silver nitrate or Histoacryl.

BLVR with Histoacrylwas associated with improvements in spirometry (FEV1 improved at 3 months from 25.93±8.14 % to 27.6±9.9 %), air trapping (residual volume improved at 3 months from 410.5 ± 164.19 % to 222.2 ± 69.7 %), (total lung capacity improved at 3 months from 171.68±46.5 % to 105.6 ± 25.96 %). Symptom scores (Medical Research Council dyspnea score at 3 months improved from 3.87 ± .35 to 3 ± .53 and COPD assessment test improved at 3 months from 34.27 ± 1.58 to 28.87 ± 3.54). 6 minute walk test showed improvement at 3 months from 125.9 ± 33.9 m to 204 ± 68.3 m. diaphragmatic excursion improved at 3 months from 2.9 ± .77 cm to 4.33± 1.13 cm.

Table (1):Age of study population.

diaphragmatic excursion % improvement	48.03	29.12	61.31	26.15	.137
RV % improvement	41.50	21.58	40.98	18.12	.571
TLC % improvement	37.12	16.17	37.37	18.74	.696
MMRC % improvement	22.78	9.69	27.78	8.72	.061
CAT % improvement	15.97	7.08	16.17	5.94	.838

Discussion

In our study, lung volume reduction was associated with improvement after 3 months in FEV1 ((8.55±12.38 %) with Histoacryl VS (10.61±11.50 %) with silver nitrate), 6MWT ((61.94±37.45 %) with Histoacryl VS (48.08±33.68 %) with silver nitrate), diaphragmatic excursion (48.03±29.12 %) with Histoacryl VS (61.31±26.15 %) with silver nitrate) , RV ((41.50±21.58 %) with Histoacryl VS (40.98±18.12 %) with silver nitrate), TLC ((37.12±16.17 %) with Histoacryl VS (37.37±18.74 %) with silver nitrate), MMRC ((22.78±9.69 %) with Histoacryl VS (27.78±8.72%) with silver nitrate) and CAT ((15.97±7.08 %) with Histoacryl VS (16.17±5.94 %) with silver nitrate).

Other researchers showed that BLVR with silver nitrate showed that at 3 months, improvement from baseline in FEV1 (10.29±9.56%)8. BLVR with autologous blood showed that at 3 months, improvement from baseline in FEV1 (15.8 ± 10.2 %), 6MWT (37.6 ± 24.6 m) and improvement in MMRC (0.29 ± 0.48)9. BLVR with Aeris biological remodeling system showed that at 3 months, improvement in in FEV1 (3.0 ± 10.2%), RV (11.8 ± 5.8%) and in 6MWT (71.9 ± 61.8 m)10.BLVR with endobronchial valves showed that at 3months, improvement in FEV1 (10.7 ± 26.2%), RV (11%) and in 6MWT with was (36.9 ± 90 m) 11.Other studies results are comparable with our study results.

In our study, we used diaphragmatic excursion to assess lung volume reduction as it was easier without any harmful radiological effect and improvement of diaphragmatic excursion would improve dyspnea score and exercise capacity.

Regarding complications in our study, in Histoacryl group, 2 patients developed complications (1 patient had pneumonia outpatient and received antibiotics for 1 week and improved and 1 patient had respiratory failure and was admitted in ICU for 1 day and improved then was discharged).

In silver nitrate group 4 patients experienced chest pain and patients were given analgesics.

So, complications in our study were limited and were treated without any residual effect.

In conclusion, Bronchoscopic Lung Volume Reduction With silver nitrate or Histoacryl may be a safe, cheap and effective therapy in patients with advanced emphysema.

Conflict of Interest: The authors declare that no conflicts of interest.

The Role of Time Zero Liver Biopsies Following Graft Reperfusion in Prediction of Early Graft Dysfunction in living Donor Liver Transplantation

Mansour D.A.[1], Elewa A.[2], Zayed N.A.[3], Mounir B.I.[4], Seleem M.E.[2], Elshazly M.A.[1], Ahmed M. Ghobashy[1]

Abstract

Introduction: Time zero biopsy may reflect hepatic post-reperfusion changes that can affect graft outcome in LDLT.Aim: to highlight the role of time-zero biopsies in predicting early graft dysfunction following Living Donor Liver Transplantation (LDLT).Patients & Methods: Between January 2017 and September 2018, Time zero biopsy was taken in 49 patients. The severity of the ischemia reperfusion injury (IRI) was graded upon the presence of neutrophilic infiltrate and hepatocyte necrosis. Patients were divided into two groups; positive IRI (moderate or severe changes) and negative IRI (nil or mild changes).Histopathological changes were correlated with graft outcomes.Results: Time-zero biopsies of 49 liver allografts revealed negative IRI (35, 71.4%) (Group 1) and positive IRI (14, 28.6%) (Group 2). Recipients with positive IRI group showed a significant rise in serum bilirubin, ALT, AST and INR on days 5,7,30 post transplantation. Fifty percent of the allografts with positive IRI had significant biochemical and hematological criteria suggestive of early graft dysfunction.

Conclusion: *Time-zero biopsies could represent an important tool in predicting EGD in LDLT.*

Keywords: *LDLT, time zero biopsy, IRI, EGD.*

Introduction

Liver transplantation (LT) represents the treatment of choice for end-stage liver disease. The shortage of transplant organs paved the way for the emergence of LDLT as a significant innovation in countries where the ever-increasing demand cannot be met by the scarce cadaveric graft pool or where cadaveric LT faces legislative, religious or cultural barriers.

Biochemical and hematological abnormalities observed in early graft dysfunction during the immediate post-transplant period have been associated with poorer graft outcomes. EGD is a manifestation of Graft IRI. In fact, several factors in the donor, recipient and operative technique, that are associated with poorer long-term outcomes, become already evident as soon as reperfusion of thegraft has occurred [1].Time-zero biopsies may predict adverse transplant outcomes. Severe IRI changes observed on time-zero biopsy may even herald early retransplantationneed [1]. Therefore, time zero biopsy assessment for IRI lends itself as an earlier and more accurate predictor of graft outcome than biochemical and hematological analysis.

The primary aim of this study was to evaluate the role of time-zero biopsies in predicting the EGD in LDLT.

Patients and Methods

Between January 2017 and September 2018, 72 patients underwent LDLT at both El-Manial Specialized Hospital andNHTMRI. The present study was conducted on 49 patients within our inclusion criteria. All grafts were harvested from adult living donors.

Correspondence Author:
Mansour D.A.
General Surgery Department, Cairo University, Egypt
Email: doaa.mansour@gmail.com

Inclusion criteria:

Donors' age ranged from 18-55 years, body mass index (BMI) <30kg/m2with compatible ABO & Rh blood grouping. A percutaneous ultrasound guided liver biopsy was routinely performed for potential donors.

Recipients were evaluated preoperatively using the Child-Pugh score and MELD score. In cases with HCC, Milan criteria were followed in the selection of patients.

Exclusion criteria:

Patients with actual GRWR less than 0.8 or who developed small for size syndrome.

Back table

Grafts were perfused with cold HTK solution through the PV on the back table.

Time Zero biopsy of the recipients

Technique: 1.5 x 1.5 cm sub-capsular wedge biopsies were obtained immediately after reperfusion and biliary anastomosis i.e. practically after completion of liver transplant.

PreparationHematoxylin and eosin staining of the samples fixed in 10%buffered formalin and embedded in paraffin was performed.

Examination:All specimens were reviewed by two pathologists who were blind to the patients' data. Histopathologic changes were evaluated separately and recorded based on mutual agreement. Specimens were examined for the following changes: neutrophilic infiltration, hepatocyte necrosis, hepatocyte ballooning degeneration, steatosis, hemorrhage and cholestasis.

Definitions and grading of histopathological changes

Neutrophilicinfiltrationwas defined as the presence of neutrophils within sinusoids as single cells or clusters and graded as follows:

0: no sinusoidal neutrophils.

1: mild infiltration.

2: moderate infiltration.

3: severe infiltration [2].

Hepatocellular necrosis: was defined as the presence of apoptotic hepatocytes based on the morphological criteria of cell shrinkage, chromatin condensation, and acidophilic bodies, classified as:

No: no necrosis (grade 0) or occasional loss (grade 1)

Yes: focal necrosis (moderate; grade 2) or confluent necrosis (severe; grade 3) [2].

Ballooning degeneration: defined as hepatocyte swelling and the presence of vacuoles in the cytoplasm, graded as present or absent [3].

Macro-vesicular steatosis: defined as the presence of a single large droplet displacing the nucleus and categorized as follows [4]:

Negligible: 0% - 4%

Mild: 5% - 33%

Moderate: 34% - 66%

Severe: > 67%

Hepatocellular cholestasis: was considered as hepatocyte discoloration by brown pigmented material and graded as present or absent [4].

Interpretation of histopathological findings in Time zero biopsy:

1- Neutrophilic infiltration and Hepatocyte necrosis:

It has been shown repeatedly that the degree of neutrophilic infiltration and hepatocyte necrosis are the most consistent indicators of IRI, therefore we used these two parameters in our definition of the presence or absence of IRI

2- Subcapsular changes:

Surgical manipulation of the liver induces subcapsular injury and inflammation and may be misinterpreted as IRI.The sub capsular biopsy allowed the examination of the deeper parenchyma avoiding this misinterpretation.

3- Other changes:

Although the degree of steatosis was discerned as a factor impacting graft outcome, we did not consider it as an IRI change. Similarly, hepatocyte ballooning, hemorrhage and cholestasis were correlated with graft outcome but not considered as IRI.

Grading of IRI:

Nil IRI: scanty infiltration of single neutrophils within the sinusoids without hepatocyte loss.

Mild IRI: Mild neutrophilic infiltrate (predominantly of single cells) with or without occasional detachment of single hepatocytes from the basement membrane or acidophilic bodies.

Moderate IRI:Presence of clustered (>5) neutrophilsassociated with any degree of hepatocyte necrosis or focal hepatocyte necrosis with neutrophilic infiltration.

Severe IRI: confluent or zonal coagulative hepatocyte loss associated with neutrophilic inflammatory infiltrate[1].

No or mild changes were defined as negative for IRI and referred to as group 1 while moderate or severe changes were considered positive for IRI and referred to as group 2.

Graft outcome

EGD was defined as the presence of at least one of the subsequent criteria: serum bilirubin exceeding 171 mmol/L on postoperative day 7, ALT greater than 2000 U/mL within the first 7 days post operation and INR at least 1.6 on day 7, with patent vascular anastomoses.

Statistical methods

Data were coded and entered using the statistical package SPSS (Statistical Package for the Social Sciences) version 24. Data was summarized using mean, standard deviation, median, minimum and maximum in quantitative data and using frequency (count) and relative frequency (percentage) for categorical data. Comparisons between quantitative variables were done using the non-parametric Kruskal-Wallis and Mann-Whitney tests. For comparing categorical data, Chi square (2) test was performed. Exact test was used instead when the expected frequency is less than 5. P-values less than 0.05 were considered as statistically significant.

Results

Preoperative data

Forty-nine recipients; 41 males (83.7%) and 8 females (16.3%) with a mean age of 46.5 (SD± 10.37) and a mean BMI of 25.75 (SD ± 2.69 kg/m2) were enrolled in our study. Their mean MELD score was 16.87 (SD ± 2.98) and the preoperative GRWR was 1.02 (SD ±0.17).

As regards co-morbidities, 17(34.7%) suffered from diabetes while 3 (6.1%) had hypertension. HCV-related cirrhosis was the indication of liver transplantation in 30 (61.2%) patients, HCC in 10 (20.4%) and other causes in 9 (18.3%) patients.

In terms of age, gender, BMI, allograft steatosis, MELD score, comorbidities and indication for transplantation both groups were equivalent (table1)

Table (1) Pre-operative donor and recipient parameters

Histopathological findings in time-zero biopsies

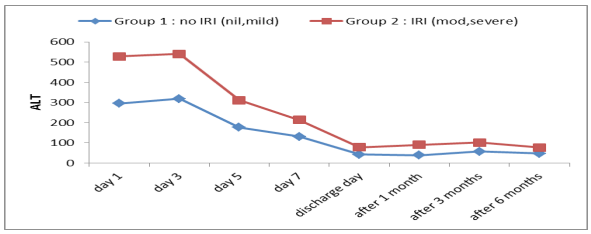
As shown in table (2).

Time-zero biopsies revealed negative IRI in 35 allografts (71.4%) (Group 1) and positive IRI in 14 allografts (28.6%) (Group 2).

Effect of IRI on Graft Outcome

EGD occurred in a total of 12 patients.

Recipients with positive IRI showed a significant rise in serum total bilirubin, ALT and INR in days 5, 7, 30 post-operative days ($p < 0.05$) compared to those with negative IRI as shown in figure (1,2,3). EGD was significantly associated with IRI on biopsy, with 50% of the severe IRI group met the biochemical and hematological criteria for EGD within the first 7 days. (Table 3) seven out of 14 versus 5 out of 35



Other non-IRI changes; grades of steatosis, cholestasis, hemorrhage and ballooning had no significant effect on graft outcome. (table3).

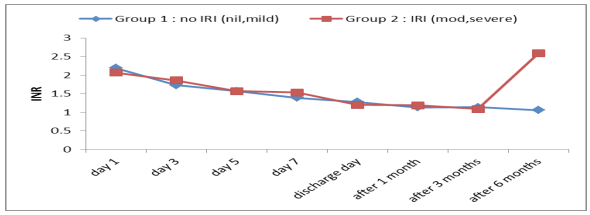


Table (2)Histopathological findings in time-zero biopsies

Histopathological finding		**Count (%)**
Hepatocyte necrosis	**Yes**	14(28.6%)
	No	35(71.4%)
Neutrophil infiltration	**No**	27(55.1%)
	Mild	19(38.8%)
	Moderate	3(6.1%)
	Severe	0(0%)
Steatosis	**Mild**	9 (18.3%)
	No	40(81.7%)
Cholestasis	**Yes**	8(16.3%)
	No	41(83.7%)
Hemorrhage	**Yes**	7(14.3%)
	No	42(85.7%)
Sub capsular hepatitis	**Yes**	28(57.1%)
	No	21(42.9%)
Ballooning	**Yes**	12(24.5%)
	No	37(75.5%)

Table (3): correlation between various zero biopsy changes with graft outcome

Histopathological changes Yes Count (%)		EGD		
		No	P value	
		Count (%)		
IRI changes	Y(group 2)	7(50.0%)	7(50.0%)	0.023
	N (group1)	5(14.3%)	30(85.7%)	
Cholestasis	Y	1(12.5%)	7(87.5%)	0.660
	N	11(26.8%)	30(73.2%)	
Hemorrhage	Y	4(57.1%)	3(42.9%)	0.051

Discussion

IRI represents a common complication of hepatic surgery and transplantation. Its impairment of liver function delays recovery and associated with increased morbidity and mortality. Hence, IRI may significantly affect clinical outcomes [1]. This created the need for an earlier and more precise predictor of IRI than the currently available biochemical and hematological parameters. Time-zero biopsies may fulfill this function. Yet, there is no available consensus as regards the value of time-zero biopsies as a predictor of EGD. In fact, several previous studies suggest that the IRI grading during time-zero biopsies significantly correlates with PNF, EGD, acute rejection, and biliary complications [2, 6, 7]. Yet, some other studies confirm this value of time-zero biopsies [8,9,10].

The aim of our work was to establish the value of time-zero biopsies as a reliable determinant of IRI and graft outcome.

In our series, we obtained subcapsular wedge biopsies instead of tru-cut needle biopsies to avoid bleeding although **Ali et al.**[1] preferred Tru-cut specimens because surgical manipulation of the liver may cause subcapsular injury and inflammation which may be confused with IRI. To avoid such misinterpretation, only the deeper parenchyma of specimens was examined. Superficial subcapsularneutrophilic infiltration was designated as a sign of surgical hepatitis and not considered as IRI. **Kocbiyiket al.**[7] used the same technique.

The 49 specimenswere examined by 2 histopathologists.In fact, correlating these findings with EGD showed that no histopathological criterion reached a statistically significant p value except neutrophilic infiltrate and hepatocyte necrosis ($p = 0.023$). This finding confirms the validity of our definition of IRI in which we considered only these 2 factors for the grading of IRI. This is largely in concordance with several other studies [1, 2,7,11] which concluded that the degree of IRI in the post-reperfusion biopsies is mainly reflected by the degree of neutrophilic infiltrate and hepatocyte necrosis.

Abraham et al.[6] suggested hepatocyte swelling as a predictor of moderate to severe rejection. He stated that centrilobular hemorrhage, hepatocyte swelling, and centrilobular necrosis can be regarded as important predictors of primary graft failure. Yet, **Shahbaziet al.**[4] found that ballooning degeneration, bilirubinostasis, portal congestion and cholestasis showed no significant

correlation with early postoperative outcome.

In our series, 14 cases (28.6%) revealed criteria of positivity for IRI i.e. moderate or severe changes while 35 (71.4%) specimens were free or demonstrated mild changes and considered negative for IRI. We analyzed the effect of IRI positivity on graft outcome. For that purpose, hepatic enzyme pattern and synthetic liver functions were compared in both groups. We found that the patients in the positive IRI group experienced a significant rise in total and direct bilirubin, ALT, AST and INR. The elevation of liver enzymes (ALT, AST), the cholestatic pattern (Bilirubin) and the impairment of synthetic function (INR) reached statistical significance on POD 5, 7 and after 1 month of transplantation. Actually, 7 (50%) out of the 14 cases positive for IRI met the biochemical and hematological criteria for EGD within the first 7 days. In the negative IRI group comprising 35 patients only 5 (14.3%) patients developed diagnostic criteria for EGD which was statistically significant.

Ali et al.[1]reportthat EGD occurred in 21.7% of their cohortandwas significantly associated with IRI. Similar to our study, more than half of the group displaying severe IRI met the laboratory criteria for EGD within the first 7 days. They conclude that IRI represents one of the most important causes of EGD.

The biochemical profile abnormalities faced in our study are consistent with **Gaffey et al.**[11]and**Shahbazi et al.**[4]who investigated the degree of correlation between zero biopsy findings and early postoperative laboratory parameters.Shahbazi et al. [4] found that there was a significant correlation between the presence of apoptotic bodies indicating hepatic necrosis and transaminases' elevation in the early post-transplant period. They concluded that these changes were a reflection of hepatocellularinjury caused by warm ischemia. On the other hand, they demonstrated a significant correlation between neutrophilic aggregates and an elevated total bilirubin which they considered a reflection of endothelial cell damage caused by cold ischemia. They conclude that apoptotic bodies found on zero biopsy represents a surrogate marker of IRI caused by warm ischemia associated with hepatocellular alterations while neutrophilic aggregates reflect IRI caused by cold ischemia presenting with a cholestatic pattern on liver function tests. Several other studies suggest time-zero biopsy IRI grading as a predictor of PNF, acute rejection, EGD, and biliary complications[2, 6, 7].

Conversely, there are several studies that did not demonstrate any significant association between IRI grade and early graft outcome [8,9,10].

As a result of our analysis a key question arises: Is time-zero biopsy justifiable in every hepatic transplant?

Our analysis demonstrates that moderate IRI influences graft outcomes, whereas milder forms have no severe impact, but why is not clear. Presumably, regardless of the particular combination of donor and recipient factors that trigger an IRI response, if severe enough, IRI causes either parenchymal or biliary liver damage that is not recoverable and results in progressive graft damage. In contrast, the damage associated with milder forms of IRI is reversible. The precise pathway is incompletely understood.

Notwithstanding, our results highlight that it is possible to identify those patients with more severe IRI early and thus those patients identified may benefit from therapies that decrease the consequences of IRI. Moreover, it might explain prolonged post-OLT cholestasis and avoid unwarranted treatment of suspected rejection.

Thoracoscopic Decortication versus Open Decortication in Chronic Empyema

Mohamed Hassan[1], Tarek Mohsen[1], Tamer Farouq Siam[1], Samy Amin[1], Waleed Adel[1]

[1]Cardiothoracic surgery Department, Faculty of Medicine, Cairo University, Cairo, Egypt

Abstract

Background: Many recent reports have encouraged the use of VATS in the management stage II empyema. The technical difficulty caused by pleural adhesions, is not considered an obstacle hindering the procedure anymore. Furthermore, thoracic surgeons around the world are increasingly trying to manage patients with stage III empyema solely using VATS. This current study aims to compare the results of surgical decortication for empyema using the VATS and thoracotomy approaches. Patients and Methods: This prospective comparative non-randomized clinical study was carried out in the Department of Cardiothoracic Surgery of Kasr el Ainy faculty of medicine Cairo University from September 2016 till May 2018. The study encompassed 60 patients who had empyema and scheduled for surgery. The study patients were divided into 2 matching groups. Group A (thoracoscopic decortication), and group B (open decortication). All were studied for early outcome. Results: In the VATS group (group A) the conversion rate to open thoracotomy was 33.3%. The mean operative time was similar in to the thoracotomy group (group B). The successful achievement of fully expanded lungs was higher in the VATS group (93.3% vs 80%, p=0.129). VATS also showed less pain (2.27 ± 1.64 vs 4.27 ± 2.05, p=0.001*), less wound complications (0% vs 13.3%, p=0.038*), and shorter hospital stay (5.27 ± 3.90 vs 8.07 ± 5.36, p=0.003*). Conclusion: We concluded that VATS is safely feasible in the organized, late stage III pleural empyema, and thus should be considered as the preferred approach when addressing chronic empyema, as long as complete re-expansion of the lung can be achieved. Moreover, conversion to the open technique should be done whenever necessary, to avoid undesired postoperative morbidity.

Keywords: *Empyema, VATS, Decortication.*

Introduction

Proper therapy of pleural infections is stage-dependent with surgery being considered whenever antimicrobial therapy and fluid drainage solely do not achieve adequate infection control and re-expansion of the lung [1]

In intermediate stage II empyema, it has been appraised controversially, if surgical treatment is more efficient than prolonged drainage therapy with/out intra-pleural fibrinolysis [2,3].

Corresponding author:
Mohamed Hassan
Cardiothoracic surgery Department, Faculty of Medicine, Cairo University, Cairo, Egypt

However, it is widely accepted, that VATS is the ideal option, once decision for surgery has been taken [2].

VATS

For evacuation of loculated fluid components and for debridement of the pleural cavity has proved to be safe and feasible with widely acceptable peri-operative results and long-term outcomes at least equivalent when compared to the open approach by thoracotomy in an intermediate stage II pleural empyema or even better [2,3].

In contrast, in late stage III empyema, the need for surgery to control the disease is undebatable; however, it is the surgical approach (thoracotomy versus VATS) which has remained disputable. Till recent years, the feasibility of complete decortication of the lung by means of VATS has been questionable, even by experienced thoracic surgeons. In fact, decortication of the visceral

pleura allowing the lung to fill up the pleural cavity completely is the by far most important achievement sought in empyema surgery. So far, the evidence for the feasibility of the VATS approach in organized stage III pleural empyema is still doubtful.[1,2].

The majority of studies include mixed populations with both stage II and stage III pleural empyema, only the vast minority described a study group of the isolated late organized stage (III) pleural empyema. [2,4,5,,6].

Since the advancement of pleural empyema from an earlier to a later stage is fluent, stratification by stage is subjective, depending on the surgeon's judgment and experience [1].

Patients and Method

This prospective comparative non-randomized clinical study was carried out in the Department of Cardiothoracic Surgery of Kasr Alainy faculty of medicine Cairo University from September 2016 till May 2018 after obtaining the approval of the local ethical committee and written informed patient consent. The study encompassed 60 patients who had pleural space infection (empyema) and scheduled for surgical intervention. The study patients were divided into 2 matching groups. Group A (thoracoscopic decortication), group B (open decortication) and group. All were studied for early postoperative outcome. Patients will be evaluated preoperatively and postoperatively according to inclusion-exclusion criteria.

Inclusion criteria:

All Patients with empyema requiring surgical intervention operated by Cairo university medical staff members.

Exclusion Criteria

Patients who responded to tube thoracostomy treatment with or without fibrinolytic agents; Patients with very poor general condition, or not fit for surgery; Associated or post-resection empyema

Patients were divided into 2 groups according to the procedure scheduled for (Open or thoracoscopy). All of patients underwent surgery for empyema: Group A: 30 patients underwent thoracoscopic decortication for stage III. (the cases that were converted to open thoracotomy were excluded from the group) Group B: 30 patients underwent open surgical decortication for stage III. Comparative study was done between Group A and group B to evaluate the minimal invasive surgery in management of stage III.

A) Preoperative Parameters:

1) History taking: A detailed history was taken from each patient including his/her age, symptoms of the disease (including fever, dyspnea, cough and chest pain), and duration of the symptoms and other comorbidities. 2) Clinical Examination: Routine general examination and local chest examination including inspection, palpation, percussion and auscultation was done in all patients. 3) Investigations: Laboratory Investigations in the form of Routine preoperative labs including hemoglobin, coagulation profile, liver and kidney function tests, Total leucocytic count (TLC), C-reactive protein (CRP) and Culture and sensitivity for pleural fluid and/or sputum, 12 lead electrocardiogram to evaluate any present ischemia or anomalies in rate or rhythm, Radiological Examination in the form of plain chest x-ray (PA and lateral views) erect position after full inspiration. Computed tomography (CT) on the chest and other investigations needed for individual cases related to comorbidities. Preoperative Counselling, in the preoperative visit prior to surgery, a brief explanation of the steps of the surgery, with possible early and late postoperative complications were explained to the patients.

B) Operative:

Choice of operation (VATS or Open), operative time (minutes). Whole 3 ports VATS was utilized for group A.

C) Postoperative:

Clinical and radiological assessment of lung expansion using chest X-ray and/or computed tomography (CT) scans (N.B. Procedure success: Our criteria for successful outcome was: A fully re-expanded lung without persistent space, clear drainage of <100 ml/24 h, and cessation of air leak); Postoperative pain: used the numeric rating scale (NRS) which is a segmented numeric version of the visual analog scale (VAS) in which a respondent selects a whole number (0–10 integers) that best reflects the intensity of their pain (7); Postoperative need for mechanical ventilation Postoperative need for Intensive care unit (ICU); Duration of chest tube (days); Wound complications; Postoperative hospital stay: calculated the postoperative

stay of the patient in our department to recover from surgery in days; Mortality: Described as in hospital or 30- days within surgery.

Results

Regarding preoperative analysis, the two groups we reasonably matched regarding the age, sex, prevalence of the comorbidities and the diseased side.

In both groups the majority of the cases, pneumonia was the leading cause of empyema, in the form of 24 cases (80%) and 22 cases (73.3%) in group A and group B respectively.

However, the remaining 6 (20%) patients in group A were caused by infected posttraumatic hemothorax while in Group B only 2 (6.7%) cases were posttraumatic, 2 cases (6.7%) were caused by spread from sub-phrenic abscess, and 4 cases (13.3%) due to lung abscess. This demonstrates a significant statistical difference (p=0.044*). Open technique was selected in these cases specifically to deal with underlying pathologies expected to be found easily.

Regarding the symptoms of the disease, 20 patients (66.7%) in each group had constitutional symptoms. Also, 28 (93.3%) patients in group A complained of dyspnea or cough while 2 cases (6.7%) complained only of constitutional symptoms and discovered the pathology upon suspicion by radiological investigations. In group B all patients (100%) complained of dyspnea, chest pain and/or cough. More importantly the mean duration of the symptoms was 48.87 ± 19.43 days in group A while in group B the mean duration was 45.53±31.49 days. (p=0.164) When we observed the results of our patients' cultures we could identify pathogens only in 14 (46.7%) and 10 (33.3%) in group A and group B respectively. The most commonly isolated pathogen in group A was Klebsiella (20%), followed by MRSA (13.3%), while in group B Klebsiella and pseudomonas were equally leading (13.3%). the operative times in our study, showed no significant difference between the two groups. In our VATS decortication group (A), 15 patients (33.3%) needed to be converted to open procedure (out of 45 patients) (12 patients to facilitate more thorough decortication, 2 patients for bleeding difficult to control with such a limited access, and in one case due to limited vision).

Observing postoperative pain in our 2 groups using the NRS, Group A had the upper hand showing significantly less pain (2.27 ± 1.64) than group B (4.27 ± 2.05). (p=0.001).

Regarding wound complications, events occurred in 4 patients in group B (13.3%), compared to none in group A (p=0.038). most of the patients in both groups had successful surgery achieving fully expanded lungs (93.3% in group A and 80% in group B), with exception of 2 patients (6.7%) had residual pouches in group A, and 6 patients (20%) in group B. Yet there was no significant difference (p=0.129). The patients with such a morbidity of residual loculations, partial collapse and persistent air leak were discharged with an empyema tube with a one-way valve for periodic reassessment and management later. The postoperative hospital stay showed a statistically significant variation between group A (5.27 ± 3.90) and group B (8.07 ± 5.36). (p=0.003). The prolonged air leak (more than 7 days) was one of the most common complications of open decortication, and significantly related to the longer chest tube duration, and postoperative hospital stay.

Discussion

Regarding preoperative analysis, the two groups were reasonably matched regarding the age, sex, prevalence of the comorbidities and the diseased side.

The most commonly isolated pathogen in group A was Klebsiella (20%), while in group B Klebsiella and pseudomonas were equally leading (13.3%). However, the results of these cultures cannot reflect the main pathogen(s) responsible for the pleural infections in the majority of cases. As the early use of antimicrobial therapy may render the cultures negative giving us the falsely negative results. Moreover, the positive cultures may highlight the highly virulent drug resistant strains appearing in cultures in spite of using antibiotics empirically.

When we observed the operative times in our study, there was no significant difference between the two groups, other studies also showed similar results, and found no significant difference between the 2 groups. [8,9].

In our VATS decortication group (A), 15 patients (33.3%) needed to be converted to open procedure other studies that focused on thoracoscopy in stage III, showed conversion rates close to ours, for example Shahin et al, conversion rate was 19%, Lardinois et al, 44%, and Waller et al, was 41.7%. [5,10,11]. Moreover, most recent studies expressed low conversion rates in stage III empyema, as 4.5 % [9] and 9.2% [12], denoting that these institutes have passed the learning curve. The aggressive pathology in our community, highly virulent organisms and most importantly the late presentation of our patients (might be due to the poor socioeconomic status), and the late diagnosis and referrals from the treating physicians, render the empyema showing very well-organized thick peels, very hard loculations and adhesions. This makes it hard sometimes to handle with minimally invasive

technique and might attribute to our higher conversion rates.

Group A had the upper hand showing significantly less postoperative pain This result confirms the superiority of VATS over thoracotomy regarding the postoperative pain, which is one of the pillars of our study. Other studies conforming with our results included Chan et al. (p=0.041) and Cardillo et al. (p<0.001). ([13],[14]). Less postoperative pain, entails less postoperative pain management (including drugs, intercostal blocks or even epidural analgesia), and facilitates almost pain free chest exercise which assists lung re-expansion and early recovery, and consequently shorter hospital stay.

Concerning the direct outcome of the operation, and the assessment of the postoperative lung expansion, most of the patients in both groups had successful surgery achieving fully expanded lungs. The patients with residual loculations, partial collapse and persistent air leak were discharged with an empyema tube with a one-way valve for periodic reassessment and management later.

Our results regarding the VATS group are close to Drain et al, studying VATS in advanced empyema, chest radiography at 6 weeks after surgery confirmed full lung expansion and resolution of pleural collection in 94% of patients[4]. Similarly, Marks and colleagues, reported that the success rate in their VATS group was 95.1% (15). Moreover, Chung and colleagues, reported a success rate of 92.9 %., [16].

The postoperative hospital stay showed a statistically significant variation between the 2 groups(p=0.003). The prolonged air leak (more than 7 days) was the most common complication of open decortication, and significantly related to the longer chest tube duration, and postoperative hospital stay.

In a meta-analysis done on similar studies comparing VATS and open techniques in management of empyema, results expressed also significant difference regarding both, chest tube duration and postoperative hospital stay (p=0.004).[17].

Conclusion

From Based on the results of our present study, we can conclude that VATS is safely feasible in organized, late stage III pleural empyema, and thus should be considered as the preferred approach when addressing chronic empyema, as long as complete re-expansion of the lung can be achieved. Moreover, conversion to the open technique should be done whenever necessary, to avoid undesired postoperative morbidity. Conversion is considered in most of the institutions as a complementary procedure and not failure of VATS.

Abstract

Background: Multiple sclerosis (MS) is a chronic disease in the central nervous system which causes a number of physical symptoms including impairments of motor functions. Purpose: to investigate the effect of low frequency repetitive transcranial magnetic stimulation (LF-rTMS) on motor functions in multiple sclerosis patients. Methods: Thirty medically stable remitting relapsing MS patients aged between 20-40 years were randomly assigned into two groups ("A" study and "B" control). Both groups were treated with a selected physical therapy program consisting of graduated active exercises, balance and gait training, but only group "A" received (LF-rTMS) ipsilateral to the weaker lower limb, five times per week for two consecutive weeks. Isokinetic dynamometer measurements including peak torque (PT), peak torque/ body weight (PT/BW), time to peak torque (TPT), total work (TW) and average power (AP) of knee flexors and extensors plus lower extremity functional performance were measured and compared for both groups before and after intervention using biodex isokinetic dynamometer and Five Repetition Sit to Stand Test (5STS) respectively. Results: Comparison of the mean values of isokinetic dynamometer measurements post-treatment between both groups showed significant difference of (PT, PT/BW, TPT) in favor of group A($P \leq 0.05$) but no considerable variations were reported among both groups concerning (TW, AP) ($P > 0.05$). Comparison of the mean values of (5STS) post-treatment between both groups showed significant difference in favor of group A ($P \leq 0.05$). Correlation results revealed significant correlation between the tested Isokinetic dynamometer measurements and (5STS). Conclusion: low frequency repetitive transcranial magnetic stimulation could improve motor functions and subsequent functional performance in multiple sclerosis patients.

Key words: *Transcranial magnetic stimulation, motor functions, functional performance*

Introduction

Multiple sclerosis (MS) is a predominant disease of the central nervous system (CNS). This disease has a diffusion of 1 per 1000 persons in the United States.

Correspondence Author:
Abdelaziz Abdelaziz Elsherif

E mail: Abdelaziz.elsherif@cu.edu.eg

There are a predestined 2.5 million persons alive with MS worldwide and about 400 000 cases in the United States [1].More recent epidemiological research observed that a direction of greater diffusion and happening of MS worldwide [2].

Multiple sclerosis generally starting with attacks of multifocal inflammation in the CNS and this is properties of relapsing-remitting MS (RRMS). The inflammation can cause demyelination and transaction of axons. There are neurodegenerative processes which lead to neuroaxonal loss (ie, atrophy) that can happen at the beginning of the disease activity, but are more

distinguished through the final path of the disease [3,4].

The central nervous system damage caused by multiple sclerosis accumulates over time and results in the progression of neurological disability [5].An early symptom of MS is weakness on one side of the body, particularly in the lower limbs [6]. Due to this unilateral weakness, people with MS (PwMS) often have a more and less-affected side of the body which lead to a different forms of asymmetries in the measurements of force, energy, muscle activity, and limb loading [7-10].

Repetitive transcranial magnetic stimulation (rTMS) is a process of noninvasive amendment of brain activity, greatly utilized in different psychiatric and neurologic cases. It's beneficial effects due to activation of brain changes in disease-specific cortical areas, which is controlled by groups of magnetic pulses that penetrate brain tissue and depolarize the affected neurons [11]. Repetitive transcranial magnetic stimulation is competent in bringing long-lasting cumulative plastic alterations of cortical mission not only in the stimulated cortex but also in the distant interconnected regions that outlast the stimulation duration [12].

Repetitive transcranial magnetic stimulation can cause alterations in the structural and molecular characteristics of neurons. Repetitive transcranial magnetic stimulation can cause alterations interfering with the ability of neurons to induce distinct forms of plasticity beyond the stimulation duration[13,14] . Evidence is increasing around the rTMS induced amendment of cerebral blood flow, glucose metabolism, and neuronal excitability in the stimulated region in addition to the interconnected brain areas. After-influences of rTMS may appear as alterations in synaptic effectiveness which called long term potentiation (LTP) and long-term depression (LTD). The equilibrium among "LTP/LTD" phenomena underlie number of processes happening in the brain as education and the memory [15].

This study was designed to investigate the effect of low frequency repetitive transcranial magnetic stimulation (LF-rTMS) on motor functions in multiple sclerosis patients.

Materials and Method

Area of study and sampling

The study used an open labeled, randomized controlled design. Intervention procedures for the enrolled patients consisted of five consecutive days per week for two weeks. Each patient in the study group(GA) was treated with(LF-rTMS)on motor cortex(hot spot) ipsilateral to the most affected lower limb(weaker lower limb) plus selected physical therapy program (Graduated active exercises, balance and gait training) while each patient in the control group (GB) was treated only with the same physical therapy program.

Thirty patients with MS from both sexes were recruited with the following criteria prior to their enrolment in the study between October 2018 to April 2019: definite diagnosis of RRMS fulfilled the Revised McDonald's criteria for diagnosis of MS 2010 [16], score of 2.0 to 4.0 on the Expanded Disability Status Scale (EDSS), age ranges from 20 – 40 years old, all patients are in the remission period, last attack occurs at least since two months, all patients are receiving the same medical treatment, patients are medically stable, ability to understand and follow instructions, Patients are free from any secondary complications such as contractures and deformities. This study was conducted in the transcranial magnetic lab of the Clinical Neurophysiology Unit, the Outpatient Physical Therapy clinic and Department 26, Faculty of Medicine, Cairo University.

Isokinetic dynamometer measurements:

All the patients were evaluated by using Biodex system III (Biodex, Shirley, NY) as regarding peak torque (PT), peak torque/ body weight (PT/BW), time to peak torque (TPT), total work (TW) and average power (AP) of knee flexors and extensors for the weaker lower limb before and after the treatment period. From sitting position with 90º hip and knee flexion the trunk, pelvis and thighs were stabilized using straps, in accordance with the equipment instructions. The rotational axis of the dynamometer was aligned with the transverse knee-joint axis and attached to the lower leg by a length adjustable lever arm three cm proximal to medial malleolus. After a standardized instruction (to contract as strongly and fast as possible) and two familiarization attempts, the subjects performed five maximal isokinetic concentric contractions at angular velocity (120°/second) for the knee extensors and flexors from 90º knee flexion to full extension(0º) and vice versa respectively.

5 repetition Sit to stand test (5STS):

The 5STS test is a measure of the time taken to complete five repetitions of the STS movement and it's a valid measure of lower extremity muscle strength of the

most affected leg and balance performance in patients with MS[17].The assessor explained how the participant should move from a sitting towards a standing position five times and demonstrate the test to the patients practically. From sitting position on standard chair with both arms crossed against the chest, the patients were asked to stand up and sitting down as fast as possible and the examiner using a stop watch to calculate the time elapsed to complete the five repetitions. The tests should be performed as fast as possible and two attempts separated by a 3 min break were given and the faster of the two attempts was used.

LF-rTMS intervention procedures:

The Magstim Rapid2 magnetic stimulator system (Model P/N 3576-23-09, Magstim Company, USA) was used to deliver 1-Hz stimulation according to current safety recommendations at 90% of the resting motor threshold (RMT) to the "hot spot" of the primary motor cortex (M1) corresponding to the leg area (0 to 2 cm lateral to the vertex) in the ipsilateral hemisphere to the weaker lower limb via a 70-mm figure- 8 coil. Each rTMS session consisted of 900 pulses. Determination of the (RMT) was done by visual observation of muscle twitch [18].

Statistical Analysis

The obtained data were collected and statistically analyzed using the statistical package SPSS version 24. Paired t-test was used for comparison of means pre and post treatment within each group. Unpaired t-test for comparison of means pre and post treatment between the two groups. Chi square ($\chi 2$) test was used for comparison of gender and Mann-Whitney test was used for comparison of EDSS between the two groups. Spearman correlation coefficient was used to correlate percent of improvement between variables in study group. Finally,($P \leq 0.05$)was considered significant.

Results

Patients' demographics and clinical characteristics

The results of the current study revealed no significant differences between both groups in patients' demographics and clinical characteristics regarding the age, weight, height, body mass index (BMI), EDSS and gender ($P > 0.05$) (Table 1).

Table (1): Patients' demographics and clinical characteristics

Variable		Study group	Control group	P- value
Age (years) (Mean±SD)		32.20± 6.72	31.13±7.32	0.6807
Weight(kg) (Mean±SD)		66.07±9.58	71.47±11.99	0.1839
Height (m2) (Mean±SD)		165.9±5.54	168±5.916	0.3316
BMI (kg/m2) (Mean±SD)		24.05±3.66	25.32±3.98	0.3701
Sex	Male (N(%))	5(33.3%)	7(46.67%)	0.456
	Female (N(%))	10(66.7%)	8(53.33%)	
EDSS (Median)IQR))		2(1)	3(2)	0.6558

BMI: Body mass index, SD: standard deviation, IQR: interquartile range, P: probability, $P < 0.05$: Non-significant.

Isokinetic dynamometer findings for knee flexors and extensors:

The mean values of isokinetic dynamometer parameters (PT, PT/BW, TPT, TW, AP) pre-treatment in (GA) and (GB) showed insignificant difference ($P > 0.05$). Comparison of the mean values of isokinetic dynamometer parameters (PT, PT/BW, TPT, TW, AP) post-treatment between groups A and B showed significant difference of (PT, PT/BW, TPT) ($P \leq 0.05$) but no considerable variations were reported among both groups concerning (TW, AP) ($P > 0.05$) (Table2), (Table3).

Table (2): Isokinetic dynamometer findings for knee flexors:

Knee flexors	Pre treatment				Post treatment			
	Study group (Mean±SD)	Control group (Mean±SD)	t-value	P-value	Study group (Mean±SD)	Control group (Mean±SD)	t-value	P-value
Peak Torque	19.67±5.038	19.53±9.724	0.04715	0.9627	31.93±9.699	24.47±8.991	2.187	0.0373*
P.T/B.W	29.4±9.84	27.87±11.22	0.398	0.6937	43.2±14.91	31.07±10.75	2.556	0.0163*
Time to P.T	341.3±153.9	364±165.7	0.3882	0.7008	214.0±51.93	281.3±88.95	2.532	0.0172*
Total Work	62.67±20.05	54.07±15.46	1.316	0.1989	95.27±37.51	74.13±24.83	1.82	0.0795
Average Power	15.87±3.796	17.00±6.601	0.5764	0.5689	29.2±13.41	22.33±5.066	1.855	0.0742

SD: standard deviation, *(P ≤0.05): Significant.

5 repetitions Sit to stand test (5STS):

The mean values of (5STS) pre-treatment in study and control groups were (15.5±1.803 and 15.93± 2.086 seconds) respectively and There was no significant difference (P =0.5476). The mean values of (5STS) post-treatment in study and control groups were (12.67±1.566 and 14.13±1.457seconds) respectively and There was significant difference (P =0.0129).

The correlation between percent of improvement of knee flexors and extensors Isokinetic variables and (5STS) in study group (GA):

The value of the Spearman correlation coefficient (ρ) between percent of improvement in Isokinetic variable (TPT) and (5STS) revealed significant positive correlation. The value of the Spearman correlation coefficient (ρ) between percent of improvement in Isokinetic variables (PT,PT/BW,TW, AP) and (5STS) revealed significant negative correlation (Table4).

Table (3): Isokinetic dynamometer findings for knee extensors:

Knee extensors	Pre treatment				Post treatment			
	Study group (Mean±SD)	Control group (Mean±SD)	t-value	P-value	Study group (Mean±SD)	Control group (Mean±SD)	t-value	P-value
Peak Torque	24.73±11.88	26.8±9.821	0.519	0.6076	42.8±13.51	33.4±7.119	2.384	0.0242*

Discussion and Conclusion

In the current study EDSS was used as an inclusion criteria to assess, classify, describe the severity and progression of the condition in PwMS, Its suitable to monitor disease progression and considered the most widely used tool to measure disease outcomes in clinical trials [19].

Isokinetic dynamometry is used in this study which is an objective and reliable tool for assessing muscle strength in PwMS. Muscle strength in these patients is impaired compared to healthy controls, particularly when performing moderate to fast concentric contractions [20].

Expanded disability status scale scores between 2.0 and 4.0 and all patients have the ability to understand and follow instructions were an important parts of the patients' selection criteria to ensure that all patients had the physical and cognitive prerequisites to perform isokinetic dynamometer testing procedures.

Application of LF-rTMS on the primary motor "hotspot" of the ipsilateral hemisphere to the weaker lower limb in multiple sclerosis patients in this study revealed significant improvement of muscle strength of knee flexors and extensors represented by isokinetic dynamometer measurements (PT, PT/BW,TPT) and functional performance represented by 5STS test time in study group(GA) compared to control group(GB). This findings might be due to the inhibitory effect of the LF-rTMS exerted upon the excited less affected hemisphere, that consequently could regain the cortical balance between both hemispheres and facilitation of beneficial functional reorganization in the most affected hemisphere. These findings agree with number of previous studies [21,22,23].

There was a significant correlation between percent of improvement of lower limb Isokinetic variables(PT, PT/BW,TPT,TW,AP) and (5STS) in the study group which might represent the improved muscle strength parameters and the subsequent improvement of functional performance and its reflection on activities of daily living. These findings agree with number of previous studies [17,24].

Further studies are needed to investigate the long term effect LFrTMS on motor functions in RRMS also to precisely identify the mechanism of its efficacy, neuroimaging modalities such as diffusion spectrum imaging or functional magnetic resonance imaging might be used.

The current study revealed that Lf-rTMS could improve motor functions and subsequent functional performance and activities of daily living in multiple sclerosis patients.

Abstract

This study aimed at evaluating the efficacy and safety of arthroereisis of subtalar joint using subtalar sinus tarsi implant in the cure of flexible flatfoot in pediatric population. Materials and methods: A prospective case series conducted on 30 feet with flexible flatfoot deformity. Their follow up was for 10 to 20 (15±3.5) months. Clinical assessment was done using scoring system (AOFAS), Radiological assessment was done using TNA& TMA to asses talonavicular coverage and talar first metatarsal angle. Results: The mean functional (AOFAS) Ankle-Hind foot score improved from 64.3±8.26 (43-77) preoperatively to 89.23±5.41 (77-98) postoperatively at last follow up (P value<0.001) using paired t-test as a significance test for evaluation of pre and post-operative AOFAS score. Our results showed median decrease in TMA is 15º (range: 4º to 29º) preoperative to 4º (range : 0º to 17º) at the final follow-up, while TNA showed median decrease from 18º (range : 12º to 45º) preoperative to 5º(range: 1ºto 44º) at the final follow up. The average decrease in both angles was statistically significant (P<0.001). Post-operative complications were detected in 5 patients (16.6%). Two patients (6.6%) developed subclinical infection.Two patients (6.6%) developed severe pain at sinus tarsi (sinus tarsitis) following surgery. One patient (3.3%) developed reactional synovitis followed by loosening of the implant and then extrusion after 3 months Debridement and reinsertion of smaller sized implant have been done. Conclusion: Subtalar arthroereisis using subtalar arthroereisis implant is suitable for the management of flexible, mild to moderate planovalgus foot deformity.The practice can be carried out in arrangement with other surgical procedures for the adjustment of severe cases.

Key Words: Subtalar arthroereisis, Flexible, Flat Foot Deformity.

Introduction

Flatfoot is a progressive congenital or acquired deformity described by plantar medial rotation of the talus, sagging of medial arch, and supination and abduction of the forefoot. There is a shift in the load from lateral column to the medial column, which may cause the medial arch to flatten further.

[1] Flexible flatfoot is described to as "collapsing pesplanovalgus" in which collapsing refers to the flexibility of the deformity.[2]A vast majority of flexible flatfeet can be treated conservatively, but the worst deformities may require surgical intervention to reconstruct the foot deformity. Several surgical methods have been illustrated as lengthening of tendon and muscle, arthroereisis, arthrodesis and osteotomies. [3]

Arthroereisis was extended since many decades, which includes insertion of different shaped implants underneath the talus for preserving inversion without excessive eversion. The function of implants are to chunk the talus displacement at forward or downward or medial aspect, thus permitting normal motion of subtalar joint with obstacle the unnecessary pronation.[4]Different implants have been expanded to this procedure, which Volger classified into 3 groups: self-locking, axis altering and impact blocking device of which the self-locking implants are the most familiarly technique used currently. [5]Various self-locking implants have a threaded intend

Corresponding Author:
Ahmed Abdel Azeem El Desouki
Orthopedic Department - Faculty of Medicine - Cairo University, Egypt. MMA-ortho@hotmail.com

with a cylindrical or conical shape can be used.[6]These implants are situated into the sinus tarsi and adjusted toward the tarsal canal, introduced similar to a screw with the threads be set to connect the sinus tarsi floor, the talar neck plantarlateral surface, the leading border of the talar body and the ligament of interosseous talocalcaneal.[7]

Materials and Method

2.1. Patients

Between 1st July 2015 and 1st January 2017, we treated 30 pediatric symptomatic flexible flat feet. The mean follow up was 10 to 20 (15±3.5) months. There were 18 female(60%) and12 male (40%). The age ranged from 8 to 13 years, with a mean age 11.7±1.6 years old patients with pathologic ligamentous laxity were not included in this study.

2.2. Surgical technique

The patient is placed supine on the operation table. The affected extremity is prepared and draped sand bag below gluteal region of operated side. A pneumatic tourniquet is used. A 1.5 to 2cm oblique incision following tension lines of the relaxed skin over the sinus tarsi at a distance of 1 cm anterior and plantar from the distal aspect of the fibula in the "soft spot" just proximal to calcaneus anterior process. Make the dissection along the course of the nerve to avoid inadvertent transection of the intermediate dorsal cutaneous nerve (a branch of superficial peroneal nerve) (Figure 1). The sinus tarsi is debrided to get rid of its fatty tissue contents with rich nerve endings.

Figure. 1. Intraoperative radiograph show oblique incision following the relaxed tension lines over the sinus tarsi.

A guide wire was quietly introduced into the two sinus tarsi portions, then assembly sure to its angle insertion at the similar direction that is anterior distal-lateral to posterior-proximal-medial. A properly positioned guide wire will result in tenting soft tissue on the medial aspect of the foot just superior to the posterior tibialis tendon medially and anterior and slight inferior to medial malleolus (Figure 2) . A cannulated soft tissue dilator is then introduced to dilate the tarsal canal and then removed

Figure.2. A guide wire inserted into both portions of the sinus tars.

The dilator, sizers, insertion tools, trials and implants are cannulated for ease of insertion and placement .Sizing is begun with six millimeter instrument Sequential sizers in 2 mm increasments are then used until desired amount of restriction of subtalar joint movement is achieved. Hindfoot motion and position are then assessed to make sure a suitable correction.The maximum amount of calcaneal eversion with the correct sizer in place, should be approximately 2 to 4 degrees (Figure 3).Once the best sizer is identified, the AP radiograph is checked. On AP fluoroscopy the leading edge of the implant should be within middle third of the talus.

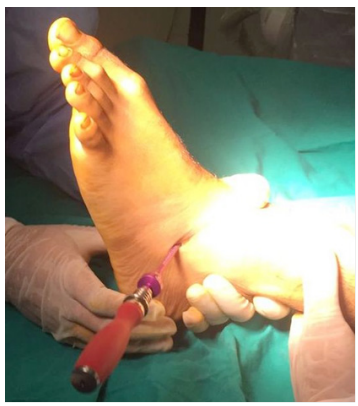

Figure3: Assessment of amount of calcaneal eversion with the correct sizer in place

Intraoperative radiographs for dorsoplantar and lateral aspect must be considered to confirm appropriate position when looking to lateral view, the implant was angled posterior and was not sitting on the calcaneus floor (Figure 4 a) On the dorsoplantar view the leading edge of the implant should be within middle third of the talus (Figure 4 b).

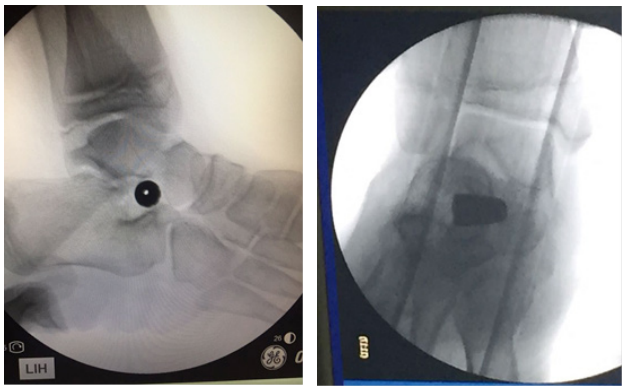

Figure 4 Intraoperative dorsoplantar and lateral radiographs to confirm appropriate position (a). On the lateral view, the implant was angled posterior and was not sitting on the floor of the calcaneus (b) dorsoplantar view the leading edge of the implant should be within middle third of the talus.

The incision close was done by a modified absorbable subcuticular for self-closure for reinforcing upon itself. Closure of deep tissue was not carried out.Then, applied of sterile and dry compression dressing on the foot and ankle. The patients were educated to much lift up the foot as possible when wakeful for the first 2 days after operative technique, and were not permitted for high weight bearing on the treated foot.

Assuming no adjunctive procedures were performed consists of protective weight bearing in a removable below-knee walking cast for 2weeks.If tendon Achilles lengthening is simultaneously performed 2weeks of non-weight bearing in below knee cast is followed by 2 weeks of partial to full weight bearing cast.

Methods of evaluation

Each patient in this study was carefully assessed clinically by taking a full clinical history and performing a thorough examination and adequate information from the child or parent to determine whether the flat foot deformity is symptomatic or not the physical examination starts with a generalized musculoskeletal examination, which should always include rotational profiles of the legs. For all patients the foot and ankle should be examined with the patient standing and sitting, as a flatfoot deformity may not be apparent in absence of weight bearing. Presence of longitudinal foot arch medially and during sitting position not disappears with weight bearing is characteristic of a flexible flat foot. The medial arch should also reform when a patient goes from standing to tiptoe standing. The arch also may be reconstituted in flexible flatfoot by the "toe raising test". If these clinical signs are not detected, the patient has a flat foot rigidity, which still flat at sitting, tip-toe standing, and the toe raise test because the subtalar joint immobility. It is significant to decide any foot pain sites. Frequently the pain raised from midfoot medially or laterally at the sinus tarsi due to local pressure on the collapsed head of talar where callus formation may be palpable and impingement of extreme subtalar joint eversion last. Also, Achilles tendon complex should be examine for assessing a child with flatfoot because this may have significant inferences for case management. Surgery was only indicated when these findings were coming together with subjective limitations of daily activities (e.g. pain and fatigue).

Patient outcomes were assessed using the standardized and validated AOFAS Ankle-Hindfoot Scale.

The score of AOFAS ankle-hind foot is concluded by 9 objects which allocated over 3 categories: pain, function and alignment (40, 50 and10 points), respectively for a total of 100 points. Functional aspects including sagittal and hind foot motion, ankle-hind foot stability, and integral foot alignment. Every category was evaluated separately, with (0 to 100) final scores rang, where 0 matches to the worst and 100 to the best of health status [8]

Standard lateral and AP X-rays were made before surgery and at time of follow-up the longitudinal arch of the foot must be assessed on a weight bearing lateral foot radiograph.

Talonavicular coverage angle:

The drawn two lines for attaching the edges of the articular surface of the talus and navicular aspect. The talonavicular coverage angle formed by both lines perpendicularly.

Lateral talar-1st metatarsal angle

This is an angle formed between the talus long axis and first metatarsal on a weight-bearing lateral view.

2.4Statistical analysis

Data analyses will be analyzed using IBM SPSS Statistics Version 22.Quantitative data was presented

as mean, standard deviation or median and range as appropriate. Qualitative data will be presented as number and percentage. Comparing numerical variables using paired t test and Wilcoxon signed rank test according to fulfilling assumption of normal distribution. P value set significant at 0.05 levels. All tests was two tailed.

Results

This study was a prospective case series conducted on 30 feet with flexible flatfoot deformity; their follow up was for 10 to 20 (15±3.5) months. Clinical assessment was done using scoring system (AOFAS), Radiological assessment was done using TNA& TMA to assess talonavicular coverage and talar first metatarsal angle .There were 18 female (60%) and12 male (40%). The age ranged from 8 to 13 years, with a mean age 11.7 ±1.6 years old14 patients (46%) reported complete relief of pain(very satisfied); 10 patients (30%) reported minor pain(satisfied), 4 patients (20%) had moderate pain(minimally satisfied) .Two patients (7%) stated that they felt worse following surgery (not satisfied at all) The patients with moderate pain had discomfort at the level of sinus tarsi site and in some cases at subtalar joint. One patient has worse pain as a result of loosening of the screw and then extrusion but pain decreased dramatically after debridement and reinsertion of a smaller size implant, other patient with worse pain with medial soft tissue reconstruction was done to him and pain mainly at medial side.

The mean functional (AOFAS) Ankle-Hindfoot score improved from 64.3±8.26 (43-77) preoperatively to 89.23±5.41 (77-98)

Postoperatively at last follow up (Pvalue<0.001) using paired t-test as a significance test for evaluation of pre and post-operative AOFAS score (Table 1)

Table 1:Pre and postoperative AOFAS significant difference

AOFAS	Mean ± SD	Paired t test	P value
Preoperative	64.3±8.26	18.48	<0.001
Postoperative	89.23±5.41		

Subtalar arthroerisis using sinus tarsi implants resulted in improvement of the mean (average) of the lateral talometatarsal angle from 16.5º preoperative to 5.5º at follow up and improvement of the mean (average) of the AP-Talonavicular angle from 23.4º preoperative to 9.4º at follow up.The median decrease in the lateral talometatarsal angle from 15º (range: 4º to 29º)preoperative to 4º (range: 0º to17º) at last follow up.

The median decrease in the Talonavicular angle from 18 (range : 12º to 45º) to 5º (range : 1º to 44º) at last follow up. The average decrease in both angles was statistically significant (P<0.001)(Table 2).

Table 2: Median variation in TMA and TNA after operative procedure.

Angle	Preoperative Median(range)	Postoperative Median (range)	Wilcoxn signed rank test	P Values
TMA	15º (4 º to 29 º)	4º (0 º to 17 º)	465.00	<0.001
TNA	18 (12 º to 45 º)	5º (1 º to 44 º)	400.00	

Post-operative complications: were detected in 5 patients (16.6 %)Two patients(6.6%) developed infection detected by erythema, lateral aspect swelling of the foot, and elevated ESR, regular follow up under antibiotic coverage for 4 weeks till normal laboratory results and clinical improvement.

Two patients (6.6%) developed severe pain at sinus tarsi (sinus tarsitis) following surgery. Conservative treatment had been tried in the form of rest, temporary and slightly inverted casting, heel lifts and physicaltherapy. In one patient pain had been resolved. The other is still complaining of pain but tolerable with no need of removal of the implant in the last follow up.

One patient (3.3%) developed reactional synovitis followed by loosening of the implant and then extrusion after 3 months Debridement and reinsertion of smaller

sized implant have been done

Discussion

Arthroereisis characterizes by a little invasive interference for curing of symptomatic flatfoot and its technical advantage represented a simplicity and rapid recovery, some authors statethat, the results is overutilization. [9]

Alternative choices described for more widespread surgery, rising operative risk and postoperative recovery. [10]

Our results was at the last follow 14 patients (46%) reported complete pain relief (very satisfied); 10 patients (30%) reported minor pain (satisfied), 4 patients (20%) had moderate pain(minimally satisfied) Two patients (7%) stated that they felt worse following surgery (not satisfied at all).

The mean AOFAS ankle-hindfoot score improved from 64.3 ±8.26 (43-77) preoperatively to 89.23±5.41 (77-98) (P value <0.001) postoperatively at follow up with a mean increase of 25 in the AOFAS score.

Viladot et al. reported that the mean score values of AOFAS are improved from 47 to 82 post surgery. [11]

Needleman et al. reported an increased 35-point i in the mean values of AOFAS score with a significant enhancement in the radiographic parameters postoperatively. [4]

In another study involved 34 feet in 20 patients, The mean score values of AOFAS were (from 67.7 to 89) and became greater than before at the end of the follow-up. [12]

Our results showed median decrease in TMA is 15º (range: 4º to 29º) preoperative to 4º (range : 0º to 17º) at the last follow-up, while TNA showed mediandecreasefrom18º (range : 12ºto45º) preoperative to 5º (range : 1º to 44º) at the final follow up. The average decrease in both angles was statistically significant (P<0.001).

Regarding the biomechanical analysis, Husain and Fallat conducted that, the motility of subtalar joint was gradually decreased by increasing implant thickness and that were affected the following strcture: lateral Talo-first metatarsal, talar declination, calcaneal inclination, first metatarsal declination, and first intermetatarsal angles. [13]

Similarly, a study included a 60 feet in 35 patients, showed a significant increased in the angles of talocalcaneal, calcaneocuboid, and first and second intermetatarsal, in addition to calcaneal inclination and talar declination angles postoperatives. [14]

Also, a study joined 68 feet in 39 patients at one year follow-up. The authors revealed a significant upgrading in the radiographic assay including angles of APTN coverage , lateral and anteroposterior talocalcaneal postoperatively. [15]

Post operative complications were detected in 5 patients (16.6%).Two patients (6.6%) developed subclinical infection. Two patients (6.6%) developed severe pain at sinus tarsi (sinus tarsitis) following surgery. One patient (3.3%) developed reactional synovitis followed by loosening of the implant and then extrusion after 3 months Debridement and reinsertion of smaller sized implant have been done.

On average, the rates of complication range from 4.8% to 18.6% with unintentional removal rates range from 7.1% to 19.3% through all types of device. [10]

However, the described incidence of implant loosening or breakage has reduced since the presence of titanium implants. [14]

Other complications include over or under correction of the hindfoot valgus, pain at sinus tarsi, cortical erosion, synovitis, talar avascular necrosis, and calcaneus fractures. [16]

To conclude this technique has the advantage of preservation of joint and ligaments. In addition, the implant has no effect on growthor operative intervention if more invasive procedures are required.

Subtalar arthroereisis remains controversial, especially in regards to patient selection and adjunctive procedures.

On the other hand to enforce our results it is important to perform large scale study for longer follow up to ensure absence of late complications that inconsistent with our results.

Influence of Different Exercise Regimens on Segmental Body Fat in Obese Primary School Children

Amir N Wadee[1], Marian M Shafeek[2] Ahmed M Tawfick[3]

[1]Department of Physical Therapy for Basic Sciences, Faculty of Physical Therapy, Cairo University, Egypt, [2]Department of Physical Therapy for Pediatrics and its surgery, Faculty of Physical Therapy, Modern University for Technology and Information, Egypt.[3] Department of Physical Therapy for Internal Medicine and Elderly, Faculty of Physical Therapy, Modern University for Technology and Information, Egypt

Abstract

Purpose: to compare the influence of different exercise regimens on segmental body fat in obese primary school children. **Method:** 100 obese children, their ages ranged from 6 to 12 years. Children were randomly allocated into: Group I (control/diet only), II (diet plus aerobic training), III (diet plus resistance training) and IV (diet plus combined aerobic and resistance training). BMI and segmental body fat (using DEXA) were measured before and after 6 consecutive months of the program. **Results**: Significance in BMI and total fat and legs fat mass/total fat mass % (P= 0.000). Insignificance in trunk fat mass/total fat mass % and limb/trunk fat mass ratio in control group (P=0.155 and 0.109 respectively) while significance in exercise groups (P<0.05).**Conclusion:** Different exercise regimens had different influences on segmental body fat in obese primary school children.

Keywords: *Exercise regimens; Segmental body fat; Obese children*

Introduction

Childhood obesity becomes the most serious public health challenges of the 21st century[1]. Approximately one from every five school-aged children is obese [2]. In Egypt, the predominance of obesity was 19.6% among primary school children [3].

Faulty dietary habits and low level of physical activity were significantly associated with childhood obesity[2]. Increasing the prevalence of obesity among the Egyptian children pushes the President El-Sisi to start a new campaign on 17th

February 2019 targeting obesity amongst Egypt's preadolescent children (12 million) [4].

The WHO has suggested lifestyle diet modifications to lessen 5–10% of body weight [1] and recommended 60 minutes or more of moderate-intensity aerobic activity every day for children [5]. Although exercise is recommended for obese children, little proof exists on which exercise regimen is ideal to reduce segmental body fat [6]. Therefore, it is important to investigate influence of different exercise regimens on segmental body fat in obese primary school children. So, the following hypotheses were settled: there would be no differences between different exercise regimens on BMI, total fat, trunk fat mass/total fat mass, legs fat mass/total fat mass % and limbs fat mass/trunk fat mass ratio.

Materials and Method

This study was conducted from January 2019 to June 2019, ethically affirmed from the ethical committee of the Faculty of Physical Therapy, Cairo University, Egypt (P.T.REC/012/002308) and registered on (PACTR201907704486152). Two copies of written consent form offering agreement to participation and publication of the results were signed by the children's parents.

Controlled randomizes trails design for one hundred primary school children aged 6–12 years, both genders

were recruited from the Weight Management and Wellness Center of medical centre of Faculty of Physical Therapy, Modern University for Technology and Information according to the following criteria: BMI were at or above the 95th percentile with no engagement in organized physical workout for the previous 3 months except school physical education classes. Exclusion criteria included: children with musculoskeletal disorders, congenital anomalies, cardiopulmonary problems or endocrine disorders (figure 1).

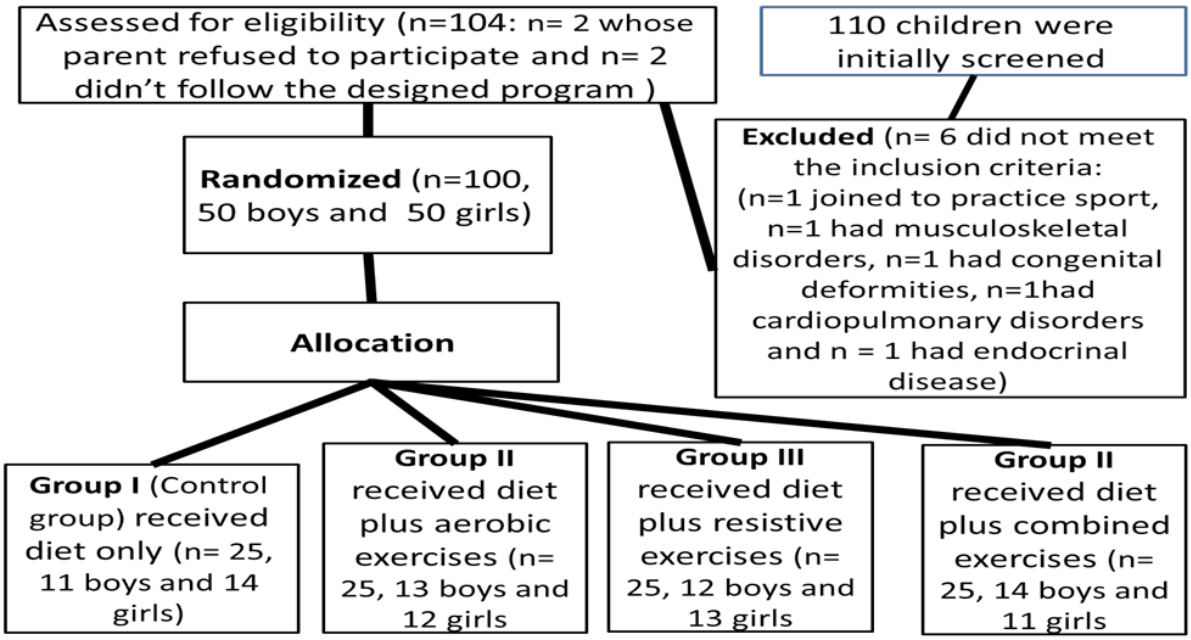

Figure (1): Participants' selection and allocation

Evaluation:

Total body fat % and segmental body fat were assessed by Dual-energy X-ray Absorptiometry (DEXA) with a whole-body scanner operated in the single-beam configuration (serial n: DF+502510, Prodigy, USA). During the measurement, each child lies on a cushioned bed for a few minutes while an imager moves over the child's body without touching him/her. Measurements were blindly repeated prior and at the end of six months.

Interventions

Participants were randomly divided, utilizing sealed envelopes, into: control group (I) (received diet only with a daily energy deficit of 250 kcal), aerobic-exercising training group (II) (received diet plus aerobic training), resistance-exercising training group (III) (received diet plus resistance training) and combined-exercising training group (IV) (received diet plus combined aerobic and resistance training).

1. Aerobic exercises (playing and recreational activities): gradually increase the intensity from moderate-intensity (brisk walking, bicycle riding with slow speed stationary)[5] to high-intensity (running and chasing such as bouncing, hopping rope and bicycle riding with high speed [5].

2. Resistive exercise (Modified push-ups with knees on the floor, wall bar climbing, crunches, weight machines, hand-held weights) [5:] gradually increase the number of repetitions for each exercise (up to 12 times) and also the amount of overload or resistance. The first and last 5 minutes of the training set should be aerobic training as warming up and cooling down.

3. combined-exercising training: Combined aerobic and resistive exercise programs with 50% of training time for each type (1:1ratio) [5].

Statistical Analysis

Statistical calculations were carried out using a computer program IBM SPSS version 22 (IBM Corporation, USA). The sample size calculations were calculated utilizing the G*Power software (version 3.0.10). Segmental body fat (for trunk, legs, and arms) was picked as the primary measure. The effect size of segmental body fat was estimated to be medium (0.25).

A generated sample size of at least 20 participants per group would be required. Taking into consideration a 20% dropout rate, it was necessary to reach a total sample level of a minimum of 100 participants. All data were homogenous (Levene's test) and normally distributed (Shapiro-Wilk test), so the parametric test was used (MANOVA). Multiple Comparisons were performed by the least significance difference test (LSD). P values were considered statistically significant if less than 0.05.

Results

Demographic data:

One hundred obese children their age, height, weight, and BMI were ranged from 6-12 years, 117- 139 Cm, 34.5- 58.45 Kg and 25.2 – 30.27 Kg/m2 (respectively). There were insignificant differences in-between groups (P>0.05) (Table 1 and figure 2).

Table 1: General demographic data

Groups	Age (Y)	Gender		Height (Cm)	Weight (Kg)	BMI (Kg/m2)
		Male	Female			
Sample	9.03 + 1.77	50	50	131.7 + 8.54	48.48 + 7.87	27.73 + 1.6
Control	9 + 1.83	11	14	131.8 + 8.69	47.77 + 7.61	27.32 + 1.68
Aerobic	8.75 + 2.09	13	12	131.05 + 9.33	48.04 + 8.47	27.73 + 1.60
Resistive	9 + 1.83	12	13	132 + 8.78	49.46 + 8.59	28.13 + 1.68
Combined	9.35 + 1.53	14	11	131.95 + 8.69	48.64 + 7.95	27.73 + 1.6
F-value	0.182			0.025	0.084	0.405
P-value	0.908			0.995	0.968	0.751

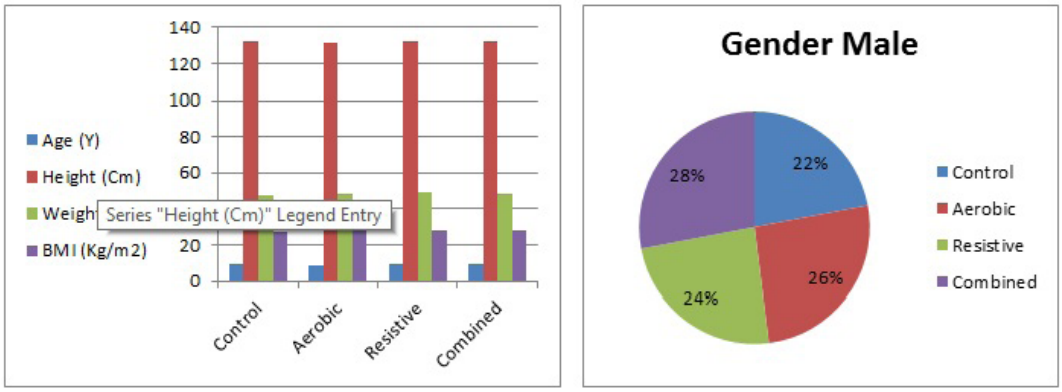

Figure (2): Demographic data

BMI: Within groups, there were significance (P= 0.000). In-between groups revealed insignificance of pre-measures while they were significant in post-measurements (F= 9.933 and P= 0.000) (table 2 and figure 3).

$\bar{x}$:Mean

Total Fat %:

The intra-group comparisons revealed significance within groups (P= 0.000). The inter-group comparisons indicated insignificance of pre-measures (F= 0.525 and P= 0.668) while they were significant in post-tests (F= 11.145, P= 0.000) (table 2 and figure 3).

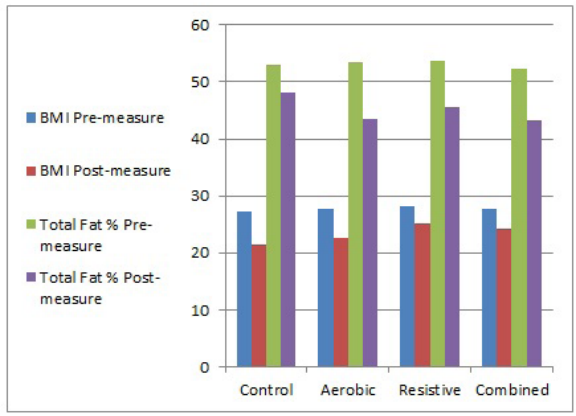

Figure (3): BMI and Total Fat %

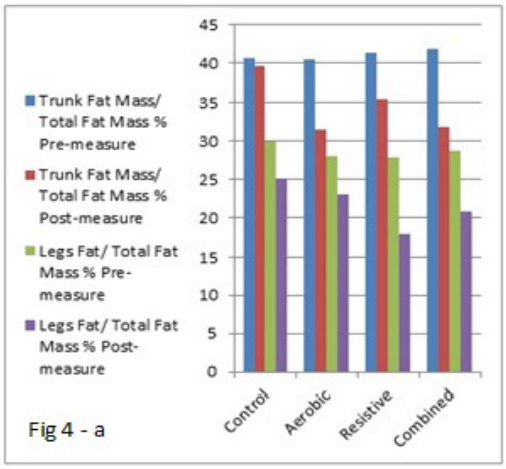
Trunk Fat Mass/Total Fat Mass %:



The intra-group comparisons revealed insignificance within the group I (P= 0.155) while they were significance within the exercise groups (P= 0.000). The inter-group comparisons indicated insignificance of pre-measures (F= 1.257 and P= 0.304) while they were significant (F= 36.974, P= 0.000) in post-measurements (table 2 and figure 4-a).

Legs Fat Mass/Total Fat Mass %:

The within- group comparisons indicated significance within groups (P= 0.000). The in-between group comparisons illustrated insignificance of pre-measures (F= 1.838 and P= 0.158) while they were significant in post-tests (F= 17.822, P= 0.000) (table 2 and figure 4-a).

Limbs Fat Mass/Trunk Fat Mass Ratio:

The intra-group comparisons demonstrated insignificance within the group I (P= 0.109) while they were significance within the exercise groups (P= 0.038, 0.000 and 0.000 respectively). The inter-group comparisons found insignificance of pre-measures while they were significant in post-measurements (F= 21.363, P= 0.000) (table 2 and figure 4-b).

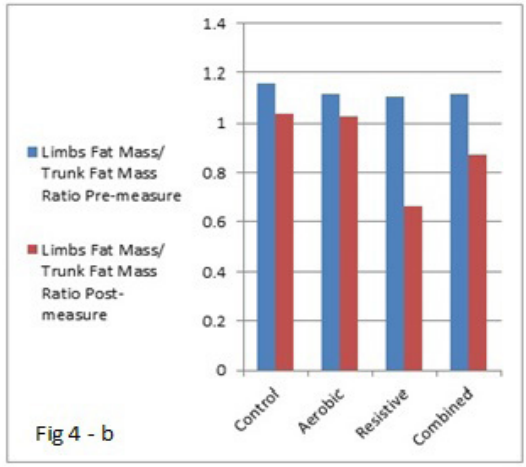


Figure (4): a- Trunk Fat Mass/Total Fat Mass and Legs Fat Mass/Total Fat Mass %. b- Limbs Fat Mass/Trunk Fat Mass Ratio

Multiple Comparisons

a. BMI results revealed the equality between group I and II (P= 0.16) which were superior to group III and IV (P= 0.000 and 0.008 respectively).

b. Total fat % results illustrated the equality between group II, III and IV (P> 0.05), and inferiority of the group I (P= 0.002, 0.03 and 0.000 respectively).

c. Trunk fat mass/total fat mass % results demonstrated the equality between group II and IV (P>0.05) which were superior to the group III (P<0.05) and inferiority of the group I (P= 0.000, 0.01 and 0.000 respectively).

d. Legs fat mass/total fat mass % results showed the superiority of the group III (P< 0.05) and equality between group II and IV (P>0.05) and inferiority of the group I (P= 0.01, 0.000 and 0.011 respectively).

e. Limbs fat mass/ trunk fat mass ratio results revealed the superiority of group III (P<0.05) followed by equality between group II and IV groups (P>0.05) and inferiority of the group I (P= 0.000) (table 3).

Table 3: Multiple Comparisons

Variable	(I) groups	(J) groups	Mean Difference (I-J)	Sig.
BMI	I	II	-0.80	0.16

		III	4.70*	0.000
		IV	2.80*	0.011
Limbs Fat Mass/ Trunk Fat Mass Ratio	I	II	0.17*	0.000
		III	0.25*	0.000
		IV	0.14*	0.000

Discussion

BMI remains a valuable measurement to recognize weight gain, as fast increments in children can be ascribed to fat instead of lean [7]. Diet-prompted weight reduction is related with a particular decrease in the total body fat, so diet-induced weight loss similar to exercise. This was confirmed in this study by significant differences in BMI of both within and in- between measures in the four groups (P= 0.000).

Although the translation of changes in BMI as proportionate changes in fatness will be misleading [8-9], BMI remains the most useful way by which to analyze wide changes in obesity. That illustrated by the pairwise comparison of BMI results that found equality between group I and II (P= 0.16) which were superior to group III and IV (P= 0.000 and 0.008 respectively).

Although adding exercise to energy restricted diet gives valuable advantages, specifically, it is conceivable that the decrease in lean tissue normally associated with diet only have been overestimated [9]. So, the hypothesis of no differences between the four groups on BMI, was accepted [10]. This was indicated by significant differences in total fat % of both within and in- between measures in the four groups (P= 0.000)

Studies found that the combination of eating regimen and exercise results in a greater reduction of regional fat and preservation of muscles compared with diet only [10]. Which illustrated by the equality between group II, III and IV (P> 0.05), and inferiority of the group I regarding the total fat % (P= 0.002, 0.03 and 0.000 respectively). For all of the exercise regimens, a generous decrease in entire body fat was noticed. So, the hypothesis of no differences between the four groups on total fat was rejected.

However, for both group II and IV we observed a greater decrease of trunk fat compared with the group III. That comes in agreement with previous studies that showing the combination of diet and exercise effect in reduction in fat from the abdomen [11]. These notes might be mostly clarified by the principal of "while a-adrenergic inhibitory impacts manage abdominal adipose lipolysis during resting conditions, b-adrenergic stimulatory impacts modulate abdominal fat lipolysis during activity" [11]. This was indicated by significant differences in trunk fat mass/total fat mass % of only exercise groups within and in- between measures (P= 0.000)

Adding, there is a stamped increment of lipids from abdominal tissue, while just a minor increment in lipolytic activity was seen in femoral fat tissue because of both aerobic and combined activities [11-12]. This was demonstrated by the equality between group II and IV (P>0.05) which were superior to the group III (P<0.05) and inferiority of the group I (P= 0.000, 0.01 and 0.000 respectively) regarding trunk fat mass/total fat mass %.

Combined training may have added impacts through improvement in the oxidative metabolism-dependent energy framework and cardiorespiratory wellness. [12]. so, the hypothesis of no differences between the four groups on trunk fat/total fat, was rejected. For the resistive group, there was increment in energy consumption from the performance of resistance workout. However, the mean energy expenditure attributable to aerobic exercise and combined groups were substantial [12]. What reported by the significant differences in legs fat mass/total fat mass % of both within and in- between measures in the four groups (P= 0.000).

The primary influence of the resistive exercise was on the gluteal adipose lipolytic activity and mobilization of the leg fat [13]. That explained the superiority of the group III (P< 0.05) and equality between group II and IV (P>0.05) and inferiority of the group I (P= 0.01, 0.000 and 0.011 respectively) regarding legs fat mass/total fat mass %. So, the hypothesis of no differences between the four groups on leg fat/total fat was rejected.

In any case, given the increment in upper and lower body strength, increments in contractile protein as well as muscle fiber volume occurred yet were covered by

declines in any of the other muscle constituents [13]. This confirmed by the significant differences in limbs fat mass/trunk fat mass ratio of both within and in- between measures in only the exercise groups (P= 0.000). Changing in muscle strength were be due to adaptations in skeletal muscles which attributable to neuromuscular factors. That illustrates the superiority of group III (P<0.05) followed by equality between group II and IV (P>0.05) and inferiority of the group I (P= 0.000). So, the hypothesis of no differences between the four groups on limb fat/trunk fat, was rejected.

Our findings provide strong evidence that different exercise regimens had different influences on segmental body fat in obese primary school children.

Early Effect of Maximal Utilization of Internal Mammary Arteries on Kidney Function in the Egypt

M. Nafeh[1], Kh. Mortada[2], A. Sayed[3]

Department of Cardiothoracic Surgery, Faculty of Medicine, Cairo University. Cairo, Egypt

Abstract

Background: Coronary artery bypass grafting (CABG) is among the most important surgical procedures in the history of medicine and remains the most durable means of revascularization for patients with coronary artery disease (CAD).

Objective: To identify the effect of maximal utilization of internal mammary arteries on kidney function.

Method: This prospective observational study was carried out from Feb.2015 until Feb.2017, in the department of cardiothoracic surgery Kasr Al Ainy Faculty of Medicine including 40 CABG surgery patients underwent maximal utilization of internal mammary artery for whom kidney functions were followed up pre and post operatively.

Results : The mean distal Number of mammary arteries utilization were 3.4 ± 1.2 , The mean on pump time were 118.1 ± 20.6 minutes , There was a statistically significant increase in mean serum Creatinine post-operatively but no need for dialysis and no mortality. .

Conclusion: Early effect of maximal utilization of Internal Thoracic mammary artery in coronary bypass graft surgery on KFT showed statistically significant increase in mean serum Creatinine post-operatively but no need for dialysis and no mortality. Future studies with long term follow up of KFT post operatively are needed.

Key words: *Total arterial, Conventional CABG, Patency and KFT.*

Introduction

Coronary artery disease (CAD) is considered one of the leading causes of death in the developed countries. Revascularization of stenotic coronary arteries greatly contributes to the treatment of CAD. There are two well-established revascularization techniques are practiced. One is Coronary Artery Bypass graft (CABG) surgery in which autologous arteries and/or veins are used to supply blood to the coronary artery downstream to the stenotic lesion, and the other is percutaneous transluminal coronary angioplasty (PTCA) in which catheter-borne devices ,including balloon, stent, atherectomy cutter, and LASER, are used to open stenosis from within the coronary artery .

Up to 15 % of saphenous vein grafts occlude within the first postoperative year and at 10 years postoperatively, only 50% to 60 % of saphenous vein grafts are patent. The clinical consequences of such saphenous vein graft disease include recurrence of angina, myocardial infarction and death.[1]

The clinical and prognostic benefits of coronary artery bypass grafting (CABG) for certain anatomical patterns of coronary artery disease are well accepted. Most patients undergoing CABG require three or four bypass grafts and the "standard" operation uses a single left internal mammary artery (LIMA) to the left anterior descending coronary artery, and supplemental saphenous vein grafts (SVGs) to the other coronary vessels .[2]

The excellent early results of CABG are limited in the long term by vein graft failure. Ten years after CABG three quarters of vein conduits are blocked or severely diseased, whereas more than 90% of ITA grafts are patent and disease free. Vein graft failure leads to reduced survival, recurrent angina, late myocardial infarction, and the need for further intervention.[3]

It was noticed that by 10–15 years after the initial operation up to 40% of patients may require redo CABG at increased risk and cost. Recently, TACR is the procedure of choice in young adults and those having porcelain aorta, etc. TACR, is possible with maximum grafts using bilateral IMAs in situ or as free grafts [4]. The development of peculiar form atherosclerosis in SVGs encourage us to pay attention to other type of grafts particularly arterial ones to improve the midterm outcome of myocardial revascularization. The two main reasons against arterial revascularization are inadequate evidence of benefit and that it increases perioperative mortality and/or morbidity. Several large studies have recently reported that multiple ITA grafts offer survival advantages over a single ITA graft.

There are meta-analytic studies of almost 16.000 patients comprising 11269 single and 4693 bilateral IMA patients matched for age, gender, left ventricular function, and diabetes, proved the benefits of the expanded use of arterial grafts and provided good proof that strongly advocated their use .[5]

Clinical results and patency associated with the use of the right internal mammary artery as part of a bilateral internal mammary artery grafting have been encouraging. [2]

Moreover, the revival of use of the radial artery (RA) as a graft has offered another easily accessible source of arterial conduits.6

Aim of work

This clinical study was done to show the effect of usage of Internal Thoracic mammary artery in coronary bypass graft surgery on KFT.

Method

I. Patient Population:

This Prospective study included 40 patients who complained of Coronary Artery Disease and subsequently underwent myocardial arterial revascularization including Maximal Utilization of InternalMammary Arteries by Faculty of Medicine, Cairo University experience since February 2015 until February 2017.

II. Selection Criteria:

In all cases Maximal utilization of internal mammary artery including left and right internal mammary arteries.

Harvesting of LIMA and RIMA by a skeletonized way.

Exclusion criteria:

1-Combined cardiac surgery as Ischemic heart disease for CABG and valve surgery .

2- Age > 25 and < 70 years

3-Obese patients BMI more than 30.

4-uncontrolled diabetic patients HbA1C more than 7

5- Unstable patients (surgical emergency)

6- Redo CABG.

Inclusion criteria include:

1- Age: 30 -70 years.

2- Gender: both males and females.

3- Operation type: on-pump or off pump

4- Operation classification: immediate

5- LV function: >25%.

6- Preoperative state: renal state

Preoperative Assessment:

A standard protocol of preoperative management was applied with special concern to the base line KFT for the patients.

IV. Operative Management:

The most frequent indications are chest pain (80%), dyspnea (20%).

Surgical technique:

In all cases, access to the heart was obtained through a median Sternotomy. Cardiopulmonary bypass with aorta common atrialcannulation.

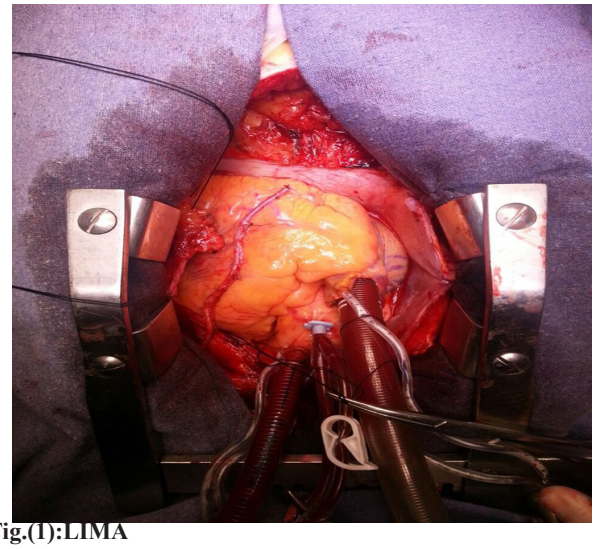

Fig.(1):LIMA

Fig. (2): RIMA

Distal Anastomosis:

Running polypropylene 8/0 sutures were used.

Was performed in the same sequence for all cases. Initially, the right coronary artery was started with followed by the posterior RCA branches (crux or PDA), then the marginal branches of the circumflex artery, and the diagonal branches of the LAD. Then LAD.

Proximal Anastomosis:

Jump graft, coronary to coronary,sequential, bucket handle, y or t graft ways were used.

Postoperative assessment:

A standard protocol of postoperative management was applied with close follow up of the KFT compare it to the base line of the patient KFT.

Results

1. **Demographic and general data**

Gender

The study was conducted on 40 patients; 36 males (90.0%) and 4 females (10.0%).

Age

The mean ± standard deviation values for age were 55.4 ± 8.2 years with a minimum of 20.0 years and a maximum of 70.0 years old.

Body Mass Index (BMI)

The mean ± standard deviation values for BMI were 28.9 ± 0.9 KG/m^2 with a minimum of 27.0 KG/m^2 and a maximum of 30.0 KG/m^2.

2. **Serum Creatinine**

There was a statistically significant increase in mean serum Creatinine post-operatively.

Table (1): Descriptive statistics and results of comparison between serum Creatinine pre- and post-operatively

Time	Mean	SD	Median	Minimum	Maximum	95% CI		*P*-value
						Lower bound	Upper bound	
Pre-operative	0.87	0.17	0.90	0.57	1.30	0.82	0.93	0.001*
Post-operative	0.94	0.19	0.90	0.50	1.40	0.87	1.00	

**: Significant at P ≤ 0.05*

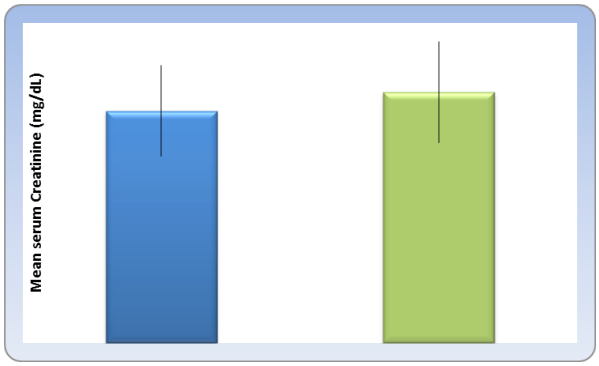

Figure (3): Bar chart representing mean and standard deviation values of serum Creatinine pre- and post-operatively

3. **Mortality**

All patients (100.0%) were alive.

4. **Ischemic time**

The mean ± standard deviation values for Ischemic time were 85.7 ± 18.9 minutes with a minimum of 51.0 and a maximum of 129.0 minutes.

5. **Number of mammary arteries utilization**

Six patients (15.0%) had utilized two arteries, 20 patients (50.0%) had utilized three arteries, and 10 patients (25.0%) had utilized four arteries while four patients (10.0%) had utilized five arteries.

The mean standard deviation values of distal Number of mammary arteries utilization were 3.4 ± 1.2

6. **Association between number of mammary arteries utilization and different variables**

There was no statistically significant correlation between number of mammary arteries utilized and different variables except for ischemic time where there was a statistically significant direct (positive) correlation between number of mammary arteries utilized and ischemic time i.e. an increase in number of mammary arteries utilized is associated with an increase in ischemic time and vice versa.

Table (2): Results of Spearman's correlation coefficient for the correlation between number of arteries and different variables

Variables	Correlation coefficient	*P*-value
Age	0.008	0.962
HbA1c	-0.260	0.110
BMI	-0.074	0.649
Pre-operative serum Creatinine	-0.043	0.790
Post-operative serum Creatinine	-0.023	0.888
Ejection fraction	-0.028	0.864
Ventilation hours	-0.044	0.788
ICU stay	-0.203	0.208
Number of blood transfusion units	-0.017	0.916
On pump time	0.263	0.101
Ischemic time	0.421	0.007*

**: Significant at P ≤ 0.05*

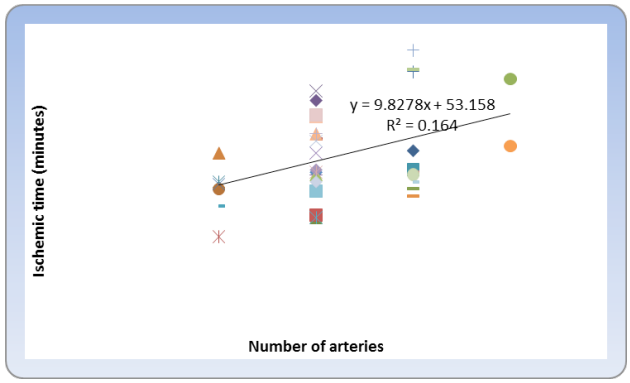

Figure (4): Scatter diagram representing direct correlation between number of arteries and ischemic time

Discussion

In study of **Rubens et al.**[7]in which 541,000 patients undergoing operations in 745 hospitals across the United Stateswas included of them (27%) of patients study BMI is more than 30 %, 33% of patients had Diabetes Mellitus,pre operative mean serum creatinine was 0.96 but 86 patients underwent to hemofilteration from total 12271 operated in form of total arterial revascularization. (48%) of study patients include in the study have EF were less than 30%. and (2%) of patients were re-explored for bleeding.

In study of **Aldea et al.**[8] 0.9% of patients presented by Renal impairment requiring dialysis although 137 patients 3.7% was complaining of Previous renal dysfunction before surgery .Sternal wound infection happened in (37%) of patients study .

In study of **Joel Price et al.**[9] 762 – patients were included in the study with a mean age of 55 ± 9. Of them 72 % of patients were hypertensive, 0.3%of patients was presented in form of renal impermaint and 0.6% underwent to renal dialysis. Patient left ventricular ejection fraction were (88.6%)>50, (10.3%) 30–49, and (1.1%)<30.In addition, mean CPB time (min) 102.025

± 35.7, Mean cross clamp time (min) 71.45± 27.95,No of bypass grafts 3.1 ± 0.8. In addition, mean no. of Reoperation for bleeding was (2.25%).Deep sternal wound infection and Mediastinitis happened in (0.55%) of patients study. The mean standard deviation for length of hospital stay of patients study was6.975 ± 5.3 days.

In our study, 40 patients the mean ± standard deviation values for age were 55.4 ± 8.2 years. of them 36 males (90.0%) and four females (10.0%). The mean ± standard deviation values for BMI were 28.9 ± 0.9 KG/m^2 with a minimum of 27.0 KG/m^2 and a maximum of 30.0 KG/m^2.

Twenty-one patients (52.5%) had Diabetes Mellitus while 19 patients (47.5%) do not have Diabetes mellitus.

In addition,the mean ± standard deviation values for HbA1c were 6.3 ± 0.8 % with a minimum of 5.0 % and a maximum of 7.8 %.

Pre-operative mean serum creatinine 0.87 of our patients and there was a statistically significant increase in mean serum Creatinine post-operatively. But increasing was in reasonable limit no one patient need to renal dialysis temporary or permanent. None of our group study died with mortality 0 %.

Conclusion

Early effect of maximal utilization of Internal Thoracic mammary artery in coronary bypass graft surgery on KFT showed statistically significant increase in mean serum Creatinine post-operatively but no need for dialysis and no mortality. Future studies with long term follow up of KFT post operatively are needed.

Recomendation

Future studies with long-term follow up period to assess the long-term outcome are needed.

Pentraxin 3 and Non-Alcoholic Fatty Liver Disease in Egyptian Patients: Merits and Flaws

Amr R Albitar[1], MahaRakha[1],Nahla Emad[1], Ahmed Yamany[1]

[1]Internal Medicine Department, Faculty of Medicine, Cairo University, Cairo, Egypt

Abstract

Background/aims: Non-alcoholic fatty liver disease (NAFLD) is one of the most common chronic liver diseases. Pentraxin 3 (PTX3) has consistently been noted in non-alcoholic steatohepatitis and has been observed to be related to the grade of fibrosis**. Objectives:** it was to assess the potential of PTX3 as a non-invasive tool for the detection and grading of NAFLD among Egyptian patients**. Methods:** Sixty Egyptian patients with NAFLD attending the outpatient clinic at Cairo University Hospitalwere compared to 60 healthy subjects as controls in terms of the body mass index (BMI), waist and neck circumferences, lipid profile, and serum PTX3 level. Additionally, abdominal ultrasound for grading of liver steatosis was performed. Non-invasive tests of liver fibrosis (FIB4, AAR & APRI) were calculated **Results:**PTX3 level was significantly greater in the NAFLD group (3.25±1.85) than in the control group (0.70±0.29, p≤0.001), but it was not correlated with the severity of steatosis or steatohepatitis. The BMI and waist and neck circumferences were correlated with the steatosis grade .Non of FIB4, AAR & APRI were correlated to pentraxin level. In addition, ultrasound measurements of the right lobe of the liver were correlated with the degree of steatosis. **Conclusion:** PTX3 could serve as a surrogate diagnostic biomarker in NAFLD; however, it does not correlate with the severity of steatosis or steatohepatitis.

Keywords: *Non-alcoholic, Fatty liver, Pentraxin 3, Steatohepatitis, Dyslipidaemia*

Introduction

Non-alcoholic fatty liver disease (NAFLD) is one of the most prevalent chronic liver diseases and has a considerable impact on the liver, varying from hepatic inflammation to progressive fibrosis and eventually cirrhosis[1]

NAFLD is strongly associated with metabolic syndrome, and it may be a prelude to its future development.[2]. In light of the potential risks of fatty liver disease, the importance of using easy diagnostic and prognostic biomarkers has been emerging[3]. Several proteins involved in the pathogenesis of fatty liver diseases have served as NAFLD biomarkers, such as apolipoprotein A1 and B, leptin, and tumour necrosis factor- alpha[4].

Pentraxin(PTX3) is mass produced at sites of inflammation by several cell types.There is a growing body of literature that recognizes the importance of PTX3 as a non-invasive serological marker of liver fibrosis in hepatitis and cirrhosis[5], Moreover, it has been proposed that PTX3 could serve as a marker for grading the severity of liver inflammation and the fibrosis stage[6].

Accordingly, the current work aimed to evaluate the serum PTX3 level in NAFLD in the Egyptian population and find a relationship between the serum PTX3 level and the ultrasonographic grading of disease severity as well as non invasive tests of fibrosis.

Methods

Study design and population:

A cross-sectional (case-control) study was conducted with a total of 120 adult Egyptian subjects selected consecutively from outpatient clinic who presen*ted with*

non-specific symptoms. The subjects were divided into *the NAFLD group (*60 patients*)* and the control group, including 60 subjects with no evidence of NAFLD, as confirmed by ultrasonography.

Patients with co-existing recent cerebrovascular stroke or recent acute coronary syndrome of less than 3 months' duration, other ch*ronic liver diseases,* hepatocellular carcinoma, diabetes mellitus, renal diseases, or hypothyroidism and subjects who were under treatment with drugs that affect PTX3 level, as amiodarone, diltiazem, statins and glucocorticoids were excluded.

The study protocol was treated with confidentiality according to the Helsinki Declaration of biomedical ethics .

Method Details

All participants were subjected to full history taking and complete physical examination

Anthropometric measures

Including body height, weight and body mass index (BMI). Hip circumference, the waist circumference, the waist-to-hip circumference ratio and neck circumference were measured.

Sample preparation:

Blood samples (10 ml) were collected after an overnight fast. After analysing the blood cell counts in aliquots of whole blood in EDTA tubes (1.2 mg EDTA/m), the serum was separated (3000 rpm for 10 min) within 30 min of blood collection and stored at -20 °C. Hepatitis C antibody and hepatitis B surface antigen (HbsAg) analysis and antinuclear antibody were measured.

Fasting blood sugar and 2 hrs postprandial, liver and kidney function tests were performed using an automated device(Beckman,Dade Behring, USA).PTX3 was measured by ELISA using the serum supernatants (Human Pentraxin 3/TSG-14 Quantikine ELISA Kit).

Non-invasive Markers of fibrosis Evaluation: we assessed Aspartate aminotransferase to platelet ratio index(APRI)=AST (/ULN)x100 divided by Platelets(109/L), Fibrosis index based on the 4 factor (FIB-4): (age [yr] × AST [U/L]) / ((PLT [109/L])×(ALT [U/L]) 1/2, Aspartate aminotransferase and alanine aminotransferase ratio(AAR): AST(U/L)/ALT(U/L)

Ultrasonographic assessment of liver steatosis and its grading were evaluated using a high-resolution B-mode scanner (SDD-5500; Aloka, Tokyo, Japan) with a 3.5-MHz transducer by single operator. Anteroposterior diameter of the right hepatic lobe, Spleen and portal vein diameter were calculated.

Results

The study was performed with 120 subjects ranging in age from 20-66 years. The majority of the subjects were female (72.5%). Of all the subjects 65 (54.2%) were classified as overweight, with a BMI≥ 25. The demographic, clinical and laboratory characteristics of the enrolled participants are summarized in table 1.

A comparison between males and females in the NAFLD group revealed no significant difference in the PTX3 level (3.02±1.84 vs 3.32±1.86, respectively, p=0.925).

The distribution of the sonographic grades in the NAFLD group revealed 14 subjects with mild disease (23.4%), 23 subjects with moderate disease (38.3%) and 23 subjects with severe disease (38.3%).

The PTX3 level did not significantly differ according to the BMI. Among the NAFLD patients, there were no correlations between PTX3 and various parameters, including anthropometric parameters, liver function test results, sonographic findings, and stage; however, there was a significant negative correlation between the serum PTX3 level and the GGT level (r=-0.270, p=0.037). Also No significant correlation between non-invasive tests of liver fibrosis (FIB4, AAR & APRI) and serum Pentraxin

A comparison of the anthropometric measures among the NAFLD sonographic grades revealed significant differences in the BMI and waist and neck circumferences according to the degree of steatosis on ultrasound, as shown in table 2

A comparison of the NAFLD sonographic grades with the other sonographic parameters revealed a significant correlation between the right lobe diameter and the degree of steatosis on ultrasound (p=0.007) as shown in Figure (1).

Discussion

The goal of the present study was to elucidate the

ability of PTX in diagnosing and grading NAFLD and determine its relationship with sonographic findings. In the current study, level of PTX3 expression was significantly greater in NAFLD patients (3.25+1.8ng/ml) than in the controls (0.7+0.29 ng/ml), which is in agreement with previous studies investigating the role of PTX3 as a non-invasive biomarker of steatosis[7,8]

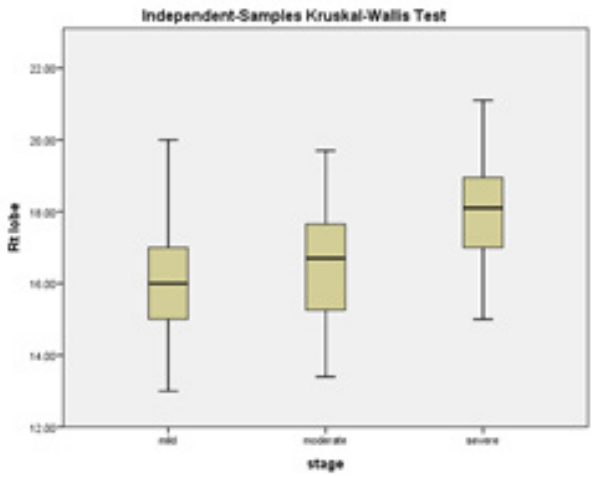

Fig. 1: Comparison between NAFLD sonographic grades and right lobe measurements

As expected, our results demonstrate that the mean BMI of the enrolled patients with NAFLD was higher than that of the controls (35.43±6.90 vs 27.53±2.11, respectively), with more than half of the study participants classified as overweight or obese that was in agreement of previous studies[9,10].

These data are consistent with those of a study conducted by Ko et al., who observed that a larger waist circumference and a higher BMI were significantly correlated with NAFLD[10]. The high frequency of overweight individuals with NAFLD compared to those without NAFLD has also been previously reported [11,12.] BMI is linearly related to NAFLD/NASH [13].

The current study reveals a significant difference in the lipid profile between the NAFLD and non-NAFLD groups, with higher LDL and triglyceride levels and lower HDL levels in the NAFLD group. Dyslipidaemia plays a role in the development of NAFLD,andi s strongly associated withN AFLD severity[14].

A high BMI and large waist and neck circumferences were found to be significantly related to the ultrasonographicseverity of NAFLD. These results confirm the findings of previous research reported by Hatipoğlu and colleagues showing that neck circumference was associated with NAFLD in children[15]. Additionally, some researchers suggested the use of neck circumference as a simple and reliable anthropometric index for predicting a high risk of NAFLD [16,17]

NAFLD may progress to severe hepatic inflammation with elevated liver enzyme levels. A study had showed

elevated ALT and GGT in NAFLD subjects [18].

Liver biopsy still is The gold standard for achieving a definite diagnosis and stage is liver biopsy[19],but as this procedure is invasive and carries the risk of complications, Hence, non-invasive markers of fibrosis have been emerging to overcome these limitations [20].

PTX3 is a specific marker of localized vascular inflammation and is synthesized by different cell types; therefore, it is linked to inflammatory processes, and consequently, it has been considered to be expressed in hepatosteatosis[21].

Boga et al. found higher PTX3 levels in NAFLD patients and biopsy-proven NASH patients than in the controls[7], Moreover, Ozturk et al. concluded that elevated PTX3 levels were associated with the presence of fibrosis in NAFLD subjects[7]On contrary to our results where there was no significant correlation between non-invasive tests of liver fibrosis (FIB4, AAR & APRI) and serum Pentraxin.

In our study, also there was no correlation between the PTX3 level and the degree of steatosis detected by ultrasonography. These findings are in concordance with the results of Maleki et al., who suggested that PTX3 could not be used to differentiate the stages of NAFLD or fibrosis[22]. In contrast to these observations, Yoneda et al. investigated the clinical value ofPTX3level to predict NASH and found that it could be considered a marker for detecting fibrosis grading the severity[23] Another observational study concluded that higher PTX levels were associated with severe fibrosis[7].

These contradictory results may be due to the different ethnicities of the studied participants and the methods used for evaluating the PTX3 level. The small cohort compared with the aforementioned studies. Also, the majority of the enrolled patients in our study were classified as mild to moderate fibrosis (61%) lacking the proven liver biopsy.

A recent study demonstrated that the ultrasound-based hepatic steatosis severity grade was significantly associated with elevated transaminase and triglycerides but no relationship with the HDL, LDL or total cholesterol levels[24].

Our results revealed that the diameter of the right lobe of the liver is correlated with the degree of steatosis. Hence, we presume that the use of this sonographic measurement as a qualitative parameter for the detection of steatosis[25].

Conclusion

PTX3 has been noted among NAFLD patients as anon-invasivebiomarker, yet it is not correlated with markers of fibrosis and cannot be used for severity grading

Value of Cardiac Enzymes in Early Diagnosis of Cardiac Dysfunction in Pediatric Septic Shock

Miriam Magdy Aziz[1], Amal El-SISI[2], Amal Abdel Wahab Mohamed[3], Mohamed Saeed Ibrahim Salem[4]

[1]Lecturer of Pediatrics, [2]Professor of Pediatrics, [3]Professor of Chemical Pathology, Faculty of Medicine, Cairo University, Egypt, [4]Msc Pediatrics, Cairo University, Egypt

Abstract

Purpose: Sepsis induced myocardial dysfunction (SIMD) is a severe complication in pediatric septic shock. The purpose of this study was to study serum cardiac troponin I (cTnI) as a biomarker for early detection of myocardial cell injury in pediatric severe sepsis and septic shock and to investigate its association with ECHO findings and clinical outcomes in pediatric septic shock. **Methods:** This study is a case control study that was carried out at Cairo University Children, s Hospital pediatric intensive care units (PICUs) from October 2016 to April 2017. Study included 80 patients whose ages ranged from 3 months to 12 years (40 normal controls coming to the outpatient clinics &40 cases in the PICUs who had clinical signs of severe sepsis and septic shock: 25 males and 15 females with a median age of 18 months). Bedside ECHO was done to the 40 included cases in the PICU to evaluate LV systolic function, LV diastolic function and RV function. **Results:** Serum cTnI was elevated in 33 of the 40 included cases (82.5%) and none of the controls showed cTnI elevation (0%). Prevalence of LV systolic dysfunction was 77.5 %, LV diastolic dysfunction was 52.5% and RV dysfunction was 52.5 %. Serum cTnI was correlated with LV systolic function but not with LV diastolic function, RV function, PRISM score or mortality. **Conclusion:** Elevated serum cTnI is highly prevalent in pediatric septic shock and is associated with decreased contractile function of the heart but not with clinical outcomes.

Keywords: *pediatric septic shock, myocardial dysfunction, troponin I, ECHO, PICU.*

Introduction

Sepsis is a clinical syndrome that complicates severe infection characterized by immune dysregulation, systemic inflammatory response, microcirculatory derangements and end-organ dysfunction[1]. Delayed recognition of pediatric septic shock is associated with worse clinical outcomes[2]. Sepsis induced myocardial dysfunction (SIMD) is defined as the intrinsic myocardial systolic and diastolic dysfunction during sepsis. Early detection of SIMD is essential to give the most efficient and suitable therapy[3]. Cardiac troponins I and T are regulatory proteins that control the calcium-mediated interaction of actin and myosin, producing myocardial contraction. Troponins normally do not exist in extracellular spaces, so their presence in serum is sensitive and specific marker of myocardial damage[4]. Although ECHO is a non-invasive test that helps assessment of the systolic and diastolic functions of the cardiac muscle during septic shock, it is user-dependent, with some inter-observer variability, affected by the loading conditions, tachyarrhythmias and mechanical ventilation[5].

Method

This case-control study was carried out at Cairo University Children, s hospital PICUs from October 2016 to April 2017. 40 normal age and sex matched controls from outpatient clinics without history of cardiac disease were included. Serum cTnI was measured for the control group. 40 cases in the PICUs with clinical evidence of severe sepsis or septic shock were included. Children less than 3 months, those with congenital heart disease, recent resuscitation or 1ry conditions associated with

myocardial ischemia were excluded.

cTnI analysis was done for the cases within 24 hours of admission by cobas 6000 auto-analyzer 2 using a sandwich principle. Samples containing precipitates were centrifuged before performing the assay. Samples, calibrators and controls were ensured to be at 20-25℃ prior to measurement. The normal level of serum cTnI according to the assay used was 0.16 n g/ ml.

Bedside ECHO was done to cases within 24 hours of admission by either the on call assistant lecturer of pediatric cardiology or pediatric ICU. LV systolic function was assessed using EF (ejection fraction), FS (fractional shortening) and the presence or absence of LV dilatation (according to Bonatto percentile curves of LV diameter relative to body surface area (BSA). Any case with EF less than 55% or FS less than 28% was interpreted as LV systolic dysfunction. LV diastolic dysfunction was expressed as the presence of abnormal E/A ratio (where E represents peak velocity across the mitral valve during rapid ventricular filling and A represents peak velocity across the mitral valve during atrial contraction). RV dysfunction was expressed as the presence of RV dilatation (according to Bonatto percentile curves of RV diameter relative to BSA) and pulmonary artery pressure (PAP) elevation.

Clinically significant data were recorded including duration of acute illness before admission, duration of stay in the PICU, number of system dysfunction, grade of sepsis severity (severe sepsis, septic shock, MOSF (multiple organ system dysfunction), inotropic needs in the first 24 hours following admission; number, types, dose of inotropes used (micrograms/kg/minute), inotropic score and vasoactive inotropic score (VIS), vital signs interpreted for age, capillary refill time (CRT), urine output, need for mechanical ventilation, FiO_2 (fraction of inspired oxygen), PaO_2/FiO_2 ratio, blood cultures, PRISM& PELOD scores and outcome (discharge or mortality).

Data management and analysis were performed using Statistical Package for Social Sciences vs. 23. Numerical data were summarized using means and standard deviations or medians and ranges and explored for normality using Kolmogrov-Smirnov test and Shapiro-Wilk test. Categorical data were summarized as numbers and percentages. Exploration of data revealed that the collected values were not normally distributed. Comparisons between 2 groups were done using the Mann-Whitney test. Fisher's test was used to compare between the groups with respect to categorical data. To measure the strength of the association between numeric variables, the Spearman's correlation coefficients were calculated. All p-values are two-sided. P-values < 0.05 were considered significant.

Results

25 cases were males and 15 females. Ages ranged from 3 months to 12 years (median 18 months). The original diagnosis was bronchopneumonia in 12 cases, gastroenteritis in 11 and other diagnoses as (encephalitis, acute renal failure, postoperative cases, systemic lupus erythematosus and juvenile rheumatoid arthritis) in 17 cases.

Duration of the acute illness before admission had a median of 3 days and the duration of stay in the PICU had a median of 11 days. 21/40 cases died (52.5%) and 19 were discharged.

Table (1): Grade of sepsis severity in cases:

	Type	Count n=40	%
Grade of sepsis severity	Septic shock	11	27.5
	MOSF	26	65
	Severe sepsis	3	7.5

Number of system dysfunctions had a mean of 3.55 ± 1.55.

Table (2): System dysfunctions in studied cases:

System dysfunction	Interpretation	Count n=40	%
CVS	yes	40	100
Hematological	No	22	55
	Yes	18	45
Respiratory	No	4	10
	Yes	36	90
Neurological	No	17	42.5
	Yes	23	57.5
Hepatic	No	28	70
	Yes	12	30
Renal	No	26	65
	Yes	14	35

Perfusion was poor in 31 cases and urine output was abnormal in 15 cases (3 cases anuric, 7 oliguric and 5 polyuric). Mean CRT was 4.3±1.1 SD and mean UOP was 1.8±1.3 SD. All cases needed inotropes. Dobutamine, epinephrine, norepinephrine, milrinone and dopamine were used in 31, 29, 14, 12 and 7 cases respectively

Table (3): number of inotropes, inotropic score and VIS in cases:

	Mean	Median	SD	Minimum	Maximum
Number of inotropes	2.3	2	0.79	1	4
IS	25	20	20.6	0	120
VIS	39.48	30	29.58	10	160

36 cases were mechanically ventilated. PaO_2 /FiO_2 was normal (≥300) in 18 cases (45%). 13 cases had acute lung injury (PaO_2/FiO_2:200-300) (32.5%) and 9 cases had ARDS (PaO_2/FiO_2≤200) (22.5%). Median PRISM III & PELOD scores were 15.5 and 22 respectively.

Serum cTnI was elevated in 33 cases (82.5%). Serum cTnI in cases had a mean of 0.837±0.972SD. None of the control group showed elevated serum cTnI. The mean serum cTnI in the control group was 0.048±0.028SD. There was a significant difference between serum cTnI of both groups (P-value<0.001).

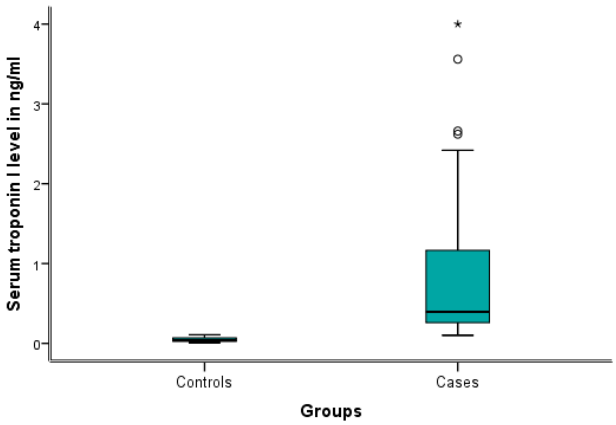

Figure (1): serum cTnI level (ng/ml) in cases and controls:

Blood cultures were positive in 24 cases (60%) which revealed growth of Klebsiella in 7 cases, Acinetobacter in 6 and others (E-coli, Pseudomonas, MRSA) in 11. Cultures other than blood (urine, sputum, wound swab, endotracheal tube and tip of catheter) were done in 29 cases of which 15 cases (37.5%) revealed no growth and 14 cases (35%) were positive (Acinetobacter in 6, Klebsiella in 2, E-coli and Pseudomonas 2 cases each, MRSA and Streptococcus pneumonia 1 case each).

ECHO findings:

Table (4): LV and RV dysfunction in cases:

	Interpretation	**Count n=40**	**%**
LV systolic dysfunction	yes	31	77.5
	no	9	22.5
LV diastolic dysfunction	Yes	21	52.5
	No	19	47.5
PAP elevation	No	23	57.5
	Yes	17	42.5
RV dilatation	No	23	57.5
	Yes	17	42.5
RV dysfunction	No	19	47.5
	Yes	21	52.5

Of 31 cases with LV systolic dysfunction, 16 had LV dilatation.

Of 21 cases with RV dysfunction, 13 had both PAP elevation& RV dilatation, 4 cases had PAP elevation only and 4 cases had RV dilatation only

There was positive correlation between the levels of serum cTnI and LV systolic function (P-value 0.013) where higher serum cTnI levels were in cases with abnormal LV systolic function. There was no statistically significant correlation between serum cTnI and LV dilatation (P-value 0.126).

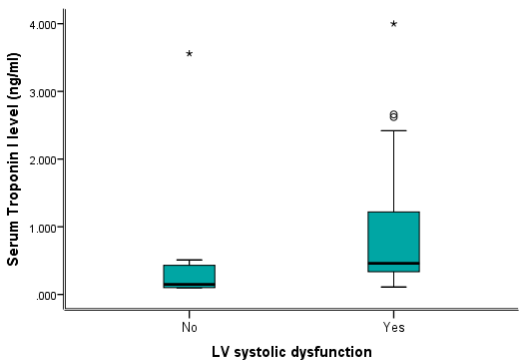

Figure (3): correlation between serum cTnI and LV systolic function.

There was no statistically significant relationship between serum cTnI and LV diastolic function, RV function, PRISM III score and outcome (P-value 0.278, 0.153, 0.283, 0.748 respectively). There was no statistically significant relationship between LV systolic function, LV diastolic function, RV function and outcome (P-value 0.583, 0.516, 0.516 respectively).

Discussion

Severe sepsis and septic shock are common presentations in PICUs with complications as MOSF and death[6]. Troponins are protein molecules that are part of the cardiac and skeletal muscles. 3 types exist: troponin I, T, and C. Troponin T binds troponin components to tropomyosin, troponin I inhibits the interaction of myosin with actin, and troponin C contains the binding sites for Ca^{2+} helping initiate contraction[7].

It is hypothesized that there is a component of myocardial dysfunction in the pathophysiology of pediatric septic shock attributed to dysfunctional microcirculation, direct myocardial cytotoxicity of the products of septic shock and mediators of sepsis (as TNFα, IL-6). Injury to the cardiac myocyte results in cell membrane damage, releasing cardiac markers as TnI, CK-MB into the circulation[8].

The aim of our study was to assess the prevalence of elevated serum cTnI, cardiac dysfunction by ECHO in pediatric severe sepsis and septic shock, to assess the relation between serum cTnI levels and ECHO findings, PRISM III score and outcome. The high prevalence of elevated serum cTnI in our cases is in agreement with **Lodha et al., 2009**[8] which showed elevated serum cTnI in 88% of cases of septic shock compared to control group (hypovolemic shock and sepsis without shock) in which 17.1% showed elevated serum cTnI. Our results were also in agreement with **Gurkan et al., 2004**[9] which showed elevated serum cTnI in 75% of pediatric septic shock cases and **El Tantawy et al., 2012**[10] **study** to assess the incidence of subtle myocardial dysfunction in critically ill children by measuring serum cTnI which was elevated in 100% of patients with severe sepsis and septic shock in contrast to control group.

Prevalence of elevated serum cTnI in 82.5 % of our cases is higher than rate of elevated serum cTnI in the study of Raj **et al., 2014**[5] (33%) and the study of **Briassoulis et al., 2001**[11] on meningococcus-induced purpura-fulminans (24%)[11].

LV systolic dysfunction was found in 31 cases (77.5%). This finding was higher than LV systolic dysfunction in previous studies on pediatric septic shock as **Williams et al**[12] (54%) and **Raj et al**[5] (37%).

Serum cTnI correlated with LV systolic function (P-value 0.013), LV FS (P-value 0.009) and LV EF (P-value 0.035). This is in agreement with **Gurkan et al**[9] which revealed correlation between serum cTnI and LV EF (P-value 0.025), **Fenton et al., 2004**[13]which revealed correlation between serum cTnI & both EF and FS (P-value 0.0022 and 0.0079, respectively)[13] and **Raj et al**[5] which revealed correlation between serum cTnI and LV systolic function (P-value 0.007). This can be explained by the decreased contractile power of the injured myocardium as a result of the toxins and mediators released in septic shock.

Our finding of LV diastolic function in 52.5% of cases is in accordance with **Williams et al., 2016**[12] (48% of septic shock cases). Although the number of cases with LV diastolic dysfunction was more in cases with elevated serum cTnI (19/33 cases i.e. 57.5%) than in cases with normal serum cTnI (2/7 cases i.e. 28.6%), there was no statistically significant relationship between serum cTnI and LV diastolic function (P-value 0.278). This is against the study of **Raj et al**[5] that used both E/A and E/e/in evaluating LV diastolic function and revealed association between serum cTnI levels and LV diastolic function (P-value 0.007)[5]. This can be explained by the fact that E/A reflects significant diastolic dysfunction and is preceded by abnormal E/e/ and thus E/A is less accurate than tissue Doppler derived E/e/.

LV dysfunction (systolic or diastolic dysfunction) was found in 80% of our cases which was close to **Williams et al**[12] (72%). Our study found RV dysfunction in 52.5% which was in accordance with **Williams et al**[12] that showed presence of RV systolic dysfunction in 54% and RV diastolic dysfunction in 35% of pediatric septic shock cases[12]. There was no statistically significant relationship between serum cTnI and RV function (P-value 0.153) although the number of cases with RV dysfunction was higher in the group with elevated serum cTnI (20/33 i.e. 60.6%) than the group with normal serum cTnI (1/7 i.e14.3%).

Mortality rate in our study was relatively high (52.5%). It was close to the mortality rate of **Lodha et al**[8] (44.4%) and **El Tantawy et al**[10] (49.2%). This can be explained by delayed admission of cases to the PICU due

to bed occupation and the presence of advanced septic shock with MOSF which causes myocardial damage in larger number of cases than PICUs of developed countries as in **Raj et al**[5](7%).

Although the mortality rate was more in the group with elevated serum cTnI (18/33 i.e. 54.45%) than the group with normal serum cTnI (3/7 i.e. 42.8%), there was no association between serum cTnI and mortality (P-value 0.748). This is in agreement with **El Tantawy et al**[10] and **Gurkan et al**[9] but not with agreement with **Lodha et al**[8] which revealed correlation between serum cTnI and mortality (P-value 0.04). The absence of association between serum cTnI and mortality in our study can be attributed to the presence of severe concomitant illnesses and systems failure other than myocardial cell injury (as ARDS, ESRD and CNS dysfunction) that might have contributed to the high mortality rate in the serum cTnI negative cases.

No association was found between ECHO parameters (LV systolic, LV diastolic and RV function) and mortality and this is in accordance with **Williams et al**[12] study. This could be due to reversibility of some ECHO abnormal parameters[3]. Different insults to various body systems are associated with different outcomes and the host immunity plays important role in determining the outcome[14].

Our study revealed no statistically significant relationship between serum cTnI and clinical aspects of disease severity (PRISM III score, PELOD, age, duration of stay, number of systems failure, VIS and IS). P-value was (0.283, 0.234, 0.593, 0.808, 0.169, 0.797, 0.509, respectively). This can be explained by our relatively small sample size, the presence of MOSF and the severe enough septic shock in the serum cTnI negative group to cause no significant difference between them and the serum cTnI positive group.

Abstract

Background: Achieving ideal goals of glycemic control in children and adolescents with type 1 diabetes (T1D) is challenging. One of the commonest adverse effects of poor control is dyslipedemia with the subsequent cardiovascular events in young adulthood.

Aim: This study investigates the prevalence of lipoprotein disorders in children with T1D and studies its possible causes.

Materials and Method: We recruited 80 type 1 diabetic child, took full history and assessed them clinically for their status of growth and puberty. Biochemical analysis including glycated hemoglobin (HbA1c) and lipoprotein profiles was done.

Results: Abnormal lipid profiles were detected in 33% and poor glycemic control in 85% of our studied patients.The group of patients with better glycemiccontrol had a significant elevation of HDL-c and a significant reduction of TG levels than those with poor control. Moreover the group of patients who did not have dyslipdemia had a significant reduction in HbA1c level.

Conclusion: Dyslipedemia is highly prevalent in diabetic children. Poor glycemic control is a strong contributing factor. Early recognition and intervention is fundamental for the prevention of its harmful sequences. Further studies are warranted to asses the effect of improving glycemic control on the status of dyslipedemia in diabetic children.

Keywords: *Dyslipedemia, T1D, children*

Introduction

Improper glycemic control has its adverse consequences in children with type 1 diabetes (T1D), of these poor growth rates, the development of insulin resistance and dyslipidemia are frequently noticed.

According to ISPAD guidelines, screening for dyslipidemia should be performed soon after diagnosis in all children with T1D from age of 11 years. Cholesterol plays an important role in the initiation and progression of atherosclerosis.[1]In addition, dyslipidemia was associated with microalbuminuria and retinopathy development in the DCCT/EDIC [2] and some other studies.[3,4]

The prevalence of hypocholesteremia approached 50% of young adults in one study [5], while elevated non-HDL cholesterol approached 25% in another study of individuals younger than 21 years of age.[6]

This study aimed at observing the prevalence of dyslipidemia in children with T1Dand studying the clinical characters of those patients.

Materials and Method

Study population:

We studied 80 children diagnosed with T1D following in the pediatric diabetes clinic, Cairo University Children Hospital over 12 months period from November 2016 to November 2017.

Patients were diagnosed according to the ADA consensus guidelines[7] that includes clinical symptoms and the laboratory findings. Patients with a minimum of 3 years diabetes duration were included. T1D Patients with known cardiovascular, hepatic, renal, systemic disease, chronic inflammatory disorder or receiving any medication other than insulin were excluded.

The protocol was approved by the local research ethics committee of the Pediatric department at Cairo University and all the participants or their guardians gave informed consent. The study complied with the World Medical Association Declaration of Helsinki regarding ethical conduct of research involving human subjects.

Clinical Measurements:

Complete clinical examination was applied to all studied patients including, blood pressure was measured on 3 different occasions and were compared to percentile curves for same age and sex. Patients lying on or higher than the 95th percentile for their height were considered hypertensive.[8]

The height was measured using Harpenden stadiometer and recorded to the nearest 0.1 cm and the weight was measured using self-calibrating electronic SECA scale that records to the nearest 0.1 kg. BMI (body mass index) was calculated as weight in kg/height in m2. We used Growth vision computer software provided by Novo Nordisk, Denmark to assess height SDS (standard deviation score), weight SDS and BMI SDS. Pubertal assessment was done following Tanner pubertal stages in girls[9] and in boys[10]. The waist circumference (WC) was measured in centimeters with a tape measure, at the narrowest circumference between the lower costal margin and the iliac crest[11] and was plotted on WC centiles.[12]

Biochemical Measurements

The most recent results of fasting lipid profile including; serum Cholesterol (TC), Triglycerides (TG), High density lipoproteins (HDL) and Low density lipoproteins (LDL) were obtained from the medical records. To define abnormal lipid profile (dyslipidemia), we followed the cut-offs of the National Heart Lung and Blood Institute. [8] Mean HbA1C levels over the preceding year presented in percentage were calculated, poor glycemic control was defined by HbA1C<7.5%.[13]TC, HDL, LDL, TG were performed by the use of standard methods on Cobas MIRA automated analyzer (Roche Diagnostics, Basel, Switzerland).

Statistical Analysis

Statistical analysis was performed using SPSS version 25 (IBM Co., Armonk, NY, USA). Student *t* tests or chi-square tests were used to compare the baseline characteristics between patient groups. All *P*-values were two-tailed, and $P<0.05$ was considered statistically significant.

Results

A number of 80 children with T1D with an age range of (11.1 to 18.1 years) were enrolled in the study. Table (1) shows the baseline clinical characteristics and biochemical parameters in those subjects.

Table (1): Clinical and biochemical data of the studied patients (n=80):

		Range
Age(yrs)	14.51±1.76	11.1- 18.1
Duration of diabetes(yrs)	5.15*	2.8-15.7
Insulin dose (IU/Kg/day)	1.25*	0.3-2.8
Weight SDS	0.2*	-4-3.1
Height SDS	-1.1*	-5.8-1.8
BMI SDSs	0.95*	-2.7-2.4
Waist circumference (cm)	79.27±6.54	64-94
SBP (MmHg)	117.56±16.27	70-160
DBP (MmHg)	78.1±11.96	50-109
Total cholesterol (mg/dl)*	170.5	133-285
Triglycerides (mg/dl)*	88	16-235
LDL-c (mg/dl)*	110	65-191
HDL-c (mg/dl)*	48.5	39-65
HbA1C (%)	10.11±2.43	5-14

Data are represented as mean and standard deviation. * median, BMI: body mass index, SBP: systolic blood pressure, DBP: diastolic blood pressure

46 Females were included in the study. Only 5% of T1D patients were considered obese with BMI SDS more than 2 and only 4 of them had their WC more than 90th centile. Hypertension was recognized in 33% of them and all of them were pubertal. Poor glycaemic control defined by HbA1C > 7.5 gm% was detected in 85%with a mean HbA1C 10.11±2.43 gm%. Regular insulin and NPH (Neutral Protamine Hagedorn; intermediate acting insulin) in a basal-bolus regimen was the most commonly used regimen with a total daily insulin dose range (0.3 to 2.8 IU/kg/day).

Dyslipidaemia was the most frequent complication detected in our T1D patients (33%), we compared between two groups of patients according to the presence of dyslipidaemias and a statistically significant elevation of HbA1C (P = 0.031) in the group with dyslipidaemia was recognized. No significant difference in BMI, insulin dose or blood pressure between the two groups.

When comparing two groups of our patients according to glycaemic control (HbA1C %), showed a statistically significant elevation of serum HDL-c levels, in addition to a statistically significant reduction in TG level in the group with good glycaemic control (HbA1C<7.5%).

Table (2): Comparison between two groups of patients according to the presence of dyslipidemia (n=80):

	Dyslipidemia (n=27)	**No dyslipidemia (n=53)**	**P value**
Age (Yrs)	14.53±1.9	14.42±1.71	0.736
Diabetes Duration (Yrs)*	5.2(4.2-8.4)	5(3.7-7.5)	0.728
Insulin Dose (IU/KG/Day)*	1.1(1-1.4)	1.3(1.2-1.5)	0.209
Weight SDS*	-0.1(-0.7-1.1)	0.3(-0.5-0.8)	0.630
Height SDS*	-1.7(-2.4- -0.2)	-1(-1.6- -0.2)	0.243
BMI SDS*	0.9(0.3-2)	1(0.1-1.5)	0.545
WC (cm)	79.24±6.49	79.29±6.67	0.979
SBP (mmhg)	115.82±15.19	118.41±16.92	0.593
DBP (mmhg)	79.53±13.24	77.32±11.4	0.550
HbA1C (%)	11.5±1.88	9.93±2.53	0.031

Data are represented as mean ± SD, or * median and interquartile range (IQR). P-value <0.05 is considered significant. BMI: body mass index; WC: waist circumference; SBP: systolic blood pressure; DBP: diastolic blood pressure; LDL-c: low density lipoprotein cholesterol; HDL-c: high density lipoprotein cholesterol; HbA1C: glycated hemoglobin.

Table (3): Comparison between two groups of patients according to glycemic control (HbA1c% cut off 7.5%) (n=80):

	>7.5% (n= 68) Poor control	**<=7.5% (n=12) Good control**	
Age (Yrs)	14.32±1.71	15.83±1.91	0.101
Diabetes duration (Yrs)*	5.15(3.9-7.5)	6.65(4.6-9.2)	0.478
Insulin dose IU/Kg/Day)*	1.2(1-1.5)	1.5(1.35-1.8)	0.132
Wt SDS*	0.2(-0.6-0.8)	0.55(-0.45-2.3)	0.416
Ht SDS*	-1.1(-1.8-0.2-)	-1.45(-1.85-0.4-)	0.850
BMI SDS*	0.94(0.1-1.6)	1.4(0.05-2.15	0.569
WC (cm)	78.82±6.47	84.50±5.69	0.096
SBP (mmhg)	118.26±15.22	109.50±27.53	0.307
DBP (mmhg)	78.87±11.61	69.25±14.22	0.124
Total cholesterol (mg/dl)*	172.5(155-197)	169(152-170)	0.339
Triglycerides (mg/dl)*	94.5(70-140)	53(50-63)	0.024
LDL-c (mg/dl)*	111(98-124)	94.00(86.5-102.5)	0.097
HDL-c (mg/dl)*	48(43-53)	59(52.5-64)	0.021

Data are represented as mean ± SD, or * median and interquartile range (IQR). P-value <0.05 is considered significant. BMI: body mass index; WC: waist circumference; SBP: systolic blood pressure; DBP: diastolic blood pressure; LDL-c: low density lipoprotein cholesterol; HDL-c: high density lipoprotein cholesterol; HbA1C: glycated hemoglobin.

Discussion

This was a cross sectional study that studied the status of dyslipidaemia in children with T1D, our results point to the high prevalence of lipid disorders in this population, and that these disorders are mainly contributed to poor glycaemic control.

The main pattern of dyslipidaemia in our study was high TG levels, which is in agreement with Osawa and his colleagues[14] and with [8]who stated that the main dyslipidaemic pattern in childhood is moderate to severe elevation of TG level, normal to mild elevation of LDL-c and reduction of HDL-c, and low HDL levels in agreement with Pérez et al.[15]who announced that low HDL-c was the most frequent dyslipidaemic pattern in patients with poorly controlled T1D, that fortunately improved by optimization of glycaemic control through intensive insulin therapy.

In the previous literature, HDL-c levels were shown to be normal or high in T1D, a finding that was explained by the high activity of lipoprotein lipase(LPL)

in adipocytes that avidly hydrolyses triacylglycerol rich particles, resulting in high HDL- c levels.[16]

Dyslipidaemia in itself has its adverse consequences on insulin sensitivity in diabetic patients as was reported by Krochick and colleagues[17],they stated that poorer sensitivity to insulin in children and adolescents with T1Dwas related to lipid disorders in those subjects.

In an attempt to understand the link between poor glycaemic control and dyslipidaemia, we searched the literature; Pang and Nardeen[18] postulated that chronic hyperglycaemia results in two metabolic pathways: accentuation of ectopic fat accretion with increased intramyocellular lipid content, interfering with insulin signaling pathways in skeletal muscles giving rise to insulin resistance, and promotes lipolysis. In the same context, Heptulla et al.[19]concluded that poor glycaemic control with the resultant glycation end products interfere with insulin action promoting lipolysis giving rise to non-esterified fatty acids which in turn impede with the insulin stimulated glucose uptake by substrate competition through the Randle cycle. These explanations point to a vicious circle of insulin resistance, poor glycaemic control and dyslipidaemia.

Another theory at hand is the reversed fat partitioning; as it is well known that insulin not only exerts its effects on glucose metabolism, but it also has profound effects on lipid metabolism via promotion of hepatic and peripheral fat storage and suppression of hepatic and peripheral fat oxidation. However in T1D, with absent pancreatic insulin secretion and its exogenous replacement, contrasting lipid handling might be predicted.[20]

Unfortunately, dyslipidaemia predispose to atherosclerotic changes that, according to ISPAD [1], start in childhood and adolescence as shown by intima-media thickness of the aorta and carotids.[21,22] Moreover, some researchers detected silent coronary atherosclerosis by intravascular ultrasound in young adults with childhood onset of diabetes.[23]

In the same boat, Schofield and colleagues reviewed the pathophysiology and implications of the alterations in lipoproteins and reported a significant association between atherosclerotic changes and serum level of Tc, TG in T1D.[24]

Conclusion

Our results point to the high prevalence of dyslipidaemia in children with T1D, emphasizing on the strong link to poor glycaemic control. The expected deleterious complications urge all physicians caring for diabetic children to monitor lipoprotein profiles periodically, trying every effort in maintaining optimal glycaemic control.

Assessment of Anatomic Anterior Cruciate Ligament Reconstruction Using Distally Inserteddoubled Hamstrings Tendons

Mohamed Samir Rashed[1], Ashraf Abd Al-Kder Al-Nahal[1], Hisham Mesbah Soliman[1], Waleed Reda Mohamed[1], Ahmad Mahmoud Gad[1]

[1]Orthopedic Surgery Department, Faculty of Medicine, Cairo University, Cairo. Egypt

Abstract

Background: The anterior cruciate ligament is an important, internal, stabilizer of the knee joint, restraining anterior translation of the knee.

Objective: Assessment of anatomic anterior cruciate ligament reconstruction by using distally inserted doubled hamstrings tendons by clinical evaluation.

Method: This study was carried out on 30 patients with ACL deficient in the period from March 2014 to July 2017. Anatomic anterior cruciate ligament reconstruction using distally based doubled hamstrings tendons performed to all patients in this study.

Results: The results show a significant improvement in Lysholm knee score postoperatively, and all its sub-score show a considerable increase.

Conclusion: The improvement of ACL reconstruction by using technique permits an anatomical ACL reconstruction with the advantage of the preservation of hamstrings tendon insertion.

Key Words: *ACL reconstruction, knee, arthroscopy and distally base.*

Introduction

Many methods of ACL reconstruction is known most of them sacrificed the insertion of the hamstring muscle[1]. The ACL, providing mechanical stability, also contributes to the proprioception sensation of the knee[2]. Proprioception is the sensory modality that encompasses the feeling of joint position and joint motion. Mechanoreceptors, along with muscle spindles for the joint proprioception, have been found in the cruciate ligaments[3]. Injury to the anterior cruciate ligament (ACL) not only causes mechanical instability but also leads to a functional deficit in the form of diminished proprioception of the knee joint4. "Functional" is often incomplete even after "anatomic" arthroscopic ACL reconstruction, as some patients with a clinically satisfactory reconstruction and proper ligament tension continue to complain of a feeling of instabilitylity and to give way [4], although the knee does not involve subluxation on clinical examinations. Factors that may play a role could be proprioceptive elements, as the intact ACL has been shown to have significant receptors[5].

Aim of the Work

The objective of this study was the assessment of anatomic anterior cruciate ligament reconstruction by using distally inserted doubled hamstrings tendons.

Patients and Methods

This study was carried out on 30 patients with ACL deficient in the period from March 2013 to January 2017.

nclusion criteria:

Normal contralateral knee.

Associated meniscal injuries had been managed either by repair or meniscectomy.

Exclusion criteria:

Large chondral lesion Tear in PCL, LCL&MCL.

Previous knee surgery

(A) Preoperative evaluation:

1 - Careful history taking.

2 - Analysis of a patient's complaint. 3 - Clinical examination.

4 –Radiographic evaluation: - Includes plain X-ray and MRI.

5 - Rating scales: - Include A- Lysholm knee score.

B- International Knee Documentation Committee score (IKDC).

(B) Operative ACL reconstruction: Timing of surgery:

In this study, the timing of ACL reconstruction from the date of injury was not the most critical issue.

The technique of surgery:

1-position of the patient: The patient was laid supine.

3- Examination under general anesthesia:

All knees examined under anesthesia .

4 - Diagnostic arthroscopy. 5-Harvesting of the graft:

The grafts harvested through 1.5-inch incision centered approximately 2cm medial to the tibial tubercle. Dissection was carried down to the sartorious fascia, which was incised parallel and distal to the palpable (ST) tendon. The (ST) ± (Gs) tendons were then released from all their fascial bands to prevent premature amputation of the tendon short of its muscle belly. As seen in Fig 1

The stripper was advanced using a slow and steady motion into the thigh, and the tendon released from its muscle belly by holding the stripper in place and slowly pulling the tendon out of the incision. The tendons are collected using a blunt tendon stripper while the knee is in 90° of flexion.

6- Preparation of the graft:

The harvested tendons sutured together.as seen in figure 2

7- Management of associated injuries: 8-Arthroscopic Reconstruction:

A 3-portal technique used. The main anterolateral (AL) and anteromedial (AM) portals created along the patellar tendon edges. The AL portal is created at the level of the inferior pole of the patella, allowing full visualization of the ACL tibial footprint from above. An accessory AM portal (AAM), located approximately 1 cm below and medial to the main AM portal, was finally created under direct visualization of the arthroscope with the help of a spinal needle. It must be located just above the medial meniscus and away from the medial femoral condyle. Initially, the scope inserted through the AL portal, and instruments introduced by way of the main AM portal. Later the AAM portal was used for instrumentation while visualizing the femoral footprint through the AM portal. The notch was debrided, saving 1 to 2 mm of ACL fibers at both the tibial and femoral footprints.

The posterior edge of the lateral femoral condyle must identified. The medial aspect of the lateral femoral condyle contains the lateral intercondylar ridge (resident's ridge) representing the superior most boundary of the femoral ACL origin. The bifurcate ridge separates the AM and PL bundle origin. The remnants of the incompetent ACL were removed with thermocautery because arthroscopic shaving may inadvertently destroy the bony references. Attempts made at preserving a small peripheral rim of ligament because these fibers are thought to contain proprioceptive elements.

6- A rosette reamer according to the size of the graft was used to ream the femoral tunnel. A 25 mm long femoral tunnel is enough usually.

Tibial tunnel placement:

1- The scope was introduced through the AL portal while the knee was hanging free in 90º flexion.

2- The guide set at a 55º angle.

3- The guide aimer passed through the AM portal.

4- The stylet tip of the guide arm put in the center of the footprint midway of the centers of both bundles of native ACL.

5- The tibial tunnel entrance was through the graft harvest incision, 1.5 cm medial to the tubercle and about 4 cm distal to the tibial articular surface. The cannulated guide arm passed to this point.

6- Drilling a guide pin through the cannulated guide arm. After penetrating the joint, the guide removed. 7-Depending on the graft size, the tibial tunnel was drilled. As seen in figure 3

Graft passage and fixation:

1-A grasper was passed through the tibial tunnel to bring out the Ethibond which pass in the femoral tunnel.

2-The Ethibond no. 5 sutures of the prepared graft are passed using the stainless wire loop from the tibial tunnel to emerge outside the skin of the thigh. 3-By pulling on the Ethibond sutures outside the thigh, the ST graft passed through the tibial then the femoral tunnel.

4- Once the endobutton is flipped over the cortical of the lateral femoral condyle, and the free portion of the graft is pulled to tighten of the distal portion of the graft

5- Scopic assessment throughout the full range of motion (ROM) to assess for impingement either on PCL or roof of the notch.

6- Prepared the free edge of the graft and continuous flexion and extension of the knee then Fixed free side by staples when the knee in 30 degrees of flexion.

Pearls and Pitfalls

The entry of the tibial tunnel should be placed high enough to prevent kinking of the tendon, which would result in damage to the vascularization and reduction of mechanical resistance.

Fig 1 . The tendons are collected using a blunt

.tendon stripper while the knee is in 90° of flexion

Figure 2. A The harvested tendons are then sutured together using 2 nonabsorbable No. 2 stitches graft

. after preparation using endobutton group20-30. Regarding sex, the majority of the patients (87.0%) were male, while only 4 cases were females.

The clinical data of the studied patients, regarding the affected side, 18 patients (60.0%) the affected side was the dominant hand, while 12 patients (40.0%) the affected side was nondominant. Regarding the cause of injury, the majority of the cases (66.7%) was sports injury while10 cases were nonsport injury.12cases(40.0%) had a torn medial meniscus,8cases(26.7%)had torn lateral meniscus,4cases (13.3%) had torn both menisci, and 6 cases had torn ACL only.

The Lysholm system based on subjective assessment of the following:

Table (1), shows the different scores pre and post-operative.

Table (1): Comparison between support score pre and postoperative in studied patients group.

	Preoperative	**Postoperative**	**t**	**p**
Limp score	2.94±1.88	4.63±0.76	5.11	0.001*

Objective evaluation (Table 2)

The **IKDC** knee examination form used for objective evaluation. This Form contains seven

Figure 3 . Drilling of the tibial tunnel from outside .

Results

The age of the patients ranged from 20- 40years with a mean of 28.53±5.82 years; the majority of the patients (70.0%) was in the age of measurement items. All patients scored for these items before and after the surgery. Four grades determined for each group:

GradeA=normal, Grade B=nearly normal, Grade C=abnormal and Grade D= severely abnormal

Group (IKDC) scoring

The pre-operative and post-operative distribution of cases according to the functions grading of the IKDC of group A showed a statistically significant differences regarding all parameters ($p<0.05$) except for lack of extension($p>0.05$)

Discussion

This study evaluates the outcome of anatomic anterior cruciate ligament reconstruction using distally inserted doubled hamstrings tendons.

This study included 30patients (30knee), the age of the patients ranged from20-40years with a mean of 28.53±5.82 years; the majority of the patients (70.0%) was in the age group 20-30. Regarding sex, the majority of the patients (87.0%)were male, while only 4 cases were females. Regarding the affected side, 18 patients (60.0%) the affected side was the dominant hand, while 12patients (40.0%) the affected side was nondominant. Regarding the cause of injury, the majority of the cases (66.7%) was a sports injury while 10 cases were a nonsport injury. 12cases(40.0%) had a torn medial meniscus,8cases(26.7%) had torn lateral meniscus,4cases(13.3%) had torn both menisci and 6 cases had torn ACL only.

In agreement with our study demographic and basic patients data,[7] **Ravi Gupta, et al., (2010)** evaluates the outcome of Preserved insertions of the semitendinosus and gracilis tendons(STG)in ACL reconstruction. They found that there were 39men and6women. Averageagewas 25.4 years (range 18-- 44years).The mode of injury was a road-side accident in 37patients, sports injury in five and fell from stairs in three. Twenty-one patients had an injury on the left side.

In a study done by **Roberto Buda**, **et al.,** which evaluated the same to are fifty-seven patient affected by unilateral ACL injury were operated by Anatomic ACL Reconstruction Using Distally Inserted Doubled Hamstrings Tendons. Patients included 32 men and 25 women with a mean age of 23.3years(range,16-32years). Meantime from injury to surgery was 2.9(range,1-6months)months. All patients were involved in sports at a recreational level.[8]

In our study, the total lysholm knee score pre and postoperative, before surgery, the Lysholm knees core was excellent in3(10.0%), good in3(10.0%) patients, fair in11 patients(36.7%)and poorin13 patients(43.3%). After surgery, the Lysholm knee score was excellent in 13 patients

(43.3%) and goodin 13 patients (43.3%) and 2patients (6.7%) was classified as fair while 2patients(6.7%)was poor. The mean lysholm score preoperative was72.31±12.68and increased significantly to be 89.0±10.73; there was a significant increase in total lysholm knee score postoperatively.

According to RaviK. Gupta, The mean Lysholmscore, at the final follow- up was 95.22 in comparison to the preoperative score of 62.4. [7]

It could attributed to the fact that the majority of patients in our country and developing countries get diagnosed late; the instability and its associated secondary damage in the knee due to delayed presentation may be the reason for a very low preoperative Lysholmscoreinour patients. [8]

Our mean postoperative Lysholm score and postoperative subjective IKDC score, of 89.0 ± 10.73, 92.87%, respectively are near that reported by Roberto Buda, MD; Alberto Ruffilli, MD; *et al*. The mean International Knee Documentation Committee subjective score at final follow-up was 97.161.4. According to the International Knee Documentation Committee objective score, [10] at last follow-up, 50 patients were rated A, and 7 patients were rated B. Among the patients rated B, 4 reported anterior knee pain related to a patellofemoral chondropathy despite an objective stable knee. The other 3 patients rated B had an objective mild instability; in 1 patient, both the Lachman and the pivot-shift tests showed a slight objective instability, whereas only the Pivot shift test was nearly normal for the other 2 patients. Summar of our result compared with the outcome of other author show in results.

In our study, 100% cases reported their knees as normal or near normal(grade +B objective IKDC) after reconstruction, and so was the case with Robert oBuda(97%). In our study, all patients scored for the IKDC knee examination items before and after the surgery.

Regarding functional evaluation before surgery, 17patients (56.7%) were graded abnormal, and

5patients(16.7%)were graded severely abnormal. After surgery, 21 patients (70.0%) were gradedas normal,6patients(20%)were graded nearly normal, and 3 patients (10%)were graded abnormal. There was a significant improvement in Functional evaluation post-operative.

Our results are consistent with those of previous authors, indicating excellent restoration of anterior and rotatory stability for most patients. Though Lachmantestisa reliable clinical test for diagnosis o fACL rupture, quantification of anteroposterior tibial displacement remains inaccurate. [9]

In this study differential anterior tibial translation(when compared with the normal knee)was following studies conducted by **Yasuda *et al.*[10].** No patient in our study reported instability during activities of daily living or doing strenuous activities.

Achieving rotatory control of the knee post ACL reconstruction has been shown to increase patient satisfaction, decrease functional instability, and potentially delay the development of osteoarthritis. The pivot shift can assess this rotatory component of knee laxity and appears to have the potential to become a benchmarking gauging the success of ACL surgery. In this study, all patients were pivot shift negative after ACL reconstruction, which is comparable with the research conducted by **Järvelä and Kim*etal*.** In there the result was slightly better than **Siebold *et al*.** and **Yasuda *et al*.** (97% each). [11,12]

Conclusion

The improvement of ACL reconstruction by using technique permits an anatomical ACL reconstruction with the advantage of the preservation of hamstrings tendon insertion and the creation of a femoral socket with an enhancement of the ligamentization process of the graft help in the excellent outcome postoperatively.

Abstract

Objective: This study was done to evaluate clinical picture, radiographic findings and results of anterior odontoid screw fixation in cases of odontoid fracture, using one hollow titanium odontoid screw, according to our limited facilities in absence of intraoperative neuronavigation or O-arm using only one C-arm to ensure ideal trajectory.

Method: The present study included 14 patients, 10 males and 4females. Their ages ranged from 19 to 56 years. Instability resulted from fracture of the odontoid process type II in12 cases, and type III in 2 cases. Single hollow titanium anterior odontoid screw was used in fixation using only one C-arm intraoperative to ensure ideal trajectory. Postoperative Philadelphia neck collar was applied for 8-12 weeks. Outcome Measures included radiological evaluation of successful bone fusion, neurological evaluation using the American Spinal Injury Association (ASIA) motor score, neck and arm pain scoring, and neck disability index (NDI). Evaluations were conducted preoperatively and at end of follow-up period which ranged from 6 to 12 months.

Results: Postoperative evaluation revealed that 50% of patients improved, while 50% of patients remained at the same ASIA score as pre-operative. Pain and neck disability scores were reduced postoperatively compared with preoperative. Fusion was achieved in 13 cases (93%) at last follow-up. Instrumentation failure occurred in only one case due to screw break.

Key words: *Trauma, Odontoid fracture, Instability, Anterior odontoid screw, C-arm.*

Introduction

The axial odontoid fractures represent about (10%-15%) of cervical fractures [1]. There are three types of odontoid process fractures, according to Anderson and D'Alonso[2]. Odontoid (O) (II) fracture which involves the base of O process is the most kinds[2, 3].

Type I odontoid fracture which involves the apex of the odontoid and Type III fracture in which the fracture line extends to the body of C2 often stable and treated conservatively with external immobilization in form of cervical collar or Halovest. Second type is a high risk of non-union and pseudoarthrosis [4-6].

Surgical approaches of O fractures were classified as either anterior or posterior approaches. Posterior C1-C2 fusion leads to limitation of rotatory movement of cervical spine, while anterior O screw rotatory movement of cervical spine is maintained with good fusion results [9-11].

With recent advancements in neurosurgery and intra operative tools as Neuro-navigation and O arm, odontoid screws could be placed safely with increase accuracy, and less morbidity [7-8]. Most of developing countries such as Egypt still invariably lack these facilities, and free hand way stills the only option of management.. So the aim of this study is to evaluate anterior odontoid screw placement, associated complications and peri-operative morbidity with odontoid fracture to limited facilities in absence of intra-operative neuronavigation or O-arm using only one C-arm to ensure ideal trajectory.

Materials and Method

This prospective study was conducted at the departments of Neurosurgery, Cairo University to allow 6-12 months follow-up for the last case operated upon. The study included 14patients who suffered from odontoid process fractures indicated for surgical fixation.

Inclusion criteria:

1. Type two odontoid fracture.
2. Shallow type three odontoid fracture.
3. The fracture is reducible.
4. Acute fracture (less than three months)
5. Posterior oblique fracture

Exclusion criteria:

1. Irreducible fracture.
2. Chronic fractures (more than three months).
3. Transverse ligament disruption.
4. Inability to achieve an appropriate screw trajectory because of a barrel chest, short neck, fixed thoracic kyphosis deformity, and fracture patterns that require a flexed position to obtain reduction
5. Anterior oblique fractures (posterior superior to anterior inferior).
6. Type three odontoid fracture with significant vertebral body involvement because of poor proximal screw fixation

There were 10 males, and 4 females and their ages ranged from 19 to 56 years.

The cause of instability was fracture of the odontoid process type II in 12 patients (86%), and type III in 2 patients (14%). Trauma was the cause of injury in all cases, road traffic accidents in 9 cases (64%), falling from height in 4 cases (29%), and blunt trauma in one case (7%).

As regards the clinical presentation, all patients had presented with posterior cervical pain with variable degrees of radiation to the occipital region. Pre- operative motor power according to ASIA motor score, 5 patients were ASIA grade E, 5 patients were classified as ASIA grade D, 2 patients were ASIA grade C, and 2 patients were ASIA grade B

Table (1): Showing ASIA score grading system (Maynard *et al.,* 1997)

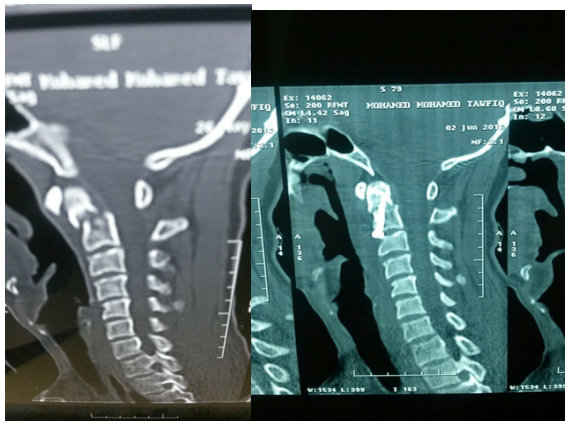
ASIA Impairment Scale	
A	Complete lesion
B	Incomplete sensory preservation
C	Incomplete motor preservation <MRC grade 3
D	Incomplete motor preservation >MRC grade 3
E	Normal neurological function

All cases had preoperative craniocervical X-ray, CT, and MRI examinations. The disease nature was explained, the procedure and the alternate routes of management were explained to all the patients and their relatives. Written consent for the management was obtained from all the patients.

Anterior odontoid fixation with single hollow titanium odontoid screw was performed in all cases. We lack an 'O' arm and navigation system to aid us in ideal placement of odontoid screws, we had only one C-arm in all cases which was used to achieve the optimum trajectory.

Following the procedure we encouraged early mobilization of the patients on a cervical collar from day 2 post surgeries, after performing a CT cervical scan to assess the direction and location of the screw. ASIA score grading system was used post-operative to assess neurological outcome. Fusion was assessed by cervical plain X-ray films and CT scan.

Results



All surgeries were conducted smoothly without intraoperative complications or vascular injury. . The mean duration of the procedure was 260 min (range 100– 300 min).

Postoperative clinical evaluation(PCE) revealed increase the neurological ASIA of 50%patients, five patients improved from ASIA score D to E, one patient from C to D, and one patient from B to D),while 7 patients (50%) remained at the same ASIA score as pre-operative, (5 patients were ASIA score E, one patientswas C, and one patient was D).

Postoperative X- rays and CT detected proper reduction and alignment with evidence of bone fusion in 13 cases (93%). Only one case (7%) suffered from progressive neck pain with limitation of neck mobility X rays and CT were done that detected screw break and misalignmentthat was managed with posterior fixation

and fusion.

Mild dysphagia in 36% of patient were improved within few days.

A B

Figure (1) (A) CT sagittal reconstruction shows odontoid fracture. (B) CT sagittal view after odontoid screw placement

Discussion

Odontoid fractures are a common type of cervical spine fractures have increased incidence in elderly.[12] Awidely used classification for O fractures is the anderson and D'alonzo classification.

A B C

Figure (2) (A) and (B) are intra operative C-arm images (lateral and AP views) show placement of the guide wire through the odontoid process. (C) C-arm AP view shows the introduction of the cannulated screw over the K-wire.

Type II fractures are common associated with higher non fusion up to 78% with fracture dislocation of 6 mm or greater [2].

Conservative management with halo vest was option and used, surgical management is comparatively so far more superior [13-14].

Anterior odontoid is initially described in in Japanese orthopedic journal in 1980 [15]. The greatest advantage is maintenance of atlanto-axial mobility[16]. Also no need for bone grafting, less invasiveness, and less soft tissue dissection via a limited anterior cervical exposure. Major limitations of the procedure are need for intact transverse ligament and the fracture to be reducable before screw placement.

With recent progression in neurosurgery and intra operative facilities such Neuro-navigation and O arm, odontoid screws can be placed safely with high accuracy and less morbidity.. Most developing countries have deficiency in facilities in most of neurosurgical centers.

Our study was carried out on 14 patients who suffered from odontoid fractures, and underwent anterior odontoid screw fixation. There were 10males, and 4females.Their ages ranged between 19 and 56 years, and the mean age was 36.1 years, this was consistent with what was reported by **Bhattarai *et al.*** [17]. In this study the cause of instability was fracture of the odontoid process type II in 12 patients (86%), and type III in 2 patients (14%) (both patients refused prolonged immobilization in halo

vest). Trauma was the cause of injury in all cases, road traffic accidents in 9 cases (64%), falling from height in 4 cases (29%), and blunt trauma in one case (7%)., also in **Bhattarai et al. [17].** Fond road accidents were common type of injury (60%) then fall injuries (26.67%).

In our study five patients were neurologically intact at the time of injury (36%), and nine patients presented with incomplete neurological lesions, also neck pain was a presenting symptom in all cases of odontoid fractures.

In this study, anterior odontoid screw was done in all cases, using single hollow titanium odontoid screw. We used intraoperative a single C-arm to obtain the ideal trajectory. All surgeries were conducted smoothly without intraoperative complications or vascular injury.

In this study 13 cases (93%) showed proper reduction and alignment with evidence of bone fusion. Only one case (7%) suffered from screw breakage and misalignment that was managed with posterior fixation and fusion. Neck pain improved in 95% and clinical evaluation revealed improvement of neurological ASIA grading in7 patients (50%), while 7 patients (50%) remained at the same ASIA score as pre-operative. These findings correspond to the results of **Bhattarai et al.**[17] fond (15) patients with odontoid fractures, had underwent anterior odontoid screw, 14 out of 15 had excellent post-operative gain, only one mortality case due to cardiac problems. Also in **levi et al.**[18] which included 32 patients with odontoid fractures, who underwent anterior odontoid screw placement, 30 patients had satisfactory healing of their fractures with (91% fusion rate). Two patients had early failure of the screw within 2 weeks of surgery due to severe osteoporosis.

Conclusion

§ Anterior odontoid screw fixation is benefit way for restoring stability after an odontoid fracture maintaining axial rotation with high fusion and less morbidity and mortality rates. However, the indications for this technique are relatively limited to acute reducible odontoid fracture with intact transverse ligament.

§ Absence of intra operative facilities such Neuro-navigation, neurophysiological monitoring and O arm isn't considered as a true obstacle to obtain favourite results.

Which is better? Transforaminal Lumbar Interbody Fusion Vs. Posterolateral Fusion in Treating Degenerative Spondylolisthesis

Mohammed Amr Gouda[1], Osama Ahmed Alfahl[1], Ahmed HamdyAshry[1], Mohamed Hafez Ramadan[1]

[1]Neurological and spine surgery department, Faculty of Medicine, Cairo University, Cairo, Egypt

Abstract

Background and Objective: Degenerative spondylolisthesis can be treated surgically with various techniques like trans-foraminal lumbar interbody fusion [TLIF] and postero-lateral fusion [PLF]which are the most common techniques used in practice. In our study we describe our experience in these techniques in treating degenerative spondylolisthesis regarding outcome and complications.

Method: This prospective study was conducted upon 32 patients with degenerative spondylolisthesis, divided in 2 groups randomly selected; one group will be operated upon by posterolateral fixation and the other group by TLIF at the Department of Neurosurgery, Cairo University KasrAlainy. We evaluated surgical outcomes in terms of clinical improvement and complications.

Results: Thirty-two patients were included in this series; divided in two groups. Postoperative mean visual assessment score (VAS) in TLIF group was 1.5 regarding leg pain and 2.75 regarding back pain, while in the PLF group was 1.56 regarding leg pain while 2.87 regarding back pain.

In TLIF group one patient suffered from canal encroachment by L5 screw causing severe sciatica and it needed reoperation and screw revision.

In PLF group two patients suffered from weakness, one of them was in the form of increase in weakness of the hip flexion and the other was new weakness in dorsiflexion and they were treated conservatively and physiotherapy, and they showed mild improvement. One patient suffered from superficial wound infection and mild dehiscence and was treated by antibiotics and bedside secondary sutures under local anesthesia.

Conclusion: No statistical significance difference in term of clinical improvement in both groups regarding back and leg pain.

Keywords: *Degenerative spondylolisthesis, TLIF, PLF, lumbar lordosis and sagittal balance.*

Introduction

Spondylolisthesis is a clinical entity results from anterior subluxation of one vertebral body (VB) on another, most commonly the upper VB is anterior to the lower one. Usually L5 on S1, the next most common is L4 on L5. It is uncommon for a herniated disc to occur at the level of the subluxation, however the disc may "roll" out and produce findings on MRI that resemble a herniated disc which termed a "pseudodisc." It is more common to see a herniated disc at the level above the subluxation.

The nerve root compression is usually due to upward displacement of the superior articular facet of the level below together with disc material and a fibrous/ inflammatory mass from the malunion, symptoms manifest as neurogenic claudication, although radiculopathy may occur[1].

Spinal fusion with instrumentation is used as an adequate treatment for degenerative spondylolisthesis[2]. Most common used techniques to manage the disease are the postero-lateral lumbar fusion [PLF] and the trans-foraminal lumbar interbody fusion [TLIF] techniques[3].

Trans-foraminal lumbar interbody fusion [TLIF] technique was first described by Harms and Jeszenszky as asubstitute to postero-lumbar interbody fusion (PLIF) and simpler than 360 degrees antero-posterior fusion techniques [4].

Several studies tried to compare between these two procedures[5]. Some reported that TLIF was better than PLF in the treatment of back pain[6]. However other studies reported nearly equivalent outcomes in both techniques [7].

Patients and methods

This prospective study was conducted upon 32 patients with degenerative spondylolisthesis, divided equally into 2 groups; one group (A) will be operated upon by trans-foraminal lumbar interbody fusion [TLIF] with cage insertion and the other group (B) by postero-lateral fixation [PLF] without cage insertion .

Patients were subjected to complete neurological examination and routine labs were done. Diagnosed with degenerative spondylolisthesis by x-ray with dynamic views of the lumbosacral spine and MRI lumbosacral spine.

Our inclusion criteria were patients with degenerative spondylolisthesis who agreed to participate into the study and undergo follow-up in our department.

Our exclusion criteria were patients with different diagnosis and refusal to participate into the study.

Surgical Procedure:

The procedure is done under general anesthesia. The patient is positioned in prone position on a Relton-Hall frame fixed on a radiolucent operation table. Careful positioning of the limbs to avoid nerve entrapments and careful padding of the pressure areas of the body is insured and the abdomen is checked so to be lax and pushed under the weight of the patient against the operating table to avoid congestion of vertebral venous plexuses.

Midline low back skin incision is leveled and fashioned using surface anatomy and confirmed byby the C arm.

Following the skin incision and the fascia after dissection from the skin, the paraspinal muscles are dissected from bones using periosteal elevator and gauzes, and then cutting the paraspinal muscles tendons with dissecting scissors.Proper hemostasis with bipolar cautery. Retracting the edge of the wound with Williams lumbar retractor and continue muscle separation laterally with monopolar cautery to reveal facet joints, pars interarticularis and transverse processes.

After proper positioning of the retractor and muscle separation we confirm the appropriate level and the facets of interest with C-arm. Putting transpedicular screws in the levels which ought to be fixed.Precautionwas taken not to open or injure the facet joints of the upper vertebra to prevent instability in the adjacent upper segment. Putting the screws early before laminectomy, discectomy and putting the cage, assist in opening the disc space by applying distraction on the contralateral screws, especially in case of narrowed disc space and cage insertion is difficult

After that, formal laminectomy is done with bone nibblers and kerrisonrongeurs for decompression and bilateral foraminotomies to decompress nerve roots. Total facetectomy and pars excision on the most symptomatic side. Care should be taken to not injure the pedicle. We open the disc space with a scalpel and evacuate its content with pituitary roungeurs and punch foreceps. Then the cartilignous end plates are removed using special instrumentations.

After preparation of the disc space and removal of the end plates, we use trials to precisely measure the appropriate size and length of the cage to be used. Packing the cage with bone taken from the facetectomy and laminectomy and inserted via TLIF approach from the symptomatic side.Confriming the proper insertion of the cage with C-arm, Rods are put and tighten with the screws in compression to restore the normal lordotic angle and prevent cage dislodgement.

The lumbar interbody fusion cages used were titanium PLIF cage from normedical (Ankara, turkey).

Putting bone fragments from the laminectomy on the transverse processes on both sides after curetting the processes with periosteal elevators to enhance fusion.

The wound is irrigated with antibiotic dissolved in saline solution, then stitched in layers after proper hemostasis with bipolar cautery. A sub fascial drain is inserted if needed which can be removed after 24-48 hours.

Postoperative clinical improvement assessed in terms of postoperative pain and complications.Patients' back pain and leg pain were assessed postoperatively with pain score on a 10 point visual analog scale [VAS] before discharge and one week postoperative. The score is specified by measuring the length (mm) on the 10-cm line between the "no pain" point and the patient's specified point, providing a range of scores from 0–100. A higher score signalizeshigher pain severity.

Data were coded and entered using the statistical package SPSS (Statistical Package for the Social Sciences) version 25. Data was summarized using mean, standard deviation, median, minimum and maximum in quantitative data and using frequency (count) and relative frequency (percentage) for categorical data. Comparisons between quantitative variables were done using the non-parametric Mann-Whitney test. For comparison of serial measurements within each patient the non-parametric Wilcoxon signed rank test was used[8]. For comparing categorical data, Chi square (c2) test was performed. Exact test was used instead when the expected frequency is less than 5 [9]. P-values less than 0.05 were considered as statistically significant.

Results

Postoperative leg and back pain was assessed using VAS scoring system at discharge of the patients in both groups.

Average preop VAS scores in group (A) were 7.88 regarding leg pain and 8.13 regarding back pain, while postop VAS scores were 1.5 regarding leg pain and 2.75 regarding back pain. Average preop VAS scores in group (B) were 7.88 regarding leg pain and 8 regarding back pain, while postop VAS scores were 1.56 regarding leg pain and 2.87 regarding back pain.

Regarding Complications:twenty eight patients (87.5%) had no complications.One patient (3.12%) suffered from canal encroachment by L5 screw causing severe sciatica and it needed reoperation and screw revision.Two patients (6.25%) suffered from weakness, one of them was in the form of increase in weakness of the hip flexion and the other was new weakness in dorsiflexion and they were treated conservatively and physiotherapy and they showed mild improvement. One patient (3.12%) suffered from superficial wound infection and mild dehiscence and was treated by antibiotics and bedside secondary sutures under local anesthesia.

In TLIF group there was 1 complication which was the screw revision, while the other complicated cases were reported in the PLF group.

Table 1: Frequency of complications.

Complications	Frequency	Percentage
Screw revision	1	3.12%
Weakness	2	6.25%
Superficial infection	1	3.12%
No complications	28	87.5%

Comparison between the 2 groups statistically

Table 2: statistical comparison between the 2 groups showing no significant statistical difference.

	TLIF group					PLF group					P value
	Mean	SD	Median	Minimum	Maximum	Mean	SD	Median	Minimum	Maximum	
Leg pain VAS	1.50	.82	1.00	1.00	4.00	1.56	1.03	1.00	1.00	5.00	1.000
Back pain VAS	2.75	.58	3.00	2.00	4.00	2.88	.72	3.00	2.00	4.00	.696

Statistical analysis shows there is no statistical difference between the two groups regarding postoperative VAS scores.

Discussion

The authentic Harms surgical technique described inserting bone graft behind the anterior longitudinal ligament [ALL] and then inserting two round titanium mesh cages as inter-body devices. The cages were inserted in the middle or posterior third of the vertebral body[10].

An advantage of PLF is an easier and simpler procedure and may be with fewer complications. While, TLIF support the anterior vertebral portion and regain the disc height (DH), which indirectly decompress the nerve root at the foramen [11].

TLIF has been used in thoery that the inter-body cage, with the bone graft, would greatlypromote better fusion between vertebrae thanpostero-lateral fusion. Recovering both disc height (DH) and lumbar lordosis (LL) are extraachieved with TLIF procedure [10].

The effect of TLIF and PLF on lumbar lordosis has been rarely compared. The purpose of this study is to compare the effects of TLIF with PLF in the treatment of degenerative spondylolisthesis using clinical and radiographic outcomes.

In our study; postoperative mean VAS score in TLIF group was 1.5 regarding leg pain and 2.75 regarding back pain, while in the PLF group was 1.56 regarding leg pain while 2.87 regarding back pain. **Fujimori et al.** [11] reported postoperative mean VAS score in TLIF group was 1.2 regarding leg pain and 3.1 regarding back pain, while in the PLF group was 2.1 regarding leg pain while 4.1 regarding back pain**.** While **Hoy et al.**[5] reported in postoperative 1-year follow-up mean VAS score in TLIF group was 3 regarding leg pain and 3.6 regarding back pain, while in the PLF group was 2.4 regarding leg pain while 3.4 regarding back pain**.**

In our study; we found that there is no statistical significant difference in results in VAS scores between both groups as the p-values where above 0.05 where the TLIF group show very mild improvement over the PLF group, keeping in mind that VAS score system is a subjective test not scientifically accurate, while **Hoy et al.** [5]reported the opposite of our resultswhere the PLFgroup show more improvement over the TLIF groupattributing that there is an nominaldirection towards the TLIF group showing more limb pain during follow-up compared to the PLF group**.**

In our study, 28 patients (87.5%) had no complications, 1 patient (3.12%) suffered from canal encroachment by L5 screw causing severe sciatica and required reoperation and screw revision, 2 patients (6.25%) suffered from weakness; one of them was in the form of increased weakness in the hip flexion and the other was new weakness in dorsiflexion (partial foot drop) due to L4 nerve root lesion and they were treated conservatively and physiotherapy, and they showed mild improvement and 1 patient (3.12%) suffered from superficial wound infection and mild dehiscence and was treated by antibiotics and bedside secondary sutures under local anesthesia.

In TLIF group there was 1 complication which was the screw revision, while the other complicated cases were reported in the PLF group.

Hoy K et al.[5]among 100 patients operated, in the TLIF group complications were 1 patient with hematoma, 2 patients with superficial infections, 1 patient with nerve root lesion, 2 patients with Dural tears and 1 patient developed pneumothorax during operation, which was treated with chest tube. In the PLF group, there were 2 patients with hematomas and 1 patient with Dural tear**.**

Among the study 9 patients were subjected to a second operation: 3 patients in PLF group had the hardware removed due to loosening or failure. 4 patients in the TLIF group had implant removal: 2 due to misplaced devices, one due to failure of fusion, and 1 due to deep wound infection. In addition, 2 patients in the TLIF group underwent second surgery to decompress another level than the performed one within 1 year.

Fujimori et al. [11]among 56 patients operated, in the TLIF group complications were non-fusion rate of 4%, 1 patient with adjacent segment failure and 1 patient with dural tear. In the PLF group, non-fusion rate of 16%, 5 patients with adjacent segment failure and 4 patients with duraltear **.**

Al Barbarawi MM et al.[12]among 120 patients operated it was reported that in the TLIF group complications were 3 patients with wound infection, 2 patients with persistent sciatica, 2 patients with partial foot drop, 2 patients with deep venous thrombosis

(DVT) and one mortality from pulmonary embolism from DVT. In the PLF group, 2 patients with wound infection, 2 patients with persistent sciatica, no patients with partial foot drop, no patients with deep venous thrombosis (DVT) and no mortality**.**

Conclusion

The primary goals in all lumbar surgical fixation techniques and instrumentations are restoration of normal spinal alignment, good bony fusion and adequate neural decompression for clinical relief.

Our Study shows no statistical significant difference in the clinical outcome in both groups regarding back and leg pain.

We recommend using TLIF techniques especially when it comes to correction of lumbar lordosis and sagittal balance especially when there is loss of disc height. However, better surgical outcomes depend mainly on patient selection, good decision making, the experience and the preference of the surgeon.

The Efficacy of Using trans-symphyseal Crossing Screws in Symphyseal Plating for the Unstable Antero-posterior Compression Pelvic Injuries: A Novel Technique and Early Radiological Results

Fady Kamal Beder [1], Ahmed H Abdelazeem[1], Ihab I El- Desouky[1], Khaled F M Abdel- Kader[1], Mohamed Salama Hamdy[1]

[1]Department of Orthopedic Surgery, Faculty of Medicine, Cairo University, Egypt

Abstract

Background and Objective: We hypothesized that the placement of trans-symphyseal crossing screws during symphyseal plating of disrupted pelvic fractures would lead to increase fixation strength and better radiological outcomes.

Methods: The study was a prospective, case-series, study that was conducted on 30 patients with unstable antero-posterior pelvic injury (APC type III).Openreduction and internal fixation with 3.5 reconstruction plate and trans-symphyseal crossing screws was done for the anterior injury and percutaneous iliosacral screw fixation for the posterior injury in all patients.

Results: The mean length of follow-up was 18 ± 5 months. The average length of crossing screws was 80.6 mm. The mean pubic space on final follow up radiograph was 6.4 ± 2.8 mm.The mean pubic space widening was 2.3 ± 1.7 mm.Neither significant pubic space widening (more than 10 mm) nor plate failure was observed.

Conclusion: Thenovel technique of cross-placement of screws during symphyseal plating could be effective among patients with unstable antero-posterior compression pelvic fractures with high excellent radiological outcomes and low complications and failure rate.

Keywords: *Anetro-posterior compression pelvic injury, Symphyseal plating, Crossing screws, and radiological outcomes.*

Introduction

Pelvic ring fractures are disabling injuries that represents 2-8% of all fractures[1]. It usually follows high-impact trauma, and they are most commonly observed in polytraumatized, young, patients[1]. According to Young and Burgess classification system, pelvic fractures can be categorized intolateral compression (LC), anteroposterior compression (APC), vertical shear (VS) injuries or combined mechanism injury (CMI)[2].

The surgical stabilization has become the main approach for management of pelvic fractures, especially in unstable injuries associated with symphysis pubis diastasis[3]. Post-traumatic pelvic asymmetry is associated with persistent pelvic pain, thus, anatomical restoration of the pelvic ring is required to ensure better functional outcomes[4]. Despite the early promising results of the external fixation, previous reports have shown that this technique is associated with high incidence of long-term complications including pin infection, loosening, and revision[5]. Thus, plate fixation –mainly the classic superior plating- has become the mainstream option for

Corresponding author:
Mohamed Salama Hamdy
Department of Orthopedic Surgery, Faculty of Medicine, Cairo University, Egypt
Email: salamaorthopedic2@gmail.com

anatomical restoration of symphyseal disruption, with satisfactory clinical results[6].

Recently, several authors advocated that the fixation strength can be achieved by oblique placing of screws into the conventional plates, previous bone models studies demonstrated that oblique screws were effective in providing stability for bone implant[7]. Therefore, we hypothesized that the placement of trans-symphyseal crossing screws during symphyseal plating of disrupted APC pelvic fractures would achieve maximum screw length within the pubic bone and to increase fixation strength and better outcomes.

Materials and Method

The present manuscript was prepared in concordance with the recommendations of STrengthening the Reporting of OBservational studies in Epidemiology (STROBE)[8]. The study's protocol was approved and registered by the ethics committee of Cairo University Teaching hospitals. We confirm that the present study run in concordance with the principles of declaration of Helsinki and applicable local regulatory laws. Written informed consents were obtained from all patients prior to study's enrollment.

Study Design and Patients:

The present study was a prospective, case-series, study that was conducted from January 2017 to May 2019 at Cairo University Teaching hospital. Skeletally-mature patients with unstable APC pelvic injury (type III) were included. We excluded patients with known infection, non-traumatic diastasis, patients with combined pelvis and acetabular fractures, and/or old fractures.

Preoperatively, all included patients underwent history taking and throughout clinical examination. Preoperative imaging evaluation using a plain radiography and computed tomography (CT) was conducted to determine the fracture type, and the degree of sacroiliac disruption (**Figure 1**). Preoperative measurement of pubic space widening was done.

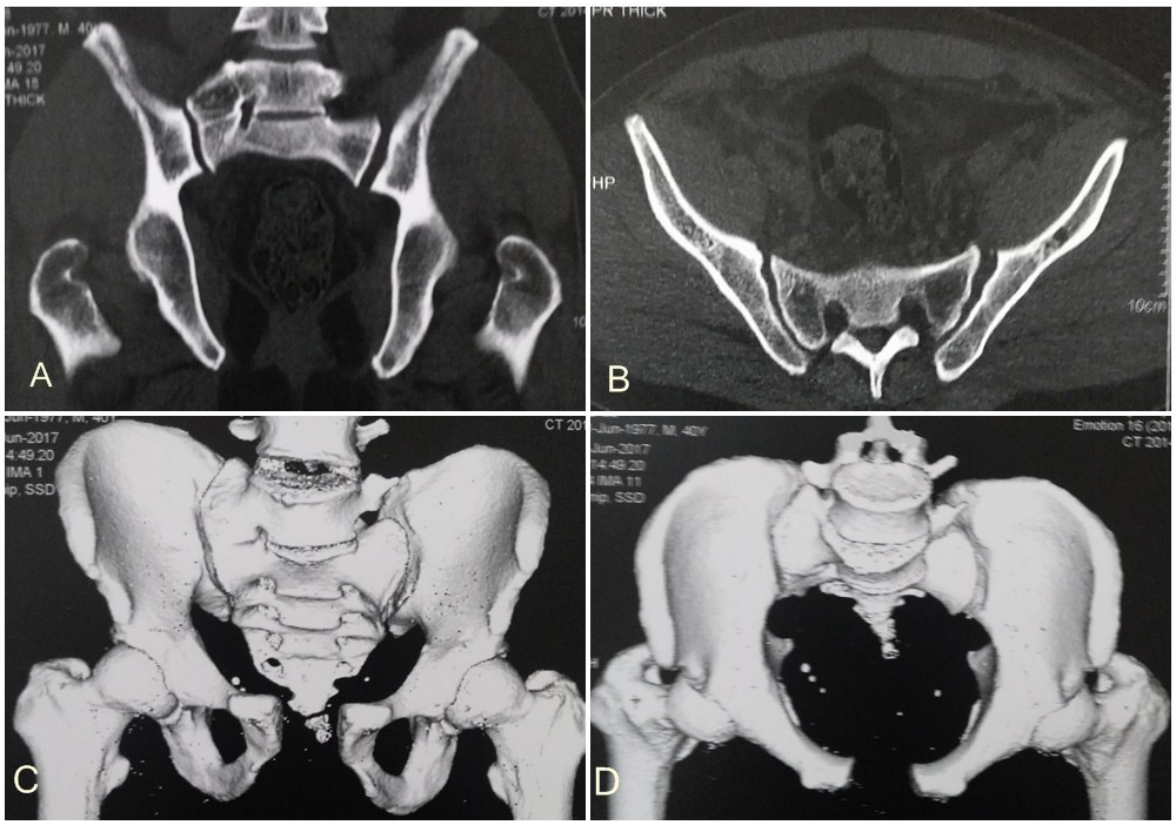

Figure 1:CT pelvis of patient with anteroposterior pelvic injury, A: Coronal cut, B: Axial cut, C and D: 3D Reconstruction.

Surgical Techniques

All operations were conducted within the three weeks after injury. The patient was positioned supine on a radiolucent flat-top table.

Pfannenstiel approach was used utilized. Once the exposure had been completed, several methods were used to achieve reduction. The simplest method was to place large, pointed reduction clamps on each side of the symphysis. Once a satisfactory reduction was achieved, an appropriate 3.5 mm reconstruction plate (4 to 6 holes) was contoured and applied to the superior aspect of the pubic body and rami. First two lateral short screws were inserted to maintain the reduction (**Figure 2**).

The direction of the medial screws in the novel technique of the current study was aimed toward the body and the inferior pubic ramus of the opposite side thus increasing the screws length. The screw plate angle that would achieve the maximum screw length in the inferior pubic ramus of the opposite hemipelvis was determined. The screw plate angle in the outlet view was between 47^{o} and 64^{o} in males and between 35^{o} and 44^{o} in females. In this technique the image intensifier was used all through the operation to obtain maximum screw length without penetration outside the pubic ramus.

Then the first medial screw was drilled carefully with a long 2.5 mm drill. In addition to visualization of the reduction, palpation of the posterior aspect of the symphysis confirmed the adequacy of the reduction. The outlet view of the pelvis was used to confirm that the screws were not penetrating the obturator foramen and not exceeding the lower end of inferior pubic ramus. The inlet view of the pelvis was very important to confirm that the screws were not penetrating anterior or posterior to the pubic ramus as the safe trajectory in this plane is. In some cases we used k-wire 2 mm as a drill when 3.5 mm screw was used. Posterior pelvic injury was managed with closed reduction and percutaneous iliosacral screw fixation in all patients.

Postoperatively, all of patients in this study received broad-spectrum antibiotic postoperatively usually 3 days, then the patient was maintained on oral antibiotics (Amoxicillin + Clavulinic Acid) till the removal of the stitches. Anticoagulation was given to all patients (clexane) subcutaneously 40 IU once daily for average body weight 70Kg patients for six weeks. Partial weight bearing was initiated after six weeks and full weight bearing was allowed after 12 weeks in all patients.

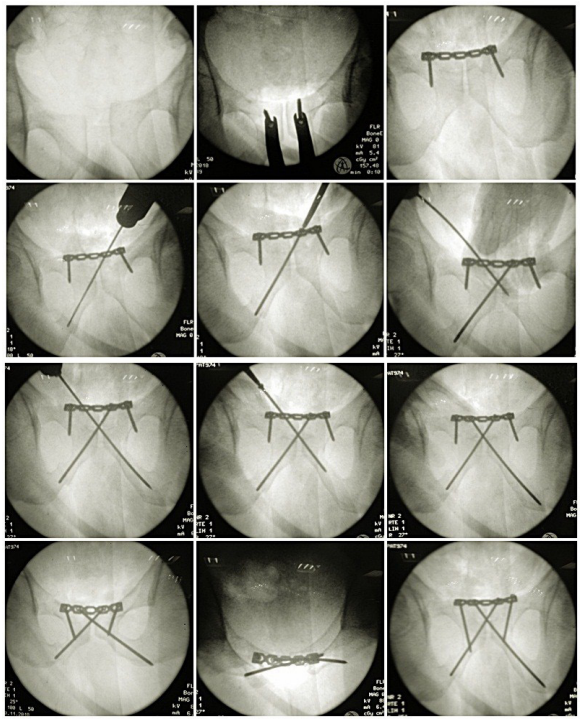

Figure 2: Intraoperative fluoroscopic images showing the steps of the new technique for reduction and fixation of symphysis pubis diastasis with 5 holes 3.5 reconstruction plate.

Follow-up and Study's outcomes:

Patients were instructed to come for follow-up after two weeks then regularly every four weeks, then at every third month, then at every six months up to 26 months. On every visit, patients were evaluated for radiological outcomes. The radiological evaluation included Matta and Tornetta grading system[9] and the degree of symphysis pubis widening.

Statistical Analysis:

Data were entered and coded via the statistical package SPSS version 25. Data was summarized, the mean and standard deviation were used for quantitative variables and frequencies and percentages was used for categorical variables.

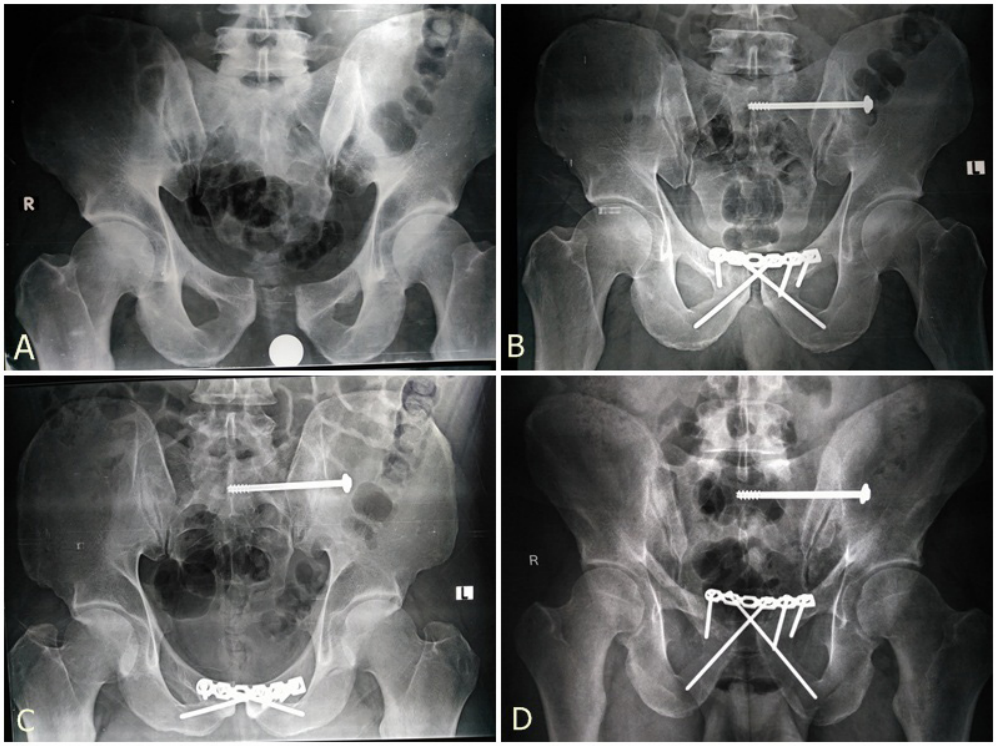
Results

The present study included 30 cases with symphysis pubis diastasis (APC type III). The mean age of the included patients was 37 ±10 years old. All fractures were classified according to Young and Burgess classification system and all patients were classified as APC type III. The mean pubic diastasis on injury was 42 mm ± 12 mm and the range was 30 – 70 mm (**Table 1**).

The operative treatment consisted of combination of anterior fixation with 3.5 mm reconstruction plate with 3.5 mm cortical screws in in all patients, the average number of holes was 5.3 (4 to 6 holes) and the average number of screws was 5.1 (4 to 6 screws). The average length of crossing screws was 80.6 mm (the longest screw was110mm). Posterior fixation was done in all patients with a single 6.5 cannulated iliosacral screw. The mean operative time 52 ± 13 minutes and one patients needed intraoperative blood transfusion. Regarding the postoperative outcomes, the mean postoperative blood loss in the current study was 203 ± 82 cc. The mean hospital stay after surgery was 3.5 ± 1.6 days and the mean length of follow-up was 18 ± 5 month.

Table 1: Demographic and Clinical Data of the IncludedPatients

Variable	Patients (N =30)
Age (years), Mean ± SD	37 ±10
Males	25 (83.3%)
Mode of injury • Road traffic accident • Falling from height • Motor bicycle accident • Motor car accident	 15 (50%) 8 (26.6%) 5 (16.6%) 2 (6.6%)
Patient's occupation • Manual worker • Student • Driver • House wife • Employee	 20 (66.6%) 4 (13.3%) 3 (10%) 2 (7%) 1 (3%)
Associated injuries • Fracture femur • Fracture spine • Fracture tibia • Fracture distal radius • Fracture olecranon • Urological injury	 2 (6.6%) 1 (3.3%) 1 (3.3%) 1 (3.3%) 1 (3.3%) 1 (3.3%) 1 (3.3%)
Degree of the preoperative pubic diastasis	42 mm ± 12



In the current study, the radiological outcomes were assessed according to Matta and Tornetta grading system. Immediate postoperative 28 patients were graded as excellent, and two patients were graded as good. At last follow up 26 patients were graded as excellent, and 4 patients were graded as good. The mean pubic space on immediate postoperative follow up radiograph was 4 ± 1.7 mm; while the mean pubic space on final follow up radiograph was 6.4 ± 2.8 mm. In the current study the mean pubic space widening was 2.3 ± 1.7 mm, no significant pubic space widening (more than 10 mm) was observed, no plate failure was noticed, no posterior fixation failure and only one case with broken one of the two crossing screws (**Table 2 and Figure 3**).

Table 2: Postoperative Radiological Data of the IncludedPatients

Variable	Patients (N =30)
Matta and Tornetta grading system • Excellent • Good • Fair	 26 (86.6%) 4 (13.3%) 0 (0.0%)
Pubic space immediate postoperative, Mean ± SD (mm)	4.16 ± 1.7
Pubic space at final follow up, Mean ± SD (mm)	6.4 ± 2.8
Pubic space widening, Mean ± SD (mm)	2.3 ± 1.7
Significant pubic space widening more than 10 mm	0 (0.0%)
Anterior plate failure	0 (0.0%)
Posterior fixation failure,	0 (0.0%)
Breakage of crossing screws	1(3.3%)

The complications were recorded in this study were immediate postoperative malreduction in 1 patient, breakage of the crossing screw reported in one patient (3.3%) without affecting the reduction, heterotopic ossification (HO) occurred in 2 patients (6.6), loosening around screws occurred in 1 patients (3.3%).

Discussion

The present study assessed the impact of trans-symphyseal crossing screws on the clinical and radiographic outcomes ofsymphyseal plating of disrupted APC pelvic fractures. Our results showed that the trans-symphyseal crossing screws achieved high rates of excellent radiographic outcomes.The technique had acceptable safety profile as well with low rates of implant failure and malunion. The length of the crossing screws was up to 110 mm witch is much longer than reported in literature and was not identical in all cases due to changes in bony morphology which differs according to the patient's gender, body habitus and the interpubic disc destruction. The second screw in this technique was usually more difficult than the first screw due to the narrow area of the pubic body and ramus especially after insertion of the first crossing screw.

Although the symphyseal plating is recommended over external fixation of symphysis pubis diastasis due to lower rates of infection and loosening, the cumulative body of evidence shows that implant failure is a major drawback of this technique[10]; previous reports showed that the rates of hardware failure and revision can be as high as 31% and 9%, respectively, followingsymphyseal plating[11, 12]. Therefore, we proposed that the addition trans-symphyseal crossing screws can lead to higher fixation strength and decrease pubic space re-widening, which would result in better radiographic outcomes. To the best of our knowledge, this is the first study that assessed the value of trans-symphyseal crossing screws on unstable APC fracture outcomes.

In the present study, we assessed the radiological outcomes of the included patients via Matta and Tornetta grading system and pubic space widening. The results showed that all included patients achieved union and the vast majority of them achieved excellent radiographic score; the mean pubic space on final follow up was within the acceptable range. Again, these findings were notably better than previously published studies that treated patients with the classic symphyseal plating.Van Loon et al reported that the postoperative radiographs was graded as excellent (a diastasis of <4 mm) in only 31.5% of the patients treated with open reduction and internal fixation of the symphysis pubis[13]. Another report showed that widening of pubic symphyseal space was observed in the majority of the patients treated with classic symphyseal plating [14]. Radiological results were excellent in 38.5% of the patients treated with classic symphyseal plating as reported by Park et al [15]. On the other hand, a previous finite element study reported that the cross-screw is preferred in the treatment of pubic symphysis diastasis as it provides better anterior and posterior pelvic stabilization [16].

As regarding the postoperative complications, the present study showed a lower rate than was reported in literature. For example, Tornetta et al.reported that four (17%) out of 23 patients had a plate breakage with three (13%) had recurrent widening of the symphysis pubis space [11]. Van Loon et al. reported that (19%) of their 31 patients had a loosening of the symphyseal implant [13]. Collinge et al. reported loosening or breakage of the hardware in 18 (90%) patients [14]. Park et al. reported that a revision surgery was required in 10 (25.6%), fixation failure in 4 (10.3%), screw breakage in 8 (20.5%), significant screw pull out or loosening in 15 (38.4%), plate breakage in 3 (12%), symphyseal re-widening (≥10 mm) in 12 (30.7%) patient [15].

Before discussing the implications of our findings, we have to acknowledge some limitations. The small sample size of the included patients was relatively small which may have affected the generalizability of our findings. Further investigation in a larger sample size and longer follow-up time is needed to obtain more overall clinical data. The minimum length of follow up was 13 months, which may have meant we failed to detect the cases of later fixation failure.

Conclusion

The novel technique of cross-placement of screws during symphyseal plating it could be an effective technique among patients withunstable APC pelvic fractures with decreasing the rate of symphysis pubis re-displacement and the rate of implant failure, loosening, and backout.

Abstract

Background: Postoperative pulmonary complications (PPC) can be associated with increased extra vascular lung water (EVLW) in patients with a cyanotic congenital heart disease (CHD). Lung ultrasonography (LUS) is a noninvasive, easily performed, bedside technique that allows assessment of EVLW.

Method: It is a prospective observational study of 80 pediatric patients with CHD with left to right shunt, scheduled for elective cardiac surgery. LUS were done preoperative, at end of surgery, then every 12 hours for 48 hours. Patients are given LUS score 0- 36. LUS results were compared to incidence of PPC.

Results: LUS score showed rise from 1.4 ±2.02 at LUS 0, to 5.6 ±6.89 at LUS 1, followed by slow decrease over time: 4.35 ±7.09, 3.15 ±7.06, 2.68 ±6.79, 2.32 ±6.67. LUS score in patients complicated by PPC showed a significant difference from non-complicated patients; in all LUS scans.

Conclusion: LUS is a safe noninvasive technique that can help predict PPC, in pediatric cardiac patients presented for correction of left-to-right shunt lesions.

Keywords: *Pediatric- congenital heart- postoperative pulmonary complications - lung ultrasonography.*

Introduction

Acyanotic congenital heart disease (CHD) is associated with left-to-right shunt of blood, and result in pulmonary overflow, volume load to the right heart and pulmonary arterial hypertension (PAH). This manifests as progressive exertionaldyspnoea, easy fatigue, recurrent chest infections and hospitalization. They include atrial septal defect (ASD), ventricular septal defect (VSD), Atrioventricularseptal defects (AVSD) and patent ductusarteriosus (PDA).[1]

There is a growing interest to interfere early with surgical correction of the anomaly to prevent Eisenmenger's syndrome and heart failure. However, surgery carries its own risks and complications. PPC is a frequent complications that impacts significantly on costs and perioperative morbidity and mortality.[2]

The pathogenesis of PPC is multifactorial. Contact of blood with the artificial surfaces of CPB machine augments an inflammatory reaction & lung is infiltrated with activated neutrophils, pouring injurious enzymes & oxygen free radicals leading to widespread lung injury and noncardiogenic pulmonary edema. Preoperative pulmonary disease, hypothermia, surgical trauma, anaesthesia, as well as pulmonary reaction to medications, temporary cardiac dysfunction, multiple blood products transfusion, excessive fluid loading may all contribute to PPC.[3]

Increased EVLW volume during critical illness is associated with PPC, prolonged mechanical ventilation and increased mortality rates. Evaluating EVLW volume

may thus allow for adopting therapeutic interventions to regulate lung water content, perhaps resulting in improved clinical outcome.[4]

Lung ultrasonography (LUS) can be used to assess lung parenchyma. It is a non-invasive, radiation-free, easily performed, reproducible, bed side tool that helps real time assessment of EVLW. Normal LUS shows regularly spaced horizontal artifacts representing reverberations of the pleural line, known as A-lines, and vertical artifacts known as B-lines. B-lines are nonspecific sonographic findings that can be seen sporadically in normal lungs. However, multiple B-lines are pathological and their numbers correlate with lung edema scores from chest radiographs and with EVLW measured invasively using the trans-pulmonary thermo dilution method. In this study we used LUS to evaluate EVLW and hence predict PPC. [5]

Patients and Method

This is a prospective observational study. It was conducted in pediatric cardiothoracic surgery unit, Cairo University, after obtaining informed consents from the patients' care-givers.

80 patients, aged from 6 months to 8 years old, both genders, with acyanotic CHD, scheduled for elective cardiac surgery were included in the study. Exclusion criteria included emergency surgery, or requiring re-exploration within 48 hours, re-do surgery, preoperative congestive heart failure, pneumothorax, chest infection (fever > 37.6° C, elevated CRP or TLC), chest wall deformity, myopathy, Eisenmenger's syndrome, any associated extracardiac anomaly, sternum left open or diaphragmatic paralysis.

All patients were evaluated by a pediatric cardiologist, then by an anesthetist. Patients were premedicated by IM injection of Atropine (0.2 mg/kg), Ketamine (1 mg/kg) and Midazolam(0.02 mg/kg). Upon arrival into the operating room, routine monitors and Warming mattress were applied. Peripheral venous cannula was inserted and secured.

Induction was carried out using Sevoflurane 4%, Fentanyl (2 µg/kg) and Pancuronium (0.1 mg/kg). A suitable size endotracheal tube was then inserted and secured. Patients were mechanically ventilated using CMV with volume mode with tidal volume of 8 mL/kg, zero cm H_2O end expiratory pressure (ZEEP), and a respiratory rate appropriate for age, to achieve end-tidal CO_2 30- 35 mmHg. FiO_2 was set to 50%, Isoflurane 0.8 to 1%. Pancuronium& Fentanyl increments were used as needed. Arterial cannula, central venous catheter, urinary catheter were inserted.

Baseline LUS was done (LUS 0), repeated at end of surgery (LUS 1), then every 12 hours in the ICU for 48 hours (LUS 12, 24, 36, 48)

Protocol for ultrasound lung assessment:

LUS was performed using the portable echograph M-Turbo (Sonosite, Bothell, WA, USA). A linear probe was chosen (frequency range, 6–13 MHz). Each hemithorax was divided into 6 regions using 3 longitudinal (parasternal, anterior, and posterior axillary) and 2 horizontal lines, one above the diaphragm and another one 1 cm above the nipples. The probe is positioned longitudinally and perpendicular to the ribs.

LUS was done by a trained anesthetist. Presence of "lung sliding" sign was assured. It indicates the absence of pneumothorax. The sum of "B" lines produced a score; reflecting EVLW, as following:

1. Normal aeration (0): "B" lines number ≤ 3.

2. Moderate loss of lung aeration (1): multiple visible B-lines with horizontal spacing ≤ 7 mm (B7 lines).

3. Severe loss of lung aeration (2): multiple fused B lines with horizontal spacing ≤ 3 mm (B3 lines).

4. Pulmonary consolidation (3): hypoechoic lung tissue, accompanied by dynamic air bronchogram.

The final LUS score of the patient was the sum of 12 lung regions (ranging from 0 to 36).[6]

After completion of surgical procedure, all patients were transferred to pediatric cardiac ICU, intubated and mechanically ventilated. Patients were assessed for development of pulmonary complications, as lung oedema (clinical and radiological evidence of congestion, hypoxia, but no infection), pneumonia (fever > 38.5◦ C, TLC >11 with shift to the left, positive CRP, or positive growth on sputum Culture & sensitivity)or ARDS (acute, diffuse, inflammatory lung injury, with hypoxemia, bilateral radiographic opacities).

Statistical methods

Sample size calculation was based on a previous

study, which noted that PPC after pediatric cardiac surgery was 12.9 to 30.8%[7], so calculated the sample size taking into consideration that negative cases (without PPC) will be four times the positive cases (with PPC). Using medcalc software, with study power 80% and alpha error 0.05, the number of cases needed will be at least 65. This number was increased to 80 to compensate for dropouts.

Data were coded and entered using the statistical package SPSS (Statistical Package for the Social Sciences) version 25. Data was summarized using mean,standard deviation, median,minimum and maximum in quantitative data and using frequency (count) and relative frequency (percentage) for categorical data. Comparisons between quantitative variables were done using the non-parametric Kruskal-Wallis and Mann-Whitney tests.For comparing categorical data, Chi square ($\chi 2$) test was performed. P-values less than 0.05 were considered as statistically significant.

Results

Studied population was: female (55%) male (45%), age (6 months to 5 years, mean 1.48), weight (4-15 kg, mean 8.99 kg).Operation: 64 VSD closure, 10 ASD, 3 AVSD, 3 PDA ligation. CPB machine was used in 77 patients (96,3%)

LUS score:

LUS examination showed initial low score at LUS 0 (mean =1.4), rise at LUS 1 (mean= 5.6), followed by gradual decline over the next 48 hours, table 1.

Pulmonary oedema was the commonest PPC (10% of all patients), table 2.

LUS score was significantly higher in pediatric patients complicated by PPC; in LUS examinations, table 3.

Comparing different subgroups of PPC and the no complications group, there was statistically significant difference in all postoperative mean LUS scores, table 4.

Table 1: LUS score preoperative, to 48 hours postoperative

	Mean	Standard Deviation (SD)
LUS 0	1.40	2.02

The following graph shows how different groups of patients scored on the LUS assessment at end of surgery. Pulmonary oedema and pneumonia groups showed statistically significant difference from the no complications group, figure 1.

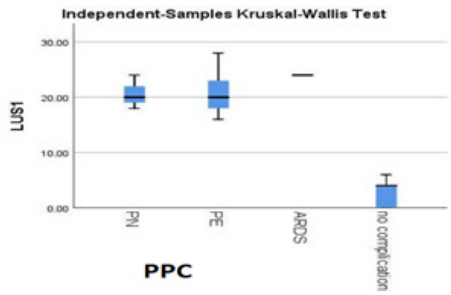

Figure 1 Different subgroups mean & SD at LUS 1using the "Independent-Samples Kruskal Wallis test".

Mean LUS scores time-trend is presented in the following graph, comparing patients who developed PPC to those who didn't develop PPC; figure 2.

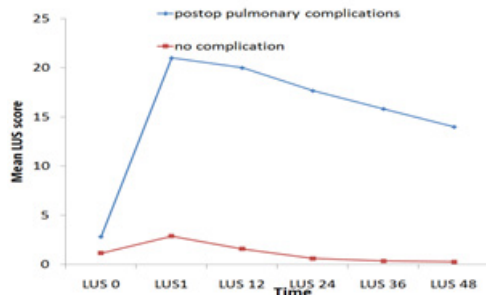

Figure 2 Mean LUS score time-trend, in PPC and no PPC patients

Discussion

In this study, we chose pediatric cardiac patients with left to right shunt lesions to assess their lung water volume by ultrasound, and relate the findings to the incidence of pulmonary complications.

Although PPC are common after cardiac surgery due to the combined effects of anesthesia, CPB machine and surgical trauma, the studied population had an added risk factor that is preoperative pulmonary congestion. The natural course of their disease includes pulmonary overflow and recurrent attacks of chest infection.[1] However, the mean preoperative LUS score (LUS 0) was 1.4 only, thanks to proper preoperative preparation at the pediatric cardiology unit. They usually use diuretics as an antifailure measure to control dyspnea and congestion. We can find statistically significant difference as regarding LUS 0; between patients who developed PPC & those who didn't, table 1, 3. This shows that having a high LUS score might be associated with a higher risk of developing PPC, and may so require postponing surgery.

There is a rise of LUS score immediately postoperative; associated with PPC, followed by gradual improvement of lung condition, figure 2. Many patients were extubated based on accepted P/F ratio and weaning criteria, while LUS still showed evidence of some congestion.

Most of the population had surgery for closure of VSD (80%). Many patients presented for PDA ligation were excluded; being younger than 6 months of age. Only 3 patients for PDA closure were accepted and they were below 1 year of age. They were operated without using CPB machine (off Bypass). Their postoperative course passed without PPC, table 4.

We excluded patients with preoperative chest infection, or conditions which would possibly contribute to PPC other than lung water volume, as presence of chest wall deformities, muscle weakness in myopathies or postoperative diaphragmatic paralysis. These conditions would lead to ineffective cough and add to lung dysfunction caused by postoperative pain, and reduced pulmonary compliance. In fact, some impairment of lung function occurs after any form of major surgery, usually due to atelectasis.

Patients with pneumothorax were excluded from the study, as pneumothorax abolishes the ultrasonic distinctive signs of assessment of lung parenchyma. B lines in fact would not appear in presence of pneumothorax. However, we didn't meet any of the fore-mentioned exclusion criteria, after enrolling patients into the study.

The commonest complication was pulmonary oedema (67% of PPC), table 2. It has many contributing factors, e.g. increased alveolar capillary permeability due to CPB machine, transfusion related or reaction to a drug. Also, reperfusion injury or atrial/pulmonary venous hypertension due to residual shunt, outflow tract obstruction or decreased ventricular compliance (diastolic dysfunction). Patients diagnosed with pulmonary oedema suffered delayed extubation. However, pulmonary oedema was associated with declining mean LUS scores after 12 hours postoperatively, unlike patients with ARDS or pneumonia who generally suffered a worse postoperative course, table 4.

Vitale et al,[8] thought they were the first to apply LUS in pediatric cardiac ICU. They retrospectively studied only 5 patients with query chest X-ray (CXR) findings, and were able to define a diagnosis of PPC and guide the clinical intervention to improved outcome. Most patients had complex CHD. They used a different scanning technique; only 4 zones. It is a simple technique, but misses the posterior lung areas, while actually we found more B lines there. They found that CXR confirmed LUS finding of improved lung condition, only 12 hours later.

The movement towards the wide use of LUS is growing. In May 2018, Cantinotti and colleagues[9] proposed LUS reclassification of query CXR data. Using a similar scanning technique, they could reach new diagnoses, and reclassify 81 CXR findings (out of 138) based on the LUS signs, and actually changed the plan of management of 29 of them, or enable completing CXR reports, where pleural effusion was accompanied by underlying atelectasis.

Limitations and future research

LUS could have been done before induction of anesthesia, since anesthesia and mechanical ventilation might impact on pulmonary vascular resistance, and hence affect the volume of shunted blood from left to right, thus affecting LUS findings. However, handling children is easier under anesthesia. Also, it allows for comparison with LUS at end of surgery, under anesthesia.

Ages included were below 5 years (mean 1.48 years). Elder children usually had one or more of exclusion criteria (re-do surgery, advanced PAH,..).

LUS is operator dependent, thus limiting the generalization of results for all ICUs. Moreover, technical difficulty increases with pediatric population, due to small size of chest, big size of linear high-frequency probe, avoiding dressings & drain sites and frequent movement. However, some authors believe that thinner chest walls and smaller lung mass in pediatrics make it ideal for ultrasound[8].

The limited places in our cardiac ICU, and the long waiting list of CHD patients hinders extending the follow up period. Also, excluding complex CHD from the study missed a lot of patients with lung complications. Patients with left to right shunt lesions generally had smoother postoperative course.

Our protocol didn't adopt strict fluid balance. We actually left it to the clinical judgment of the anesthesiologist, perfusionist and intensivist. Defining a strict fluid balance protocol might impact on the hemodynamics. In fact, we focused on lung water volume as seen by LUS, & related it to incidence of PPC. Further studies should investigate the role of diuretics, ultrafiltration and strict regimen of IV fluids on EVLW. A growing debate surrounds this concept, as strict fluid balance might not always define EVLW. Interestingly, Kaskinen and colleagues[10] found no correlation between B lines and patient's fluid balance,

although their protocol consisted of meticulous, daily calculations aimed at avoiding positive balance between fluid losses and infusions, and none of their patients underwent dialysis. So, they suggest that the B-lines resulted from increased EVLW due to reasons other than fluid overload.

Conclusion

LUS is a safe noninvasive technique that can help predict PPC, in pediatric cardiac patients presented for surgical correction of left-to-right shunt lesions

Assessing Right Ventricular Deformation by 2D Global Longitudinal Strain in Patients Undergoing CABG pre vs Post Procedure

Deena Mustafa[1], Yehia Balbaa[2], Wael M El Naggar[3]

[1]Cardiology Specialist at Dar Al Fouad Hospital. Giza, Egypt, [2]Professor of Cardiothoracic Department, Faculty of Medicine, Cairo University, Egypt, [3]Professor of Cardiovascular Medicine Department, Faculty of Medicine, Cairo University, Egypt

Abstract

Introduction: RV dysfunction after CABG is common finding in one fourth of patients after cardiac surgery. RV global longitudinal strain (RVGLS), has several advantages over other conventional echocardiographic parameters of RV systolic function.

Method: The study included 50 patients electively planned for CABG surgery. All patients were examined pre-operatively and 3 months after procedure with transthoracic echocardiography focusing on the RV systolic function by conventional methods along with global longitudinal strain.

Results: Data analysis found significant deterioration of the RV systolic function in the 2D longitudinal strain along with the all the conventional echocardiographic parameters.

Data showed reduced all parameters, FAC from median 53% to 45% P value <0.0001, TAPSE from median 2.2cm to 1.3cm P value <0.0001, S´ wave TDI from median 14cm/s to 9cm/s P value <0.0001 and global longitudinal strain from median -19%, to -11.7% P value <0.0001.

Conclusion: RV global longitudinal strain, as measured by 2D STE, declines for up to 3 months after surgery. This may add to the current literature about 2D speckle tracking information for RV assessment in CABG patients, confirming the RV systolic impairment post procedures. As well adding incremental value to the GLS assessment for RV.

Keywords: *Right ventricle, Coronary artery bypass graft, global longitudinal strain, speckle tracking.*

Introduction

Right ventricle (RV) systolic dysfunction is a known independent prognostic marker for several cardiovascular diseases, never the less the RV systolic function accurate assessment by conventional echocardiography is problematic[1]. Owing to the complex anatomy and different functional mechanism, it is difficult to objectively evaluate; despite of having several conventional echocardiographic indices that can assess the RV systolic function, there is no echocardiographic parameter yet to represent intrinsic myocardial properties. Cardiac magnetic resonance imaging (CMR) is gold standard in the RV assessment of the ejection fraction along with evaluation of RV structure[2].

Strain derived 2D speckle tracking by echocardiography is dimensionless parameter and measure a as changing in length between 2points before and after movement. It can provide a good non-invasive marker of myocardial contractility[3]. After application of strain echocardiography of the RV for measurement of the systolic function, it became popular as research tool[4]

RVGLS has prognostic ability for several cardiovascular diseases[5].

RV dysfunction after CABG is common; it occurs in nearly one fourth of patients who undergo cardiac surgery. Intraoperative or post procedure RV dysfunction is linked to high post- operative mortality [6,7].

The aim of this study is to address the post operative RV function by using deformation echo indices by 2D speckle racking along with the conventional methods of RV evaluation as this will provide an incremental value to the traditional TV indices.

Method

Study subjects: Patients enrolled prospectively from January 2016 to January 2017. The study included 50 elective patients planned for elective CABG.

Imaging protocol: All patients were examined pre-operatively with transthoracic echocardiography focusing on the RV systolic function and again at follow up after three months. The study was performed by the same experienced operator to exclude the inter-personal variations using GE vivid E90 software. 2D echocardiographic images were analysed offline for deformation analysis. Strain measurements were performed by an experienced investigator in the interpretation of echocardiographic images; 2D measurements (RV free wall and septum). The other echocardiography parameters were calculated as following:

1. Right Ventricular Fractional Area Change calculated through the following formula: (end-diastolic area × end-systolic area)/end diastolic area.

2. Tricuspid Annular Plane Systolic Excursion measured using M-mode for the RV free wall.

3. Tissue Doppler imaging study and assessing tricuspid annulus, calculating S` wave velocity index.

The study was approved by the hospital ethical committee with all patients giving informed consent.

Exclusion criteria included LV systolic dysfunction less than 55%, RWMA involving the septum to avoid the effect of the septal inter-dependance on the global longitudinal strain, recent less than a month RV infarction, atrial fibrillation, pulmonary HTN more than 30mmHG, significant valvular diseases defined as more than mild valve disease, and left bundle branch block.

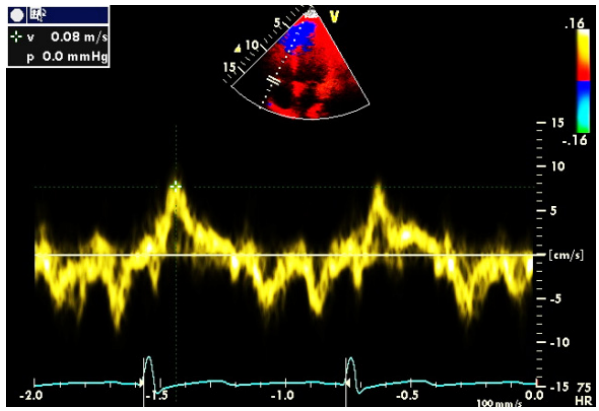

Figure (1): Showing impaired S´ wave velocity with tissue Doppler.

Statistical Analysis

Qualitative results presented as numbers and ratio (%) and significance of their associations measured by the Chi-square or Fisher's exact. Continuous data studied for Normal distribution by Kolmogorov-Smirnov and Shapiro-Wilk tests and then presented as median and range. Their distribution among patients' groups were compared using the non-parametric Mann-Whitney test or Kruskall and Wallace test, as appropriate. The Wilcoxon signed rank test was used to evaluate the significance of change of right ventricular function parameters, as recorded initially and after 3 months. Analysis was performed by statistical package software IBM- SPSS for MAC, version 23.

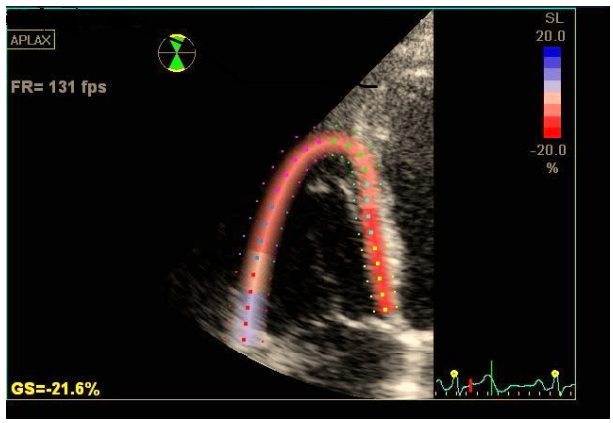

Figure (2):• Showing measurement of global longitudinal strain by speckle tracking

Results

Males represented 92%; the mean age was 60 ± 10years. Smokers represented 32%, 84% were hypertensive and 60% had diabetics (Table 1).

Table 1: Showing clinical characteristics of the patients

	Patients		P value
	No.	%	
Smoker	16	32%	0.556
Hypertensive	42	84%	0.059
Diabetes mellites	30	60%	0.047
Age	60+10	92%	0.059
Male gender	46	96%	0.047

Data analysis showed significant deterioration of the RV systolic function in the 2D longitudinal strain along with the all the conventional echocardiographic parameters.

Data showed reduction of all parameters, FAC reduced from median 53% to 45% P value <0.0001, TAPSE from median 2.2cm to 1.3cm P value <0.0001, S′ wave TDI from median 14cm/s to 9cm/s P value <0.0001 and global strain from median -19%, to -11.7% P value <0.0001. (table 2)

Table (2): Showing the values of RV function parameters pre and post follow up and their significance.

Median		Pre		Post		P-value
		Range	Median	Range		
	FAC	53%	41 – 66	45%	30 – 56	<0.0001
	TAPSE	2.2cm	1.6 - 2.9	1.3cm	1.1 - 1.6	<0.0001
	TDI	14cm/s	10 – 20	9cm/s	8 – 11	<0.0001
	RVGLS	-19%	- 23.2- -31.5	-11.7%	-6 - -17.2	<0.0001

Fractional area change (FAC), tricuspid annular plane systolic excursion (TAPSE), tissue Doppler imaging (TDI) and global longitudinal strain (GLs).

Discussion

The main aim of this study was to assess the changes in the RV function using established deformational RV techniques against the old conventional methods in the CABG patients, comparing pre vs 3 months post procedure. The study population enrolled 50 patients who underwent cardiac surgery with dedicated TTE for RV assessment with special focus on the global longitudinal strain. The findings of this study are as follows: 1.all patients had significant RVGLS systolic dysfunction at three follow up, 2. All other conventional methods showed the same results as shown in table (2). Some previous studies demonstrate that there is decline in RV function measured by 2D conventional indices including TAPSE and S′ with transthoracic echocardiography (TTE)[8]. Similar to our study but intra-operatively, the Unsworth et al. evaluated TAPSE and S′ after pericardial opening and found that these declined acutely intraoperatively[9] but according to our results these changes remain for as long as 3 months postoperative.

Another study done by Yadav et al.[10] tested the hypothesis of selective RV impairment in CABG patients, they found a significant and selective impairment of the RV functions following CABG surgery, the study was conducted on 20 patients, after 3 month follow up showed a significant reduction in RV S′ velocity TDI from preoperative [10]. As well similar to this study, Rong et al.[11], who collected comprehensive echocardiographic data during elective cardiac surgery before sternotomy and immediately after surgery; it showed decline in TAPSE, RV systolic velocity (S′), and RV FAC by transesophageal echo (TEE).

For the meantime, 2D global longitudinal strain by speckle tracking is relatively new imaging technique. Not similar to Doppler interrogation, strain assessment throughout 2D is angle independent and easier than tissue Doppler interrogation (TDI) as well the other indices that is unfortunately depends on the expert of the

operator.

This study had several limitations. First is the use of the 2D rather than the 3D technique for RVGLS, Second, the lack of clinical correlation and impact of RV dysfunction on post-operative morbidity.

Conclusion

RV global longitudinal strain, as measured by 2D STE, declines for up to 3 months after surgery. This may add to the current literature about 2D speckle tracking information regarding RV assessment in CABG population, confirming the RV systolic impairment post procedure. As well adding incremental value to the GLS assessment for RV.

Filling Without Drilling - A Review On Resin Infiltration Technique For Enamel And Early Cavitated Lesion

Chandrapooja.J[1], Jayashri. P[2]

[1]Graduate Student, [1]Saveetha Dental College, Saveetha Institute of Medical and Technical sciences, Saveetha university,Chennai, [2]Senior Lecturer, Department of Public health Dentistry, Saveetha Dental College, Saveetha Institute of Medical and Technical sciences, Saveetha university, Chennai

Abstract

The aim of this review is to present the scientific background, principles, concepts and recent advancements on resin infiltration for management of enamel and early cavitated lesion. 'Prevention is better than cure'. Numerous preventative measures have been adapted to slow the demineralisation process and enable effectiveness remineralisation of enamel and just before proceeding into cavitated lesion stage. One among this measures will be resin infiltration which act as the intermediate treatment modality between prevention and restoration. Management of early cavitated lesion has always been a challenge in the modern dentistry. A new technology in dealing with such lesions is this resin infiltration technology. It seems to provide a intermediary treatment modality between prevention and restorative therapy. The concept was introduced as micro-invasive approach for the management of smooth surface curious lesion and proximal non-cavitated various lesion. The rationale for using resin infiltration is based on the success achieved in obliterating the diffusion pathways of demineralised enamel with a low-viscosity resin. After treating enamel surface with an acid, rinsing and drying, this resin is infiltrated into the lesion's porous enamel, filling the voids and arresting carious lesion progression.

Keywords: *Resin infiltration alization,[26priwere effective in comptaken for examinashed in distilled water fir, Cavitated lesion, White spot lesions, smooth surface lesions, proximal lesions.*

Introduction

Dental caries is a multifactorial disease caused by an ecological shift in the composition and activity of the bacterial biofilm when exposed over time to fermentable carbohydrates, leading to a break in the balance between demineralization and remineralization[1].

Enamel demineralization and remineralization are continuous process that occurs throughout the entire life of a tooth. White spot lesions or non-cavitated lesions & early enamel lesions are probably considered as a first sign of dental caries disease[2]. These lesions can occur on any tooth surfaces, but dental surfaces with deep pits and fissures are particularly more prone to caries[3] and in general, caries on occlusal and buccal/lingual surfaces account for almost 90% of caries experienced in children and adolescents[4].

Non-cavitated lesion refers to pits and fissures in fully erupted teeth that may display discoloration not due to extrinsic staining, developmental opacities or fluorosis. The discoloration may be confined to the size of a pit or fissure or may extend to the cusp inclines surrounding a pit or fissure. The tooth surface should have no evidence of a shadow indicating dentinal caries, and, if radiographs are available, they should be evaluated to determine that neither the occlusal nor the proximal surfaces have signs of dentinal caries[5].

Demineralization is an inevitable adverse effect associated with fixed orthodontic treatment, especially when associated with poor oral hygiene[6].The acidogenecity of plaque bacteria are responsible for the enamel demineralization and formation of white spot lesions (WSL) [7].Gorelick et al. showed that the prevalence of white spot lesions (WSL) in patients undergoing fixed orthodontic treatment is 49.6% versus 24% in an untreated control

group[8].

With the advancements in preventive and adhesive technologies, newer techniques are available for preventing and reversing the carious process with the aim to preserve and regenerate the tooth structure: so called "non invasive" and "minimal invasive dentistry". Minimal invasive dentistry is "a systematic respect for the original tissue" by removing and replacing with as little tissue loss as possible[9].The Concept of minimally invasive techniques in dentistry requires a good diagnosis of risk and lesions, the use of the right preventive treatment to stop disease, the restorations of the lesions with as little healthy tissue loss as possible, the use of durable materials and the prevention of recurring disease [10].

Caries infiltration is an another promising approach which fills the gap between prophylaxis and filling. It gives us more time for observation and gives tooth the possibility to heal[11].Caries infiltration is defined as a micro-invasive technology that fills, reinforces, and stabilizes demineralized enamel without drilling or sacrificing healthy tooth structure. The micro-invasive infiltration can be used to treat smooth surface and proximal carious lesions up to the first third of dentin (D-1).It prevents lesion progression and increases life expectancy of a tooth. It provides an alternative to microabrasion and other restorative treatments for cariogenic white spot lesions. Resin infiltration technique is a novel technology that seems to bridge the gap between noninvasive and minimally invasive treatment of initial dental caries, postponing as long as possible the need for a restoration [12].

From a primary prevention perspective, anatomic grooves or pits and fissures on occlusal surfaces of permanent molars trap food debris and promote the presence of bacterial biofilm, thereby increasing the risk of developing carious lesions. Effectively penetrating and sealing these surfaces with a dental material—for example, pit and fissure sealants, Topical fluorides, Resin infitrants, ACP-CPP—can prevent lesions and is part of a comprehensive caries management approach[5].

Principle Of Resin Infiltration

The principle of resin infiltration is to perfume porous enamel with resin by capillary action. This aims to arrest lesion progression by occluding the microporosities that provide diffusion pathways for the acids and dissolved materials[13].It has been debated that bacteria entrapped at the base of lesions could trigger and spread the caries process. It has been well established that the count of bacteria in non-cavitated lesions is low and not determental[13].Enamel carious lesions are characterized by mineral loss in the body of the lesion, whereas the surface remains comparably highly mineralized[14,15].The pores within the body of enamel caries provide diffusion pathways for acids and dissolved minerals.

Therefore, an alternative approach for superficial sealing might be to arrest carious lesions by infiltration of these pores with light-curing resins, creating a diffusion barrier within the lesion without establishing any material on the enamel surface. Based on the available laboratory and clinical studies, it seems convincing that resin infiltration of enamel lesions should reduce (or even stop) the progress of white spot lesions[16].

Resin Infiltration Technique

Caries infiltration technique offers a micro-invasive option for the management of proximal lesions that are confined to the outer and inner enamel and to the outer third of dentine as diagnosed by radiographs. Caries infiltration technique aims to arrest the lesion progression by occluding the microporosities that provide diffusion pathways by acids and dissolved minerals[15].The resin infiltrate exhibits a very low viscosity, low contact angles to the enamel, and high surface tension to allow complete penetration of resin into the lesion body of enamel[17].Resin infiltration technique is a novel technology that seems to bridge the gap between noninvasive and minimally invasive treatment of initial dental caries, postponing as long as possible the need for a restoration[18].

The concept of caries infiltration was first developed at the Charité Berlin and the University of Kiel as a micro-invasive approach for the management of smooth surface and proximal non-cavitated caries lesions. It is marketed under the name Icon®[19]enamel with resin by capillary action. This aims to arrest lesion progression by occluding the microporosities that provide diffusion pathways for the acids and dissolved materials. It has been debated that bacteria entrapped at the base of lesions could trigger and spread the caries process. It has been well established that the count of bacteria in non-cavitated lesions is low or not determental is not sealed properly[20].

Resin Infiltration Steps

Despite the novelty of the resin infiltration technique, several studies were conducted in vitro and in vivo that tested the effect of different etching agents on the enamel surface of the initial caries lesions and the subsequent penetration ability of different adhesive systems[21-25].

The results advocate the use of 15% hydrochloric acid gel for 2 minutes, followed by drying of the surface and application of a low viscosity resin of type TEGDMA (tri-ethylene glycol dimethacrylate). The procedure for resin infiltration is fairly simple and acceptable by operators and patients[26].ICON® is marketed in two different forms: Proximal surface and vestibular surface kits. The principle of usage in both is similar except for the need for separation in case of proximal lesion treatment[27].As the mineralized surface layer of the non-cavitated lesions hampers resin from because of the shrinkage of the material after the first application resulting in the generation of space that can be then occluded by a second application [28,29]. Polishing of the infiltrated lesion was found to improve the stability of the masking effect most likely due to reduction in surface porosity and possible removal of oxygen inhibition layer[30].

Resin Infiltration Technique On White Spot Lesion

White spot lesions are an early stage of tooth decay formation. White spot lesions are commonly associated with the fixed orthodontic treatment and it poses a significant problem in the clinical setup. These lesions are caused by tooth demineralization which results in visible enamel changes[31].

In a study conducted by Martignon et al. the rate of failure of resin infiltration in non-cavitated proximal lesions after 1, 2 and 3 years of follow-up was 15.8%, 24.3% and 32.4%, respectively. The failure rates obtained in the control group (placebo) were 47.4%, 62.2% and 70.3% for the same follow-up periods[32]. Dental caries activity is higher in temporary molars than in premolars and permanent molars, which may explain the difference between the results obtained by Ekstrand et al. and other studies[33].

Ekstrand et al may possibly be explained by a higher proportion of dentin lesions that were infiltrated by them and consequently a higher rate of its progression and reduced efficacy of infiltration[34].

The results of various studies conducted in order to define an effective resin infiltration protocol show that a higher rate of inhibition of caries progression occurs with the application of a 15% hydrochloric acid gel for 2 minutes in order to dissolve the superficial hypermineralized enamel surface and to allow a greater penetration of resin [35].This layer reflects the remineralization that characterizes the dynamics of tooth decay and, if not removed, it behaves as a barrier to resin infiltration [36].Considering the resin characteristics needed for a good infiltration, the resin should have a low viscosity, a small contact angle on enamel, a high surface tension and a high penetration coefficient. Among the different studied materials, triethylene glycol dimethacrylate (TEGDMA), without added solvent, has proved to be the resin which is capable of giving better results [25,37,38].

Having in mind the particularities of TEGDMA, it becomes of paramount importance to maintain a dry tooth surface prior to its use, which is achieved through the removal of water by dehydration with ethanol. When this dehydration is not fully effective, which happens more easily at the lesion margins, an incomplete infiltration is obtained [39].

The polishing of the infiltrated lesions should be performed. It is related to the stability of the aesthetic, the reduction of the porosity and the removal of the oxygen inhibited layer.

The resin infiltration technique is indicated for active and non-cavitated carious lesions, whose depth does not exceed the outer third of dentin, on smooth surfaces (proximal, buccal and lingual) [40].The application of this technique is particularly interesting in proximal lesions, taking into account the destruction of healthy tissue that is required to access the lesion while using other techniques and its indication should be ascertained through bitewing radiographs [40,41].

Conclusion

Under the limitations of this report, the resin infiltration technique is a promising microinvasive approach in arresting caries progression and preservation of demineralized enamel. Prognosis of this case depends on oral hygiene, available fluorides, re/demineralization

periods, biological behavior of materials used as infiltrants and clinical sensitivity of application procedures.

Analysis of Condylar Morphological Variations Using Digital Panoramic Radiographs-A Retrospective Study

Abarna Jawahar[1], G.Maragathavalli[2]

[1]Post graduate Student, Department of Oral Medicine and Radiology, [2]Professor. & Head, Head of the Department, Department of Oral Medicine and Radiology, Saveetha Dental College and Hospital, Saveetha Institute of Medical and Technical Science (SIMATS), Chennai 600077, India

Abstract

Aim- The aim of the study is to retrospectively analyse the condylar morphological variations using digital panoramic radiographs

Background- Digital panoramic radiographs are commonly utilised by dentist to visualise the teeth, maxilla, mandible and the surrounding structures. OPGs are cost effective and are also relatively low in radiation exposure to the patients. Human mandibular condyle may be classified into four types basically as oval, diamond, bird beak and crooked finger. Variations in the condylar morphology may occur due to developmental variations, trauma, endocrine disturbances and radiation therapy.

Materials and Method- This study comprised of radiographic evaluation of 200 condyle after including 100 digital panoramic radiographs retrospectively taken for routine investigation. The radiographs included in the study comprised of 50 male and 50 female. Human condyles were classified based on Chaudhry et al into 4 types. Most commonly occurring shape in males and females were evaluated.

Results- Of the 100 pairs of mandibular condyle evaluated 58.5% were oval in shape, followed by 21% were bird beak in shape, 9% were diamond in shape, 14% were crooked finger in shape. When evaluated whether there is any symmetry between the two sides oval-oval was the commonly occurring combination with 90 pairs showing symmetry and 10 pairs were asymmetrical.

Keyword- *Digital panoramic radiographs, mandibular condyle, temporomandibular joint, oval, diamond*

Introduction

Temporomandibular joints (TMJ) is one of the unique joints in the human body which is formed by the articulation between the mandibular condyle and squamous portion of the temporal bone at the base of the skull[1].The functions of TMJ includes maintaining proper occlusion, enabling a smooth and efficient movement of the mandible during mastication, swallowing, speech and to prevent dislocation of the mandible from external or abnormal forces[2]. Even after growth cessation, the mandibular and temporal parts of the TMJ are both thought to maintain its capacity for remodelling[3]. Due to functional and mechanical requirements there is an adaptive response of the TMJ which is thought to be the reason for continued capacity for morphologic changes[4,5].Various factors have been found to alter the TMJ morphology and position including age, sex, pathological processes, functional variations and occlusal forces[6,7,8]. Several studies have been done on dimensional analysis of the condyle and its surrounding structure, less attention has been given towards the variations in the condylar morphology[9]. Orthopantomogram is one of the most commonly prescribed and interpreted radiographs by dentists. OPGs are cost-effective with comparatively low dose of radiation exposure to the patients[10,11].

The aim of the study is to analyse and evaluate the morphological variations on an OPG and thereby, whether the determination of shapes could aid in

diagnostics. It is often assumed that normal condylar head will have a convex configuration and there is symmetry between the contra-lateral sides in the same individual. After several researches, it is found that there is great variation in size and shape with age, gender, facial type, occlusal force, functional load, malocclusion type[9].Yale et al. in 1961 reported about the different shapes of the mandibular condyle for the first time[12]. The mandibular condyle was classified by Yale initially based on their superior view into concave, convex and flat , but it was simplified into four categories as convex, flattened, angled and rounded[12,13,14]. Developmental disturbances involving TMJ might result in anomalies of the size and shape of the condyle such as hyperplasia, hypoplasia, agenesis and formation of a bifid condyle. Any trauma or infection during development can also lead to condylar growth disturbances[15].

Various syndromes can result in abnormalities of the jaw and face which might affect the structure, shape, size, organisation and function of hard and soft tissues. Hemifacial microsomia, Treacher Collins Syndrome, Hallermann-Steiff Syndrome are the three syndromes which causes hypoplasia of the mandibular condyle[16-26]. Aplasia of the mandibular condyle is seen in Hemifacial Microsomia and Occula mandibulo dyscephally[16-23]. Apart from developmental anomalies, there might be variation in the size and shape of the mandibular condyle due to cyst and tumours in region of condyle, arthritic conditions, endocrine disturbances and radiation. A proper understanding of the anatomy and morphology of the condyle is necessary in-order to differentiate a normal variant from pathological condition[27]. The objective of this study was

1)To determine the shape predominantly seen in population

2)To analyse the variation in shape of mandibular condyle in adult Indian population

3)To assess whether there is any particular shape dominant in each gender.

Materials and Method

A retrospective study was done on 100 digital OPGs taken for routine investigation purpose taken in Department of Oral Medicine and Radiology, Saveetha Dental College and Hospitals. The OPGs which revealed full condylar view on both the sides with optimal density and contrast, free of any projection errors were selected for this study. The study included OPGs of 50 male and female of all the age groups. Classification of condyle by Chaudhry et al. identified as Type I- Oval shape, Type II- Diamond shape, Type III- Bird beak shape, Type IV- Crooked finger shape as shown in fig 1

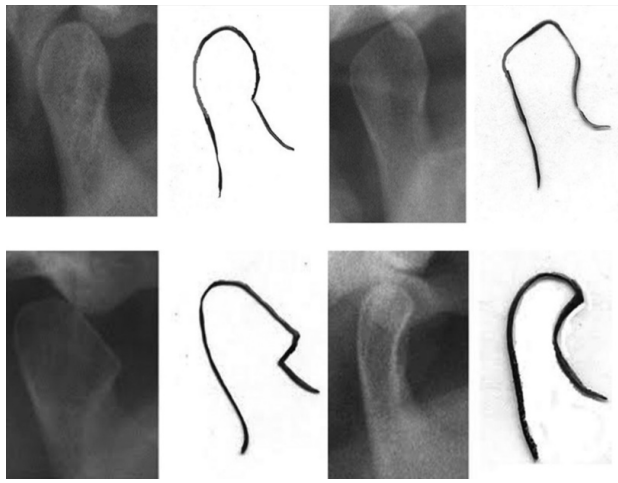

Fig 1-Shapes of condyle on radiograph

Results

A total of 200 condyles were analysed from 100 subjects of different age groups, which included 50 males and 50 females.

1. The following shapes were observed among the Indian population namely-

i) Oval ii) Diamond iii) Bird beak iv) Crooked finger

2. The most common shape observed was Oval (58.5%) followed by bird beak (21%), diamond (9%) and crooked finger (14%) shown in fig 1.

3. The most common shape observed among males was oval, bird beak, diamond and crooked finger (fig 2)

4. The most common shape observed among females was oval, diamond, bird beak and crooked finger (fig 3)

5.The predominantly occurring shape in both the sex was determined. 58% of the males and 59% of the females exhibited oval shape which is observed as the most commonly occurring shape.

4. Fig 4 depicts the commonly occurring combinations of the condyle shape radiographically. Among which the oval-oval (54%) combination was the most common followed by bird beak-bird beak (18%), diamond-diamond (11%) and crooked finger-crooked finger (7%) in our study.

5. Fig 5 shows the different combinations of shapes of oval-bird beak (5%), oval-diamond (4%) and diamond-bird beak (1%).

Discussion

Mandibular condyle is a bony ellipsoid structure approximately 20mm long mediolaterally and 8-10mm thick anterposteriorly.The shape of mandibular condyle varies greatly among each individuals and age groups. The variations in the size and shape of the condyle may be physiological and pathological[28].A study on mandibular condyle morphology in relation to malocclusion in children during the 1980s revealed that the condyle was greater in size in males when compared to females and midline discrepancy significantly altered the increase in condylar size during growth[29].Human mandibular condyle can be categorized into 5 basic types as flattened,convex,angled,rounded and concave. Morphological variations of the condyle may be resulted due to several factors such as developmental variations, remodelling, trauma, endocrine disturbances, various diseases,syndrome and radiation therapy.Panoramic radiograph still remains to be one of the most common screening modalities among various imaging techniques for TMJ abnormalities because it enables to view both maxillary and mandibular dental arches along with surrounding structures like Temperomandibular Joint(TMJ), maxillary sinus, nasal cavity, styloid process and hyoid bone.OPG is a standard imaging modality prescribed by dental surgeons for obtaining general information about the oral cavity as it is also has a favourable cost-benefit relationship and relatively low dose of radiation exposure to the patients[30]

This study is done to determine the prevalent radiographic shapes of the head of the condyle on OPG. From the evaluation of 200 condyles it is found that 58.5% were oval in shape followed by 21% bird beak, 13.5 % diamond, and least seen was 7% crooked finger. The study also determined whether TMJ followed any typical feature of symmetry.It was found that 90% of pairs of condlye was same combinations in which oval-oval was the most commnly occuring combination followed by bird beak-bird beak in both male and female.10% showed different combination of pairs comprising the oval-bird beak followed by oval-diamond and the least being diamond-bird beak.Radiographs are two dimensional visualisation of three dimensional object. Hence the temperomandibular joint has to be viewed from several positional aspects.Recently developed imaging modalitiy like cone beam volumetric imaging can be used which will give more detailed information of the condyle.

Conclusion

Variablity in the shapes and sizes of the condyle must be considered as an important factor in diagnosing the disorders of the temperomandibular joint.Cost effectiveness and low exposure dose makes OPG a standard choice of imaging prescription.Evaluation of condyle on OPG enables to study and analyse fine observations.From this study pertaining to Chennai population we conclude that oval is the most common shape in both genders and oval-oval being the most common combination of pair.Increased sample size and advanced imaging modality may help in giving more information on the morphology of condyle in a population.

Herbal Formulation Mediated Synthesis of Silver Nanoparticles and Its Antifungal Activity Against *Candida albicans*

Ankita Komal labh[1], S Rajeshkumar[2], Anitha Roy[2], J Santhoshkumar[3], T Lakshmi [2]

[1]Undergraduate Student, [2]Associate Professor, Department of Pharmacology, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, Tamil Nadu, India, [3]Researcher, Department of Biotechnology, School of biosciences and technology, VIT, Vellore, Tamil Nadu, India

Abstract

Background : *Candida albicans* is known to cause a variety of diseases like oral candidiasis, vaginal candidiasis, invasive candidiasis etc. Although there are anti-fungal drugs in use for the treatment of these diseases, alternative medicine is required for their prophylaxis and improved prognosis. For this purpose, silver nanoparticles (Ag-NPs) can be used as antifungal agents. They are already in use as anti-microbial and anti-fungal agents in agriculture and can potentially be used as targeted drugs for the human body. The aim of this research is to study the anti-fungal efficacy of silver nanoparticles synthesised using a herbal formulation of *Andrographis paniculata* and *Moringa olifera* against *Candida albicans*.

Materials and Method: Herbal formulation was created using the leaves of *Andrographis paniculata* and *Moringa olifera.* Silver nitrate solution was added to this and the solution was transferred to an orbital shaker for silver nanoparticle preparation. The powder of Ag-NPs was created. The bioreduction of pure $AgNO_3$ was characterized by UV-visible spectroscopy. *Candida albicans* was isolated using serial dilution method and a fresh fungal suspension was dispersed on Rose Bengal agar. Both disc diffusion and agar well diffusion methods were used. Different concentrations of Ag-NPs (50, 100 and 150 microliter) were incorporated into the wells, discs, and plates and these were incubated at 37°C for 24 hours. The antifungal agents were used as positive control. Zone of inhibition was recorded in each plate. Proper documentation methods were used.

Results: Colour change was seen after the preparation of silver nanoparticles. The peak in UV-vis spectroscopy was seen to be at 400 nm. The zone of inhibition was seen to increase with an increase in the concentration of Ag-NPs in the agar wells. The plate dispersed with the highest concentration of Ag-NPs had the lowest cultural population.

Conclusion: The herbal synthesis of Ag-NPs is highly eco-friendly and should be practised more than chemical synthesis of the same. The antifungal activity of Ag-NPs was comparably effective to the control used and in the future they can be administered as an antifungal drug for the prophylaxis and treatment of various types of Candidiasis.

Keywords: *Antifungal, Silver nanoparticles*, *Candida albicans*, *Andrographis paniculata*, *Moringa olifera*

Introduction

Nanotechnology

Nanotechnology has emerged as a science of varied uses over the past years. This is mainly due to its ability to be of use in a plethora of disciplines. It has been of use in agriculture, the petroleum industry, medicine,

physics, engineering etc [1]. This can be attributed to the many beneficial properties of nanoparticles (NP) such as anti-bacterial action, anti-fungal action, anti-wear property, anti-friction property, property to smoothen surfaces, potential for bio-synthetic production etc [2]. The bio-synthesis of nanoparticles is being given great weight because it does not involve toxic chemicals in its synthesis.

Silver Nanoparticles

Silver nanoparticles (Ag-NP) can be sourced form a variety of agents like bacteria [3], flowers, fruit extracts [4], leaf extracts [5], bark etc. They are of excellent use as antimicrobial agents, nano-fungals, nano-pesticides in the agriculture industry, and additives in base oil etc. The anti-bacterial action of Ag-NP improves the shelf life of biodiesel and prevents it from going rancid. It has been put forward in studies that Ag-NPs can be the answer to drug-resistant micro-organisms.

Antifungal activity of Nanoparticles

Candida albicans is known to cause various mucosal [6] as well as deep tissue infections [7]. Some of these being oropharyngeal, oral, esophageal, vulvovaginal candidiasis [8]. The possibility of infection by *Candida* increases due to biofilm formation on medical devices [9]. Although there are antifungal drugs in use for the treatment of these diseases, alternative medicine is required for their prophylaxis and improved prognosis. For this purpose, silver nanoparticles (Ag-NPs) can be used as antifungal agents. They are already in use as antimicrobial and antifungal agents in agriculture [1] and can potentially be used as targeted drugs for the human body. The aim of this research is to study the antifungal efficacy of silver nanoparticles synthesised using a herbal formulation of *Andrographis paniculata* and *Moringa olifera* against *Candida albicans*.

Materials and Method

Preparation of plant extract: Leaves of *Andrographis paniculata* and *Moringa olifera* were collected from Chennai. The collected leaves were washed 3-4 times using distilled water and dried in shade for 7-14 days. The well dried leaves were then crushed into powder by using mortar and pestle. The collected powder of the leaves was stored in air tight containers. 1 gram of *A. paniculata* leaf powder was dissolved in distilled water and boiled for 5-10 minutes at 60-70°C. The same was done for the powder of *M. olifera*. The solutions were then filtered using Whatmann No. 1 filter paper. The filtered extract was collected and stored in 4°C for further use.

Synthesis of nanoparticles: 1 milli molar of silver nitrate was dissolved in 90 mL of double distilled water. The plant extracts of *A. paniculata* and *M. olifera* were added with the metal solution and this solution was made into a 100 ml solution. The colour change was observed visually and photographs were taken for the record. The solution was then kept in a magnetic stirrer/ orbital shaker for nanoparticle synthesis.

Characterisation of silver nanoparticles: The synthesis of nanoparticles is primarily characterised by using UV-vis-spectroscopy. 3 mL of the solution is taken in a cuvette and scanned in UV-vis-spectrometer under 350 nm to 550 nm wavelength. The results were recorded for graphical analysis.

Preparation of silver nanoparticle powder: The Ag-NP solution was centrifuged using lark refrigerated centrifuge. The centrifugation was done at 8000 rpm for 10 minutes and the pellet was collected and then washed with distilled water twice. The final purified pellet is collected and dried at 60°C. Finally, the nanoparticles powder was collected and stored in an air tight eppendorf tube.

Study of antifungal activity of Ag-NPs against *Candida albicans*: The *Candida albicans* isolate was isolated using serial dilution method and confirmed using specific media. The agar well diffusion method and disc diffusion method were used to determine the antifungal activity of Ag-NPs. Different concentrations of Ag-NPs were tested against the oral pathogen *C. albicans*. The fresh fungal suspension was dispersed on the surface of Rose Bengal agar plates. Different concentrations of Ag-NPs (50, 100 and 150 µl) were incorporated into the wells and then the plates and discs were incubated at 37°C for 48 hours. The antibiotics were used as positive controls. Zone of inhibition was recorded in each plate.

Results and Discussion

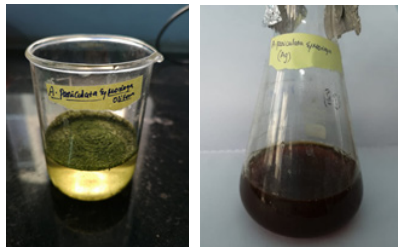

Figure 1: Visual Observation

Visual Observation

Colour change was seen after the production of silver nanoparticles (Figure 1). Initially the extract solution was green in colour and after the synthesis it turned dark brown. The colour change from green to brown preliminarily confirms the synthesis of Ag-NPs. This change takes place due to the excitation of the surface plasmon resonance.

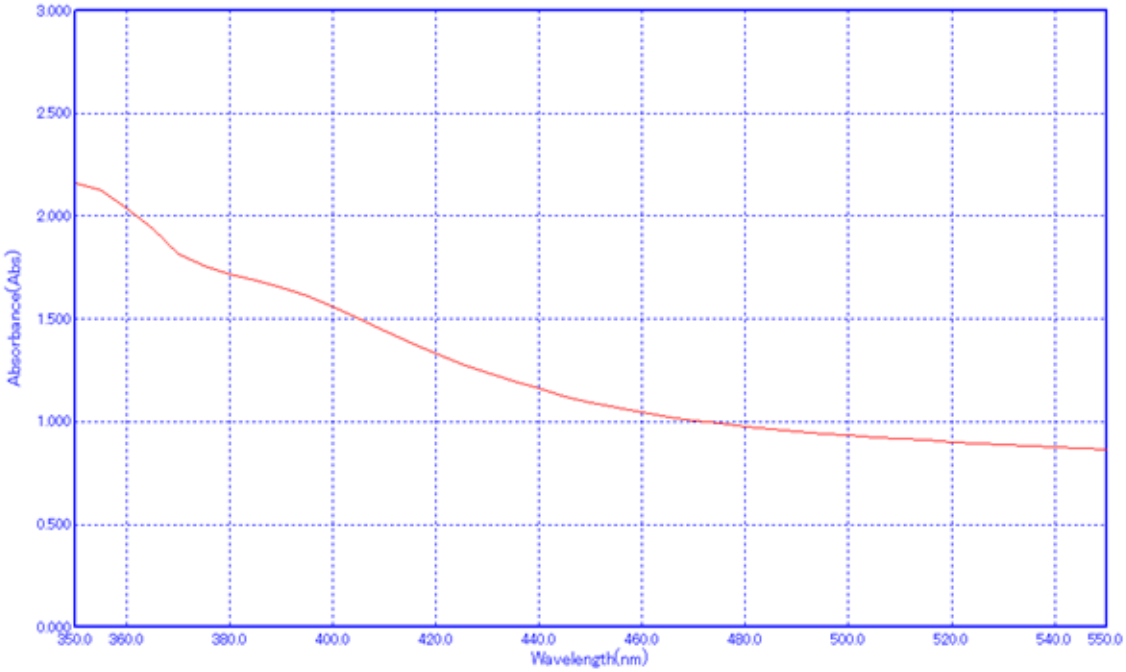

Figure 2: UV-vis Spectroscopy:

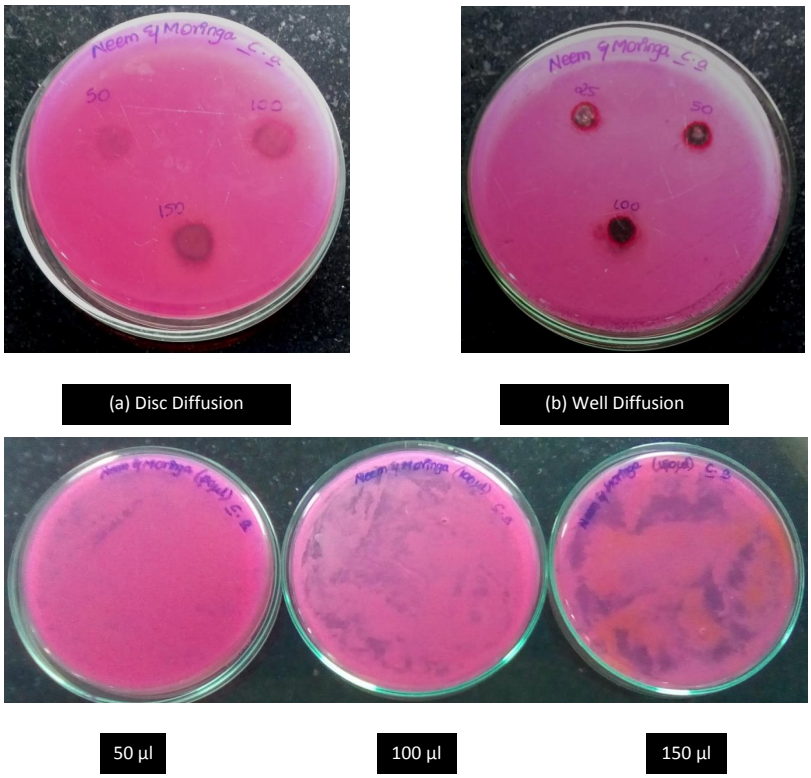

Figure 3: Antifungal Activity

UV-vis Spectroscopy

Figure 2 shows the UV absorption spectra of the synthesized silver nanoparticles using the leaves of *Andrographis paniculata* and *Moringa olifera.* The formation and stability of silver nanoparticles was monitored and the plasmon resonance band for silver nanoparticles was peak positioned at 400 nm.

Antifungal Activity

The growth of the *Candida albicans* isolate is seen to decrease with an increase in the concentration of suspended Ag-NPs in Rose Bengal agar plate. This proves that silver nanoparticles are potent anti-candidal agents.

In recent years, there has been an increase in the resistance of *Candida* sp. towards antifungal therapy. This has led to treatment failure and recurrence of infections [10]. The need to produce alternative antifungal drugs arises due to the fact that *Candida albicans* is one of the most opportunistic pathogens and can cause recurrent infections in immunosuppressed individuals[11].

Another problem with antifungal drugs is that their variety remains extremely limited when compared to the number of diseases caused by fungi. This can be attributed to the fact that fungi are eukaryotic organisms with a structure and metabolism that are similar to those of the eukaryotic hosts they inhabit [12].

When compared to common antifungal agents, Ag-NPs inhibit the growth of fungi at a much lower concentration thus preventing drug toxicity [13]. Studies have showed that a pathogenic state called Dental Stomatitis that is caused by Candida biofilm formation in complete denture wearers can be prevented by the usage of Ag-NPs [14].

Conflict of Interest: The authors declare there is no conflict of interest.

Nano Structured Bioactive Glass on Dental Disease

Anitha.D.R[1], P. Jayashri[2]

[1]Graduate Student, [2]Senior Lecturer, Department of Public Health Dentistry, Saveetha Dental College, Saveetha Institute of Medical and Technical Science, Saveetha University, Chennai, India

Abstract

Bioactive Glass (BG) has recently become one of the most promising biomaterials, a consequence of discoveries that its unusual properties elicit specific biological responses inside the body.Recent developments in nanotechnology have introduced opportunities for materials sciences to advance dental and bone therapies.The first generation biomaterials were selected to be as bio-inert as possible and thereby minimize formation of scar tissue at the interface with host tissues. Bioactive glasses were discovered in 1969 and provided for the first time an alternative; the second generation, interfacial bonding of an implant with host tissues. Tissue regeneration and repair using the gene activation properties of Bioglass provide a third generation of biomaterials. Among these important properties are the capability of BG to form strong interfaces with both hard and soft tissues, and its release of ions upon dissolution. Bioactive glass can also be used as a tooth paste, these kinds of toothpastes are used, Bioglass particles adhere to the dentine and form aHAp layer; therefore, blocking of the tubules relieves the pain for longer periods. Bioactive glass is an effective remineralizing agent as the effects of bioactive glass containing products were investigated on remineralization of artificial induced carious enamel lesion. This review is to identify the status and usage of nano structured bioactive glass on dental disease.

Key words: *Bioactive Glass Nanostructured, Remineralization*

Introduction

Bioactive glasses are inorganic materials with clear bone bonding and osteoinductive properties. The surface characteristics of these materials lead to rapid bonding and colonization of bone forming cells. Because of the release of ions after contact with body fluids, especially Cu, Zn, and SR, specific activation and differentiation of bone forming cells occurs. Moreover, they are effective in treatment of osteomyelitis and are associated with the release of angiogenic factors. By varying their chemical composition and structure, both degradation and bioreactivity can be influenced[1].

Bioactive glasses are a group of biomaterials which are used in the fields of dentistry and orthopaedics [2].The function of biomaterials has been to replace diseased or damaged tissues. Developed some 40 years ago, bioactive glass has recently become one of the most promising biomaterials, a consequence of discoveries that its unusual properties elicit specific biological responses inside the body [3]. Among these important properties are the capability of BG to form strong interfaces with both hard and soft tissues, and its release of ions upon dissolution.

Recent developments in nanotechnology have introduced opportunities for materials sciences to advance dental and bone therapies[4].The first generation biomaterials were selected to be as bio-inert as possible and thereby minimize formation of scar tissue at the interface with host tissues. Bioactive glasses were discovered in 1969 and provided for the first time an alternative; the second generation, interfacial bonding of an implant with host tissues[5]. Tissue regeneration and repair using the gene activation properties of Bioglass provide a third generation of biomaterials[6].

Bioactive glasses have a wide range of applications, particularly in dentistry[7]. These glasses can be used as particulates or monolithic shapes and porous or dense constructs in different applications such as remineralization or hypersensitivity treatment. Dentin hypersensitivity (DH) is an oral problem which is attributed to the root surface exposure due to periodontal disease, toothbrush abrasion orcyclic loading fatigue of the thin enamel near the cemento-enamel junction[8]. A bioactive glass mineralizes tiny holes in the dentine and reduces the sensitivity of the tooth.

Bioactive glasses have unique remineralizing properties and are generally introduced into various dentifrices as very fine particles to provide calcium and phosphorus to the tooth surface. Some properties of bioactive glasses such as antibacterial properties can be promoted by adding different elements into the glass[9]. During dissolution of bioactive glass, the pH rises due to cation release and such condition can kill the microbes. Bioactive glasses can also be used to modify different biocompatible materials that need to be bioactive[10].Consequently, fixed restorative ceramics would be modified in a way that they could stimulate bioactive behavior around the fixed restorations margins and provide a bioactive surface, through the tissue regenerative techniques; they could develop periodontal tissue attachment and create complete sealing of the marginal gap[11]. This sealing could prevent the failure of fixed ceramic restorations by eliminating secondary caries, micro penetration of the oral bacteria and their adhesion on cement surface[12]. This article is to identify the status and usage of nano structured bioactive glasses in dental diseases.

Types of bioactive glasses

Bioactive glasses are bioceramics that are solid, nonporous, and hard materials, which consist of the main component silicon dioxide (or silicate) and three other basic components: sodium dioxide, calcium oxide, and phosphorous[13]. By varying all of these components, different forms of bioactive glasses can be made. Bioactive glasses have been investigated for decades and have shown good results in bone regeneration. In all these years several types of bioactive glasses are developed: the conventional silicate glass (45S5 bioactive glass or Bioglass®), glass ceramics (S53P4 bioactive glass or BonAlive®), and borate-based glasses (19-93B3 bioactive glass)[14,15,16]. The biocompatibility of bioactive glasses generally depends on the silicate part of the glass and reaches an optimum graft-bone bonding between when the glass contains 45–52% silicate[17]. The process of graft-bone bonding of bioactive glasses starts with the release of soluble ions after which a silica gel layer is formed on the bioactive glass surface. After the formation of the silica gel layer, amorphous calcium phosphates precipitate on this layer where they form a natural hydroxyapatite layer due to crystallisation. The hydroxyapatite layer activates the osteoblastic cells to start the formation of new bone. This graft-bone bonding is one of the two mechanisms involving degradation of the bioactive glasses, where the second mechanism is based on the dissolution of different ions and thereby activating osteogenesis. The degradation speed of bioactive glasses is depending on the composition of the glasses and can vary from several hours to months[18]. For instance, of borate bioactive glass is known that it degrades much faster than silicate bioactive glass.

In the past decade the popularity of bioactive glasses in the treatment of infections increased. Their versatility in composition and physiological properties enables us to use bioactive glasses in treatment of infection based on different antibacterial mechanisms. These antibacterial properties can be divided into three principles. The first principle is based on the change of local physiological conditions due to dissolution of ions that results in a bactericidal environment. S53P4 bioactive glass (commercially available as BonAlive® bioactive glass) is a bioactive glass with the ability to inhibit bacterial growth. This mechanism is proven bactericidal on different bacterial strains, such as Staphylococcus aureus, without causing any signs of cytotoxic effects or adverse reactions on their environmental tissues[19]. Second principle is based on adding element as silver to the bioactive glass during the manufacturing process because of their bactericidal effects. As well silicate as borate bioactive glasses are tested as silver-doped antibiotic glasses. Silver-doped silicate bioactive glasses showed slow degradation rates and uncontrollable silver release profiles, where silver-doped borate bioactive glasses showed that due to the manufacturing process there is a controlled release of silver, which is favorable in infection treatment. Despite the good in vitro results for eradication of infection, there is a little in vivo evidence for silver-doped bioactive glasses; this might be explained due to the toxicity and adverse reactions when using high concentrations of silver that is favorable in infection treatment. The third

and last principle uses antibiotic-loaded bioactive glass that elutes antibiotics during degradation compared to the previously mentioned bone graft substitutes. The bioactive glasses used as an antibiotic delivery device have a different composition compared to conventional bioactive glasses because the conventional glasses are nonporous and too dense. The bioactive glasses applied for antibiotic delivery are mainly composed as sol–gel-derived carriers or glass-composite carriers[20]. The sol–gel-derived glasses have low release rates of antibiotics (only 20–25% after 3 months) and have a low strength what makes them less applicable in treatment of bone infections. The composite glasses showed better release rates compared to gel–sol-derived glasses. An in vitro study showed release rates up to 80–85% after 21 days for a chitosan borate glass composite, where an in vivo study showed release rates up to 90% after approximately 14 days for phosphate-cement borate glass composites[21].

Mechanism of action

The underlying mechanisms that enable bioactive glasses to act as materials for bone repair have been investigated since the first work of Hench et al. at the University of Florida[22]. Early attention was paid to changes in the bioactive glass surface. Five inorganic reaction stages are commonly thought to occur when a bioactive glass is immersed in a physiological environment:

1) Ion exchange in which modifier cations (mostly Na+) in the glass exchange with hydronium ions in the external solution.

2) Hydrolysis in which Si-O-Si bridges are broken, forming Si-OH silanolgroups, and the glass network is disrupted.

3) Condensation of silanols in which the disrupted glass network changes its morphology to form a gel-like surface layer, depleted in sodium and calcium ions.

4) Mineralization in which the calcium phosphate layer gradually transforms into crystalline hydroxyapatite, that mimics the mineral phase naturally contained with vertebrate bones.

Later, it was discovered that the morphology of the gel surface layer was a key component in determining the bioactive response. This was supported by studies on bioactive glasses derived from sol-gel processing. Such glasses could contain significantly higher concentrations of SiO2 than traditional melt-derived bioactive glasses and still maintain bioactivity (i.e., the ability to form a mineralized hydroxyapatite layer on the surface)[23].

Previously, it was known that a complex interplay existed between bioactive glasses and the molecular biology of the implant host, but the available tools did not provide a sufficient quantity of information to develop a holistic picture[24]. Using DNA microarrays, researchers are now able to identify entire classes of genes that are regulated by the dissolution products of bioactive glasses, resulting in the so-called "genetic theory" of bioactive glasses. The first microarray studies on bioactive glasses demonstrated that genes associated with osteoblast growth and differentiation, maintenance of extracellular matrix, and promotion of cell-cell and cell-matrix adhesion were up-regulated by conditioned cell culture media containing the dissolution products of bioactive glass[25].

The mechanism of HAp layer formation on bio-active glasses

Hydroxyapatite is similar to the bone mineral and can interact with collagen fibrils of damaged bone to bond with it. Osteogenesis, due to the dissolution products of the glass on osteoprogenitor cells, stimulates new bone growth[21].

The mechanism of HAp layer formation on bioactive glasses has been widely studied in vitro and in vivo. This process involves different stages; calcium ions dissolve from the bioactive glass into the body fluid while a silica-rich interlayer forms on the glass surfaces. The nucleation of HAp is now possible because the surrounding fluid is supersaturated with re- spect to HAp due to the dissolution of the calcium ions. In addition, silica-rich interlayer dissolves a considerable amount of silicate ion and provides favorable sites for the nucleation. The process of nucleation and growth of the HAp layer continues by the reactions of the calcium, phosphate, and hydroxide ions. It is possible that carbonate or fluoride anions incorporate in the reactions, as well[20, 21, 26].

In 1980, Hench showed that the in vivo formation of the HAp layer can be reproduced in Tris buffer solution at pH 7.4. Later, Kokubo and Hench independently confirmed that apatite can form on the surface of Bioglass® in SBF. In 1991, it was suggested that a simulated body fluid (SBF) which has the ion concentrations equal to

human blood plasma can reproduce HAp formation[22]. Thin film X-ray diffraction (TF-XRD), Fourier transform infrared spectroscopy (FTIR), scanning electron microscopy (SEM) and transmission electron microscopy (TEM) were used to confirm the similarity of the composition and structure of HAp formed in SBF to the bone mineral[27]. Hence, immersion in SBF can be used for in vivo bone bioactivity prediction before animal testing; this reduces the number of animals used and the duration of experiments and, there- fore, increases the possibility of the development of new types of bioactive materials[22].

SBF is a solution that simulates human blood plasma with ion compositions similar to human blood, but without any proteins, hormones, glucose, or vitamins[28]. During immersion in SBF, different processes occur simultaneously which result in structural and chemical changes to the surface of the material. These processes are leaching, degradation, and precipitation[29]. In the leaching process, through the exchange of the cations H+ and H3O+, metal ions like Na+ and Ca2+ are released and the pH at the interface increases up to 7.4. In parallel, hydroxyl ions locally break the silica-oxygen bonding. Then, silicon as silicic acid, Si (OH)4, is released into the solution. The hydrated silicic acid on the surface is surrounded by at least one hydroxy group; subsequently, a silicic acid gel layer forms. Simultaneously, the glass releases calcium and phosphorus and an amorphous calcium phosphate-rich phase is formed on the surface. The CaP phase then crystallizes into a hydroxyapatite (HAp) structure[29].

Bioactive glass on remineralisation

Demineralization and remineralization are natural processes which continuously occur for teeth. Physiological processes as well as bacterial acids and foods cause demineralization, while remineralization results from the deposition of mineral (calcium and phosphorous) from saliva or oral fluid. Since natural remineralization is not enough for having strong enamel, bioactive glasses are used to augment the process. Bioactive glasses have unique remineralizing properties and are generally introduced into various dentifrices as very fine particles to provide calcium and phosphorus to the tooth surface[30].

Conclusion

Bioactive glasses are able to bond to both soft and hard tissue and promote the bone growth. The bioactivity behavior of these glasses is related to the formation of a biologically active hydroxyapatite layer on the surface of the glasses. The mechanism of bonding of bioactive glasses to tissues includes a series of surface reactions that occur when the glass is exposed to an aqueous environment. These glasses are produced via two main methods, melting and sol-gel processing. Bioactive glasses have a wide range of applications, such as bone grafts, scaffolds, coating materials, and are used for hypersensitivity treatment.

Assessment of Dental Caries Status Using Caries Assessment Spectrum and Treatment (Cast) Index

Abarna Jawahar[1], G.Maragathavalli[2]

[1]Post graduate Student, Department of Oral Medicine and Radiology, [2]Professor. & Head, Department of Oral Medicine and Radiology, Saveetha Dental College, Saveetha Institute of Medical and Technical Science, Saveetha University, Chennai, India

Abstract

Aim: The study is aimed to assess the dental caries status in patients visiting the Department of Oral Medicine, Radiology and Special Care dentistry in Saveetha Dental College and Hospitals using Caries Assessment Spectrum and Treatment Index (CAST).

Background: A new epidemiological index is introduced for assessment of dental caries which is known as Caries Assessment Spectrum and Treatment (CAST). Spectrum is considered as backbone of this index which covers the entire carious lesion progression from no caries to caries involving enamel, dentin and pulp. It also includes codes for teeth that has developed an abscess/fistula in relation to carious teeth and teeth lost due to dental caries.

Materials and Method: The study population was patients visiting the Department of Oral Medicine, Radiology and Special Care Dentistry in Saveetha Dental College during the month of January 2019.The patients who were aged between 20-50 were included randomly and all third molars, any developmental dental anomalies and those undergoing orthodontic treatment were excluded. The patient's dental caries status was examined using mouth mirror, periodontal probe under proper illumination and was recorded in a predesigned proforma.

Results: From the study we find that 82.64% were caries free, 2.57% had restorations, 1.35% had enamel caries which gives us the information that 86.56 % can be considered healthy (caries free). The lesion involving the dentin were 2.13% and pulp were 5.78%, which leads us that about 7.91% are caries affected. The advanced stage of carious lesion which is abscess or fistula were 0.92% and the teeth lost due to dental caries was 3%.

Conclusion: Our study concludes the CAST index presents a simple hierarchical structure of carious lesion spectrum and is a promising index for epidemiological studies with complex quantifiability.

Introduction

Dental caries is a dynamic disease which may involve enamel and dentin. The rate of carious lesion progression can be controlled by various measures. In carious lesion involving enamel and dentin, further caries progression can be prevented. If caries-controlling measure are not effective, caries may affect large parts of the tooth leading to pulpal involvement, ulceration,

fistula, abscess and infection of the alveolar bone and surrounding tissue[1]. Dental caries continues to be a serious problem worldwide. A continued surveillance of the dental caries epidemiological status is required[2]

Due to recommendation of the World Health Organisation (WHO) the Decayed, Missed and Filled teeth (DMFT) index is the most commonly used tool in epidemiological surveys. But it has failed to meet the challenges of the 21st century[3]. In-order to overcome the difficulties encountered with DMFT index a new visual and tactile dental caries detection system was established known as the International Caries Detection and Assessment System (ICDAS). Few changes were made in this original index by the committee and was finally named as ICDAS II[4,5,6]. This system requires an air compressor for drying each tooth surfaces necessating additional financial resources and electricity. The coding is complex for use, encumbers data analysis and difficult to present the results in an easy-to-read method[7,8,9].

In a population with high caries prevalence and more severe carious lesion progression Pulpal involvement - Ulceration-Fistula-Abscess (PUFA) and Pulpal involvement root sepsis (PRS) can be applied. The shortcoming of PUFA index is that it covers only a part of the wide range of carious lesion progression[10,11].

Due to serious difficulties encountered to report using ICDAS II and PUFA indices separately in an epidemiological survey in a child population in Brazil, the development of new index was necessitated. This led to the search for a new caries index which is consistent, sensible, organised, pragmatic and have easy way of reporting the results. The newly proposed index by Francken et al was a combination of ICDAS II, PUFA and 'M' 'F' components of DMF index, with a view to overcome the disadvantages of these systems. The fusion of the three indices resulted in the development of the new Caries Assessment Spectrum and Treatment (CAST) index. It includes the total carious lesion progression from no carious lesion, caries protection (sealant), caries cure(restoration) to carious lesions in enamel and dentin and the advanced stages of carious progression in pulp and tooth-surrounding tissues. It also includes tooth lost due to dental caries[12].

The face and content validity of the CAST instrument was done by the Research and Development (RAND) modified e-Delphi consensus method, with 56 researchers from 24 countries involved in the process[13]. The index has been validated in extensive in vitro and in vivo studies which have proven its high specificity, sensitivity and reliability in epidemiological surveys[14,15]. However the CAST index should be used in independent surveys to be become established as an plausible index.

Materials and Methodology

The study aimed at assessment of dental caries status using Caries Assessment Spectrum Treatment (CAST) index. The study population was patients who visited the Department of Oral Medicine Radiology and Special Care, Saveetha Dental College and Hospital during the month of January,2019. The study included patients between the age group of 25-50 years, while all the third molars, any developmental dental anomalies and those undergoing orthodontic treatment were excluded. 50 patients were randomly selected based on the inclusion and exclusion criteria. The study was conducted after obtaining an informed consent from the patients. The dental evaluation was done according to the CAST codes which covers the entire carious lesion progression. The codes are arranged in a hierarchical manner. The examination was carried out under proper illumination using mouth mirror and a periodontal probe to remove any debris or plaque. If two conditions were present on the same surface, that is superficial lesion in one pit and a deep one in another, the higher score were recorded. A well-structured proforma was developed in order to enable proper documentation of the study, in which score of each tooth was recorded.

Results

The results of the study are tabulated below

Characteristic	Code	Teeth Affected In Number	Teeth Affected In Percentage
Sound	0	1157	82.64%
Sealed	1	0	0

Cont... **The results of the study are tabulated below**

Restored	2	36	2.57%
Enamel	3	19	1.35%
Dentin	4	12	0.85%
	5	18	1.28%
Pulp	6	81	5.78%
Abscess/Fistula	7	13	0.92%
Lost	8	42	3%
Other	9	22	1.57%

From the study we find that 82.64% were caries free, 2.57% had restorations, 1.35% had enamel caries which gives us the information that 86.56 % can be considered healthy. The lesion involving the dentin were 2.13% and pulp were 5.78%, which leads us that about 7.91% are caries affected. The advanced stage of carious lesion which is abscess or fistula were 0.92% and the teeth lost due to dental caries was 3%, by which we can say that about 3.92% were severely affected by dental caries and untreated.

Discussion

Dental Caries continues to be a major public health problem in many developing countries like India. It has engrossed its tentacles deep into the regions where there is lack of public awareness, motivation and devoid resources for dental treatment are present[16,17]. Early detection of incipient caries is essential in modern dentistry to create awareness among the community. Epidemiological studies use DMFT index most often for assessment of dental caries which does not cover the total spectrum of carious lesion progression. Advantage of this index includes simplicity, ease of use, easy to report and can be compared with results in another countries. The limitation of the index is that it does not record the initial white spot lesions, absence of specific codes for recording enamel lesions and deep penetrating lesions[18,19,20].

The modern concepts of caries indices are based on the idea of incorporation of all stages into one tool. CAST differs from other caries indices in a way that its codes are in a hierarchical order of severity of caries process that totally covers the entire spectrum of the caries progression. In CAST system the codes are ranged from 0-9, of which code 0,1,2 represents sound, sealed, restored respectively. Code 3 represents enamel caries 4 and 5 dentinal caries, 6 and 7 pulpal involvement. Dental caries prevalence is considered starting from code 3.A

A study done in Telangana about assessment of caries status among school children according to decayed-missing-filled teeth/decayed-extract-filled teeth index, ICDAS, CAST index concluded that both ICDAS and CAST system quantified the whole spectrum of dental caries precisely[21].

A similar type of study was done using CAST index among the school children visiting the University Dental Hospital Sharjah for routine check-up and treatment as a part of School Dental Program. The pattern of dental caries was assessed using Caries Assessment Spectrum Treatment (CAST) Index. They concluded that CAST is a valuable tool which expresses the severity of caries, clinical progress and outcome of management[22].

Only few studies have been done using CAST index among the populations. The importance of CAST index is prevention and risk assessment. It will enable the health professionals to present the real picture of preventable carious lesions. The studies done using CAST index concluded that it is a promising index for epidemiological studies with complex quantifiability[23-27].

Conlusion

The present study evaluated the prevalence of dental caries using Caries Assessment Spectrum and Treatment (CAST) index among the patients visiting the Department of Oral Medicine, Radiology and Special Care dentistry in Saveetha Dental College and Hospitals. The spectrum of dental caries was predominantly characterized by sound teeth followed by caries involving the pulp chamber. From the study we conclude that CAST index is a hopeful index for epidemiological surveys.

Conflict of Interest: The authors declare there is no conflict of interest

Antibacterial Activity of Silver Nanoparticles Mediated *Aloe vera* with Neem Against Dental Pathogens

Sathvika K[1], S Rajeshkumar[2*], Anitha Roy[2], J Santhoshkumar[3], T Lakshmi [2] Deepa Gurunathan[4]

[1]Undergraduate Student, [2] Associate Professor, Department of Pharmacology, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, Tamil Nadu, India, [3]Researcher, Department of Biotechnology, School of biosciences and technology, VIT, Vellore- 632014, Tamil Nadu, India, [4]Professor, Department of Pediatric and Preventive Dentistry, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, Tamil Nadu, India

Abstract

Background : When left unchecked, dental pathogens cause chronic diseases like periodontitis and dental caries that lead to the irreversible loss of tooth structure. However, with proper prophylactic measures, we can inhibit the excessive proliferation of pathogenic oral flora. The aim of this study was to examine the plausible antibacterial potential of silver nanoparticles synthesized using neem and *Aloe vera* against four dental pathogens - *Streptococcus mutans*, *Staphylococcus aureus* and the *Enterococcus* and *Pseudomonas* species.

Materials and Method: Leaves of *Azadirachta indica* and *Aloe vera* were made into a filtered herbal formulation. A metallic solution of silver nitrate was added to it and the conjunction was kept in an orbital shaker for the synthesis of nanoparticles. After centrifugation, the resultant pellet was powdered. The agar well diffusion method was used to determine the antibacterial efficacy of Ag-NPs. Fresh bacterial suspensions of *Staphylococcus aureus*, *Streptococcus mutans*, the *Enterococcus* and the *Pseudomonas* species were dispersed on the surface of Muller-Hinton agar containing plates. Ag-NP concentrations of (25, 50 & 100) µl were incorporated into the wells and the plates were then incubated at 37°C for 24 hours. Antibiotics were used as a positive control. The zone of inhibition was recorded for each plate.

Results: A colour change was observed after the synthesis of Ag-NPs. The prepared particles were then characterised by a peak seen at 425 nm in UV-vis-spectroscopy. The zone of inhibition increased in size with an increase in Ag-NP concentration. They increased in the order of: *Staphylococcus aureus*, the *Enterococcus* species, *Streptococcus mutans* and the *Pseudomonas* species - with *Staphylococcus aureus* being the smallest and the *Pseudomonas* species being the largest.

Conclusion: Ag-NPs synthesized using neem and *Aloe vera* is an effective antibacterial agent against *Streptococcus mutans* and the *Pseudomonas* species. It is eco-friendly, rapid, easy to synthesize and effective. These Ag-NPs are a non-toxic solution for multiple-drug resistant bacteria.

Introduction

With the growing demand for better products, science encompasses the need for utilizing the benefits of nanotechnology and nanomaterials. Its use allows specific solutions to be tailored based on its modifiable size-dependant physical and chemical properties in various fields. Nanoparticles have been effectively exploited as an industrial catalyst, in functional

nanocomposites, in food packaging, for improving texture, for nutrient delivery, in waste water treatment, as pollutant scavengers, in cancer therapy, to reduce pesticides, in tissue engineering [1] and as fluorescent biological labels [2]. It is also being weighed as a possible solution for neurodegenerative disorders such as Alzheimer's, Parkinson's and others [3].

It is a well-established fact that silver has a relatively low toxicity, thus greatly increasing its potential of being used in medicine and health-care [4]. One amongst its many beneficial properties is its antibacterial efficacy.

Interestingly, it was found that bacteria killed by silver showed significant anti-bacterial activity against a *viable* population of the same bacterium. This is because the killed bacteria act as a reservoir for silver and promotes further bactericidal activity. Thus, it exhibits a desirably long lasting and persistent biocidal effect. This subsequently prevents bacterial re-colonization and proliferation [5].

With the intension of harnessing the benefits of silver, nanoparticles were synthesized using silver nitrate. This was mediated by a herbal formulation of *Azadirachta indica* (Neem) and *Aloe vera*. Although silver nanoparticles can be conventionally synthesized by employing physical and chemical methods, biosynthesis proves to be a better alternative as it does not involve the use of hazardous chemicals and it is simple, high yielding, cost-effective, rapid and non-toxic [6,7]. Biologically synthesized silver nanoparticles also exhibit high stability and solubility [8].

Both Neem and *Aloe vera* have been used for centuries in Ayurvedic, Unani and Siddha medicine [9]. Neem is considered to be the cynosure of modern medicine owing to its vast number of biologically active compounds. Its constituents exhibit anti-inflammatory, antifungal, antiviral, antibacterial, antihyperglycemic, antioxidant and antimalarial properties [10]. *Aloe vera* is frequently used in the fields of dermatology and cosmetology, but controlled trials are needed to confirm its safety and actual efficiency. It promotes wound healing, has antiseptic and anti-inflammatory properties, is a potential laxative and can be used as an anti-aging substance [11].

As of 2015, it was estimated that about 2.3 billion people have dental caries in their permanent teeth [12]. Their occurrence in both children as well as adults is only on the rise as of recent years [13]. It is well-established that the incidence of dental caries only increases with age despite having widespread access to free dental care [14-16]. Also, once the tooth structure is lost, it cannot be regenerated.

Thus, it is important to devise preventive measures against dental pathogens such as *Streptococcus mutans*, *Streptococcus* oralis, *Streptococcus sanguis*, *Streptococcus sobrinus*, the *Pseudomonas* species, *Streptococcus mitis* and also cross-infectious bacteria like *Staphylococcus aureus* [17]. The *Enterococcus* species has also been associated to dental caries, periodontitis, endodontic infections and peri-implantitis [18, 19]. Adopting dental prophylaxis as our objective, we have attempted to synthesize antibacterial nanoparticles from silver nitrate using a herbal formulation of neem and *Aloe vera*, against *Streptococcus mutans*, *Staphylococcus aureus* and the *Enterococcus* and *Pseudomonas* species.

Materials and Method

Preparation of the plant extract

This study was approved by the institutional review board with the number SDC/2018/23 Leaves of *Azadirachta indica* and *Aloe vera* were freshly collected from Chennai in the month of November, 2018 and were thoroughly washed 3-4 times in distilled water. They were then shade-dried for 7-14 days. The well dried leaves were powdered using a mortar and a pestle and was stored in air tight containers. Later, 1 g of the powdered *Azadirachta indica* was dissolved in distilled water and was boiled for 5-10 minutes at (60-70) °C and the same was done using the powdered *Aloe vera*. The two solutions were then filtered using Whatman No. 1 filter papers. Finally, the filtered plant extracts were collected and stored at 4°C for further use.

Synthesis of nanoparticles

1 millimolar of silver nitrate was dissolved in 90 mL of double distilled water. The plant extracts of *A. indica* and *A. vera* were added to this metal solution and was then made into a formulation of 100 mL. Its colour change was visually observed and photographs were taken for systematic recording. The formulation was later kept in a magnetic stirrer/orbital shaker for the synthesis of its nanoparticles.

Characterization of the synthesised silver nanoparticles

Primarily, the synthesis of silver nanoparticles (Ag-

NPs) is characterised by using UV-vis-spectroscopy: 3 mL of the formulation was taken in a cuvette and was scanned in a UV-vis-spectrometer under 300 nm to 700 nm of wavelength. The results were recorded for its graphical analysis.

Preparation of silver nanoparticle powder

The Ag-NP solution was centrifuged in a refrigerated centrifuge (Lark). The centrifugation was done at around 8000 rpm for a duration of 10 minutes and the resultant pellet was collected and washed with distilled water twice. The final pellet was purified and dried at 60°C. In the end, the Ag-NP powder was collected and stored in an air tight tube (Eppendorf tube).

Study of antibacterial activity of Ag-NPs against dental pathogens

The agar well diffusion method was used to determine the antibacterial efficacy of Ag-NPs. Different concentrations of Ag-NPs were tested against *Staphylococcus aureus*, *Streptococcus mutans*, the *Enterococcus* and the *Pseudomonas* species. The fresh bacterial suspension was dispersed on the surface of Muller-Hinton agar containing plates. Ag-NP concentrations of (25, 50 & 100) µl were incorporated into the wells and the plates were then incubated at 37°C for 24 hours. Antibiotics were used as a positive control. The zone of inhibition was recorded for each plate.

Results and Discussion

Visual observation

A colour change was visually observed after the synthesis of nanoparticles. The extract had turned a dark brown from its initial green colour (Figure 1). This colour change from green to dark brown preliminarily confirms the presence of Ag-NPs.

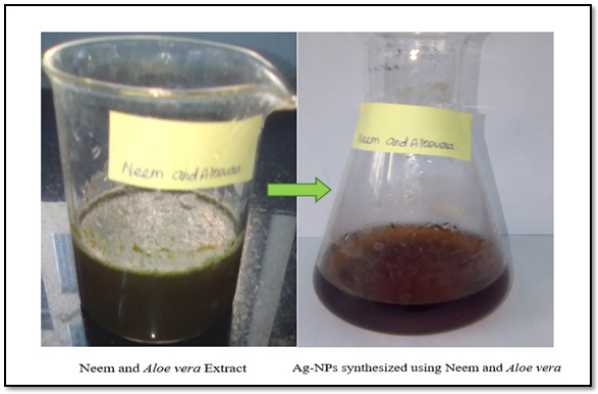

Figure 1: Visual observation

UV-vis spectroscopy

The bio-reduction of pure $AgNO_3$ to Ag-NPs was characterised by using UV-vis-spectroscopy (Figure 2). This was carried out to oversee the formation and stability of the silver nanoparticles. It was done using a UV-vis-spectrometer in the range of 300 – 700 nm of wavelength. The peak was noted at 425 nm.

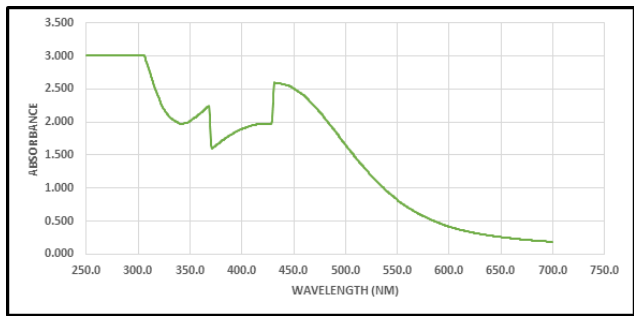

Figure 2: UV-vis spectroscopic analysis

Anti-bacterial activity

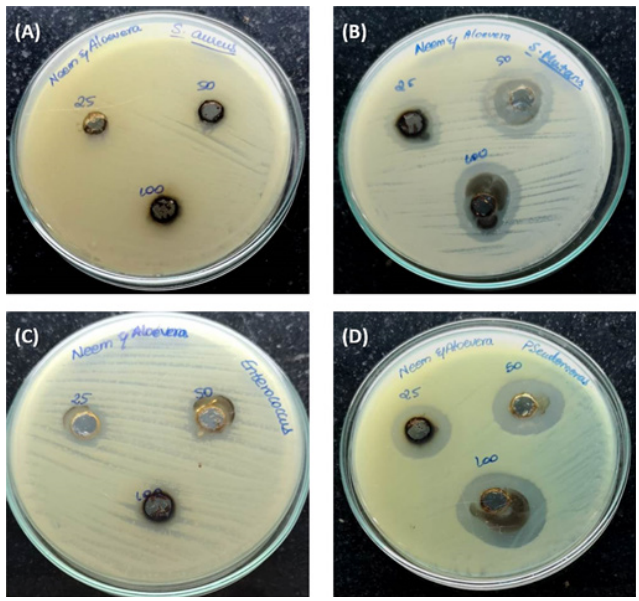

Figure 3: Antibacterial activity of silver nanoparticles: *(A)* *Staphylococcus aureus* - Effect of Ag-NPs on *Staphylococcus aureus* (B) *Streptococcus mutans* - Effect of Ag-NPs on *Streptococcus mutans* with a moderately sized Zone of Inhibition (C) *Enterococcus* species - Effect of Ag-NPs on *Enterococcus* species with its Zone of Inhibition (D) *Pseudomonas* species - Effect of Ag-NPs on *Pseudomonas* species with a highly apparent Zone of Inhibition

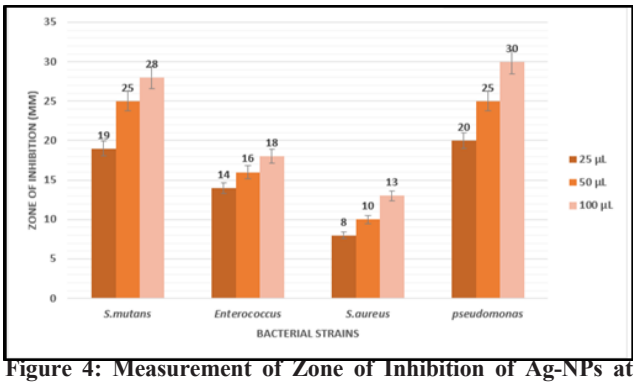

Figure 4: Measurement of Zone of Inhibition of Ag-NPs at different concentrations

As inferred from Figure 3, the zone of inhibition for all four bacterial colonies increase in size with an increase in the concentration of Ag-NPs (Figure 4)

Staphylococcus aureus – A gram-positive, round-shaped bacterium that is very commonly associated with hospital-acquired infections [20]. The colony shows a 13 mm zone of inhibition with 100 µl of Ag-NPs as seen in Figure 4. Out of the four colonies, this has the smallest zone of inhibition, and is thus the least responsive to Ag-NPs (Figure 3A).

Streptococcus mutans – A gram-positive coccus that is commonly found in the oral cavity and is an established cause for dental decay and periodontal diseases [21]. The plate shows a 28 mm zone of inhibition with 100 µl of Ag-NPs as seen in Figure 4. Out of the four colonies, this has the second largest zone of inhibition (Figure 3B). Thus, Ag-NPs have a very good anti-bacterial action against *Streptococcus mutans*.

***Enterococcus* species** – They are gram-positive cocci that often occur in pairs and have been associated to dental caries, periodontitis, endodontic infections and peri-implantitis [18,19]. Here, the colony shows a zone of inhibition of 18 mm with 100 µl of Ag-NPs as seen in Figure 4. Out of the four colonies, this has the third largest zone of inhibition (Figure 3C).

***Pseudomonas* species** – They are rod-shaped gram-negative bacteria. They have an excellent ability to thrive even in harsh conditions due to their tough cell walls which contain porins. They are also resistant to most antibiotics due to the action of multi-drug efflux pumps, which pump out certain antibiotics before they can act on the bacterium. Here, the colony shows a zone of inhibition of 30 mm with 100 µl of Ag-NPs as seen in Figure 4. Out of the four colonies, this has the largest and most prominent zone of inhibition (Figure 3D). Thus, Ag-NPs have an excellent anti-bacterial action against the *Pseudomonas* species.

From the above results, it is clear that Ag-NPs synthesized using Neem and *Aloe vera* have a good bactericidal effect on the *Pseudomonas* species and *Streptococcus mutans* when compared to the *Enterococcus* species and *Staphylococcus aureus*.

Since the Pseudomonas species was the only gram-negative bacteria amongst the four bacterial colonies, a conclusion cannot be drawn regarding whether silver nanoparticles are more effective against gram-positive or gram-negative bacteria.

Due to the complex mode of action of Ag-NPs, it is difficult for pathogens to build effective resistance against silver [22]. Thus, it can also be used as an anti-bacterial agent against bacteria that show multiple-drug resistance.

Conclusion

Through the results of our study we have concluded that silver nanoparticles synthesized using neem and *Aloe vera* possess an evident antibacterial efficacy against dental pathogens, especially against the *Pseudomonas* species and *Streptococcus mutans*. It is eco-friendly, rapid, easy to synthesize and effective against bacteria that show multiple-drug resistance. Thus, Ag-NPs could possibly be used as a non-toxic alternative for conventional antibiotics.

Awareness, Knowledge, Attitude and Practices of E-Cigarettes among Undergraduate Dental Students

Savitha P[1], P. Jayashri[2]

[1]*Graduate Student,* [2]*Senior lecturer, Department of Public Health Dentistry, Saveetha Dental College, Saveetha University, Saveetha Institute of Medical and Technical Science, Chennai, Tamil Nadu*

Abstract

Background: The electronic cigarette (e-cigarette), first developed in China in 2003, is a battery-powered nicotine delivery device that provides inhaled doses of vaporized nicotine solution and is designed to look and feel like a traditional cigarette.Electronic cigarettes have garnered much attention among the public in recent years due to rising sales and contentious harm-reduction debates.

Aim: The study aims at assessing the awareness, knowledge, attitude and practices of E-cigarettes among undergraduate dental students.

Materials and Method : A cross sectional study was conducted amongundergraduate dental students in Chennai. Following convenience non-randomized sampling of 150 dental students were selected. A self administrated questionnaire was distributed and descriptive data in terms of frequency and percentage were analysed using SPSS software.

Results: Dental students who received questionnaire were returned the completely filled forms. Of these 75 (50%) were males and 75 (50%) were females. The age group of the study subjects ranged from 18-23 years with majority of study subjects in 22-24 years. The awareness about E-cigarettes among study subjects were yes (73.3%), No (22.7%). The study subjects perception about composition of e-cigarettes were nicotine (16.7%), diethyl glycol/propyl (10.7%), glycerol (3.3%), all of the above (38%), unaware (31.3%).Out of 150 study subjects, 64% of subjects mentioned that e-cigarettes help to quit smoking where as No (10%), unaware (26%).

Conclusion: It can be concluded that majority of the dental students were well aware of e-cigarettes, but most of them lack the knowledge on composition of e-liquid, working mechanism, health related risk and also lack in attitudes of the dental students towards e-cigarettes.

Introduction

Smoking is responsible for 100 million deaths world-wide [1]. A large number of oral diseases and conditions such as staining of teeth and restorations, halitosis, impaired wound healing, periodontal diseases, failure of implants and surgical treatments, acute necrotising ulcerative gingivitis and life-threatening precancerous and cancerous lesions are attributed to smoking[2,3,4,5]. There are long lists of known risks of smoking cigarettes. Cigarette smoke contains over 4000 chemicals, many of which are serious carcinogens like arsenic or volatile organic compounds. These compounds cause serious cardiovascular and respiratory disease, including lung cancer, currently leading to the death of one out of every 10 adults worldwide[6,7]. These health risks have

Corresponding author:

Email id:-shrijaya2009@gmail.com

led to the development of materials that may assist people in smoking cessation, one of which is electronic cigarettes.E cigarettes have existed for a long period of time, as they were first patented in 1965 by HA Gilbert as a device that looked like a conventional cigarette but did not contain the carcinogens of tobacco, designed to replace the use of Conventional cigarettes. The idea of the EC did not gain momentum until a second patent of the modern EC was taken out by H Lik in 2003 [6,7,8].

Electronic cigarettes are the devices that are used recreationally or as smoking cessation tools, and have become increasingly popular in recent years. Electronic cigarettes are battery-operated products that can deliver a nicotine- containing aerosol, mistakenly termed by many as 'vapour,' to users by heating a chemical concoction known as the e-liquid (composed of propylene glycol and/or glycerol, varying levels of nicotine, and flavouring agents)[9]. Unlike conventional cigarettes, these products do not contain tobacco nor produce combustion products such as smoke and tar[10].

E-cigarettes are manufactured to mimic the sensory feeling of using a conventional cigarette. A user generally presses a switch to initiate a heating process of the e-liquid solution and inhales from a mouthpiece the aerosol produced, which is visible as fine mist or vapour.E-cigarettes have continued to evolve ever since they first penetrated the market, a prototypical product has the following basic parts: a cartridge, which contains the e-liquid; a battery, which provides the power to heat and aerosolize the e- liquid; the heating elements (atomiser, heating coil, and wick), which produce the aerosol; and a light which is used as an indicator [11]. Nowadays, a wide variety of e-cigarette brands is easily accessible in retail and online shops [12].

Electronic cigarettes have surged in popularity with an increase in awareness of product, rise in Internet search queries and growth in sales. The major contributor to the enormous sales of these products is the frequent use of the marketing claims. These include: e-cigarettes are healthier and cleaner than conventional cigarettes; e-cigarettes are smoking cessation aids; and the aerosols emitted are safe for people who are exposed, among others.[9].The youth are of particular concern with regard to the rising popularity for E-cigarettes. The battery, on the other hand, can allow the user to heat the e-liquid at higher voltages, hence producing more aerosol. The variations in battery output voltage and unit circuitry have been found contribute to the formation of toxicants in the aerosol emitted[13].

The amount of nicotine present in the e-liquid is chose by users depending on their wish to use. Nicotine is usually offered by stores at concentrations from 0 to 18 milligrams per millilitre (mg/mL), though some may reach levels as high as 20, 24, or 36 mg/mL.A typical conventional cigarette contains 1 milligram nicotine, and a puff from an e-cigarette usually yields 0-35 micrograms of the drug [14]. Therefore, it should take around 30 puffs to achieve the same amount of nicotine contained in a conventional cigarette. By designing the E cigarettes to appear and work like a conventional cigarettes, the ergonomics appeal to the psychological aspect ofaddiction to smoking. In addition, the optional nicotine content satisfies the physiological aspect of smoking addiction. These factors make it more likely that people will give up smoking for this "safer" device. However, the question remains as to how much safer electronic cigarettes are than conventional cigarettes , if at all[15].

The concentrations of nicotine in these products can put people at risk for accidental overdose. Nicotine has both muscarinic (salivation, vomiting, diarrhoea, and bronchial constriction) and nicotinic (fasciculations, hypertension, tachycardia, and muscle cramps) effects. Treatment of these toxic effects is largely supportive. Exposure to the primary ingredient of the e-liquid, propylene glycol, is generally considered safe, but this chemical can cause irritation to the upper and lower respiratory tract. When heated, it produces acetaldehyde and formaldehyde which are both toxic [16].

Materials and Method

Study design: A cross sectional survey.

Study area: Saveetha dental college, Chennai.

Study population:A list of 100 dental students were selected for this questionnaire study using convenience non- randomized sampling. A self administrated questionnaire was distributed to the selected number of dental students.

Eligibility Criteria:

Inclusion criteria

- Dental students who were willing to participate were included in this study

- Undergraduate second, third, fourth year and interns were included in this study

Exclusion criteria

- Dental students who were not willing to participate were excluded from this study.
- Undergraduate first year students were not included in this study.

Ethical clearance:

- Prior to the start of the study ethical clearance was obtained from institutional ethics committee, Saveetha University.
- Verbal/oral consent was obtained from the study participants.
- The anonymity of the participants was maintained.

Scheduling:

- Data collection was scheduled in the month of January 2018

Sample size:

N= 150 (95% power @ 5% alpha)

Sampling:

- A list of dental students who willing to participate was obtained. Following conveniencenon-randomized sampling of 150 dental students were selected.

Survey instrument:

A pre tested, structured and self administrated questionnaire was adapted. The survey tool consisted of several parts. The first section collected demographic information of the participants such as age, gender and year of study.

The second part of questionnaire consisted of questions to assess the participant's level of knowledge, awareness and attitude towards the electronic cigarettes among study participants. An opportunity was given in the questionnaire to openly specify the answers for a question regarding socio economic status plays in using e cigarettes.

Participants knowledge was gathered about aware, different kinds of E cigarettes available at markets, composition, smoking quitting aids, functions, effects on health, side effects etc. One of the factors that is responsible for someone attitude and behavior is knowledge. Knowledge can be described as level of understanding of an individual towards facts, information, skills and many more.

Survey methodology:

After a brief introduction on the purpose and intent of the study, the questionnaire were distributed to the dentists and filled questionnaire were collected. Only filled forms were considered for analysis.

Statistical analysis:

- Data collected was entered in Microsoft Excel spreadsheet and descriptive data in terms of frequency and percentage were analysed using SPSS software (version 17.0).

Results

Dental students who received questionnaire were returned the completely filled forms. Of these 75 (50%) were males and 75 (50%) were females. The age group of the study subjects ranged from 18-23 years with majority of study subjects in 22-24 years (refer to table 1).

The awareness about E-cigarettes among study subjects were yes (77.3%), No (22.7%) (refer to figure 1). The study subjects who aware of e-cigarettes were came across friends (33.6%), internet (63%), mass media (3.4%). Table 2 shows study subjects perception about composition of e-liquid in 3-cigarettes were nicotine (16.7%), diethyl glycol/propyl (10.7%), glycerol (3.3%), all of the above (38%), unaware (31.3%). Out of 150 study subjects, 64% of subjects mentioned that e-cigarettes help to quit smoking where as No (10%), unaware (26%) (refer to figure 2).

Table 3 shows the study subjects perception about e-cigarettes function were product that delivers a nicotine containing aerosol (49.3%), product that delivers nicotine as smoke (8.7%), does not delivers nicotine (3.3%) and unaware (26%). 82.6% of study subjects thinks that nicotine use could lead to cancer where as No (2%) and unaware (15.3%) (refer to figure 4). Out of 150 study subjects, 71.3% of them thinks e-cigarettes were almost less harmful to health when comparing to conventional

cigarettes whereas disagree (6%) and unaware (22.7%) (refer to figure 3).

Out of 150 study subjects, 40% of subjects thinks e-cigarettes have side effects only on oral cavity whereas disagree (34.7%) and unaware (25.3%). 74.7% of study subjects thinks socio economic status plays an important role in using e-cigarettes and No (25.3%). Most of them mentioned that e-cigarettes were costly, low economic status people unawareness about e-cigarettes and they might think it is harmful to use electronic products for smoking.

Table 1 : Distribution of study subjects according to age and gender

Age group (in years)	Gender				Total	
	Male		Female			
	n	%	n	%	N	%
18-20	16	23.8	24	28.9	40	26.7
21-22	23	34.3	28	33.7	51	34
23-24	28	41.8	31	37.3	59	39.3
Total	67	100	83	100	150	100

Table 2: Dental students perception about the composition of e-liquid in e-cigarettes.

Composition	Percentage (%)
Nicotine	16.7
Diethyl glycol/propyl	10.7
Glycerol	3.3
All of the above	38
Unaware	31.3

Table 3: Dental students knowledge on working mechanism of e-cigarettes

Mechanism	Percentage (%)
Product that delivers nicotine aerosol	49.3
Product that delivers nicotine as smoke	8.7
Does not deliver nicotine	3.3
Unaware	26

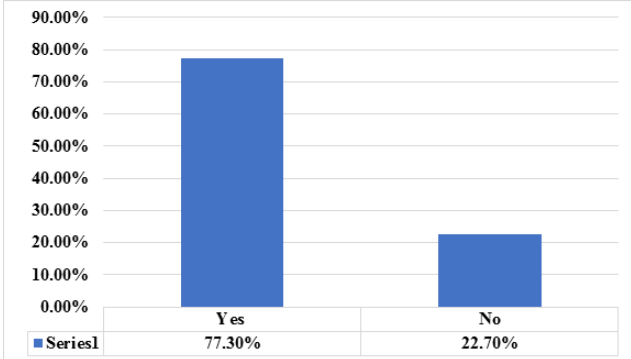

Figure 1: Awareness about E-cigarettes among dental students

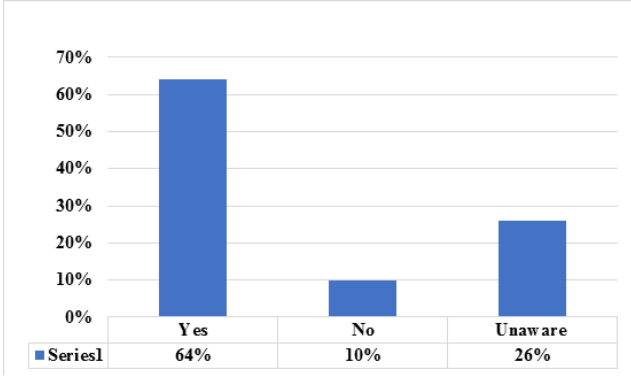

Figure 2: Dental students attitude on E-cigarettes help in smoking cessation

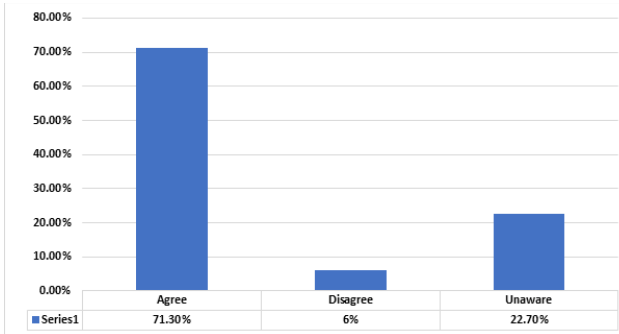

Figure 3: Dental students knowledge on E-cigarettes are less harmful than conventional cigarettes

Discussion

In this study 73.3% of the study subjects were aware of e-cigarettes. Most of all the students reported that they had heard about e- cigarettes, indicating a high level of awareness. Similarly, in other study conducted in Malaysia found that95% of respondents were aware of e-cigarette[17].73.3% of study subjects who were aware of E-cigarettes where got knowledge about e-cigarettes through friends(33.6%), internet (62.9) and mass media (3.4). 51.3% of the study subjects were aware of the different kinds of e-cigarettes available at market.

The surveyed study subjects were requested to indicate which of the following components present in e-liquid, 38% had given accurate answer regarding composition, whereas 31.3% were unaware of the composition of e-liquid of e-cigarettes. This shows that the study subjects who were aware of composition were more or less equal to the study subjects who does not know about composition of e-liquid.

The study subjects response for smoking cessation were 64% students agreed that e-cigarettes help in quitting smoking whereas 10% disagreed and 26% unaware of the condition that e-cigarettes help in smoking cessation. These results when compared with Awan KH 2016[18], more than two-thirds of the students reported that e- cigarettes could aid smoking cessation. Out of 150 study subjects, 49.3% were aware of the working mechanism of e-cigarettes where as 50.6% were unaware of the mechanism.

Results of the present study indicate that 71.3% of the respondents reported that e-cigarettes were less harmful to health when comparing to conventional or traditional cigarettes whereas 6% disagreed and 22.7% unaware. These results when compared with Awan KH 2016 [18], More than half of the students who were aware of e-cigarettes believed that e-cigarettes are less dangerous than traditional cigarettes, with the highest percentage (63.3%). In other studies such as Sutfin EL et al 2013[19], 17% agreed that e-cigarettes as harmful as conventional cigarettes. Ambrose BK et al 2014 [20], 30.6% agreed that e-cigarettes were less harmful than traditional or conventional cigarettes.Gallus S et al 2014 [21], 65% believe that e- cigarettes are less harmful than traditional cigarettes.

Conclusion

Based on the findings of the present study, it can be concluded that majority of the dental students were well aware of e-cigarettes, but most of them lack the knowledge on composition of e-liquid, working mechanism, health related risk and also lack in attitudes of the dental students towards e-cigarettes.

Conflict of Interest: Nil

Ethical Clearance: Ethical clearance was obtained from the institutional Ethics Committee, Saveetha University

Can Probiotics Prevents Dental Caries -A Review

Suvitha Suresh[1], P. Jayashri[2]

[1]Graduate Student, [2]Senior Lecturer, Department of Public Health Dentistry, Saveetha Dental College, Saveetha University, Saveetha Institute of Medical and Technical Science, Chennai, Tamil Nadu

Abstract

In recent years, bacteria known as probiotics have been added to various foods because of their beneficial effects for human health. However, the main field of research has been in the gastrointestinal tract.But, in the past few years probiotics have also been investigated in the oral health perspectives.The mechanism of action of probiotics is related to their ability to compete with pathogenic microorganisms for adhesion sites, to antagonize these pathogens or to modulate the host's immune response. The potential application of probiotics for oral health has recently attracted the attention of several teams of researchers. Although only a few clinical studies have been conducted so far, the results to date suggest that probiotics could be useful in preventing and treating oral infections, including dental caries, periodontal disease and halitosis. This review article summarizes themechanism of action and currently available data on the potential benefits of probiotics for oral health.

Keywords: *probiotics, lactobacillus species, dental caries, streptococcus mutans.*

Introduction

The role of diet in well-being and overall health is universally acknowledged. With the evolution of the science of nutrition, research is now directed towards improving the understanding of specific physiologic effects of the diet beyond its nutritional effect. Bulgarians lived longer with healthy, pain free and disease free lives, Dr.Metnikofftook a notice of this and wondered what would be the reason? Then in early 1900's he stated that their diet consisted of yogurt, sour dough, bread and butter milk. He paved way for probiotics by discovering that fermented foods contained beneficial bacteria which are cable of digesting putrescence foods and releasing by products that are nutritious and distroythe foul odors in the human body[1].He worked at the Pasteur Institute in Paris and had discovered Lactobacillus bulgaricus, a strain and introduced them into commercial production of sour milk products in European countries[2]. He provided his last few years of life for the study of Lactic acid producing bacteria as a means of increasing human longevity.In this aspect, probiotics are the subject of intense and widespread research in food and nutritional science[3].

The term probiotic, is derived from the Greek language, meaning "for life". Probiotics was first used by Lilly and Stillwell in 1965 were the first person to described probiotics as "substances secreted by one microorganism which stimulates the growth of another" and they coined the term antibioticfor probiotics. It can be defined as living microbes, or as food ingredients containing living microbes, that beneficially influence the health of the host when used in adequate numbers. As adopted by the International Scientific Association for probiotics and prebiotics, "Live microorganisms, which when administered in adequate amounts, confer beneficial effect on the health of the host[4].

The human gut contains 10 times more bacteria than cells elsewhere in the human body. Studies says that there are numerous microflora consists of 400 known bacterial species that are responsible for metabolic activity and are important for human health[5]. Those friendly bacteria which fight against the pathogens from causing disease were termed Probiotics. This ecosystem

gets disrupted when exposed to toxics in the form of polluted water and food as well as injudicious use of antibiotics. Antibiotic resistance, with the emergence of multiple resistant strains, is an increasingly important global problem. This causes destruction of beneficial bacteria, leaving resistant ones, pathogenic[6].

Of late, it has been realized by health care professionals and prompted them to seek alternative therapeutic options. Use of beneficial bacteria was found to be an alternative nutritional therapy, the probiotics, which stimulate health– promoting indigenous flora and reverting back the change[7].“Viable microbial food supplements which beneficially influence the health of human.” Which was widely accepted definition of Guarner et al[8]. These bacteria must belong to the natural flora of body in order to resist gastric secretion and survive during intestinal transit. They must adhere to the intestinal mucosa and must have the ability to inhibit pathogens present in gut[9-11].The important source of probiotics is the bacteria in yogourt and fermented milk products.Such major probiotics which belong to the genera Lactobacillus, streptococcus,Bifidobacterium and Propionibacterium. Many clinical studies have already put froth the significant use of certain probiotics in the treatment of systemic and infectious diseases such as acute diarrhea and Crohn disease.Some other studies have shown importance of probiotic applications in the treatment of cardiovascular disease, urogenital infections, oro-pharyngeal infections and cancers[12-14]. This Review article emphasizes on role of probiotics in preventing dental caries and periodontal diseases.

Prebiotics, synbiotics

Gibson and Roberfroidcoined the term ‘prebiotic’,known as a non digestible food ingredient that gives benefits to host by stimulating growth of selective beneficial bacteria or a group of bacteria for human health[15].prebiotic are diatary carbohydrates such as oligosaccharides of glucose and fructose, and inulin. They are indigestable substance which escapes digestion in upper gastrointestinal tract and enters the gut for altering the bacterial composition along with existing microbial population of the gut.

When a bacterial stains contains both probiotics and prebiotic are termed as synbiotic. This term came in to application for the product in which the prebiotic compound selectively favors the probiotic compound[16].

Dental caries formation

Keyes stated,there are three prerequisites for dental caries development, they are tooth, plaque and food substrate [17]. According to tooth the caries development varies for each tooth depending upon its morphology, varying organic and inorganic composition, position and location which will eventually leads to plaque retention. Caries does not develop with out the bacteria and food substrate. The bacteria requires acidogenicenvironment for destruction of mineralized enamel. Of this bacterial species streptococcus mutants, a gram positive acidophillic bacteria associated with initiation of dental caries. They ferment the food substrate that is dietary saccharides along with production of lactic acid which in turn *s.*mutans produces glycosyltranferaseactivity to extra cellular glucans that will attach to enamel. Colonization of bacteria occurs in smooth surface of enamel and causing demineralization of hydroxyapatite crystals. In the absence of sugar foods S.mutansproduces intracellular polysaccharide that gives acidic end products. Microbes such as lactobacillus which are non adhesive bacteria produces different type of acids that contribute to caries progression once the initial demineralization has caused by S.mutans , once a notch is created lactobacillus increases the time of progression of dental caries.Caries does not occurs in a single day, it takes time to progress depending upon the modifying factors like quantity and quality of saliva, time taken by bacteria to access the substrate at the plaque enamel interface,use of protective factors like fluorides, variations in food substrate depending on the availablity and location of residencies.

Enamel, dentin and cementumconsists of an inorganic component (approximately 86%-45% respectively) and an organic component (approximately 4%-30% respectively) remaining are water.Dental plaque and oral fluids contains calcium and phosphate ions, these ions maintain the PH of oral environment. These minerals maintain the oral environment saturated , under or supersaturated. Demineralization occurs when environment is undersaturated, remineralization occurs when it is supersaturated. Critical PH for tooth destruction varies from 5.0-5.7 , while optimal PH is 7, this optimal PH tent to decrease immediately after consumption of fermentable substrate just below the critical value. This fall in PH will be counteracted by the buffering effect of saliva and it will bring mineral ions to the oral environment. Hence addition of minerals is always beneficial by increasing the degree of saturation.

Saliva plays an important role in prevention of dental caries, saliva containing n number of microbes including lactobacillus species which are non adherents to tooth and mucosa, hence this proves that saliva containing lactobacillus and probiotic containing lactobacillus species helps in preventing dental caries formation. We must realise that any induced changes in the oral environment will be counteracted by the oral hemoeostasis[18].

Mechanism of probiotics

Probiotics act as an antagonist to some pathogens through the production of antimicrobial substances like organic acid, hydrogen peroxide's and bacteriocins[19]. They mainly works on gastrointestinal tract by modifying PH level of the gut or regulation of oxidation-reduction changes in the gut, they fight against pathogen by competing for receptor site in mucosa for nutrition and growth factors, stimulate immunological cells that is non specificimmunity, modulate humoral and cellular immune responseand their by produces lactase, and modifies immune system through several molecular mechanisms[20].

In oral environment probiotics shows almost the same mechanism of action as in gastrointestinal tract. They involve in production of antimicrobial substances like organic acids, hydrogen peroxide and bacteriocins, binding to the oral cavity there by competes with pathogens for receptor site. They metabolize the substrates for available nutrition, also act as immuno modulator, stimulate non specific immunity, modulates humoral and cellular immune response, modifying oral environment by modificationof oxidation reduction potential and PH level of saliva[21].

Probiotics modification

Dental caries consists of increasing number of acidogenic and acid tolerating species, such as streptococcus mutans, lactobacillus species ,bifidobacteria, non mutant streptococci, actinomycetes species , propionibacterium species, veillonella species and Atopobium species so on. Probiotic contains several beneficial microbes that act against those microbes present in dental caries.

Studies have shown different methods to reduce cariogenic bacteria, earlier studies used bacteriocin expressing bacteria or bacteriocin like inhibitory substances (BLIS) that mainly prevents the growth of cariogenic bacteria.Other motheds are selecting suitable antagonist against relevent bacteria, also selecting probiotics bacteria and food substrate that colonaise on surface of teeth causing supragingival plaque.Using a recombinant strain of S.mutans expressing urease, shows a promising results in reduction of cariogenicity of plaque in an animal. This method of genetically modified probiotics with effective properties against bacteria was called as designer probiotics. One of the important recombinant method that is a recombinant strain of lactobacillus that expresses antibodies which target the major receptor of S.mutans that enable to reduce both the count of S.mutansand dental caries score in an animal[22].

Probiotics in food products

There are numerous organisms that can be classified as probiotics. Genera of lactobacillus and bifidobacterium are the most common probiotic strains. There are several probiotic strains that belongs to lactobacillus species, includes L.acidophilus, L.casei, L.johansonii, L.rhamnosus, L.gasseri, and L.reuteri. And the Bifidobacterium genera includes B.bifidum, B.longum andB.infantis.

Products that contains probiotics are

- Food beverages (fruit juices)
- Prebiotic fibres
- Inoculated in dairy products such as milk, yogurt, and milk containing drinks
- Non dairy products (dietary supplements, dried cells packaged)

Probiotics are administered for oral health by different means of vehicles such as lozenges, straw, tablets, yoghurt, cheese, rinse solution, capsule, liquid and yogurt drink[23].

Recently , a probiotic mouthwash product containing three naturally presenting species of oral streptococcus strains, S. oralis KJ3sm, S.uberis KJ2sm and S.rattus JH145, that afffects the dental caries pathogens S.mutants in saliva and periodontal pathogens P.gingivalisandcampylobacter rectus in subgingival plaque[24].

Action of probiotics in dental caries

Probiotics works in three main steps, attachment,

adhesion and oral colonization[25]. Adhesion of probiotics to oral surfaces is an important issue for the prolonged effect of the microorganisms. There are several adhesion mechanisms, adhesion systems using saliva-coated hydroxyapatite, and hydroxyapatite coated with buffers, proteinsare the important two methodof adhesion.Lactobacillus are most commonly used strains found in oral cavity, this was first used in research in the year 1984 by hull and his coworkers. Caries risk was reduced by producing a growth inhibitory substance against Streptococcus sobrinuswith help of probiotics called lactobacillus rhamnosus GG, ATCC [26].This was isolated from human intestinal flora and was given with the names of its discoverers, Sherwood Gorbach and Barry Goldin. Streptococcus salivarius strains was found to be excellent member of oral probiotics, as they are the important member of tongue micro biota of healthy persons and they colonies early in the oral surfaces[27]. The abundant strains of oral lactobacilli shows inhibitory effects against S.mutans, Aggregatibacteractinomycetemcomitans, Porphyromonasgingivalis and Prevotellaintermedia,and also they have capacity to tolerate environment side effects [28].

Action of probiotics in periodontal diseases

Probiotics has a capacity to alter the salivary pellicle. Formation of salivary pellicle is the first step in plaque formation which eventually leads to periodontitis. Orally administered probiotics can also benefits chronic periodontitis. Periodontal pathogens are recognized by antagonistic interactions. Studies shows decreased rate of bleeding gums and reduction in gingivitis with the help of L.reuteri[29].

Conclusion

The oral cavity with a well-maintained balance of species and species interactions may be a potential source for health-promoting probiotic bacteria. Probiotics play an important role in combating issues with overuse of antibiotics and antimicrobial resistance. Further studies are required to understand the ability of probiotic bacteria to survive, grow, and have a therapeutic effect when used for treatment or when added to foods, to fix the doses and schedules of administration of probiotics. Hence, randomized controlled trials and systematic studies are needed to find out the best probiotic strains and means of their administration in different oral health conditions and oral health promotion. With fast evolving technology and integration of biophysics with molecular biology, designer probiotics pose huge opportunity to treat diseases in a natural and non-invasive way.

Abstract

Burkitt's lymphoma is a highly aggressive B-cell non-Hodgkin lymphoma and is the fastest growing human tumour. The disease is associated with Epstein-Barr virus and was one of the first tumours shown to have a chromosomal translocation that activates an oncogene (c-MYC). Burkitt's lymphoma is the most common childhood cancer in areas where malaria is holoendemic. The incidence is very high in immunosuppressed patients in non-endemic areas, especially when associated with HIV infection. Outcome with intensive chemotherapy has improved and is now excellent in children, but the prognosis is poor in elderly adults. The success of intensive treatment relies on good supportive care. The therapy offered in oncology units in low-income countries is not as aggressive as in centres in high-income countries and outcomes are less successful. Adjuvant monoclonal antibody therapy with rituximab shows promise for improved outcomes and reduced toxic effects in the future.

Key Words: *Burkitt's lymphoma, Malaria, Histopathology, Prognostic Markers, Tumours*

Introduction

Burkitt's lymphoma has had an important role in the understanding of tumorigenesis. It was the first human tumour to be associated with a virus [1] one of the first tumours shown to have a chromosomal translocation that activates an oncogene [2, 3] and the first lymphoma reported to be associated with HIV infection [4]. Burkitt's lymphoma is the fastest growing human tumour, with a cell doubling time of 24–48 h, and was the first childhood tumour to respond to chemotherapy alone [5]. It is the most common childhood cancer in areas where malaria is holoendemic eg: equatorial Africa, Brazil, and Papua New Guinea. The so-called Burkitt's lymphoma belt stretches across central Africa 15° either side of the equator where the climate is hot and wet (more than 50 cm annual rainfall). The epidemiological maps of malaria and Burkitt's lymphoma overlap [5–7].

Early in the 20th century, Sir Albert Cook, a missionary doctor in Uganda, and other medical staff working in west, east, and central Africa noted the high frequency of jaw tumours and childhood lymphomas [8–10]. In 1958, Denis Burkitt, an Irish surgeon working in Uganda, reported cases of children presenting with rapidly growing jaw or abdominal tumours [11]. Burkitt suggested that these tumours were round-cell sarcoma. However, in 1960 George O'Connor, a pathologist, concluded that the cancer was of lymphoma lineage [12]. Meanwhile, Burkitt travelled through eastern and central Africa to map the tumour spread and found records of affected children in all the malarial areas of the region [13].

Epidemiology

The distribution of endemic Burkitt's lymphoma across Africa and Papua New Guinea corresponds to areas of holoendemic malaria and the early acquisition of EBV [13, 14–20]. The annual incidence has been estimated at 40–50 per million children younger than 18 years [21]. In these high-risk areas endemic Burkitt's lymphoma comprises about half of all childhood cancer diagnoses

and up to 90% of lymphoma diagnoses. Incidence peaks at age 6 years and the disease is twice as common in boys as in girls. Sporadic Burkitt's lymphoma occurs most commonly in children aged 3–12 years (median 6–8 years) and is 3·5 times more common in boys than in girls [22,23].

Immunodeficiency-associated Burkitt's lymphoma occurs at an incidence of 22 per 100 000 person-years in the USA [24].

Cofactors

Epstein-Barr virus

Several observations suggest a direct causative role for EBV in endemic Burkitt's lymphoma. For example, EBV is consistently present in these tumours; [25] infection of malignant B cells precedes tumorigenesis; [26] EBV induces immortalisation of B cells in culture; and very high EBV antibody titres are recorded in children before development of the disease [27]. However, the underlying mechanism linking EBV infection of B cells to the emergence of malignancy remains undiscovered.

Malaria

In Africa, pronounced seasonal, temporal, and spatial variations in the incidence of Burkitt's lymphoma have long been linked to the prevalence of malaria,[28,29] and in 2008, direct evidence of a link between malaria, EBV, and endemic Burkitt's lymphoma emerged [30,31]. Two epidemiological studies showed that the risk of Burkitt's lymphoma was greatest in people with the highest titres of antibodies against both EBV and Plasmodium falciparum[32].

HIV infection

Burkitt's lymphoma occurs in HIV-infected patients with high CD4 T-cell numbers, which suggests that immunosuppression is not in itself the cause of the malignancy. HIV-infected patients with Burkitt's lymphoma have high serum concentrations of soluble CD30 and CD23— markers of B-cell activation—before emergence of lymphoma [33–35]. Patients with chronic HIV viraemia, even if on antiretroviral therapy, have a higher risk of developing HIV-associated lymphomas than those with un measureable viral loads [36, 37]. The enzyme has been detected in peripheral lymphocytes in HIV-infected patients with lymphoma, but not in HIV-positive patients without the malignancy, nor in healthy controls [38].

Other Possible Cofactors

Arboviruses and schistosome parasites have both been suggested as causative cofactors of endemic Burkitt's lymphoma, although evidence is sparse. The plants Euphorbiae tirucalli and Jatropha curcas are common in areas where the endemic type of the disease occurs. The milky sap of these plants contains dipterene esters that can activate latent EBV and induce rearrangements of chromosomes in about 10% of exposed EBV-infected B cells [39-41].

Clinical Presentation

Patients with endemic Burkitt's lymphoma most frequently present with jaw or periorbital swelling, or abdominal involvement (of retroperitoneal tissue, gut, ovary, or kidney) [42]. 15% present with sudden paraplegia and incontinence. Infiltration of bone marrow is rare. Jaw involvement is common in young children (peak ages of incidence 3–7 years) [43].

Histopathology and Immunocytochemistry

The cells are always of B-cell lineage (CD20 positive and CD79a positive). CD10 and Bcl-6 are commonly coexpressed, but the cells are generally negative for Bcl-2. There is a scarcity of T cells in the background [44]. Epstein-Barr-encoded RNA can be identified by fluorescence in-situ hybridisation. Classification is difficult when the cells have the morphology of diffuse large B-cell lymphoma but the genetic and immunophenotypic features of Burkitt's lymphoma. Some of these cases are now classified as "B-cell lymphoma, unclassifiable, with features between diffuse large B-cell lymphoma and BL [Burkitt's lymphoma]" [45]. However, distinct molecular changes in Burkitt's lymphoma could provide a more reliable diagnosis.

Diagnosis

High-Income Countries

Diagnosis of Burkitt's lymphoma should be confirmed by microscopy and immunocytological analysis. The recommended approach is to remove and examine the most accessible disease-containing tissue. This sample could be a superficial lymph node or malignant pleural fluid. Excision biopsy of a lymph node is preferable to fine-needle aspiration, which does not provide sufficient tissue for all the investigations required. In some cases a laparotomy or laparoscopy is necessary to obtain tissue.

The radiograph should be done before any anaesthetic is given, to look for mediastinal lymph nodes with or without pleural effusions. After confirmation of the diagnosis, bilateral bone-marrow aspirates, trephine cores, and cerebrospinal fluid should be examined for the presence of malignant cells [46].

Management

High-Income Countries

Treatment of Burkitt's lymphoma in most centres is guided by the FAB LMB study (cooperative study between the Children's Cancer Group and the UK Children's Cancer Study Group) [47,48] or Berlin–Frankfurt–Munster protocols.

Management of Burkitt's lymphoma can be divided into three broad groups of patients. Children with localised disease that has been completely removed surgically need only two cycles of moderately intensive chemotherapy such as cyclophosphamide, vincristine, prednisolone, and doxorubicin. Children with residual or stage III disease need at least four cycles of dose-intensive chemotherapy, such as two cycles of cyclophosphamide, vincristine, prednisolone, doxorubicin, and high-dose methotrexate, followed by two cycles of cytarabine and high-dose methotrexate with concurrent intrathecal treatment. Children with CNS or bone-marrow involvement are given similar treatment to the second group, but receive up to eight courses of dose-intensive treatment. This therapy typically involves two courses of cyclophosphamide, vincristine, prednisolone, doxorubicin, and high-dose methotrexate followed by two courses of high and low doses of cytarabine, and etoposide) and four courses of maintenance with varying combinations of vincristine, prednisolone, high-dose methotrexate, cyclophosphamide, doxorubicin, cytarabine, and etoposide. Intrathecal therapy is given alongside systemic chemotherapy.

The use of rituximab (anti-CD20) in primary therapy has been assessed, and some small single-centre studies report encouraging results. [49]. Data are awaited from a Children's Oncology Group pilot study on toxic effects (ANHL01P1) in which rituximab was given to patients with stage III and IV Burkitt's lymphoma. The next UK trial will randomise the use of rituximab for stage III and IV patients.

Low-Income Countries

Therapy needs to be modified in accordance with local conditions to avoid unacceptable treatment-related mortality. The intensity of treatment is determined by the amount of available supportive care, a child's tolerance of chemotherapy, and the extent of comorbidities. In Malawi, for example, the treatment for Burkitt's lymphoma of all stages is intravenous cyclophosphamide (40 mg/kg on day 1 and oral cyclophosphamide 60 mg/kg on days 8, 18, and 28). Intrathecal hydrocortisone (12·5 mg) and methotrexate (12·5 mg) are given with each treatment cycle. The cost of this 28-day treatment is less than US$50.88 Previous attempts to use intensive treatments with high-dose methotrexate resulted in unacceptably high treatment-related mortality (11 of 42 participants) [50].

Conclusion

In low-income countries better diagnostic testing is needed. When only morphology is available, tumours are probably incorrectly classified as Burkitt's lymphoma. Additionally, a high standard of supportive care and medical infrastructure is necessary to deliver the most effective therapy. New, effective, and inexpensive therapies are needed for low-income countries. In the 1980s Guy de Thé described Burkitt's lymphoma as "the Rosetta stone of cancer". This description remains true now. In attempting to understand Burkitt's lymphoma, much is still to be learnt about how all cancers develop, grow, and are treated.

Prevalence of Malocclusion and its relationship with Dental caries among 12-15 years old school children of Chandigarh, India

P.Jayashri[1], Joseph John[2], Meignana Arumugham.I.[3], R.Pradeep Kumar[3], D.Srisakthi[4]

[1]Senior lecturer, [2]Former Professor, [3]Professor, [4]Reader, Department of Public Health Dentistry, Saveetha Dental College, SIMATS, Chennai, TamilNadu

Abstract

Background: Malocclusion has a negative impact on the oral health-related quality of life and has all been associated with an unacceptable dental appearance. Dental caries is a common complication of malocclusion. Epidemiological data on malocclusion and dental caries is of interest for dental public health programs, clinical treatment, screening for treatment priority and resource planning. Therefore the objective of the present study is to determine the prevalence of malocclusion and its relationship with dental caries among 12 to 15year Old School Children of Chandigarh, India.

Method: The present study was conducted among 1368 school going children of Chandigarh in the age group of 12 to 15years. The subjects were selected from four randomly selected schools of Chandigarh. Dentition status was assessed using the DMFT index by Klein, Palmer, Knutson, and Malocclusion were quantified based on the presence or absence of dentofacial anomalies which was recorded in a structured format.

Results: Prevalence of malocclusion and dental caries in the present study was found to be 28.9% and 31.4%. A significant negative correlation was observed between Malocclusion and Dental caries among subjects having Normal occlusion and Malocclusion.

Conclusion: Prevalence of malocclusion and dental caries was greater among older than younger children Results from the present study revealed that Normal occlusion and malocclusion had no or weak significant effect on overall dental caries.

Key words: *Dental caries, Malocclusion, School Children.*

Introduction

Oro-facial region is a noticeable and significant concerned area because it draws the most attention from other people in interpersonal communications and is the predominant source of vocal, physical, and emotional communication.(1)

Corresponding Author:
P. Jayashri,
Senior lecturer, Department of Public Health Dentistry, Saveetha Dental College, SIMATS, Chennai, TamilNadu, Email: shrijaya2009@gmail.com

Malocclusion is "any deviation from normal occlusion of teeth". The teeth are in abnormal position in relationship to the basal bone of maxillary and mandibular alveolar process, to the adjacent contra lateral and opposing dentition. According to Angle "occlusion is the normal relation of the occlusal inclined planes of the teeth when the jaws are closed".(2)

Even though malocclusion is not life threatening, it is considered to be a dental public health issue as it compromises the oral health and also can lead to social and psychological disorders.(3) It is the second most common dental disorder in children and young adults next to dental caries.(4) Therefore, it has been reported that the prevalence range from a value as low as 19.6%

(Miglani DC, Chennai 1961) to as high as 90% (Sidhu SS, Delhi) among Indian children.[5]

Dental caries is a usual complication of malocclusion. Due to the presence of maloccluded teeth, it is difficult for the patients to maintain good oral hygiene which in turn results in increased plaque accumulation on the teeth surfaces and hence more susceptible for dental caries.[6] Prevalence studies on dental caries in India have shown a results ranging from 31.5% to 89%.[7-11]

School years ranges from period of childhood to adolescence. These are sensitive stages in people's lives where persistent significant oral health related behaviours, as well as knowledge and attitudes, are being developed. Children are particularly more amenable during this period and the earlier the habits are deep rooted, the long lasting, the impact .[12]

According to World Health Organization (WHO), the main oral diseases should be subjected to periodic epidemiological surveys. The epidemiological data on malocclusion and dental caries is of interest for dental public health screening programs, orthodontic treatment services, and resource planning.[13]

The present study which was conducted as a part of the extensive screening, a joint initiative of Saveetha University and Times of India, to assess the Prevalence of malocclusion and its relationship with Dental caries among school children aged 12 - 15 years in Chandigarh, India. Therefore the null hypothesis of the present study will be Prevalence of malocclusion and dental caries does not exist among 12 - 15 year old school children of Chandigarh, India and there exist no relationship between malocclusion and dental caries among the study subjects.

Materials and Method

Study design, Study area: The present study was a cross-sectional study conducted as a part of the extensive screening- India Smile Campaign to create awareness about oral health among school children in India. There are 29 states and 7 union territories in India. On a map, India was divided in to North, South, East, West and Central. A total of 16 places and 79 schools were selected from all the zones which includes 21 schools from North, 41 schools from South, 4 schools from East, 9 schools from West and 4 schools from Central. Out of 79 schools, four schools were randomly selected from Chandigarh city.

The ethical clearance for the study was obtained from the institutional Ethics Committee (SRB reference No: SRB/SDMDS12ORT15). School permissions were obtained from The Educational Department, Chandigarh. Written Group informed consent was obtained from the Headmasters of the school. Data Collection was scheduled in the month of November 2014.

Training and calibration of examiners:

Examiners were calibrated through a set of clinical guidance prior to the initiation of the study and were assisted by a recorder. Inter-examiner reliability was calculated by examining a group of 20 school children and the re- examination was carried out atleast 30 minutes after the initial examination and hence a kappa statistical value of 0.78 was derived which denoted considerable level of agreement between the investigators.

Clinical Examination:

The examination of school children was carried out in school premises based on ADA type III guidelines using disposable mouth mirror, dental explorer and torch light. The school children were seated comfortably on an ordinary chair with adequate back rest. Clinical examination involved dental caries assessment and malocclusion.

Assessment of Dental caries was done using DMFT index designed by Henry Klein, Carole.E.Palmer & Knutson.J.W for permanent dentition and Malocclusion was quantified based on presence or absence of dentofacial anomalies which was recorded on a structured format.

Statistical Analysis

Data was analyzed using SPSS software (IBM SPSS Statistics, Version 20.0, Armonk, NY: IBM Corp.). Descriptive data was expressed in terms of Frequency and Percentage. Inferential statistics such as One-way ANOVA were used to compare the mean Mean DMFT according to age groups. Malocclusion and Dental caries relationship was estimated using Spearman Correlation coefficient. Statistical significance was set at a value of $p<0.05$.

Results

It is apparent from Table 1 that Malocclusion was found to be highly prevalent at 13 years of age both in males 83(6.0%) and females 64(4.7%). Out of 845 males,

606(44.3%) had normal occlusion and 239(17.4%) had malocclusion and among 523 female subjects, 366(26.8%) had normal occlusion and 157(11.5%) had malocclusion. Mean DMFT score was observed to be more at 15 years of age both in males (1.02±1.70) and females (1.29±1.64) (refer Table 2). Table 3 shows the comparison of mean DMFT score according to age. The mean DMFT score was found to be significant statistically ($p<0.001$) using One way ANOVA test. Table 4 depicts the Correlation between Malocclusion and Dental caries among subjects having Normal occlusion and Malocclusion. A significant negative correlation was observed among the study subjects using Spearman correlation coefficient. Figure 1 depicts Scatter plot of Malocclusion Vs Mean DMFT score. An Inverse linear relation was observed between malocclusion and dental caries suggestive of negative correlation coefficient using spearman correlation coefficient.

Table 1: Prevalence of Malocclusion among the study subjects according to age and gender

Gender	Age (years)	N	Occlusion	
			Normal occlusion	Malocclusion
Male	**12**	279	201(14.7%)	78(5.7%)
	13	320	237(17.3%)	83(6.0%)
	14	178	120(8.8%)	58(4.2%)

Table 2: Mean Dental caries experience based on age and gender

Gender	Age in years	N	Mean±SD
Male	12	279	0.64±1.24
	13	320	0.55±1.21
	14	178	0.88±1.48
	15	68	1.02±1.70
	Total	845	0.69±1.33
Female	12	180	0.58±1.11
	13	230	0.77±1.44
	14	79	0.98±1.40
	15	34	1.29±1.64
	Total	523	0.77±1.35

Table 3: Comparison of mean DMFT score according to age using One way ANOVA

Age in years	N	Mean±SD	F value	P value
12	459	0.62±1.19	6.128	P<0.001
13	550	0.65±1.31		
14	257	0.91±1.46		
15	102	1.11±1.67		
Total	1368	0.72±1.34		

One way ANOVA, significance level p<0.05

Table 4: Correlation between Malocclusion and Dental caries among subjects having Normal occlusion and Malocclusion

Occlusion	N	DMFT Mean±SD	Spearman rho	P value
Normal occlusion	845	0.79±1.38	-0.101	P<0.001
Malocclusion	523	0.56±1.23		
Total	1368	0.72±1.34		

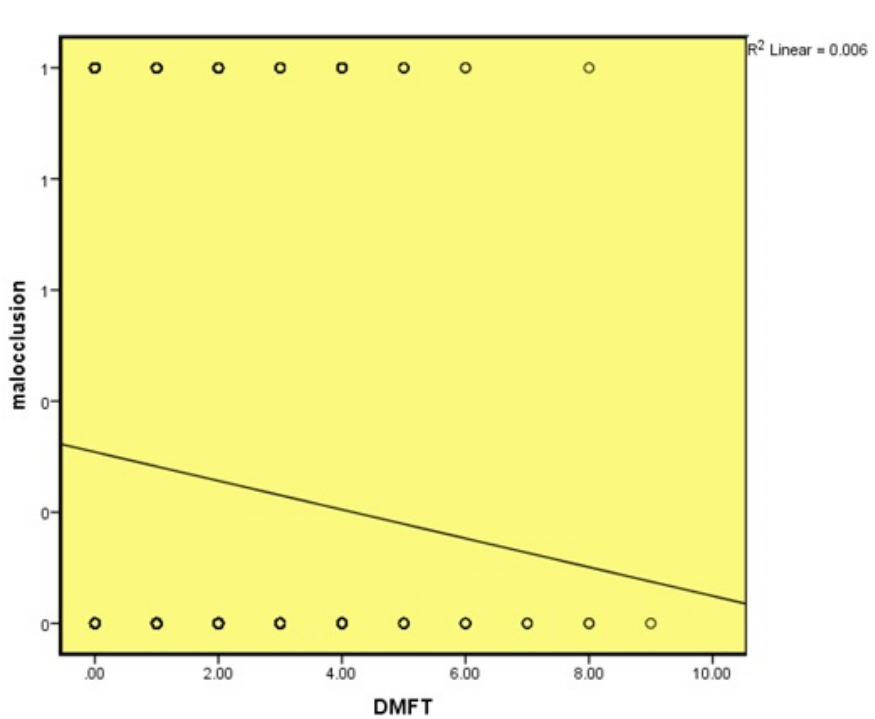

Figure 1: Scatter plot of Malocclusion Vs Mean DMFT score.

Discussion

The present study reported a malocclusion prevalence of 28.9% and was consistent with prevalence observed by Gaikwad SS et al(14) which was 26.8% conducted among 12 to 15 years old children and Otuyemi OD et al (15) showed a prevalence of 22.6% among 12 to 18 year old Nigerian secondary school children.

On the contrary, a increased prevalence of malocclusion of 71.5% was stated by Hemapriya S (16) among 12 and 15 years old rural school children in Kancheepuram district which mainly attributes to the ignorance about the deleterious effects of malocclusion and its effect on oral health related quality of life.

The reason for less prevalence of malocclusion in this study is mainly due to the awareness and positive attitude of parents towards dental procedures and interceptive orthodontic treatment at early stage of life.

Deepak Chauhan et al (17) reported very low prevalence of malocclusion (8.0%) among 9-and 12-year-old school children. This varied range could be attributed to study setting, access to dental care, knowledge and attitude of people towards preventive and interceptive orthodontic care.

Decrease in prevalence of malocclusion according to age in the present study is found to be analogous to that reported by Sudhanshu Sanadhya et al [(18)]and Estioko LJ.[(19)] Knutson stated a reasonable explanation that the transient malocclusion can be corrected with age, since the child outgrows adverse oral habits and dental relationships are returned to normal.[(19)]

Caries prevalence in the present study was observed to be 31.4% which is less than the reported caries prevalence of India (i.e. 53.8%) in National Oral Health Survey.[(20)] Wide variation of caries prevalence in this age group was observed. In a study conducted by Malvania *et al.* (2014),[(21)] a caries prevalence of 17.15% was observed.

Lower caries prevalence in the present study is mainly due to the fact that majority of the primary teeth are shedded and premolars are not present in the oral cavity long enough for dental caries process to set in.

Mean DMFT was slightly higher among females (0.77±1.35) as compared to males (0.69±1.33) This is in consistent with the findings of Shailee *et al.* (2012).[(22)] This is attributed to the fact that girls have the habit of consuming snacks between meals due to their increased time of indoor stay in comparison to the boys who spend more time on outdoor activities. The other plausible explanation could be that tooth eruption occurs earlier among girls than boys, which means that their teeth have been exposed to oral microflora for longer duration than boys of the same age. [(23)]

In the current study, significant negative correlation was obtained between Malocclusion and Dental caries among subjects having Normal occlusion and Malocclusion. Similar findings were reported in an epidemiological survey carried out by Stahl F.[(24)] On the contrary, significant relation was observed between increased DMFT score and orthodontic treatment needs in a study done by Col Prasanna Kumar et al.[1] This difference might be related to study setting and study population. Therefore, the null hypothesis for this present epidemiological survey has been rejected.

Conclusion

The following conclusion were drawn from the present study

1) Dental caries and malocclusion was highly prevalent among older school children.

2) Malocclusion was highly prevalent among males than females whereas dental caries was slightly higher in female subjects than male subjects.

3) Normal occlusion and malocclusion had no significant effect on dental caries.

Abstract

Background : The present work mainly deals with the study pertaining to the synthesis, characterization and evaluation of copper nanoparticles using avocado. The copper nanoparticles were synthesized by using a rapid, single step and completely green synthesis method.

Materials and Method: The synthesized copper nanoparticles were characterized by using various instrumental techniques such as ultraviolet-visible spectroscopy (UV-vis), Fourier Transform Infrared Spectroscopy (FTIR) TEM (Transmission Electron Microscope). The synthesized copper nanoparticles were found to be spherical in shape with average diameter of 35.6 nm. The synthesized nanoparticle solution is primarily characterized by using UV-vis-spectroscopy, 3mL of the solution is taken in cuvette and scanned in double beam UV-vis spectrophotometer from 300 nm to 700 nm wavelength.

Results: In the UV-vis spectrum, a single, strong and broad surface plasmon resonance (SPR) peak was observed at 420 nm that confirmed the synthesis of AgNPs. Transmission electron microscope result showed 2-6 nm difference.
