Indian Journal of Public Health Research & Development

EXECUTIVE EDITOR

Vidya Surwade

Associate Professor, Dr Baba Saheb Ambedkar, Medical College & Hospital, Rohinee, Delhi

INTERNATIONAL EDITORIAL ADVISORY BOARD

1. **Dr. Abdul Rashid Khan** B. Md Jagar Din, *(Associate Professor)*
   Department of Public Health Medicine, Penang Medical College, Penang, Malaysia
2. **Dr. V Kumar** *(Consulting Physician)*
   Mount View Hospital, Las Vegas, USA
3. **Basheer A. Al-Sum,**
   Botany and Microbiology Deptt, College of Science, King Saud University, Riyadh, Saudi Arabia
4. **Dr. Ch Vijay Kumar** *(Associate Professor)*
   Public Health and Community Medicine, University of Buraimi, Oman
5. **Dr. VMC Ramaswamy** *(Senior Lecturer)*
   Department of Pathology, International Medical University, Bukit Jalil, Kuala Lumpur
6. **Kartavya J. Vyas** *(Clinical Researcher)*
   Department of Deployment Health Research, Naval Health Research Center, San Diego, CA (USA)
7. **Prof. PK Pokharel** *(Community Medicine)*
   BP Koirala Institute of Health Sciences, Nepal

NATIONAL SCIENTIFIC COMMITTEE

1. **Dr. Anju D Ade** (Professor)
   Community Medicine Department, SVIMS, Sri Padamavati Medical College,Tirupati, Andhra Pradesh.
2. **Dr. E. Venkata Rao** *(Associate Professor)* Community Medicine, Institute of Medical Sciences & SUM Hospital, Bhubaneswar, Orissa.
3. **Dr. Amit K. Singh** *(Associate Professor)* Community Medicine, VCSG Govt. Medical College, Srinagar – Garhwal, Uttarakhand
4. **Dr. R G Viveki** *(Associate Professor)* Community Medicine, Belgaum Institute of Medical Sciences, Belgaum, Karnataka
5. **Dr. Santosh Kumar Mulage** *(Assistant Professor)*
   Anatomy, Raichur Institute of Medical Sciences Raichur(RIMS), Karnataka
6. **Dr. Gouri Ku. Padhy** *(Associate Professor)* Community and Family Medicine, AII India Institute of Medical Sciences, Raipur
7. **Dr. Ritu Goyal** *(Associate Professor)*
   Anaesthesia, Sarswathi Institute of Medical Sciences, Panchsheel Nagar
8. **Dr. Anand Kalaskar** *(Associate Professor)*
   Microbiology, Prathima Institute of Medical Sciences, AP
9. **Dr. Md. Amirul Hassan** *(Associate Professor)*
   Community Medicine, Government Medical College, Ambedkar Nagar, UP
10. **Dr. N. Girish** *(Associate Professor)* Microbiology, VIMS&RC, Bangalore
11. **Dr. BR Hungund** *(Associate Professor)* Pathology, JNMC, Belgaum.
12. **Dr Sartaj Ahmad,** PhD Medical Sociology, *Associate Professor,*
    Swami Vivekananda Subharti University Meerut UP India
13. **Dr Sumeeta Soni** *(A*ssociate Professor)
    Microbiology Department, B.J. Medical College, Ahmedabad, Gujarat,India

NATIONAL EDITORIAL ADVISORY BOARD

1. **Prof. Sushanta Kumar Mishra** (Community Medicine)
   GSL Medical College – Rajahmundry, Karnataka
2. **Prof. D.K. Srivastava** *(Medical Biochemistry)*
   Jamia Hamdard Medical College, New Delhi
3. **Prof. M Sriharibabu** *(General Medicine)* GSL Medical College, Rajahmundry, Andhra Pradesh
4. **Prof. Pankaj Datta** *(Principal & Prosthodentist)*
   Indraprastha Dental College, Ghaziabad

NATIONAL EDITORIAL ADVISORY BOARD

5. **Prof. Samarendra Mahapatro** *(Pediatrician)*
   Hi-Tech Medical College, Bhubaneswar, Orissa
6. **Dr. Abhiruchi Galhotra** *(Additional Professor)* Community and Family Medicine, AII India Institute of Medical Sciences, Raipur
7. **Prof. Deepti Pruthvi** *(Pathologist)* SS Institute of Medical Sciences & Research Center, Davangere, Karnataka
8. **Prof. G S Meena** *(Director Professor)*
   Maulana Azad Medical College, New Delhi
9. **Prof. Pradeep Khanna** *(Community Medicine)*
   Post Graduate Institute of Medical Sciences, Rohtak, Haryana
10. **Dr. Sunil Mehra** *(Paediatrician & Executive Director)*
    MAMTA Health Institute of Mother & Child, New Delhi
11. **Dr Shailendra Handu,** *Associate Professor,* Phrma, DM (Pharma, PGI Chandigarh)
12. **Dr. A.C. Dhariwal:** *Directorate* of National Vector Borne Disease Control Programme, Dte. DGHS, Ministry of Health Services, Govt. of India, Delhi

Print-ISSN: 0976-0245-Electronic-ISSN: 0976-5506, Frequency: Quarterly (Four issues per volume)

Indian Journal of Public Health Research & Development is a double blind peer reviewed international journal. It deals with all aspects of Public Health including Community Medicine, Public Health, Epidemiology, Occupational Health, Environmental Hazards, Clinical Research, and Public Health Laws and covers all medical specialties concerned with research and development for the masses. The journal strongly encourages reports of research carried out within Indian continent and South East Asia.

The journal has been assigned International Standards Serial Number (ISSN) and is indexed with Index Copernicus (Poland). It is also brought to notice that the journal is being covered by many international databases. The journal is covered by EBSCO (USA), Embase, EMCare & Scopus database. The journal is now part of DST, CSIR, and UGC consortia.

Contents

Volume 10, November 11 November 2019

1. Insights for Pharmaceutical Manufacturers on New Age Women: Influence of Media on Purchase and Usage of Medication in India 1
B. Akshaya, Sudha Ramaiah

2. A Study to Assess the Effectiveness of Yoga Therapy on Menopausal Symptoms among Women in a Selected Area at Mangaluru 5
Amrutha V., Vinaya Kumary T., Janet Prima Miranda

3. Compare the Physiological Parameters and Behavioural Responses among Mixed Fed Versus Formula Fed Preterm Babies 9
Rafia Islam, Anila K.P.

4. Household use Patterns of Iodized Salt in Urban Slums of Meerut 15
Chhavi Kiran Gupta, Antara Sinha, Parkhi Mehta, Shaavi Mittal, Rohan Sirohi, Narendra Kumar

5. Effect of Intermittent Pneumatic Compression Device (IPCD) Versus Graduated Compression Stockings (GCS) for Venous Thromboembolism Prophylaxis (VTE) in High Risk Surgical Patients 21
Arya Shirish Kulkarni, Rupali Salvi, Nisha Naik

6. Assessment of Level of Streess among the B.Sc. Nursing Students 26
Ashisbala Mohapatra

7. Assessment of Stain Removal Efficacy of Two Commercially Available Polishing Agents: Proxyt Paste (Active Ingredient-Xylitol) and Shine N Smile Paste (Active Ingredient-Alumina) 31
Avineet Kaur, Deepak Kochar, Shanam Kansil

8. Knowledge and Level of Awareness about the Use of Interdental Aids and Proper Brushing Techniques amongst Medical Students 35
Avineet Kaur, Deepak Kochar

9. Ailments of Women Beedi Labourers in Tirunelveli District, Tamil Nadu 39
B. Chithirairajan, S. Thangamayan, N. Manivannan

10. A Study on Internet Banking System and Customers Satisfaction in Namakkal District 43
B. Chithirairajan, Telu Suvarna, E. Rajarethinam

11. Quality of Life of People with Type 2 Diabetes 47
Aldrin Vas, Elsa Sanatombi Devi

12. Effectiveness of Child to Child Programme on Knowledge Regarding Management of Minor Ailments among School Children 51
Ashly Lukose, Binu Margaret E, Bharathi R. Nayak

13. A Comparative Study on Bilateral and Unilateral Task Oriented Exercises for Improving Upper Extremity Motor Function in Post-Stroke Subjects with Learned Nonuse Phenomenon 56
Brundha Tanavarapu, P. Kiran Prakash, P.R. Sri Thulasi, Patchava Apparao, Ganapathi Swamy Chintada, Choppala Mary Margrett.

14. Correlation of Waist Hip Ratio with Standing Stork Test among College Students....61
D. Malarvizhi, M. Arvind

15. Patanjali Yoga Practice and its Effect on Mental Health and Moral Judgment amongst Juvenile Delinquents....65
Dayal Sandhu, Amit Kumar, MonikaAgarwal

16. Internalizing Behavioural Problems among Children of Alcoholic Parents 70
Dayananda Bittenahalli Omkarappa, Sreevani Rentala

17. Effect of Dynamic Stretching Warm-Up Protocol on Hamstring Flexibility in Roller-Skaters: An Experimental Study 76
Deepika Jayprakash Surve, Prasannajeet Pramod Nikam.

18. Re-Engineering of Discharge Process with Emphasis on Sustainability: A Six Sigma Approach 81
Deepu Rani, Shalini D., Arun Mavaji S.

19. Nutritional Status of Pre-Schoolers in the Border Areas of Jammu....86
Deepakshi Vaid, Devaki Gokhale

20. Prevalence of Depression among Elderly in Rural South India 92
Dhasarathi Kumar, Alex Joseph, Arulmani Thiyagarajan, Shyamala Shree

21. Working Women's Experiences on Domestic Violence and its Consequences: An Urban Mangalore Study 96
Dinesh Abhijeeth Shanker, G. Shiny Chrism Queen Nesan, Rashmi Kundapur

22. Structural Relationship between Dimensions of Psychological Empowerment, Customer Oriented Behaviour and Job Satisfaction of Employees in Public Sector Banks....101
E. Sharanya, K. Vasanthi Kumari

23. Factors Influencing the Development of Chronic Cough Following Common Cold....105
Rahul Yelgoi, Jayakumar Jeganathan, Pavan M.R.

24. A Study on Role of Human Resources Management (HRM) Practices in Training Transfer with References it/ites Organization....108
A. Mani, G. Murugesan

25. Role of Human Resource Management Practices in Knowledge Management with Reference in it/ites Organisation....114
G. Murugesan, A. Mani

26. Observational Survey for Assessment of Helmet Usage among Two Wheeler Users in the Metropolitan City of South India 120
Gulappa Devagappanavar, Pallavi Sarji Uthkarsh

27. Awareness of PC PNDT Act among Mothers Attending Tertiary Care Centres in Dakshina Kannada: A Cross Sectional Study 125
Santosh Rai, Rashmi Kundapur, Harshitha H.N., Sudhir Prabhu, Anusha Rashmi, Shreyaswi Sathyanath

28. Tobacco and Betel Nut Chewing Behaviour and its Association with Potentially Malignant Disorders in Chennai 130
Aparnaa M., Herald J. Sherlin

29. Evaluation of the Relationship between Maternal Periodontitis and Preterm Low Birth Weight Infants: A Case Control Study 136
Radhika Murali, Jaiganesh Ramamurthy

30. Ridge Augmentation: An Overview 143
Rupesh Srivastava, Gatha Mohanty, Rinkee Mohanty, Rashmita Nayak

31. Oral Piercing Fascinations and Complications 146
Nikita Sahu, Debasruti Naik, Karishma Rathore, Sudipta Sahu, Sashikant Sethi

32. Growth Hormone Disorders and its Oral Manifestations 150
Karishma Rajan Rathor, Gatha Mohanty, Stithaprajna Lenka, Neelima Katti

33. Scars in Orthodontics: A Review 153
Abhik Sinha, Rahul Roy

34. CAD CAM Nasoalveolar Molding and its Recent Advances 159
Ananya Panda

35. Endodontic Sealers: Current Concepts of Sealers 163
Anshuk Ghosh, Sthitaprajna Lenka

36. Bite Mark Analysis in Dentistry: An Emerging Probe of Criminal Investigation in Judicial System 166
Rashmi Kumari

37. Alloys Used in Fixed Prosthodontics: An Overview 170
Debarchita Sarangi, Upasana Mohapatra

38. Cantilever Fixed Dental Prosthesis on Periodontally Treated Abutment: A Case Report 173
Debarchita Sarangi, Mohit Das, Abhaya Chandra Das, Manoj Kumar, Rinkee Mohanty

39. Diagnosis of Impacted Canine: An Overview 177
Sashikant Sethi, Subhrajeet Narayan Sahoo

40. Cleft Lip and Cleft Palate: A Review 181
Shreya Kotish

41. Altered Microflora in Orthodontic Patients 186
Sumita Mishra, Lipika Mali

42. Antibiotic Drug Resistance: A New Initiative....190
Lenali Baral, Sthita Prajana Lenka, Karishma Rajan Rathor, Barsha Ray, Lovlin Barik

43. Assessment of Dehiscence and Fenestration in Bilateral Cleft Lip and Palate Patients....193
Amrita Sahu

44. Nicotine Replacement Therapy: A Review....199
Basanta Kumar Choudhury, K.L. Sushmita, Namrata Mishra

45. Fibrous Dysplasia: A Rare Case Report....202
Basanta Kumar Choudhury, Smita Rani Priyadarshini, Rupsa Das, Suvranita Jena, Snigdha Sagar

46. Dental Implants in Diabetic Patients....205
Camelia Saha

47. Initial Management of Maxillofacial Trauma....209
Chinmayee Chidanandini Kar, Sthitaprajna Lenka, Karishma Rajan Rathor, Prateek Kumar Sundaray

48. Antibiotic Use in Dental Practice: A Review....212
Debasrita Ghosh

49. Squamous Cell Carcinoma Secondary to a Verrucous Carcinoma of Tongue and Redial Fore Arm Free Flap as a Reconstructive Option: A Case Report....215
Harsh Mohan Pathak, Sobhan Mishra, Subrat Kumar Padhiary, Kalyan Sundar Pal

50. A Case of Orthodontic Treatment- Induced Invasive Cervical Resorption....219
Lora Mishra, Manoj Kumar, Shaneel Ahmed

51. An Alternative Treatment Method Using a Minimally Invasive Approach Employing: Ceramic Veneer to Replace Discolored Composite Veneer: A Case Report....223
Lora Mishra, Manoj Kumar

52. Nutrition & Oral Health: An Overview....226
Madhusmita Sahu

53. Gingival Enlargement, a Diagnostic Indicator of Leukaemia?....230
Manoj Kumar, Satya Ranjan Misra, Saurav Panda, Rupsa Das

54. Central Ossifying Fibroma of the Mandible: A Case Report....234
Mirna Garhnayak, Subrat Kumar Padhiary, Swagatika Panda, Sangram Panda

55. Chemo Mechanical Caries Removal Technique: A Review Article on Lost and Found Approach towards Painless Dentistry....239
Mrinali Shukla, Antarmayee Panigrahi, Susant Mohanty, Sulagna Pradhan, Sonali Bhuyan

56. Antimicrobial Activity of Moringa Oleifera Extracts against Common Periodontal Pathogens: Potential Application in the Prevention and Treatment of Oral Diseases....243
Ramesh Nagarajappa, Nikhil V. Bhanushali, Gayathri Ramesh, Parin V. Bhanushali, Pankaj Aapaliya, Piyush Pujara

57. Gorlin-Goltz Syndrome: Multiple Approach to Diagnosis and Treatment....249
Neeta Mohanty, Devi Prasad Mandal, Snigdha Sagar

58. Flap Design in Third Molar Surgery: A Review 254
Pallabi Behera, Sthita Prajna Lenka, Barsha Ray, Abhishek Jagdish

59. Safeguarding the Socket: A Review of Techniques 258
Prachi Khuntia, Rashmita Nayak, Abhaya Chandra Das, Rinkee Mohanty, Saurav Panda, Sharmistha Das

60. Occlusal Appliance-When and Where? Management of Temporomandibular Joint Pain Dysfunction Syndrome 264
Priyanka Debta, Anurag Dani, Santosh Kumar Swain, Fakir Mohan Debta, Somalee Mahapatra

61. Implant Protective Occlusion–Modern Gnathological Concepts 269
Priyanka Debta, Anurag Dani, Fakir Mohan Debta, Santosh Kumar Swain, Somalee Mahapatra, Mirna Garhnayak

62. Chemotherapy in Head and Neck Squamous Cell Carcinoma: An Overview 275
Sachitananda Meher, Santosh Kumar Subudhi, Stithaprajna Lenka, Aditi Ava Rath, Waseem Alam, Radha Prasanna Dalai

63. Osseointegration: A Comprehensive Overview 280
Sangram Panda

64. Evaluation of Biomarker: A Review 285
Sashikant Sethi, Sourav Chandra Bidyasagar Bal, Radha Prasanna Dalai, Amit Mehta

65. Non-Invasive Chairside Diagnostic Techniques: A Review 289
Shayari Niyogi, Saswati Priyadarshini

66. Inappropriate Prescribing of Antibiotics by Practitioners 294
Shrestha Singh

67. Application of Bisphosphonates in Dentistry: A Review of Literature 299
Sitish Nayak

68. Dentistry as a Career Option: A Gender-based Study about Scope of Dental Education 304
Sobhan Mishra, Pankaj Kumar Panda, Kamrakali Mishra, Shelly Mishra, Susant Mohanty

69. Implant & Dental Plaque: A Close Bonding 309
Sourav Chandra Bidyasagar Bal, Radha Prasanna Dalai, Sashikant Sethy, Sukhvinder Oberoi, Amit Mehta

70. A Rare Case Report on Temporomandibular Dislocation 313
Sthitaprajna Lenka, Santosh Subudhi, Stiti Pragnya, Aditi Ava Rath, Kalyan Sundar Pal

71. Unicystic Hemangioameloblastoma: A Rare Clinical Entity 317
Sreepreeti Champatyray, Priyanka Debta, Shubhangi Pareek, Neeta Mohanty, Saurjya Ranjan Das

72. Birn's Hypothesis and its Implications 322
Subham Sekhar Parida

73. Sports Dentistry: A Recent Upcoming Field in Dentistry 325
Sudipta Sahu, Kajal Kiran Sahoo, Sashikant Sethy, Nikita Sahu

74. Diagnosis and Evidence Based Interventions for Oral Potentially Malignant Disorders: Are We Vigilant Enough? 329
Swagatika Panda, Paresh Behera, Gunjan Srivastava, Neeta Mohanty

75. Occupational Hazards Associated with the Use of Mercury in Dental Office 335
Upasana Mohapatra, Susant Mohanty, Antarmayee Panigrahi, Gatha Mohanty

76. Awareness, Mindset & Method Associated with Infection Control Measures in Dental Students 338
Karishma Rajan Rathor, Stithaprajna Lenka, Dharmashree S., Sashikant Sethy, Radha Prasanna Dalai

77. Dental Problems in School Children: An Overview 343
Shalini Mohanty

78. Serological Investigations in Denistry 348
Dr. Shanta Saraswati

79. Various Surgical Managements of Oroantral Fistula 352
Shritashriya Misra, Sthitaprajna Lenka, Karishma R. Rathor

80. Effect of Hormonal Imbalance on Jaw Growth 356
Subhrajeet Narayan Sahoo

81. Recent Advances in Local Anaesthesia 361
Soumya Kanti Roy, Sthita Prajana Lenka, Sobhan Mishra, Santosh Kumar Subudhi, Subrat Kumar Padhiary

82. Bisphosphonates Related Osteonecrosis of Jaws 366
Suchismita Kundu, Smita Rani Priyadarshini

83. Wegener's Granulomatosis in a Limited form as an Oral Manifestation: Its Recognition 371
Naina Pattanaik, Rinkee Mohanty ***This article has been retracted on authors request.***

84. Distraction Osteogenesis for Correction of Mandibular Deficiency and Disorder: An Overview 375
Sthitaprajna Lenka, Aditi Ava Rath, Loknath Sahoo, Karishma Rathor

85. Current Status and Call for Action: Regenerative Endodontics 380
Sumit Dash, Debkant Jena, Siba Prasad Jena

86. Ceramic Veneers: Technique Overview with a Case Report 383
Gunjan Srivastava, Sreeprada Dash, Manoj Kumar, Lora Mishra, Subrat Kumar Padhiary

87. Diagnostic AIDS for Detection of Oral Precancerous Condition 388
Tariq Soyab

88. Radiographic Differential Diagnosis of Ossifying Fibromas of the Jaws. A Case Series 392
Abhishek Ranjan Pati, Rajat Panigrahi, Smita Priyadarshini, Basanta Choudhury, Sayari Niyogi, Swastik Mishra

89. Revolution of Graphene in Dentistry 397
Sudipta Sahu, Debasruti Naik, Kajal Kiran Sahoo, Nikita Sahu, Sashikant Sethi

90. Antioxidants and its Role in Periodontal Health 401
Someswar Chakraborty, Manoj Kumar

91. Botox and Dermal Fillers: Expanding the Horizon of Dentistry 404
Tulya Shubh

92. Different forms of Tobacco and its Bad Effects on Our Health and Society 409
Sourav Chandra Bidyasagar Bal, Radha Prasanna Dalai, Sashikant Sethi, Varun Darshan

93. Toxic Effects of Amalgam on Body 413
Sushma Swaraj

94. Peripheral Odontogenic Fibroma: A Case Report 416
Manoj Kumar, Lora Mishra

95. Evaluation of Correlation between Chronological Age and Delayed Eruption in Down Syndrome: An Original Research 419
Satyabrata Patnaik, Swati Saraswata Acharya, Sobhan Mishra, Abhik Sinha, Payada Patnaik, Amrita Sahu

96. Storage Media to Preserve the Avulsed Tooth 423
Susant Mohanty, Antarmayee Panigrahi

97. Hypothesising the Research Question 427
Swati Patnaik, Shakti Swaroop

98. Comparing the Anti-Plaque and Anti-Gingival Effectiveness of Punica Granatum and Chlorhexidine Containing Mouthwash: A Single Blinded Randomized Clinical Trial 431
A. Ashwatha Pratha, Jayashri Prabakar

99. Adherence of Hypertension Drugs among 30 Years and above Age Group Urban Population of Eluru, India 438
Ratna Balaraju, K. Chandra Sekhar, Shatrughna Bhayya

100. A Study on Attitude of Female Teachers Towards Inclusive Educationwth Special Reference to Schools in Chennai District 443
K. Kalaiselvi, M. Vetrivel

101. A Descriptive Study to Assess the knowledge on Fertility and Infertility among Adolescent Girls in a Selected College at Kanchipuram District Tamil Nadu, India 448
R. Renuga, R. Vaishnavi, S. Saritha, K.Vanitha

102. A Descriptive Study on Practice of Self Medication in Urban Field Practice Area of Perambalur Municipality, Tamil Nadu, India 451
Karthikeyan K., Tamilarasan M., Rock Britto

103. Prevalence and Determinants of Depression among the Elderly in Rural Field Practice Area of a Medical College in Perambalur District, Tamil Nadu: A Cross-Sectional Study 457
Karthikeyan K., Sriandaal V, Tamilarasan M.

104. CT Guided Radiofrequency Ablation of Osteoid Osteoma 463
Murugesh E., Devimeenal J., Krishna Prasanth B., Pavan Kumar N.

105. Factors Affecting the Unmet Dental Needs and Dental Service Utilisation among Urban Slum Dwellers of Chennai City, India 469
Lakshmi Krishnan, Arthi Balasubramanium, Kiran Iyer, P.D. Madan Kumar

106. Alteration of Serum Vitamin D in Patients of Myocardial Infarction and Ischemic Heart Diseases.....475
Lata Mullur, Kusal K. Das , M.S. Biradar

107. A Study to Assess the Level of Knowledge on Water Borne Disease among Adults in Selected Village at Kanchipuram District, Tamil Nadu, India 479
S. Gowtham, A. Mohamed Khalith, K. Naveen Kumar, R. Sasikala, S. Vimal Raj, N. Thivya

108. Working Capital Management and Ratio Analysis of Paper Mills 482
C. Ganesan, M. Nirmal Dev

109. A Study on Farmers' Opinion Towards Marketing of Agricultural Seeds: An Analysis.....488
M. Vetrivel, K. Indira

110. A Study on Consumer Behaviour Towards Durable and Non-Durable Goods in Cuddalore District.....494
R.V. Suganya, M. Vetrivel, R. Lakshmi

111. Magnetic Resonance Imaging Evaluation of Normal Ocular Anterior-Posterior Diameter and Interzygomatic Length in Healthy Adult and Pediatric Eastern Indian Population: A Retrospective Study.499
Manoranjan Mohapatra, Ranjan Kumar Sahoo, Saroj Ranjan Sahoo, Manoj Kumar G.

112. Assessment of Quality and Safety Aspects of Home Healthcare Services Provided by Tertiary Care Hospital.....504
Meenal Kulkarni, Ankita Tyagi, Radhika Raut

113. Myocardial Bridging and Coronary Artery Dominance: A Cadaveric Study 509
Mohandas G.V., Shanta kumari B., Sitansu ku.Panda

114. Somatotype Characteristics of School Going Children with Visual Disabilities 513
Mohd Arshad Bari, Hussein Ali Hasan Alghazal, Haq Nawaz Mir , Muzaffar Husain

115. The Effects of Exercise on the Sympathovagal Regulation of Heart and Functional Capacity in Patients Following Coronary Artery Bypass Grafting 519
N. Venkatesh, T. Senthil Kumar, R. Yogeswari, S. Sridevi

116. Assessing the Awareness of Anti-Tobacco Laws among Adults in Chennai-Need for Strengthening Legal Actions.....524
Naziya K. Babu, Meignana Arumugham Indiran, Pradeep Kumar Rathinavelu, Sakthi Doraikannan

117. Personal Mastery Model on the Ability to Self Care in the Primary Hypertension 530
Abdillah Fatkhul Wahab, Nursalam, Oedojo Soedirham, Noer Saudah

118. A Study to Assess the Effect of Community based Educational Programme Regarding Prevention of Anxiety Related to Child Birth among Primi Gravida women in Selected Rural Community of Pune District 535
Prachi Shete, S.G. Joshi, Mangesh Jabade

119. Customer Perception Towards Organic Products: An Exploratory Study 540
Prakash N., S. Gurusamy

120. Assessing the Knowledge of Post Natal Mothers Regarding Danger Signs of Neonates at Various Health Facilities in Bihar: A Survey.....545
Preysi Chauhan, Abhinandan Anand, Poonam Joshi

121. Effectiveness of Structured Teaching Programme on Prevention of Urinary Tract Infection among Women with Type 2 Diabetes in Selected Teritary Care Hospital, Kanchipuram District, Tamil Nadu.....550
Divya K.V., Bhuvana A.A., Pushpakala K.J.

122. Migrant Labour Resource Management a Channel for Sustainable Development in Tamil Nadu.....555
R. Bharathi Rajan, R. Lakshmi, S. Thangamayan

123. The Impact of Natural Disasters on Economic Growth: A Study of Kerala Floods 559
R. Bharathi Rajan, R.V. Suganya, S. Thangamayan

124. Impact of Self-Efficacy of Middle-Level Managers on Implementing Innovation.....563
R. Vimaladevi, D. Ganesan

125. A Cognitive-neuroscience Module to Enhance Spiritual and Physical Well-being.....569
Rajarethinam Emmanuel, Chithirai Rajan, S. Saravanan, Telu Suvarna

126. Does Season Worsen Air Quality: Comparison of Pollutant Levels for Summer and Winter in New Delhi 574
Rudraksh Gupta, Manju Rawat Ranjan, Usha Mina, Rajul Kumar Gupta,

127. Implementation Challenges of Universal Health Coverage–Arogya Karnataka in a Tertiary Care Hospital 578
Ramya Y.P., Khyathi G.V., Narendranath V.

128. Evaluation of Serum IL-21, TNF-α and hsC-Reactive Protein in Patients with Chronic Periodontitis.....584
Rani Lokhande, J.G. Ambekar, K.G. Bhat, Nilima N. Dongre

129. Community Household Survey Utilization of EPI Cluster Sampling Style.....590
Renu G., Asha Kamath

130. Radiological Study on the Anterior Loop of Inferior Alveolar Nerve 595
Roshene R., Jayanth Kumar V.

131. Refugee Women: Problems and Health Concerns 600
Rubina Grewal, R.L. Koul

132. Investors Attitude Towards Investment in Private Insurance Companies in Madurai City, Tamil Nadu State 605
S. Chandrachud, M. Ramesh, E. Rajarethinam, Telu Suvarna

133. The Economic Impact of FDI in Indian Chemicals Sector.....610
S. Chandrachud, S. Thangamayan, R. Premalatha, Telu Suvarna

134. A Study on Labour Laws with Special Reference to Industrial Dispute Act, 1947 615
G. Senthil Kumar, S. Chandrachud

135. The Economic Impact of FDI in Indian Shipping Sector.....620
S. Chandrachud, S. Venkataganesh

136. Interlinking of Rivers of India; Problems and Prospects.....624
S. Suresh, S. Jansi Rani

137. Availability and Sectoral Demand for Water in Tamil Nadu.....629
M. Ramesh, S. Thangamayan, S.N. Sugumar, S. Ramakrishnan

138. Physical and Financial Performance of Women Welfare in the Marriage Assistance Schemes of Tamil Nadu....633
S. Gunaseelan, S. Thangamayan

139. An Analysis of Women Empowerment through Self Help Groups....638
S. Sudha, S. Thangamayan, Premalatha

140. Agriculture and Women's Health....642
R. Shakeela, Dr. S.N. Sugumar

141. Finger Theraphy-Clensing and Revitalizing Human Health....646
S.N. Sugumar, M. Shanmugapriya

142. Energy Medicine & Herbal Brain–Top Five Brain Inducing Herbs of India its Impact on Health and Economy....650
Mouthu Kumarasamy, S.N. Sugumar

143. Blood Pressure–Some Issues and Traditional Remedical Measures....654
S.N. Sugumar, G. Raguram

144. An Analysis of Health Status in Tamil Nadu....659
R. Premalatha, S. Thangamayan, S.N. Sugumar, S. Chandrachud

145. An Analysis of Industrial Labourer in India with Special Reference to Tamil Nadu....664
S. Saravanan, S. Thangamayan, S.N. Sugumar, S. Chandrachud

146. An Analysis of Tax Revenue and Non Tax Revenue in Tamil Nadu....668
S. Thangamayan, R. Premalatha, B. Chithirai Rajan, Telu Suvarna, S.N. Sugumar, S. Chandrachud

Eman Ali Hussein Al-Saidy, Zainab Abdul Jabbar Ridha Al-Ali

413. Evaluation of Prolactin, Total Testosterone and Anti Mullarian Hormones in Women with Hypothyroidism at Misan City Iraq.....1835
Eman Kamil Aati, Zainab Abdul Jabbar Ridha

414. Synthesis, Antioxidant, Antimicrobial and Docking Study of Novel 2-Pyrazoline Derivatives Bearing Imine Moiety 1842
Ban Hasan Taresh, Ahmed Mutanabbi Abdula, Mustafa Taha Mohammed

415. Influence of Autologous Platelet Concentrates on the Dynamics of Regenerative Processes in Treatment of Trophic Ulcers of Lower Extremities 1850
Baranovskiy Yu.G., Ilchenko F.N., Shapovalova E.Y., Kaliberdenko V.B., Shanmugaraj K., Keerthanaa B.

416. Anemia in Children Due to Airborne Lead Exposure of Used Lead-Acid Battery Recycling Area in Jabodetabek, Indonesia.....1856
Basuki Rachmat, Haryoto Kusnoputranto, and Inswiasri

417. Prototyping Personal Health Records for Type 2 Diabetes Mellitus Prevention 1862
Berly Nisa Srimayarti, Kemal N. Siregar

418. Correlation Between Zinc Level of Mothers and Case of Babies with Non-Syndromic Cleft Lip and Palate 1868
Chairunas, Sjarif Hidajat Effendi, Harmas Yazid Yusuf, Eriska Riyanti, Rachmad Suhanda, Nurhasmadiar Nandini

419. Effect of Psychoeducation-Modification on the Improvement of Spiritual Response, Perception Stigma, Anxiety Level and Cortisol Levels among Lepers 1873
Cucu Herawati, Agus Suwandono, Suhartono Taat Putra, Fifin Luthfia Rahmi, M. Amin Syukur, Hastaning Sakti, Nursalam

420. EEBE-HOTS: Developing Environmental Enrichment Book Eco-label Based on Higher Order Thinking Skills for 21st Century Learning 1879
Diana Vivanti Sigit, Mieke Miarsyah, Ilmi Zajuli Ichsan

421. The Association of Triglycerides Glucose Index with Diabetic Retinopathy in Patients with Type 2 Diabetes Mellitus 1885
Ekhlas Khalid Hameed, Zina Hassan Abdul-Qahar, Tahrir Etihad Kadium

422. Analysis of Risk Factors Related to the Events of Early Marriage in the Wetland 1891
Fahrini Yulidasari, Fauzie Rahman, Meitria Syahadatina Noor, Nita Pujianti, Dian Rosadi, Nur Laily, Nor Hidayah

423. Analysis of Homology and Phylogenetic Genes Encoding Fusion (F) Protein of Newcastle Disease Virus (NDV) Isolated Swan (Cygnus Olor) 1895
Naimah Putri, Rahaju Ernawati, Suwarno, Kusnoto, Wiwiek Tyasningsih, Fedik Abdul Rantam

424. Early Detection of Risk Factors and Severity of Airway Obstruction Through Measurement of Critical Values of FVC and FEV_1 on Bus Terminalofficers 1900
Sudiro Sudiro, Martono Martono, Nursalam Nursalam, Ferry Efendi

425. Preceptorship Method Development Based on Experiential Learning to Improve Preceptor Clinic Competency 1905
Fitri Chandra, Nursalam, Slamet Riyadi Yuwono

426. High Risk Obstetrics in Developing Countries: Root Cause Analysis and Viable Mitigation Strategies 1908
Frincy Francis, Sheeba Elizabeth Johnsunderraj, Lily Bera, Rosemol M.A., Sumitra Melinamani, Aniamma Abraham

427. Effect of Chemomechanical Caries Removal with Papacarie Gel on Bond Strength of Composite Resin Restoration 1914
Gamal A.M., Khattab N.M.

428. Establishing Nursing Diagnoses Profile for Patients with Multiple Sclerosis: Maslow's Model Application 1920
Hadeer Salah Eldin Abd Elsamea, Hanan Ahmed Al Sebaee, Heba Ahmed Mohammed

429. Socioeconomic Determinants of Complete Immunization Status in Under-Five Children in Slum Inner Capital City 1926
Hartono Gunardi, Andini Strirartnaputri, Fatimah Saidah, Yaulia Yanrismet, Bernie Endyarni Medise, Angga Wirahmadi, Elizabeth Melina

430. Effects of Serum Ferritin and White Blood Cell on Overweight and Obesity in South Korean Adults 1932
Hea Shoon Lee

431. Comparative Study of Antimicrobial Activity of Seven Ficus Species Cultivated in Egypt 1938
Heba A. Hassan, Sayed F. Abdelwahab, Samar Y. Desoukey, Khaled M. Mohamed, Mohammed S. Kamel

432. Life Skill Improvement of the Hydrokura Method on the Community at Astambul Subdistrict of Banjar District.....1944
Husaini, Laily Khairiyati, Rudi Fakhriadi, Lenie Marlinae, Fauzie Rahman, Dian Rosadi, Idham Azhari

433. Support and Self Efficacy of Tuberculosis Lung Clients: Literature Review 1949
Ikbal Fradianto, Astuti Yuni Nursasi

434. Comparison of Child Development between Aterm and Premature Birth at Age 2-3 Years Old in Kabupaten Probolinggo, Indonesia.....1954
Innas Tiara Ardhiani, Ahmad Suryawan, Martono Tri Utomo

435. OCOP "One Caregiver One Pregnancy" Intervention to Increase Knowledge, Attitude and Family Facing Practices in Pregnancy Care 1959
Ita Rahmawati, Anies, Sakundarno Adi, Cahyono Hadi

436. TB Treatment and Multidrug-Resistant of Tuberculosis (MDR-TB) in Central Java of Indonesia: A Case-Control Study.....1965
Noor Alis Setiyadi, Wongsa Loahasiriwong, Bhisma Murti, Teerasak Pajan, Kritkantorn Suwannaphant

437. The Effectiveness of Northeast Thai Local Dance (Champasri) Training for Risk group Type 2 Diabetes mellitus in Thai Rural Elderly Women.....1971
Nuanprang Duangsawang, Chuloporn Sota, Ampornpun Theeranut, Pongsawat Rattanasang

438. Health Education in Increasing Prevention Behavior of Dengue Hemorrhagic Fever in Families at Gubeng Village, Surabaya, Indonesia 1977
Nur Hasanah, Indriatie

439. Effectiveness of Eduche Method (Education Card Healthy) Reducing the Event of Osteopenia in Adolescent Private Vocational School, Martapura River Region 1982
Atikah Rahayu, Fauzie Rahman, Fahrini Yulidasari, Meitria Syahadatina N, Dian Rosadi, Nur Laily, Hadianor

440. Analysis of Fish Derived Protein Intake Adequacy and Cultural Factors and its Correlation with the Occurrence of Stunting among Children Under Two Years Old in Martapura Riverbanks, Banjar District Area 1987
Atikah Rahayu, Fahrini Yulidasari, Andini Octaviana Putri, Nur Laily

441. Contributing Factors of Neonatal Death Frommother with Preeclampsia in Indonesia.....1992
Ernawati, Kristanti Wanito Wigati, Austana Nur Hafizh, Budi Santoso, Nursalam

442. Mental Health Nurses and Community Leaders' Roles in Mental Health Enforcement: A Phenomenological Study 1997
Nurul Arifah, Merryana Adriani, Hanik Endang N.

443. The Influence of Perceived Quality, Sacrifice and Value toward Customer Satisfaction at Inpatient Installation of Dr. Soetomo Hospital Surabaya, Indonesia 2002
Florentina Joestandari, Stefanus Supriyanto, Joni Wahyuhadi, Ade Nurma Ruditya, Alexander Patera Nugraha

444. Assessment of Health Knowledge on Pregnancy, After Delivery and Newborn Baby Danger Signs among Migrant Mothers in Tak Province at Thailand-Myanmar Border.....2006
Nyunt Naing Thein, Wongsa Laohasiriwong, Aung Kay Tu, Thin Thin Soe

445. A Prototype System for the Analysis of Sentiment Regarding Drug and Food Issues in Indonesia.....2011
Oke Dwiraswati, Kemal N. Siregar

446. Reconstruction of Groin Defects Using the Extended Dissection Technique of the Gracilis Myocutaneous Flap.....2017
Omar Amr Khattab, Magdy Ibrahim El Sherbiny, Mohammed Ahmed Rifaat, Abdel Hamid Hussein Ezzat, Medhat Mohamed El Sebaii

447. Comparative Evaluation of Plaque Removal Efficacy of Plaque-Indicating Dye Dentifrice Vsnon-Dye Dentifrice in Enhancing Oral Hygiene among Orthodontic Patients. A Double Blind Randomized Clinical Trial.....2022
Priyanka Shenoy B., P. Jayashri

448. Prevalence of Disability in Uttar Pradesh: A District-wise Study.....2028
Ravi Prakash Jha, Krittika Bhattacharyya, Durgesh Shukla, Nisha Tiwari, Pawan Kumar Dubey

449. Lumbosacral MRI Findings in Chronic Lower Back Pain 2035
Kermanj Ismail Bakr, Israa Mohammed Sadiq, Saman Anwer Nooruldeen

450. Spatial Association Patterns of Geographic Factors and Opisthorchis Viverrini Infection in the Northeast of Thailand 2041
Kittipong Sornlorm, Wongsa Loahasiriwong

451. The Effects of Cigarette Smoke on Serum Immunoglobulin Levels of Patient with Chronic Periodontitis (Comparative Study).....2046
Lekaa M. Ibraheem, Ziyad Nizar Al-Talib, Ayat M. Dhafer

452. Adequacy Level of Energy and Nutrients and Nutritional Status of School-Aged Children with Working Mothers were Lower than those with Non-Working Mothers 2051
Lilik Kustiyah, Novia Purnawati, Naufal Muharram Nurdin

453. Spatial Study of Malaria Events and the Effect of Plasmodium SP Density. Against Anemia, Thrombocytopnia and SGPT/SGOT in Malaria Patientsin Southeast Minahasa District 2017 2057
Elne Vieke Rambi, Joy V.I. Sambuaga, Linda Augustien Makalew

454. Silver Nanoparticles that Synthesis by Using Trichoderma Orientlae and Evalute Antifungal Activity.....2063
Liqaa Y. Mohsen, Frial Gemeel Abd, Wameedh A.K. AL-Yasari

455. Correlation Between the Level of Milk Urea Nitrogen (MUN) when Insemination with Pregnancy Rate and IGF-1 Profile on Frisien Holstein Dairy Cow 2069
M. Ardiansyah, Tita Damayanti, Tri Wahyu Suprayogi, Imam Mustofa, Ismudiono, Wurlina

456. Anxiety and its Relationship of Scoring Skill on Football Young Players 2074
Mahmoud Abdul Jalil Abdul Zahra Tamimi, Imad Nasser Hussein, Fadhil Breesamshair

457. Assessment of Iron Chelation Therapy Compliance among School Age Children with Thalassemia 2078
Marwa A. Abdel Rahman, Azza A. Attia, Mona K. El Ghamrawy, Asmaa M. Hassan

458. The Relation between Health Literacy and Cataract Screening in Elderly People, Kalasin Province, Thailand 2084
Metinee Methaneedol, Chulaporn Sota, Olan Suwan-apichon

459. Study of Dental Enamel Ions (ca^{+} & sr^{+}) Using XRF Device-After Bleaching 2090
Mhd. Salem Rekab, Raian Alzoaabi

460. Radiographic Evaluation of Supporting Structures Around Mini Implant Retained Over Denture Utilizing Three Different Denture Base Materials.....2094
Moataz Alhosainy Hassan, Amr Mohamed Ismail Badr, Gehan Fekry Mohammed

461. Using of Omega 3 to Reduce the Toxic Effect of Antituberculosis Therapy on Hepatorenal Function and Some of Blood Parameters of Albino Male Rats.....2100
Moayad Mijbil Ubaid

462. Evaluation of Antimicrobial Effect of Conventional Calcium Hydroxide, Calcium Hydroxide Nanoparticle and Combined Calcium Hydroxide with Silver Nanoparticle as Intracanal Medication against Enterococcus Faecalis 2107
Mohamed Salah Mohamed Fahmy Ali Hegazi, Magdy Mohamed Ali, Reham EL Sayed Hassan

463. Expression of Amylin and Preptin in Iraqi Patients with Type 2 Diabetes Mellitus.....2113
Mohammed I. Hamzah, Israa A. Abdul Kareem, Mohammed ALbayati

464. Impact of Occupation and Lifestyle on Prevalence of Non-Specific Low Back Pain among Common Population: A Cross-Sectional Study 2118
Mohan Kumar. G., Jibi Paul, Sundaram M.S., Mahendranath P., Priya C., Premnathmargabandhu

465. Gene Analysis Polymorphisms INSR and Level SHBG, as Risk Factors in Polycystic Ovary Syndrome (PCOS) in Madurese.....2124
Zakkiyatus Zainiyah, Budi Santoso, Soetjipto, Ni Wajan Tirtaningsih, Harianto Notopuro, Aulani 'am

466. Accuracy of 3D Ultrasound in the Diagnosis of Uterine Pathology in Patients with Postmenopausal Bleeding.....2128
Nihal M. El-Demiry, Hassan M. Gaafar, Mohamed F. Ibrahim, Hany M. El-Didy

467. Antibacterial Activity of Zinc Oxide Nanoparticles on the Growth of Enterococcus Feacales, Candida and Total Root Canal Microbiota (in Vitro Study).....2134
Salah A. Hadi, Abbas S. Al-Mizraqchi

468. Behavioral Risk Factors Associated with Intestinal Parasitic Infestations among Children in Rural Areas2140
Samar G. Selim, Azza A. Attia, Sanaa A. Mahmoud, Azza I. Ismail

469. Legal Perspective about the Management of Fishery and Marine Investment Management in Indonesia ..2146
Samsul Wahidin

470. Evaluating the Setup Uncertainties by Different Registration Method in 3DCRT CA Breast Patients Using Onboard Cone Beam CT 2151
Sarath S Nair, Meena Devi, Krishna Sharan, Jyothi Nagesh, Shambhavi C, Sajeesh S Nair

471. Effect of Coordination Training on the Ability to Distribute Attention in Children with Different Types of Nervous System 2156
Georgiy Georgievich Polevoy

472. Molecular Characterisation of B-Casein Gene in Cattle Breeds of Kerala (Genetic Polymorphism and Comparative Analysis of β-Casein (Exon 7) Gene in Crossbreed and Vechur Cattle) 2161
Pranamya C. Haridas, Varuna P. Panicker, K.K. Jayavardhanan, Raji K.

473. Participation in Student Group with Awareness of Aids and Drugs (Kspan) Associated with Knowledge of HIV & AIDS among Junior High School Students in Denpasar, Bali, Indonesia 2165
Putu Erma Pradnyani, I. Gusti Ngurah Edi Putra, Ni Luh Eka Purni Astiti

474. Measurement and Simulation of Noise in Manufacturing Industry in Malang City, Indonesia 2170
Qomariyatus Sholihah, Dewi Hardiningtyas, Ishardita Pambudi Tama, Oyong Novareza, Sylvie Indah Kartika Sari

475. Evaluation of Serum Thyroid Hormones and its Effect/Complications During Pregnancy 2176
Raakad Kamel Saadi, Mohammed Mohammud Habash

476. Comparative Study between Mesh Repair Versus Mayo's Repair in Surgical Treatment of Paraumblical Hernia 2180
Rabah Ali Hussein, Basim Ghaib Hussein, Jameel I. Azzawi

477. The Relation between Bullying Workplace, Organizational Support, and Work Engagement as perceived by Staff Nurses 2184
Rasha Mohamed Nagib Ali, Ebtsam Ahmed Mohamed

478. Socioeconomic Disparities in Hospital Utilization among Elderly People in Indonesia 2192
Ratna Dwi Wulandari, S. Supriyanto, Bagus Qomaruddin, Agung Dwi Laksono

479. To Compare and Determine the Presence of Voids in Calcium Hydroxide, Epoxy Resin, and Tricalcium Silicate when Used as a Sealer in Single Cone Obturation Technique-An in Vitro Study 2197
S.V. Satish, Krishnaprasad Shetty, Jintu C. Thomas, Rathnakar P., Jwala Chaitanya, Alexander M. Luke

480. Impact of Fertilization Rate on ICSI Outcome and Pregnancy Rate for Unexplained Subfertile Couples 2202
Saad Mashkoor Waleed Al-Zaiyadi, Abdulhasan Mahdi Salih, Iqbal Ajrash Sabr, Sahib Yahia Al-Murshidi, Ali B. Roomi, Athraa Mohammed Dheyaa, Mohammed Kadhim Al-koofee

481. Development of Score Computation Concept of Desirable Dietary Pattern as a New Approach for Measurement of Consumption Quality 2207
Sabila Fabi Hanida, Dadang Sukandar, Hidayat Syarief

482. Parental Style and Its Relation to Adolescents' Self-Concept and Depression 2212
Safaa Mohammed Zaki, Manal Hassan Abo Elmagd, Nagat Farouk Abo Elwafa

483. Leader Empowering Behavior and Faculty Stress and their Relationship to Job Satisfaction among Faculty Staff....2220
Safaa Mohammed Zaki, Rasha Mohammed Nagib, Ebtsam Ahmed Mohammed

484. Diagnostic Study and Some Pathological Aspects of Parasites Associated with Appendicitis in Al-Najaf Al-Ashraf Governorate....2228
Sahira Ayed A. Al-Musawi

485. Supporting Factors that Influence of Mental Health Cadres in Implementing the Role in Wonokromo Village Surabaya....2232
Sahriana, Merryana Adriani, Hanik Endang Nihayati

486. Organoleptic Quality of Nugget Products Seluang Fish and Gabus Fish with Tempe Formulation as Food Products of Protein Sources for Toddler Kep....2237
Yasir Farhat, Ermina Syainah, Sari Novita, Niken Widyastuti Hariati

487. Association between Social Capital, Mental Health and Quality of Life among Migrant Workers in Myanmar....2242
Yi Myint Swe, Kittipong Sornlorm, Wongsa Laohasiriwong

488. Evaluation of Implant Stability of Supported Mandibular Overdenture Retained by Telescopic Crowns Over Screw Retained and Self-locking Conical Abutment Connection....2248
Shaima'a Ahmed Radwan, Ahmed Gamal Ahmed Hassan, Emad M.T. Agamy, Gehan Fekry Mohammed

489. Stress Factors Influence on the Male Health in Crime an Republic....2253
Sukhareva I.A., Tretyakova O.S., Rybalko O.N., Shanmugaraj K., Keerthanaa B.

806. A Study on Clinical Features and Dermatopathology of Palmar Lesions 3858
Pappuri Keerthana Bhaskar, Jayakar Thomas

807. Common Dermatoses with Palmar Lesions....3860
Pappuri Keerthana Bhaskar, Jayakar Thomas

808. A Comparitive Study of Serum Zinc Level in Male and Female of Febrile Seizure Patients....3862
Dunnuthala Sreenivasulu Reddy, P. John Solomon

809. A Prognostic Study of Diagnostic Laparoscopy in Chronic Abdominal Pain at SBMCH....3866
A.Muzamil Ahmed, Chinni Vikram, R.G.Santhaseelan

810. A Study on Age and Sex Demogrpahics in Unstable Pelvic Fractures....3869
Arshad A.R, M.R. Rajashekar, Srinivasan

811. A Study on Dermatoglyphic Pattern in Palmar Lesions 3873
Sruthy.SR, Jayakar Thomas

812. A Study on Functional Outcome of Surgical Mangement in Unstable Pelvic Fractures....3876
Arshad A.R, M.R. Rajashekar, Srinivasan

813. Alopecia Areata An Over View....3882
Kovi Sneha, Jayakar Thomas

814. Age and Sex Distribution of Patients of Giddiness with Significant Findings on MRI 3886
Amish Aggarwal, I. Venkatraman, M. Prabakaran

815. Evaluation and Description of Colorectal Pathologies Using CT Colonoscopy 3890
Beno Jefferson, I.Venkatraman, M.Prabakaran

816. Evaluation of Self-Medication Practices in Urban Area of Kancheepuram District, Tamil Nadu 3895
V.Aljin, Savitha A K, S. Suthanthira Kannan

817. A Study of Airtraq Optical Laryngoscope for Intubation in Adult Surgical Patients, A Prospective Randomized Controlled Study....3901
Jayakar Thomas, K. Manoharan

818. A Study of Injection 0.75% Ropivacaine for its Duration of Anaesthesia / Analgesia in Transversus Abdominis Plane Block for Unilateral Inguinal Hernia Repair Under Ultrasound Guidance 3906
Dunnuthala Sreenivasulu Reddy, P. John Solomon

819. Ki-67 Proliferative Marker in Thyroid Lesions 3911
Prabhu K, Archana Rajasundharam, Jayakumari.S, Durga Devi.G

820. To Compare the Side Effect Profile of Azithromycin Pulse Therapy with Doxycycline in Acne Vulgaris Treatment: An Open Labelled, Randomised , Parallel Group, Hospital based Study 3917
P. Mohan Kumar, Savitha A K, S. Suthanthira Kannan

821. Role of MRV in Cerebral Venous Sinus Thrombosis..... 3923
Revathy Pradeep, W.M.S.Johnson, Vathsala Venkatasan, Kavimani

822. Serum Hepcidin as a Marker of Anemia in Chronic Kidney Disease..... 3928
Jyothi Elizabeth Roy, B. Shanthi, V.S. Kalaiselvi

823. Serum Hepcidin Levels in Chronic Kidney Disease..... 3934
Jyothi Elizabeth Roy, B. Shanthi, V.S. Kalaiselvi

824. Serum Zinc Level in Children with Febrile Convulsion in Comparison with Normal Children..... 3938
Dunnuthala Sreenivasulu Reddy, P. John Solomon

825. Serum Zinc Level in Children with Febrile Convulsions in Comparison with Febrile Children without Convulsions 3941
Dunnuthala Sreenivasulu Reddy, P. John Solomon

826. Sex Distribution of Padindiabetic Patients..... 3944
Rudach Mitul, V.Padma

827. Assessment of Socio-Demographic Characteristics and Immunization Status of Under-Five Children in An Urban Area of Kancheepuram District 3948
Arshad A.R, M.R. Rajashekar, Srinivasan

828. Sonological Evaluation of the Clinically Negative Axilla in Women with Breast Cancer 3956
Shreya Rajkumar, P.Darwin, C.T.Karthikeyan

829. Specificity and Sensitivity of Ultrasound and Mri in the Diagnosis of Unicornuate Uterus 3960
D. Prabu, T.Ramachandra Prasad, M.Prabakaran

830. Spectrum of MRI Findings in Patients of Giddiness 3963
Amish Aggarwal, I. Venkatraman, M. Prabakaran

831. Prevalence of Self-Medication Practices in Urban Area of Kancheepuram District, Tamil Nadu..... 3968
D. Prabu, T.Ramachandra Prasad, M.Prabakaran

832. A Study on Socio Demographic Profile of the Prisoners Lodged in Central Prison, Chennai 3973
Dunnuthala Sreenivasulu Reddy, P. John Solomon

833. Crouzon Syndrome – A Case Report..... 3977
Shanthi Ramesh, Sundari S

834. Acute Phenytoin Intoxication In A 4-Year Old Mimicking Viral Meningo-Encephalitis 3979
Shachi Bhanuda, Ravanagomagan, Jagadeeswari, Sundari S

835. Evaluation of Anemia in Pregnant Mothers in Correlation with Anthropometry Measures in Tertiary Care Hospital..... 3982
K. Saraswathi, Ritu Bawa, Nirupa.S.

836. A Various Etiologies of Intestinal Obstruction – A Case Series 3986
V.Naveen Kumar, S.Karthikeyan, K.S.Ravishankar

837. Evaluation of Non Immune Mediated Thrombocytopenia in Children at Tertiary Health Care Center, Chennai..... 3990
Tirumala Kanakadurga Sripati, Govindarajan, Hemalatha ganapathy

838. Assessment of the Functional Outcome of Proximal Femoral Nailing in Unstable Trochanteric Fractures..... 3993
Mohammed Irshad Basha.A, Venkatachalam K

839. Hearing Assessment in Myringoplasty 3999
M.K. Rajasekar, Sumitha.R

840. Histomorphological Study of Lesions of Upper Respiratory Tract 4003
K.Anbukkarasi, Hemalatha Ganapathy

841. Consequence of Early Versus Late Cord Clamping on Neonatal Outcome 4008
Vimalshika R, Yuvarani R

842. Histopathological Study of Lesions of Nasal Cavity and Paranasal Sinus 4015
K.Anbukkarasi, Hemalatha Ganapathy

843. Evaluation of Incidence of Postapartum Urinary Retention in Vaginal Delivery 4020
I.Indu, K.Saraswathi

844. Postpartum Voiding Dysfunction in Vaginal Delivery: Identifying the Risk Factors 4023
I.Indu, K.Saraswathi

845. Evaluation of Incidence and Risk Factors of Postpartum Urinary Retention in Women with Vaginal Delivery..... 4027
I.Indu, K.Saraswathi

846. Isolation and Identification of Klebsiella Species from Various Clinical Samples at a Tertiary Care Hospital, South India..... 4033
Sathyavathy.K, Kiran Madhusudhan.B

847. Study on Carcinomas of Breast with Special Reference to Expressions of Vascular Endothelial Growth Factor (VEGF) 4037
C. Ramakrishnan, G. Jagan, R. Vedamanickam

848. Clinicopathological Spectrum of Breast Carcinoma Cases in Sree Balaji Medical College and Hospital 4041
V.S. Kalaiselvi, K. Sumathi

849. Expression of Ki – 67 AND Bcl – 2 in Endometrial Hyperplasia 4046
P. Shalini, Natrajan Suresh, Hemalatha Ganapathy

850. Ki – 67 Expression in Endometrial Hyperplasia 4050
P. Shalini, Natrajan Suresh, Hemalatha Ganapathy

851. KI-67 Expression in Scc of Upper Respiratory Tract 4054
K.Anbukkarasi, Hemalatha Ganapathy

852. Prosepective Study of Conchal Cartilage and Temporalis Graft in Myringoplasty 4059
M.K. Rajasekar, Sridharanarayanan. D

853. To Estimate and Compare Serumlipoprotein (a)Value in Hypothyroid Patients and Healthy Control 4063
Leishangthem Rina, B. Shanthi, V.S. Kalaiselvi

854. To Evaluate the Role of MRV in Normal Variants of Cerebral Venous Sinuses 4067
Revathy Pradeep, M. Prabakaran, I. Venkataraman

855. Ultrasound Mediated Brachial Plexus Block (Supraclavicular) 4071
A.Shanmuga Priya, Parri Madhusudhana Rao

856. Examination of Displaced Acetabular Fractures in Adults Treated qith Open Reduction and Internal Fixation 4075
Venkata Kiran Pillella, V. Vijaynarasimman Reddy

857. Functional Outcome Analysis of Open Reduction and Internal Fixation of Complex Acetabular Fractures 4080
Venkata kiran Pillella, V. Vijaynarasimman Reddy

858. Analysing the p16INK4a Stained Uterine Cervical Biopsy Specimen Histopathological Findings ... 4087
Amish Aggarwal[1], I. Venkatraman[2], M. Prabakaran[3]

859. Evaluation of the Clinical History with It's Features with the Histological Findings with P16ink4a Stained Cervical Biopsy 4092
Jyothi Elizabeth Roy, B. Shanthi, V.S. Kalaiselvi

860. Steroids for Nasal Polyposis and its Impact on Quality of Life 4098
Dunnuthala Sreenivasulu Reddy, P. John Solomon

861. The Role of Computed Tomography in Evaluation of Nasal Polyposis 4104
P. Mohan Kumar, Savitha A K, S. Suthanthira Kannan

862. Comparison between Conventional Gastric Adenocarcinoma and EBV Assocated Gastric Carcinoma 4109
Arshad A.R, M.R. Rajashekar, Srinivasan

863. Proximal Femoral Nailing in Unstable Trochanteric Fractures -Demographic Study (Age, Sex and Mode of Injury) 4116
P. Shalini, Natrajan Suresh, Hemalatha Ganapathy

864. To Study Dermoscopic Findings in Alopecia Areata 4122
Arshad A.R, Jayakar Thomas

865. A Study on Ocular Problems among Automobile Workers in Chennai 4127
Amish Aggarwal[1], I. Venkatraman[2], M. Prabakaran[3]

866. A Study on Oral Cavity Problems among Automobile Workers in Chennai 4133
Vimalshika R, Yuvarani R

867. A Study on Genito Urinary Problems among Automobile Workers in Chennai 4139
Vimalshika.R, Yuvarani.R

868. A Study on Maternal Zinc and Cord Blood Zinc Levels in Aga and SGA 4145
I.Indu, K.Saraswathi

869. A Study on Maternal Blood Zinc Level – Aga Vs Sga in Tertiary Care Hospital in Chennai 4148
I.Indu, K.Saraswathi

870. Distribution of Hypertensive Patients Associated with Development of Open Angle Glaucoma 4151
A.muzamil Ahmed, Chinni Vikram, R.G.Santhaseelan

871. Appropriation of Ocular Perfusion Pressureand its Relationship in Development of Open-Angle Glaucoma 4155
Arshad A.R, M.R. Rajashekar, Srinivasan

872. A Study on Life Style Habits of the Life Convicts Lodged in Central Prison, Chennai 4162
A.muzamil Ahmed, Chinni Vikram, R.G. Santhaseelan

873. Study of Prevalence of Non-alcoholic Fatty Liver Disease In Already Diagnosed Metabolic Syndrome Patients in Selected South Indian Population 4166
Pinky Karam, B. Shanthi, Kalai Selvi

874. Study of Lipid Profile in Metabolic Syndrome Patients 4172
Pinky Karam, B. Shanthi, Kalai Selvi

875. Study of Prevalence of Thyroid Lesions of Patients Coming to Department of Pathology, SBMCH 4177
P. Shalini, Natrajan Suresh, Hemalatha Ganapathy

876. Study of Role of Agnor in Thyroid Lesions 4184
Sathyavathy K, Kiran Madhusudhan B

877. Study of Thrombocytopenia in Adults Due to Decreased Production 4189
Tirumala Kanakadurga Sripati, Govindarajan, Hemalatha Ganapathy

878. Study to Determine the Potential Risk Categories and Risk Factors for Developing Steatohepatitis in NAFLD Cases with Metabolic Syndrome 4193
Sathyavathy.K, Kiran Madhusudhan.B

879. A Study on Risk Factors of Nocturnal Enuresis in Children 4201
R. Sushmitha, Shanthi Ramesh, Sundari

880. A Study on Clinical Profile and Risk Factors of Nocturnal Enuresis in Children 4203
R. Sushmitha, Shanthi Ramesh, Sundari

881. A Study on Clinical Profile of Nocturnal Enuresis in Children 4206
R. Sushmitha, Shanthi Ramesh, Sundari

882. Role of 3Dct in Fractures Around the Knee Joint 4208
A.muzamil Ahmed, Chinni Vikram, R.G. Santhaseelan

883. Efficacy of Metformin Monotherapy 1Gm in Newly Diagnosed Type 2 Diabetes Mellitus- A Prospective Open Label Study 4211
Hemalatha Ganapathy, Rajalakshmi.V

884. Neurostimulation Guided Brachial Plexus Block (Supraclavicular) 4215
A.Shanmuga Priya, Parri Madhusudhana Rao

885. Occurrence of Euthyroid Sick Syndrome in Acute Myocardial Infarction and their Prognostic Significance 4219
Nithesh Kumar A, Noorul Ameen

886. Occurrence of Euthyroid Sick Syndrome in Acute Myocardial Infarction and their Duration of ICU Stay 4223
Nithesh Kumar A, Noorul Ameen

887. Occurrence of Euthyroid Sick Syndrome in Acute Myocardial Infarction and Their Relation to Type of Myocardial Infarction 4227
Durga Devi G, Rahe R

888. A Various Outcomes of A Patients with Acute Intestinal Obstruction – A Case Series 4231
V.Naveen Kumar, Bharathi Raja, K.S.Ravishankar

889. Comparision of Pre-Operative & Post-Operative Pain Grading after Diagnostic Laparoscopy in Patients Presenting with Chronic Abdominal Pain at SBMCH 4235
A.Muzamil Ahmed, Chinni Vikram, R.G.Santhaseelan

890. Comparison of Fine Needle Aspiration Cytology with Histopathology in Thyroid Swellings & its Diagnostic Accuracy 4237
Mary Lilly.S Ramamoorthy.V

891. Efficacy of Autologous Platelet Rich Plasma Injection in Lateral Epicondylitis and Plantar Fasciitis 4241
Vivek K, Padma V

892. Functional Consequence of Antegrad Unreamed Humeral Interlocking Nailing in Adults 4246
P Vivekanandhan, Venkatachalam K

893. To Study Clinical Manifestaion of Hyperandrogenism in Adult Male with Acne 4250
Paavai S, Thomas Jayakar

894. Malignancy in Solitary Thyroid Nodules: A Study on Incidence & Evaluation of Risk 4253
Padma V Ramakrishnan C

895. Antimicrobial Activity and Surface Characterization of a Denture Relining Material Coated with ***Reynoutria Elliptica*** Extract....4256
Song-Yi Yang, Min-Kyung Kang

896. The Effect of Simulation-based SBAR Education Programs of Nursing Students....4262
Min-Jeong Chae

897. Study of Change of Character of Nursing Students through Team-Based Learning (TBL) Humanities Class....4268
Ok Hee Koo

898. A Longitudinal Analysis on Ethical Values of Nursing Students....4274
Myung Sook Kim, Ok Hee Koo

899. Factors Influencing Depression in Postmenopausal Women by Subjective Health Awareness....4280
Myoungjin Kwon, Sun Ae Kim

900. The Influence of Nursing Students' Self-Esteem on Depression: Mediation Effect of Rejection Sensitivity....4287
Yun Ju Lee, *Sung-Yun Ahn*

901. Comparison of knowledge and Performance after Cardiopulmonary Resuscitation Training at 3, 6, 9 Months....4294
Tai-Hwan Uhm, Jee-Hee Kim, Sang-Kyu Park, Eun-Jwoo Kwag, Young-Lim Ham

902. Factors Related to Early Childhood Caries Using Infant Examination....4300
Youn-Soo Shim, So-Young Park, Jong-Bin Kim, Ji-Sun Shin, So-Youn An

903. Effects of a Mixed Herbal Extract on the Corpus Cavernosum of Male Rabbits....4306
Sun Young Park

904. A Study on the Effects of Eucommiae Cortex on Male Osteoporosis....4312
Ho Hyun Kim, Sun Young Park, *Ki Bong Kim, Sang Hyun Ahn*

905. Association between Homeboundness and Depression in the Elderly Population According to Gender....4318
Eun hi Choi, *Hye-sun Jung*

906. The Study for Reform of the Korean Care Helpers National Licensing Examination....4324
Sung-HeeBaik, Jae-Kwan Koo, Hyun-Gyung Kim, Tae- Sik Lee

907. The Effect of Health Behavior, Depression and Stress on Metabolic Syndrome in Korean Adults....4330
Kyung-Shin Paek

908. A Prediction Model of Suicidal Ideation among Male Elderly Living Alone in Korea....4336
Sun Kyung Kim

909. The Effect of an Oral Self-Care Intervention Program on the Oral Care of Diabetic Elderly....4343
Yeo-Ju Kim, Jung-EunPark, Kyung-Sook Jo, Keun-YooLee, Jong-HwaJang

910. The Effects of Positive Thinking and Stress on the Ability for Interpersonal Relationship in Nursing Students 4349
Young-Sook Kwon

911. Effects of the Child -Woman Health Nursing Convergence-based Simulation Practice Program on the Critical thinking, Communication Competency, Learning Flow, Clinical Judgment for Nursing Students 4356
Heejeong Kim, *Misun Yoon*, *SoyounYim*

912. Development of Career Counseling Program for Nursing University Students according to Adler's Theory 4361
Hwa jin Lee

913. Factors Affecting the Positive Perception of Marriage of Unmarried Men and Women in South Korea 4367
Hye-gyeong Cha

914. A Study on the Influence of Nursing College Student's Service Satisfaction on Moral and Psychological well-being 4374
Min-Suk Kim, Soon-Young Yun

915. Factors Influencing the Preparation of Manuals for Emotional Labor and the Provision of Programs Depending on Type of Trade in South Korea 4381
Hye-sun Jung, Eun hi Choi, Sewan Oh

916. Relationship Between Hyperglycemia and Periodontal Symptoms in Korean Type 2 Diabetes Mellitus Patients Aged ≥ 50 Years 4387
Jun-Seon Choi

917. Affecting Factor of Nursing Professionalism among Nurses in Geriatric Hospitals 4393
Jin-hee Kwon, Bong-sil Choi

918. An Analysis of the Need For Aid Tools in Dementia Patients: Focusing on the Normal Elderly, Dementia Patients, and Caregivers of Dementia Patients 4399
Hwan-Hee Kim

919. The Effects of a Brain-Activating Dementia Prevention Program on the Elderly: Improving Cognitive Capacity, Depression, and Quality of Life 4406
Hwan-Hee Kim

920. The Effect of Participation of Clinical Dental Hygiene Care Program on the Level of Dental Fear in Some Adults 4412
Jung-Eun Ha, Ki-Hun Ye

921. The Effects of Simulation-Based Education Program on Communication Ability, Problem Solving Ability and Critical Thinking among Nursing Students 4418
Chung-Sin Shim, Seung-Ju Kang, Young-Me Kim, Hae-Jin Shin

922. The Factors Affecting Satisfaction with College Life among Nursing School Students 4424
Joo-Young Lee, Do-Young Lee

923. Effects of Occupational Therapy using CO-OP on Activities of Daily Living and Balance Ability of People with Intellectual Disability using Day care Center 4431
Won-Jin Bae, *Nam-hae Jung*

924. Relations on Communication Competence, Job Satisfaction and Nursing Performance of Clinical Nurse 4436
Eun-Hong Kang, Sung-Ja Yoon

925. Associated Determinants of Successful Ageing among Older Koreans : from the 7th KNHANES ... 4442
Hye-Sook Choi, Moon-Hee Kwon

926. A Study on Attitude of Menstruation, Menstrual Discomfort and Coping Method in Female College Students 4450
Hyun-Jung, Jang

927. Factors Affecting the Occurrence of Work-related Accidents during Night Shifts 4456
Miyoung Lee, *Eun-Hi Choi, Minkyoung Lee*

928. A Case Study on the Effects of Pelvic Exercise Using Virtual Reality on Balance and Gait of an Incomplete Spinal Cord Injury Patient 4463
Je-Hyeok Lee, Beom-Cheol Jeong

929. Relationship between Water intake, Xerostomia, Halitosis, Stress and Salivary Cortisol in the Elderly 4469
Hye-Young Joung, *Yeonim Choi*, *In-Hoo Jung*

930. The Effects of Applying Havruta Learning Method in Nursing Classes 4475
Eunae Burm, Ae-Sook Choi, Jeung-Ah Gu, Hyun-Gyung Kim, Eunju Lee, Oonhee Yee

931. Nurses' Perception of Nursing Malpractice Liability Insurance 4481
Mi Joon Lee, *Mi Yeon Lee*, *Hye Won Min*

932. Correlations of Mothers' Oral Health Knowledge and Verbal Oral Health Literacy with Children's Oral Health Behaviors in a Daycare Center 4487
Jong-HwaYum, Hye-jin Kim

933. Correlation between Pelvic Tilt Angle and Erector Spinae 4495
Seong-Jun Choi, Min-Geong Park, Soo-In Lee, Dong-Yeop Lee, Jae-Ho Yu, Jin-Seop Kim, Ji-Heon Hong

934. A Study on Change of Pennation Angle based on Gastrocnemius Stretching and Additional Muscle Exercise 4501
Su-Hyeon Park, Su-Min Oh, Yun-Ju Jo, Dong-Yeop Lee, Jae-Ho Yu, Jin-Seop Kim, Ji-Heon Hong

935. Antioxidant and Whitening activity of Korean Mistletoe (***Viscum album Coloratum***) Extract 4507
Seon-Hee You, *Mi-Yun Yoon*, *Ji-Sun Moon*

936. Heavy Metal Inspection of Essential Oils for Aromatherapy 4513
Mi-Ra Jeong, *Yang- Yi Lim*

937. Effects of Training of Activities of Daily Livings on Occupational Performance and Motivation in People with Intellectual Disability using Day Care Center 4519
Nam-hae Jung

938. Evaluation of Accuracy of Stereotactic Body Radiotherapy Using 3D Moving Phantom 4526
Gha-Jung Kim

939. A Study on Perception of Nursing School Students on Long-Term Care Hospital 4532
Sunyoung Jang

940. Related Determinants of Eye Disease, Cataract, Glaucoma and Macular Degeneration Among Adults of Korea: from the 7thKnhanes 4537
Hye-Sook Choi, Moon-Hee Kwon

941. Change of Histological Shape and Gene Expression of Thymosin β_4, c-Myc, Erb-B_2 and TGF-$\beta_1$byAcute Hepatotoxicity 4544
Jean-Soo Kim, Dong-Yeop Lee

942. Factors Associated with Psychological Well-being among Korean Nursing students 4550
Hyunjin Lee, Kawoun Seo

943. Effects of Resilience and Authentic Leadership on Job Embeddedness of Clinical Nurses in Korea. 4557
Jeonghwa Cho, Junghee Yu, Kawoun Seo

944. The Factors Affecting Unmet Medical Needs of the Elderly Aged more than 65 Years 4563
Ju-Youn Hong, *Yun-Hee Jeon*

945. Novel Approach on the Introduction of Clinical System for the Prevention of Heart Arrhythmia 4570
Seong-Ran Lee

946. Analysis of Experimental Data for Improving Bone Density in Osteoporosis Women Over the Age of 50 4575
Seong-Ran Lee

947. Effect of Quality Management Initiative to Improve Patient Identification Behavior of Nurses 4581
Young Mee Kim

948. Difference of Medial Elbow Joint Space According to Load and External Rotation Angle 4587
Hyeon-Sik Hong, Su-Mi Bang, Min-Seon Choi, Ji-heon Hong, Jin-Seop Kim, Dong-Yoep Lee, Jae-Ho Yu

949. Antimicrobial Effect and Physical Properties of ***Paeonia Lactiflora*** Coated on the Denture Base Resin 4593
Yu-Ri Choi, Min-Kyung Kang

950. Integrative Literature Review on Resilience of Family with the Elderly Dementia 4598
DooRee Kim, *Jeoung A Kwon*, *Eun Kyoung Han*

951. Physical, Biological and Antimicrobial Properties of Polymethyl Methacrylate Coated with ***Cnidium Officinale*** Extract 4603
Myung-Jin Lee, Min-Kyung Kang

952. Surface Characterization and Antimicrobial Efficacy of Denture Base Resin Coated with ***Glycyrrhiza uralensis extract*** 4609
Yu-Ri Choi, Song-Yi Yang, Myung-Jin Le, Min-Kyung Kang

953. Relationship between Critical Thinking Disposition, Self-efficacy, Self-esteem and Optimism of Nursing Students 4615
Bo Ram Choi, JungIm Kim

954. The Influence Factors on the Stages of Exercise Behavior Change of Female Nursing University Students in Transtheoretical Model 4622
Hyea-Kyung Lee

955. Study on Subjectivity of Nursing Students toward Patient with Dementia 4629
Sunyoung Jang

956. The Effect of Resilience and Nursing Professionalism on the College Life Adaptation of Nursing Students 4634
Miyoung Lee, Mi-Kyoung Lee, Youngshin Song

957. The Effect of Exercise-Induced Hyperthermia on the Achilles Tendon 4641
Eui Chan Jang, *Hee Jeong Kim*, *Hyeong Seok Jeong*

958. Relationship among Nunchi, Communication Skills and Critical Thinking Disposition in Nursing Students 4647
Sunsook Sim,*Miran Bang*

959. Effect of Combined Exercise on Bone Related Factors, Cardiovascular Function and Hemodynamic Change in Emerging Adulthood 4653
Hoe-WonKim, Sun-Ho Kim

960. Relationship among Sleep Quality, Fatigue, Resilience, and Nursing Performance Ability in Shift Work Nurses 4659
*Sunsook Sim***,** *Sangbok Lee***,** *Miran Bang*

961. The Effect of Balance Capability on Cold Application of the Soles 4664
Myung-Chul Kim, Hang-Sik Park, Hae-In Kim

962. Path Analysis of Social Pre-Parental Role of Unmarried Men and Women 4670
Meera Park, *Nam Joo Je*

963. Effects of Planck Exercise on the Cranio-vertebral Angle, Round shoulder Postureand Forward Head Posture 4678
Sang-Ho Lee, Won-Jong Yu, Dong-Yeop L ee

964. Normative Study of Attention Tests in a Computerized Comprehensive Neurocognitive Function Test in Adults 4684
Soo-Yeon Kim, Jong-Hoon Moon, Jin-Hwa Jung

965. A Study on the Enhancement of Male Reproduction Function due to Eucommiae Cortex 4691
Sun Young Park, *Sang Hyun Ahn*

966. Beneficial Effects of Alpiniae Oxyphyllae Fructus (AOF)on Male Reproductive Function.....4696
Ho Hyun Kim, Sun Young Park, Ki Bong Kim, Sang Hyun Ahn

967. The Relationship between Resilience and Self-Identity: A Latent Growth Model 4701
Kyoung Eun Kim, *Jung-Hyun Choi*

968. A Comparison of Angle of Active Knee Extension During Various Modified Contract–Relax PNF Technique : A Cross-Over Study 4707
Jong-Hoon Moon, *Sung-Jin Heo*, *Jin-Hwa Jung*

969. Effects of Repetitive Arm Cycling Exercise on Post-Stroke Upper Limb Function and Satisfaction: A Preliminary Study.....4713
Jong-Hoon Moon, *Sung-Jin Heo*, *Jin-Hwa Jung*

970. A Study on Effect of Massage Therapy on Physical Changes.....4720
Su-Jeong Ryu, *Myung-Sun Lee*

971. A Study on the Resident Radiation Protection Methodology from the Nuclear Emergency: Focused on the Disaster Vulnerable Population 4726
Sang Tae Kim, Seokki Cha, Minsu Cho

972. The Effect of Employee Silence on Organisational Commitment and Turnover Intention of the Public Sports Organisation in South Korea 4731
Sung-Duck Kim, *Jongchul Park*

973. A Study on Development of Nursing Curriculum Customized to the Clinical Field 4737
Do-Young Lee, Jin Hee Park

974. Changes in Balance and Proprioceptive Sensation According to Trampoline Exercise Posture and Resting Time 4743
Da-Hee Kwon, Tae-Min Kim, Ji-Hwan Park,Dong-Yeop Lee, Jae-Ho Yu, Jin-Seop Kim, Ji-Heon Hong

975. Emotion Classification from EEG Brain Signal using Weighted Stacking of Ensemble Classifiers...4749
Pradeep Kumar Mallick, Shruti Mishra, Sandeep Kumar Satapathy, Amiya Ranjan Panda

976. Evaluate the Efficacy of C Arm in Measuring the Range of Dynamic Movement in Temporo-Mandibular Joint 4753
Sanat Kumar Bhuyan, Ruchi Bhuyan, Manoj Kumar Sahu, Jayasankar HP, Sidhant Bhuyan, Mihir Narayan Mohanty

977. Correlated Levels of Anti-Inflammatory Interleukins (IL-4 and IL-10) with Allergic Conjunctivitis (AC) in Iraqi Patients.....4758
Nihad Khalawe Tektook, Osamah Jihad Abdul Qader

978. The Role of Zinc Sulfate in Subchronic Cadmium Chloride Toxicosis in Male Mice.....4764
Ahmed D. Khudhair, Duraid A. Abass

979. Correlation Between Glugometer and Laboratory Methods in Measuring Capillary and Venous Blood Glucose Levels in Type 2 Diabetic Patients.....4772
Ahmed Mohammed Alwan, Hamza Ali Saleh

980. Effect of ***Toxoplasma gondii*** Infection on DNA Sequence among patients with Testicular Cancer. 4776
Ammer Abd. Mohammed, Rana S. Nasir

981. Correlated level of interleukin (IL_10) with Allergic Rhinitis and Effect Study of Steroid in its Levels 4780
Anas Ahmed Saleh, Inas Abd Al Majed Rasheed

982. Association of Hyperuricemia with Knee Osteoarthritis and Generalized Osteoarthritis in Iraqi Patients 4784
Abbas Hamza Zainel, Sundus Awni Wahab, Yahya Abdel Aziz Mohammed

983. Relationship Serum Thyroid Stimulating Hormone with Body Mass Index in Patients with Thyroid Disorder 4790
Athraa Fouad Kadhuim

984. The Long Term Outcome of Graft Urethroplasty by Buccal Mucosa in Penile and Bulbar Stricture. 4795
AzzawiM.Hadi, Yassir Ismael Abbass, Mazin Anwar Yadgar

985. Hardness and Roughness of Flexible Denture Base at Different Injection Time and Different Temperature 4801
Amal Abdul Latif Rashid

986. Prophylactic Antiepileptic Drugs for Intraparanchymal Hemorrhage Patients in Salah Al-Den General Hospital..... 4807
Ayied Mutob Turki, Mohamed Ghalib Zakari, Abdulsattar Hussein abdullah

987. Comparison of Prophylactic Effect of (Metoclopramide Plus Dexamethasone) And (Ondansetron) in Female Patients Underwent Laparoscopic Gynecological Surgeries 4814
Enas Ibrahim Mehdi , Abdulrahman E. Abdulsattar

988. Effect of Silver Nano-Fillers and Aging on Tensile Strength of Heat Cured Acrylic 4819
Hawraa Khalid Aziz

989. Formulation and Evaluation of Acetic Acid Lotion for the Treatment of Wound Infection 4827
Fitua Al-Saedi, Ibtihal Abdulkadhim Dakhil, Adil Hummod, QabasNather

990. Evaluation the Effects of Incorporation of Silver Nitrate on Some Mechanical Properties of Soft Liner Materials 4833
QussayAbdl-Latif Hassan, Israa Mohammed Hummudi

Insights for Pharmaceutical Manufacturers on New Age Women: Influence of Media on Purchase and Usage of Medication in India

B. Akshaya[1], Sudha Ramaiah[2]

[1]III year B.Tech–Computer Science and Engineering with Bio Informatics, School of Computing Sciences,
[2]Associate Professor, Medical and Biological Computing Laboratory, School of Biosciences and Technology,
Vellore Institute of Technology, Vellore, India

Abstract

Media is considered to be an important factor which may influence purchase behaviour. But for medicines bought without prescription of doctors there might be some other factors which the pharmaceutical companies need to probe in .This study envisage about the relationship between Media influence, Personal Reasons, Marketing factors with Brand Experience. Around 236 questionnaires were distributed to women in and around Tamilnadu in the medical shops. The findings of the study show the best relationship by applying multiple regression analysis by using Statistical Package for Social Science SPSS (21.0). The results shows that the brand experience of Indian women (between 18 to 53 years) is not related with respect to media and marketing factors but they are significant with respect to personal reasons alone. This research shall favour the pharmaceutical marketers to understand about the brand experience of Indian women.

Keywords: *Pharmaceutical Medicines, Brand experience, Personal reasons, Indian Women, Media Influence, Marketing factors.*

Introduction

According to Indian Brand Equity Foundation (IBEF), Indian healthcare sector, single highest mounting sectors will be US$ 372 billion by 2022. Indian pharmaceutical sector approximately accounts to 3.1 percent to 3.6 percent of the worldwide pharmaceutical trade[1]. The expected growth by 2025 is nearly US$100 billion. India's pharmaceutical export stand is likely to attain US$ 20 billion by 2020. For the period of April–September 2017, India exported pharmaceutical goods is worth Rs. 411.3 billion[2] . The direction of the pharmacy products is a substance of apprehension predominantly in Indian Women particularly in the age group of **28 to 48 years w**ho are termed as New Age.

Medicines without Prescription: Over-the-counter (OTC) medications, also acknowledged as non-prescription drugs, drug that can be obtained devoid of a prescription from the registered medical practitioner. These drugs are primarily used for the demeanour of the wellbeing that can be self-medicated.

OTC drugs are listed by government regulatory authorities as harmless for self-medication. According to Food and drug administration (FDA), there are surplus 300,000 OTC drug product present in the market, several familiar applications of OTC drugs are aches, itches and others.

Non-prescription drugs are most imperative and easily purchased by public as wellbeing aids for the treatment of general / mild conditions or symptomatic relief [3]. Over-the-counter drugs encompasses products like cough and cold products acne treatment to weight control products. Pharmaceutical manufacturers relied on physicians and pharmacists to offer the information about medicines to Passover to the patients,

Over-the-counter (OTC) drugs are medicines that are obtainable for sale directly to a consumer. According to the U.S. Food and Drug Administration (FDA), OTC drugs are definite as the medications that can be used safely and effectively by the general public even without a prescription.

Over-the-counter drugs are those which:

- Don't require a prescription provided by healthcare professional.
- Can be easily purchased in any stores.
- Ingredients, doses, formulations, and labelling are in substantiation with the existing monographs do not necessitate FDA review for marketing. Are used to self-treat minor symptoms / conditions that do not necessitate the advice of a physician.

The OTC drugs insist for cold, cough and allergy will engage the traditional seasonal drift, lashing a stable development during the estimated period. In such a scenario pharmacy brand should play a role in decision making .The intention is to find what predicts the brand experience .

Objectives of the Study

- To analyse the relationship between personal reasons, marketing factors and Media influence on brand experiences related to unprescribed medicines

Materials and Method

The research methodology[4] for the study is descriptive in nature.

Population: Any New age Indian women using OTC medicines (Infinite Population). **Target population:** New Age (18 to 48 yrs) literate Indian Women **Sampling Location:** Pharmacy outlets, Shopping Malls**,** Clinic/ Hospital**,** Ladies Hostels and few companies.

Sampling Element (Unit of Analysis): New Age (18 to 48 yrs) literate Indian Women based on the classified based on residence Urban, Semi Urban,Rural area of Tamilnadu **Sampling Technique:** Stratified Random Sampling (Infinite Population) and anysis will be done by statistical package for social sciences 21.0[5]

Sample Size: 236 questionnaire

The questionnaire consists of **Section A:** Consumers' demographic profile, like age, work experience, income, marital status, Number of members in family occupational sector, residence etc was the attributes listed in this section and **Section B:** This measures personal reasons, marketing factors, media influence and for purchase of branded OTC medicines the reliability of the questionnaire was more than 0.8 for all the four variables as well as for the total items [6] .

Data Anaylsis & Interpretations: To unite the independent and dependent variable a Multiple Regression analysis was performed. The items in the questionnaire was used to Compute variables done by SPSS 21.0 and four variables were created by adding the items in 7,8,9 and 10.

H_0:Brand Experience depends on Media Influence, Personal Reasons and Marketing Factors

Table No. 1 .Model Summary

Dependent variable	Independent variable
Brand Experience	Constant Media Influence, Personal Reasons, Marketing Factors
R	0.844
R Square	0.818
Adjusted R Square	0.601
F	6.836
Sig	0.000

From the above Table No.1, where the brand experience is the dependent variable, table no.1 provides inference that the ability of prediction for model was articulated by R value 0.834 and R^2 value 0.818 which shows 81.8% of variance exist in the dependent variable is from the independent variables. F-value is 6.836 showing that there exists a relationship between Media Influence, Personal Reasons, Marketing Factors with Brand Experience. The p-value is 0.000 which is <0.05 showing a significant relationship between Media Influence, Personal Reasons, Marketing Factors with Brand Experience. Hence from the above test we conclude that Media Influence, Personal Reasons, Marketing Factors Predict Brand Experience.

Table No. 2 Coefficients of the Model

Dependent Variable	Independent Variable	Unstandardized Coefficient		Standardized Coefficients	T	Sig
Brand Experience	(Constant) Personal Reasons Marketing Factors Media Influence	B	Std Error	Beta		
		23.57	2.161		10.906	.000
		.219	.084	.246	2.611	.010
		.115	.080	.153	1.425	.156
		-.011	.102	-.012	-.104	.917

From the above Table No.2, it is inferred that the beta value is 0.219 for variable 1 (Personal Reasons) and 0.115 for variable 2 (Marketing Factors) and –0.011 for variable 3 (Media Influence). There is a significant relationship between Personal Reasons[7] and Brand Experience the P value is <0.05 which is 0.010. There is no significant relationship found Influence OTC Medicine and Brand Experience since the P value is >0.05 which is 0.156. There is no significant relationship between Media Influence and Brand Experience since the P value is >0.05 which is 0.917. Thereby the final regression equation is derived by the incorporating the coefficients as follows:

Brand Experience=23.572+0.219
(Personal Reasons)
+0.115(Marketing Factors)-0.011(Media Influence)

From the above equation it is incurred that the Personal reasons is the most vital variables significantly contributing towards the brand experience of New Age Indian women[8] when they buy Medicines in Pharmaceutical outlets[9] .Chart No.1 is the histogram of the regression residuals and Chart No.2 is the P-P Plot which plots the samples in the regression line.

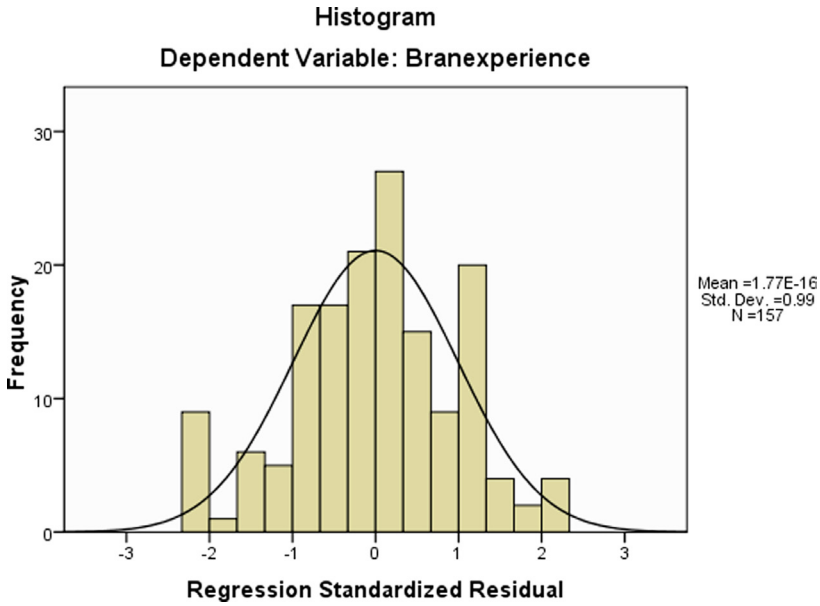

Chart No: 1 Multiple Regression

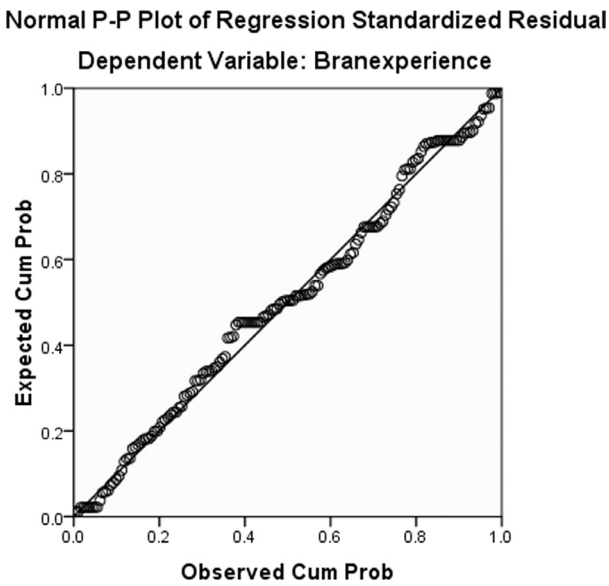

Chart No.2 P-P Plot

Conclusion

- Over all the factors for purchasing OTC is the perception about quality, Company name, brand image, No substitute, previous experience and easy to use. They are least bothered about the size or advertisement in this case.
- Personal reasons to select a branded OTC Medicine is Health Consciousness, Doctor's recommendation previously, healthy life, economical, effective and personal usage .They do not try any new product nor they are addicted to it .There by new age Indian women are health conscious to certain extent .
- The marketing factors are price and **Brand image**. They are not bothered about any sale or other patient referrals
- Television is the media which has influenced the purchase followed by magazine and banner .Then comes Websites, Newspaper and the least one is radio. There by the marketers should tap TV and print media to position their brands in the minds of new age and Gen Z Indian women.
- Spouse and parents play a vital role as Social factors followed by friends and relatives minor role for any sales representative as they do not interact directly to the consumers.
- Displays in shops and social media also do have much influence.

Conflict of Interest: The author assures that there is no conflict of Interest between any parties

Source of Funding: The study was conducted by self as part of extra learning in flexible curriculum system

Ethical Clearance: The questionnaire has statement of informed Consent for the respondents who volunteered for the study and no medication is administered to any respondent.

A Study to Assess the Effectiveness of Yoga Therapy on Menopausal Symptoms among Women in a Selected Area at Mangaluru

Amrutha V.[1], Vinaya Kumary T.[2], Janet Prima Miranda[3]

[1]MSc. Nursing, [2]Asst. Prof, [3]HOD, Department of Obstetrics and Gynecological, Yenepoya Nursing College, Yenepoya (Deemed to be University), Deralakatte, Mangaluru, Karnataka, India

Abstract

Background: Many menopausal women use complementary therapies to cope with the symptoms and yoga is one among them. The evidence suggesting that even the short-term practice of *Yoga* can decrease both psychological and physiological risk factors for menopausal symptoms.

Objectives: The experimental study assessed the effectiveness of yoga therapy on menopausal symptoms among perimenopausal women.

Materials and Method: A menopausal rating scale (10 items) was used to assess the effectiveness of yoga therapy among perimenopausal women.

Results: The mean post test score 51.3 in the experimental group were found to be lesser than the mean pre-test scores 70.0. Mean post-test scores 69.3 and mean pre-test stress scores 72.9 in the control group had some variation. In order to find the significant difference, unpaired 't' test was computed for experimental group ('$t'_{(49)} = 25.27$; $p < 0.001$) and control group ('$t'_{(49)} = -7.8$; $p < 0.001$).

Conclusion: The study concludes by showing that yoga therapy was effective to reduce some menopausal symptoms of women.

Keywords: *Menopausal symptoms, yoga therapy, women*.

Introduction

A woman's life is divided into different stages beginning with the young girl, the ancestor virgin, who moves into maturity as the mother and at the end of her child bearing years, closing in on 50, she enters the ugly phase of her life[1]. This phase is one such transitional period which brings about important changes in a woman. One of those important changes that occur in this stage of her life is menopause.

In the developed countries, mean life expectancy for women is increased from 50-81 years. The life expectancy of the population around the world is estimated to be 75 to 80 years. It is estimated that there are over 200 million menopausal women worldwide and 40 million in India. The average age of menopause of Indian woman is 47.5 years[5]

Various health problems and complication are found during peri-menopause in a woman's life. The most common menopausal symptoms include hot flushes, night sweats, fatigue, pain, decreased libido, and mood changes. These symptoms may persist for several years after attaining menopause[9].

Three levels of approaches can be considered as treatment for menopausal symptoms like life style

changes, alternative medicine, medication and surgery. Among these, lifestyle changes is a better way to treat the symptoms where as other therapies may lead to risk of different types of cancer, heart diseases and strokes among women. So the women can undergo natural therapy which also includes yoga therapy, an effective tool to reduce physical and psychological symptoms[11].

Materials and Method

Study setting and sample size: The research design selected for this study was quasi experimental non randomised two group pre-test post-test design. The study was carried out in Kotekar and Beeri area in Mangaluru taluk, Dakshina Kannada district. In the present study, samples consist of 60perimenopausal women 30 each in experimental and control group who were selected by Non probability Purposive sampling, based on inclusion criteria.

Tools and techniques: The tool consisted of demographic data and obstetric data (14items) to collect the baseline characteristics. Menopausal rating scale 10 items with 22 subheadings (r=0.791) to collect data on menopausal symptoms among perimenopausal women.

Data analysis: The data was collected after obtaining prior permission from the concerned authority to conduct the study. The participants were assured about the confidentiality of their responses. The data was analyzed in terms of objectives of the study using both descriptive and inferential statistics. The data obtained was plotted in the master sheet.

Results

Majority of the subjects,51.6% in experimental group and 60% of women in control group belongs to the age group of 46-50 years, 63.3% of participants and 45.2% in experimental group were housewife, 54.8% in experimental and 66.7% of women in control group did not have adequate information on effectiveness of yoga therapy [Table 1, Fig1].

Majority (56%) of experimental group and 73.3% of control group had marked level of symptomsThe post-test scores of present study depicted that, in experimental group and control group, all the women in experimental group and 56.7% of respondents in control group had reduced the symptoms from marked to moderate. and 43.3% had marked level of symptoms in control group [Table2, 3].

The post-test area wise mean, median and standard deviation were respectively 24.3+2.39 and 26.9+2.59, whereas in control group it was 34.4+2.47 and 34.9+2.67 in area one and two. In order to find the significant difference, unpaired 't' test was computed for experimental group ($t'_{(49)} = 25.27$; $p < 0.001$) and control group ($t'_{(49)} = -7.8$; $p < 0.001$) [Table 4, 5]

In the experimental group there is association of the pre-test level of menopausal symptoms with some of the selected demographic variables such as age ($\chi^2 = 12.44$, p=0.05), socio-economic status ($\chi^2 = 12.085$, p=0.017) and use of contraceptive ($\chi^2 = 18.596$, p=0.017) at 0.05 level of significance.

In the control group, there is association of pre-test level of menopausal symptoms with selected variable like age (χ^2=32.503, p=0.009) at 0.05 level of significance.

Table 1: Frequency distribution of women according to their pre-test level of menopausal symptoms in control and experimental group as measured by structured menopausal rating scale n = 60

Level of symptoms	Range of Scores	Experimental group		Control group	
		F	%	F	%
Asymptomatic	Score below 1	-	-	-	-
Mild	1-35	-	-	-	-
Moderate	36-70	13	43.3	8	26.7
Marked	71-105	17	56.7	22	73.3
Severe	106-125	-	-	-	-
Total		**30**	**100%**	**30**	**100%**

Table 2: Frequency distribution of women according to their post-test level of menopausal symptoms in control and experimental group as measured by structured menopausal rating scale n = 60

Level of symptoms	Range of Scores	Experimental group		Control group	
		f	%	f	%
Asymptomatic	Score below 1	-	-	-	-
Mild	1-35	-	-	-	-
Moderate	36-70	30	100	17	56.7
Marked	71-105	-	-	13	43.3
	Total	30	100%	30	100%

Table 3: Level of mean pre-test and post-test level of menopausal symptoms of women within the group n=60

Group	Mean pre-test score	Mean post-test score	Mean difference	df	Paired 't' test
Experimental group	70.06	51.33	18.3	29	25.27* P<0.05
Control group	72.93	69.36	3.6	29	2.63* P<0.05

$t_{(29)}$=2.05 *Significant

Table 4: Level of mean pre-test and post-test level of menopausal symptoms of women between the experimental and control group n=60

Group	Mean	Mean difference	df	Unpaired 't' test
Experimental group			58	7.82* P<0.05
Pre-test	70.0667	18.3		
Post-test	51.33			
Control group				
Pre-test	72.933	3.6		
Post-test	69.3667			

$t_{(58)}$ = 1.671 *Significant

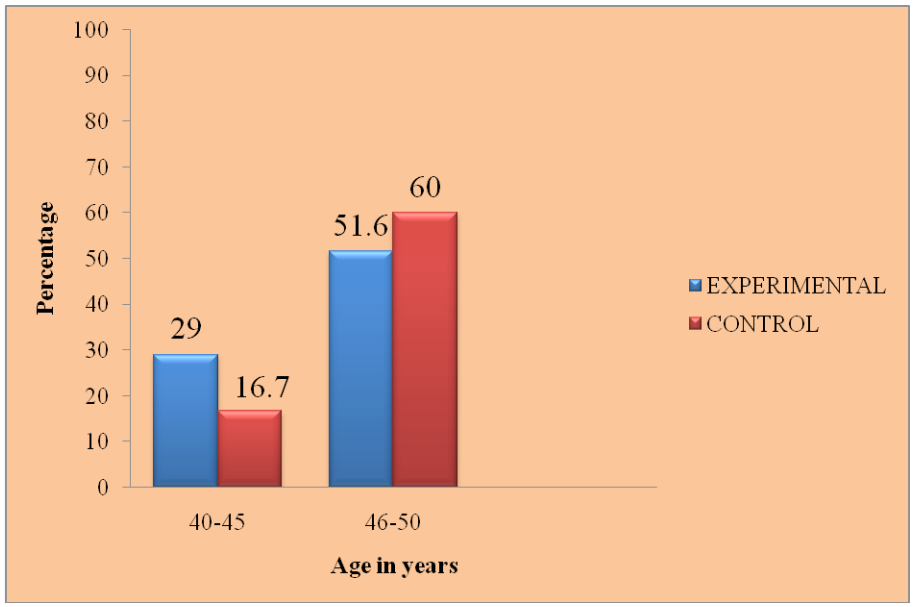

Figure 1: clustered column chart showing frequency and percentage distribution of women according to age

Discussion

The present study revealed that, in both experimental and control group, majority (51.6% and 60% respectively) of the samples were of age group 46-50 years. The study findings are supported by A cross sectional study conducted at anjarakandy, kerala revealed that the mean age of attaining menopause was 48.26 that is (44.3%). maximum number of women were educated 96.2% and 83.1% of women were home maker.

In the present study most (54.8%) of the women in experimental and in control group 66.7% of women did not have adequate information on effectiveness of yoga. A similar study was conducted at Isra university hospital, Pakistan, which was to determine the knowledge and investigate the symptoms experienced by women among 863 women of age group 42-80 years. Results showed that only 15.8% women knew about menopausal affects and symptoms while 78.8% of women had little knowledge on the same[54]

The mean post test score 51.3 in the experimental group were found to be lesser than the mean pre-test scores 70.0. Mean post-test scores 69.3 and mean pre-test stress scores 72.9 in the control group had some variation. In order to find the significant difference, unpaired 't' test was computed for experimental group ($t'_{(49)}$ = 25.27; $p < 0.001$) and control group ($t'_{(49)}$ = -7.8; $p < 0.001$). A randomized controlled trial was conducted at Gujarat to find out the effect of yoga on menopausal symptoms using MRS among 210 women. The result was observed that in the post test the scores in yoga group showed a reduction in score on all the subscales from moderate to mild[55].

Conclusion

The study depicted that most of the women are affected with one or the other menopausal symptoms with may lead to a serious condition, So the yoga therapy was effective in relieving some of the menopausal symptoms partially but not completely.

Compare the Physiological Parameters and Behavioural Responses among Mixed Fed Versus Formula Fed Preterm Babies

Rafia Islam[1], Anila K.P.[2]

1 M.Sc. Nursing, [2]Professor,Department of Child Health Nursing, Amrita College of Nursing, Amrita Institute of Medical Sciences, AMRITA Vishwa Vidyapeetham, Kochi, Kerala, India

Abstract

Introduction: Preterm birth is the most common causes of death among infants in worldwide. Prematurity causes the largest number of admissions to the Neonatal Intensive Care Unit (NICU). And appropriate nutrition is essential for the growth and development of preterm infants.

Objective: The aim of the study was to compare the physiological parameters and behavioural responses among mixed fed versus formula fed preterm babies admitted in AIMS, Kochi.

Method:A descriptive approach was taken, sample were selected by convenience sampling technique, data had been collected by semi structured questionnaires and used record sheet and FENTON Growth chart to assess the physiological parameters and behavioural responses of the preterm baby.

Results: Weight gain, length, head circumference in mixed fed preterm babies were highly significant compared to formula fed preterm babies. Body temperature was very highly significant between two groups. The heart rate and mean respiratory rates were progressively higher in formula fed preterm babies than mixed fed preterm babies. Blood pressure was very highly significant between two groups and was higher than formula fed preterm babies. In majority, the oxygen saturation level was decreased in formula fed preterm babies than mixed fed preterm babies. Sucking reflex was absent among 74.3% of formula fed preterm babies and it was statistically significant. Rooting reflex was also absent in 42.9% of formula fed preterm babies.

Conclusion: The study findings revealed that the mixed feeding is very effective and beneficial to gain weight, height, to maintain body temperature, heart rate, respiratory rate and oxygen saturation compared to formula feeding.

Keywords: *Physiological Parameters, Behavioural Responses, Mixed Feeding, Formula Feeding, Preterm Babies.*

Introduction

Birth of a baby is perhaps the most joyful moment for any parent. They want their baby to be healthy and have the best of emotional and physiological environment.[1] Due to some different risk factors like multiple pregnancies, pregnancy induced hypertension and placental problems, when the baby is born before 37 weeks of gestational age, is called preterm baby. Due to short transition from intrauterine life to extra uterine life; the preterm baby is having the state of physiological and anatomical immaturity of various organs and systems at the time of birth. Immaturity of various organ systems places babies at the risk for variety of complications like hypothermia, respiratory distress, weight loss, hyper-bilirubinemia, poor sucking pattern, altered heart rate and altered oxygen saturation etc.[2]

Preterm birth is the most common causes of death among infants in worldwide.[3] Prematurity causes the largest number of admissions to the Neonatal Intensive Care Unit (NICU). Preterm birth occurs for a variety

of reasons. Most preterm births happen spontaneously, but some of them are due to early induction of labor or cesarean birth, whether for medical or non-medical reasons.[4]

According to World Health Organization (WHO, November 2016) every year an estimated 15 million babies are born as preterm (before 37 completed weeks of gestation), and this number is rising. Preterm birth complications are the leading causes of death among children under five years of age, responsible for nearly one million deaths in 2015. Across 184 countries, the rate of preterm birth ranges from 5% to 18% of babies' born.[5] India has the highest number of death due to premature birth and ranked 36th in the list of preterm birth globally out of 199 countries. In India, total 27 million babies are born annually. Among them 3.6 million babies are born preterm according to Indian Foundation for Premature Babies (2010).[6]

Due to immaturity of various organs, preterm babies are not able to breast feed properly. Mother won't be able to provide enough breast milk to their preterm babies. As an alternative, mixed feeding (combination of breast milk and formula milk) or formula milk alone is provided to maintain optimum development.

The purpose of the study was to compare the physiological parameters and behavioural responses in mixed fed versus formula preterm babies. This study was also intended to find association between the physiological parameters and behavioural responses of the preterm babies with their selected demographic variables.

Materials and Method

A descriptive study was conducted among 70 preterm babies between 32-35 weeks of gestational age admitted in NICU at AIMS, Kochi. The data collection was started after obtaining Ethical Clearance certificate from the Ethics Committee and Scientific committee of Amrita Institute of Medical Sciences and Research Centre (AIMS), Kochi. The sample was selected by convenience sampling technique based on inclusion criteria. Data had been collected by semi structured questionnaire, used record sheet and FENTON Growth chart to assess the physiological parameters and behavioural responses of the preterm baby. Preterm babies were identified through their clinical records. After building rapport with the parents, written informed consent was obtained from each parent. The demographic and clinical data were collected by using a semi-structured questionnaire. After completing the questionnaire, the entire sample were observed on alternative day basis at the same time by the investigator.

The collected data were organized, tabulated, summarized and analyzed by using descriptive statistics and inferential statistics in terms of objectives of the study. Demographic data were analyzed in terms of frequency and percentage distribution. Physiological parameters and behavioral responses of mixed fed versus formula fed preterm babies were determined by paired t-test. Associations of physiological parameters and behavioral responses with the selected demographical variables were determined by chi-square test.

Results

During the study period, a total of 70 preterm babies were reviewed and among mixed fed preterm group 17 (48.6%) of them were boy babies and 18 (51.4%) were girl babies and among formula fed preterm group 20 (57.1%) of them were boy babies and 15 (42.9%) were girls.

n=70 (35+35)

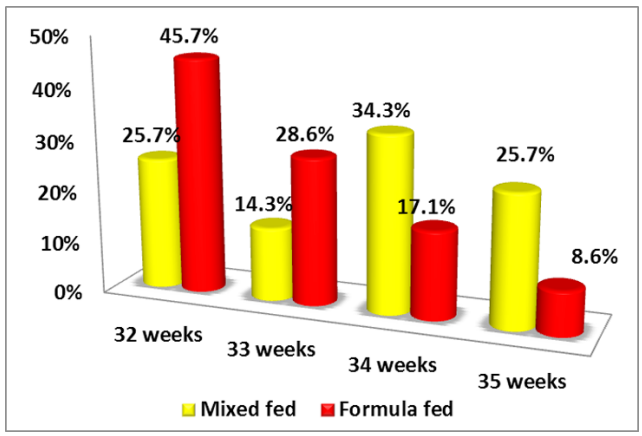

Figure 1: Comparison of gestational weeks of birth among mixed fed versus formula fed preterm babies.

Based on gestational week, Figure 1 shows that 9 (25.7%) of mixed fed preterm babies were born on 32 weeks of gestation, 5 (14.3%) of them on 33 weeks of gestation 12 (34.3%) of them on 34 weeks of gestation and 9 (25.7%) of them on 35 weeks of gestation. In comparison to formula fed preterm babies, 45.7% of them were born 32 weeks of gestation, 28.6% on 33 weeks of gestation, 17.1% on 34 weeks of gestation and 3 (8.6%) on 35 weeks of gestation.

Table 1: Standard deviation and p-value of body weight among mixed fed versus formula fed preterm babies. n=70 (35+35)

Body Weight	Mixed fed Preterm babies		Formula fed Preterm babies		p-value
	Mean	SD	Mean	SD	
Day 2	1.702	0.28	1.588	0.24	0.07
Day4	1.674	0.26	1.567	0.24	0.08
Day6	1.665	0.26	1.549	0.25	0.06
Day 8	1.688	0.25	1.543	0.24	0.019*
Day 10	1.722	0.25	1.551	0.24	0.006**

* p-value <0.05 Significant; ** p-value <0.01 Highly Significant; *** p-value <0.001 Very Highly Significant

Table 1 illustrated that there were significant changes in body weight with p-value <0.05 on day 8 and highly significant with p-value < 0.01 on day 10. According to the above table body weight among mixed versus formula fed preterm babies were not significant on day 2, day 4 and day 6.

Table 2: Mean body temperature among mixed fed versus formula fed preterm babies. n=70 (35+35)

Body Temp-erature	Mixed fed Preterm babies		Formula fed Preterm babies		p-value
	Mean	SD	Mean	SD	
Day 2	98.23	0.47	97.5	0.67	0.0001***
Day4	98.19	0.46	97.7	0.48	0.0001***
Day6	98.28	0.35	97.6	0.54	0.0001***
Day 8	98.25	0.46	97.7	0.48	0.0001***
Day 10	98.17	0.42	97.7	0.47	0.0001***

* p-value <0.05 Significant; ** p-value <0.01 Highly Significant; *** p-value <0.001 Very Highly Significant

Table 2 shows that, mixed fed preterm babies maintained their mean body temperature on day 2 in between (98.23±0.47) ºF, on day 4 (98.19±0.46) ºF, on day 6 (98.28±0.35)ºF, on day 8 (98.25±0.46)ºF and on day 10 (98.17±0.42) ºF. The formula fed preterm babies were maintained body temperature on day 2 (97.5±0.67) ºF, on day 4 (97.7±0.48) ºF, on day 6 (97.6±0.54) ºF, on day 8 (97.7±0.48) ºF and on day 10 (97.7±0.47)ºF. There were very highly significant changes in their body temperature with p-value <0.0001.

Table 3: Comparison of mean heart rate at different follow ups in both mixed fed and formula fed preterm babies. n=70 (35+35)

Heart rate	Mixed fed Preterm babies		Formula fed Preterm babies		p-value
	Mean	SD	Mean	SD	
Day 2	147.9	6.66	155.4	12.75	0.003**
Day4	147.6	6.95	156.1	10.70	0.0001***
Day6	149.2	7.76	157.4	11.2	0.001**
Day 8	146.4	20.22	157.34	10.10	0.006**
Day 10	146.3	19.85	157.69	13.41	0.007**

* p-value <0.05 Significant; ** p-value <0.01 Highly Significant; *** p-value <0.001 Very Highly Significant

Table 3 shows that, mixed fed preterm babies maintained their mean heart rate on day 2 in between (147.9±6.66) bts/min, on day 4 (147.6±6.95) bts/min on day 6 (149.2±7.76)bts/min, on day 8 (146.4±20.22)bts/min and on day 10 (146.3±19.85) bts/min. The formula fed preterm babies were maintained heart rate on day 2 (155.4±12.75) bts/min on day 4 (156.1±10.70) bts/min on day 6 (157.4±11.2) bts/min, on day 8 (157.34±10.10) bts/min and on day 10 (157.69±13.41)bts/min. On day 4 there were very highly significant changes in their heart rate with p-value <0.0001.

Table 4: Comparison of mean respiratory rate at different follow ups in both mixed fed and formula fed preterm babies. n=70 (35+35)

Respiratory rate	Mixed fed Preterm babies		Formula fed Preterm babies		p-value
	Mean	SD	Mean	SD	
Day 2	51.29	5.86	56.17	7.57	0.004**
Day4	50.8	6.73	57.4	8.10	0.0001***
Day6	52.09	7.00	57.03	8.46	0.010*
Day 8	54.2	6.83	57.86	8.09	0.04*
Day 10	53.3	7.81	58.46	8.58	0.01*

* p-value <0.05 Significant; ** p-value <0.01 Highly Significant; *** p-value <0.001 Very Highly Significant

Table 4 shows that mixed fed preterm babies maintained their mean respiratory rate on day 2 in between (51.29±5.86) breaths/min on day 4 (50.8±6.73) breaths/min on day 6 (52.09±7.00)breaths/min on day 8 (54.2±6.83)breaths/min and on day 10 (53.3±7.81) breaths/min. The formula fed preterm babies were maintained mean respiratory rate on day 2 (56.17±7.57) breaths/min on day 4 (57.4±8.10) breaths/min on day

6 (57.03±8.46) breaths/min on day 8 (57.86±8.09) breaths/min and on day 10 (58.46±8.58)breaths/min. On day 4 there were very highly significant changes in their respiratory rate with p-value <0.0001.

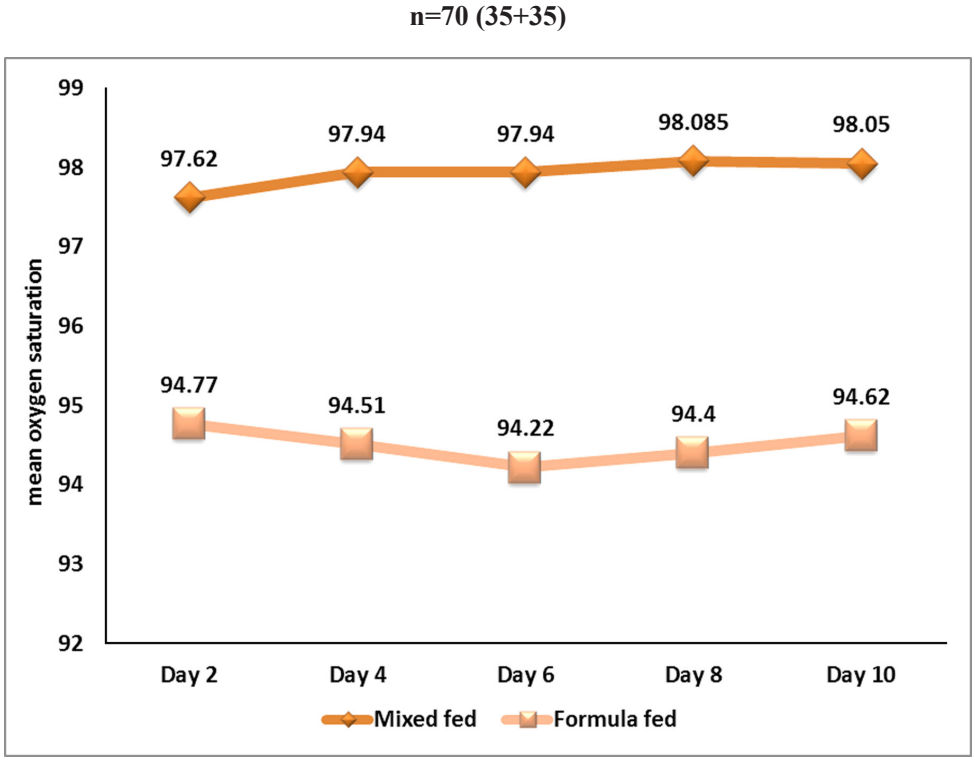

Figure 2: Comparison between mean oxygen saturation levels among mixed fed versus formula fed preterm babies

Figure 2 illustrated that from day (2-10) in mixed fed preterm babies mean oxygen saturation level on day 2 was (97.62±1.57)%, (97.94±1.32)% on day 4, (97.94±1.76)% on day 6, (98.08±1.46)% on day 8, (98.05±1.41)% on day 10 compared to formula fed preterm babies (94.77±1.41)%, on day 4 (94.5±1.63)%, on day 6 (94.2±1.84), on day 8 (94.4±1.76)%, day 10 (94.62±2.073)%.

Table 5: Comparison of rooting reflex at different follow ups in both mixed fed and formula fed preterm babies. n=70 (35+35)

Variables	Mixed fed Frequency (f)	Mixed fed Percentage (%)	Formula fed Frequency (f)	Formula fed Percentage (%)
Rooting reflex				
Present	24	68.6	20	57.1
Absent	11	31.4	15	42.9
Sucking reflex				
Present	23	65.7	9	22.9
Absent	9	34.3	26	77.1
Crying pattern				
Present	30	85.7	23	65.7
Less active	5	14.3	7	20
Absent	0	0	5	14.3
Pattern of sleep				
Good	34	97.1	34	97.1
Poor	1	2.9	1	2.9

Table 5 shows that 24 (68.6%) mixed fed preterm babies had rooting reflex and 20 (57.1%) formula fed preterm babies had rooting reflex. In case of sucking reflex, it was present 23 (65.7%) in mixed fed preterm babies and 9 (22.9%) in formula fed preterm babies. Crying pattern was present 30 (85.7%) in mixed fed group and 23 (75.7%) in formula fed group. Pattern of sleep (good) for both groups were 34 (97.1%).

Table 6: Comparison of rooting reflex at different follow ups in both mixed fed and formula fed preterm babies. n=70 (35+35)

Variables	Pearson Chi-square	p-value
Rooting reflex	0.97	0.322
Sucking reflex	11.28	0.001**
Crying pattern	6.25	0.04*
Pattern of sleep	0.0	1.0

* p-value <0.05 Significant; ** p-value <0.01 Highly Significant; *** p-value <0.001 Very Highly Significant

Table 6 illustrated that, between two groups, there were highly significant in sucking reflex with p value <0.001 and it were significant in crying pattern with p value <0.05. There were no such significant values for rooting reflex and pattern of sleep for both mixed fed versus formula fed preterm babies.

Discussion

Adequate nutrition is so important for the healthy growth and development of all new born babies. Preterm birth survivors are at a higher risk of growth and developmental disabilities compared to their term counterparts. Appropriate nutrition is essential for the growth and development of preterm infants. Early administration of optimal nutrition to preterm birth survivors lowers the risk of adverse health outcomes and improves cognition in adulthood.[7]

Weight gains in mixed fed preterm babies were highly significant with p-value <0.01 on day 8 and day 10, compared with formula fed preterm babies. The length and head circumference of both groups of preterm babies were statistically highly significant with p-value <0.01 from day 2 to day 10. D Singh, N Devi and TS Raghu Raman reported that the preterm infants lost an average of 90 g, at a negative growth rate of 12.80 g/d in the first week of their life. They had a brisk catch up phase with a growth rate of 20 g/d in the second week and 28-32 g/d thereafter.[8]

There were also studies which suggested results to the contrary. Cooper conducted a study on compared growth of a group of VLBW infants fed a formula specifically developed for such infants with another group fed expressed breast milk. The result showed that weight gain was faster in the formula-fed infants after a caloric intake of 100 kcal/kg/d was achieved. Increments in head circumference and skin fold thickness were also greater in the formula-fed group. In another study by the same authors, VLBW infants fed premature formula had significantly greater weight increments and length increments than those on own mother's milk.[9]

Consistent with other studies, preterm infants fed on breast milk or donor milk have significantly slower growth compared with those fed solely preterm formula. [10]

Body temperature was very highly significant in between two groups with p-value <0.0001. The heart rate was progressively higher in formula fed preterm babies than mixed fed preterm babies and it was very highly significant on day 4 with p-value <0.0001. The mean respiratory rate of formula fed preterm babies were increased from day 2 to day 10 progressively compare to mixed fed preterm babies. Blood pressure was very highly significant from day 2 to day 10 with p value <0.0001 between two groups. The blood pressures of mixed fed preterm babies were higher than formula fed preterm babies. Another study revealed that body temperature of the baby increases during breast feeding and oxygen saturation is decreased in breast feeding than bottle feeding and there is a change in physiological parameter during feeding conducted by Snell B J.[11]

In majority, the oxygen saturation level was decreased in formula fed preterm babies than mixed fed preterm babies. Crying pattern was more active among mixed fed preterm babies compared to formula fed preterm babies. Among both groups, rooting reflex was present in 68.6% of mixed fed preterm babies and 57.1% in formula fed preterm babies. Sucking reflex was absent in 74.3% of formula fed preterm babies and statistically significant with p value <0.001. Correlation was found for peripheral oxygen saturation when compared with gestational age and with the level of oral feeding skills.[12]

Conclusion

In the present study, the physiological parameter and behavioral responses compared in between two groups. The study result revealed that the mixed feeding

is very effective and beneficial to maintain physiological parameters and behavioural responses of preterm babies compare to formula fed. The formula fed preterm babies are not having adequate sucking reflex properly and mothers also not having enough milk production.

Household use Patterns of Iodized Salt in Urban Slums of Meerut

Chhavi Kiran Gupta[1], Antara Sinha[2], Parkhi Mehta[3], Shaavi Mittal[3], Rohan Sirohi[3], Narendra Kumar[3]

[1]Asst. Professor, [2]2nd Year P.G., [3]Third year MBBS students, Dept of Community Medicine, Subharti Medical College, Meerut, India

Abstract

Background: The present study was carried out to estimate the consumption of adequate iodized salt by PSI salt testing kit, knowledge related to the health benefits of iodine and practices with respect to storage and use of iodized salt at the household level in the field practice area of Subharti Medical College, Meerut. **Aims:**To assess the level of knowledge and salt keeping practices among the households and to estimate the iodine content of salt and its determinants in those households. **Settings and Design:**This Cross Sectional study was conducted in 250 households in urban slums in Multan Nagar, Meerut by taking verbal informed consent from the family followed by interview with a self-designed schedule.

Method and Material: The households were selected by simple random sampling and rapid PSI (Plasti Surge Industries) spot testing kit was used in the survey to assess iodine content in the salt used in those households.

Statistical analysis used: The collected data was entered in Microsoft excel and analyzed using SPSS software version 19.0.

Results: More than half of the households (65.2%) had no knowledge regarding iodized salt and nearly 3/4th of the households (73.6%) had no knowledge about benefits of iodized salt. Practice regarding keeping the salt was found to be good as 98.8% of households stored salt in containers with lid and 96.8% buy packet salt.

Conclusions: There is a pertinent need for health education regarding proper use and keeping practices of iodized salt. For the prevention of iodine deficiency disorders, education campaigns should reach grass root level.

Keywords: *Iodized Salt, PSI Salt Testing Kit, Households.*

Introduction

Iodine, a known metallic trace element, is required by humans for proper growth and development. Iodine does not occur naturally in foods rather it is present in soil, ocean water and sea foods. The recommended dietary allowance (RDA) for iodine intake is150 microgram in adults, 220 microgram in pregnant women, & 290 microgram per day in lactating women[1].

Iodine deficiency is the world's single greatest cause of preventable mental retardation[2]. Iodine deficiency disorders affect 2 billion people worldwide[3]. Iodine deficiency disorder (IDD) has been recognized as a public health problem in India[2]. An estimated 167 million people in India are at risk of IDDs[2]. Surveys conducted in various states showed that no state in the country is free from IDD [4].

Globally iodine deficiency disorders are associated with many thyroid related diseases including hypothyroidism, hyperthyroidism, goiter and cretinism

Contact: 7500881417

and also inherit real risk of coronary heart diseases[4]. The thyroid gland is home to the body's largest iodine stores as it requires the mineral for synthesis of hormone it secretes. It proves even more vital for pregnant and nursing mothers where iodine deficiency can lead to still births, spontaneous abortions, impede fetal and child development, and increase mortality.In fact this prenatal deficiency is the most common cause of preventable brain damage in the world. Iodine deficiency also decreases Intelligence Quotient (IQ)[2].

Iodine deficiency can be prevented effectively and inexpensively by supplying iodine from external source in food we commonly eat. Iodized salt is most suitable vehicle for iodine supplementation as salt is most important food item consumed everyday by everybody and most important ingredient used in the kitchen.

The salt iodization program was introduced in India in 1962 by the government of India as National Goiter Control Program (NGCP) aimed at replacement of ordinary salt by iodized salt, particularly in the goiter endemic regions. In August, 1992,NGCP was renamed as National Iodine Deficiency Disorders Control Programme (NIDDCP) with a view of wide spectrum of Iodine Deficiency Disorders like mental and physical retardation, deaf, mutisim, cretinism, still births, abortions etc[5]. Under the national iodine deficiency disorder program in India, level of iodization is fixed at minimum of 30 ppm (parts per million) at production level and 15 ppm at consumer level[6].Salt is iodized by addition of fixed amounts of potassium iodide or iodate as either a dry solid or an aquaeous solution at the point of production.

Salt may be sold to the consumer packaged or in bulk. Packaging materials in wide use in developing countries include paper, high-and low-density polyethylene, and woven bags made of jute, straw, or high density polythene.Salt samples stored in dry places were 1.5 times more likely to retainiodine compare to samples stored near to heat/fire or in a moist area.

Universal salt iodization has been truly one of the most successful interventions in eliminating IDDs as it is feasible, economical, safe and broadly accepted. Most Indian states have introduced mandatory salt iodization through legislation. The salt department and state government are responsible for monitoring the salt iodine content at both the consumption and production level.

Keeping this in mind, the present study was carried out toassess the level of knowledge and salt keeping practices among the households and to estimate the iodine content of salt and its determinants in those households of Multan Nagar, Meerut.

Method

It was a community based, cross sectional study doneto assess knowledge regarding iodized salt and salt keeping practices in urban slums of Multan Nagar, Meerut(catchment area of Community Medicine department of Subharti Medical College).

Considering the prevalence of consumption of iodized salt of Uttar Pradesh as 93.7% according to NFHS-4[8], permissible error of 3%, and a confidence interval of 95%, the sample size calculated was 250.67, rounded off to 250 households. Verbal informed consent was obtained fromthe participating member of the households willing to take part.After informing about the study, they were interviewed with a self-designed schedule. The households which were locked or themembers not present at the day of data collection and/or not willing to participate were excluded and the immediate next household was selected. The respondents were asked questions regarding salt purchasing and consumption habits, salt storage, awareness and benefits of iodized salt, iodine deficiency diseases and practicing regarding iodized salt.

Rapid PSI(Plasti Surge Industries)spot testing kit was used in the survey to assess iodine content. Salt samples (50 grams) were collected from selected households in airtight plastic pouches. They were stored in brown paper envelopes and coded accordingly.

The collected datawas entered in Microsoft excel and analyzed using SPSS software version 19.0. For test of significance chi square test was used and the statistical significance was set at p-value less than 0.05.

Results

In the present study, majority of the population were Hindu (88%) and belonged to Upper Middle Class (36%) & Middle Class (38%) and were found to be significant [Table1]. The association between Knowledge regarding Iodized salt and benefits of dietary iodine with ppm is found to be significant (Table 2). The maximum source of infection among households regarding importance of Iodized salt use is Television followed by Newspaper and

least by Friends and relatives (Graph1). The association of ppm (parts per million)with practices regarding iodized salt such as buying salt from fixed shop, buying packet salt, type of container used for storage of salt, place of storing salt, time of adding salt while cooking and habit of reading information on salt packets was also found to be statistically significant (Table 3).

Discussion

The present study revealed that despite a long running National Iodization Program, there is major ignorance regarding the benefits and use of iodized salt. In the current study more number of households knew about iodized salt (34.8%) than knowing about the benefits of iodized salt (27.2%) and almost similar findings were obtained by Singh AK et al[6] in which 55.15% house holds knew about iodized salts and only 25.59% knew about its benefits (Table 2).

According to NHFS 4,coverage of households using iodized salt in rural areas of UP[8] was 92.4% while in urban areas it was 97.3%. Similarly, data for Meerut[9] was 96.8% and 97% in rural and urban areas respectively. In the present study similar findings were reported as it was seen that 98% of the study households were consuming iodized salt (Table 3).

In this study, it was found that nearly half of the households (51.2%) were using adequately iodized salt whereas 45.2% of the households were using inadequately iodized salt and 3.6% of the households were using salt with nil iodine. However in study done by Singh et al[6] in rural area of district Bareilly, U.P. 42% of the households were consuming adequately iodized salt, while about 44% of the households were consuming inadequately iodized salt. Nearly 14% of the households were consuming salt with nil iodine. Whereas in study done by Rupali Roy et al[2], 62.5% of the households were using adequately iodized salt.

In this study, the common sources of information for iodized salt, though less, were television (29.2%) followed by newspaper (12%). Other sources of information included the academic knowledge (9.6%) followed by radio (6.8%) and friends and relatives

(5.2%) whereas in study done by Roy R et al television (31.1%) and radio (30%) were the commonest sources of information regarding iodized salt[2]. In the study by Srivastava R et al, source of knowledge regarding iodized salt was mainly the newspapers (51%) and television (46%) followed by shopkeepers (21%), neighbors (18%) and radio (18%)[7] (Graph 1).

This study revealed that 96.8% of the households were using packet salt and rests of the households were using either open salt or crude salt (3.2%). Almost similar results were found by Roy R et al[2] where 93.7% of the households were using packet salt and rest of the households was using either open salt (2.8%) or crude salt (3.6%). Whereas, in study by Singh AK et al[6] 72.3% of households were using powdered salt and 27.7% were using crystal salt.Reasons for not using packet salt were-disliked the taste, influenced by relatives for using non iodized salt and believing in the fact that iodized salt is adulterated and non iodized salt being the purest form of salt (Table 3).

In the current study, 75.6% of the households always bought salt from a fixed shop followed by 20.8% of households which often and sometimes used to buy salt from a fixed shop and only 3.6% households never bought salt from a fixed shop. This finding was obtained in current study only and was not seen in other studies. Most of the people kept salt in plastic containers (91.2%) and with lid containers (98%) whereas 2% of the households kept salt in metal containers and only 8% of the population kept salt in glass containers. The place for storage of salt was dry and cool for 79.6% of the households and moisture area in 19.2% whereas 1.2% of the households kept salt near fire area/sun. In the study done by Singh AK et al[6] only 36.68% of households were storing salt in closed air tight container and maximum (63.32%) were storing in open container (Table 3).

Most of the households (93.2%) bought salt in 1 kg packets and only 23.2% of the households always read packaging of salt whereas 5.6% of the households often, 18.8% of households sometimes and 52.4% of the households never read the packaging of salt. Most of the population (87.6%) adds salt in the beginning of the cooking whereas only 6.8% of the population adds salt in the middle (4.8%) and end (6.8%) of the cooking. These findings were obtained in current study and were not seen in other studies (Table 3).

In conclusion, despite a successful NIDDCP(National Iodine Deficiency Disorders Control Programme), there is a pertinent need for health education regarding proper use and keeping practices of iodized salt. Till the education campaign reaches grass root level, this national effort will not reach its peak as far as the prevention of iodine deficiency disorders are concerned.

Effect of Intermittent Pneumatic Compression Device (IPCD) Versus Graduated Compression Stockings (GCS) for Venous Thromboembolism Prophylaxis (VTE) in High Risk Surgical Patients

Arya Shirish Kulkarni[1], Rupali Salvi[2], Nisha Naik[3]

[1]M.Sc. Nursing, [2]Principal, [3]Associate Professor, Dr D. Y. Patil University, Pimpri, Pune

Abstract

Background: VTE is a leading cause of morbidity and mortality in high risk surgical patients. VTE prophylaxis is recommended for approximately 60% of high-risk surgical patients and 40% of hospitalized medical patients.[4]

Objectives: The objective of the study is to assess the effect of Intermittent Pneumatic Compression Device (IPCD) versus Graduated Compression Stockings (GCS) for Venous Thromboembolism prophylaxis in high risk surgical patients

Materials and Method: An evaluative study with two group post-test only design was used to assess the effect of Intermittent Pneumatic Compression Device (IPCD) versus Graduated Compression Stockings (GCS) for Venous Thromboembolism prophylaxis in high risk surgical patients. 60 samples were taken using non-probability purposive sampling technique from selected hospitals, of which 30 were using IPCD and 30 were using GCS. The data was collected using self-structured demographic data, Caprini risk assessment scale and observation checklist.

Results: The analysis was done by using descriptive and inferential statistics. Researcher applied two sample t-tests for comparison of effects of IPCD and GCS in high risk surgical patients based on observation checklist. On first observation, average VTE risk score was 3.2 for GCS group which was 2.5 for IPCD group. On second observation, average VTE risk score was 2.9 for GCS group which was 2.1 for IPCD group. On third observation, average VTE risk score was 1.8 for GCS group which was 1.1 for IPCD group. T-values for this comparison were 1.7, 1.7 and 2 with 58 degrees of freedom. Corresponding p-values were 0.048, 0.044 and 0.023 which are small (less than 0.05), the null hypothesis is rejected. It is evident that the IPCD group had low risk of VTE which indicates that it acts as a better prophylaxis for VTE.

Conclusion: VTE can cause problems that may affect for the rest of life. One may have long-term problems with breathing, a higher chance of getting another clot and swelling that will not go away and may even lead to sudden death. It is important to check the different policies and protocol set for VTE prophylaxis and have the uniform protocols and standardization post-surgery among high risk patients in different hospitals.

Introduction

Safer Surgery can be defined as a reduction in avoidable harm to a surgical patient. Surgery is regarded as a high risk and complex industry. Complications of surgical care have become a major cause of death and disability worldwide.[2] Venous thromboembolism (VTE) is the number one cause of potentially preventable death

in hospitalized patients. Venous thromboembolism accounts for 100 000 patient deaths per year.[3]

Surgical procedures are known to produce a high incidence of DVT because muscle relaxants, anaesthetic agents, and surgery itself affect each of the Virchow's triad of causes. Pharmacologic prophylaxis is currently widespread, addressing the blood coagulability changes during surgery; however, excessive bleeding can be a complication. Physical method of prophylaxis, in contrast, are less well known and have generally been thought to prevent venous blood stasis. [5]

Rudolf Virchow first described the DVT phenomenon in 1846. He has quoted stasis of blood flow, endothelial injury, and hypercoagulability as three factors in Virchow's triad of thrombosis that contribute to the pathogenesis of venous thrombosis. Trauma patients not only are exposed to these risk factors but often possess all three factors concomitantly.[6]

Graduated compression stockings are effective method of thromboprophylaxis during the long-term maintenance of volume in lymphedema. For superficial thrombophlebitis, there may be some benefit from wearing graduated compression stockings in combination with surgery.[7]

Intermittent pneumatic leg compression is an effective method for preventing postoperative deep vein thrombosis. Because deep vein thrombosis is the precursor for pulmonary embolism, it has been assumed that this widely used modality is effective in reducing the frequency of fatal and nonfatal pulmonary embolism.[8]

Thus, seeing the increasing incidence of venous thrombo-embolism in hospitalised patients and the different types of VTE prophylaxis used for post-surgery patient, the researcher felt the need to conduct a comparative study on assessing the effect of IPCD and GCS on venous thrombo-embolism prophylaxis in high risk surgical patient.

Materials and Method

Study objectives:

1. To assess the effects of IPCDs and GCS in high risk surgical patients.
2. To compare effects of IPCD and GCS in high risk surgical patients.
3. To identify the association between IPCD and GCS with demographic variables of high risk surgical patients.

Study design: The study used evaluative approach with two group post-test only design was used to assess the effect of Intermittent Pneumatic Compression Device (IPCD) versus Graduated Compression Stockings (GCS) for Venous Thromboembolism prophylaxis in high risk surgical patients. 60 samples were taken from selected hospitals, 30 of which used IPCD and 30 used GCS, using non-probability purposive sampling technique. The settings of the study is at Dr D.Y.Patil Hospital and Research Centre, Pimpri, Pune and Aditya Birla Memorial Hospital, Thergaon, Pune. The data was collected using self-structured observation checklist, Caprini risk assessment scale and demographic data.

Findings: Section I: Analysis of data related to the effects of IPCDs and GCS in high risk surgical patients

Table 1: Effect of GCS in high risk surgical patients based on Observational checklist n=30

Observation	Risk of VTE	GCS	
		Freq	%
OBS-1	Low risk (Score 0-7)	30	100.0%
	Moderate risk (Score 8-14)	0	0.0%
	High risk (Score 15-21)	0	0.0%
OBS-2	Low risk (Score 0-7)	30	100.0%
	Moderate risk (Score 8-14)	0	0.0%
	High risk (Score 15-21)	0	0.0%
OBS-3	Low risk (Score 0-7)	30	100.0%
	Moderate risk (Score 8-14)	0	0.0%
	High risk (Score 15-21)	0	0.0%

Table 1 indicates that in GCS group, all the patients had low risk of VTE at all the three observations.

Table 2: Paired t-test for the effect of GCS in high risk surgical patients based on Observational checklist n=30

Observation	Mean	SD	t	df	p-value
OBS-1	3.2	1.9			
OBS-2	2.9	1.9	2.1	29	0.024
OBS-3	1.8	1.3	4.3	29	0.000

Researcher applied paired t-test for the effect of GCS in high risk surgical patients. Average risk score based on observational checklist was 3.2, 2.9 and 1.8 on three observations. T-values for test were 2.1 and 4.3 with 29 degrees of freedom. Corresponding p-values were 0.024 and 0.000 on second and third observations.

This is evident that the GCS is significantly effective on second and third observations.

Table 3: Effect of IPCD in high risk surgical patients based on observational checklist n=30

Observation	Risk of VTE	IPCD	
		Freq	%
OBS-1	Low risk (Score 0-7)	30	100.0%
	Moderate risk (Score 8-14)	0	0.0%
	High risk (Score 15-21)	0	0.0%
OBS-2	Low risk (Score 0-7)	30	100.0%
	Moderate risk (Score 8-14)	0	0.0%
	High risk (Score 15-21)	0	0.0%
OBS-3	Low risk (Score 0-7)	30	100.0%
	Moderate risk (Score 8-14)	0	0.0%
	High risk (Score 15-21)	0	0.0%

In IPCD group, all of the patients had low risk at all three observations.

Table 4: Paired t-test for the effect of IPCD in high risk surgical patients based on observational checklist n=30

Observation	Mean	SD	t	df	p-value
OBS-1	2.5	1.6			
OBS-2	2.1	1.6	2.0	29	0.029
OBS-3	1.1	1.5	5.0	29	0.000

Researcher applied paired t-test for the effect of IPCD in high risk surgical patients. Average risk score based on observational checklist was 2.5, 2.1 and 1.1 on three observations. T-values for test were 2 and 5 with 29 degrees of freedom. Corresponding p-values were 0.029 and 0.000 on second and third observations. This is evident that the IPCD is significantly effective on second on third observation.

Section II: Analysis of data related to comparison of effects of IPCD and GCS in high risk surgical patients

Table 5: Comparison of effects of IPCD and GCS in high risk surgical patients based on observation checklist n=60

Observation	Risk of VTE	GCS		IPCD	
		Freq	%	Freq	%
OBS-1	Low risk (Score 0-7)	30	100.0%	30	100.0%
	Moderate risk (Score 8-14)	0	0.0%	0	0.0%
	High risk (Score 15-21)	0	0.0%	0	0.0%
OBS-2	Low risk (Score 0-7)	30	100.0%	30	100.0%
	Moderate risk (Score 8-14)	0	0.0%	0	0.0%
	High risk (Score 15-21)	0	0.0%	0	0.0%
OBS-3	Low risk (Score 0-7)	30	100.0%	30	100.0%
	Moderate risk (Score 8-14)	0	0.0%	0	0.0%
	High risk (Score 15-21)	0	0.0%	0	0.0%

Based on observational checklist, all the high-risk surgical patients for GCS and IPCD groups had low risk of VTE.

Table 6: Two sample t-test for comparison of effects of IPCD and GCS in high risk surgical patients based on observation checklist n=60

Observation	Group	Mean	SD	t	df	p-value
OBS-1	GCS	3.2	1.9	1.7	58	0.048
	IPCD	2.5	1.6			
OBS-2	GCS	2.9	1.9	1.7	58	0.044
	IPCD	2.1	1.6			
OBS-3	GCS	1.8	1.3	2.0	58	0.023
	IPCD	1.1	1.5			

Researcher applied two sample t-tests for comparison of effects of IPCD and GCS in high risk surgical patients based on observation checklist. On first observation, average VTE risk score was 3.2 for GCS group which was 2.5 for IPCD group. On second observation, average VTE risk score was 2.9 for GCS group which was 2.1 for IPCD group. On third observation, average VTE risk score was 1.8 for GCS group which was 1.1 for IPCD group. T-values for this comparison were 1.7, 1.7 and 2 with 58 degrees of freedom. Corresponding p-values were 0.048, 0.044 and 0.023 which are small (less than 0.05), the null hypothesis is rejected. It is evident that the IPCD group had low risk of VTE which indicates that it provides better VTE prophylaxis.

Discussion

Present study was done on 60 high risk surgical patients, to assess the effect of IPCD and GCS on VTE prophylaxis. The samples were divided in two groups, 30 patients using IPCD and 30 patients using GCS.

Comparison between effects of IPCD and GCS indicates that all the high-risk surgical patients for GCS and IPCD groups had low risk of VTE based on observational checklist. Researcher applied two sample t-tests for comparison of effects of IPCD and GCS in high risk surgical patients based on observation checklist. On first observation, average VTE risk score was 3.2 for GCS group which was 2.5 for IPCD group. On second observation, average VTE risk score was 2.9 for GCS group which was 2.1 for IPCD group. On third observation, average VTE risk score was 1.8 for GCS group which was 1.1 for IPCD group. T-values for this comparison were 1.7, 1.7 and 2 with 58 degrees of freedom. Corresponding p-values were 0.048, 0.044 and 0.023 which are small (less than 0.05), the null hypothesis is rejected. It is evident that the IPCD group had low risk of VTE which indicates that it provides better VTE prophylaxis.

Conclusion

The purpose of the study was to assess the effects of intermittent pneumatic compression device (IPCD) versus graduated compression stockings (GCS) for venous thromboembolism prophylaxis in high risk surgical patients. The research was a learning experience for the investigator which gave her better exposure. In this study since the ($p < 0.05$) H_0 (null hypothesis) was rejected. It is evident that the IPCD group had comparatively low risk of VTE than GCS group which indicates that they provide better VTE prophylaxis for high risk surgical patients. Researcher recommend to have uniform protocols for use of VTE prophylaxis across the hospitals.

Assessment of Level of Streess among the B.Sc. Nursing Students

Ashisbala Mohapatra

Principal, Hi-Tech College of Nursing, At. Pandara, PO. G.G.P, Bhubaneswar, Odisha

Abstract

Back ground of the study: Nursing is a noble profession. Nursing education is tough and needs discipline and sincerely throughout the training period. During this period, students have to face different level of stress. Stress reacts physically, mentally and emotionally to various conditions. The aim of this study was to find out the level of stress among the students and its association with selected demographic variables.

Materials and Method: Study was conducted on 180 students of B.Sc. (N) course (1st yr, 2nd yr, & 3rd yr) of Hi-Tech College of Nursing. The research design used was non-experimental descriptive design.

Result: The present study reveals that 52% had average to high level of stress. Majority of the sample 75% had average level of stress among 2nd year students. A statistically significant association was observed for the stress and education and also with type of work.

Conclusion: Level stress during student period was observed among the students. Majority 70% had average to high level of stress during 1st year, majority 75% had average level of stress during 2nd year and majority 10% from each year students has low level of stress. Also, stress is significantly associated with type of work.

Keywords: *Assessment, Stress, level of stress, pss (perceived stress scale), B.Sc.(N) students (1st yr, 2nd yr & 3rd yr).*

Introduction

The term "stress' was first coined in late 1930s. Stress as a whole is defined as a state produced by a change in the environment that is perceived as challenging, threatening or damaging to the person's dynamic balance or equilibrium.

Stress is a state of physical and psychological strain which imposes demands for adjustment upon the individual. It has been reported that student nurses are affected with the stressors in academic, clinical, financial due to parental expectations, competition for grades and career choices.[1 & 2]

Naturally, student period gives some stress to the students. As per research, there is an excessive secretion of hormones. This process creates emotional stress which can be very severe. Stress is unfortunately a common and ordinary side effect of living. Stress can however be particularly harmful, thus it is important to take correct measures to reduce the stress and anxiety levels in student period. [3]

Aims and Objective: The aim of the study was to find out the level of stress among the nursing students (1st yr, 2nd yr, 3rd yr) B.Sc. (N) of Hi-Tech College of Nursing, Orissa, India.

Objectives of the Study:

1. Identify the stress among the nursing students in three years.
2. Compare the level of stress among the students in three years.
3. Associate the level of stress among the students and selected demographic variables.

Materials and Method

The study was conducted on 180 students and the sample were selected by convenience sampling technique based on inclusion criteria and rapport was established with them. The researcher explained the purpose of the study and obtained an informed consent from them and the tools were administered. The demographic data was obtained from the subject themselves.

The data regarding stress was obtained using perceived stress scale (PSS)[4] each sample took 15 minutes to fill the questionnaire. The data obtained was analyzed using descriptive and inferential. Statistics and association was assessed using chi-square.

Data Collection Instruments

1. **Tool-I:-Demographic proforma:** A semi-structured questionnaire was constructed to assess the demographic and other datas. The tool consists of two sections, section-A was socio-demographic data and it consists of questions regarding age, type of family, year of study, education, type of stay, monthly income, type of work etc.

   Section-B comprises questions regarding the problems related to education, sharing of the problem with anyone, way of facing stress, physical and psychological changes occur during stress, type of recreational activates used etc.

2. **Tool-II, Stress Scale:** The stress scale used for the study was a standardized tool:-Perceived stress scale (Pss). Pss is the most widely used psychological instrument for measuring the perception of stress. It is a measure of the degree to which situations in one's life are appraised as stressful. The questions in the PSS ask about their feeling & thoughts, problems etc. The scale contains 10 items and the data collected will be evaluated on the rating of-"o"-Never, I-Almost Never, 2-Sometimes, 3-Fairly often, 4-Very often.[5 & 6]

Results and Discussion

Section-I: Socio-demographic characteristic of the subject.

Table-I: Distribution of subjects based on socio-demographic characteristics. N=180

Variables	Frequency	Percentage
Age in years		
18-21	56	31.11
22-25	78	43.33
26-29	46	25.55
Year of study		
1st year	60	33.33
2nd year	60	33.33
3rd year	60	33.33
Education		
Higher secondary	72	40
Graduation	83	46.11
Post-graduation	25	13.88
Monthly income		
5000-10,000	42	23.33
10,001-20,000	68	37.77
>20,000	70	38.88
Type of work		
Sedentary	32	17.77
Moderate	120	66.66
Heavy	28	15.55
Type of stay		
Staying in Hostel	104	57.77
Staying with family	54	30
Others	22	12.22
Type of family		
Nuclear family	98	54.44
Joint family	48	26.66
3rd generation	34	18.88

Out of 180 students, Majority 78 (43.33%) belongs to the age group 22-25 years. Regarding education, 83 (46.11%) were undergoing nursing training after general graduation, 120 (66.66%) were moderate workers. Majority of the students 104 (57.77%) were staying in the hostel, Majority of them 98 (54.44%) belongs to nuclear family. Also, Majority of the students. 70 (38.88%) family income was > 20,000/-.

Level of Stress among the Students

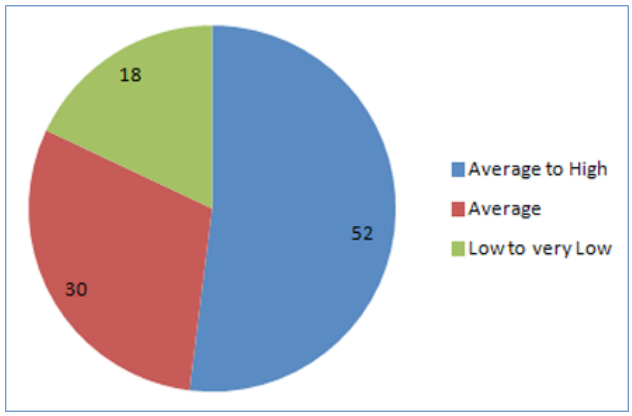

Fig I: Pie chart on stress level on the students

The study findings revealed that 52% had average to high level of stress 30% had average level of stress and 18% had low to very low level of stress during student period. (Fig-I).

Comparision of Stress among three Different Years of Study

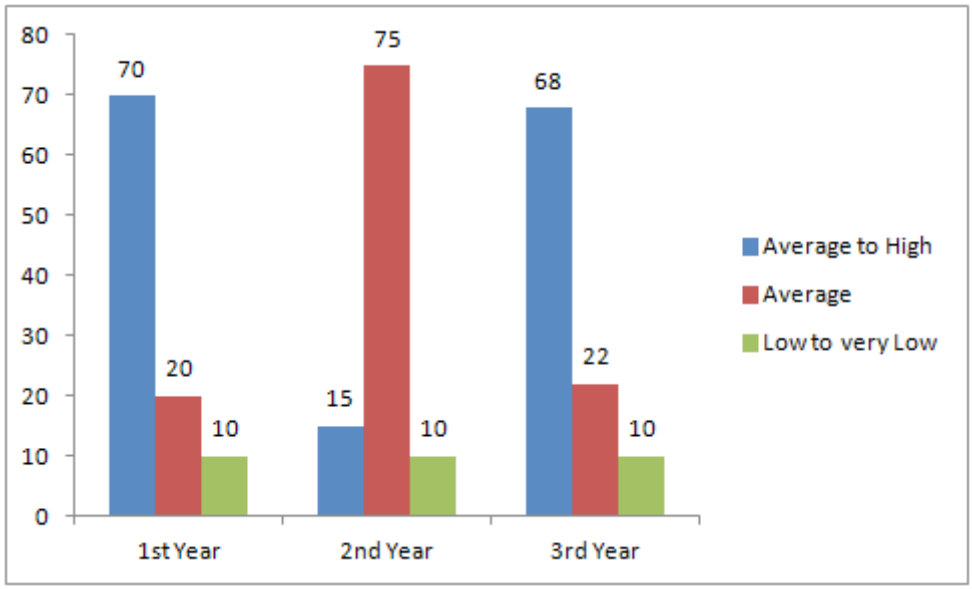

Fig. 2: Comparison of levels of stress among three different years of study

The study findings revealed that most of the students (70%) with average to high level of stress during 1st year while comparing stress among these three years. Most of the 2nd year (75%) students had average level of stress. In these three years in each group (10%) of the students had low to very low level of stress. (Fig-II).

Table 2: Association between the stress and selected demographic. N=180

Variables	PSS Very low + low	PSS Average + High	df	X^2 Value	P Value
Age					
< 20	82 (78.6%)	29 (52.2%)			
• 20	26 (49.2%)	43 (59.6%)	1	0.005	0.982
Education					
Higher secondary	38 (48.6%)	34 (43.2%)			
Graduation	43 (49.8%)	40 (46.2%)	2	0.702	0.619
Post-graduation	10 (40%)	15 42.3%)			
Type of work					
Sedentary	29 (43.2%)	31 (41.3%)			
Moderate + Heavy	86 (76.8%)	34 (43.2%)	1	4.723	0.049
Type of stay					
Hostel	83 (73.4%)	21 (50.2%)			
With family	38 (47.5%)	16 (43.2%)	1	0.105	0.649
Monthly income					
< 10,000	28 (41.2%)	14 (38%)			
• 10,000	78 (69.2%)	60 (49.2%)	1	0.543	0.701
Year of study					
1st yr	48 (49.9%)	12 (32%)			
2nd yr	36 (46.2%)	24 (50.1%)	1	1.823	0.123
3rd yr	32 (43.1%)	28 (52.1%)			

Data in Table-2 slows that there was significant association between the level of stress and type of work. (x^2 = 4.723, P = 0.049). However, no association was found between the level of stress and selected variables like age, education, type of stay, type of family, monthly income etc. Therefore, it can be stated that type of work has a direct influence on the stress experienced by the students.[7]

Discussion

Stress may lead to several problems. Stress reacts physically, mentally and emotionally to the various conditions. The present study reveals that 52% had average to high level of stress, 30% had average level of stress and 18% had low to very low level of stress. Another study conducted by Rajesh Kumar and Nancy in a private institute of nursing in Punjab affiliated with Baba Farid University of Health Sciences, Faridkot to assess stress level and coping strategies among nursing students. Total of 180 students participated in the study. Perceived stress scale-14 (PSS-14) was used to assess stress level and ACOPE was used to identify the coping strategies. Results revealed that 34% students were having moderate stress and 33% each were having mild and severe stress. Class of students and their courses were found to be significantly associated with the stress level of nursing Students.[8]

The findings of the present study reveals that there is a difference in the level of stress in different years of study. It is identified that comparatively higher level of stress (70%) was among the 1st yr students as they are new to the course, as well as to the college and hostel. Another study conducted by b. Kalavathi, S.S Shabana, Rajeswari. H and Indira A. A sample of 60 1st yr B.Sc Nursing students were selected by using simple random sampling technique. Modified student stress scale was used to assess the level of stress. Data was analyzed by using the descriptive and inferential statistics. It revealed that 15 (25%) students had mild stress. 22 (36.7%) students had moderate stress, 23 (38.3%) students had severe stress. In post test 15 (25%) students had very mild stress, 22 (36.7%) students had moderate and 16 (26.7%) had severe stress. Association between level of stress and socio-demographic variables is significant.[9]

The reason may be the fears, anxieties and stress related to the professional course, new environment as they are going to expose to the new college and hostel.

It is also identified that in the present study there is significant association between the level of stress among the students and type of work. Another study conducted by Prasad C.V, Suresh A, Thomas DK, Pritty M.K, Beelis, and Multarim V. aimed to determine the level of stress and coping mechanism adopted by 1st yr B.Sc (N) students. The sample size was 60 and non-probability sampling technique was used. The result shows that only one student (1.7%) has severe stress, 46.7%) has moderate stress and the remaining 51.6% has mild stress. Majority of the students (100%) had average coping.[10]

Conclusion

Nursing education and training is the tough one for the students. Nursing students are more prone towards stress. Stress creates emotional and physical disturbances which causes variety of problems in their personal and professional life, which will hamper quality education and training. Therefore, measures must be taken like providing continuous counseling and guidance, psychological support to reduce the level of stress among the students.

Assessment of Stain Removal Efficacy of Two Commercially Available Polishing Agents: Proxyt Paste (Active Ingredient-Xylitol) and Shine N Smile Paste (Active Ingredient-Alumina)

Avineet Kaur[1], Deepak Kochar[2], Shanam Kansil[3]

[1]Assistant Professor, [2]Professor, Department of Periodontics and Oral Implantology, M.M College of Dental Sciences & Research, Maharishi Markandeshwar (Deemed to be University), Mullana, Ambala, [3]Dental Implant Clinic and Oral Surgery, Landmark Hospital, Sec 33-C, Chandigarh

Abstract

Background: Tooth polishing is a procedure carried out as a part of oral prophylaxis in most dental practices. In the present study, the stain removal efficacy of two commercially available polishing agents was compare: Proxyt paste (active ingredient-xylitol) and Shine N Smile paste (active ingredient-alumina).

Materials & method:20 subjects in the age group of 20 to 40 years with extrinsic stains were included in the studyand a split mouth study design was employed. After thorough scaling was done, a split mouth study design was employed for comparing the two pastes. On the right side proxyt pastewas used and on the left side Shine N Smile paste was used to polish the teeth using rubber cup technique for 15 seconds on each tooth. Lobene stain index was used to assess the intensity and extent of the stains before and after the polishing procedure was performed.

Results: Pre-treatment and post-treatment score difference for the proxyt group and Shine N Smile group was 0.98 and 1.23 respectively. Significant results were obtained while comparing the mean post-polishing score and difference (pre-treatment and post-treatment) score in between proxyt paste group and shine N smile group.

Conclusion: Shine NSmile paste showed better results in comparison to proxyt paste. However; further studies with larger sample size are recommended.

Keywords: *Polishing, Proxyt paste, Shine N smile paste.*

Introduction

In much the same way an artist uses brush and paint to create his or her art, we too must approach what we do using the teeth and our instruments to do the same (tooth polishing). Tooth polishing is a procedure carried out as a part of oral prophylaxis in most dental practices. It is an act of smoothening the tooth surfaces to make it glossy and lustrous.[1-3] Although the term polishing has been used to describe the professional removal of soft deposits and stains from the tooth surfaces, in reality, this includes both cleaning and polishing. Polishing helps in smoothening the tooth surfaces and makes them glossy and lustrous.[4-6] American Academy of Periodontology has defined tooth polishing as "the removal of plaque, calculus and stains from the exposed and unexposed surfaces of teeth by scaling and polishing as a preventive measure for the control of local irritational factors". Different abrasive and polishing agents being used are pumice, sodium bicarbonate, zirconium silicate, xylitol, aluminium trihydroxide, calcium carbonate, erythritol, glycine etc.[7,8] In the present study the stain removal efficacy of two commercially available polishing agents

Corresponding Author:

Professor , Department of Periodontics and Oral Implantology, M.M College of Dental Sciences & Research, Maharishi Markandeshwar (Deemed to be University), Mullana, Ambala

was compare: Proxyt paste (active ingredient-xylitol) and Shine N Smile paste (active ingredient-alumina).

Materials And Method

The present study was conducted at Department of Periodontology Gian Sagar Dental College Ramnagar Rajpura with the aim of comparing the stain removal efficacy of two commercially available polishing agents: Proxyt paste (active ingredient-xylitol) and Shine N Smile paste (active ingredient-alumina).20 subjects in the age group of 20 to 40 years with extrinsic stains were included in the study and a split mouth study design was employed.

Inclusion Criteria:

- Patients presenting with plaque, calculus and extrinsic stains
- Patients with full complement of teeth
- Patients having good general health

Exclusion Criteria:

- Patients presenting with contagious diseases
- Systemic diseases such as uncontrolled diabetes, patients with valvular heart disease, acute infections
- Patients with malocclusion or wearing orthodontic appliances.

After thorough scaling was done, a split mouth study design was employed for comparing the two pastes. On the right side Proxyt paste was used and on the left side Shine N Smile paste was used to polish the teeth using rubber cup technique for 15 seconds on each tooth. Lobene stain index was used to assess the intensity and extent of the stains before and after the polishing procedure was performed. All the results were analysed by SPSS software. Paired t test was used for assessment of level of significance.

Results

In the present study, 20 subjects in the age group of 20 to 40 years with extrinsic stains were included in the study and a split mouth study design was employed. On the right side Proxyt paste was used and on the left side Shine N Smile paste was used to polish the teeth using rubber cup technique for 15 seconds on each tooth. Mean score of the Proxyt paste group before polishing and after polishing was 2.3 and 1.32 respectively. Mean score of the Shine N Smile paste group before polishing and after polishing was 2.27 and 1.04 respectively. Pre-treatment and post-treatment score difference for the proxyt group and Shine N Smile group was 0.98 and 1.23 respectively. Significant results were obtained while comparing the mean post-polishing score and difference (pre-treatment and post-treatment) score in between Proxyt paste group and Shine N Smile group.

Table 1: Pre-polishing and post-polishing results

Observation	Polishing agent	Mean	Std. Deviation	Paired difference			
				Mean	Std. Deviation	t	Sig. (2-tailed)
Baseline (Before polishing)	PROXYT	2.30	1.58	0.032	0.217	1.137	0.260
	SHINE N SMILE	2.27	1.61				
After Polishing	PROXYT	1.32	0.98	0.286	0.249	8.879	0.000
	SHINE N SMILE	1.04	0.91				
Difference (Before-After)	PROXYT	0.98	1.10	-0.254	0.355	-5.545	0.000
	SHINE N SMILE	1.23	1.14				

Discussion

It is important to understand the patient's expectations when considering tooth polishing. They simply like the look and feel of polished teeth. Taste and smell are the next important factors from the patient's point of view. They prefer this procedure over debridement with instruments for many reasons. An important factor is that patients respond positively to the smooth and clean feel that polishing produces. Furthermore, it is less painful and stressful than scaling; and easier for the patient to understand and tolerate. Polishing produces tangible benefits, which the patients can see, and feel.[9, 10]

In the present study, 20 subjects in the age group of 20 to 40 years with extrinsic stains were included in the study and a split mouth study design was employed. On the right side Proxyt paste was used and on the left

side Shine N Smile paste was used to polish the teeth using rubber cup technique for 15 seconds on each tooth. Mean score of the Proxyt paste group before polishing and after polishing was 2.3 and 1.32 respectively.Mean score of the Shine N smile paste group before polishing and after polishing was 2.27 and 1.04 respectively. Chowdhary Z et al compared the efficiency of three different polishing systems on enamel as well as on cementum surfaces by scanning electron microscope (SEM). A total of 120 samples were divided into three groups randomly–Group 1 (bristle brush), Group 2 (rubber cup), and Group 3 (air polisher)–with 20 samples each of enamel and cementum, which were subdivided into 10 control and 10 test group (subjected to polishing). Polishing with bristle brush demonstrated less surface roughness and debris when compared to air polisher at P = 0.58, P = 0.03 for enamel surface and P = 0.003, P = 0.21 for cementum, respectively. The surface roughness was reduced considerably by rubber cup at P = 0.03 for enamel and P = 0.003 for cementum, compared to air polisher at P = 0.99 and P = 0.21 for enamel and cementum, respectively. The results indicated that polishing with rubber cup was more effective and statistically significant when compared to bristle brush polishing and air polisher for the crown and root surface smoothening and debris removal.[9]

In the present study, pre-treatment and post-treatment score difference for the proxyt group and Shine N Smile group was 0.98 and 1.23 respectively. Dental staining is one of the most common problems in aesthetic dental appearance. The use of a rubber cup and pumice is a widely known method among professionals to remove dental stains and plaque. However, this method has limitations because stains in grooves and maligned teeth cannot be accessed. To overcome these limitations, air polishing has been introduced for stain removal. The stain removal efficacies of a rubber cup with pumice and air polishing are similar, but the time required to remove all stains is longer for a rubber cup and pumice than for air polishing. In addition, air polishing can remove stains more efficiently than a curette.[10]

In the present study, significant results were obtained while comparing the mean post-polishing score and difference (pre-treatment and post-treatment) score in between Proxyt paste group and Shine N Smile group. Hongsathavij R et al compared the stain removal efficacy of sodium bicarbonate powders with grain sizes of 65 and 40 μm and to evaluate patient acceptance and operator opinion after using both air polishing powders. A double-blind, randomized, split-mouth study was conducted with 35 participants with moderate to heavy dental staining on both sides of the upper teeth. Removal of dental stains on the index teeth was performed using sodium bicarbonate powders with a grain size of either 65 or 40 μm. The time taken to completely remove all dental stains was recorded. After treatment, a questionnaire was used to evaluate patient acceptance and the operator's opinion. The average time for the removal of all stains by powder was 4.5 ± 3.6 min with a grain size of 65 μm and 4.4 ± 3.8 min with a grain size of 40 μm. The difference in the average time between the two groups was not significant (P = 0.461). The operator's opinions of the two powders were identical, and patient acceptance did not differ significantly between the two types of powders. The 40 μm sodium bicarbonate powder removed dental stains as efficiently as the 65-μm powder.[11]

Conclusion

Under the light of above results, the authors conclude that Smile N Shine paste showed better results in comparison to Proxyt paste. However; further studies with larger sample size are recommended.

Knowledge and Level of Awareness about the Use of Interdental Aids and Proper Brushing Techniques amongst Medical Students

Avineet Kaur[1], Deepak Kochar[2]

[1]Assistant Professor, [2]Professor, Department of Periodontics, M.M. College of Dental Sciences & Research, Maharishi Markandeshwar (Deemed to be University), Mullana, Ambala

Abstract

Background: Oral hygiene practice is an effective measure for maintaining good oral health. The present study was conducted to investigate the status of knowledge and level of awareness about the use of interdental and proper brushing technique among medical students.

Materials & Method: The present study was conducted on 100 medical students of age group 18-22 years of both genders. A questionnaire was prepared that were served to medical students to elicit their response about interdental cleansing aids and proper brushing techniques.

Results: There were 23 male and 21 female with age <20 years and 31 male and 25 female with age >20 years. 28 males and 23 females brush once daily, 36 males and 31 females brush before meal, brushing method was directed seen in 42 males and 39 females, head was 28 males and 31 females were suing zigzag head king of brush, frequency of changing brush was bi-monthly seen in 33 males and 14 females, tooth pick was most common interdental aid used by males and dental floss by females. The difference was non-significant (P> 0.05).

Conclusion: The students had good knowledge on the basic oral health measures necessary to maintain proper oral health, but their attitude and practices towards oral health were relatively poor.

Keywords: *Awareness, Knowledge, Tooth brushing.*

Introduction

Oral hygiene practice is an effective measure for maintaining good oral health which is an integral part of one's general health. As plaque is the primary aetiological factor in the development of chronic inflammatory periodontal disease so measures should be taken to remove it thoroughly. Although brushing is successful in removing plaque at buccal, lingual and occlusal surfaces but it can't completely clean the interdental surfaces. So good interdental oral hygiene aids are required that can penetrate between adjacent teeth.[1]

Oral hygiene behaviour and seeking oral healthcare can depend on a number of factors. Patients comply better with oral healthcare regimens when informed and positively reinforced. Lack of information is the major reason for non adherence to oral hygiene practices.[2] Further, oral health attitude and beliefs are significant for oral health behaviour. Keeping a healthy oral profile requires joint efforts from the dentist as well as the patient himself. One of the most important factors that decide the dental health of a population is the outlook of its people toward their dentition.[3]

The prevalence of caries is related to a low frequency of brushing and a higher consumption of

sweets.[4] Also consumption of fluoridated water coupled with a reduction in non-milk extrinsic sugar intake is effective means farcies prevention. Poor oral and dental health has also been linked to heart and lung disease, diabetes, stroke, low-birth weight, and premature births. Therefore, there exists a need to assess the association between knowledge and behaviour amongst individuals.[5] The present study was conducted to investigate the status of knowledge and level of awareness about the use of interdental and proper brushing technique among medical students.

Materials & Method

The present study was conducted in the department of community medicine. It comprised of 100 medical students of age group 18-22 years of both genders. The study was approved from institutional ethical committee. All participants were informed regarding the study and written consent was obtained.

A questionnaire was prepared that were served to medical students to elicit their response about interdental cleansing aids and proper brushing techniques. Results thus obtained were subjected to statistical analysis. P value less than 0.05 was considered significant.

Results

Table I: Distribution of patients

Gender	<20 years	>20 years
Male	23	31
Female	21	25
Total	44	56

Table I, shows that there were 23 male and 21 female with age <20 years and 31 male and 25 female with age >20 years.

Table II: Oral hygiene habits among the study population

Habit	Male	Female	P value
Brushing teeth			
Once	28	23	0.35
Twice	26	23	
Brushing method			
Directed	42	39	0.87
Undirected	12	7	
Brushing time			
Before meal	36	31	0.94
After meal	18	15	
Type of toothbrush			
Hard	7	4	0.26
Medium	34	24	
Soft	13	18	
Head			
Straight	26	15	0.12
Zig-Zag	28	31	
Frequency of changing brush			
Monthly	21	32	0.002
Bi-monthly	33	14	
Interdental aid			
Tooth pick	29	15	0.07
Dental Floss	16	23	
Inter-dental brush	9	8	

Table II shows that 28 males and 23 females brush once daily, 36 males and 31 females brush before meal, brushing method was directed seen in 42 males and 39 females, head was 28 males and 31 females were suing zigzag head king of brush, frequency of changing brush was bi-monthly seen in 33 males and 14 females, tooth pick was most common interdental aid used by males and dental floss by females. The difference was non-significant (P> 0.05).

Table III: Knowledge regarding oral hygiene habits among the study population

Habit	Male		Female		P value
	Yes	No	Yes	No	
Do you brush your teeth regularly	51	3	43	2	0.82
Do your gums bleed while brushing	5	49	3	43	0.78
Have you heard about interdental aids	29	25	24	22	0.84
Do you floss regularly	7	47	5	41	0.81
Sharp objects like pins are harmful to gums	38	16	36	10	0.37
Do you know about powered toothbrush	19	35	16	30	0.94
Are you aware of oral irrigation devices	10	44	9	37	0.89

Table III shows that 51 males and 43 females brush their teeth regularly, 49 males and 43 females gums do not bleed while brushing, 47 males and 41 females do not floss regularly, 38 males and 36 females knew that sharp objects like pins are harmful to gums, 19 males and 16 females know about powered toothbrush, 10 males and 9 females were aware of oral irrigation devices. The difference was non-significant (P> 0.05).

Discussion

It has been observed that oral hygiene does not get the attention and seriousness it deserves. Majority of the people are unaware about the relationship between oral hygiene and systemic diseases. Many diseases show their first appearance through oral signs and symptoms and they remain undiagnosed or untreated because of the missing awareness. According to consumer usage and attitudes study done in 2010 nearly half of the Indian population does not use a toothbrush and only 51% brushed their teeth using a toothbrush and toothpaste.[6] A majority of the Indians are unaware of the fact that good oral health not only ensures freedom from pain and suffering associated with oral health problems, but is also essential for the overall health improvement and elevation of self-esteem, quality of life, and performance at work. Oral hygiene if adopted properly can help get rid of oral diseases. Many studies have proved that better knowledge in oral health practices and their attitude are linked to good habits with healthier oral cavity.[7] The present study was conducted to investigate the status of knowledge and level of awareness about the use of interdental and proper brushing technique among medical students.

We found that there were 23 male and 21 female with age <20 years and 31 male and 25 female with age >20 years. 28 males and 23 females brush once daily, 36 males and 31 females brush before meal, brushing method was directed seen in 42 males and 39 females, head was 28 males and 31 females were suing zigzag head king of brush, frequency of changing brush was bi-monthly seen in 33 males and 14 females, tooth pick was most common interdental aid used by males and dental floss by females.

A et al[8] found that 55.60% of population know that soft drinks will cause dental problems while 36.40% said it will not cause any problems and rest 8% had no idea whether it may cause dental caries or not. 33.6% of population visit dentist regularly while 32.80% don't visit regularly, 20% said that they had never been to a dentist and rest 13.60% said that they visit a dentist rarely. 21.2% had a dental consultation 3 months ago while 45.4% a year ago and the rest 32.4% recalled their exact visit to the dentist and few even mentioned that they didn't have a dental consultation.

In the present study, although brushing was the commonly used method of cleaning, the percentage of subjects brushing their teeth twice daily was 26% which is very less as compared with 58% of the recruits in a study by Dilip et al.[9] It is noteworthy that 58% of the respondents brushed their teeth using medium sized bristles which will jeopardize the tooth structure. This finding is in agreement with the study done by Gopinath et al[10] where 60% of the sample did the same.

33% participants changed their toothbrush bimonthly and surprisingly 67% changed their brush only when it is useless. There is generally lack of use of interdental aids as a preventive tool as only 5-7% had used any kind of interdental aid. In contrast, Kaur [11] found that 44% of sample they studied used interdental aids. This emphasizes the urgent need for educating and motivating the students to use this efficient method for oral health care. We found that 10% of the total subjects reported bleeding gums. This study was in contrast with studies of Al-Kheraif al[12] who showed that self reported bleeding gums was high in percentage. In the present study only 19% of individuals had heard about powered toothbrushes whereas only 10% were aware about the use of oral irrigation devices which indicates that the present population was not very much aware about these devices.

Conclusion

The students had good knowledge on the basic oral health measures necessary to maintain proper oral health, but their attitude and practices towards oral health were relatively poor. Oral health education programs should be conducted with reinforcement so that students can bridge the gap between knowledge and practice by changing their attitude from negative to positive one. Students should be educated not only about the proper brushing techniques but also about the usage of interdental aids so that they can maintain their oral health in an excellent state. They should be motivated to get regular dental check ups done, as they are the future health providers who pave the way for better society in the creation of better oral hygienic conditions.

Ailments of Women Beedi Labourers in Tirunelveli District, Tamil Nadu

B. Chithirairajan[1], S. Thangamayan[2], N. Manivannan[3]

[1]Assistant Professor of Economics, Department of Economics, [2]Assistant Professor of Economics, Department of Economics, [3]Assistant Professor of Commerce, Department of Commerce, VELS Universty (Deemed to be University), Pallavaram, Chennai

Abstract

This paper major aim to address the ailments of women beedi labourers in Tirunelveli district, Tamil Nadu state. Women empowerment is a smart key to develop their any nation according to women skill and capacity. Now-a-days the plenty of people are living under below poverty line because they are not getting a minimum employment facilities in their life. Further, majority of the people are depends on indoor jobs such as match box works, candle works, and beedi works, especially, women people are dominated and working under indoor jobs than that of men. Beedi works is one of the informal or unorganized sectors in India. It plays a vital role for improving economic development like the beedi work provides employment facilities, improving their living conditions, reduce poverty also. Health is one of the major factors and this present research directly to measure the ill health effects of beedi rolling workers. The measurement of ill health effects in terms of the workers affected by headache, stomach pain, eye problems, skin pain and others. In view these circulstances, the research is based on ailments of beedi workers in Tamil Nadu. The main aim of this paper is to find out the ailments of women beedi workers among well-off households and poorer households in the study region. By this study has used primary data survey method and totally 51 sample respondents are taken from two villages like Alangulam and Sankarnagar in selected Alangulam block of selected district. As a result found that, the women of poorer household respondents have mostly affected such health problems like head ache, eye problems and skin problems as compared to that of women well-off household in selected area.

Keywords: *Ailments,informal sector, women health problems, employment opportunity,well-off households, poorer households.*

Introduction

Statement of the Problem: In view of this economic importance, the entire economy meets many controversial issues like poverty, employment problems, mass population, pollution and etc. These critical issues are leads to inflation or deflation, problems arising in exchange rate policy, and to collapse the economic development. Now-a-days the plenty of people are living under below poverty line because they are not getting a minimum employment facilities in their life. In view of this, majority of the people are depends on indoor jobs such as match box works, candle works, and beedi works, especially, women people are dominated and working under indoor jobs than that of men[3]. Ansari (2015) pointed out that, "beedi making industry is one of the age old industries and it provides largest job opportunities under unorganized sector in India. Further, the author stated that, most of them women workers are engaged under home based works like the beedi rolling activities who fall comes from below poverty line"[6]. Beedi works is one of the informal or unorganized sectors in India. It plays a vital role for improving economic development like the beedi work provides employment facilities, improving their living conditions, reduce poverty also. Since the beedi work is considered a major livelihood source in rural economy. The beedi work raw materials are provided by the contractors and finally the work is finished by the employee and it is replaced to the contractors[1]. Furthermore, it is engaged on labour intensive work, it is home based production activity work and the beedi roll is produced by manually. Further, the small scale industries occupy a unique position and

volatile of economic life of the home based workers[4]. At this juncture, the present study makes an attempt to analyse the ailments of women beedi workers among well-off household workers and poorer–household workers with special reference to Tirunelveli district, Tamil Nadu. In Tamil Nadu, the informal sector like the beedi rolling industry is one of the biggest industry with more than 5 lakhs labourers are involved in beedi works in Tirunelveli district[7]. Further, the other districts are also involved in beedi rolling works in Tamil Nadu like Vellore, Thoothukudi, Kanyakumari, Erode, Thiruvallur, Chengalpattu, Tiruvannamalai etc[10]. But, the Tirunelveli district is occupied prime position to involved in beedi works. Majority of the beedi workers are comes from rural area like Alangulam, Keelpacoor, Tenkasi, Pavoorchatthiram, Ambasamudram, Pappakudy etc. By and large, wage and health factors are ultimate role to improve their social status in any countries. Health is one of the major factors and this present research directly to measure the ill health effects of beedi rolling workers. The measurement of ill health effects in terms of the workers affected by headache, stomach pain, eye problems, skin pain and others. In view these circulstances, the research is based on ailments of beedi workers in Tamil Nadu.

Objectives:

1. To find out the ailments of women beedi workers among well-off households and poorer households in the study region.
2. To suggest the suitable measures to improve their health conditions among beedi workers.

Hypothesis:

1. Women poorer household workers may be affected more health problems as compared to women well-off households.

Methodology: Drawn from the present study is based on multi-stage random sampling method. This paper makes an attempt to field survey method i.e., the survey collected from primary investigation system and it is prepared by well interview questionnaire method. In view of this multi-stage sampling method, the first stage, the Tirunelveli district has selected in Tamil Nadu state, because this selected district is a pioneer district among the beedi work is involved in high level and most of them women are engaged to work in beedi rolling industries. Followed by the second stage, the Alangulam block has selected in Tirunelveli district, it is selected by using lottery method. Further, the Alangulam block is one of the revenue blocks in selected district. In third stage, two villages have selected like Alangulam village and Sankarnagar village in selected block. With respect to fourth stage, 51 sample households are selected and it is selected by using simple random sampling method. In view of these selected respondents in Alangulam village, 30 respondents are selected. Out of this sample household, 10 respondents are selected from women well-off households and the remaining 20 households are poorer households. On the other village i.e., Sankarnagar village, 21 respondents are selected. Out of this 21 respondent, 9 households are selected from well-off household and the remaining 12 respondents are covered from poorer household. In totally, 19 sample households are selected from well-off households and the remaining 32 sample households are selected from poorer households in selected villages in Tirunelveli district. By and large, the present study has employed with using percentage method for income pattern, opinion about health problems, and symtoms of health problem among beedi workers in selected district.

Results and Discussions

Table 1: Income Pattern of Women Beedi Workers

Income	Women Well-off Households	Women of Poorer Households	Total Respondents
Less than Rs 3000	2(10.5)	17(53.1)	19(37.3)
Rs 3000-4500	4(21.1)	10(31.2)	14(27.5)
Rs 4500-6000	6(31.6)	3(9.4)	9(17.6)
More than Rs 6000	7(36.8)	2(6.3)	9(17.6)
Total	**19(100)**	**32(100)**	**51(100)**

Source: Primary Data

Table 1 explains the distribution of selected workers according to their household monthly income basis. It is cleared from the table that, out of the whole respondents, majority 37.3% of them earned less than Rs 3000, followed by 27.5% of the respondents earned between Rs 3000 to Rs 4500, and the remaining each 17.6% of the respondents earned between Rs 4500-6000 and more than Rs 6000. According to women well-off workers most of them earned Rs more than Rs 6000 which constitute 36.8% followed by 31.6% at Rs 4500-6000, 21.1% at Rs 3000-4500 and the least income level at Rs less than Rs 3000 which constitute 10.5% . Whereas women of poorer household, and majority more than

half of them (53.1%) earned the monthly income level as Rs less than 3000, followed by 31.2% at Rs 3000-4500, 9.4% at the Rs 4500-6000 and rest of them 6.3% earned at Rs more than 6000. As result found that, the women well-off household respondents has earned more income as compared to that of women poorer households.

Table 2: Opinion about Health Problems of Beedi Workers

Health Problems	Women Well-off Households	Women Poorer Households	Total
Yes	8(42.1)	25(78.1)	33(64.7)
No	11(57.9)	7(21.9)	18(35.3)
Total	**19(100)**	**32(100)**	**51(100)**

Source: Primary Data

Table 2 indicates that health problems among the selected workers. It is observed from the table that on the whole, more than half of the respondents (64.7%) showed some health problems such as; burning of the eyes, head ache, etc., and the rests of them 35.3% of the respondents have good health in both households. According to women well-off household, 57.9% of the respondents stated that they have good health and the remaining 42.1% of the respondents argued not so for it. But in the case of women of poorer households, a majority more than three fourth of the respondents (78.1%) mentioned some health problems and the remaining 21.9% of the respondents spent out they have good health. The comparison between these groups, women of poorer household affected more health problems as compared to that of women well-off households.

Table 3: Opinion to welfare facilities in working places

Welfare facilities	Women well-off	Women of poorer	Total respondents
Yes	12(63.2)	9(28.1)	21(41.2)
No	7(36.8)	23(71.9)	30(58.8)
Total	**19(100)**	**32(100)**	**51(100)**

Source: Primary Data

Table 3 shows that the selected workers opinion to welfare facilities in working places. Out of the total selected respondents, more than half of the respondents (58.8%) stated that there is still needed to be provided with the benefits and welfare facility and the remaining 41.2% of the respondents have been attained welfare facility with benefits in both households. According to women well-off households a majority of 63.2 % of the respondents opined about they have attained welfare facility and benefits and rest of them 36.8% of the workers there are still demanded to be attained welfare facilities and benefits. Whereas the women of poorer households, nearly three-fourth of the respondents (71.9%) have demand to be provided welfare facilities and the remaining 28.1% of them recorded attained the welfare facilities and benefits. As a result found that, the women of the poorer households demand to be provided such welfare facilities and they required hospital facilities, medical facilities, and good environmental facilities.

Table 4: Ailments of Women Beedi Labourers

Ailments	Women Well-off Households	Women of Poorer Households	Pooled Respondents
Headache	2(25)	4(16)	6(18.2)
Burning of eyes	1(12.5)	5(20)	6(18.2)
Back/neck/ stomach pain	2(25)	7(28)	9(27.2)
Cough	1(12.5)	3(12)	4(12.1)
Skin problem	2(25)	4(16)	6(18.2)
Others	0(0)	2(8)	2(6.1)
Total	**8(100)**	**25(100)**	**33(100)**

Source: Primary Data

Table 4 analyse the ailments of women beedi labourers in selected area. The report includes various symptoms such as head-ache, burning of eyes, back pain, neck pain, stomach pain, coughs, skin problems and other related problems. It is clear from the table that, 27.2% of the respondents affected by back pain/neck pain/ stomach pain, followed by head ache, burning of eyes, skin problems have recorded 18.2% of the respondents each, 12.1% of the problem affected by coughs, and least 6.1% of the respondents opined that other such related problems in both selected households. It regards to women well-off household, 25% of them respondents each affected by headache,backpain/neck/stomach pain and the remaining 12.5% of the respondents each affected by burning of the eyes and skin problems. On the other hand the women of poorer households, 28% of them affected by back/neck/stomach pain, followed by 20% of the respondents affected by burning of the eyes, 16% of the respondents each affected 4 by headache and skin problems, 12% of them recorded to cough problems, and the least 8% of the respondents by other such problems such as, hand pain, leg pain, breathing problem, etc., It is focused from the table the women of poorer household

has majority affected by back/neck/stomach pain as compared to other problems. By and large, as a result found that, the women of poorer households have mostly affected such as many health problems as compared to that of women well-off households in Tirunelveli district.

Policy Suggestions:

1. The standard of living condition is poor among the beedi workers. Hence, the Government should try to provide hospital facilities, medical facilities, and housing facilities.
2. Among the beedi workers now get only low wages. Hence, the Government should take necessary action and to suggest follow the minimum wage rate policy.
3. More number of beedi workers is affected by health diseases. Hence, they require good working places, better air condition facilities and environmental facilities and further, they need for free health check-up facilities also. So, the Government should try to provide free health check-up facilities and other facilities also.

A Study on Internet Banking System and Customers Satisfaction in Namakkal District

B. Chithirairajan[1], Telu Suvarna[1], E. Rajarethinam[1]

[1]*Assistant Professors, Department of Economics, VISTAS (Deemed to be University), Pallavaram, Tamil Nadu*

Abstract

The internet banking system is an innovative banking method and it is otherwise called online or electronic banking system. In view of this internet banking system is typically related with core banking system which has been operated by a bank with internet. The internet banking system refers to that the monetary transactions are involved through electronically from one person account to another person account with using internet, it does not depend upon physical transaction process. Under the following internet technologies, the banks have benefitted in several ways such as, it has the result found in reducing costs, saving time and energy, and has developing revenue from various channels. Further, the prime objective of the study is, to examine the usage of online banking facilities among gender wise classification in Morepalayam panchayat of Namakkal District. Next objective is that, to analyse the customer satisfaction among the usage of internet banking facilities in Morepalayam panchayat of Namakkal District. The design of the study is based on primary data analysis and using well-structured interview scheduled method. With respect to primary data collection, 85 samples have taken for this present research. Out of the whole 85 sample respondents, 48 respondents are male and the remaining 37 respondents are female. The period of the study is covered from 1st April 2018 to 31st July 2018. As a result found that, 41.18 percent of them respondents are strongly agree among the usage of internet banking facilities for the purpose of funds transferring from one account to another account.

Keywords: *Internet banking, customer satisfaction, fund transaction, technology and innovation.*

Introduction

The present contribute to summarize the role of internet banking system and customers satisfaction in rural areas. The internet banking system is an innovative banking method and it is otherwise called online or electronic banking system. At present the internet banking system plays a vital role to improve their banking transactions among rural areas in India. The internet or online banking system was first introduced by 1980s in New York (US). Almost simultaneously with the US, online banking system is also started in United Kingdom. The United Kingdom's pointed out that the first home online banking service is called Home-link was set up by Bank of Scotland at Nottingham Building Society in 1983[2]. In India, internet banking system was first announced by ICICI bank to its customers in 1996. In view of this internet banking system is typically related with core banking system which has been operated by a bank with using internet which enables them lower level of cost than that of traditional brick and mortar banks. In simple terms, the internet banking system refers to that the monetary transactions are involved through electronically from one person account to another person account with using internet, it does not depend upon physical transaction process[1]. Under the following internet technologies, the banks have benefitted in several ways such as, it has resulted in reducing costs with saving time, energy, and has developing income from various channels. Further, the number of customer need to their convenient in anywhere banking system. The internet and newer technology may be reduced human mistakes and errors[4]. The internet process is a way to access and analyse various data in anytime with providing a strong reporting system. Moreover the introduction of electronic funds transfer and the implementation of ATM channel have found that the convenient of any-time banking method.[5] By and large, the National Electronic Funds Transfer (NEFT) is contributing easiest way for electronic payment system according to the amount of funds transferred between one account to another account. Moreover, the Immediate Payment Service is

called IMPS; it is also one of the major processes for the funds transfer facility system and it is given by National Payments Corporation of India (NPCI) which is working in 24 X 7. At this juncture, the present study makes an attempt to analyse the online banking system and customer satisfaction in rural area.

Importance of Internet Banking System in India

i. The internet banking system is much easier and faster for both customers and banks.

ii. The major important view is that to save time and energy.

iii. It is easier to transfer the funds from one bank to other banks.

iv. It is well organized method for cash management through internet optimization.

v. The internet or online banking system is functioning throughout the year 24 X 7 from any place through internet access.

vi. It provides more privacy to customers by using newer technologies.

vii. It makes better relationship between customer and bank officers.

Research Objectives:

i. To examine the usage of online banking facilities among gender wise classification in Morepalayam panchayat of Namakkal District.

ii. To analyse the customer satisfaction through internet banking facilities in Morepalayam panchayat of Namakkal District.

Research Methodology: The present study has adopted primary data analysis method with using well-structured interview scheduled method. It is specified by multi-stage sampling techniques method and the simple random sampling method was used. In view of this content, Namakkal district has selected in first stage, followed by the second stage, Morepalayam panchayat has selected in Namakkal district. Among third stage, Paruthipalli and Ramapuram villages have selected. Among the fourth stage, the sample respondents have selected with proper interview scheduled method. On the basis of this primary data, 85 samples have taken for this present research. Out of the whole 85 sample respondents, 48 respondents are male and the remaining 37 respondents are female. With respect to that data collection, the period is covered from 1st April 2018 to 31st July 2018. Further, in view of this tools for analysis, the percentage method has used.

Results and Discussion

Table 1: Gender Wise Classification of Internet Banking Facilities

Age / Gender	Male	Female	Total
Upto 20 Yrs	6(12.5)	4(10.81)	10(11.76)
20–30	21(43.75)	18(48.65)	39(45.88)
30–40	14(29.17)	11(29.73)	25(29.41)
40–50	5(10.41)	4(10.81)	9(10.59)
Above 50 Yrs	2(4.17)	0(0)	2(2.36)
Total	**48(100)**	**37(100)**	**85(100)**

Source: Field Survey

Table 1 explains the gender wise along with age wise classification of sample respondents which represents the usage of internet banking facilities in selected Namakkal district. Out of the total 85 respondents, most of them 45.88 percent of the respondents are stated that funds transferred from one person account to another person account with using internet banking facilities fall under the age group between 20-30 years, next 29.41 percent of them pointed out that using internet facilities for the purpose of transferring funds among the age group of 30-40, 11.76 percent of them recorded under the age group of upto 20 years, 10.59 percent of them recorded among the age group between 40-50 years and the least 2.36 percent of them opined that using internet facilities for their funds transferring from one person to another person account as it fall in the age group of above 50 years. As a result found that the comparative between male and female respondents, the female respondents are using internet facilities for transferring funds from one person account to another person account as it is more than that of male respondents who are fall in the age group between 20-30 years.

Table 2: Types of Internet Banking Facilities

Age / Gender	Male	Female	Total
Mobile Banking	20(41.67)	15(40.54)	35(41.18)
NEFT Using	17(35.42)	13(35.14)	30(35.29)
Other Facilities	11(22.91)	9(24.32)	20(23.53)
Total	**48(100)**	**37(100)**	**85(100)**

Source: Field Survey

Table 2 interprets the types of internet banking facilities in selected district. It could be noticed that, the male respondents (41.67%) are using mobile banking facilities through internet at high level as compared to that of female respondents (40.54%). Followed by NEFT using facilities, the male respondents are recorded higher level (35.42%) as compared to female respondents (35.14%). Remaining other facilities through internet, the female respondents are recorded high level (24.32%) as compared to that of female respondents (22.91%). As a result found that most of them 41.18 per cent of the respondents are recorded their funds transferred from one account to another account with using mobile banking facilities through internet in selected area.

Table 3: Customer Satisfaction Through Internet Banking Facilities

Perception	Male	Female	Total
Strongly Agree	20(41.67)	15(40.54)	35(41.18)
Agree	13(27.08)	12(32.43)	25(29.41)
Neutral	10(20.83)	3(8.11)	13(15.29)
Disagree	2(4.17)	5(13.51)	7(8.24)
Strongly Disagree	3(6.25)	2(5.41)	5(5.88)
Total	**48(100)**	**37(100)**	**85(100)**

Source: Field Survey

Table 3 analyse the customers satisfaction through the usage of internet banking facilities in Namakkal district. It is noticed that, 41.67 percent of the male respondents are opined that strongly agree with high level satisfied among the usage the internet banking facilities as compared to female respondents which contribute 40.54 percent. Followed by the female respondents (32.43%) agree with high level using internet banking facilities than that of male respondents (27.08%). Under neutral level, the male respondents are satisfied with using online banking facilities as compared to that of female respondents. The female respondents (13.51%) are opined that disagree about using internet banking facilities than that of male respondents at 4.17 percent. By and large, the male respondents (6.25%) stated that strongly disagree with using internet banking facilities than that of female respondents at 5.41 percent in selected area. It could be resulted that, 41.18 percent of them respondents are strongly agree among the usage internet banking facilities for the purpose of fund amount transferring from one account to another account.

SWOT Analysis of Internet Banking Facilities

Strengths	Weaknesses
✓ It is possible for quick transaction between one account to another account among throughout the year 24 x 7 with internet access. ✓ It is possible for booking bus ticket, train ticket, boarding and lodging facilities through internet access. ✓ It gives more relationship between customers and bank officers. ✓ Using internet facility, it is optimized for cash management process in banking sector. ✓ Internet is a way for reducing cost and increasing efficiency.	× Need for huge investments for maintaining online banking method. × Lack of awareness about consumer side due to following digitalization process in our society. × Online banking system arise the gap between personal human touch. × Online banking system arises various types of risks and it is difficult to manage them. × Lack of Technology in rural areas × Lack of trained staffs

Opportunities	Threats
• To improving Customer Services • To reduce competitive pressure • To increase revenue • To replacing old scheme systems • To reducing human error • To encourage efficiency • To evaluate their technology and assess internet banking systems • To expand marketing through the usage of internet amenities.	• Outsourcing risks are high. • Operational risks are at high level. • Difficult to handling newer technologies. • Lack of well-trained staff • In remote villages, internet is not working in properly. • Legal risks are arising at various ways. • Arising information technology risks. • Internal audit problem also arising under online banking method.

Conclusion

In view of this economic importance, online banking system is a good driven for improving relationship between customer care support and bank officers. It could be noticed that, the internet banking system is support to assess the efficiency for technology. Further, the internet banking system is an innovative banking system and it growing business in the market. The internet banking system to facilitate account management for business people and it is useful for foreign currency transactions. By offering speed and fast internet system is to reduce time and to manage various transactions. Thus the study concluded that, our society need for quality and efficient

banking system like as eco-friendly manner, secure and privacy, convenient and reducing cost, saving time and go green method. The way of internet banking system is fully depends upon quality of services, to attain sustainable development, and maintaining customers satisfaction.

Quality of Life of People with Type 2 Diabetes

Aldrin Vas[1], Elsa Sanatombi Devi[2]

[1]PhD Scholar, [2]Professors, Manipal College of Nursing, ManipalAcademy of Higher Education, Manipal

Abstract

Purpose: A descriptive survey design has been used to assess the quality of life among people with type 2 diabetes.

Method: This descriptive survey was carried out among 180 people with type 2 diabetes who admitted to tertiary care hospital at Udupi from June 2015 to January 2016. Data collected were basic demographic information andclinical items like HbA1c and BMI. Quality of life (QOL) was assessed with quality of life instrument for Indian diabetes Patients (QOLID) tool.

Results: This study reveals poor quality of life among 22 (12.2%) people with type 2 diabetes and moderate level in 158 (87.8%) of them.

Conclusion: Considerable number (12.2%) of people with type 2 diabetes is experiencing poor quality of life which calls for appropriate intervention.

Keywords: *Type 2 diabetes, Quality of life, self management.*

Introduction

Diabetes is on the rise. Every 40 seconds a new case is diagnosed[1]. Individuals are living with diabetes across the world are estimated about 415 million and by the year 2040this number may rise to 642 million[2]. 75% of them will be living in developing countries. Concerning age group 40-59 years constitutes majority.

Estimated number concerning diabetes for south East Asia, is 78.3 million and India constitutes majority of them i.e. 69.2 million[2]. In India 1.1 million deaths occurred due to diabetes where the number for South East Asia is 1.2 million[3]. Prevalence rate of diabetes in urban Indian is about 8.7% which is a decade earlier when compared to western population. This reveals that young people i.e. below 50 years of age are affected with diabetes which is supposed to be most productive time of their life with a possibility of higher risk of complications[4]. Maintaining good quality of life challenging since diabetes is a chronic life long illness, require regular monitoring and evaluation throughout their life.

This present study aimed to assess the quality of life of people with type 2 diabetes at selected hospital in Udupi district. We alsoaimed to find out the associations of quality of lifeand demographic variables. Good understanding of it is essential to provide effective health care.

Summary Statement

What is already known about this topic?

- Quality of life among people with type 2 diabetes is a multidimensional construct.
- Perceived quality of life is considered as an essential output of an intervention

What this paper adds?

- This study focuses on various aspects of quality of life among people with type 2 diabetes which aids to become aware of it.
- Awareness about different aspects of quality of life will help to design interventions to improve it.

The implications of this paper

- Shift of focus from symptomatic care to holistic approach where overall quality of life will be the goal of intervention.
- Innovative approaches to strengthen the ability of self management of their condition to maintain a good quality of life of people with type 2 diabetes

Materials and Method

A descriptive survey was carried out to determine the quality of life of people with type 2 diabetes in a selected tertiary care hospital at Udupi from June 2015 to January 2016. After satisfying inclusion criteria a total of 180 people who admitted with type 2 diabetes were participated in the study. Inclusion criteria were people with type 2 diabetes aged more than 30 years, suffering from diabetes for more than 3 months, able to communicate in regional language Kannada, willing to participate in the study, whose glycosylated haemoglobin (HbA1c) is 6% and above

Tool description

Demographic proforma: Demographic proforma was constructed to collect the characteristics of the study participants. This tool consisted of 12 items like age, gender, religion, education, occupation, family monthly income, dietary habit and clinical items like onset, duration of illness, regular check up, HbA1c and BMI.

Quality of life tool: Quality of Life Instrument for Indian Diabetes Patients (QOLID) tool developed by Jitendernagpal et.al was used in the survey with authors' permission. Tool consisted of 34 items covering 8 domains like general health, role limitations due physical health, symptom frequency, physical endurance, treatment satisfaction, financial worries, diet advice satisfaction and mental health. Items were scored 1 to 5, maximum possible score was 169 and minimum was 34. The quality of life was classified into good (125-169), moderate (79-124) andpoor (34-78)[5].

Data collected, analysed and interpreted as per the study objectives using descriptive and inferential statistics with the use of SPSS 16 version

Ethical consideration: This study was carried out after getting the clearance from institutional ethical committee and written informed consent from the study participants. Institutional ethical committee approval number: ECR/146/Inst/KA/2013

Results And Discussion

Sample Characteristics

Table 1: Frequency and percentage distribution of people with type 2 diabetes n=180

Variables	Frequency (f)	Percentage (%)	P-value
Age (Years)			
30-39	21	11.7	.835
40-49	32	17.8	
50-59	59	32.8	
60 -69	45	25.0	
70 and above	23	12.8	
Gender			
Male	121	67.2	.266
Female	59	32.8	
Income			
below 5000	27	15.0	.124
5001-10000	105	58.3	
10001-15000	39	21.7	
15000 above	9	5.0	
Dietary habits			
Vegetarian	72	40.0	.224
Non vegetarian	108	60.0	
Duration of illness			
Less than 1 year	40	22.2	.024
1-5 years	70	38.9	
More than 5 years	70	38.9	
Onset			
Before 30 years	2	1.1	.959
30 –39years	34	18.9	
40–49years	57	31.7	
50–59 years	53	29.4	
60–69years	31	17.2	
After 70 years	3	1.7	
Regular Check up in a year			
None	5	2.8	.333
Once	15	8.3	
Twice	69	38.3	
Thrice or more	89	49.4	
Don't know	2	1.1	
HbA1c (gm %)			
Below 8	94	52.2	.034
8.1 - 10	37	20.6	
10.1 -12	28	15.6	
Above 12.1	21	11.7	
BMI			
<25	84	46.7	.871
25 - 30	92	51.1	
>30	4	2.2	

Sample characteristics reveals that majority (57.8%) of the patients are in the age group of 50 to 69 years. Concerning to gender, 121 (67.2%) were males,167 (92.8%) belongs to Hindu religion, 121(67.2%) were had schooling not more than higher secondary,156 (86.7%) were married, 105 (58.3%) had monthly family income of 5001 to 10,000 Indian Rupees and 108 (60%) were non vegetarians.

Concerning to duration of illness 140 (77.8%) of them had diabetes more 1 year. Most of them i.e. 57 (31.7%) had onset of illness between41 to 50 years. Most of them i.e.89 (49.4%)gone for regular check up thrice or more in a year,92 (51.1%) had information regarding diabetes and its management. 94 (52.2%) maintained blood glucose level below 8gm%of HbA1c and96 (53.3%)had BMI more than 25.

Quality of life

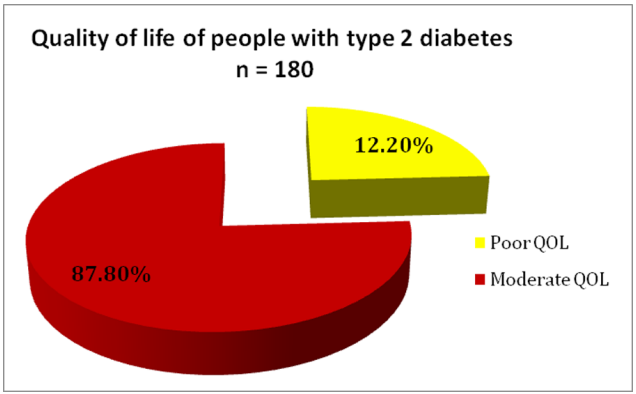

Figure: Pie chart on quality of life of people with type 2 diabetes.

Association between quality of life and selected variables among people with type 2 diabetes

Table 2: Association between quality of life and selected variables n=180

Variable	Freq-uency	Overall QOL		P value
		<Median (86)	≥ Median (86)	
Duration of illness				
Less than 1year	40	15	25	.299
1-5 years	70	36	34	
More than 5 years	70	36	34	
Onset				
Before 40 yrs	36	17	19	.419
41 - 50yrs	57	32	25	
51 - 60yrs	53	25	28	
After 60	34	13	21	
Regular Check up in a year				
Others	22	6	16	.060
Twice	69	32	37	
Thrice or more	89	49	40	
HbA1c (gm %)				
Below 8	94	45	49	.199
8.1 - 10	37	21	16	
10.1 -12	28	9	19	
Above 12.1	21	12	9	
BMI				
<25	84	38	46	.437
25 and above	96	49	47	

Data in the table 2 shows that there is no significant association found between clinical items like onset(P=.419), duration of illness(P=.299), regular check up(P=.060), information on disease condition(P=.771), HbA1c (P=.199) and BMI (P=.437).

Quality of life with regard to different domains

Table 3: Quality of life with regard to different domains n=180

Quality of life domains	Minimum	Maximum	Max. possible score	Mean	Std. Deviation	Median	Std. Error
Physical Health	10	22	30	15.61	2.439	16	.257
Physical Endurance	9	27	30	15.45	2.904	15	.306
General Health	4	12	15	7.585	1.426	8	.150
Treatment Satisfaction	6	17	20	10.56	1.991	10	.210
Symptom Botherness	5	13	15	7.87	1.605	8	.174
Financial Worries	5	16	20	9.75	1.850	10	.195
Emotional/Mental Health	7	23	25	12.67	2.484	13	.262
Diet Satisfaction	3	13	15	7.30	1.764	7	.186
Over all QOL	68	123	169	86.83	8.391	86.00	.884

Quality of life of people with type 2 diabetes was assessed in 8 different domains. Mean and standard deviation of physical health 15.61 ± 2.439, physical endurance 15.45 ±2.904,general health 7.585±1.426, treatment satisfaction 10.56±1.991, symptom botherness 7.87±1.605, financial worries 9.75±1.850, emotional/ mental health 12.67±2.484, diet satisfaction 7.30±1.764. And overall quality of life found to be moderate among people with type 2 diabetes. Major concern was seen in the area of financial aspect and diet also was other area of concern for the people with diabetes.

Discussion

This study revealed that 22 out of 180 i.e. 12.2% had poor quality of life. People with diabetes had a low mean score in all the domains quality of life[6]. Result showed that 30.6% had poorquality of life[7]. 32.9 % people with type 2 diabetes had poor quality of life[8]. The Health related quality of life also found to be poorin the study participants[9].

This study revealed that there was no association between quality of life and demographic variables. There were no statistically significant associations between health-related quality of life scores and age, duration of illness, education, marital status, and treatment type[10]. Quality of life assessment should be routinely practiced in diabetic clinics[11]. Selfmanagement of the condition will help to enhance the quality of life of people with type 2 diabetes.

Conclusion

This study revealed about quality of life of people with type 2 diabetes and domains which needs attention. Health professionals, patient and patient's support system can focus on those domains and efforts can be made to maintain better quality of life.

Effectiveness of Child to Child Programme on Knowledge Regarding Management of Minor Ailments among School Children

Ashly Lukose[1], Binu Margaret E[2], Bharathi R. Nayak[3]

[1]M.Sc. Nursing, Manipal College of Nursing, [2]Assistant Professor-Selection Grade, Department of Child Health Nursing, Manipal College of Nursing, [3]Assistant Professor, Manipal School of Nursing, Manipal, Manipal Academy of Higher Education, Manipal, Karnataka

Abstract

Background: Suffering from minor ailments is the most frequent episode in childhood experiences. A productive and energetic population cannot grow from unhealthy children who are chronically affected by repeated minor ailments. The school children could be equipped with the right knowledge in managing the ailments encountered in their day to day life through the child to child programme.

Objective: To evaluate the effectiveness of child to child programme in increasing the knowledge of school children regarding management of minor ailments among in selected schools of Udupi taluk.

Materials and Method: The present quasi experimental study was conducted among 50 school children(25 experimental and 25 control group) selected by simple random sampling from English medium schools of Udupi taluk. The demographic proforma and structured knowledge questionnaire was used to collect data. Child to child programme conducted in 1:1 ratio to the younger children.

Results: The results showed that majority of the children had average knowledge on management of minor ailments in the pretest both for the control group 24(96%) and experimental group 23(92%). A significant difference was found between the mean pretest and post test knowledge scores of the experimental group ($t=11.294$, $p<0.05$). The mean posttest scores of the experimental and control group ($t = 11.29$, $p<0.05$)was significantly different.

Conclusion: The study concluded that the child to child programme was effective in bringing the desired changes in the knowledge of the school children.

Keywords: *Child to child programme, Knowledge, School children, Minor ailments, India, Fever, Common cold, Diarrhoea, Worm infestation, Conjunctivitis, Dental caries, fainting.*

Introduction

Children are the future of a nation. It is absolutely essential to protect child's health if we are to build a sound foundation for the health of the nation.[1] School children are exposed to various epidemiological factors in the environment which influence their present and future state of health. Suffering from minor ailments is the most frequent episode in childhood experiences. A productive and energetic population cannot grow from unhealthy children who are chronically affected by repeated minor ailments. The common minor ailments among school children include fever, cough, common cold, dental caries, sore throat, conjunctivitis, diarrhoea, vomiting, worm infestations etc. The so called minor ailments if untreated are often the beginning of serious disabling disease.[2] A study done by Crocitti, etal. in

Corresponding Author:

Assistant Professor, Department of Child Health Nursing, Manipal College of Nursing, Manipal, ManipalAcademy of Higher Education, Manipal, Karnataka, India-576104
e-mail: binumarg@gmail.com

2001 indicated that parents still have a problem to care the fever in children[3]. Acute respiratory tract infection account for 67% of all morbidity in India. The incidence of respiratory ailments in Bangalore's children has risen sharply from 9 % in 1979 to 30 % in 1999[4]. About 30-50% of rural children suffer from much morbidity like anemia, worm infestation, under nutrition, and dental carries. Worms affect an estimated 400 million school-aged children in the developing world. Health education to school children in their formative age is the most effective method for protection and promotion of their health. Innovative approaches to education for health are essential to gain the interest, support, involvement and commitment of students. A randomized control trial conducted by Walvekar PR, Naik VA and Wantamutte AS showed that child to child programme had made a significant improvement in the knowledge, change in attitude and practice of the study group students after the intervention when compared to control group students.[5] Child to child programme is based on the concept that children in schools and family members need to be considered as partners in spreading health messages as well as benefiting from them. They are makers of change.[6] In developing countries, where ill health is a problem "every school child is a health worker". As minor ailments continues as a matter of concern among school children, knowledge regarding the same in school children will ensure self helpwhich enables timely detection and management and thereby averting the unwanted complications. Moreover child to child programme has been proved effective in transferring knowledge and inculcating healthy attitudes and practices in young generation.[7] Therefore the researcher felt the need to equip the school children with the right knowledge in managing the minor ailments encountered in their day to day life, thus empowering the future generation to lead a healthy life and work as agents of change for improved health of their families and communities. The present study is an attempt to assess the effectiveness of child to child programme on management of minor ailments among school children in selected schools of Udupi taluk, Karnataka.

Materials and Method

The study was a quasi experimental study conducted among nineth and seventh class students from selected English Medium Schools of Udupi taluk. Simple random sampling was used for the selection of schools and the schools were randomly assigned to the experimental and control group. After the selection of schools, 25 nineth class students were randomly selected and trained to transfer the knowledge to the younger children in seventh class. An one hour teaching session for two days regarding selected minor ailments like fever, commoncold, cough, dentalcaries, conjunctivitis, worm in festations and diarrhea was discoursed to the nineth class children. The demographic proforma and structured, pretested, valid and reliable knowledge questionnaire was administered to the children. The knowledge questionnaire included multiple choice questions from various aspects of minor ailments like meaning, causes, signs and symptoms, management and prevention with a maximum score of 36. Each correct answer was given a score of one. The scores from the knowledge questionnaire were arbitrarily classified into good, average and poor knowledge.

The child to child programme was conducted in 1:1 ratio to the younger children. Child to child programme was a formal teaching programme done by 25 older children to 25 younger children. No intervention was given to the control group. A pretest was administered to both the invention and control group and after seven days of child to child programme, a post test was conducted. A structured knowledge questionnaire was used to assess the knowledge of the school children in both the groups.

Ethical Clearance was taken from Institutional Ethical Committee of Kasturba Hospital, Manipal. Administrative permission was taken from the school authorities.

The statistical analysis was done using SPSS version 16. Frequency, percentage, chi-square, independent t test and paired t test were the statistical tests used for the data analysis with the level of significance at 0.05.

Results

Among the older children, most 17(56.7%) of the children were in the age of 14 years and 10(33%) children were in the age of 15 years. Most of the children, 14 (46.7%) belonged to Hindu religion. Fifty percentage of the children had previous knowledge regarding minor ailments and teachers were the major source of information for them. Majority 17 (56. 7 %) of children had average knowledge in the pretest on management of minor ailments and only 4(13.3%)of children had poor knowledge.

Among the younger children, majority of the children in the experimental group 18(72%) and 11(44%) in the control group belonged to the age of 12 years. Most of the children 13 (52%) of the experimental group and 21(84%) of the control group belonged to the Hindu community. Majority 17(68%) of the children in the experimental group and most of the children in control group 10(40%) were from nuclear and extended family. Most of the children 13 (52%) and 12 (48%) in experimental group and control group received previous information about minor ailments and their major source of information was teachers and friends.

Majority of the children had average knowledge in the pretest on management of minor ailmentsboth for the control group 24(96%) and the experimental group 23(92%), whereas in the posttest, 19(76%) had good knowledge in the experimental group which showed that child to child programme had an influence in the increase of knowledge scores of the younger children in the intervention group. [Table 1]

There was a significant difference between the mean pretest (18.80 ± 4.072) and mean post test (27.88 ± 4.503) knowledge scores of the experimental group which indicated that the child to child programme was effective in improving the knowledge on management of minor ailments among the younger children. ($t=11.294$, $p<0.05$). The mean posttest knowledge scores of the experimental (27.88 ± 4.503) and control group (17.88 ± 4.622) was significantly different which proved that the child to child programme was effective in improving the knowledge on management of minor ailments among the younger children ($t = 11.29$, $p<0.05$).

The area wise analysis of data presented in the table 2 shows that there was an increase in the mean in the area of common cold and cough between the pretest (4.12 ± 1.269) and posttest (6.72 ± 1.061). In the area of dental caries, mean and standard deviation has increased from (2.92± 1.288) in the pretest to (4.16± 0.850) in the posttest. In diarrhea, the mean and standard deviation has increased from (2.36± 1.221) in the pretest to (4.60± 1.633) in the posttest. This shows that in all the areas of minor ailments, there was an increase in the knowledge scores after the child to child programme which shows its effectiveness.

Table 1: Comparison of pretest and posttest knowledge scores in frequency and percentage of experimental and control group n= (25+25) = 50

	Level of knowledge	Pretest		Post test	
		Frequency (f)	Percentage (%)	Frequency (f)	Percentage(%)
Experimental group	Poor	2	8	0	0
	Average	23	92	6	24
	Good	0	0	19	76
Control group	Poor	1	4	3	12
	Average	24	96	19	76
	good	0	0	3	12

Table 2: Area wise comparison of pretest and posttest knowledge scores on management of minor ailments among younger children of experimental group. n= 25

Areas of knowledge	Maximum possible score	Pretest		Post test	
		Mean	SD	Mean	SD
Introduction on minor ailments	2	1.36	0.490	1.80	0.408
Fever	3	2.24	0.879	2.84	0.374
Common cold and cough	8	4.12	1.269	6.72	1.061
Dental caries	5	2.92	1.288	4.16	0.850
Conjunctivitis	3	1.68	0.748	2.04	0.935
Worm infestation	4	1.92	1.288	2.76	1.012
Diarrhea	7	2.36	1.221	4.60	1.633
Fainting	4	2.44	1.158	2.96	1.207

Discussion

Child to child programmes plays a pivotal role in the transfer of knowledge from the older children to the younger children. The child becomes a teacher for spreading the health messages. It encourages the school-age children to have concern about themselves with regard to health and also take the responsibility of transferring the knowledge which they have acquired to their younger pre-school brothers and sisters, neighbors, their families etc. This will further benefit the community at a large scale.

The findings of the present study showed that majority of the children had average knowledge on management of minor ailments in both control group 24(96%) and the experimental group 23(92%).These findings of the present study are supported by another descriptive study conducted by Harikiran A G etal to assess the knowledge towards oral health among 11-12 year old school children in a government-aided missionary school of Bangalore city. The study findings revealed that 58.4%, received information regarding oral health mainly from television. Only 20.9% considered keeping natural teeth was important. It was found that 75.1% thought that brushing teeth prevents tooth decay and gum disease and 48.9% (46%: Male; 52.6% Female) knew the reason that eating sweets causes tooth decay. Only 36.3% knew that fluoride prevents tooth decay.[8]

Regarding the child to child programme,the findings of the present study shows that there was a significant difference in the mean post test level of knowledge on the management of minor ailments between the experimental and control group ($t= 11.29$, $p<0.05$).Thus the child to child programme was effective in improving the knowledge on management on minor ailments. The present study finding is supported by an evaluative study conducted by Shobha H J to assess the effectiveness of child-to-child approach through role play on prevention of Worm Infestation in school children of selected school in Bangalore in 2006. The results revealed that the pretest mean knowledge was 5.20±3.19 and posttest knowledge score was 18.03±1.87.The difference in mean knowledge about worm infestation score observed was statistically significant ($P<0.05$).[9]

Also a randomized control trial conducted by Walvekar P R,Naik V A, Wantamutte A S in 2006 to assess the impact of child to child programme on knowledge, attitude and practice regarding diarrhea among rural school children in Belgaum district in Karnataka showed that there was an overall improvement in the knowledge of study group students.[5]

Conclusion

Child to child programme was effective in bringing the desired changes in the knowledge of younger children on management of minor ailments. Hence, it can be used as an effective teaching strategy among the school children to spread health messages.

Abstract

Objective: This study is to compare the effects of bilateral and unilateral task-oriented exercises and to determine the effective approach for improving the upper extremity motor performance in post-stroke subjects with learned nonuse phenomenon.

Method: 68 subjects were taken, 65 of them met the study criteria, and were divided into two groups by systemic randomized sampling, 33 in Group-A (Unilateral group) and 32 in Group-B (Bilateral group). 56 subjects completed the intervention. Both groups received 30 minutes of task-oriented training, Group-A performs the task exercises using only the affected upper extremity, where as in the Group-B tasks are performed using both the affected and unaffected upper extremities. These interventions were held for, 30 minutes 5 days a week for 4 weeks. The outcome measures in the study were Motor activity log (MAL),and its two components Amount of use (AOU) & Quality of use (QOU)And the Fugl Meyer assessment of upper extremity (FMA-UE).The pre-test and post-test assessment differences were taken to see the improvements.

Results: Statistical analysis data revealed that both the groups have shown improvement in motor function in post stroke subjects with learned nonuse phenomenon. There is no significant difference, in between the groups.

Conclusion: This study concluded that there is no difference in bilateral and unilateral task training in improving motor function in post stroke subjects with learned nonuse phenomenon, and they are equally effective.

Keywords: *Stroke, Bilateral task-oriented exercise, Unilateral task-oriented exercises, Fugl Meyer assessment, Motor activity log.*

Introduction

Stroke is one of the main causes of morbidity and mortality of adults in the developed world, resulting in a vast burden of disability [1]. About 10% of deaths in the industrialized countries were due to stroke [2]. One third of all strokes occur in the people who had a previous cerebrovascular attack. Hypertension, Heart disease and Diabetes are the major risk factors for stroke, where cigarette smoking, alcohol, blood cholesterols, obesity and physical inactivity are the other risk factors[3]. The Global burden of disease reports stated that the incidence of stroke in young and middle-aged adults was increased because of increase in metabolic risk factors like obesity and diabetes mellitus. Increase in stroke survivors in recent times was due to the modifiable stroke risk factors, population growth and as well as the improved stroke care[4]. Impaired motor functions, sensory deficits, visual and auditory deficits, aphasia are

seen in the stroke survivors where the rehabilitation is the key for recovery [3].

Functional recovery of the affected upper limb has been a long-standing struggle for 80% patients with a dominant functional limitation factor [5]. Patients use of affected upper extremity decreases because of dependency on the unaffected upper extremity for normal activities [6]. This leads to limited range of motion which can result in Non-use, which will be developed either after unsuccessful repeated attempt of using the affected arm or after negative results from paretic limb use. In order to improve the motor functions of the affected upper extremity patients should be provided with opportunities to use the affected upper extremity more [7].

"Non-use" is the difference between what the individual can do when constrained to use the paretic arm and what the individual does when given a free choice to use either arm [8]. Evidence suggests that task-specific practice may be the best way to promote functional recovery after stroke [9-11]. Task oriented training is the practice of goal-directed, functional movement carried out in a natural environment, involving a variety of practices to help patient to derive optimal control strategies for solving the motor problems. This task training mainly focuses on specific functional tasks that are associated with the musculoskeletal and neuromuscular systems[12].

Previous studies on bilateral task-oriented exercises for arm motor function concluded that there were improvements in motor function [5,13-16]. Studies on unilateral task training also showed improvement in the motor activity [17,18]. Some studies concluded that both interventions are equally effective without any significant difference in the outcome [19-21]. But future research is recommended with an increased number of tasks for better results, limited studies were present in relation to the learned nonuse phenomenon. According to our knowledge there is no study comparing these two groups in the post-stroke subjects with learned nonuse phenomenon till date. The aim of this study is to compare the effects of bilateral and unilateral task-oriented exercises in improving the upper extremity motor performance in post-stroke subjects with learned nonuse phenomenon. The hypothesis of the study is that the bilateral task training will be beneficial than the unilateral task training.

Materials and Method

This was a Prospective Cohort Study, with 68 patients, both men and women suffering with motor impairment of upper limb with learned nonuse phenomenon due to stroke were taken. Subjects who are willing to participate in the study were recruited from department of physiotherapy, neurology department, GSL Medical College and General Hospital, Rajahmundry, Andhra Pradesh, India. All the participants signed the informed consent and the rights of the included participants have been secured. As per the study 65 subjects met the study criteria.Inclusion Criteria: Age 30-80,oth male and female patients diagnosed with unilateral stroke, Residual movement capacity-30 degrees of shoulder Elevation,20 degrees wrist extension,10 degrees of finger extension, Opening capability of hand so that a ball can fit in and Considerable nonuse of the affected upper limb (Amount of use score-MAL<2.5).Exclusion Criteria: Stroke relapse/seizures during the intervention, Uncontrollable hypertension, Spontaneous recovery, Sensory impairments, Neurological/orthopedic conditions involving upper limb like per arthritis shoulder, Rheumatoid arthritis, Evidence of neglect, Inability to follow two-step commands, Balance problems and Patient following other treatments apart from drugs.

Subjects were allocated into two groups by systemic randomized sampling, 33 in Group-A (unilateral task exercises) and 32 in Group-B (Bilateral task exercises),the treatment duration was 30 minutes a day, 5 days a week, for 4 weeks (20 sessions),Study was held for 1 Year 2 months. (MAY -2017 to JUNE - 2018). Group-A-unilateral task-oriented exercises followed by conventional therapy, Group-B-bilateral task-oriented exercises followed by conventional therapy. The outcome measures were Motor Activity Log and Fugl-Meyer assessment upper extremity. The upper-extremity MAL-14 is a structured interview that elicits information about 14 activities of daily living. Patients are asked to rate Quality of Movement and Amount of Use for assessing how well and how often they use their more impaired arm to complete each activity[22]. The FMA-UEwas the most frequently used outcome measure, applied in 36% of the studies for Motor activity [23].

Tasks were selected in such a way that they can easily be implemented in both groups, there were 8 training tasks. The progression was done using shaping principles. All members in this study participated

in regular physiotherapy as of the regular treatment followed in rehabilitation setting. The training was carried out during the hospitalization period. Tasks include: i) Pick up a coin and manipulate it, ii) Catch a ball, iii) Sweep with a towel on table, iv) Elbow extension during horizontal reach, v) Lifting glasses, vi) Lifting a glass to drink and picking up a spoon to feed, vii) Reaching forward/upward for cup and replacing it elsewhere and viii) Staking cups and putting back in upright position.

Protocol for Unilateral Task Oriented Training Group–A: Subjects were made to sit in a chair in front of a table of comfortable height and perform specific tasks. In this group the subjects were asked to perform tasks using only the affected upper extremity,Each task is repeated for 8-10 times with a rest time of one minute between each task. The goal is to produce the movement by simple task-oriented training, by concentrating only on the affected extremity. Conventional physiotherapy treatment is followed by the intervention.

Protocol for Bilateral Task Oriented Training Group–B: Subjects follow the same treatment procedure of Group –A, the main difference in this is that the patients were made to perform tasks using both the hands that is the affected and the unaffected upper extremities. Both arms are used simultaneously/alternately according to task. Conventional physiotherapy treatment is followed by the intervention.

Findings: Statistical analysis was done using the statistical software SPSS 20.0 version for this purpose the data was entered into Microsoft Excel – 2007 spreadsheet, tabulated and subjected into statistical analysis. For all statistical analysis, $p<0.05$ was considered as statically significant. Descriptive statistical data was presented in the form of mean +/- standard deviation, percentage (%).56 subjects completed the entire study protocol of 4 weeks in the training session and 4 subjects were excluded 2 from each group. The groups mean ages were like group-A=55.3, group-B=54.3.To observe the treatment impact before and after the treatment in the groups, the analysis was carried out using statistical tests, for the outcome measures – MAL and FMA-UE,Within the group differences were checked with paired student-T test and between the group's differences are checked using independent student-T test.Both the components of MAL i.e. the Amount of use (AOU) and Quality of use (QOU), as well as the FMA-UE has shown differences in their pre-test and post-test values. But on comparing the means of both groups there was no significant difference to conclude that one intervention is superior over the other. Both the interventions have improved the motor activity in the post stroke subjects with learned nonuse phenomenon.

Table 1: Analysis of pre-test and post-test means of MAL-AOU, MAL-QOU& FMA-UE between Group-A and Group-B.

Outcomes	Group	Scoring	N	Mean	Std. Deviation	Std. Error Mean	P-Value
MAL-AOU	A	Pre-test	28	1.56	0.395	0.074	0.157*
	B		28	1.71	0.385	0.072	
	A	Post-test	28	2.79	0.246	0.046	1.157*
	B		28	2.89	0.279	0.052	
MAL-QOU	A	Pre-test	28	1.77	0.458	0.086	0.576*
	B		28	1.84	0.442	0.083	
	A	Post-test	28	3.03	0.270	0.051	0.091*
	B		28	3.16	0.299	0.056	
FMA-UE	A	Pre-test	28	34.78	5.652	1.068	0.748*
	B		28	34.35	4.165	0.787	
	A	Post-test	28	55.78	3.359	0.634	0.509*
	B		28	55.21	3.059	0.578	

* No significant difference.

Discussion

Both bilateral and unilateral task-oriented exercises were evidently effective in improving the motor function in post stroke subjects. In this study subjects were assessed for motor impairment and nonuse phenomenon using the MAL-AOU & QOU for evaluating nonuse

and FMA-UEfor motor functionat baseline and at the end of the intervention. There were nine drop outs from the study, fivein Group-A and fourin Group-B. There is a significant difference between pre-test and post-test values within the groups. But there were no significant differences in between the Group-A and Group-B.

Functional task training is considered to have more effect on the upper extremity motor functions recovery in stroke patients than training with simple movements. The unilateral training results in reorganization of the ipsilesional cortices. Bilaterally distributed neural networks linked via the corpus callosum, controls bilaterally identical synchronous movement that appears to occur centrally through and involves cortical and subcortical areas [8].

Thielman et.al, stated that subjects with decreased functional levels and coordination between the shoulder joint and elbow joints were improved when they underwent task-related training than performing gradual resistive exercises [9].Ackerley et al, concluded both unilateral and bilateral task exercises are equally effective, and also stated that the mechanism cannot be specific to bilateral training. And the mechanism may be because of the effects of rhythmic, synchronized movement, which facilitates a generalized increase in cortical excitability, possibly leading to use dependent plasticity [19].

Turton et al. explained that localized lesion of the primary motor cortex depletes the Cortico-motoneuron (CM) pool necessary for movements. The interconnections between CM cells which form the neural network for skilled actions are depleted by the lesion. This result in disruption of the unique temporal and spatial organization of CM excitability, which is required for a task execution, the CM recruitment is task-specific[24].On performing a strictly unilateral movements there will be a "non-mirroring" process that will restrict the motor output within the contralateral hemisphere and suppresses motor activation of the hand[25].

Neurophysiological studies stated both bilateral and unilateral synchronized movements facilitate an increase in cortical excitability during the rhythmic movements 'results in long-term improvements in synaptic efficacy of motor cortex. These neural changes will provide the optimal conditions for learning a new motor task [13].

The rehabilitation period is to provide patients with frequent and continuous chances to use the affected arm in their activities. In both types of training patients must use their most affected arm, both induce plastic changes in the central nervous system [21]. The study accepted null hypothesis as the statistical analysis has not shown any significant difference between the unilateral and bilateral task groups.

Conclusion

This study concluded that both bilateral task-oriented exercises and unilateral task-oriented exercises are equally effective. So bilateral task training is not superior to unilateral task training in improving the motor function in post stroke subjects with learned nonuse phenomenon.

Correlation of Waist Hip Ratio with Standing Stork Test among College Students

D. Malarvizhi[1], M. Arvind[2]

[1]Dean I/C, SRM College of Physiotherapy, [2]BPT Final Year Student, SRM College of Physiotherapy, SRM Institute of Science and Technology, Kattankulathur, Kancheepuram District, Tamilnadu, India

Abstract

Background: Standing stork test is a balance test which is used to assess the static balance state of an individual. Waist Hip Ratio is the measure of dimensionless ratio of waist circumference to the hip circumference. So this study was done to check how much Waist Hip Ratio plays a major role in standing stork balance test. The aim of the study is to find the correlation of Waist Hip Ratio with standing stork test among the college students.

Methodology: 30 participants of age 18-25 years, SRM college of physiotherapy participants were separated into four groups based on the category of the WHR norms. Each group of participants was asked to perform the standing stork balance test. Three trails were conducted and the mean value was noted. The outcome measures were done by standing stork balance test. The participants with recent fracture in leg, diabetes, any neurological conditions like CVA, vertigo, tinnitus were excluded in this study

Results and Conclusion: The mean values, standard deviation and p values are calculated and tabulated. The p value of Waist Hip Ratio (excellent, good and fair) categories are greater than 0.05 with Standing Stork Balance test. Hence, all the three categories of the Waist Hip Ratio do not correlate with the Standing Stork Balance test.

Keywords: *Standing stork test, waist hip ratio.*

Introduction

Waist Hip Ratio is a procedure in which is a measure ratio of circumference of waist to the circumference of the hip. According to the World Health Organization, waist circumference can be measured from the midpoint between the lower margin of the last palpable rib and the top of the iliac crest. Hip circumference can be measured from the widest part of the buttocks and the tape parallel to the floor. For both the measurements the person must be with equally distributed weight on both of the legs. While taking the measurement the person must be relaxed with normal respiration control. Some research shows that the apple- shaped bodies (more weight around waist) has more risk problem than pear – shaped bodies (more weight around the hips. It is mainly use as an indicator of health and the risk of developing serious conditions[1]. Waist Hip Ratio is considered as an useful tool in finding out the state of obese with waist and hip circumference and the early diagnosis of any related serious conditions. The National Institute of Diabetes, Digestive and Kidney diseases states that the women with Waist Hip Ratio of more than 0.8 and males with above 1.0 have more danger of health due to more amount of fat distribution. Normally Waist Hip Ratio is generally an important indicator for cardio vascular disease more than Body Mass Index and Waist circumference. The body fat percentage gives an exact measure of body weight more than that of relative weight[2].

Normally the deficiency in growth hormone also leads to increased Waist Hip Ratio measure for adults. Adults with untreated congenital growth hormone deficiency have increased measures. Growth hormone deficiency has been correlated with the Waist Hip

e-mail: malarvizhi.d@ktr.srmuniv.ac.in

Ratio in prepubertal children. It is also suggested that congenital adrenal hyperplasia also have increased measures. The stress hormone named cortisol is regulated by hypothalamic-pituitary-adrenal (HPA) axis which has been highly associated by abdominal fat thus increases the Waist Hip Ratio measure[3].

Balance is a stable condition in which all forces acting on the body falls in a same line. It is a dynamic process in which the position of the body is maintained in the equilibrium with the centre of mass or centre of gravity is maintained over its base of support. The centre of pressure is the point at which vertical projection of ground reaction force. Equilibrium is classified into two groups which include static equilibrium which is at rest and dynamic equilibrium which is a steady state of motion. The balance control is normally maintained by the musculoskeletal and nervous systems along with the contextual effects[4].

The body's position and control of the movements which is controlled by the visual, somatosensory and vestibular systems. There are three types of balance control which consists of Static balance control to maintain stable antigravity position while at rest such as when sitting and standing. Dynamic balance control to stabilize the body when the support surface is moving, Automatic postural reactions to maintain balance in response to unexpected external disturbances[4].

Standing stork balance test is a measure of static balance of an individual. Normally the person who performs the test with more than 50 seconds have an excellent static balance control, person with 40 – 50 seconds are good, 25 to 39 seconds are average, 10 – 24 seconds are fair and less than 20 seconds have poor static balance control[5,6]. The aim of the study is to find out the correlation of Waist Hip Ratio with standing stork balance test among college students.

Methodology: The study design was non experimental, Observational type. 30 samples were selected based on inclusion and exclusion criteria, Study setting was SRM college of physiotherapy. Subjects with any addiction to alcoholism, fracture in hip, knee and ankle or any musculoskeletal injuries or any neurological conditions like vertigo, Parkinson and Cerebro-vascular accidents were excluded from the study. The subjects with the age of 18 to 25 years of age college boys and the subjects with Waist Hip Ratio from less than 0.84 to 0.95 and above were included in this study. Institutional Ethical Committee approval and informed consent also obtained before starting the study. Outcome measure was done by standing stork balance test. The subjects Waist circumference and Hip circumference were noted and the ratio was taken. Waist Hip Ratio was calculated by waist circumference divided by the hip circumference. The participants were separated into four categories excellent(<0.85), good(0.85-0.89), average(0.90-0.95) and at Risk (>0.95)based on the Waist Hip Ratio criteria. After separating into groups the subjects were asked to perform the standing stork balance test. The standing stork balance test was done by removing the shoes and the hands were to be placed over the hips. The subject has to place the non supporting foot over the knee of supporting leg. After starting the stop watch the subjects have to stand on the ball of the foot. The subjects were given with one minute of practice time. The stop watch is stopped if the subject takes off the hand from the hip or the heel touches the floor or the subject hops in any directions. Three trials were done and the mean value was taken. The correlation of Waist Hip Ratio and standing stork test was calculated.

Data Analysis: Correlation of Waist Hip Ratio with the standing stork balance test values were measured and tabulated by using IBM SPSS version 20.

Table 1: Correlation of Waist Hip Ratio Excellent Category with the Standing Stork Balance Test

Variable name	Mean	r value	p value (significant)
Waist Hip Ratio	0.79	1	0.133
SSBT	10.19	.482	.133

In this table 1 shows that the person with an excellent WHR ratio of 0.79 performs a SSBT Score of 10.19 seconds averagely and has the p value >0.05. So Waist Hip Ratio excellent score and Standing Stork Balance Test were not significantly correlated

Table 2: Correlation of Waist Hip Ratio Good Category with Standing Stork Balance Test

Variable Name	Mean Value	R Value	P Value
Waist Hip Ratio	0.86	.075	0.827
SSBT	7.83	.095	0.780

In this table 2, the subject with the good WHR ratio of 0.86 performs a score of about 7.83 seconds averagely and has the p value > 0.05. The Waist Hip Ratio good category does not correlate with the Standing Stork Balance test.

Table 3: Comparison of Waist Hip Ratio Fair Category with Standing Stork Balance Test

Variable Name	Mean Value	R Value	P Value
Waist Hip Ratio	0.91	.772	0.072
Ssbt	5.25	.213	0.686

The table 3 shows that the mean value of Waist Hip Ratio fair category and the Standing Stork Balance Test is 0.91 and 5.25 respectively. The p value is >0.072 so that the Waist Hip Ratio fair category does not correlate with the Standing Stork Balance test.

Results

From the table 1, the mean values of Waist Hip Ratio of excellent category and the Standing Stork Balance Test is 0.79 and 10.19 respectively. The p value is > 0.05. Hence it shows that the Waist Hip Ratio of excellent category does not correlate with the Standing Stork Balance test.

From the table 2, the mean values of the Waist Hip Ratio of good category and the standing stork balance test is 0.86 and 7.83 respectively. The p value is >0.05. Hence it shows that the Waist Hip Ratio of good category does not correlate with the Standing Stork Balance test.

From the table 3, the mean values of the Waist Hip Ratio of fair category and the standing stork balance is 0.91 and 5.25 respectively. The p value is > 0.05. Hence it shows that the Waist Hip Ratio of fair category does not correlate with the standing stork balance test.

Discussion

The main objective of this study is to find out how much the waist circumference and hip circumference correlates with the standing stork balance test.

Normally in this study the subjects with the excellent Waist Hip Ratio of 0.79 performs the stork test for about 10.19 seconds, the person with good Waist Hip Ratio of 0.86 and the person with the poor has the stork balance score of 7.83 seconds, and the subject with poor Waist Hip Ratio 0.94 performed the stork test of average 5.25 seconds.

Benedicte I Deforche et al., concluded that the overweight prepubertal boys displayed lower capacity on static and dynamic balance. Overweight boys showed a poor postural sway velocity. With the body mass index increase in weight gain of a person would affect the proprioception of the joints so that the balance control is reduced for the overweight individuals. In this study, it is clearly shown that the person with an excellent Waist Hip Ratio have a better balance control than that of average and poor Waist Hip Ratio values. According to the criteria of the Standing Stork Balance Test the person with the holding time of< 10 seconds considered as a poor score of static balance control[7].

Johanna M seddon et al., concludes that the overall and abdominal obesity increased the risk of progression to advanced Age related muscular degeneration. Individual muscle strength, joint flexibility and good postural control can significantly helps to balance the body. Obesity is a state in which there will be an increase in the normal adiposity. It plays a central role in the patho physiology of diabetes mellitus etc. So the person with increased fat gain in the waist and hip can perform the balance activities well if he has a good muscle power and flexibility. Increase in Waist Hip Circumference also decreases the average value of standing stork balance test the with each other. This mean value proves to be that change in Waist Hip Ratio reduces the static balance control but it does not make a higher improvement in balance[8].

.**Ragiba Zagyapan et al.,** states that there was a relationship between the changes in the muscle length and the balance type. There is a significant correlation between the Waist Hip Ratio and the postural balance type[9].

Angyan L et al., states that there are various factors affects the postural stability among younger adults. The body mass index, back strength and endurance capacity plays an important role in maintaining the balance control. Weakened muscle strength, stiffness over the joints and tightness of the muscles also plays an important role in maintaining the balance control.

Limitations for the Study:

- Less samples are taken for the observation
- Three groups are considered. Subjects who are at risk as per WHR norms are not included in this study
- This study is conducted among the young students.
- Only men are included in the study

Recommendations for Study:

- More sample size has to be increased

- The fourth category (at risk) is to be included and must be correlated with balance
- This study must be conducted to all age groups in the further study.
- Further studies can be performed over women and men

Conclusion

This study concluded that the Waist Hip Ratio does not correlate with the standing stork balance test. Person with an excellent Waist Hip Ratio values perform a poor score of standing stork balance test and the subjects with fair Waist Hip Ratio values perform poor balance score. Hence, the circumference of the waist and hip of the body does not affect the balance control of an individual.

Patanjali Yoga Practice and its Effect on Mental Health and Moral Judgment amongst Juvenile Delinquents

Dayal Sandhu[1], Amit Kumar[2], MonikaAgarwal[3]

[1]Assistant Professor, Faculty of Education, GLA University, Mathura, [2]Research Scholar, Department of Pedagogical Sciences, Faculty of Education, Dayalbagh Educational Institute (Deemed University), Agra, [3]Research Scholar, Faculty of Education, GLA University, Mathura (U.P.), India

Abstract

Research awareness and involvement in yoga for health-related results are growing worldwide. PatanjaliYoga relieves stress and fatigue which haves turned into one of the few major challenges confronting the medical fraternity in present times. Yoga let go the body from any type of muscular or chronic strain and rejuvenates the body from exhaustion, body aches, stress, aids to ease the body and mind, enhances concentration and alertness, and frees the soul. It helps one to create integrity amongst his outward self as well as his innermost self. If the practices are followed meticulously then Patanjali Yoga develops a constructive effect both in the inward and outer selves of an organism. Patanjali's yoga practice aims to bind the individual self with the Ultimate One and one can achieve this union by regulating and discarding the ever- arising 'vrittis' or amendments of the mind. With Patanjali Yoga mind can be balanced through the exact kind of discipline and training. The purpose of this paper was to study the effect of Patanjali Yoga practice on mental health and moral judgment of experimental group of juvenile delinquents. Pre and post experimental design was used in this research work. Patanjali Yoga practices were used as independent variables whereas mental health and moral judgments of delinquents as dependent variables. A sample of 70 delinquents of age group (13-18 years) from Government Observation Home in Agra district was chosen with random selection method. There were two groups –experimental group (n=35) and control group (n=35). Patanjali Yoga practices were imparted to delinquents for 90 days with duration of one hour each day. For measuring the moral judgment of delinquents, moral judgment test by Juri Baruh (2004) and for measuring mental health, mental health battery by A.K. Singh and Alpana Sen Gupta(2008) were used. Mean, Standard deviation and t-test were carried out for data analysis. The findings suggest that mental health factors like emotional stability, adjustment, autonomy, security-insecurity and self-concept were found to be of average level and intelligence ranged from average to low in experimental and control group delinquents. It was also found that Patanjali Yoga plays a significant role by strengthening emotional stability, adjustment and self -concept in delinquents, however, the Patanjali yoga does not significantly affects mental health factors like autonomy, security-insecurity and intelligence in delinquents. The findings also concluded that Patanjali Yoga does not affect moral judgments of delinquents.

Keywords: *Patanjali Yoga, Mental Health, Moral Judgment, Juvenile Delinquents.*

Introduction

Children are greatest national asset and resource. Children should be allowed and provided opportunity to grow up to become robust citizens, physically fit, mentally alert and morally healthy, endowed with skills and activations needed by the society.

In recent years, it has become very clear that juvenile delinquency is the most important aspect of the subject matter of criminology. The juvenile is a child who is alleged to have committed/violated some law which declares the act or omission on the part of the child as an offence. Delinquency is an act or conduct of a juvenile which is socially undesirable. Juvenile delinquency generally means the failure of children to meet certain obligations expected of them by the society. Research awareness and involvement in yoga for health-related results are growing worldwide. Patanjali Yoga relieves

stress and fatigue which haves turned into one of the few major challenges confronting the medical fraternity in present times. Yoga let go the body from any type of muscular or chronic strain and rejuvenates the body from exhaustion, body aches, stress, aids to ease the body and mind, enhances concentration and alertness, and frees the soul. It helps one to create integrity amongst his outward self as well as his innermost self. If the practices are followed meticulously then Patanjali Yoga develops a constructive effect both in the inward and outer selves of an organism. Patanjali's yoga practice aims to bind the individual self with the Ultimate One and one can achieve this union by regulating and discarding the ever- arising 'vrittis' or amendments of the mind. With Patanjali Yoga mind can be balanced through the exact kind of discipline and training.In Patanjali's Yoga Sutra, the eightfold path is called *ashtanga*, which literally means "eight limbs" (*ashta*=eight, *anga*=limb). These eight steps which are Yama (control),Niyama (rules of conduct),Asana (posture),Pranayam (control of breadth),Pratyahara(withdrawal of sensory perceptions),Dharana (concentration),Dhyana (uninterrupted meditation), Samadhi (effortless meditation,absorption, equilibrium)basically act as guidelines on how to live a meaningful and purposeful life. They serve as a prescription for moral and ethical conduct and self-discipline; they direct attention toward one's health; and they help us to acknowledge the spiritual aspects of our nature.

Objectives of the Study

1) To study the effect of Patanjali Yoga Practice on mental health of experimental group of juvenile delinquents.
2) To study the effect of Patanjali Yoga Practice on moral judgment of experimental group of juvenile delinquents

Hypothesis of the Study

1) There is significant effect of Patanjali Yoga practice on mental health of experimental group of Juvenile delinquents.
2) There is significant effect of Patanjali Yoga practice on moral judgment of experimental group of Juvenile delinquents.

Operational Definition

Juvenile Delinquents: In the present study, Juvenile delinquents is in context with those who are unaccepted through society and are punished through law and justice and they are kept at government observation homes for improvement through rehabilitation method.

Mental Health: In the present research, mental health is in context with to six factors incorporated in tool constructed by Sen and Gupta (2008) and these six factors are emotional stability, adjustment, autonomy, security-insecurity, self-concept and intelligence.

Moral Judgment: In the present research, moral judgment is in context with in which a person takes decision in perspective of moral standards and moral values in different circumstances.

Patanjali Yoga: In the present research, Yoga is in context with Patanjali's Ashtanga Yoga and its three stages that is Asana, Pranayama and Dhyana.

Methodology

Method: In the present research, pre and post experimental design was used for studying the effect of mental health and moral judgment on juvenile delinquents.Juvenile delinquents were divided in two groups that is Experimental (N=35) and Control (N=35) group.Patanjali Yoga practices were imparted to Juvenile Delinquents for 90 days with duration of one hour each day.

Variables of the study: Patanjali Yoga practicesand its three stages that is Asana, Pranayama and Dhyanawere used as independent variables whereas mental health and moral judgment of delinquents are dependent variables

Sample of the Study: A sample of 70 delinquents of age group (13-18 years) from Government Observation Home in Agra district waschosen with random selection method.

Research Tool: For measuring the moral judgment of delinquents, moral judgment test by JuriBaruh (2004) and for measuring mental health, mental health battery by A.K.Singh and AlpanaSenGupta(2008) were used.

Statistical Techniques

Mean: In the present research, Mean was used for knowing average achievement of mental health and moral judgment factors of juvenile delinquents.

Standard Deviation: In the present research, standard deviation was used for knowing how much deviation is there between obtained scores of mental

health and moral judgment factors of juvenile delinquents from average sores.

T-test: In the present research, t-test was used for knowing significant difference between pre and post obtained scores.

Delimitation of the study

1) Present study was delimited to Government observation home in Agra district, India.
2) Present study was delimited to juvenile delinquents of 13-18 years of age group.
3) Yoga practices were delimited for 90 days with duration of one hour each day.
4) There was no usage of any other psychological treatment other than Patanjaliyoga practices.

Analysis And Interpretation Of Data: For knowing the effect of Patanjali yoga practice on juvenile delinquents the researcher calculated mean and standard deviation of obtained scores of pre and post patanjali yoga practice (after three months) as given in table1.

Table 1- Exhibiting mean, standard deviation and t-test value of obtained scores of mental health of juvenile delinquents in reference to Patanjali yoga practice

Group Test	Control Group (N=35)		Experimental Group (N=35)		T-test	Significance Level
	Mean	Standard Deviation	Mean	Standard Deviation		
Pre Test	71.51	13.72	72.28	12.16	0.90	<0.05
Post Test	71.97	11.42	87.20	6.94	6.95	>0.01

From table 1 it is revealed that before giving Patanjali yoga practice mean of obtained scores are 72.18 and 71.51 whereas standard deviation is 12.16 and 13.72. When t-test was computed value came out to be 0.90 which was found insignificant at 0.05 level of significance and hence at the time of pre-test there is uniformity between control and experimental group. From table 1 it is also revealed that t-test value has been found 6.95 between experimental group of juvenile delinquents whom Patanjali yoga practice has been given and control group of juvenile delinquents whom Patanjali yoga practice has not been given which is found significant at 0.01 level of significance. Hence, it can be said that Patanjali yoga practice makes mental health of juvenile delinquents remarkable.

From Table 2 it is revealed that there is significant effect of Patanjali yoga practice on mental health factor 'emotional stability' between experimental group of juvenile delinquents which has been given Patanjali yoga practice and control group of juvenile delinquents which has not been given Patanjali yoga practice which is confirm by t-test value which is found to be 5.45 which is significant at 0.01 level of significance.

Table 2: Exhibiting mean, standard deviation and t-test value of obtained scores of mental health factor emotional stability of juvenile delinquents in reference to Patanjali yoga practice

Group Test	Control Group (N=35)		Experimental Group (N=35)		T-test	Significance Level
	Mean	Standard Deviation	Mean	Standard Deviation		
Pre Test	8.40	2.52	9.14	2.18	0.27	<0.05
Post Test	9.17	2.53	11.94	1.32	5.45	>0.01

From the table 2 it is also revealed that before giving Patanjali yoga practice to experimental and control group of juvenile delinquents the t-test value found to be 0.27 on the basis of the obtained scores of mental health factor 'emotional stability' which is found to be insignificant at 0.05 level of significance. Hence, it can be said at the time of pre test there is uniformity between control and experimental group of juvenile delinquents.

From Table 3 it is revealed that there is significant effect of Patanjali yoga practice on mental health factor 'adjustment' between experimental group of juvenile

delinquents which has been given Patanjali yoga practice and control group of juvenile delinquents which has not been given Patanjali yoga practice which is confirm by t-test value which is found to be 5.34 which is found to be significant at 0.01 level of significance.

Table3: Exhibiting mean, standard deviation and t-test value of obtained scores of mental health factor adjustment of juvenile delinquents in reference to Patanjali yoga practice

Group Test	Control Group (N=35)		Experimental Group (N=35)		T-test	Significance Level
	Mean	Standard Deviation	Mean	Standard Deviation		
Pre Test	23.80	4.79	25.62	4.03	0.12	<0.05
Post Test	24.45	4.76	30.22	3.50	5.34	>0.01

From table 4 it is revealed that there is insignificant effect of Patanjali yoga practice on mental health factor 'autonomy' between experimental group of juvenile delinquents which has been given Patanjali yoga practice and control group of juvenile delinquents which has not been given Patanjali yoga practice which is confirm by t-test value which is found to be 0.24 which is found to be insignificant at 0.05 level of significance.

Table 4: Exhibiting mean, standard deviation and t-test value of obtained scores of mental health factor autonomy of juvenile delinquents in reference to Patanjali yoga practice

Group Test	Control Group (N=35)		Experimental Group (N=35)		T-test	Significance Level
	Mean	Standard Deviation	Mean	Standard Deviation		
Pre Test	9.77	2.71	9.54	2.16	0.72	<0.05
Post Test	9.25	2.04	9.82	2.37	0.24	<0.05

From table 5 it is revealed that there is insignificant effect of Patanjali yoga practice on mental health factor 'security-insecurity' between experimental group of juvenile delinquents which has been given Patanjali yoga practice and control group of juvenile delinquents which has not been given Patanjali yoga practice which is confirm by t-test value which is found to be 0.87 which is found to be insignificant at 0.05 level of significance.

Table 5: Exhibiting mean, standard deviation and t-test value of obtained scores of mental health factor security-insecurity of juvenile delinquents in reference to Patanjali yoga practice

Group Test	Control Group (N=35)		Experimental Group (N=35)		T-test	Significance Level
	Mean	Standard Deviation	Mean	Standard Deviation		
Pre Test	8.94	2.19	8.68	2.23	0.65	<0.05
Post Test	8.74	2.22	8.82	2.007	0.87	<0.05

From table 6 it is revealed that there is significant effect of Patanjali yoga practice on mental health factor 'self-concept' between experimental group of juvenile delinquents which has been given Patanjali yoga practice and control group of juvenile delinquents which has not been given Patanjali yoga practice which is confirm by t-test value which is found to be 3.28 which is found to be significant at 0.01 level of significance.

Table 6: Exhibiting mean, standard deviation and t-test value of obtained scores of mental health factor self -concept of juvenile delinquents in reference to Patanjali yoga practice

Group Test	Control Group (N=35)		Experimental Group (N=35)		T-test	Significance Level
	Mean	Standard Deviation	Mean	Standard Deviation		
Pre Test	9.14	2.95	8.17	2.34	0.10	<0.05
Post Test	9.34	3.13	12.11	1.94	3.28	>0.01

From table 7 it is revealed that there is insignificant effect of Patanjali yoga practice on mental health factor 'intelligence' between experimental group of juvenile delinquents which has been given Patanjali yoga practice and control group of juvenile delinquents which has not been given Patanjali yoga practice which is confirm by t-test value which is found to be 0.001 which is found to be insignificant at 0.05 level of significance.

Table 7: Exhibiting mean, standard deviation and t-test value of obtained scores of mental health factor Intelligence of juvenile delinquents in reference to Patanjali yoga practice

Group Test	Control Group (N=35)		Experimental Group (N=35)		T-test	Significance Level
	Mean	Standard Deviation	Mean	Standard Deviation		
Pre Test	11.65	5.09	11.40	6.12	0.80	<0.05
Post Test	11.00	5.05	14.25	2.68	0.001	<0.05

From table 8 it is revealed that there is insignificant effect of Patanjali yoga practice on moral judgment between experimental group of juvenile delinquents which has been given Patanjali yoga practice and control group of juvenile delinquents which has not been given Patanjali yoga practice which is confirm by t-test value which is found to be 0.018 which is found to be insignificant at 0.05 level of significance.

Table 8: Exhibitingmean, standard deviation and t-test value of obtained scores of moral judgment of juvenile delinquents in reference to Patanjali yoga practice

Group Test	Control Group (N=35)		Experimental Group (N=35)		T-test	Significance Level
	Mean	Standard Deviation	Mean	Standard Deviation		
Pre Test	17.97	3.97	18.17	4.34	0.84	<0.05
Post Test	16.34	4.35	18.68	4.14	0.018	<0.05

Findings and Conclusions

It can be said that Patanjali yoga practice makes mental health of juvenile delinquents remarkable. There is significant effect of Patanjali Yoga practice on mental health factors which are emotional stability, adjustment and self concept. It is also revealed that there is insignificant effect of Patanjali Yoga practice on mental health factors which are autonomy, security-insecurity and intelligence. It was also found that Patanjali yoga practice do not effect moral judgment of juvenile delinquents. Hence, after having conversation with authority it was clear that there was a positive change seen amongst juvenile delinquents due to Patanjali Yoga practice and they want these yoga practices to be contionusly scheduled from time to time.

Internalizing Behavioural Problems among Children of Alcoholic Parents

Dayananda Bittenahalli Omkarappa[1], Sreevani Rentala[2]

[1]Associate Professor, HOD, Department of Psychiatric Nursing, Kempegowda College of Nursing, K.R. Road, V.V. Puram, Bangalore, [2]Professor, HOD, Dept. of Psychiatric Nursing, Dharwad Institute of Mental Health and Neuroscience, Dharwad, Karnataka

Abstract

Context: Emotional and behavioural problem in children of alcoholic parents is an important public health issues. However, there is limited epidemiological evidence about internalizing behavioural problems such as anxiety, Depression and low self-esteem.

Aims: To assess the internalizing behavioural problems among children of alcoholic parents and to find out the correlation between anxiety, depression and self-esteem.

Method and Material: A cross sectional descriptive Survey research design was adopted for the present study. The study was conducted at Three Govt High school located in Bangalore urban. Hundred children of alcoholic parents were recruited by simple random sampling method. Children of alcoholic screening test (modified)were used for identifying children of alcoholics. This study utilized Spence Children's Anxiety Scale, Center for Epidemiological Studies Depression Scale for Children (CES-DC) and Rosenberg Self-Esteem Scale.

Statistical analysis used: Data were analyzed using Statistical package for the social Sciences software package (Version 23).

Results: The result shown that 23% of boys & 16% of girls are showing elevated level of anxiety, 31% of children are showing elevated depression,and 53% of children are having low self-esteem. Anxiety is positively correlating with depression (0.359) and Anxiety is negatively correlating with self-esteem (-0.223). A Very low negative correlation seen between depression and self-esteem (-0.166) which is not significant.

Conclusion: The study concludes that children of alcoholic parents are at risk for internalizing behavioural problems and a positive correlation was observed between anxiety and depression.

Keywords: *Anxiety, Depression, self-esteem and children of alcoholic parents.*

Introduction

Child mental health problems are reflected by a variety of categories of behaviour problems.[1] According to Achenbach & Edelbrock, behavior problems can be grouped into two major categories: internalizing and externalizing behaviors.[2] There is growing consensus that behaviour problems are apparent in early childhood, and that they often persist into adulthood – particularly those associated internalizing behaviour.[1]

Globally, around 10 to 20 % of children suffer from a mental health problem.[3] A study conducted in five developing countries suggest that 10.5 % of children suffer from mental health problems.[4] An Indian study shows that Prevalence of behavioural and emotional problems in adolescents was found to be 30%, with girls

exceeding boys in all age groups. Internalizing syndrome was the most common (28.6%) problem.[5]

The family provides emotional support to an individual as well as plays a major role in the formation of one's personality. The quality and nature of the parental nurturance that the child receives will profoundly influence his future development.[6] Children growing up in families with substance abuse would expect to have deficits in coping skills and the dysfunctional family coping will result in negative and adverse effects on children's and adolescents' development.[7] Several studies shows that children growing under parental alcoholism are suffering from behavioural problems.[8,9] Father alcoholism shows greater internalizing symptoms among children of alcoholic parents. [10]

Research findings indicate thatchildren of alcoholic parents are having lower self-esteem[11] and lower academic performance in reading and arithmetic than did children of non-alcoholic parents.[12] A study conducted on High school students shows that male students with paternal drinking problems showed significantly increased risk of anxiety and female students with paternal drinking problems showed significantly increased risk of depression.[13]

The Studies have shown that child behavior problems have negative impacts on children's social, educational and economic performance in later life.[14] Childhood behavior problems also predict involvement in anti-social behavior and multiple substance abuse in later part of life.[15] The externalizing problems will be exhibited by child and can be noticed by parents and teachers, whereas internalizing problem gets unnoticed and results in complications during childhood and even in early adulthood. It is very important to identify problems at earliest age, in order to explore feasible, acceptable, and effective ways of addressing such problems.

The Objectives of the Study:

1. To assess the internalizing Behavioural problems among children of alcoholic parents.
2. To find out the correlation between anxiety, depression and self-esteem
3. To find out the association between Internalizing Behavioural problem scores with selected socio-demographic variables.

Method

A cross sectional descriptive Survey research design was adopted for the present study. 100 children of alcoholic parents were recruited by simple random sampling method at Three Govt High school, Pottery town, Hosaguddadahalli and attigupe, Bangalore urban and data was collected from June to August 2017. The sample comprised of 100 children of alcoholics. 497 children were screened; those who scored more than 3 in Children of alcoholic screening test (modified) and aged between 12-16 years are selected for study. Children with learning disorders and single parents are excluded from the study. The study protocol was approved from ethical committee of Kempegowda college of Nursing. Formal permission was obtained from Block Education Officer, Head Master and informed consent was taken from child and their parents.Data were analysed using Statistical package for the social Sciences software package (Version 23) and results were presented in table form.

Data collection Instrument:

1. Socio-demographic proforma: It includes questions on their age, sex, religion, class, educational qualification of Father, educational qualification of mother, Occupation of Father, Occupation of mother, Monthly family income, type of family, Number of siblings and Birth order.
2. Spence Children's Anxiety Scale: This scale was developed by Susan H Spence, self-administered four-point likert scale containing 44 items, of which 38 reflect specific symptoms of anxiety and 6 relate to positive, filler items to reduce negative response bias. Children are asked to rate on a 4 point scale involving never (0), sometimes (1), often (2), and always (3), the frequency with which they experience each symptom. The responses are summed to determine possible scores ranging from Zero to 114, with the higher scores indicating a severity of anxiety. A total score of 33 & above for boys and 39 & above for girls are classified as elevated level of anxiety. The internal consistency of the total score (Cronbach alpha =. 93) and sub-scales was high, and 12-week test-retest reliability was satisfactory. [16]
3. Center for Epidemiological Studies Depression Scale for Children (CES-DC): This scale was developed initially by Laurie Radloff and consists of 20-item self-report depression inventory with

possible scores ranging from 0 to 60. Each item is scored as follows: 0 = "Not At All" 1 = "A Little" 2 = "Some" 3 = "A Lot" However, items 4, 8, 12, and 16 are phrased positively, and thus are scored in the opposite order. A cut-off score of 15 as being suggestive of depressive symptoms in children and adolescents. Previous studies shows good internal reliability (α =. 86) and test-retest reliability (r = .85).[17]

4. Rosenberg Self-Esteem Scale: This scale was developed byDr. Morris Rosenberg and consists of 10 items 4-point Likert scale format ranging from strongly agree to strongly disagree. Items 2, 5, 6, 8, 9 are reverse scored. "Strongly Disagree" 1 point, "Disagree" 2 points, "Agree" 3 points, and "Strongly Agree" 4 points. Sum scores for all ten items. Higher scores indicate higher self-esteem. An Indian studies shows test-retest reliability of 0.80.[18]
5. Children of alcoholic screening test (modified) were used for identifying children of alcoholics.

Results

In the present study, Majority (41%) of the respondents were in the age of 14 years, most of them were male (55%). Majority (68%) of the respondents were Hindusand highest numbers (42%) of the respondents were studying in 8th std. Majority (29%) of the respondent'sfather educational qualification is Secondary education and mother educational qualification is No formal education (42%). Majority (45%) of the respondent'sfather occupation is private joband MotherOccupation is House maker (45%). Highest number (61%) of the respondent'sfamily monthly income is Rs 5000-9000 and Majority (60%) from Nuclear family. Majorities (69%) of the respondents are having Two Siblings and Majorities (53%)are born as first child. The findings shows that 23% of boys & 16% of girls are showing elevated level of anxiety with Mean of 35.32±7.89, 31% of children are showing elevated depression with Mean of 13.86±3.95 and 53% of children are having low self-esteem with Mean of 19.57±4.18. With regards to anxiety subscale majority (47%) of respondents scored positive for generalized anxiety followed by Separation anxiety & panic/agoraphobia (38%) and lowest number (10%) of respondents scored positive for Obsessive compulsive problems.

Pearson's correlation was calculated to examine the relationship between the anxiety scores, depression scores and self-esteem scores. Anxiety is positively correlating with depression (0.359), indicating that as anxiety scores are increasing depression scores also increased. Anxiety is negatively correlating with self-esteem (-0.223), indicating that as anxiety scores are increasing self-esteem scores decreases. A Very low negative correlation seen between depression and self-esteem (-0.166) which is not significant.

Chi-square was calculated to examine the association between anxiety, depression and self-esteem with selected demographic variables (Table 1). It is revealed that there is significant association found between anxiety with class in which children are studying. Depression with age group, class and birth order. Self-esteem with occupation of Mother. No association was found between remaining demographic variables.

Discussion

The study revealed that 31% of respondents scored positive for depression. Our findings echo previous research evidence which shows that elevated level of depression among COAs.[12] The study also revealed that 23% of boys & 16 % of girls are having elevated level of anxiety and this findings is supported many previous studies. [12] The Indian prevalence studies on anxiety among school children found prevalence from 2%- 24% and also found that females are affected more which is contradictory to our findings.[19]

The present study revealed that 53% of children are having low self-esteem and this is supported study conducted by Jenefer KMshows that significant association was observed between parental problem drinking and adolescents self-esteem.[11] The study revealed that a positive correlation between anxiety and depression (0.359) and this is supported by many previous studies which shows the comorbidity between anxiety and depression.[20] The study also revealed that anxiety is negatively correlating with self-esteem (-0.223) and this is supported by study conducted by Maldonado L

shows that adolescents with anxiety disorder had lower self-esteem.[21]

The study revealed that significant association found between anxiety and depression with class in which children are studying and this is supported study conducted by Rama rao KT shows that significant association was found between emotion and behavioural problems with high school students.[22] Early identification of developmental disabilities is a high priority for the World Health Organization to allow action to reduce impairments.[23] Even research findings shows that if problems are identified at earliest age, the impairment can be prevented. [11,12]

Limitations: The study is limited to small sample size (100) and small number of subjects limits generalization of the study.

Conclusion

The study findings shown that Children of alcoholics are at risk for anxiety, depression and low self-esteem. A behavioral problem during childhood is linked with variety of negative experience in adolescence and adulthood, so early identification by health care team is very important for prevention of complications. Further research is needed to identify effective strategies for using primary care for recognizing, diagnosing, and treating mental health problems in children and adolescents.

Effect of Dynamic Stretching Warm-Up Protocol on Hamstring Flexibility in Roller-Skaters: An Experimental Study

Deepika Jayprakash Surve[1], Prasannajeet Pramod Nikam.[2]

[1] Intern, Krishna College of Physiotherapy, [2]Assistant Professor, Department of Sports Physiotherapy, Krishna College of Physiotherapy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharahstra, India

Abstract

Purpose of the study: To find the effect of dynamic stretching warm-up protocol on hamstring flexibility in roller-skaters.

Materials and methodology: Subjects fulfilling the inclusion and exclusion criteria were included. After taking consent from parents, the skaters were assessed for their hamstring flexibility using the sit and reach test and 90-90 Straight Leg Raise (SLR). The skaters were then asked to perform set of 8 stretching exercises daily for 4 weeks. Prior to exercise the skaters had to do warm-up and post stretching, cool down. The entire protocol was supposed to be performed before their practice. After 4 weeks, post assessment was taken for their flexibility using the 90-90 SLR and the sit and reach test. Statistical analysis was done using the unpaired t test.

Result: The statistical analysis showed considerable extremely significant improvement in 90-90 SLR and Sit and reach test with p value <0.0001

Conclusion: The above study concluded that dynamic stretching warm-up had significant improvement on flexibility of hamstring muscles, both clinically and statistically.

Keywords: *Dynamic stretching, flexibility, hamstrings, sit and reach test, 90-90 SLR.*

Introduction

Hamstring, a bi-articular muscle lying in the posterior aspect of thigh is one of the frequently injured muscle in athletes.(1) Hamstring injuries are more common in sports requiring jumping, sprinting, etc. Muscle overload, imbalance, tightness, fatigue and poor conditioning often predisposes it to injuries. Quadriceps being more powerful than hamstring, there occurs an imbalance between the two and in-turn the hamstrings become fatigued more easily;thereby predisposing them to injury during high speed activities.(2) Age, gender, tissue temperature, strength training, and reduced warm-up period during exercise alters hamstring flexibility.(3)

Skating, a unique combination of athleticism, gracefulness, endurance involves many jumps, spins, and complex moves.(4) The most common musculoskeletal injury includes patella-femoral syndrome which occurs when the hamstrings and quadriceps have poor flexibility. Hence flexibility is an important factor in skaters.(5)Reduction in ability of muscle to deform leads to muscle tightness and in turn decrease in range of motion at the joint where is performs its action.(6) Hence a proper warm-up protocol is required to not only minimize but also prevent injuries.

Stretching, is a general term used to describe any therapeutic manoeuver designed to increase the extensibility of soft tissues, thereby improving flexibility by elongating structures that have adaptively shortened

and have become hypomobile overtime. The various modes include static, ballistic, cyclic, proprioceptive neuromuscular facilitation and dynamic stretching technique. The techniques which produce positive effect on muscle are then incorporated as a part of routine warm-up protocol. The most common technique to be used is static stretching as according to literature, it is known to be the safest form.[7]

In static stretching, the soft tissues are elongated just past the point of tissue resistance and then held in the lengthened position with a sustained stretch force over a period of time.[8] However recent studies indicate that static stretching has little or no effect on muscle performance.[9,10] Itmay cause decrease in dynamic constantexternal resistance strength, maximal concentric isokinetic strength, maximal isometric strength, peak twitch force output and rate of force development, maximal power output and balance. This phenomenon has been collectively termed as the *stretching induced force deficit*.[11]

To overcome this, researchers have focused on dynamic stretching as an alternative to static stretching as evidence suggests that it has positive effects on muscle performance as well as on flexibility. It consists of functional based exercises which use sports specific movements to prepare the body for activity.[12, 13, 14] The muscles are actively and rhythmically contracted to stretch the target muscle thereby raising muscle temperature. In dynamic stretching, a contraction by the antagonist muscle causes the joint crossed by the agonist to move through the full ROM at a controlled, slow tempo. Stretching begins from a neutral position, followed by a slow movement (4-5sec), of the limb to the end range, a brief hold at the end range (4-5sec), and ends with slowly moving the limb back to the original neutral position using an eccentric contraction. The contraction by the antagonist causes the lengthening muscle to relax due to the principle of reciprocal inhibition. Therefore dynamic stretching is a more natural way to elongate the muscle.[13, 14]

The other benefits of preferring dynamic stretch over stretch include that rather than focussing on a specific muscle, it focuses on individual muscle, approaches to work on movements. Secondly, the dynamic nature helps to maintain the elevation effects of the first period. Thirdly, the movements are more specific to those found in the sport and lastly, it is extremely time efficient. Additionally it has a physiologically different approach. The physiological effects of dynamic stretching include elevation of core body temperature, enhancement of motor unit excitability, improvement of kinaesthetic awareness, maximization of active ROM and development of fundamental movement skills. This creates a more optimal power production by enhancing neuromuscular function. This phenomenon has been referred to as the*post activation potentiation*. In this way preparation for activity is enhanced as muscles are activated as well as mobilized through key movements as post activation potentiation has its greatest effect on fast-twitch fibres.[15]

In order to recommend dynamic stretching as a suitable stretching exercise during warm-ups for various sports activities, previous findings are insufficient. Hence, the effects of dynamic stretching exercise on flexibility needs to be examined.

Materials and Methodology

After ethical clearance, the skaters were screened for their inclusion and exclusion criteria. Accordingly, 38 skaters were selected. For assessment of hamstring flexibility, 90-90 SLR and sit and reach tests were used. The skaters were asked to perform exercises prior to their practice. The exercise protocol was as follows-Warm-up:5min

- Dynamic warm-up: 8 exercises (15sec of each)
- Cool down: 5min.
- Total duration: 12-15min

Warm-Up:

- Jogging
- Bench stepping
- Jumping jacks

Entire Body Dynamic Warm-Up Protocol:

Bear squatwith kneeling foot stretch: Kneel sitting ⟶ quadripud ⟶ mountain pose ⟶ kneel sitting

Spider stretch with hamstring: Start with high plank position ⟶ step right foot outside right hand ⟶ drop right elbow down into the step of your right foot. ⟶ Sit back on left heel and straighten right leg ⟶ feel a stretch down your hamstring.

Dynamic pigeon stretch: Sit on the ground and keep foot in front. Keep knee bent to 90° and feel a stretch in the glute. Straighten back leg as much as

possible. start by reaching out to the left and then slowly move your hands to the right. When you reach as far as you can to the right, sit up and circle back around to the left side. Switch to the other.

Butterfly stretch with reach: Seated, place the bottom of your feet together and then draw your heels in as close as possible. Press your knees down towards the ground. Then try to reach your feet. Repeat with other leg.

Dynamic squat stretch: Stand with feet shoulder width apart. Bend forward as much as possible and try to reach your feet while keeping your legs straight. Bend your knees such that you assume a squatting position. Extend your hands towards the ceiling, make sure your heels don't come off the ground. Straighten your legs and get back to standing position.

Standing quadriceps stretch with reach: Stand on your right foot, grab left ankle with left hand. Pull left heel into your buttock. Hold for a few seconds. Repeat with other leg.

Standing hamstring and IT band stretch: Standing, cross your left leg over right leg. Clasp your hands together and reach up overhead. Bend forward, reach the ground. Hold for a few seconds.

Plank with reach back and out.

Cool Down

- Jogging in place(light and easy)
- Bench stepping(light and easy)

After a duration of 4 weeks, the skaters were again assessed for their flexibility using 90 – 90 SLR and Sit and reach test. Statistical analysis was done using the unpaired t test and confirmed with instat software.

Results

1. Sit And Reach Test

Interpretation: The pre-interventional sit and reach was 20.08±5.12 and post intervention sit and reach was 23.37±5.27. The P value was<0.0001 which was statistically considered extremely significant (t=7.66) This shows improvement in sit and reach test.

The analysis was done using 'paired t test'.

2. 90 – 90 SLR

Interpretation: The pre –interventional 90 – 90SLR was151.16±17 and post intervention 90 – 90SLR was 156.11±17.14. The P value was<0.0001 which was statistically considered extremely significant (t=11.23) This shows improvement in 90 – 90SLR.

The analysis was done using 'paired t test'.

Discussion

The study "Effect of dynamic stretching warm-up protocol on hamstring flexibility in roller-skaters" was conducted to find out the effect of dynamic exercises i.e. sports specific exercises on the flexibility of hamstring muscles. Skating, a unique combination of athleticism, strength, endurance, gracefulness and artistry involves complex moves, jumps and spins thereby requiring a good combination of strength and flexibility. The most common injury includes patella-femoral instability which occurs due hamstring-quadriceps instability. Eccentric contraction of hamstrings is important for the skaters hence they need to have a good amount of flexibility.

Strength, flexibility and endurance is the basic necessity for maintaining normal mobility of the body. Prior to warmup teams participate in a warm – up program so as to prepare the body for activity thereby preventing injuries. Warm – up includes stretching and exercises. Benefits of stretching include increase in core body temperature, increase in extensibility of the tissues and in turn minimizing the risk of injury.

The most common means for pre – activity warm-up is the static stretch. According to literature, tension created during static stretch is approximately half than during other forms of stretching. However according to recent studies, static stretching has been shown to have little or minimal effect on muscle performance what is known as the *stretching induced force deficit.*

Researchers have focused on dynamic stretching as an alternative to static stretching as evidence suggests it has positive effects on muscle performance and flexibility. Dynamic stretching consists of functional based exercises which use sports specific movements to prepare the body for activity. The benefits of dynamic stretching include a more natural way of tissue elongation as contraction of the antagonist causes the lengthening muscle to relax, in accordance to the principle of reciprocal inhibition and it approaches to work on movements. Secondly, the dynamic nature helps to maintain the elevation effects of

the first period. Additionally, it also has physiologically different approach which include elevation of core body temperature, enhancement of motor unit excitability, kinaesthetic awareness, and maximization of active ROM, which is together known as the *post activation potentiation.*

The objectives of this study were to provide a precise and concrete protocol for pre-activity warm-up that targets specific muscles required for activity thereby eccentrically elongating them.

The study was conducted on 38 roller-skaters. They were selected based on their inclusion and exclusion criteria. Inclusion criteria was both girls and boys below 16yrs of age. Exclusion criteria was any history of musculoskeletal or neurological injuries and history of previous surgeries.

Prior consent was taken from them after – which they were assessed for hamstring flexibility. Sit and reach test and the 90 – 90 Straight leg raise test (SLR) was used to measure hamstring flexibility.

In the sit and reach test, the skaters were asked to bend forward as much as possible such that they try to touch their feet.

For assessing hamstring flexibility using the 90-90 SLR, the subjects were asked to keep their hip and knee at an angle of 90° after which their flexibility was measured using goniometer.

After assessment, prior to stretching, the skaters were asked to perform a set of warm-up exercises which included jogging, bench stepping and jumping jacks. Stretching includeda set of 8 exercises i.e. bear squat with kneeling stretch, spider stretch with hamstring, dynamic pigeon stretch, butterfly stretch with reach, dynamic squat stretch, standing quadriceps stretch with reach, standing hamstring stretch and IT band stretch and plank with reach back and out. This was followed by cool down exercises which included jogging in place(light and easy) and bench stepping (light and easy).

The whole treatment intervention was about 12-15min. After 4 weeks, post intervention assessment was taken. The results ofthis study indicated increase in hamstring flexibility. This was confirmed using statistical analysis by using the 'Paired T test.'

In the sit and reach test, pre and post intervention was statistically considered extremely significant ($p=<0.0001$) and the 90-90 SLR pre and post treatment was considered extremely significant($p= <0.0001$)

Post training improvement is considered to be due to increase in eccentric contraction of the hamstring muscle, development of fundamental movement skills, elevation of core body temperature. Among few participants, there may not be major changes, due to lack of regularity.

Conflict of Interest: Nil

Sources of Funding: Self

Ethical Clearance: Ethical clearance was given by Institutional Ethical Committee.

Conclusion

The above study concluded that dynamic stretching warm-up had significant improvement on flexibility of hamstring muscles, both clinically and statistically.

Re-Engineering of Discharge Process with Emphasis on Sustainability: A Six Sigma Approach

Deepu Rani[1], Shalini D.[2], Arun Mavaji S.[3]

[1]Postgraduate student, Department of Hospital Administration, M.S. Ramaiah University of Applied Sciences,
[2]Assistant Professor, Faculty of Management and Commerce, M.S. Ramaiah University of Applied Sciences,
[3]Assistant Hospital Administrator, Ramaiah Memorial Hospital, Karnataka

Abstract

A quality improvement initiative is incomplete if the improvement is not sustained. The concept of sustainability is not limited to achieving the change and adhering to it, but further commitment is required from the staff for continuous improvements in the organization. The application of Six Sigma for process efficiency and achieving break through results are quite obvious, but evidence on its sustainability is limited. So, the current study was designed to re-explore the applicability of Six Sigma to re-engineer the discharge process with emphasis on determinants of sustainability factors. The methodology chosen was DMADV approach of Six Sigma. Define phase involved scrutinizing the finer details of process and resources utilized. The mean Turn-Around Time was measured for credit (269 mins) and cash (241 mins) patients using a time motion study. The NHS sustainability model was utilized for assessing the existing sustainability score of process. Minitab and Minitab Companion software was used for analysis of process capability and value stream metrics analysis. The process was re-engineered by streamlining the activities based on the standards given by NABH 4th Edition, JCI 6th Edition and best practices followed in different healthcare settings. Specific roles and responsibilities of staff were re-defined for the improved process. Failure Mode and Effect Analysis and control and impact matrix was conducted and provided to process stakeholders for ease of implementation. Validation of process improvement was done by value stream metrics analysis and discussion with the hospital administrator. The outcomes of the study were simplified process and discharge pro-forma which can be further utilized for application of Six Sigma in similar healthcare settings.

Keywords: *Quality Improvement, Discharge Process, Six Sigma method, Sustainability, Re-Engineering.*

Introduction

Healthcare industry is undergoing tremendous transformation in recent years with the technological advances. The two views expressed in one of the study were, patient's view which is supported by urbanization and awareness about health needs. The standpoint of hospitals was to uphold quality as crucial factor[1]. *According to the study conducted across 195 countries to assess Healthcare Access and Quality using HAQ index in 2016 gave India 145th rank with the quality score of 41.2[2]. To improve this ranking further there is need for quality improvement initiatives in every healthcare setting.* The two concepts that all levels of staff in an organization need to focus are, to do the job efficiently and improve on a daily basis[3].

Six Sigma in Indian Healthcare: Six Sigma is an organized, parallel- meso structure to reduce variation in organizational processes by using improvement specialists, a structured method and performance metrics with an aim of achieving strategic objective[4]. Six Sigma targets improvements or solutions for root causes of the defects, it is believed to reduce or eliminate reworks. Healthcare industries' essence lies in understanding the ascendancy of minimally defined services, immense involvement of human resources, uncertainty of outcomes of care and regulations, and different modes of payment options like insurance, providers from non-profit organizations etc[5]. Several hospitals have been applied Six Sigma for process efficiency in Operation Theatre, Radiology, Laboratory and to reduce waiting time in several departments etc.

Sustainability of Process Improvements: The key for sustainability lies in having a same goal spread across the organization in terms of continuous

quality improvement. The levels of sustainability are individual, teams, departments, organization and the entire healthcare care system. As the scale of change grows there is upward surge of requirement of expertise, skills, and resources for sustaining an improvement in the organization[6]. Quality improvements are successful only when there is transformation in organization culture to fire prevention rather than only on firefighting. A comprehensive review done on assessing the effectiveness of Six Sigma methodology concluded 67% of the process improvement in key process metrics, and only 9% were reported with sustained improvements. 8% reported with enhanced revenue and 28% reporting of cost savings was noted. The study highlighted the need for further application of Six Sigma with significant focus on sustainability[7]. This leads to the current study by re-exploring the Discharge process at a tertiary hospital with emphasis on sustainability.

Literature Review: The review article on the discharge process improvement studies concluded that, core issue with the process is lack of standardization of process across hospital and involvement of staff in fragmented episodes[8]. Another major factor related to the quality of discharge process is the provision of discharge summary by the hospital. Often, the discharge summary is the only form of communication that accompanies the patient to the next setting of care[9]. A Veterans Affairs Hospital affiliated by the university was experiencing poor outcomes of care and often discontinuity which lead to design and implementation of the electronic discharge summary tool for maintaining the timeliness of discharge summaries. The variables evaluated during pre and post implementation were time lapsed from discharge orders till patient received comprehensive discharge summary note, availability of note of discharge summary and satisfaction of outpatient providers with the discharge summary note. The results achieved were in favor of introduction of a novel discharge summary tool. The outpatient providers 86% found the discharge note was comprehensive for continuity of care[10]. Boson Medical Centre conducted a study with the intervention of RED (Re-Engineered Discharge) a standardized program with an objective to provide essential information to patients and their caregivers, which would prepare them to continue with the care at home. Enhancing the information availability and quality of patient education for adult patients with basic educational background helped in reduction of unplanned re-admissions and improve patient experience. The National quality forum recognized the components of RED program as the best practices. The toolkit and components was developed in accordance with the Agency for HealthCare and Research[11]. A study with a concern for investigating the effectiveness of implementing Six Sigma for hospital process improvements conducted a pre and post intervention study for a period of 10months using DMAIC methodology. It focused on improving the administrative processes that contributed for delays. A complete statistical analysis was conducted to analyse trends in daily discharge times, special cause variation, common cause variation, and assess process stability. The prominent limitation of study was sustainability of the process and appropriate staffing and lastly the data reliability[12].

Methodology

Aim: The study aims to realize the nature of process and assess factors required for its enhancement such that better outcomes could be achieved and sustained.

Objectives:

1. To study the current discharge process and attributes for sustainability (Define phase)
2. To measure and analyze the process and sustainability factors (Measure and analyze phase)
3. To redesign the process incorporating sustainability factors (Design Phase)
4. To Verify/Validate the re-designed process

The objectives of the study were designed in accordance with DMADV approach.

The study was carried out in tertiary care hospital in Northern Bangalore. The inpatient ward chosen for study was Corporate General ward. The methodology adopted was observational, descriptive and cross sectional study. Convenient sampling was done. The turn-around time of 40 credit patients belonging to different specialties were tracked and 20 cash patients. The further method, resources and tools used are been described in DMADV phases below.

Define Phase: The process to be studied was defined and co-related with the existing literature. The existing Discharge policy of the hospital was scrutinized with NABH 4th Edition standards. The determinants of sustainability were explored. Define Phase further involved preparing a project charter and SIPOC (Supplier, Input, Process, Output, customer) tools.

Measure Phase: The data collection tool was prepared for recording the time for each activity and case specific delays. Process Baseline was measured and process capability test and run charts was done for credit patients. Probability tests were carried out for the cash patients.

Calculation Defects per million Opportunities and Current Process Sigma level: Total no of patients (Both Cash & Credit) = 58 Total opportunities for delay in core process steps = 6 per patient, Total defects = 75, DPMO = (No of defects/No of units * No of opportunities) * 1000000 = 215517

Process Sigma level = 2.29, Process yield (%) = 78.45, Defects (%) = 21.55

Sustainability Scores: The scores for process factors score was 15 and staff factors was 22.6 which were required to be improved for the simplified process.

Analysis Phase: The detailed process analysis was done and counter measures were first drafted. The causes of delays were analyzed with cause and effect matrix was carried out for prioritizing the factors to be addressed. The identified areas crucial for improvement were discharge summary sub-process, patients leaving the wards, and billing related.

Design Phase: The discharge policy redefined as required by NABH 4th Edition standards. Patient's readiness for discharge and resources allocation factors was included for discharge planning. Specific roles and responsibilities of staff were re-defined for ease of carrying out process with less hassle. Process was simplified by proper specified steps under planning of discharge and on the day of discharge. The sustainability factors were addressed by method to involve the senior and clinical leadership. Technological solutions were reviewed to select the best options available. Failure Mode and Effect Analysis (Annexure - 1) was done assessing the potential failures and action plans were provided.

Validation or Verification phase: First the process was discussed with administrator and the quality personnel for implementation purpose. Next Minitab companion software was used for value stream metrics analysis to show the reduced waiting time and non-value added activities in the process. The discontinuity in the process was prioritized and addressed. The waiting time was reduced for administrative activities.

In Control and High Impact 1. Prioritizing the Discharges 2. Assessing readiness of patient and planning for discharge 3. Availability of transport resources 4. Availability of investigation reports at the time of doctor's rounds	**Out of Control But High Impact** 1. Physician rounds 2. Adequate staff 3. Prior preparation of discharge summary draft
Low Impact but In control 1. Training general duty assistants 2. Training of staff for plan for discharge	**Low Impact and Out of Control** 1. Patients paying the bills

Fig: Control and Impact Matrix

Results

During the define phase with the resulted process map the areas of discontinuity and deficiency in the existing discharge policy were identified and evaluated. Measure phase involved real time data collection and case specific delays for analysis using Cause and Effect matrix and Pareto's chart. Six-pack Process Capability tool on Minitab software was used to assess the current process capability for credit patients. The mean turn-around time for credit patients was 269mins and process capability was only 0.7.

The current process capability is 0.72 which is lesser than the normal value which is 1.33 and far away from the Six Sigma value which is 2. This also interprets the process is incapable of providing the requirements or producing outside the specification limits. The analysis of delays in the process identified discharge summary sub-process, patient leaving the ward and provision of final bill estimation information for patients were the factors for improvements. The control impact matrix provided attributes that are under management and controlling and monitoring them on regular basis will enhance the process efficiency and sustainability of changes. Design phase involved simplification of process and appropriate staffing. Validation of process was done through discussion with hospital administrator and value stream metrics.

Discussion

The lack of standardized process is the first issue that is been common with study done in other institute[8]. The mean time recorded during the measure phase was 269 mins for credit patients and 241mins for cash patients. The two studies did have a closer or similar mean time during the measure phase i.e., 247mins[13] and 234.35mins[14]. The additional 15-20mins variation noted

could be with the type of staff and technological resources currently in use. Another potential reason for delay as noted by study conducted in another healthcare setting[14], was related to processing of bills at the multitask desk. The queue time was addressed by increasing billing hours. In the current study the critical issue with bills was no provision for prior information on estimated time for bills payment to patient's care takers/relatives.

The process simplification was done by removing over processing of work and defining the specific role and responsibilities for staff which was similar in the study conducted at a community hospital[15]. Appropriate use of enterprise resources planning software[13] was reviewed for ease of the process and support for the staff and in-charges. The cause and effect matrix was another tool to be compared with the study. During addressing the system changes an additional staff[14, 15] was been added for well-being of patients after discussion with staff. The current study focused on reducing the number of staff involved in order to reduce the opportunities for delay.

Previously re-engineering of discharge process has been done with a focus on reducing the re-hospitalization[16], patient safety, re-admissions and post hospitalization return to emergency department[11], optimizing bed utilization and discharges before afternoon[17]. Current study focused on sustainability of process improvements by simplifying the process for standardization, appropriate staffing, and introducing a process monitoring system.

The National Institute for Health Research Collaboration for Leadership in Applied Health Research and Care for Northwest London (CLAHRC NWL) evaluated the applicability of NHS sustainability model. From the on-going projects the responses and formal reviews were collected by three different teams. Of the 19 teams selected and the feedback from 12 teams was positive towards the use of model. The remaining teams had negative feedbacks and found its usefulness was questionable and required deeper understanding for better applicability[18]. Many different attempts have been made to develop organization specific success tools for sustaining the improvements. During final conclusion the authors found the importance of involvement of stakeholders in developing a practical tool that can be applied in the different healthcare settings[19].

Recommendations: The recommendations involved provision and implementation for simplified discharge process and defined roles of staff. Further upgradation of ERP software, reallocation of transport resources and process monitoring system would help in reducing the overall turn-around time and improve efficiency.

Conclusion

The current study scrutinized the number of staff involved in the process to be standardized with specific roles and responsibilities which can actually reduce the number of opportunities for causing defects or delays. The sustainability of process improvements can be assured with enhanced leadership training for staff in-charges and purpose of quality improvement adequately spread across the organization.

Nutritional Status of Pre-Schoolers in the Border Areas of Jammu

Deepakshi Vaid[1], Devaki Gokhale[2]

[1]P.G. Student, [2]Assistant Professor, Nutrition and Dietetics Programme, Symbiosis School of Biological Sciences, Pune, India

Abstract

The nutritional status and overall development of children living in the border areas is affected to a greater extent due to restricted movements and lack of food during armed conflicts. Quality nutrition remains a distant dream for children residing in such areas due to lack of care and nourishment in their routine. Total number of 130 children aged 3-6 years were selected from border areas of R.S Pura (65) and Kathua (65), Jammu. Information regarding the socio-demographic profile, feeding practices and impact of armed conflicts on affordability, accessibility and availability of food was collected from mothers who voluntarily agreed to participate. Nutritional status was assessed by computing weight for age, height for age and B.M.I for age as per z-scores and percentiles by W.H.O. Data was entered into SPSS software version 23.0. Chi-square test was used for testing relationships between categorical variables, Pearson correlation to measure strength of linear association between two variables along with t-test to find mean differences between variables. Children of R.S Pura had better diet diversity scores (4.89 ± 1.10) compared to Kathua (4.32 ± 0.812) as majority of the father's were employed in government sector in R.S Pura (66.2%) and ration was provided during period of turmoil by government authorities. t-test revealed children to be normal for HAZ (-1.82 ± 1.520, -0.42± 2.150), WAZ (-0.05 ± 1.763, 0.62 ± 1.497) in both R.S Pura and Kathua however as per BMZ for age children were at a risk for being overweight in R.S Pura (1.86 ± 1.248) compared to normal children in Kathua (0.95 ± 1.430).Weaning was found to be statistically significant and 65.6% children were weaned at an appropriate age in R.S pura compared to 34.3% in Kathua.

Keywords: *Anthropometry, border areas, Jammu, Nurtritional status, ration facilities.*

Introduction

Malnutrition and diet are by far the biggest risk factors for the global burden of disease[1]. Childhood is a period of rapid growth and development,and nutrition is one of the influencing factors in this period[2]. Globally under-nutrition is associated with almost half of all childhood deaths[3]. India having a population of 1,236,344,631[3] and 112,782,125 children below the age 6 the prevalence of undernutrition is 42.5%[4] in comparison to 15% of under-six children in the world who are under-weight. According to National Family Health Survey-4 (NFHS- 4) estimates, nearly 42% of children in India are stunted and 38% are underweight in rural areas[5]. Jammu contributes to only 1% of India's share of population and the prevalence of undernutrition is 33.8%. *(NFHS III)*[6].

The environment in which a child grows affects the nutritional status especially in the armed conflict areas where everyday activities of children are affected due to restricted movements leading to compromised food choices and altered growth. Thus, anthropometric indices along with diet diversity are reasonably sensitive indicators for assessing immediate and general causes of undernutrition[7]. It has been postulated that the risk of mortality is inversely related to children's weight-for-age, height-for age and hence anthropometric indices have been useful to estimate the prevalence of under-nutrition among pre-school children[8,9]. Nutrition on other hand too has its fare share in contributing towards undernutrition. Children who become refugees,

e-mail: devakijgokhale@gmail.com

migrant and are uprooted from their homes due to armed conflicts are deprived of basic necessities/human right such as food which further contributes to nutritional deficiencies and ultimately undernutrition[10].Thus considering vulnerability of children in disturbed areas, observing the nutritional status of these children is of prime importance.

Materials and Method

The current study was a cross sectional study in which 130 stratified samples were chosen from disturbed areas of R.S Pura and Kathua, Jammu. Ethical clearance was obtained from Independent Ethical Committee of Symbiosis International University. Children aged 3-6 years were studied from November,2016 to February, 2017. 2 samples were excluded for incomplete information. The objective of the study was to assess the nutritional status of children in the disturbed areas of Jammu aged 3-6 years. Considering 33.8% as the prevalence rate of underweight children (NFHS III)[6] in Jammu, margin of error 8% and confidence level at 95% sample size was calculated using the formula $N= Z^2pq/e$. Based on the formula the sample size was 132.

Objectives of the study were explained to the principal, staff and mother of the children chosen. Written informed consent form was filled by those who voluntarily agreed to participate in the study. Information regarding date of birth,parents occupation were recorded from the school records..

Anthropometric data such as height, weight, Mid upper arm circumference and chest circumference were measured through caliberated instruments. Light indoor clothing was allowed to be worn and footwear was removed when readings were taken.

Nutritional status among 3-6 year old children was assessed by computing weight for age (z-scores and percentile), height for age (z-scores and percentile), B.M.I. for age (z-scores and percentile) using W.H.O growth charts. Dietary data was recorded using diet diversity questionnaire by FAO[11]. 24 hour diet recall was taken, various food groups consumed were recorded, scores assigned and accordingly dietary adequacy were computed as low, medium and high. Children who had dietary scores below 3 had low diet adequacy, those having 4-5 score had medium diet adequacy and high diet adequacy was for those having dietary score above 6.

The data was checked for completeness, coded and entered into Microsoft Excel and analyzed using SPSS version 23.0. The data was analyzed using descriptive statistics comprising of percentage, frequencies and measures of central tendency.

Growth parameters and their interpretation for the World Health Organization charts[12]			
Z Score (Percentile)	**Length/Height for age**	**Weight for age**	**B.M.I for age**
>3 (99)	May be abnormal	May be abnormal (Use B.M.I)	Obese
>2 (97)	Normal	Use B.M.I	Overweight
>1 (85)	Normal	Use B.M.I	Risk of overweight
0 (50)	Normal	Use B.M.I	Normal
< -1(15)	Normal	Normal	Normal
< -2 (3)	Stunted	Underweight	Wasted
< -3 (1)	Severely stunted	Severely underweight	Severe wasted

Result

Table 1: Feeding practices of children among the two areas

Initiation of breastfeeding	**Locale**		**Chi-square value**	**p- value**
	R.S Pura	**Kathua**		
<6 hours	52.2% (59)	47.8% (54)	1.692	0.193
>6 hours	35.3% (6)	64.7% (11)		
Weaning				
4-6 months	100% (11)	0% (0)	32.5	0.000**
6-12 months	65.6% (40)	34.4% (21)		
>12 months	24.1% (14)	75.9% (44)		

**Correlation is significant at the 0.01 level (2 tailed)

From table 1 it can be seen that feeding practices were better in R.S Pura than in Kathua. Even though initiation of breast feeding was not statistically associated with the locale of the child, 65.6%(40) children were weaned at an appropriate age (6-12 months) in R.S Pura when compared to 34.4%(21) in Kathua.

Table 2: Parent's occupation and nutritional status

Father's occupation	Locale		Chi-square value	p- value
	R.S Pura	Kathua		
Government employee	66.2% (43)	33.8% (22)	44.82	0.000**
Farmer + Daily wagers	8.2% (5)	91.8% (56)		
Mother's occupation				
Housewife	81.5% (53)	35.4% (23)	11.25	0.024*
Government employee	4.6% (3)	1.5% (1)		
Farmer + Daily wagers	13.8% (9)	63.1% (41)		

*Correlation is significant at the 0.05 level (2 tailed), **Correlation is significant at the 0.01 level (2 tailed)

The above table depicts that majority of the father's in R.S Pura were employed in the government sector(66.2%) ensuring fixed salary even during period of turmoil when compared to children in Kathua whose father's either practiced farming or were daily wage workers. Among the two areas, Kathua had relatively less number of housewives (35.4%) when compared to R.S Pura(81.5%).

Table 3: Meal intake and starvation period

Number of meals in a day	Locale		Chi-square value	p- value
	R.S Pura	Kathua		
2	1.5% (1)	4.6% (3)	13.25	0.004*
3	20% (13)	16.9% (11)		
4	43.1% (28)	67.7% (44)		
>4	35.4% (23)	10.8% (7)		
Starvation				
4-6 hours	27.7% (18)	33.8% (22)	2.005	0.367
7-12 hours	4.6% (3)	9.2% (6)		
None	67.7% (44)	56.9% (37)		

*Correlation is significant at the 0.05 level (2 tailed)

From Table 3 it was seen that 4.6% children in Kathua consumed limited meals to as much as 2 in a day. Children in R.S Pura showed better dietary patterns as almost 35.4% (23) consumed more than 4 meals in a day in comparison to 10.8% (7) in Kathua. Statistically starvation faced by children during armed conflicts was not associated with the border areas these children hailed from.

Table 4: Local market distance and ration facilities

Local market distance	Locale		Chi-square value	p- value
	R.S Pura	Kathua		
1-3 km	36.9% (24)	63.1% (41)	8.892	0.003
4-7 km	63.1% (41)	36.9% (24)		
Ration				
Yes	100% (65)	3.1% (2)	1.22	0.000
No	0% (0)	96.9% (63)		

**Correlation is significant at the 0.01 level (2 tailed)

Table 4 depicts the accessibility of food in terms of local market distance to the population living in both R.S Pura and Kathua region. It was found out that people living in Kathua had local markets nearby their place of residence i.e. within 1-3km (36.9%) whereas in R.S Pura 63.1%(41) had to travel 4-7km for buying the essential commodities. However during armed conflicts there was provision of ration facilities by the government authorities to the children of R.S Pura in comparison to those from Kathua.

Table 5 :Coefficient of correlation between meal intake

Component	Correlation test	p value	r value
Number of meals in a day	Distance between home and local market	0.000	-0.312**
	Diet diversity score	0.003	0.258**
	Mid-upper arm circumference	0.032	0.188*

**Correlation is significant at the 0.01 level (2 tailed), *Correlation is significant at the 0.05 level (2 tailed), (Mean value for MUAC =18.85 ± 1.75)

Table 5 shows that children whose meal consumption was appropriate for a day (more than 4 meals) had better diet diversity (p = 0.003, r = 0.258) and MUAC (p = 0.032, r = 0.188). However number of meals consumed in a day and market distance were negatively correlated.

Table 6: Anthropometric characteristics

Anthropometry 3-6 years	R.S Pura	Kathua	t value	p value
	Mean ± SD			
HAZ	-1.82 ± 1.520	-0.42± 2.150	-4.287	0.000**
WAZ	-0.05 ± 1.763	0.62 ± 1.497	-2.306	0.023**
BMZ	1.86 ± 1.248	0.95 ± 1.430	3.855	0.000**
Height for age (Percentile)	14.75± 26.25	40.58±40.38	-4.324	0.000**
Weight for age (Percentile)	48.71±38.20	63.38±31.627	-2.386	0.019**
B.M.I for age (Percentile)	86.55±22.36	71.42±28.76	3.350	0.001**

**Correlation is significant at the 0.01 level (2 tailed)

From Table 6 it can be seen that children in both R.S Pura and Kathua children were found to be normal for height-for-age and weight-for- age (z-score and percentile). However on assessing the z-score for B.M.I for age, children of R.S Pura were found to be at risk of being overweight (1.86 ±1.248) in comparison to children of Kathua who were normal (0.95 ±1.43) for their age.

Table 7: Consumption of food groups in disturbed areas

Food Groups	R.S Pura	Kathua	t value	p value
	Mean ± SD			
Cereals	3.25 ± 0.919	2.94 ± 0.76	2.07	0.04*
Carotene rich fruits and vegetables	0.74 ± 0.619	0.49 ± 0.64	2.22	0.028*
Dark green leafy vegetables	1.02 ± 0.71	0.75 ± 0.77	2.00	0.047*
Meat and Poultry	0.15 ± 0.40	0.03 ± 0.17	2.25	0.026*
Milk and Milk Products	1.00 ± 0.84	0.52 ± 0.58	3.72	0.000**
Diet diversity score	4.89 ± 1.10	4.32 ± 0.812	3.34	0.001**

**Correlation is significant at the 0.01 level (2 tailed), *Correlation is significant at the 0.05 level (2 tailed)

The consumption of food groups was very low as per recommended allowances for children 3-6 years in both the areas. However dietary adequacy of children in R.S Pura (4.89 ±1.10) was better than those who were residents of Kathua (4.89 ±1.10).

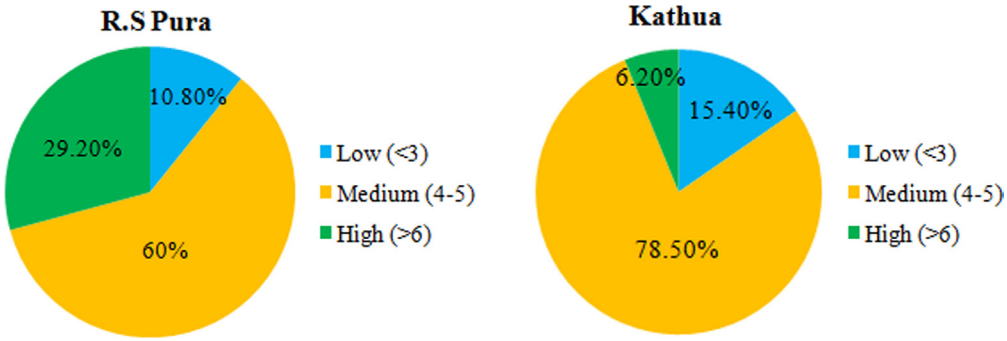

Figure 1: Diet diversity scores of children in R.S. Pura and Kathua

Due to the governmental aid and ration provided to the children of R.S Pura during period of turmoil, it can be seen that 29.2% children had high diet diversity score when compared to only 6.2% children having a high diet diversity score in Kathua. These dietary scores were computed on the basis of 24 hour diet recall in which exchanges of different food groups were taken into consideration and accordingly scores assigned.

Discussion

The findings of the current study reveal thatas per the z-score for B.M.I for age, children of R.S Pura were found to be at risk of being overweight (1.86 ±1.248) in comparison to children of Kathua who were normal (0.95 ±1.43) for their age. However in a study conducted by R Martorell et al in the border areas ofNepal[13] it was found that out of 510 children 65% were found to be stunted for their age.

Children in R.S Pura had better diet diversity scores (4.89 ± 1.10)better than those who were residents of Kathua(4.32 ± 0.812) due to better availability and food provided by government authorities during the period of turmoil.Steyn et al[14] in his study revealed that diet diversity scores were indicators of child growth.

It was seen thatas the distance between local market and place of residence increased, the number of meals consumed by a child in a day decreased due to restricted movement because of curfew imposed and ceasefire violations making it difficult to access food items from the nearby market.However it was seen that as the consumption of meals in a day increased,the diet diversity score improved along with the nutritional status as MUAC revealed that the children were well nourished($p = 0.032$, $r = 0.188$). Contradicting result was found in a studyconducted by Briend André, et al[15]where it was concluded that there was no significant correlation between weight of the child and MUAC. MUAC alone could be used as a preferable indicator for assessing the nutritional status of children

It was found that 23 children of R.S Pura(35.4%) consumed more than 4 meals in a day compared to only 7 children (10.8%) in Kathua.This could be due to reason that majority of children's father being employed in a government job and getting a fixed salary per month aiding to better affordability of food. It was also observed that only 1(1.5%) child consumed 2 meals in a day in R.S Pura region and 3(4.6%) children consumed 2 meals in a day in Kathua which is very less for children 3-6years old depriving them of the essential nutrients. Starvation during violations and armed conflicts along with lack of availability and affordability of food was the main reason for consuming such less meals.Even though children in R.S Pura 63.1%(41) had to travel 4-7km for buying the essential commodities in comparison to 36.9%(24) who had local markets nearby their place of residence i.e. within 1-3km in Kathua.However provision of ration by government authorities during conflicts was very active for people in R.SPura than in Kathua; Rice,sugar,wheat,oil the essential food items were made available within the vicinity of houses of R.S Pura by the government as ration facilities.

Initiation of breastfeeding and locale of the child were not statistically significant, however 65.6%(40)

children were weaned at an appropriate age (6-12 months) in R.S Pura when compared to 34.4%(21) in Kathua.Rasania and Sachdev observed a significant association between undernutrition in children when weaning was delayed[16].

Summary and Conclusion

The vulnerability of children living along the border areas increases as access to food, water and shelter is hampered due to ongoing armed conflicts which places health security at risk.Jammu has been witnessing such conflicts since Independence and nutritional status of children is affected to greater extent as extreme curfews,immobilization of human troops disrupts healthcare system,immunization schedules.Children cannot avail nutritional or healthcare services due to violence outside. It is of prime concern that authorities at the centre as well as state level adopt policies and schemes that would help organize camps and provide timely ration so that quality nutrition does not remain a distant dream to children who are prone to the armed conflict areas.

Prevalence of Depression among Elderly in Rural South India

Dhasarathi Kumar[1], Alex Joseph[2], Arulmani Thiyagarajan[1], Shyamala Shree[1]

[1]MPH, [2]Assistant Professor, School of Public Health, SRM Institute of Science and Technology, India

Abstract

Objective: Depression is gaining a major attention in perspectives of public health problem. The present study aimed to survey the prevalence of depression among elderly in the Kancheepuram district, Tamilnadu, India. Further objectives were to find the relationship between Depression and Old age.

Method: The study was designed as a cross-sectional study to assess the depression level among elderly in Kancheepuram district of Tamilnadu, India. The simple random sampling method was used for selecting the research participants. A short version of the Geriatric Depression Scale consists of 15 questions was used as a tool for measuring their depression status. Based on the scoring criteria, level of the depression status was measured and categorized them as no depression, mild depression, moderate depression and severe depression.

Results: A majority of the subjects were in the age group of 60 to 69 years (76.5%). The mean age of the participants was 66 years (mean ± SD: 66 ± 3.8).The prevalence of depression in the current study was 72%. There was a statistically significant relationship between age and depression. There was no significant relationship between gender and depression, as both genders had depression approximately closer to each other**.** There is a negative association between sleeping hours and depression score. As the sleeping hours reduces, the depression score of the individual increases.

Conclusion: Thus the present study aimed to find the prevalence of depression among elderly in rural population of Tamilnadu, India. Increased age and sleeping hours are the major determinants of depression.

Keywords: *Depression; Elderly; prevalence.*

Introduction

Depression is gaining a major attention in perspectives of public health problem. According to literature, it is predicted that by 2020, depression would be the second major leading cause of morbidity after ischemic heart disease.[1] As per the WHO reports, one in twenty people reported having depression in their life due to various reasons. Depression ranges from mild illness to severe pathology seeking immediate attention.

Individuals of 60 years and above constitute the elderly as per World Health Organization. There are nearly 104 million elderly persons in India as per Census 2011. In the words of Seneca; “Old age is an incurable disease”. As Sir James Sterling Ross said, “You do not heal old age, you protect it, you promote it and you extend it”. These are in fact the basic principles of Preventive Medicine.

India alone has around 100 million elderly at present, and the number is expected to increase to 323 million, constituting 20 percent of the total population, by 2050. Ageing is a Physiological process that affects almost all the systems of the body due to changes happening in body structures. Many elderly patients have an increased risk for malnutrition compared with other adult population.[2] It is estimated that depression affects one in seven people among elderly. However depression is not the natural process of aging, it is reversible with appropriate

treatment. Depression has a critical impact on well-being and quality of life of the elderly. Generally, Females tend to have more depression level than males.[3,4,5,6] The factors such as Co-morbidity, social network losses, low social support and negative life events.[7,8,9,10]

The present study aimed to survey the prevalence of depression among elderly in Kancheepuram district, Tamilnadu, India. Further objectives were to find the relationship between Depression and Old age.

Method and Materials

The study was designed as a cross-sectional study to assess the depression level among elderly in Kancheepuram district of Tamilnadu, India. The simple random sampling method was used for selecting the research participants. Kancheepuram consists of 15 blocks, in that totally Kattankulathur block consist of 39villages according to Census of India 2011. Eleven villages were selected by a lottery method in that 12 elderly peoples were selected from each village. Based on the overall prevalence of depression in India sample size is calculated, the sample size is 134 with the prevalence of depression 21.9%, 95% of the confidence interval and 7% of marginal error. Inclusion criteria are people aged 60 and above, those who all are the permanent resident of those particular areas (thirupporur,Kattankulathur). The non-respondents and those who are not willing to participate in the study were excluded. The study purpose was explained to the subjects. After which Oral and written consent were obtained from them. Pre-tested and validated geriatric depression scale (Short version) was used to assess their depression status.

Study instrument: A short version of Geriatric Depression Scale consists of 15 questions was used as a tool for measuring their depression status. Based on the scoring criteria, level of the depression status was measured and categorized them as no depression, mild depression, moderate depression and severe depression.

Results

A majority of the subjects were in the age group of 60 to 69 years (76.5%). The mean age of the participants was 66 years (mean ± SD: 66 ± 3.8).The prevalence of depression in the current study was 72%. In the present study, the prevalence of depression was found to increase with increasing age. It was found that nearly 30 % were at depression in the age group of 60 to 69 years, while 45% were depressed in the age group of 70 to 79 years of elderly people and it was 67% were depressed in the age group of 8 to 89 years. There was statistically significant relationship between age and depression (p-value<0.05)

Nearly 45% were belonging to the Upper middle class, 36% were in the middle-class group and 19% under lower class to the lower-middle-class group. In that 43% of the lower middle-class group had depression, whereas upper middle class was having 13 % of depression.

There was no significant relationship between gender and depression, as both genders had depression approximately closer to each other (p-value >0.05). Nearly 28 % of the respondents had no depression, while 39 % were having mild depression, 18% were having moderate depression and 19 % had severe depression. Overall 72 % of the elderly had depression in general, which signifies with high depression rate among elderly as per the reported documents.There is a negative association between sleeping hours and depression score. As the sleeping hours reduces, the depression score of the individual increases (Pearson correlation value = -0.077)

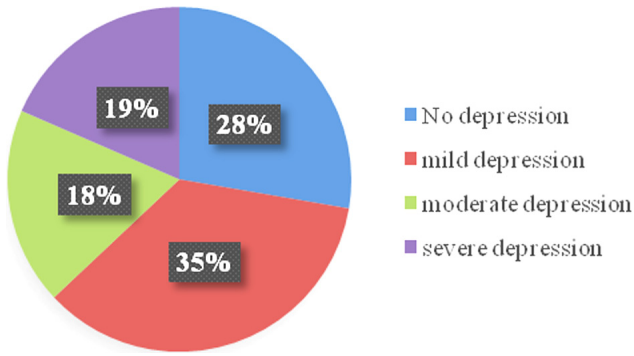

Figure 1: Depression Status n=134

Discussion

The chronic non-communicable diseases are rising as the geriatric population increases, therefore it is expected that magnitude of depression prevalence will also increase year by year. The result of this study suggests that prevalence of depression among elderly is approximately 72% which is very high compared to studies conducted previously. [11]The prevalence rate of depressive disorders reported between 4.7 to 16% as per the meta-analysis of 74 studies conducted among 487,275 elderly individuals and also suggested that higher prevalence rate of 21.9% in India.Similarly higher prevalence of depression was observed in a study conducted in Surat city with 39% prevalenceand a study in Udupi, Karnataka with the prevalence of 48%.

The prevalence of depression in the present study is comparatively high.[12,13,14,15]

This difference in the prevalence of this study might be due to the different instruments used for measuring depression and also their different sample size. In the present study, depression was found more among females as compared to males, but this difference was not statistically significant. In the same way, the observation was made from the study conducted in Manipal and Nellore district.[12,13] There was a significant statistical relationship between the depression and increasing age. As per the existing literature, the results validate that the depression is increasing among elderly as the age increases.[12,15]

To have a peaceful life, economic status of the individual act as one of the main factors in the day to day life. As per the study conducted in Pakistan which suggested that lower-middle-class people have depression that was due to increased age and lack of education, in our study people of the lower middle class have higher depression score when compared to other class people(43%). [16]Gender had no significant role in depression in our study. Similarly, the study conducted among community-dwelling elderly in Tamil Nadu found that age, female gender were not significantly associated with the depression score.[17]

Many article and literature suggest that sleep deprivation has a direct impact on our body as well as our mind. Seven hours of quality sleep is must for all, as it can seriously play a role in our daily activities. Insomnia and Depression are always related to each other and in our study, there is a negative association between sleeping hours and depression (Pearson correlation value = -0.077). As the individual sleeping hours decreases, the depression score increases which indicates, depression level of the individual increases.[18]

Conclusion

Thus the present study aimed to find the prevalence of depression among elderly in rural population of Tamilnadu, India. Increased age and sleeping hours are the major determinants of depression. By providing counseling and improving the general health condition can make the elderly patient less depressed and also sleep exercises are advised to them in order to attain proper sleep and thereby to improve the mental status.

Ethical Statement: The study was approved by Institutional Review Board of Ethics committee, School of Public Health, SRM University. Permissions were obtained from Panchayat president and Village Head members of the concerned villages for conducting the study.

Availability of data and materials: The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

Working Women's Experiences on Domestic Violence and its Consequences: An Urban Mangalore Study

Dinesh Abhijeeth Shanker[1], G. Shiny Chrism Queen Nesan[2], Rashmi Kundapur[3]

[1]Intern, K.S. Hegde Medical Academy, NITTE Deemed to be University, Mangalore, [2]Assistant Professor, Dept of Community Medicine, Saveetha Medical College & Hospital, Saveetha Nagar, Thandalam, Chennai, [3]Professor, Department of Community Medicine, K.S. Hegde Medical Academy, NITTE Deemed to be University, Mangalore

Abstract

Context: Women experience gender inequality and violence in every society which has a negative impact on their life, triggering physical and mental stress that in turn leads to decreased quality of life.

Aim: To determine the pattern of domestic violence and its association with decision making power, economic status, educational status of both partners, age at marriage and to determine legal and health consequences on working women in urban Mangalore.

Method and Material: A cross sectional study done using pre-validated, structured and self-administered questionnaire among 210 working women selected by universal sampling method andchi square test was done to find associations.

Results: The prevalence of emotional abuse (28.8%) was more compared to physical and sexual abuse. 10 - 11% were slapped and beaten, 1 - 2% were hit with objects and kicked. 20% were humiliated, let down and teased often and 4.3% had forced to have sex. 11.8% were physically abused for arguing back and drunken husbands abused their wives often. 51.4% reported depression and 69% visited doctor for various reasons due to domestic violence in past one year. None filed case against their partner to save family reputation (14.3%) and fear on husband (3.8%). Husband's education had significant association with the act of beating, slapping, forceful sex and emotional trauma.

Conclusions: Women majorly suffered emotional abuse followed by physical and sexual abuse.

Keywords: *Women, Domestic violence, Urban, Physical abuse, Sexual abuse, Emotional abuse.*

Introduction

Domestic violence defined by Protection of Women from Domestic Violence Act 2005[1] as physical, sexual, verbal, emotional and economic abuse against women by partner or a family member residing in a joint family.[2] According to WHO, it is seen that women in South-East Asia are more prone to partner abuse when compared to their counter parts in Europe, Western Pacific and American[2,3] Global estimates show 35% of women experience either physical or sexual violence by intimate partner or non-partner sexual abuse in their lifetime.[4] India falls in the higher end of this range with third round of NFHS-3[5] reporting a burden of domestic violence as 37 percent among married women in reproductive age group.[2] In a patriarchal Indian society, deep rooted long standing cultural norms such that of female subordination, selective female foeticide are common factors and are responsible for domestic violence. In India, Protection of Women from Domestic

Violence Act was passed in 2005. This was a milestone event against domestic violence.[6]

It is found that domestic violence varies with local social norms and literacy level of women[7] it is important to assess the problem for initiating supportive measures. The aim of this study is to determine the pattern of domestic violence and its association with decision making power, economic status, educational status of both partners and age at marriage of the women and to determine legal and health consequences of it.

Subjects and Method

A cross sectional study was conducted among all the married, educated women (teaching and non-teaching staff) working in a professional college of Mangalore city, Karnataka. Data was collected for 2 months from December 2017 to January 2018. The minimal sample size was calculated as 204, using the formula $4pq/d^2$ in which p=15%[8] of Spousal violence in Urban Karnataka and 5% allowable error. Universal sampling method was used. A standard, pre-validated and self-administered questionnaire consisting of 35 items prepared as per WHO guidelines given in WHO report of Violence on intimate partners[9] was distributed to the 385 women in the campus. The questionnaire included questions regarding physical, sexual and emotional abuse by their husbands/partners. The questions for reporting of health and legal consequences were added after the face validation and linguistic validation (Crohn backs alpha score being 0.82). [7] Informed consent was obtained from the participants. They were explained about the nature of the study and were made sure that the information provided will be maintained with utmost confidentiality. Women willing to participate were included in the study. Designated drop boxes were placed in different parts of the campus so that they may place their answered questionnaire in the box to maintain privacy. The participants were given one week time to fill and drop the questionnaires in these designated boxes. At the end of one week, we received 210 questionnaires back. Thus, the data was analysed based on responses from 210 participants.

This study had obtained ethical clearance from institutional ethical committee. The collected information was summarized using descriptive statistics such as frequencies and percentage. Chi square test was used to find association of domestic violence with respect to the decision-making power, economic status, educational status and age at marriage of both the partners. P value <0.005 was considered significant. Data management and analysis was done using Microsoft excel and SPSS version 16.

Results

Among the study participants, prevalence of physical, sexual and psychological abuse was found to be 13.3%, 4.8% and 28.1% respectively. Most the participants(72.4%) belonged to the age group 21-40, 63.3%of the women got married between the age 20 and 25 years and 70% were married for 1 to 10 years. On assessing the educational status of the wife, 40% of the women had graduated from college. 46.2% of the husbands held professional degree 48.1% of the women earned between 10,000 – 50,000 Rupees while 42.9% of husbands earned over Rupees 1, 00,000. 23.3% of women felt that the marriage was done only for the sake of social security and 18.6% felt that their husband is the boss of the home than a better companion for them. It was observed that in 71% of homes, husband was the major decision maker and in 15.2% homes, both the husband and wife take decisions. 35.9% of women reported that their spouses consume alcohol. **Table 1** lists the patterns of domestic violence faced by the women and extend of emotional abuse. It was observed that majority of them suffered Emotional abuse by their partners. **Table 2** elaborates various reasons for the domestic violence faced by the women as reported by them. It was observed that main reason for physical abuse was for not obeying their husband (24.1%) while most common reason (12.4%) for women emotional abuse was on the grounds of dowry and 2.4% were sexually abused by their alcoholic husbands. We also noted that some of the reasons were linked to more than one type of abuse. We also analysed the association of domestic violence with respect to decision making power, age and age at marriage of women and economic/education status of both partners. It showed that the educational status of the husband had significant association with physical, sexual and emotional violence (*p=0.021, p=0.006 and p=0.017* respectively) and majority of them were professionals with highest educational qualification. **Table 3** enumerates the health consequences of domestic violence among the women. Two-thirds of the women visited the doctor 1-3 times in the last year in relations to domestic violence. Most of the women (51.4%) suffered depression as reported by them. Less than 50% experienced headache as a long-term consequence of domestic violence. None of the women reported hearing

loss, vision loss, miscarriage, early delivery, mentally traumatising sexual acts, homicidal wounds or threats and STDs. None of the women reported a case on domestic violence. Various reasons as stated by them for not reporting were fear of losing family reputation (14.3%), 'ready to suffer domestic violence in silence' (7.1%) and fear of husband (3.8%).

Table 1: Patterns of Domestic violence among women and extend of emotional abuse

Patterns of Abuse	Responses (N = 210) N %	
Physical Abuse		
Slap	23	11.0%
Beat	22	10.5%
Kick	3	1.4%
Hit with objects	2	1.0%
Sexual Abuse		
Forced sex	9	4.3%
Abnormal sex	0	0
Emotional Abuse		
Letting down	43	20.5%
Humiliating	41	19.5%

Seizures	0	0
Substance abuse	0	0

Discussion

Due to the sensitivity of the subject and ones understanding of the questions related to violence, the results have been analyzed with utmost care and caution. Our data along with the world-wide literature confirm that domestic violence is a universal phenomenon existing in all communities.[8,10-16] Babu et al[6] in their study of married women from the states of Eastern India found urban residence, older age, lower education and lower family income are associated with occurrence of domestic violence. In our study, we noted that physical, sexual and psychological abuse were associated with educational status of the husband i.e. higher the education level, more the abuse was observed but a similar study done in Karnataka[7] showed lower the education, more the abuse. The proportion of physical violence is comparable in the two studies but the women in their study faced quadruple and double the amount of sexual and psychological abuse respectively, when compared to our study.

Pewa et al[17]in their study done in Rajasthan observed that more than half were physically abused (54.7%) and 20% were abused emotionally. This is higher than what was observed in our study. They report that alcoholism, low literacy status and having a girl child were the main reasons for domestic violence while we found that reasons such as not being a good wife, questioning the husband and not being an obedient wife were the main reasons for abuse.

In various studies conducted in northern India[10,18,19],they found reasons such as dowry and alcohol consumption, higher educational status and higher income of the wife where the patterns noted in households with higher percentage of domestic violence. On comparing with a multi- country study done by Garcia-Moreno et al[20] in 2006, the physical violence was almost same when compared to the women in Japan while the sexual violence among them was just over 3 times the rate seen in our study. As seen in our study, sexual violence had a lower prevalence than physical violence.

Ali et al[21] in their study explored the effects of domestic violence on mental health, that the women subjected to physical and sexual violence were 4 times at risk of having suicidal thoughts at some point. In our study, 51.4% reported to suffer from depression but none had reported suicidal thoughts.. It is observed that higher the education of husband more the violence being caused.

Conclusion

This study reaffirms the high prevalence of different types of violence that women face. Husband's with higher education is seen to be associated with more domestic violence. Domestic violence has an impact on the health of the women both physically and mentally. Institutions need to be created to cater the needs of women that face domestic violence. Literature reviews shows that women around the world still face domestic violence in some form. Our study reinforces the same and the need to bring more reforms and empower the women so that they are not subjected to different forms of domestic violence.

Major limitation to our study is that the responses of the women may vary according to their perspectives and understanding of abuse or violence which may cause information bias. Some women might not have been able to follow the questions as it is self-administered. Responses for health consequences were taken as reported by the women which may have caused discrepancies in the results.There is a need for recognizing this issue at the national level and there should be enough educational programs in all societies and cultures, both for women and men at all the levels.

Structural Relationship between Dimensions of Psychological Empowerment, Customer Oriented Behaviour and Job Satisfaction of Employees in Public Sector Banks

E. Sharanya[1], K. Vasanthi Kumari[2]

[1]Research Scholar, Bharathiyar University, [2]Head and Assistant Professor, Department of Business Administration, R.V. Government Arts College, India

Abstract

This study aimed to examine the structural relationship between dimensions of psychological empowerment, customer-oriented and Job satisfaction among the employees in public-sector Banks. Psychological empowerment promotes the employees to use their knowledge, experience, capacities and innovative ness by bearing accountability for their jobs and it leads to customer-oriented behavior. Customer oriented behavior provides basis for forward progress and continued existence of banks in a highly competitive banking environment and increases their profitability. Customer oriented behavior is highly mediating relation between psychological empowerment and quality of service and it enhances satisfaction of customers and their loyalty towards banks. The results revealed that the impact, competence, self-determination and meaningfulness are positively and directly influencing customer-oriented behavior of employees in public sector banks. Besides, customer-oriented behavior is positively and directly influencing job satisfaction of employees in public sector banks. This study offers new insights into the existing literature and provides implications and directions for future research.

Keywords: *Employee empowerment, psychological empowerment, customer-oriented behavior, Job satisfaction.*

Introduction

The banking is a financial institution that offers services for effective managing of cash to customers, encompassing the operations of different portfolios and their bank accounts. The banking system in India is not only free from jumbles, but it has capability to overcome the problems due advanced technological improvements and also internal and external issues. For the last 40 years, Indian banking system has a numerous outstanding achievement to its magnificence. The public-sector banks are the main players in the financial market of India.

In order to attain the goals and objectives of banking system in India, employees are the highly important resources for banks. The employees are the storehouse of, skills, competencies and capabilities that cannot be emulated by the competitive banks. At the same time, these employees are not efficiently utilized in Indian banking system. Nowadays, banks are ready to empower their employees psychologically, but employees are not ready to take responsibilities. Psychological empowerment provides the employees a certain level of power and authority and it influences their job satisfaction and commitment.

Psychologically empowered employees help the banks in increasing competitiveness, creativeness and responsiveness to their customers. Psychological empowerment enhances quality of services and exposes motivation and talents of employees. Psychological empowerment promotes the employees to use their knowledge, experience, capacities and innovativeness by bearing accountability for their jobs and it leads to

customer-oriented behavior. Customer oriented behavior provides basis for forward progress and continued existence of banks in a highly competitive banking environment and increases their profitability. Customer oriented behavior is highly mediating relation between psychological empowerment and quality of service and it enhances satisfaction of customers and their loyalty towards banks.

Literature Review anr Theoretical Background

Psychological/Motivational Empowerment: The psychological empowerment concept can be defined as "a state of mind in which an employee experiences the feelings of control over how the job can be done, have enough aware to the work tasks that being performed, a great level of responsibility to both personal work outcome and overall organizational advancement, and the perceived justice in the rewards based on individual and collective performance" (Melhem, 2006, p: 586).[14] Spreitzer (1995) also offers a more traditional definition of this concept, defining it as "a motivational state that reflects an employee orientation toward work characteristics that rely on four determinants that are competence, impact, meaning and self-determination" (Spreitzer, 1995, p: 1441).[2] Also, Borghei et al. (2010) view the psychological perspective as subjective feelings and phenomena, meaning that this perspective is considered an internal motivational construct.[10]

Customer Oriented Behaviour: "The ability to identify, evaluate, understand, and meet customer needs" (Reychav and Weisberg, 2009, p: 354). [13]Mechinda and Patterson (2011) define it as "specific behaviors that frontline employee displayed during service contact point with aim to make customer more satisfied with service" (Mechinda and Patterson, 2011, p: 103).[7]

Job Satisfaction: Job satisfaction refers to how well a job provides fulfillment of a need or want, or how well it serves as a source or means of enjoyment. Job satisfaction is the degree to which individuals feel positively or negatively about their jobs.

Need for the Study: The need for Psychological Empowerment gained great importance in service-oriented institutions like banks. As employees in a service organization have frequent contacts with the customer, they usually serve as representatives for both the organization and their products and services to the customer at contact point. When service interactions are not properly controlled and handled, the outcome is poor perception of service quality that leads to customer dissatisfaction. The quality of service and satisfaction that the customer may derive will be an assessment of the entire service experience. The employees play a major role in determining whether a customer would enjoy the experience or turn to their competitors for better solutions.

Research Methodology

The descriptive research design is applied for the present study. The present study is done in Thanjavur district. The public-sector banks namely Indian Bank, Indian Overseas Bank, State Bank of India, Canara Bank, Bank of India, Corporation Bank and Union Bank of India are chosen based on number of employees. The employees of these banks are selected by using simple random sampling method. The data are gathered from 517 employees of public sector banks through questionnaire method. The Structural Equation Model (SEM) is constructed to knowstructural relationship between dimensions of psychological empowerment,customer-orientedbehavior and job satisfaction of employees in public sector banks.

Findings and Discussions: To study the structural relationship between dimensions of psychological empowerment,customer-orientedbehavior and job satisfaction of employees in public sector banks, the Structural Equation Model (SEM) is built and the results are presented in table 1.

Table 1: Standardized Structural Path Coefficients

Path	Standardized Coefficients	CR	P-Value
COB ←SD	.451	4.977	***
COB ←CO	.463	5.133	***
COB ←IM	.502	5.866	***
COB ←ME	.413	4.299	***
JS ← COB	.671	8.723	***

Source: Primary Data *** indicates significant at one per cent level

From the above table, it is obvious that the standardized coefficient for Customer Oriented Behavior (COB) against Self Determination (SD) is 0.451, the standardized coefficient for Customer Oriented Behavior (COB) against Competence (CO) is 0.463, the standardized coefficient for Customer Oriented Behavior (COB) against Impact (IM) is 0.502

and the standardized coefficient for Customer Oriented Behavior (COB) against Meaningfulness (ME) is 0.413 and these co-efficient are significant at one per cent level. Thus, impact, competence, self determination and meaningfulness are positively and directly influencing customer-orientedbehavior of employees in public sector banks.

In the meantime, the standardized coefficient for Job Satisfaction (JS) against Customer Oriented Behavior (COB) is 0.671 which is significant at one per cent level. Hence, customer-oriented behavior is positively and directly influencing job satisfaction of employees in public sector banks.

The path diagram for job satisfaction of employees in public sector banks is shown in figure 1.

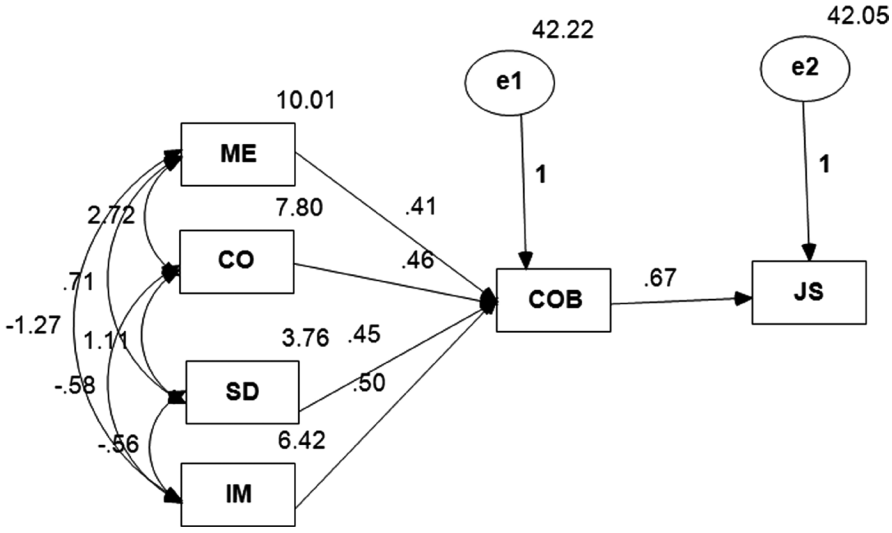

Figure 1: Path Diagram for Job Satisfaction of Employees in Public Sector Banks

The model fit parameters are presented in Table. 2

Table 2: Model Fit Parameters

Chi-Square Value	P-Value	GFI	CFI	RMR	RMSEA
1.44	.000	0.99	0.98	0.06	0.03

Source: Primary Data

The chi-square value of 1.44 is significant at one per cent level revealing that the model is an excellent fit. The Goodness of Fit Index (GFI) is 0.99 and Comparative Fit Index (CFI) is 0.98. These GFI and CFI show perfect fit.The standardized Root Mean Residual (RMR) is 0.06 and Root Mean Square Error of Approximation (RMSEA) is 0.03 indicating excellent fit.

Limitations of the Study: The present research is carried out in Thanjavur district. The present study is done based on data gathered from primary source of employees of public sector banks. The demerits and constraints of field survey are highly relevant to the present study. The data received from employees of public sector banks have recall bias.

Conclusion

On the basis of the results it is concluded that the impact, competence, self-determination and meaningfulness are positively and directly influencing customer-oriented behavior of employees in public sector banks. Besides,customer-oriented behavior is positively and directly influencing job satisfaction of employees in public sector banks. Thus,the bank employees like their jobs more when they find their work meaningful, when they feel capable of performing their work well, when they have freedom to make decisions about their work and when they feel that they can have an impact on organizational outcomes.

Factors Influencing the Development of Chronic Cough Following Common Cold

Rahul Yelgoi[1], Jayakumar Jeganathan[2], Pavan M.R.[2]

[1]Resident in Medicine Dept., Kasturba Medical College, Mangaluru, [2]Associate Professor in Medicine Dept., Kasturba Medical College, Manipal Academy of Higher Education, Mangaluru

Abstract

Introduction: Following common cold most of the patients recover within a week. However a few people go on to develop chronic cough. There have been no studies looking at simple patient characteristics which may tell us which patients may go on to develop chronic cough.

Materials and method: The main Aim was to study factors that determine which group of patients develop chronic cough following common cold. A total of 131 patients were included in the study. They were followed up for 3 weeks. They were divided into 2 groups based on whether they had cough for more than 3 weeks and less than 3 weeks. The collected data was analyzed using Chi square test.

Results: Among 131 individuals who underwent study 45 had chronic cough. Age group less than 20 yrs and more than 60 years, smoking history and a low PEFR (Peak Expiratory flow rate) were associated with development of chronic cough.

Conclusion: Extremes of age, smoking history and low PEFR were associated with the development of chronic cough following common cold.

Keywords: *Chronic, Cough, Common cold, Characteristics, Predictors.*

Introduction

Following common cold most of the patients recover within a week. However a few people go on to develop chronic cough (more than 3 weeks). Chronic cough is associated with significant morbidity and interruption with daily activities of the individuals. As of now most of the studies that have looked at the duration of respiratory symptoms following common cold have mainly been done in pediatric age mainly by looking at factors like etiological organism (type of viruses) or in adults using special testing for airway hyper-reactivity using tests like methacholine challenge test. [1] There have been no studies looking at simple patient characteristics which may tell us which patients may go on to develop chronic cough.

Materials

The aim of this study was to study which factors determine that the patients may develop chronic cough following common cold. This was an observational study done in a tertiary care centre in south India. The permission from the local ethics committee was obtained. Informed consent was obtained from all participants. All participants who were more than 18 years and who presented within the first week following common cold were included in the study. All patients who had prior respiratory diseases and who were on ACE inhibitors were excluded from the study. Sample size was estimated using the formula n= Z 2 pq/e. By using this formula with 80% power, 95% confidence interval, and adding 10% non-response error the sample size came to 110. Total of 131 patients who fitted into the inclusion criteria were included and these patients were followed

up for 3 weeks. Patient characteristics like smoking, allergic rhinitis, family history of atopy, post nasal drip, PEFR, occupational exposure were noted. Actual PEFR (Peak expiratory flow rate) was measured using peak flow meter. Ratio of test PEFR to predicted PEFR was calculated. Percentage of the ratio was obtained for each individual & divided into 3 class intervals. The patients were divided into 2 groups based on duaration of cough of more than 3 weeks and less than 3 weeks. Collected data was analyzed using Chi square test. P value of less than 0.05 was considered significant.

Results

Out of 131 subjects who were included in the study 45 had chronic cough. Among 45 patients who had chronic cough 32 were Males & 13 were females. In the age group below 20 years, 4 out of 11 had chronic cough, 11 out of 58 in the age group 21-40, 18 out of 44 in the age group 41-60 & 12 out of 18 in the age group above 60 years had chronic cough. Elderly individuals developed chronic cough. It was statistically significant with a P value of 0.02. Ratio of the test PEFR to predicted PEFR was calculated and divided into 3 class intervals. As seen in Table 1. Among 8 individuals in the class interval of 70-80%, 6 had chronic cough, 27 out of 45 in the 81-90% class interval had chronic cough, only 12 out of 78 in the class interval above 90% had chronic cough. People belonging to the group of 70-80% had statistically significant more chance of developing chronic cough with a P value of 0.03. Among the 29 smokers 24 of them developed chronic cough which was statistically significant (P value 0.002). When analyzing the family history of atopy, among the 17 individuals with family history of atopy, 7 of them developed chronic cough. This was not statistically significant. Total 13 patients had post nasal drip out of which 7 had chronic cough after 3 weeks. However when P value was calculated it was statistically insignificant.ROC curve plots were drawn in relation to PEFR ratio & chronic cough. As seen in Table 2. The area under curve was found to be highly significant with an area of 0.822. When a PEFR ratio percentage cutoff of 73.2 was taken it had a sensitivity of 100% & 0% specificity of predicting the development of chronic cough, When a cut off of 86.45 was taken it had a sensitivity of 88% & specificity of 62.2%, and a cut off of 92.3 had a sensitivity of 66.3% & specificity of 84.4%. Total 21 patients had history of allergy rhinitis out of which 8 developed chronic cough, which was statistically insignificant.

Table 1. Correlation of PEFR and chronic cough

PEFR (%)	Chronic cough Yes No	Total
70-80	6(75%) 2(25%)	8
81-90	27(60%) 18(40%)	45
Above 90	12(15.4%) 66(84.6%)	78
Total	**45(34.4%) 86(65.6%)**	**131**

Table 2. Area under the curve: Result Variable(s): PEFR Percentage

Area	Std. Error(a)	Asymptotic Sig.(b)	Asymptotic 95% Confidence Interval	
			Lower Bound	Upper Bound
.822	.040	.000	.744	.899

Discussion

In our study it's observed that 45 out of 131 (34.35%) had chronic cough. In a study conducted in Mysore prevalence of chronic cough was found to be 2.5%. [2] In another study they found that global prevalence of chronic cough was 9.6%.[3] Our study results showed males developed chronic cough more often and were different from the data showed in the study done by Mats Bende & Eva Millqvist where it showed females were more risk to have chronic cough.[4] Elderly developed chronic cough more often in our study Siilarly, Chabbra observed that age below 30 years had less prevalence & age above 70 years had high prevalence of chronic cough.[5] As the PEFR ratio decreased prevalence of chronic cough increased. Primhak PA in their study did not find any relation between PEFR and recent cold.[6] Significant number of smokers in our study developed chronic cough. The same conclusion was drawn by PA Mahesh in their study.[2] Family history of atopy did not show any correlation with the development of chronic cough in our study. There were hardly any studies that looked at this parameter in predicting the development of chronic cough. Post nasal drip was also a factor that did not show any correlation to the development of chronic cough. Our results were quite different from the study conducted by Pratter where he found that post nasal drip alone or in combination with other factors was the most common cause of chronic cough. When a PEFR ratio percentage below cutoff of 86.45 was taken it had a sensitivity of 88% & specificity of 62.2% of predicting the development of chronic cough. There were no studies that looked at this parameter to predict the development of chronic cough. Presence of allergic

rhinitis did not have any significant effect on predicting the development of chronic cough.

Conclusion

Following common cold it was found that elderly, males, smokers and people with PEFR of below 86.45 had a higher chance of developing chronic cough.

Ethical Clearance: Taken from the institutional local ethics committee before the start of the study.

A Study on Role of Human Resources Management (HRM) Practices in Training Transfer with References it/ites Organization

A. Mani[1], G. Murugesan[2]

[1]Associate Professor, [2]Professor, Department of Management Studies, Vinayaka Mission's Kirupananda Variyar Engineering College, Vinayaka Mission's Research Foundation (Deemed to be University), Salem, Tamil Nadu, India

Abstract

As organizations endeavor to improve execution through their human capital, trainers and professionals in the working environment are progressively anticipated to provide better results. HR today is a key benefactor towards unraveling authoritative issues and accomplishing significant business results. The market situation after the subsidence has prompt radical changes in the IT business. Now and again there is a requirement for the researchers to stop and think about the status of the HR practices. Best HR practices will help the organization in achievingradical improvement as opposed to incremental ones. The examination recognized two arrangements of primary factors, the traditional HR practices and the advanced HR practices.

The paper discusses the importance of training transfer and the role of human resources management in providing effective training and development practices to the employees in IT/ITES industry. Related theories on training transfer have been provided to justify the effectiveness of implementing training programs for the employees of the organizations. The paper used Structural Equation Modeling as an instrument to show the relationship between the variables as identified in the study.

Keywords: *HRM, Training transfer, HR practices, organizations, IT/ITES industry.*

Introduction

Human Resource Management (HRM) is a relatively new way to deal with overseeing individuals in any association. Individuals are viewed as the key asset in this approach. It is concerned about the general population measurement in management of an association. Since employees are a collection of individuals, their acquisition, development of aptitudes, motivation for more elevated amounts of achievements and in addition guaranteeing support of their level of commitment are generally critical activities that fall in the area of HRM. Huselid (1995)[1] stated in his observational examination that superior work practices and good fit of model should prompt positive results for a wide range of firms. Nevertheless, training involved in best practice reports, or particularly for the transfer of training is restricted due to lack of practicality or it's subjective in nature.

The current literature contains couple of actual researches led in India that feature the idea of human asset management (HRM) frameworks pertinent to the IT/ITES part and a significant part of the literature that is accessible on the Indian IT/ITES industry talks just about the ceaseless issue of high attrition rates of the business. The present examination centers on the nature and structure of work and association of Indian IT/ITES and in addition the vital pretended by HRM in such organizations. The discoveries feature the way particular HRM practices, for example, recruitment, training and development, execution evaluation and pay, prizes and recognition, vocation development, employee turnover and maintenance are actualized.

Overview of it/ites Sector: IT/ITES industry has two noteworthy segments: IT Services and Business Process Outsourcing (BPO). The development in the administration segment in India has been driven by the IT/ITES segment, contributing significantly to increment in GDP, exports and employment. As indicated by NASSCOM, the IT-BPO industry in the Indian IT division is required to develop at a rate of 12% to 14% for

Financial Year 2016-2017. The division is additionally expected to triple its yearly income at present to achieve US$ 350 billion by Financial Year 2025.

The spending on Information Technology by security and banking firms in India grew up to 8.6% year-on-year that resulted in US$ 7.8 billion in 2017. Though India's web economy is relied upon to reach 10 trillion (US$ 146.72 billion) by end of 2018, representing 5% of the nation's GDP. Top IT firms like Infosys, Wipro, TCS and Tech Mahindra in India are broadening their contributions and displaying driving thoughts in block chain and artificial intelligence to customers utilizing innovation hubs, R&D centers, keeping in mind the end goal to make separated contributions.

Training Transfer: There is a solid conviction that training is imperative not just in light of the fact that it is necessary for building and keeps up a powerful workforce, yet in addition since it drives corporate prosperity and furnishes organizations with a competitive favorable position. However, if training is to give organizations' a competitive advantage and enhance firm execution, learners should first apply and exchange what they realize in training at work. Training refers to learning skills and information for completing a specific occupation and expands skills required for work. Training is concerned about keeping up and enhancing present place of employment execution. Consequently, it has a transient point of view. Off-the-work training technique happens far from typical work situations, inferring that the employee does not consider a specifically productive specialist while such training happens. Off-the-work training technique likewise includes employee training at a site far from the real workplace.

Learner's Behavior: Learner's behaviorinclude attributes regarding the ability of a trainee, personality, motivation,expectations, perceptions, or attitudes that influence training transfer.

Trainer's Attitude: Knowledge of trainers on the topic, proficient experience, and information of encouraging standards is critical and they should have the adaptability to adjust to every learner's learning style and needs (Burke and Hutchins, 2008)[2].

Work Environment: Work Environmentrefers to any influence on training that occurs or happens outside the learning mediation including the assessment of training transfer.

Training Content: Training professionals must ensure to design training content in line with the job task which correlates with training transfer.

Employee Motivation: Positive personality traits, initiative, commitment to professional growth, self efficiency and love of learning influence the employees and motivate them for organizational learning and obtain better training transfer from professionals.

Organizational Performance: Organizational performance is identified by the behavior of the learners and attitude of the trainers which are important for training transfer to take place successfully within an organization (Baldwin and Ford, 1988)[3].

Theories on Training Transfer:

Theory of Identical Elements: E.L. Thorndike proposed the theory of identical elements which explains the part of identical elements between the learning circumstance and the implementation circumstance as a component of the procedure of training transfer. The examination could substantiate that similitude between training and day to day work circumstances positively affects both transfer training and transfer motivation. Yamnill & Mclean (2001)[4] identified that anemployee's focus during training session is estimated in high rate of participation. Similarly,attention of employees during problem solving and has no positive effect on training transfer or subjective transfer estimates.

As per this theory, conducting training transfer by the trainer to that of the learner is relative to the level of likeness in circumstances. In more straightforward words, it can be stated that the higher the likelihood, the effective and quicker, the transfer is. Moreover, the rate of transfer and additionally the pace of the transfer increase as the number of comparable components increases.

Cognitive Theory: Cognitive Theory is a cutting edge theory when contrasted with the elective speculations of the training transfer. As indicated by this hypothesis, the pace and the viability of the way toward transferring the training can extraordinarily be expanded by concentrating on the people's psychological models, maintenance of data and understanding. In addition, the principle indicates that makes it unique in contrast to other transfer hypotheses is its intense level of applicability under nearly a wide range of circumstances.

Capacity of training, especially intellectual capacity is a solid indicator of exchange results (Burke and Hutchins, 2007)[5]. Such evaluations regularly measure by and large insight, which mirrors people's capacity to comprehend complex thoughts, adjust to their surroundings, gain from encounters and take part in different types of thinking (Neisser et al., 1996)[6], which can all be basic to learning and applying preparing content.

Research Objectives:

- To determine the role of HRM practices in training transfer in IT/ITES organizations
- To provide suggestions for Human Resources Management in IT/ITES organizations to improve training and development activities

Need for The Study: Human resource is an essential intensity of IT Industry. It is basic to investigate the changes occurring in human resource strategies, variables, system and procedure, plan of selection and recruitment in IT sector. It is the strategy when innovation is changed with entry of time, code of HR which is being trailed by couple of decades additionally imperative to be changed to adapt up to the evolving environment. Moreover, IT division needs receptive, dedicated and idealistic individuals who are able of applying their cognitive behavior in a sensible and keen way to accomplish their organizational objectives and enhancing by and large operational adequacy. Along these lines, it is urgent for the IT/ITES part to give careful consideration to recruit and train the employees and to their expanding practices and complete methodical Human resource management practices for more years to come.

Review of Literature:

Barney (1991)[7] mentioned that attention to the organizations could create vital capability and for accomplishing this, the key objective will be to make firms, which are more intelligent and adaptable than their rivals. The human asset administration work has risen as one which goes about as the differentiator among different firms.

Hendry and Pettigrew (1990)[8] suggested that various inward factors, for example, the organizational culture, structure (situating of HR), initiative, level of innovation utilized and business yield specifically add to framing the substance of HRM.

Snell and Dean (1992)[9] concurred that Human Resource Practices were the essential means by which firms put resources into their employees. Human Resource Management has moved its concern from a residential concentration to multi-national concentration, all the more heightening concern for issues like a natural, social insurance, and lack of education. They likewise demonstrated that Human Resource Practices to be employee-driven and should be business-driven too.

Taylor (2009)[10]stated that the best HR Practices empower the organization to influence radical enhancements, not simply incremental ones.

Shantz et al (2012)[11] clarified the estimation of HR works in business and its effect on higher productivity, upgraded quality, better client benefit, great mechanical relations and lower cost which impact the gainfulness of an association. Viable HR practices could assume the important part in accomplishing all the significant factors.

Research Gap: Although previous literature review could recognize various investigations analyzing determinants which enhance transfer of training as the basic connections of and between the latent factors and interdependencies remain to a great extent overlooked. There is, at this moment, no complete, integrative studies on training transfer under consideration of input, the process and the output and in addition a methodical investigation of which vital determinants help or hold back the training activity. Keeping in mind the end goal to do the genuine intricacy of the exchange procedure integrity, there ought to be a more prominent comprehension of it as a multidimensional procedure. Future examinations must endeavor to expect a more far reaching and integrative point of view while deciding exchange of preparing impacts and determinants thereof.

Research Methodology: The research was limited to the study of a leading Development Group of IT/ ITES Organization, about the role of HRM Practices in Training Transfer. A structured questionnaire was developed using parameters identified from previous surveys.

Research Frame: The research frame considered for the present study involved employees serving in IT/ ITES Organizations.

Population: The initial number of respondents taken for this study was 330, out of which 29 responses were

eliminated due to ambiguity. Hence, the data collected from 301 respondents were appropriate to be used for the research analysis and the response rate was 80%.

Research Tool: Structural Equation Modeling (SEM) is the significant research tool used for analyzing the data gathered from the respondents.

Hypothesis

$H_{01.1}$ Organizational performance has positive impact on training transfer.

$H_{01.2}$ Employee Motivation has positive impact on training transfer.

Conceptual Framework

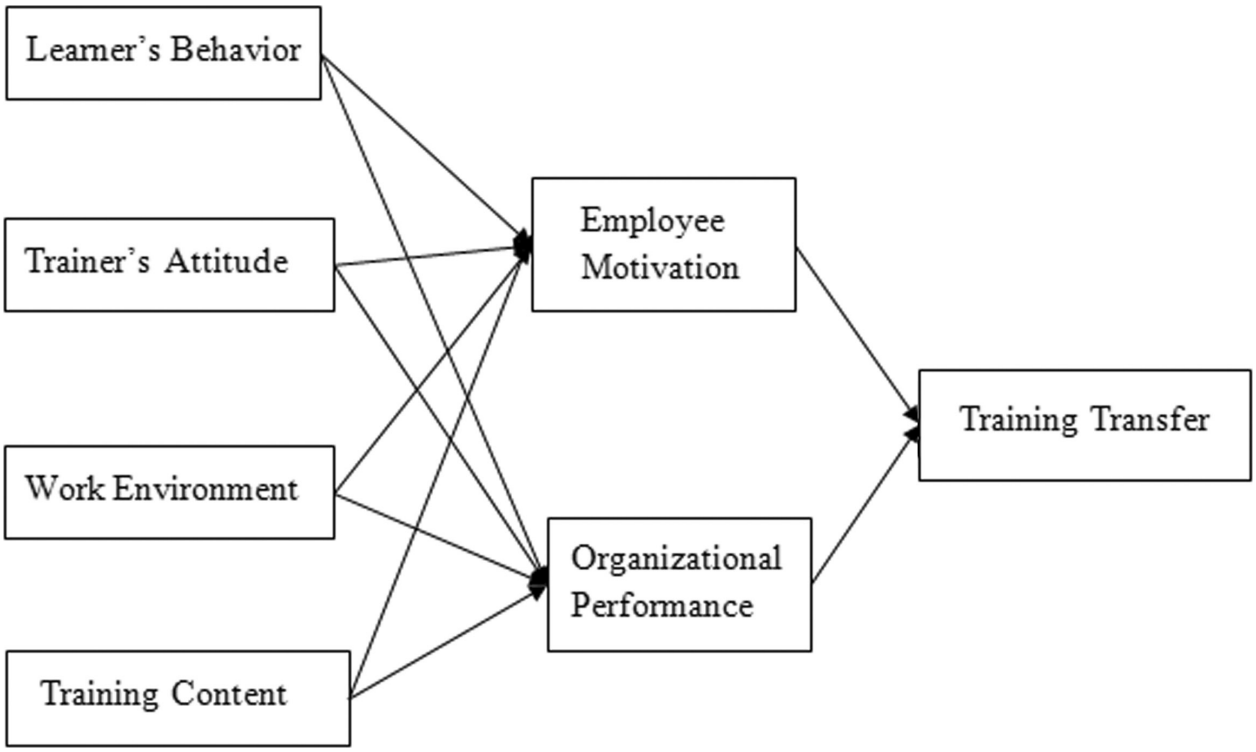

Figure 1: Conceptual Framework

The conceptual framework implies that HRM plays a significant role in providing Training Transfer to the employees which revolves around the behavior of learner, attitude of worker, work environment and relevant training content. These elements impact the motivational level of the employee and performance of the organization thus influencing training transfer.

Data Analysis and Interpretation: This chapter basically presents the results and analysis of the data gathered from the managerial department of IT/ITES organizations. The data are grouped appropriately to carry out the significant analysis. In the initial segment, it is proposed to exhibit in detail, the view of the respondents on different parts of Strategic Human Resource Management practice in Training Transfer in factors like Learners' Behavior, Trainer's Attitude, Work Environment, Training Content, Employee Motivation and Organizational Performance which paves way for better Training Transfer within the organization.

Structural Equation Modelling (SEM): Structural equation modeling is a multivariate statistical analysis technique that is used to analyze structural relationships. This method is preferred by the researcher because it estimates the multiple and interrelated dependence in a single analysis.

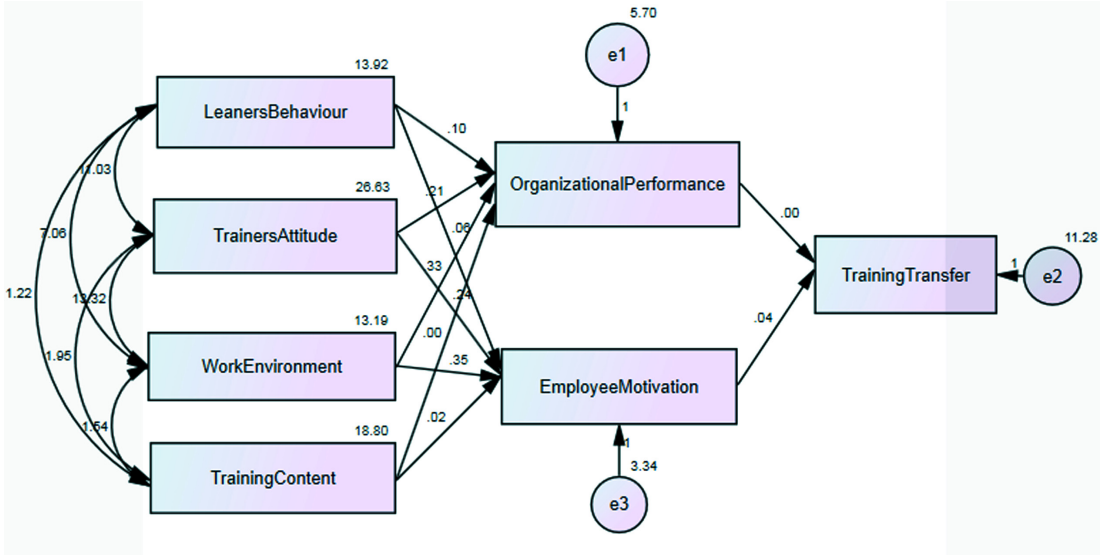

Figure 2: Structural Equation Model

According to Aragón et al (2014)[12], it can be comprehended that organizations must promote organizational learning capability in order to achieve better performance. Organizational learning and development helps in increasing organizational knowledge and understand the needs of the customers during any competitive situations. Training transfer helps in processing information faster and enables the employees to develop themselves as well as the workplace, thus taking the organization forward towards a competitive advantage.

Major Model Fit Indices Summary

Parameters	Acceptable values for Good Fit	Research Model Values
GFI	>0.9	0.927
AGFI	>0.9	0.921
CFI	>0.9	0.905
RMSEA	<0.06	0.039
RMR	<0.08	0.061

Source: Primary Data, SPSS AMOS output, Haier et al. (2009); Hooper et al. (2008); Steiger (2007); Hu and Bentler (1999).

Interpretation: The Goodness of Fit index (GFI) value was 0.927, Adjusted Goodness of Fit Index (AGFI) value was 0.921 and Comparative Fit index (CFI) value was 0.905. All these values were greater than 0.9 indicating a very good fit. It was found that Root Mean Score Error of Approximation (RMSEA) value was 0.039 (lesser than 0.06) and Root Mean Square Residual (RMR) value was 0.061 (lesser than 0.08).

Discussion

The result obtained from the analysis proves that the model fit is good for the research. Thus, employee motivation and organizational performance promotes a good training transfer for the employees within the organization.

Findings: The results indicate that leaner's behavior, trainer's attitude, work environment and training content show a positive relationship with Training Transfer, practiced by the HRM in IT/ITES organization.

Suggestions:

1. Rigorous training to be offered to individuals from staff on general basis keeping in mind the end goal to accomplish the destinations of the get together. Human resource management should concentrate more on creative training and development issues for workers to perform better.
2. Management of the organization should invest a feasible amount of money for improving the training and development practices.
3. Management must ensure to provide training with content relevant to the job.
4. It can also be suggested that human resource management must arrange on and off training sessions to the employees of the organization.

Conclusion

Employees were extraordinarily enhanced at their occupations because of preparing programs. It is subsequently simple to infer that organizations do complete preparing and advancement to a sensible degree, and this enhances their execution altogether. On the basis of the development, training and findings, it is a call for concern in the present developing society on the grounds that if performances of the workers are inadequate, it will influence the association. Being an imperative method for overcoming human resource management it is essential to determine the quality and lack of employees. They may make the essential move or remedial estimates in this way adjusting work approach vital in accomplishing the objectives and goals of the organizations. As of late numerous organizations have come to acknowledge the significance of the part of training and development as it increases the effectiveness, abilities and profitability of the organization.

Ethical Clearance: This research was approved by Head of the Department of Management Studies, Vinayaka Mission's Kirupananda Variyar Engineering College, Vinayaka mission's Research Foundation. The research was reviewed and discussed under the guidance of Research Supervisor of Vinayaka Mission's Kirupananda Variyar Engineering College, Vinayaka mission's Research Foundation.

Source of Funding: The research was self funded. This research obtained no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

Conflict of Interest: There is no potential conflict of interest reported in light of the current research.

Role of Human Resource Management Practices in Knowledge Management with Reference in it/ites Organisation

G. Murugesan[1], A. Mani[2]

[1]Professor, Department of Management Studies, [2]Associate Professor, Department of Management Studies, Vinayaka Mission's Kirupananda Variyar Engineering College, Vinayaka mission's Research Foundation (Deemed to be University), Salem, Tamil Nadu, India

Abstract

Human Resource Management (HRM) includes all the management decision and practices that directly affect the general population, or human resources, who work for the organization. The present study intends to survey the commitment of the businesses assigned to the HRM practices. The purpose of this paper is to research the role of human resource management (HRM) pactices in knowledge management in IT/ITES Organization.

This research paper highlights the context within which IT/ITES Industry has developed in India and the degree of human resource management (HRM) practices and systems practiced in the sector. The results feature particular HRM practices, such as, Recruitment, Performance appraisal, Training and development, Leadership and Career Management. Respondents considered for this empirical research are senior and center level managers over every practical department. An organized poll was directed at individual meetings to elicit respondent perspectives and proposals. Human Resource Management practices have likewise expanded in India and a great deal of research work is additionally completed on compelling implementations of HRM standards for the development of any business enterprise.

Keywords: *HRM Practices, IT/ITES Industry, knowledge management.*

Introduction

India had been seeing a remarkable development in its economy since 1990. The Information Technology/ Information Technology Enabled Service industry had enlisted a gigantic development of employment level from 1999 and till date the opportunities for pursuing job in this industry is enormous. The demand for web based shopping, cloud computing and social media are elevating and the interest for experts in the IT/ITES area are getting remarkable step by step and moving towards competitive edge. Also, the gauge extends the market size of Indian IT industry to develop at a rate of 12-14% for FY2016-17 in steady money terms. The area is likewise anticipated that would triple its present yearly income to achieve US$ 350 billion by FY 2025 (Vaish and Sengupta, 2017)[1]. Along these lines, with circumstance and development in the industry few overwhelming difficulties have additionally raised which calls for prompt consideration with unique reference to high steady loss rate in the activity section of IT/ITES organizations.

Human Resource Management (HRM) includes practices and decision making by the management that specifically influences the general population, or HR, who work for the association. Human Resources act as important strategic handler and help in sustaining competitive advantage. In this manner, HRM practices ought to be vital to the hierarchical system (Shahnawaz and Juyal, 2006)[2]. Knowledge Management has been broadly utilized as of late by firms and associations keeping in mind the end goal to enhance basic leadership, product development efficiency and benefits. Information is subject to individuals and that HRM issues, for example, enlistment and determination, training and improvement, execution administration, pay and reward, and in addition the production of a learning society are crucial for overseeing knowledge contained within organization (Edvardsson, 2008)[3]. Thus, it can be comprehended from the statements of the authors that the origin of Knowledge Management is traced to changes in HRM practices.

Role of HR Managers in IT Organization: HR Managers are in charge of providing training for career development and genuine execution feedback to workers, perceiving open doors for advancement, and provoking representatives about potential openings for work. Directors should successfully reinforce workers in characterizing clear destinations and individual objectives, assessing potential, recognizing vocation options, and giving development openings through assignments, formative tasks, visibility and introduction to various parts of the leaders and organization (Ijaz Khan and Shamsudin, 2016)[4]. Therefore, the role of Human Resources is to act as a device and provide resources to workers to manage their career and line up with business and organizational needs by acting as representatives for managers.

Career Management: The Chaos Theory of Career (CTC), proposed by Pryor and Bright in 2003 has added to the way toward trying to deal with contemporary profession improvement challenges together with inter alia, the board utilization of Information and Communication Technology (ICT), the velocity of progress, the globalization of business, the association of economies and particularly budgetary foundations all through the world and the authoritative and long winded nature of much contemporary work (Pryor and Bright, 2014)[5]. From the analysis of these statements, it can be implied that Chaos Theory of Career has both introduced new terms to the field and been able to integrate some recent concepts into a coherent theoretical framework.

Recruitment: Recruitment and determination work is being dealt with as an apparatus for acknowledging vital expectation. A portion of the basic recruitment systems incorporate continuous recruitment, worker referrals, and reasonable job reviews, assurance of obvious choice criteria. The organizations that opt to use Knowledge Management for the most part execute it in such conditions which are perplexing in eccentric circumstances. Updating the process of selection and recruitment process can help in gathering evidence with regards to knowledge building behavior of individuals (Khasnis, 2014)[6]. Thus, recruitment practice carried out by HRM is influenced by knowledge management process.

Training and Development: Individuals Development and Training are fundamental for the consistent achievement of each organization. Worker training and development empowers employees to build up the skills and abilities important to improve bottom-line results for their organization. Skill repetition is quick in the Indian IT Industry, with the changing time and even quick changing advancements Indian companies have begun understanding the significance of corporate training and to defeat this sign organization give the outrageous priority to training and skill enhancement programs consistently (Boateng, 2011)[7]. Therefore, all the employees of an organization has to be responsive of the latest technology and development in the industry. HR managers must motivate employees to increase professional knowledge and recruit people who can enhance the knowledge of existing employees in the organization.

Leadership: The HRM capacities in companies work on a collaborative model with their potential leaders, which implies that the job of individuals development isn't left to the HRM work or the leaders alone. Rather, the potential leaders are recognized and then their performance is connected to the empowering and strengthening of others to climb the chain. At the end of the day, the ability to spot talent and recognize leaders for what's to come is finished by both the HRM work and the senior management who work in tandem in this effort (Plessis and Sukumaran, 2015)[8]. Thus, Leadership is a mix of characteristic abilities and the organizational sustaining of the employees with those skills. Henceforth, this exchange amongst nature and sustain is the thing that decides the achievement or generally of the HRM work and the senior management endeavors to create leadership in companies.

Performance and appraisal: Performance is the reflection of the training, which works as a scale for the performance appraisal of a worker. It is an objective framework to judge the ability of an individual worker to play out his undertakings. Incentives to employees assume a vital role in propelling and retaining them in the organization. In addition to these, measuring the performance of an employee's work contribute to knowledge sharing (Horvat, Sharma and Bobek, 2018)[9]. Thus, the procedure of Performance Appraisal has turned into the core of the HRM framework in Indian IT Industries in relation to knowledge sharing activities.

Relation between HRM and Km in it/ites Organization: Knowledge workers are experts extending from HR and showcasing experts to programming engineers, venture chiefs, and business investigators. Information is the key component of their work, so they

expand and produce it regularly, yet they avoid random schedules. Since they are included with the outline of mechanical or intelligent items utilizing educational frameworks, they are relied upon to take in information, process it and disseminate it to different individuals from the association (Kumar and Balasubramanian, 2016)[10]. Thus, it is clear that the activities carried out by Human Resource Managament extend to the employees through knowledge sharing activity.

Theoretical Framework of KM Model: The KM procedure is part into four phases. Administration must find the wellsprings of knowledge. At that point, they should compose this knowledge in order to survey the company's strengths and shortcomings and decide its importance and reusability. This is trailed by socialization, where different strategies are utilized to encourage share and published it to whoever needs it in the association. At long last, the knowledge is internalized through utilizing (Louay et al., 2009)[11]. This is a consummately real way to deal with KM where the attention is on the sharing and recovery of existing information, yet it does not satisfy the extent of the knowledge management definition.

The Knowledge Management Process Model: This model attempts to offer a more realistic overview of the KM process. There are three wide classifications namely, Dissemination and knowledge sharing, Knowledge capture and organizing and Knowledge Creation and sensing have common characteristics. These three categories have common characteristics and interrelate to each other. The focus is on managerial initiatives. It is noteworthy that this model does include the creation of new knowledge as a specific KM initiative (Horvat, Sharma and Bobek, 2018)[12]. The model further shows which of the three categories are more people oriented and which are more technology focused. Whether or not knowledge sharing should be largely technology focused is certainly debatable and it is something that I will address in future sections (Tilchin and Essawi, 2013)[13]. However, for better or for worse, this is largely how organizations tend to approach the issue i.e. as a technological rather than organizational and social challenge.

Research Objectives

1. To study about the role of Human Resources Management in Knowledge Management
2. To analyse the influence of knowledge management on various practices of HRM in IT/ITES Organization
3. To analyse the casual relationship between the different study variables.

Review of Literature

Tiwari and Saxena (2009)[14] analyzed the HRM Practices executed by driving IT Companies, for example, TATA, Infosys and Wipro in India. They built up the Framework of HRM practices and recognized Training and Development, Employer-Employee Relations, Recognition through Rewards, Culture building, Career Development, Compensation and Benefits as imperative HRM Practices. Driving IT/ITES organizations pretty much take after, HR Practices, for example, Safe, Healthy and Happy Workplace, Open Book Management Style; Performance based Bonuses, 360 Degree Performance Management Feedback System, Fair Evaluation System for Employees, Knowledge Sharing, Open house dialogs, criticism Mechanism and Reward Ceremonies.

Minbaeva et al., (2010)[15] depicted the blend of ability, inspiration and opportunity as "conditions of individual activities". This tripartite construction is a key instrument for accomplishing knowledge streams within an organization.

Sheldon (1971)[16] mentioned about the managed and quality results, individuals within should haul out past the person and additionally workgroup levels and match them with the organizational yearning keeping in mind the end goal to make an effective contribution.

Barney and Wright, (1997)[17] A considerable measure of research work is done on HRM for the sheer reason of its significance in dealing with the firm and the measure of effect it makes on the performance of the firm. HRM practices, for example, job examination, recruitment and determination, training and development, work environment and performance appraisal may enhance the fitness of employees for elite separated from cooperation with innovation and procedures, relations with employees working within the departments and the collaboration of such effective teamwork choose the operational success.

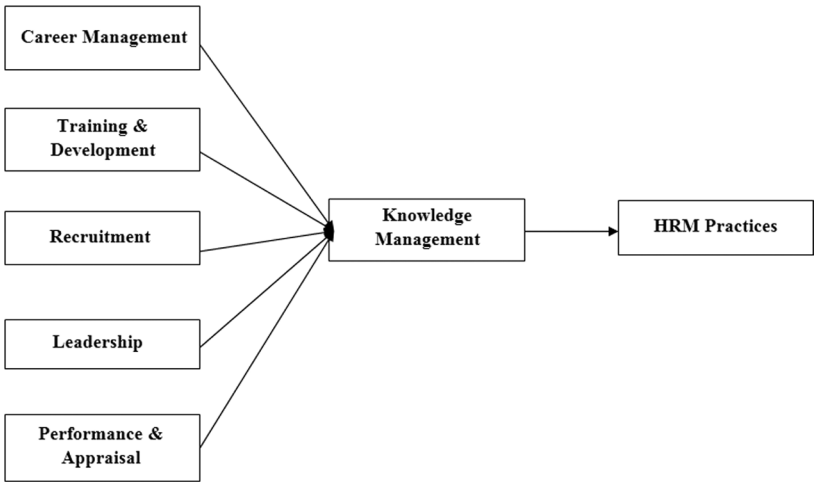
Research Methodology: The research was limited to the study of a leading Development Group of IT/ ITES Organization, about the role of HRM Practises in Knowledge Management. A structured questionnaire

was developed using parameters identified from previous surveys.

Research Frame: The frame comprised HR manangers serving in IT/ITES sector.

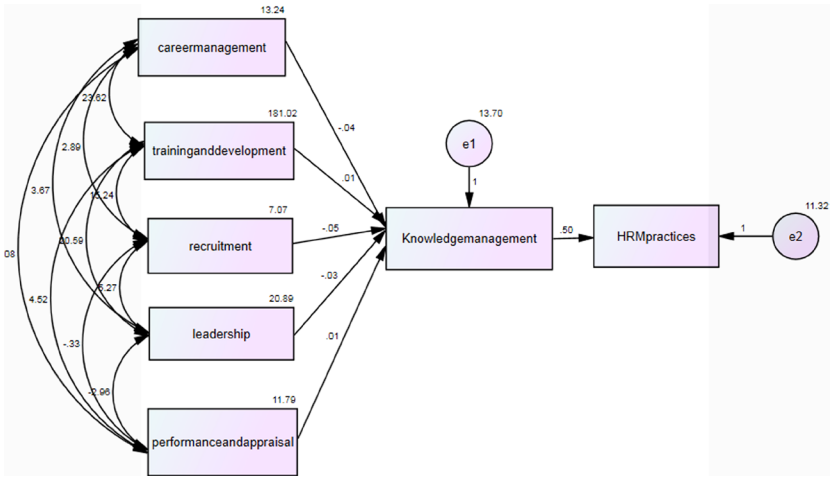
Population: The response rate was 75% and the descriptive data for 617 respondents is presented below.

Research Tool: SEM (Structural Equation Modelling).



Hypothesis:

$\mathbf{H_{01}}$ HRM practices are influenced by knowledge management



$\mathbf{H_{02}}$ Knowledge Management has a positive impact on HRM practices

Analysis and Interpretation: This chapter essentially presents the results and analysis of the data gathered from the managerial department of IT/ITES organisations. The data are grouped appropriately to carry out the meaningful analysis. In the initial segment, it is proposed to exhibit in detail, the view of the respondents on different parts of Strategic Human Resource Management rehearse in knowledge management in factors like recruitment, performance appraisal, training and development, Leadership and Career Management. The last part of the section has focused on testing of speculation. The entire research hypotheses which were formulated are tested using SEM.

Conceptual Frame Work

Structural Equation Modelling (SEM): Structural equation modeling is a multivariate statistical analysis technique that is used to analyze structural relationships. This method is preferred by the researcher because it estimates the multiple and interrelated dependence in a single analysis.

Major Model Fit Indices Summary

Parameters	Acceptable values for Good Fit	Research Model Values
GFI	>0.9	0.998
AGFI	>0.9	0.990
CFI	>0.9	0.979
RMSEA	<0.06	0.000
RMR	<0.08	0.04

Interpretation: The Goodness of Fit index (GFI) value was 0.998, Adjusted Goodness of Fit Index (AGFI) value was 0.990 and Comparative Fit index (CFI) value was 0.979. All these values were greater than 0.9 indicating a very good fit. It was found that Root Mean Score Error of Approximation (RMSEA) value was 0.00 (lesser than 0.06) and Root Mean Square Residual (RMR) value was 0.04 (lesser than 0.08).

Discussion

The result in the above table shows that the model fit is good for the research analysis.

Findings: The results indicate that recruitment, Leadership, Training and development, and performance & appraisal, Career Management show a positive relationship with knowledge Management, practiced by the HRM in IT/ITES organization.

Suggestions

1. Rewards have to be provided based on employees' performance and productivity to keep the motivational levels high.
2. HR managers must focus on knowledge management by constantly updating latest technology
3. Lateral employees must be recruited by HR department to enhance the knowledge of existing employees in the organization.

Practical Implications: Findings from this study should be beneficial for HRM managers in developing countries, who plan to develop a spirited, knowledge management competencies through the implementation of HRM practices.

Conclusion

The study of the role of HRM practices in knowledge management of IT/ITES organizations has been conducted and this study has analyzed the impact of key human resource management factors on the performance of an organization. It has likewise joined different factors like recruitment, performance appraisal, training and development, leadership and career management which were equally considered to be highly impacting the performance of the organisation. A research display which was created in broad view of literature review has been tried and all the research theories are observed to be impacted positively by the performance of the organization. A great deal of research can be taken upon the model produced for this study. It is earnestly anticipated that the findings and conclusions would really benefit all the organizations of IT/ITES industry.

Ethical Clearance: This research was approved by Head of the Department of Management Studies, Vinayaka Mission's Kirupananda Variyar Engineering College, Vinayaka mission's Research Foundation. The research was reviewed and discussed under the guidance of Research Supervisor of Vinayaka Mission's Kirupananda Variyar Engineering College,Vinayaka mission's Research Foundation.

Source of Funding: The research was self funded. This research obtained no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

Conflict of Interest: There is no potential conflict of interest reported in light of the current research.

Observational Survey for Assessment of Helmet Usage among Two Wheeler Users in the Metropolitan City of South India

Gulappa Devagappanavar[1], Pallavi Sarji Uthkarsh[2]

[1]Guest Faculty, Karnataka State Rural Development and Panchayat Raj University, Department of Public Health, Gadag, [2]Associate Professor, Rajiv Gandhi Institute of Public Health and Centre for Disease Control 4th T Block, Jayanagar Bangalore

Abstract

Objectives: Assessment of helmet usage among the two wheeler users.

Method: It is a cross sectional study, where 1471 two wheeler riders, pillions were observed at randomly selected 6 traffic junctions using an observation checklist with different intervals of the time in weekdays and weekends.

Results: In observational survey 1471 two wheeler users were observed at the 6 selected traffic junctions, among riders (82.18%),pillions (72.82%) wore helmet. the helmet usage in weekdays was 6% more than in weekends among riders.

Conclusion: Nearly 20% of riders and 30%of pillions were not wearied helmets. Compliance to ISI (Indian Standard) helmets and buckling of the helmets was poor in both the users.

Keywords: *Helmet Usage,Helmet Compliance, Helmet law, Head Injury prevention, Bangalore, Karnataka.*

Introduction

Road traffic injuries are a major cause of death and disability globally, with a disproportionate number occurring in developing countries. Road traffic injuries are currently ranked ninth globally among the leading causes of disability adjusted life years lost, and the ranking is projected to rise to third by 2020[1].

In India 13 States accounted for 87.8 % of share in persons injured in road accident in the entire country during the calendar year 2016. Tamil Nadu stood on top in persons injured in road accidents in the entire country with a percentage share of 16.6 % followed by Madhya Pradesh 11.7 % and Karnataka 11.0 % respectively[2]

The road accident scenario in Karnataka causes a great concern. More than 10000 persons die every year due to road accident[3] Nearly 90% of road traffic crashes are due to human errors and faulty human perceptions. Among fifty million plus population cities, Delhi reported highest number of deaths followed by Chennai and Bangalore [2]

Increasing individual modes of transport, heterogeneous traffic mix, rapid addition of high speed vehicles and less emphasis on the safety of vulnerable road users are some contributing factors. Increasing speeds, non-use of helmets, drinking and driving, poor visibility, failure to implement safety laws and poor trauma care are some factors recognized in India[4] The most vulnerable group for road traffic injuries is identified as pedestrians, cyclists and those using motorized two and three-wheelers, they account for 46 % of the global road deaths.

Two-wheelers being smaller in size and not highly visible on the road make the rider particularly vulnerable to crashes. In the event of a two-wheeler crash, the head of the driver or pillion directly hits a mobile or immobile

object causing injury. Several studies point to the fact that head is the most commonly injured organ among two-wheeler occupants in case of crashes. It is found that about 40 to 50 % of those injured and more than one-third of those killed in two-wheeler crashes are found to have sustained brain injuries such as concussion, contusion and haemorrhage [6]

Bangalore, a silicon of India,city is a capital of Karnataka state, which has a vehicular population of about 1.5 million, with an annual growth rate of 7-10% and two wheelers constitute more than 70% of the total volume. On November 6, 2006,Karnataka introduced partial (only for riders)helmet legislation at Bangalore, The Karnataka Motor Vehicle Rules,1989, rule 230 makes it mandatory for motor cycle riders[8]

On 1st January 2016 Karnataka state Government made Gazette notification that Karnataka motor vehicles, Rules 1989,in rule 230, for sub rule [1] Every persons while driving or riding (both for rider and pillion riders) a motor cycle of any type i.e to say motor cycles, scooters and mopeds irrespective of brake horse power of the vehicle within the limits of Karnataka state shall wear protective headgear (Helmet)[3]

Compulsory helmet law was enforced in Bangalore (2016) for riders and pillions. No study had been under taken to evaluate helmet law enforcement in Bangalore. Hence current study had been planned to evaluate the adherence of two wheeler users to mandatory helmet law.

Objectives of the Study:

1. To evaluate the compliance of motorized two wheeler users towards mandatory helmet law.
2. To assess the current compliance of motorized two wheeler users towards ISI standard and buckling of helmets.

Method

Study Design: A cross sectional study was conducted to assess the helmet usage among the two wheeler users direct observational survey method was used to obtain the data.

Study Settings: Bangalore city has two major traffic divisions such as, East and West. East had Twenty number of traffic divisions and west had Twenty three number of traffic divisions. Further junctions were divided in to outer and inner city junctions.

Total 6 junctions, three from each division were selected by random sampling method. Out of three selected junctions, two were from inner city junctions and one was from outer city junction. Madivala traffic junction, Wilson garden traffic junction from inner city junction and Konnapana agrahara traffic junction in outer ring road area were selected from East division. AnandRao traffic junction, K R Market traffic junction from inner city junction and Kodigehalli-Hebbala traffic junction in outer ring road area from West Division.

Data was collected by using observational survey to assess the compliance of two wheeler users. study was conducted from the July 2017 to December 2017.

Study Participants: Two wheeler users i.e Riders and Pillion riders

Variables: Independent variable as Helmet usage and dependent variables as different timings of the day, weekdays, weekends, inner city road users and highway road users,gender.

Data Sources: Direct Observation of two wheeler users was done standing at the safest road side at selected traffic junctions during both weekdays and weekends at different timings of the day such as morning 9-10:30 am, afternoon 12-1:30 pm and evening 5-6:30 pm, to ensure the change in traffic volume and traffic composition at different timings of the days.

Both two wheeler riders and pillions in each traffic junctions were observed at traffic junctions when vehicles were stopped for red signal. Riders and pillions of vehicles traveling in one direction and those who have stopped at one side of the curb were observed to avoid confusions. A pretested checklist was used to collect information's such as, gender, type of vehicle, rider/pillion, helmet/ no helmet, type of helmet and strapping pattern.

Study Size: Totally 1471 two wheelers were observed by at the selected traffic junctions.

Quantitative Variables: Helmet usage was taken as independent variable for both riders and pillion riders gender, different timings, weekdays and weekends, Standard of helmets, bucking of the helmets, inner city & high way road helmet usage percentage was measured.

Statistical Method: Data were expressed in frequencies and percentages, Odds ratio was done to assess the helmet usage among riders and pillions and Z–test was done to assess the mean proportion of helmet usage.

Results

Table 1: Helmet usage among riders and pillions

Helmet Users	No. of Observations	Helmet wearing %	95% CI	Odds Ratio
Riders	1471	1209(82.18)	0.8015-0.8406	1.755
Pillions	920	670(72.82)	0.6986-0.7560	

Helmet usage among riders and pillions: Observations in the current study showed that the odds of helmet usage among riders is 1.75 times more compared to pillions (Table 1).

Table 2: Helmet usage among riders and pillions in weekdays and weekends

Two wheeler users	Weekdays		Weekends		Z-Test	P-value
	No. of observations	Helmet users	No. of observations	Helmet users		
Riders	653	559(85.60)	818	649(79.33)	3.115	0.001
Pillions	450	331(73.55)	470	339(72.12)	0.486	0.6241

Helmet usage in weekdays and weekends: Usage of helmet by two wheeler users was more in weekdays compared to weekends and the difference of helmet usage by riders in weekdays and weekends was found to be significant ($p<0.05$) (Table 2)

Table 3: Riders and pillions adherence to strapping pattern of helmet

Strapping pattern	Riders N-1209	Pillions N- 670	Z test	P-Value
Strapped	880 (72.78)	430 (64.17)	3.889	0.001
Unstrapped	329 (27.22)	240 (35.83)	3.889	0.001

Adherence to ISI mark and fastening of helmets: Hardly half of the riders and one fourth of the pillions did use ISI marked (Indian Standard) helmet and more than 30% of helmet users never strapped the helmet (Table 3)

Table 4: Helmet usage among riders and pillions according different traffic locations in Bangalore

Two wheeler users	Inner City junction		Outer ring road junction		Z -Test	P-value
	No. of Observations	Helmet users	No. of observations	Helmet Users		
Rider	842	738(87.64)	629	471(74.88)	6.327	0.001
Pillions	772	587(76.03)	78	43(55.12)	4.017	0.001

Helmet usage in inner and outer city junctions: Helmet usage among riders in inner city junction (87.64%)was 12% more compared with outer ring road junction (74.88%) and also helmet usage among pillions in inner city junction (76.03%) was 15% more compared with outer ring road junction (55.12%). There was a significant difference in the compliance of two wheeler users to helmet in inner city junctions and outer city junctions. ($p<0.001$) (Table 4)

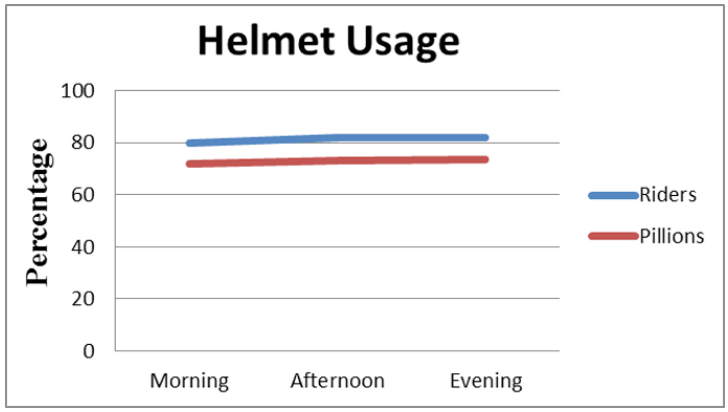

Figure 1: Helmet usage among Riders and Pillions in different timings of the Day

Helmet usage in different timings of the day: Observations did not show much difference in usage of helmet on different timings of the day but the usage of helmet between riders and pillions in different timings of the day found to be significant ($p<0.05$) (Fig 1)

Table 5: Gender and Helmet usage among Riders and Pillions in Bangalore.

Helmet usage	Male			Female		
	Riders N=979	Pillions N=670	Total N=1649	Riders N=492	Pillions N=250	Total N= 742
Helmet used	796(81.30)	482(71.94)	77.50%	413(83.94)	188(75.20)	80.99%
Helmet not used	183(18.70)	188(28.06)	22.50%	79(16.06)	62(24.80)	19.01%

Gender vs Helmet Usage: There was no much gender difference in helmet usage as a rider or pillions (table 4) but on the whole, total 3% more helmet usage was found among females (table 5).

Helmet usage in Bangalore before and after Mandatory helmet law for both riders and pillions: Various studies done to assess the helmet usage among riders before the Mandatory helmet law showed that the prevalence of helmet usage was below 65% in the riders. After the Compulsory Helmet law was enforced in 2016 for riders and pillions, the helmet usage was more in two wheeler users in Bangalore.

Discussion

The Indian motor vehicle act-1988 in its section 129, mentions that the driver and the person riding pillion on a motorized two wheeler (except in side car) in a public place, shall wear a helmet (Protective headgear) that conforms to the specifications of the bureau of Indian standards. On November 6,2006 Karnataka introduced partial helmet legislation (In selected cities and only for riders)This study is the first field based observational survey to assess the helmet compliance in both riders and pillions in Bangalore after the enforcement of compulsory helmet law for riders and pillions in the year 2016 following Karnataka state Government Gazette notification in January 2016.

Nearly 80% of riders wore helmet in Bangalore, where as a observation study done in Bangalore in 2010 by NIMHANS reported that nearly 60% of riders used of helmet[2]. Showed the increase of 20% since last six years. Usage of helmet among pillions was assessed first time in Bangalore through this study, which reported nearly 70 % of pillions using a Helmet.

Where as a study conducted in Delhi, an other city in India showed that 88.4% of pillions wore helmets following the enforcement[7]. This adds to the evidence that legislation and enhanced enforcement increases helmet use while the use decreases when the laws are repealed[8]

In the current study it was found that helmet usage among riders and pillions was 15-20% more in inner city junctions compared to outer or peripheral junctions, which is similar to a study in Bangalore in 2010[2]. which might be due to highly vigilant police at inner roads compared to outer or peripheral roads.

In the current study it was found that the helmet usage of riders in weekdays 6% more than in the weekends which is similar to the study done in Bangalore in 2010 which is similar studies done in parts of other developing countries like which reported drop in helmet usage over weekends[9 & 10]

In this study it was observed that helmet wearing status among riders and pillions was more in the morning compared to afternoon and evening. which is similar to study done in Cambodia[11] and China[9] Not more than half of the riders and one fourth of pillions were using ISI Standard (brand) helmets and more than 30% of them had not strapped their helmets. Similar study done by NIMHANS in 2010 reported that more than half of the riders who used helmets were wearing construction hat like helmets, and many had not strapped helmets, which were more likely to fall off any time[2] studies done in other low income countries showed hat 54% were using non-standard helmets[12] this might be due to increase cost of standard helmets or lack in strict enforcement of standard helmets. Making standard helmets available at affordable prices can increase helmet ownership while enhanced enforcement can encourage both helmet ownership as well as helmet usage[13]

Conclusion

Helmet usage was more after the enforcement of mandatory helmet law in 2016 but nearly 20% of riders and 30% of pillions were not wore helmets. Compliance to ISI (Indian Standard) helmets and buckling of the helmets was poor in both the users.

Conflict of Interest: None

Awareness of PC PNDT Act among Mothers Attending Tertiary Care Centres in Dakshina Kannada: A Cross Sectional Study

Santosh Rai[1], Rashmi Kundapur[2], Harshitha H.N.[3], Sudhir Prabhu[4], Anusha Rashmi[5], Shreyaswi Sathyanath[5]

[1]Associate Professor, Department of Radio diagnosis, Kasturba Medical College (KMC) Mangalore, Manipal Academy of Higher Education, [2]Professor, Department of Community Medicine, K.S. Hegde Medical Academy, Deralakatte, [3]Postgraduate, Department of Community Medicine, K.S.Hegde Medical Academy, Deralakatte, [4]Associate Professor, Department of Community Medicine, Father Muller Medical College, Mangalore, [5]Assistant Professors, Department of Community Medicine, A.J. Institute of Medical Sciences and Research

Abstract

Introduction: According to the 2011 census report, the 0-6 child sex ratio decreased by 5 points registering 947 female children to 1000 male children in Dakshina Kannada district as compared to the 2001 census. Pre-conception and Pre-natal Diagnostic Techniques (Prohibition of sex selection) Act passed in the year 1994 by Govt. of India was later amended in 2003 with the focus to prevent fetal sex determination.

Objectives: *(*a) To assess the Knowledge and attitude of PC PNDT Act among the mothers (b) To check association between knowledge, attitude and socio demographic factors

Methodology: A Cross sectional study was conducted in Tertiary Care Hospitals (Medical College) of Dakshina Kannada. Total sample size obtained using prevalence formula was 336. Pretested and validated questionnaire were used for data collection. Knowledge and attitude were graded. +1 was given for the correct answer and -1 for the incorrect answer. Chi-square analysis was done to find the association of the socio-demographic profile with knowledge and attitude towards the PC-PNDT Act

Results: 66.9% had an average knowledge and 70.4% had the good attitude to PC PNDT Act. There was a significant association of occupation, education, religion and annual income with knowledge. The significant association was found between type of family and attitude.

Conclusion: Majority had average Knowledge on PC-PNDT and attitude was found to be good in the majority. There is a need to raise the awareness regarding the consequences of declining child sex ratio.

Keywords: *Sex ratio, Pre-conception and Pre-natal Diagnostic Techniques Act, coastal Karnataka.*

Introduction

Ultrasonography (USG) a method used extensively for detection of foetal anomalies is now being used even for foetal sex determination. At a gestational age as early as 14 weeks, sex of the foetus can be determined with 99-100% precision by the use of ultrasonography.[1] This aids in sex-selective abortions in the late first trimester and early second trimester. According to the 2011 census report, the 0-6 child sex ratio decreased by 5 points registering 947 female children to 1000 male children in Dakshina Kannada district as compared to the 2001 census. [2] In 1994, the Government of India passed the Prenatal Diagnostic Techniques (Regulation and Prevention of Misuse) Act with the aim of

Ph. No.: 9535435255

preventing female foeticide. At this point, the focus was more on invasive procedures and centres were termed genetic clinics. It was later amended and replaced in 2002 by the Pre-conception and Pre-natal Diagnostic Techniques (Prohibition of sex selection) Act. After the amendment ultrasound was bought within its ambit and provision for more stringent punishments. The practice of female foeticide is evident by declining sex ratio in the country for the past few decades. Even after two decades of the introduction of Act the awareness of the PC-PNDT Act still remains limited. In a study done in Maharashtra, 46% of the radiologists admitted that over the last year they had been approached by patients for foetal sex determination during a routine ultrasound examination.[3] This lack of awareness can lead to conditions where they pressurize the doctor to know the sex of the foetus prenatally. PC-PNDT Act is one of the important medico-legal aspects about which the Indian radiologists need to be cautious about. The gravity of offense under the Act is "Cognizable, Non-bail able and Non-compoundable" i.e. arrest without warrant, non-issuance of bail and non-allowance for out of court settlement respectively.[4] A cross sectional study was done in Nasik district, Maharashtra by Tawri P et al showed that post awareness programme regarding PC-PNDT Act and declining trend of sex ratio the desire to know the gender of the fetus came down to 4% from 15%.[5] In spite of the implementation of Act like PC-PNDT in which we track the pregnancies, MTP's and birth registration in order to improvise the gender ratio awareness plays a key role.[6] This study aims to know the knowledge and attitude of mothers towards the PC-PNDT Act and also an association of knowledge and attitude with socio demographic characteristics of the population with which we can work towards raising awareness about PC-PNDT Act.

Methodology: A Cross sectional study was conducted in Tertiary Care Hospitals (Medical College) of Dakshina Kannada. The sample size for the study was calculated using the prevalence formula. Taking Knowledge of PC PNDT Act as 30% and d being 5% sample size was estimated to be 336. [3]

There is a total of 8 Medical college Hospitals in Dakshina Kannada District. Taking 50% as the sample (thumb rule) we have taken 4 Medical college Hospitals for obtaining sample required. From each Hospital 84 participants were taken.

For study fixed day survey method (random sampling) was used. Operational definitions were made for study participants. Mothers registered for pregnancy (mothers who are at least 8 weeks of pregnancy and attending ANC clinic in one of the teaching hospitals) mothers with under 5 children (mother having at least one under 5 child and in the reproductive age group 15 years - 49 years) were taken as study participants. Face validation (content and construct) and also the linguistic validation of the questionnaire was done before the data collection. All the investigators were trained to a level so that questionnaire administration is with uniformity. The questionnaire was administered after obtaining written informed consent. Ethical clearance was obtained from each Medical college separately before conducting the study.

Statistical Analysis: Data were cleaned and analyzed using SPSS Version 16. Knowledge was graded on the basis of knowing must know, should know and nice to know, +1 was given for the correct answer and -1 for the incorrect answer. Scoring was done. Score < 1 was considered as poor knowledge, 1-3 considered as average knowledge and >3 as excellent knowledge. The attitude was also scored, +1 was awarded for positive attitude and -1 was awarded for negative attitude. Score less than 1 was termed as poor attitude, 1-3 as average and more than 3 was taken as a good attitude. Chi-square analysis was done to find the association of the socio-demographic profile with knowledge and attitude towards the PC-PNDT Act. The p value <0.05 was considered significant.

Results

Majority of the study subjects were in the age group of 20-30 years and belonging to the Hindu community. It was found in our study that 26.3% had a poor knowledge i.e. score of <1, 66.9% had an average knowledge i.e. score of 1-3 and only 6.8% had an excellent knowledge i.e. score of >3 on PC PNDT Act. (Fig1) The attitude on PC PNDT Act was found to be in poor in 9.8%, average in 19.8% and good in 70.4% of the participants. Among homemakers, 60% had average knowledge regarding the Act and 74.2% had a good attitude regarding the Act. (Table 1) Among the participants who had completed education till 12th std. 70% had average knowledge on PC-PNDT Act. (Table 2) 76% of the study participants living in the joint family were found to have a good attitude towards

the Act. (Table 3) There was a significant association of occupation, education, religion and annual income with knowledge. The significant association was found between type of family and attitude. From the results, it is evident that the majority and average knowledge regarding the PC-PNDT Act but the attitude was good among the majority. 95.9% denied on having tried any method for sex determination. 95.3% did not know of any place where sex determination is done. 93.8% said that no one had discussed with them regarding the PC-PNDT Act. Only 26.8% of the participants said that they will discuss the Act with others.

Discussion

In this study, it was found that majority of the participants were found to have an average knowledge and good attitude on the PC-PNDT Act. It can be found that the majority of the professional women had average knowledge on PC-PNDT Act but the attitude was good in the majority. Even among homemakers even though the knowledge was average regarding the PC-PNDT Act was average attitude was found to be good. Knowledge was found to be significantly associated with the occupation of the participants while the attitude was not. In our study, it was found that TV (media) was the major source of information for knowing that prenatal sex determination is possible. Knowledge was found to be significantly associated with education, it can be observed that people who were educated up to 7th std had poor knowledge on PC-PNDT Act and as the educational status improves the majority of them had average knowledge. There was a significant association between the type of family and attitude towards the PC-PNDT Act, participants living with the joint family were found to have a good attitude. This is probably due to the family environment and the possibility of discussion of sensitive topics like this.

In this study, 19% of the study participants were found to have the awareness that pre-natal sex determination can be done by various techniques and 75% of them answered that ultrasound is the technique used for the sex determination. Similar studies conducted by Seema Mehta et al, Sonal R Deshpande et al, Roy A, where awareness of pre-natal sex determination was 77.5%, 80.5%, and 44.82% respectively.[7,8,9] The knowledge was found to be higher in other studies as compared to the current study. At the time of the interview, it was perceived that participants were anxious about answering the particular question. In our study, we can find that the majority of the participants i.e. 88.5% knew that pre-natal sex determination is a punishable offense. Similar studies in the past have shown that knowledge regarding the fact that prenatal sex determination is a crime was lower in the population. A study by Pavithra M B et al and Giri P showed that the percentage of participants knowing that prenatal sex determination is a crime was 59% and 53% respectively.[10,3] There is raising awareness that prenatal sex determination is a punishable offense. This is clearly evident by the study as more number of participants are aware of legal aspects of prenatal sex determination there is apprehension on even answering the question regarding awareness of the possibility of pre-natal sex determination.

Conclusion

Majority had average Knowledge on PC-PNDT and attitude was found to be good in the majority. There is a need to raise the awareness regarding the consequences of declining child sex ratio in the community.

Tobacco and Betel Nut Chewing Behaviour and its Association with Potentially Malignant Disorders in Chennai

Aparnaa M.[1], Herald J. Sherlin[2]

[1]Undergraduate Student, [2]Professor, Department of Oral Pathology, Saveetha Dental College, SIMATS, Chennai, India

Abstract

Background: Betel nut and tobacco chewing habit is considered to be common amongst the individuals of Asian origin. It is associated with oral and oropharyngeal cancer and other potentially malignant disorders (PMD). Attributes like the frequency, duration of chewing, placement of betel nut and tobacco seems to plays a significant role in the initiation of potentially malignant disorders and oral squamous cell carcinoma.

Aim: To assess the Tobacco & Betel nut chewing behaviour& its association with PMDs in chennai population.

Materials and Method: The study group consisted of 20 tobacco & betel nut chewing individuals from sub-urban and rural areas near Chennai with the habit > 1 year. A questionnaire consisting of 16 questions relevant to tobacco and betel nut chewing habits were given and the data was acquired, Clinical examination was done to document the oral findings of the study population associated with PMDs.

Results: There was presence of oral leukoplakia (50%), OSMF (34%) and oral lichen planus (18%) among the study population.

Conclusion: Betel nut and tobacco chewing behaviour and its patterns plays a major role in causing potentially Malignant disorders and it is considered to be one of the major risk factor for the development of Oral squamous cell carcinoma.

Keywords: *Tobacco, betel nut, Potentially malignant disorders, chewing habits.*

Introduction

Oral cancer is the most common malignant neoplasm which is found on the lip, floor of the mouth, cheek lining, gingiva, palate or in tongue. [1] Mostly oral cancer affects the people from the lower socio- economic status and people in rural area. Betel nut and tobacco chewing habits are considered to be the primary independent cause of oral cancer. [1]

Corresponding Author:
Dr. Herald J. Sherlin

Betel nut and tobacco chewing habit is considered to be common amongst the individuals of Asian origin and is shown to have number of ill - effects on oral health.[2]Betel nut consist of major chemical components like arecoline, polyphenols like tannins and alkaloids contribute to oral submucous fibrosis(OSMF) like changes in the oral mucosa.[2] Whereas,Tobacco consist of nicotine which contributes to various potentially malignant disorders(PMDs) like leukoplakia, erythroplakia, OSMF and leads to the development of oral squamous cell carcinoma(OSCC).[3]

Regular chewing may induce chronic irritation and inflammation that damage epithelial cells of the oral cavity.[3]Arecoline and/or other areca nut components have been shown to induce a number of pro-carcinogenic changes including the production of carcinogenic agents like nitrosamines and reactive oxygen species which

induces the modulation of matrix metalloproteinases and their tissue inhibitors, inhibition of collagenases and increased collagen cross-linkage, up-regulation of heat-shock proteins and integrins and increased expression of inflammatory cytokines,which induces oral preneoplastic disorders with a high propensity to progress to cancer. [4]Attributes like the frequency, duration of chewing, placement of betel nut and tobacco seems to plays a significant role in the initiation of PMDs and OSCC.[5,6]

Therefore, a survey was conducted among the subjects with PMDs to assess the pattern, duration and frequency of tobacco and betel nut use and thereby correlate with the morphological characteristics of various PMDs and OSCC.

Materials and Method

Questionnaire: The study group consist of 20 tobacco and betel nut chewing individuals associated with PMDs from sub-urban and rural areas near Chennai who have the habit for a period of more than 1 year. The questionnaire consisted of socio demographic questions and 16 questions relevant to tobacco and betel nut chewing habits of the people associated with PMDs. The individuals were asked to fill the questionnaire and the data was acquired.

Clinical examination: The subjects were examined for the presence of PMDs. PMDs were diagnosed based on the WHO 2005 guidelines. The location, distribution, size, shape, consistency, colour and surface texture of oral mucosal lesions found associated with the individuals with PMDs were documented and subsequently correlated with their tobacco and betel nut chewing habits.

Statistical analysis: The collected data was entered in Microsoft excel worksheets and were subjected to statistical analysis using SPSS version 20. To describe about the data descriptive statistics mean and standard deviation were used. To find the relationship between the patterns and behaviour of the tobacco and betel nut chewing habit chi–square test was used. The p value was calculated and considered to be significant at $p < 0.05$.

Results

A total of 20 people were included in the study. The age group were between 16-30 years (10%), 31-45 years(53%), 46 to 60 yrs of age (33%), above 60 years (14%). The participants originated from rural (60%), semi- urban (36%) and urban areas (4%). A total of (76.7%) of the people were illiterate, (24%) completed high school, whereas (9%) of the people were graduates. (Table 1)

The participant responses to the duration, frequency and chewing practices are summarized in Table 2. On clinical examination, 10 out of 20 had oral leukoplakia (50%) whereas 7 people had OSMF (34%), and 3 people had oral lichen planus (OLP) with lacy patches (16%). (Table 3). Other symptoms associated with these habits are summarized in Table 4. The association between tobacco and betel nut chewing behaviour and the development of PMDs was found to be statistically significant. ($p<0.001$) The PMDs were found to be more common among males (86%) than females (14%). This was found to be statistically significant ($p<0.001$).

Around 82% of the people were ready to quit the habit on knowing the ill effects of tobacco whereas 16% were unwilling to quit the habit due to other reasons.

Discussion

This study was conducted with the objective of assessing the Tobacco and betel nut chewing behaviour and its association with PMDs in Chennai. Data were collected using a pretested survey questionnaire and the clinical examination of the individuals were assessed and the oral findings of the people examined were documented. The direct interview minimized incomplete submission and clarification if any were done on the spot.

From the present study, the overall prevalence of oral PMDs were as follows oral leukoplakia (50%), OSMF (34%) and OLP (18%).Similar findings and similar spectrum of distribution of oral PMDs were detected in a study in Taiwan. [7] In a recent screening program conducted in India by Warnakulasuriya[8], to detect PMDs within a workplace, a similar prevalence of leukoplakia (34%)was found. OSMF had highest prevalence (43%) among the diagnosed oral PMDs similar to the findings of Mehrotra.[9] In the present study, OLP was also found in 18% of the patients. OLP is considered an immunological disease, the findings of the present study indicate that it is also seen in individuals associated with the habit of chewing Tobacco and betel nut. The findings of the present study and other previously reported studies,[10] indicated a varied distribution in the prevalence of Oral PMDs. This may be attributed to difference in betel nut or tobacco consumption and cultural, dietary, and environmental factors.

In the present study, male gender was found to be significantly associated with development of oral PMDs with males being at higher risk to develop oral PMDs. In a review done by Nair, [11] the prevalence of oral PMDs and OSCC was found to be more in males. This gender discrepancy may be attributed to the fact that the habit of tobacco consumption is more in males which may lead to development of PMDs in males.[12]In the present study 84% were males and hence the high prevalence of PMDs among males.

In the present study, most of the individuals place the tobacco or betel nut in the buccal mucosa for >1 hr and they eventually chew and spit out, which had caused ill effects like burning sensation after eating food, xerostomia, decreased mouth opening which is similar to the previous studies [13,14] in which 56% of the participants had an history of chewing betel nut or tobacco and placing it in the buccal mucosa for a long time span. In the present study participants developed oral lesions, as most of them had the habit for more than 5 years. Similarly,Yuvette et al has shown results that the participants with PMDs had a long duration of use of tobacco and betel nut. [15]

In the present study, Major reasons for the first experience of this habit is said to be the peer pressure, it made them to continue this habit throughout as it relieves tension. Previous studies have shown that peer pressure is one of the major cause of the people ‘s first experience in chewing tobacco and betel nut. [16]These were the most common attitude of the people in chewing tobacco and betel nut with various PMDs and was found to be highly significant ($p< 0.001$)

More than 60 known carcinogens have been detected in tobacco and betel nut.[17] This chemical after coming in contact with oral mucosa accelerates inflammatory process and on long term abuse is responsible for atrophic and hypertrophic changes in the oral mucosa.[17]

Awareness regarding the negative health effects of the betel nut use was minimal. Therefore,there is a need to improve the level of awareness. [18] Although betel nut chewing may be a pratice of tradition, it is not a safe habit.[19] Various factors like the placement of the betel nut or tobacco, method of chewing,frequency of chewing, duration affects the mucosa and cause oral lesions, hence continuous use of this may lead to malignancy like OSCC.[20] The main strategy of the present study is to know about the association of tobacco and betel nut chewing behaviour among the people and to find its association with PMDs.

Conclusion

From the above results, we conclude that the betel nut and tobacco chewing behaviour and its patterns plays a major role in causing PMDs and it is considered to be one of the major risk factor for the development of OSCC. By conducting this survey and clinical examination we had covered a subset of the population with these habits.. It is noteworthy to know that most of the people are ready to quit the habit on knowing the ill effects caused by the tobacco and betel nut chewing habits, whereas the others were not ready to leave the habit due to many other reasons. We could examine more people by organising camps and creating an awareness about the ill effects of tobacco and betel nut chewing which may help in the early identification and prevention of various PMDs

Table 1: Socio-demographic data of the participants

Gender	**Percentage**
Male	84%
Female	16%
Age-Group	
31-45 years	53%
46-60 years	33%
Above 60 years	14%
Origin	
Rural	60%
Semi - urban	36%
Urban	4%
Level of education	
Illiterate	76%
Completed high school	24%
Graduate	9%

Table 2: Duration, frequency and Chewing practices among the participants.

Factors	Categories	%	Mean	SD	P Value
Presence of Betel nut or tobacco chewing habit	->Yes ->No	81.8% 18.2%	1.24	0.452	<0.001
Duration of the tobacco or betel nut chewing habit	->1 yr ->2 yrs ->3-4 yrs ->5 or more than 5 yrs	0% 4.3% 56.5% 39.1%	1.18	0.368	<0.001
Packets of betel nut or tobacco used per day	->1 ->2 >More than 2	43.6% 11.8% 54.5%	1.20	0.406y	<0.001

Evaluation of the Relationship between Maternal Periodontitis and Preterm Low Birth Weight Infants: A Case Control Study

Radhika Murali[1], Jaiganesh Ramamurthy[2]

[1]Graduate Student, [2]Professor, Department of Periodontics, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Tamil Nadu

Abstract

Introduction: The relationship between periodontal disease in pregnancy and children born prematurely or with low birth weight has been increasingly investigated showing both positive and negative results. Various factors found to be associated with preterm and low birth weight infants include age of mother, height, weight, socio-economic status, ethinicity,smoking, alcohol, nutritional status and stress. The objective of this study was to evaluate the association between Maternal Periodontitis and preterm delivery or low birthweight.

Materials and Method: In this case-control study, 30 pregnant women without systemic diseases or other risk factors for preterm labour were chosen. The control group (n=15) had term labour (infants $\geq$ 37 weeks) and the case group (n=15) had preterm labour (infants< 37 weeks). Birth weight of the infant, bleeding index, plaque index, probing depth and loss of attachment of the mother were measured.

Results: The data of plaque index (cases 1.22 $\pm$ 0.36, control 0.83 $\pm$ 0.32), bleeding index (cases 2.16 $\pm$ 0.52, control 1.32 $\pm$ 0.51), probing depth (case 5.13 $\pm$ 0.32, control 3.20 $\pm$ 0.31), loss of attachment (case 3.25 $\pm$ 0.13, control 2.03 $\pm$ 0.03), and birth weight (case 2.34 $\pm$ 0.21, control 2.97 $\pm$ 0.52) (odds ratio 135.5, P value <0.0001) revealed a statistically significant difference between the two groups.

Conclusions: A noticeable relationship between periodontal health and duration of pregnancy can be established. Hence periodontal disease may be considered as a risk factor for preterm labour. Oral hygiene maintenance therefore should be considered a part of prenatal care protocol.

Introduction

Periodontitis is an infectious disease that involves specific bacteria and characteristic humoral and cellular host responses. The host response is characterized by the dense infiltration of Tand B lymphocytes, macrophages in the inflamed connective tissues of the periodontium. The main etiological agents are varied microbial species organized in the form of a biofilm[1]. Periodontal diseases characterized by inflammation and degeneration of the gingiva, supportingbone, periodontal ligament and cementum. Biofilm bacteria colonize the subgingival area and forms colonies. They trigger inflammatory reaction, area below the junctional epithelium are affected and junctinal epithelium loses its attachment with the connective tissue. The epithelium of the gingiva migrates along the tooth surface forming periodontal pockets that provide an ideal environment for the growth and proliferation of the microbes[2].

There are various factors that have been found to be associated with preterm and/or low birth weight infants. Maternal risk factors include age, height, weight, socio-economic status, ethnicity, smoking, alcohol, nutritional

e-mail: dr.r.jaiganesh@gmail.com

status, and sometimes stress[3,4]. In addition to this, certain factors such as maternal hypertension, infections, and cervical incompetence may also be important[5,6].

The role of maternal infection on preterm delivery remains controversial, which might support as an indirect effect of production of inflammatory mediators that shorten the gestational age. It is also possible that micro-organisms may gain direct access to the amniotic fluid and foetus in several ways, ascending via the vagina through the cervix or via the endometrium which might have been previously infected, or through any other haematogenous route[7].

There are a number of studies that have established an association with severe periodontitis and a variety of systemic conditions. These include cardiovascular diseases, insulin dependent diabetes mellitus, and respiratory diseases[8,9].

Hence the aim of the study was to find the relationship between maternal periodontal disease and preterm low-birth weight infants in the patients reporting toSaveetha Medical College and Hospitals, Chennai.

Materials and Method

A case-control study was conducted involving populations attending Saveetha Medical College Hospitals, Chennai. A sample of 30 systemically healthy women were examined retrospectively after delivery and divided into 15 cases and 15 controls depending on whether they had preterm labour or term labour. Exclusion criteria was:

- women with systemic medical problems
- women receiving antibiotics at the time of examination
- womenwho had taken dental treatment within 6 months.

The nature of the study was explained to the subjects and consent was obtained for their participation prior to commencement of the study. Case defined as premature delivery occurring less than 37 weeks of gestation and generally accompanied by low birth weight i.e. birth weight less than 2500g. Control defined mothers with delivery occurring after 37 weeks without any previous complications, and newborns with birth weight $\geq$ 2500g.

History of information about age, education status of the mother, occupation, socio economic status of the family, number of previous pregnancies, previous preterm low birth weights and miscarriages were noted. Recording of the following parameters were done, Sillness and Loeplaque index, Muhlemann and Sulcus bleeding index, Probing depth and Loss of attachment. Probing depth and Loss of attachment were measured to the nearest mm at 6 sites per tooth, i.e. around mesiobuccal, midbuccal, distobuccal, mesiolingual, midlingual, distolingual, using disposable William's Periodontal probe. According to Gomes-Filho[10], women with probing depth > 4mm and loss of attachment > 3mm at the same site in at least 4 teeth is considered as localised chronic periodontitis. Weight of the newborn was analysed using a manual machine by the gynaecologist. The patient's hospital record was verified to confirm the data obtained for any variation. All the periodontal examinations were completed within three days post partum.

A statistical analysis was performed containing descriptive statistics and univariate/multivariate logistic regression analysis. Categorical variables were compared by chi-squared test and continuous variables by the student's t test. Statistical significance was defined as $P < 0.05$.

Results

When comparison of mean and standard deviations of different variables in cases and controls were done, bleeding index, plaque index, birth weight, and education status of the mother are highly significant whereas age does not show any significance, as shown in table 1.

Table 1: Comparison of different variables in case and control groups

Variable	Case	Control	P value
Age	22.5 $\pm$ 2.8	24.3 $\pm$1.5	0.74
Education status of mother			
schooling	73%	61%	<0.001
college	27%	39%	
Post graduate	0%	0%	
Socio economic status			
Lower	57%	60%	0.86
Middle	43%	40%	
Upper	0%	0%	
Previous pregnancies:			
No	96%	94%	0.7
Yes	4%	6%	
Previous preterm low birth weights			
No	7%	98%	<0.001
yes	93%	2%	

Table 2: Comparison of Variables in case and control groups

Variable	Case	Control	P value
Birthweight	2.34 ± 0.21	2.97 ± 0.52	<0.0001
Plaque index	1.22 ± 0.36	0.83 ± 0.32	<0.0001
Bleeding index	2.16 ± 0.52	1.32 ± 0.51	<0.0001
Probing depth	5.13 ± 1.52	3.2 ± 0.31	<0.0001
Loss of attachment	3.25 ± 0.13	2.03 ± 0.03	<0.0001

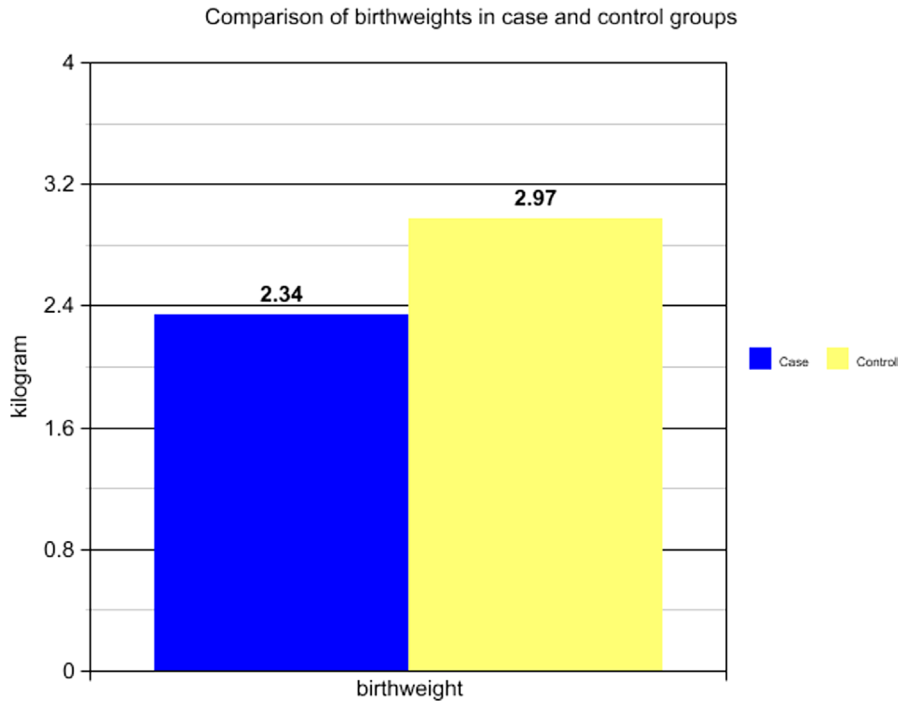

Fig 1

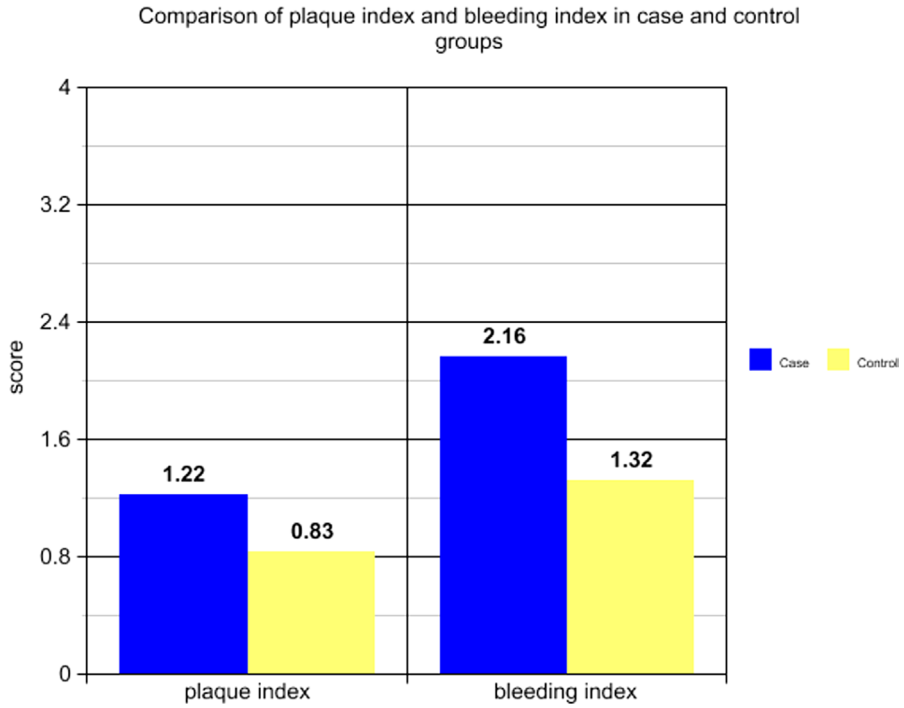

Fig 2

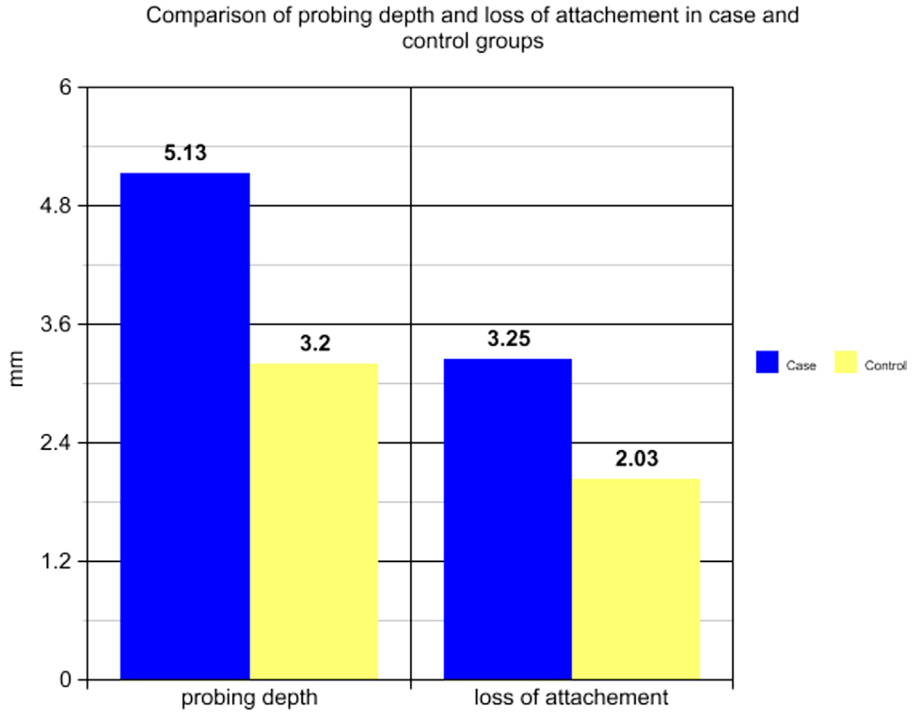

Fig 3

The comparison of mean values of different subjective variables in both groups are graphically represented in Fig 1, Fig 2 and Fig 3.

When the probing depth and loss of attachment were compared between the cases and controls, there was high significance observed at 1% level (P<0.001). This is seen in Table 2. When the education status of the mothers was compared at different levels between cases and controls, high significance was observed at 1% level (P<0.001). When the socio economic status of the families was compared at different levels between cases and controls, there was no observable significance, as seen in Table 1.

Table 3: Univariate Logistic regression analysis

Independent Variable		Regression Coefficient	P Value	Odds Ratio [95%CI]
Age		0.02	0.74	0.97[0.85 to 1.15]
Education status of mother	Schooling	2.75	<0.001	17.03 [2.85 to 106.56]
	College	1.67	<0.001	5.66 [2.42 to 14.90]
	Post graduate	---	--	1.0
Socioeconomic Status	Lower	0.09	0.86	0.92[0.45 to 2.06]
	Middle	0.09	0.86	0.95[0.45 to 2.08]
	Upper	--	---	1.0
Previous Pregnancies	Yes	6.87	0.7	134.5
	No	7.58	0.7	134.5
Previous Low birthweight	Yes	6.59	<0.001	1435.65
	No	7.95	<0.001	1435.65
Birth weight		2.64	<0.001	3.44[1.45 to 8.88]
Plaque Index		3.58	<0.001	23.45[6.90 to 113.5]
Bleeding Index		1.54	<0.001	4.21 [2.06 to 8.65]
Probing Depth		4.53	<0.001	135.51[25.52 to 685.11]
Loss of Attachment		4.92	<0.001	135.51[25.52 to 685.11]

As seen in the univariate logistic regression analysis(Table 3), the age comparison between the case and control groups was found to have an Odds ratio of 0.97. The education status was found to have an odds ratio of 17.03 and 5.66 for schooling and college respectively. The socioeconomic status was found to have an Odds ratio of 0.92 and 0.95 for lower and middle class respectively. Comparison of the incidence of previous pregnancies was found to have an odds ratio of 134.5. Significant associations were found between pre term low birth weight and periodontal disease (P<0.001) when univariate logistic regression was done. Plaque index, bleeding index, probing depth, loss of attachment, and education status of the mother were significantly associated with pre term low birth weight in the univariate analysis. Other non significant variables include age of the mother, socio economic status and previous pregnancies, as shown in Table 3.

Discussion

Most of the variables were found to be well known risk factors associated with pre term low birth weight, showing high significance between periodontitis and pre-term low birth weight. However, age of the mother did not show much of significance, this may be due to the presence of several antenatal factors such as socioeconomic conditions, infections, or any other complications.

The plaque index showed highly significant differences (P<0.001 with an odds ratio 23.45) in both cases and controls. This is similar to the study conducted by Yalcinet al[11]. It was suggested that during pregnancy, the oral microflora uses the progesterone and estrogen hormones as vitamin K growth factors and they form plaque on the gingival and tooth surfaces. However, in the studies conducted by Radnaiet al[12], there were insignificant plaque index values in cases and controls.

The bleeding index also showed significant differences (P<0.001 with an Odds ratio of 4.21) in both cases and controls. This is similar to the findings of Zadeh-Modarreset al[13]who indicated that the control group had a better periodontal condition than the case group. This may be attributed to the increasing levels of progesterone in the body, which cause increased dilatation of the gingival capillaries, causing increased permeability with gingival exudates which can result in increased redness and bleeding. Also, physiological female hormones during pregnancy also affect these tissues.

Highly significant association between probing pocket depth and loss of attachment with preterm low birth weight was observed (P<0.001). This is similar to the studies conducted by Goepfort[13] and Aguedaet al[14]. However, this was not the case in studies conducted by Gursoyet al[15].

In the present study, the periodontal status of the mother was found to be highly influenced by her educational status (P<0.001). This is similar to the findings of Siqueriaet al[16], and Toygar et al[17]. This may be due to the fact that educated mothers would take more preventive measures than less educated mothers. On the contrary, an insignificant difference was found in some studies such as that conducted by Davenport et al[18].

In case of previous pregnancies, an insignificant association (P<0.7) with pre term low birth weight was observed. This is similar to the findings conducted by Davenport et al[18]. This may be because most of the women were admitted for their first delivery.

A significant association was found between previous low birth weight and pre term low birth weight (P<0.001) in the study. This is similar to the studies conducted by Augedaet al[14], and Davenport et al[18], who found significant results between previous preterm low birth weights are pre term low birth weight.

Thus the results of the following study establish a strong evidence that maternal periodontal disease is an independent risk factor for an adverse outcome of pregnancy, iepre-term low birth weight, showing significant differences in both cases and controls. This is in agreement with several studies conducted bySatheeshMannemet al[19], and Pitiphat et al[20]. This can be attributed to the following mechanisms. First, women with periodontal disease may experience more frequent and severe bacteremia than periodontally healthy women. As a result, the uterine cavity may get exposed to periodontal bacteria and their byproducts. Once they reach the maternal fetal unit, oral bacteria may elicit an inflammatory cascade. It leads to production of prostaglandins and they have the tendency to cause uterine contractions. These uterine contractions which are premature to normal gestational period leads to preterm labour. Secondly, cytokines generated within the periodontal disease may enter the systemic circulation and precipitate a similar cascade, again leading to spontaneous preterm labour and birth[21]. On the contrary, certain studies conducted by several authors did not

provide a connecting link between maternal periodontitis and preterm delivery[22].

On the basis of these findings, periodontal infections in pregnant women can be viewed as a potential obstetric risk factor. Increasing awareness among women about risk periodontal infections during pregnancy remains of utmost importance[22, 23]of considering the fact that periodontal infections are both preventable and readily treated, this study provides opportunities for intervention strategies to reduce the incidence of preterm low birth weight.

Conclusion

From the above results, the following conclusions were arrived at

1. Periodontal disease in women is an important obstetric risk factor for preterm low birth weight.
2. Chronic periodontitis is associated with preterm low birth weight
3. Antenatal factors and periodontal status contribute for preterm low birth weight in pregnant women.
4. Thorough dental examination is advised for mothers who are planning for gestation

Compliance with Ethical Standards: Authors Radhika Murali and Jaiganesh Ramamurthy hereby declare that there is no conflict of interest for this study

All procedures followed were in accordance with the ethical standards of the responsible committee on human experimentation (institutional and national) and with the Helsinki Declaration of 1975, as revised in 2008.

Informed consent was obtained from all patients for being included in the study. Study was presented to our institutional review board and approved for the same.

Ridge Augmentation: An Overview

Rupesh Srivastava[1], Gatha Mohanty[2], Rinkee Mohanty[3], Rashmita Nayak[4]

[1]Intern, [2]Senior Lecturer, [3]Professor & Head, [4]Professor, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The amount and standard of bone is a big antecedent for success of any prosthesis. Alveolar ridge defects are common and might be a significant problem in any dental treatment and rehabilitation. Following extractions, dimensional changes takes place in ridge morphology. Starting with initial rapid resorption in the first 2-3 months, the process continues. Periodontal diseases,trauma, tumour or congenital diseases could be the possible cause of alveolar ridge defects. Since this possesses a great degree of functional,hygienic and esthetic concern,it is imperative for the clinician to be aware of the same and execute it in treatment planning protocol. This article reviews the available materials for alveolar ridge augmentation and highlights on their success rates and possible complications.

Keywords: *Prosthesis; Alveolar ridge defects; Alveolar ridge augmentation.*

Introduction

Surgical placement of implant in a posture where the function and esthetics of dental prosthesis is not compromised is the most crucial step. For the placement of implant at the posture where function and esthetics will not be affected, the reconstruction of deficient alveolar ridge is very influential. The sufficient amount of horizontal and vertical bone measurement ensures the success of implant. Advances in biologic understanding of bone regenerate technique have increased the chances of reconstruction of ridge defects. It is very contrasting to note that the similar rate of success for implant is reported for augmented bone and natural bone. So all the cases exactly do not require bone augmentations. It should be done in esthetic area or when there is proximity to anatomic structure i.e. maxillary sinus or mandibular canal.

Carlson et al 1967 reported that 25% of bone loss occurs after first year and 40-60% after three years of loss of tooth. The ridge deficiency that follows causes gradual loss of horizontal dimension as well as loss of bone height.[1]

Seiberts classification of alveolar crest defects (1983)[2]

Class 1: Bone deficiency in horizontal direction

Class 2: Bone deficiency in vertical direction

Class 3: Deficiency in both horizontal and vertical direction

Hammerle and Jung classification of crest defects in fresh extraction sockets[3]

Class 1: Intact bone wall around socket

Class 2: Socket with marginal dehiscence or fenestration of buccal bone after one month of extraction

Class 3: Large dehiscence in buccal wall after tooth extraction.

Objectives of treatment: To establish sufficient availability of bone for safe and predictable implants and get adequate bone thickness around implant.

To get 2mm of bone on buccal side and avoid complication around functional implants.

Bone augmentation therapy:

Melcher 1976 developed the concept of use of barrier membranes to guide the biologic process of wound healing.[4]

Nyman et al 1982 observed that exclusion of soft tissue invasion of defect by barrier membrane allowed regenerative potential cells to migrate to site. [5]

Principle of Bone Regeneration

Scaffolding: The fibrin clot that forms initially after wound formation acts as a scaffold.

Protection of clot-according to Schenk et al 1994,this is important for formation of granulation tissue and bone formation.[6]

Space creation beneath membrane-To completely isolate the defect to be regenerated.

Cell exclusion-to prevent the ingrowth of epithelial cells and fibroblasts into wound.

Factors assisting in wound healing:

1. **Primary wound closure promotion-**there should be passive and tension free wound closure.
2. **Enhancement of cell proliferation and differentiation-**to provide blood, nutrients and oxygen to tissues acting as a source of angiogenesis and osteogenic cell.
3. **Protection of initial wound stability and integrity.**

Barrier membrane: Non resorbable-e-PTFE membrane requires a second surgical intervention to remove them.

Hammerle and Jung 2003(3) reported that e PTFE barriers have demonstrated more favourable results when compared to resorbable devices due to their ability to make space, long barrier function, lack of resorption.

Resorbable:

a. Synthetic membranes include polylactide, polyglycolic acid, Cargile membrane, vicryl mesh etc.

b. Natural collagen membrane

Bone Graft

Nature of ideal bone graft should be:

1. Easily conformable.
2. It should not promote ankylosis.
3. Easily available.
4. Should activate osteogenesis and cementogenesis.
5. Innocuous.
6. Biocompatible.

Materials available for bone grafting: Based on properties like osteogenicity, osteoinductiveness, osteoconductiveness and their combinations various materials are used for bone grafting

On the basis of their origin, they are classified into natural and synthetic material.

Natural materials: Autograft, allograft, xenograft

Synthetic materials

- Alloplast are synthetic materials. These were developed to overcome problems like disease transmission associated with autografts and xenografts. Example-synthetic hydroxyapatite, tricalciumphosphate, bioactiveglass, dicalcium phosphate
- Autografts are obtained from the sites within the same individual.They can be cortical, cancellous or combination of both.
- Allografts are harvested from members of same species. These are mostly prepared as fresh, frozen,froze-dried,mineralized and demineralised.
- Xenograft are derived from the species other than humans. They are considered to be bio-compatible and have osteoconductive properties. Commonly used are bovine bone grafts and coralline calcium carbonate (obtained from a natural canal, rites).

Currently, BMPs (Bone morphogenic proteins) are being researched and developed as they have the ability to differentiate osteoprogenitor cells into mineral forming osteoblast and stimulate vascular proliferations.

Choice of bone graft material: Xenografts have slower resorption rate demonstrated better preservation of socket walls than for small bone defects requiring horizontal bone augmentation, use of xenografts and

alloplasts have given better results than nongrafted site.[7] For horizontal and vertical defects, block grants are better.[8]

Ridge augmentation procedures

1. **Ridge preservation:** Vignotelli et al 2012 reported that any therapeutic approach that is immedietly carried out after extraction aims to preserve architecture of socket and provide maximum bone around implant.[9]
2. **Ridge split or expansion:** Increases lateral bone width.
3. **Vertical ridge augmentation:** GBR, onlay bone block grants, distraction osteogenesis.
4. **Horizontal bone augmentation**
5. **Bone regeneration in extraction wound.**

Newer technologies

Cell therapy: They can accelerate edentulous ridge regeneration through primary to mechanism.

a. Cells used as carriers to deliver growth or cellular signals.

b. Provision of cells are able to differentiation into multiple cells types to promote regeneration.

c. Collagen tubes with bone and hydroxyapatite (**Gongloff RA** 1992)[10]

d. Growth factors-To increase bone volume

Example PDGF

BMPs

e. Computer based application is scaffold design and fabrication.

f. Scaffolding matrices to deliver cells and genes.

Conclusion

There are technical and biological limitation that continue to challenge implant dentistry. However,ridge regeneration procedureshave become predictable with various available technique and biomaterial that are key to success rate.

Oral Piercing Fascinations and Complications

Nikita Sahu[1], Debasruti Naik[2], Karishma Rathore[1], Sudipta Sahu[1], Sashikant Sethi[1]

[1]Tutor, [2]Former Post Graduate Trainee, Department of Public Health Dentistry, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Oral piercing is one of the very popular body art among younger generation. Piercing considered as a growing phenomenon in Western culture also reflects all the fashion, risk, daring, independence or sexuality whereas other people do it on impulse and to enhance perceived body image or for spiritual reasons. The aim of this paper is to present the local and systemic complications and the usual effects of oral piercing.

Keywords: *Oral piercing, Complications, Dentist recommendations*

Introduction

"Piercing" is a term which is a practice usually done without anaesthesia in order to pop in the jewellery on a site which gets drilled through needles into the skin.[1] Now society has begun to be broader minded with open self-expression that most of us nowadays come across different forms of body arts. Oral piercing is one of the very popular body art among younger generation. Piercing considered as a growing phenomenon in Western culture also reflects all the fashion, risk, daring, independence or sexuality whereas other people do it on impulse and to enhance perceived body image or for spiritual reasons. Oral and peri-oral piercing has now became exceptionally popular in industrialized countries are also associated with religious, tribal, intellectual or sexual symbolism.[2,3]

Oral piercing sites: Tongue, lips and cheeks are the most popular oral piercing sites. Based on the arithmetical absence of most important vessels or nerves, such as the midline of the tongue or lip, oral piercing site is chosen and done without local anaesthesia. Jewellery consists of studs, barbells or hoops made of stainless steel, 14-18 carat gold, titanium or niobium. The jewelleries should be removable. There is the demanding popularity of tongue and lip piercing, where there is insertion of jewellery into soft oral tissues including the lips, cheeks and tongue and rarely uvula.[4,5] It is found that the most prevalent oral piercing site is tongue which is typically pierced in the midline and just anterior to the lingual frenum.[6]

Down the line, dentistry as well as dental treatments are one of the needed aspects of a healthy normal life, fashion aspects and aesthetics are also getting incorporated into it. Dentistry have developed into box fashion where more than normal aesthetic plus smile enhancing procedures are getting incorporated which include oral piercings, dental tattoos plus tooth jewellery. The aim of this paper is to present the local and systemic complications and the usual effects of oral piercing. This article also help to enhance the awareness of generalpublic toward oral piercing in addition to significance of dental professionals are important in the prevention and treatments of the most regular infections developed from oral piercings and in the treatment of the sequels connected.

History of oral piercing: The ancient Aztecs, Mayans, and tribes of the American Northwest pierced their tongues. Religious rituals performed by shamen and priests and their purpose are to communicate.[7] During the Epic of Mahabharata: masked as Brahmin, Krishna asks for gold in donation where as Karan proves his worth by donating his gold filled tooth which indicates the reality of dentistry even around 2500 BC, where defective teeth were restored with gold.[7] Around 700 BC Piercing tongue was first done by the Mayans and later. But in 1521, the Spanish conquistadors reached on the

American continent and they wiped out the practice of tongue piercing ofthe Aztec people.[8]

Transition of piercing into mainstream: Oral piercing gained popularity in the 1970's. Piercing becomes more widespread form of body art with self expression in the society trends and was also glamorized by the media. In 1992, first case tongue piercing was recorded in western medical literature.[8] Unlike many other piercings, the appearance of tongue piercing in current times has deep sexual connotations.[8] Even today also in many parts of the world lip piercing has been practiced for thousands of years. The members of the ethnic grouptribal people as a sign of great beauty and their ownership,wooden plugs into the lips of women were inserted by the men of the African Makololo tribe.[9]

In tongue splitting process literally a person's tongue is splitted into two halves which resembles a "forked" like appearance. For splitting tongues lay people used various primitive techniques like without anaesthesia, scalpels are used followed by a cauterizing pen, or fishing line may be threaded through the pierced tongue and pulled forward.[5,8]

Varieties of Piercing used in the mouth: Frequently applied oral and perioral piercings are captive-bead ring, labret and barbell. The captive bead ring opens at the end of which is screwed as a metal ball and also widely used as the first piercing in the labial area. This captive bead ring is easy to maintain and it does not create any early edema.[10, 11] The lip piercing is usually applied on the lower lip near the corners of the mouth where the lips meet but it can be made anywhere on the vermillion border.[12] Inside the oral cavity the site for tongue piercing can be on the dorsal-ventral or dorsal lateral side, but dorso ventral is the most common and safer among them. Proper care should be taken while piercing as tongue piercing is commonly made in the middle of the tongue which requires the avoidance of major blood vessels during the procedure.[13] Another type of piercing is tongue frenulum piercing which is done through the frenulum underneath the tongue and is also known as the frenulum linguae.[14]

In the cheek portion of the face, piercing is usually done at the level of the dimples ahead of the first molar to minimize the risk of damage of the Stensen duct, which opens in the vestibule in the correspondence of the second upper molar. According to statistical data, the tongue piercing is very less documented with complications as compared to the cheek piercing which is associated with frequent complications. Piercing studios are inspected every 2 years in Texas and are subject to more frequent inspections depending on the number of complaints against the establishment. No formal license or CPR certification is required of the piercing artist. [12, 15]

Common side-effects of oral piercing[16-21]: During X-ray examinations Oral and perioral piercings must not be worn as they produce radiopaque areas thus the piercings must be removed.

Localized horizontal bone loss in or perioral piercings.

Bone dehiscence has been reported in various studies due to constant contact between jewellery and mandibular gingival.

Stimulation of salivary flow (sialorrhea) due to piercings in the oral/perioral cavity has been observed up to 63% in various studies.

Adverse effects of oral piercing[16-22]: Because of the presence of piercing jewellery inside the oral cavity and especially on the tongue, there is a disturbance in normal functioning that hampers chewing, phonation and speaking and distorts the pronunciation of certain sounds, e.g., "s", "sh", "th", "ph", "t" or "v".

Digestive or respiratory disorders:The jewellery can be ingested or aspirated in piercings with barbells, labrets or rings, because of incorrect fixing, poor handling during placement or exertion of high pressure,

Magnet piercing has higher risk of ingestion. There is now substantial controversy that has arisen over the need to take out oral piercing during surgery under general anaesthesia.

Short Complications of oral piercing: Infection and bleeding at site on piercing is common of aseptic procedures are not followed. Inflammation or swelling of the tongue after piercing is very common with severe pain. Severe cases lead to serious breathing difficulties. Excessive bleeding may happen if blood vessels are split within piercing process. [22]

Long term complications

a. Infection

b. Prolonged bleeding

c. Pain and swelling

d. Chipped or cracked teeth

e. Injury to the gums

f. Nerve damage

g. Hypersensitivity

h. Blood-borne diseases

i. Endocarditis

j. Ludwig's angina

k. Cerebellar brain abscesses

Influence of tongue piercings on speech received only little attention. Studies reported speech difficulties during the first days or weeks after piercing. [23-25]

Adolescent and Young Adults and Trend in Piercing: Firoozmand LM et al observed that the use of oral piercing among students aged 14-18 years was 3.6% where as Bosello R et al found that tattooing and piercing among adolescents is 4% and 24% respectively by. 19 years old remains the mean age of an individual having his tongue pierced and around 49 adolescent children have their oral piercing in five high schools of New York. Students from state schools have more number of oral piercings than those from private schools. According to a MEDLINE search which is conducted by Lester B et al revealed that tattoo prevalence ranging from 10% in adolescents to 25% in 15-25-Year-old. Mayers LB found 50% of University undergraduates to have some type of piercing. Levin L et al observed in a study in the age group of 18–24 years that 81 patients are having some form of oral piercings.[26-32]Life span of oral piercings

Oral piercings can stay in your mouth indefinitely providing your mouth remain free of infection as well as do not interfere with normal function. But at the early sign of pain or problems, be very sure to visit your dentist immediately.[21]

Advice for those who choose to pierce: Piercing should always be done is in a safest place which should be a well equipped professional like studio with all sterilization and infection control procedures. All individuals whoever will be doing the oral piercing upon themselves should enquire for a public health services inspection certificate and should looked into all the sterilizing procedures such as an autoclave sterilizer and disposable items such as gloves and swabs must be there. Jewellery and all devices must be stored in sterilized packages. There should be enough knowledgeable studio staff should be present to answer questions and explain the procedures required for preventing post piercing complications.[22, 33]

Dentist recommendations after oral piercings: If you have oral piercings then some mandatory instructions must be followed to lessen the complications. Good quality plastic jewellery is preferable than metallic ones. Remove jewellery before joining any sports and before sleeping. After having a piercing, regular to visit dentist in every six months is mandatory to monitor any potential damage to lips, teeth and gums.[22]

Conclusion

In this fast modern and cosmetic world, oral piercings are a growing trend now and is getting incorporated to dentistry. Having adequate knowledge to provide quality care to such patients and to educate the patient about the possible complications of oral piercings prior to the procedure is important in our ever-more-cosmetic society. As compared to other practitioners dental professionals can provide better awareness of the adverse effects with closer follow-up of patients with oral and perioral piercing. Therefore, individuals with oral/perioral piercing should do a visit to the dentist in regular interval for oral examination to detect early detection.

Growth Hormone Disorders and its Oral Manifestations

Karishma Rajan Rathor[1], Gatha Mohanty[2], Stithaprajna Lenka[3], Neelima Katti[4]

[1]Clinical Tutor, Community Dentistry, [2]Senior Lecturer, Periodontics and Oral Implantology, [3]Professor, Oral and Maxillofacial Surgery, Institute of Dental Sciences, Siksha O Anusandhan Deemed to be University, Bhubaneswar, [4]Associate Professor, Department of Periodontics, SCB Dental College and Hospital, Cuttack, Odisha, India

Abstract

Hormones are organic substances that are mainly produced by the endocrine glands and are secreted into the blood stream directly. Human Growth Hormone (HGH) Somatotropin is a peptide that stimulates growth, cell production and cell generation in humans and animals and is of importance in development of humans. Individuals with growth hormone deficiency develop pituitary dwarfism with delayed growth of skull and facial appearance for their age. There is a marked effect on oral and facial structures due to the hypo and hyper pituitarism. Excessive action of the glandular epithelium of the anterior lobe leads to Hyperpituitarism and diminished functional activity of the anterior lobe causes Hypopituitarism.

Keywords: *Growth hormone, Disorders, Gigantism, Oral manifestations.*

Introduction

The endocrine system is made up of several endocrine glands that are located in different parts of the human body. Endocrine glands are sometimes called-ductless glands because they secrete their products directly into the blood or into the interstitial space. Endocrine disorders, apart from diabetes mellitus and thyroid diseases are uncommon. They are rare causes of oral disease, but occasionally oral changes can lead to their diagnosis. Hypersecretion of growth hormone results in gigantism or acromegaly, a condition associated with significant morbidity and mortality, while deficiency of growth hormone results in dwarfism, growth retardation in children, and the growth hormone deficiency syndrome in adults. This article aims at reviewing the various oral manifestations seen in pituitary gland disorder.

Somatotropin: Somatotropin is a Growth hormone composed of 190 amino acids synthesized and secreted by cells in the anterior pituitary (somatotrophs)[1]. It participates in control of several complex physiologic processes such as growth and metabolism.

Growth Hormone and its Physiologic Effects

It has two types of effects:

Direct effects: Growth hormone binds to its receptor on target cells. Adipocytes have growth hormone receptors. The growth hormone stimulates the adipocytes to break down triglyceride and thereby supresses the ability to take up and accumulate circulating lipids[2].

Indirect effects are primarily mediated by insulin-like growth factor-I (IGF-I)[3].

Effects of somatotropin on Growth: Growth is a complex process, and requires the coordinated action of several hormones. Growth hormone has a direct effect on growth of bone by stimulating differentiation of chondrocytes. The major role of growth hormone is to stimulate the liver and other tissues to secrete IGF-I which in turn enhances chondrocytes stimulation and increases bone growth[4].

Effects on metabolism: Growth hormone has important effects on lipid,protein and carbohydrate metabolism. IGF-I is sometimes the critical mediator, and in some cases both direct and indirect effects are at play.

- **Protein metabolism:** growth hormone stimulates protein anabolism. This effect is reflected by increase in amino acid uptake, increase in protein synthesis and decrease in oxidation of proteins.

- **Fat metabolism:** Growth hormone increases the utilization of fat by stimulation of triglyceride breakdown and hence oxidation in adipocytes[5].
- **Carbohydrate metabolism:** Growth hormone serves to maintain blood glucose within a normal range. Sometimes administration of growth hormone stimulates insulin secretion, leading to hyperinsulinemia[6].

Control of growth hormone secretion: Many factors modulate the production of growth hormone secretion. Ex. Stress, sleep, nutrition, exercise, GH itself. Primarily controlled by 2 hypothalamic hormones-GHRH and somatostatinand a stomach hormone **Ghrelin**[7].

Disease States: Growth hormone deficiency and excess states relate to the importance of this hormone in normal physiology. Such disorders can be seen either in the hypothalamus, the pituitary or in target cells. There can be a deficiency state from a deficiency in production of the hormone nor in the target cell's response to the hormone.

The manifestation of growth hormone deficiency depends upon the age of onset of the disorder and can result from either heritable or acquired disease.

Hyperpituitarism: It results from hyper function of anterior pituitary. Under this heading we place Acromegaly and Gigantism.

Gigantism and its Oral manifestations: A rare condition characterized by abnormal growth in children. There is excessive growth and increase in height that is significant and more than average. Prognathic mandible, dental malocclusion,frontal bossing, and spacingin interdental region are the few oral abnormalities associated with this condition. Intra oral radiographs have shown hypercementosis of the radicular region[8].

Acromegaly and its oral manifestations: This condition is seen in adults. Pituitary gland produces excessive growth hormones leading to this condition[9]. Usually associated with a pituitary gland tumor, it is known as pituitary adenome. There is occurance of soft tissue swelling. Hands, feet, nose, lips and ears are enlarged. Unique featue is brow protrusion along with ocular distention (frontal bossing). Facial changes are large lips and nose, frontal skull bossing and cranial ridges, mandibular prognathism and overgrowth along with spaces between teeth. There is buccal tipping due to enlarged tongue.

Health problems can be seen as Acromegaly progresses. Its complications may include

- High blood pressure
- Spinal cord compression
- Vision loss
- Diabetes mellitus
- Cardiovascular diseases, particularly enlargement of the heart
- Sleep apnea

Hypopituitarism: Deficiency in hormone secretion by anterior lobe.

Pituitary dwarfism is a disease resulting when the body fails to use the pituitary growth Hormone (GH). In pituitary dwarfism anomalies of the dental apparatus from morphological profile and in terms of development are seen[10].

The maxilla and mandible of affected patients are smaller than normal and face appears smaller. Cranium and face develop slowly, face is small compared to Cranium. Frontal sinuses are underdeveloped. There is retardation in development of teeth and jaws. Retarded growth of the ramus causes failure in increase of the height of the mandible. There is reduced inter maxillary space and crowding of teeth[11].

Table 1: Overall picture of clinical features.

Pituitary Gigantism	Acromegaly	Hypopituitarism
Malocclusion	Large sized tongue	Wrinkles around eyes
Hypercementosis of radicular region	Mandibular prognathism	Crowding of teeth
Generalised spacing between teeth.	Malocclusion class 111	Delayed eruption of teeth

Conclusion

The oral cavity being in critical anatomical location has a role in many physiologic processes, such as digestion, respiration, and speech. In many instances, appearance of other symptoms or lesions at other locations is preceded by oral manifestations. Endocrinologist and dental practitioners must communicate with each other to for conducting diagnostic tests, compare the results

and monitor treatment plans, and prescribe medications that addresses the problems. The dental professional should be able to detect the pituitary disease and also the first healthcare provider to come across such patients.

Scars in Orthodontics: A Review

Abhik Sinha[1], Rahul Roy[1]

[1]Former Post-Graduate Trainee, Department of Orthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Orthodontic treatment helps to establish a balance between functional harmony and an improved esthetics, yet, rendering such treatment comes across with potential risks in terms of both hard and soft tissue damage. Such potential risks to various hard and soft tissue damages may include–enamel demineralization, pulp degeneration, root resorption, gingival enlargement, lacerations, allergic reactions and Temporomandibular joint disorders, apart from the fact that the treatment procedure may fail in itself. All such potential risks should be considered and addressed while making the final decision to render orthodontic treatment on an individual. The benefits achievable from the treatment should outweigh the risks involved with it. The orthodontist, thus, should have a thorough knowledge of all the risk factors to which the patient gets susceptible and preventive measures should be taken accordingly. This article reviews the various risks that may be associated with orthodontic treatment and the ways to manage them.

Keywords: *Esthetics, root resorption, gingival enlargement, lacerations, risk factors.*

Introduction

Some of the concerns that make an individual seek orthodontic treatment includes–crowding, spacing and protruded teeth. While the orthodontist is able to address almost all of these concerns and also improve appearance, function and self-esteem of the patient, sometimes the orthodontic appliances also carry certain risks.[1] Some patients, in this context, are at more risk than others and have to be identified early to manage them accordingly.

The treatment process itself causes pain and discomfort to the patient, along with probable damage to the hard and soft tissues. Orthodontic scars may also sometimes manifest during or after treatment and has to be addressed appropriately to achieve a successful result.[2] A broad classification of the orthodontic scars has been given here. (Table 1)

Various problems associated with different orthodontic scars

1. **Dental problems**

   a. **Enamel decalcification/White spot lesions:** During fixed orthodontic treatment, poor oral hygiene standards results in bacterial plaque accumulation around the orthodontic attachments and release acid.[3] This causes demineralization of the enamel surface. The early manifestation for such a lesion are white and opaque spots[4] (**Figure 1**) which, with further demineralization can progress to frank caries.[5] Their prevalence ranges between 2%–96%with the male patients being more susceptible than females.[6] The most common site is the labiogingival area of the lateral incisors where the lesions start clinically manifesting within first 4 weeks of treatment.[7] They are less common in the Maxillary posterior segments though.[8] The enamel demineralization scale is given in **Table 2**.

   Prevention: Oral hygiene maintenance is essential to prevent white spot lesions. In addition, use of anti-cariogenic agents such as fluoride application in the form of–0.05%

sodium fluoride[9], 1.2% acidulated phosphate fluoride[10], 0.4% stannous fluoride gel[11] and fluoride varnish[12] can be done for compliant patients. In case the patient is non-compliant, fluoride containing cements/bonding agents[13] and fluoride releasing elastomeric ligatures[14] are available.The use of such agents also prevents the colour changes to enamel brought about by composite resins for bracket bonding.

b. **Physical damges on enamel (Enamel wear/ Enamel fractures):** Enamel damage usually occurs from occlusal/incisal contact with ceramic brackets, followed in the order by metal and composite brackets. Thus, the incisal edges of the upper anterior teeth, buccal cusps of the upper posterior teeth and upper canine tips are the ones most frequently affected.[15] Other causes of enamel damage include– trauma from band seaterorband remover, large restorations with unsupported enamel cusps as well as debonding of both metal and ceramic brackets.[16]Zachrisson et al reported fractures in about 6% of the debonded or banded teeth compared to only 4% in untreated teeth.[17] Lau et al concluded that ceramic brackets make the teeth 9 to 38 times more prone for fracture compared to the metallic brackets.

These can be prevented by–restoring all carious lesions before the start of orthodontic treatment, avoiding direct contact between the orthodontic brackets and opposing teeth, and use of a night guard. Special precautions should be taken in deep bite cases, where ceramic brackets should not be used in the lower incisors until adequate overjet has been obtained. The same should be followed for bonding ceramic attachments on canines while they are in a class II relationship and maxillary incisors during retraction.

The debonding technique should be appropriate and aimed to break the link between the adhesive and the bracket. The residual bonding materials should then be removed with tungsten carbide burs at a low speed, followed by pumicing to prevent plaque accumulation. Ogaard and Field reported that horizontal enamel cracks are almost always associated with orthodontics.[18] Enamel erosions if present prior to orthodontic treatment should be recorded and they should be asked to avoid carbonated drinks and pure juices during fixed appliance therapy.

c. **Pulpal degeneartion:** Orthodontic forces are known to disturb circulation within the pulp, and especially so when a greater force is used or the force is applied for a longer time. Although this leads to a reversible or transient pulpitis and loss of vitality is rare, yet it is advisable to only apply light forces to bring about tooth movement and the pulp should be monitored every 3 months to check its vitality.

d. **Root resorption:** Rudolf stated that orthodontic treatment makes a patient 20 times more susceptible to root resorption with the predilection being greater in females than males. Root resorption is more common in the incisors and the apical third is most commonly affected.

The root resorption can be classified into 3 types;

i. **Surface resorption:** These constantly appear as micro-defects periapically and repair normally by themselves when the inciting agent is removed.

ii. **Inflammatory resorption:** These occur when resorption has progressed into the infected pulpal tissue.

iii. **Replacement resorption:** Bone replaces the resorbed tooth surface causing ankylosis of the tooth.

The factors that influence root resorption include local factors such as–periodontitis, diabetes, allergy, agenesis, ectopia, traumatized tooth, and endodontically treated tooth. The systemic factors include–hypothyroidism, hypopituitarism, hyperparathyroidism, hyperpituitarism, hypophosphatemia and Paget's disease. Orthodontic reasons such as– heavy retraction forces using headgear, increased treatment duration and tooth movements like intrusion and torquing. (**Figure 3**).

Prevention: Root resorption can be avoided by rendering orthodontic treatment for a shorter duration and using light forces. Care should also be taken to avoid moving the roots into cortical bone.Periapical radiographs should be taken every 6 months and if root resorption is detected, then active treatment should be

suspended for 2–3 months.

2. **Periodontal tissues**

   a. **Gingivitis or Gingival enlargement:** Gingival inflammation is inevitable with almost all orthodontic procedures initially. The inflammation is greater in the interproximal areas than the facial surfaces and posterior teeth greater than anterior teeth.[19] (**Figure 4**) These, however, subside in a few weeks after debonding. Adult patients with their pre-existing periodontal condition and presence of systemic diseases such as–diabetes and epilepsy are at a greater risk. Phenytoin-based drugs can cause gingival hyperplasia. Treatment modifications should be–application of light forces, quarterly periodontal checks and routine scaling.[20]

   b. **Gingival recession:** Alveolar bone loss and gingival recession have often been associated with orthodontic tooth movement.[21,22] This is more common during the labial movement of the mandibular incisors, and due to the use of bands which are subgingivally placed.

   c. **Dark triangles:** These appear when crowded and rotated teeth are corrected orthodontically, and there is loss of periodontal attachment resulting in open gingival embrasures.[23]

   These can be prevented by following proper oral hygiene instructions while making use of adjuncts like–sonic electric toothbrushes, interproximal brushes, chlorhexidine and fluoride mouthwashes etc. If they have already developed, then reshaping the proximal surface and moving the contact point more apically too finally close down the space would help.[36,37]

3. **Soft tissue damage:** Intraoral and extraoral soft tissues can be damaged in the following ways:

   a. **Direct damage by removable or fixed components:** Removable appliances are used to carry out minor orthodontic corrections or as retainers following fixed orthodontic treatment. These appliances make the patient susceptible to tissue injury from wire components–clasps, springs, retractors. Allergy to unpolymerized material of acrylic resin is also a risk with these appliances. Sharp edges from the acrylic should be carefully rounded off to prevent trauma.

   During Fixed appliance therapy, archwires, brackets and bands cause lacerations and ulcerations of the gingiva and oral mucosa. This happens due to the rubbing of the lips and cheeks with the appliance. Such trauma can be prevented by using dental wax, rubber tubing etc. while also carefully rounding off sharp edges of the appliance.

   Transpalatal arches: The use of transpalatal arch may cause trauma to the tongue, palate and lingual mucosa if adequate clearance is not given during their fabrication.

   Headgears: Headgears can also cause injury if they get dislodged during sleep or while playing. The inner bow of the facebow is usually contaminated with microorganisms and any eye injury with it would lead to serious infections. Safety precaution would be to properly disengage the strap of the headgear before removing the facebow.[24]

   Loops and utility arches: Tissue impingements with these may result in tissue hyperplasia around the loop which may later require surgical excision for removal.

   Accidental ingestion of appliance parts: If the accidentally ingested parts reach the gastrointestinal tract, it has a 90% chance to be passed off uneventfully. However, any tracheobronchial obstruction would result in coughing, dyspnoea or choking and call for its immediate removal.

   Burns: Procedures like–acid etching, electro thermal debonding and hot sterilized instruments have the ability to inflict thermal or chemical burns and appropriate care should be taken while using them.

   b. **Indirect damage by allergic reactions**

   Nickel: Hypersensitivity to Nickel is present in 30% of the general population with a predilection for females.[25] They may manifest symptoms while undergoing orthodontic treatment with wires, brackets, bands and headgear which contain nickel. Intraoral signs may include–metallic taste, numbness, loss of taste, burning sensation, soreness at the lateral borders of the tongue, erythema, gingivitis even without plaque, and angular cheilitis.[26,27] For such symptoms to manifest intraorally,

however, nickel concentrations have to be very high. In patients sensitive to nickel, epoxy coating of the wires are recommended.

Latex: Latex allergy is manifested most commonly in the gingiva and tongue of sensitive patients while using latex gloves, intra and extraoral elastics and elastomeric ligatures.[28-30] In such patients, use of steel ligatures and self-ligating brackets can be promoted. The treatment plan should be modified to avoid use of class II or class III elastics for traction unless non-latex elastics are made available.[46]

c. Soft tissue complications related to implants[31,32]: The microimplants provide excellent skeletal anchorage and their ease of use makes them comfortable to the patient. However, they can bring about the following complications:

i. Inadequate primary stability if the cortical bone thickness is less than 0.5 mm with a low trabecular bone density.

ii. Trauma and ulceration to the soft tissue overlying the implant is likely. This can be prevented by covering the implant head with a layer of composite or a piece of wet cotton.

iii. The gingival tissue around the implant may get inflamed causing peri-implantitis. Thus, maintenance of a high level of oral hygiene using 0.2% chlorhexidine mouthwash is necessary.

iv. Delayed mobility of the implant occurs if forces beyond 450 N is applied. Such screws then have to be removed and replaced.

v. Lateral forces during miniscrew removal or partial osseointegration on being left in the patient's mouth for a very long time may result in implant fracture.

4. Miscellaneous

a. Temporomandibular joint problems: Orthodontic treatment should aim at producing occlusal harmony while eliminating centric prematurities and non-working contacts during mandibular excursions. Any failure to achieve this would result in TMJ disorders.

b. Cross-infection: Infections spreading between patients, between the doctor and patient or by a third party should be prevented by using masks, gloves, sterilized instruments and a clean working area.

c. Infective endocarditis: Patients suffering from endocarditis would require antibiotic coverage for procedures like–extraction, separator placement, band placement and band removal following consultation by a cardiologist. It is preferable to use bonded attachments in these patients in order to avoid separators and bands.

d. Cytotoxicity of polymers: Cured orthodontic bonding resins still leach chemical components which interferes with atmospheric oxygen to compromise the polymerization. Thus, excess bonding adhesives should be removed from teeth using scalers.

Table 1: Classification of orthodontic scars

Orthodontic scar	Associated problems
1. Dental problems	a. Enamel decalcification/White spot lesions b. Physical damages on enamel (Enamel wear/Enamel fractures) c. Pulp degeneration d. Root resorption
2. Scars of Periodontal tissues	a. Gingivitis/Gingival enlargement b. Gingival recession c. Dark triangles
3. Soft tissue damage	a. Direct damage by removable/fixed appliances and their component parts: i. Impingements–by lingual arch, loops, archwires, brackets and bands ii. Lacerations–due to brackets, molar tubes and ligature ties iii. Ulcerations–due to brackets, molar tubes and ligature ties iv. Injury to eyes–by headgears, facebow injury b. Indirect damage by allergic reactions to: i. Nickel ii. Latex c. Soft tissue complications related to Implants i. Primary mobility ii. Ulceration of overlying soft tissue iii. Periimplantitis iv. Delayed mobility and failure v. Fracture during removal
4. Miscellaneous	i. TMJ problems ii. Cross infection iii. Cytotoxicity of polymers

Table 2: Enamel demineralization scale

Scale	Enamel demineralization
0	No enamel opacity or surface disruption
1	An opacity without surface disruption, or mild demineralization
2	An opacity having a roughened surface, or moderate demineralization
3	An opacity requiring a restoration, orsevere demineralization

Figures with Captions

Figure 1: Post-debonding photograph showing areas of enamel decalcification

Figure 2: Colour changes integrated to usage of composite resins for bracket bonding

Figure 3: Radiographs showing Changes in the root apex due to orthodontic treatment

Figure 4: Gingival inflammation after placement of fixed appliance

Conclusion

Iatrogenic damage during orthodontic treatment can occur from innumerable sources. However, patients with severe malocclusion would benefit more from treatment and hence show a greater motivation. The benefits should be weighed against the risk factors involved to decide the course of treatment for each individual patient. A discontinuation of treatment before its completion would leave the malocclusion worse than it was before treatment.

CAD CAM Nasoalveolar Molding and its Recent Advances

Ananya Panda

Post Graduate Student, Department of Orthodontics and Dentofacial Orthopedics, Institute of Dental Sciences, Sikhsha O Anusandhan (Deemed to be University), Bhubaneswar

Abstract

Among the various congenital craniofacial defects, one of the most common congenital craniofacial defect is cleft lip and palate. Its treatment requires a group of doctors whose primary motto is to restore the normal form and function of the patient by reconstructing the nasoalveolar segments. Before the reconstruction, the impaired tissues should be stretched and the ill positioned structures should be positioned in their actual place before surgical treatment. In patients with cleft lip and palate, nasoalveolar molding helps to develop the nasal deformity with a stent or prosthesis and this has to modified because of the continuous growth of the individual leading to change in size of the dentoalveolar region or there might be some improvement in the cleft. During the modification the stent has to be placed on a new plate. This requires long patient appointments or multiple appointments. To minimize the long and multiple appointments, few studies have been done and a quick chair side procedure for the nasal stent exchange has been introduced, which is referred to as Rapid NAM. The CAD/CAM NAM and its advanced version Rapid NAM drastically improved the height of the cleft-nasal side and a considerable symmetry of the nose was achieved. The quick lock technique reduces the wire adaptations as the previously used prosthesis or stent can be made to use again. This advanced technique is a combination of the CAD/CAM technology and the conventional components of NAM.

Keywords: *Cleft lip and palate, CAD/CAM, Nasoalveolar molding.*

Introduction

Nasoalveolar molding was started by Grayson et al. By one week of birth, the nasoalveolar molding is done and generally, it persists till the first lip and nasal reconstruction. Firstly, a simulated model of the defective dentoalveolar region is made which is one the important aspect of the treatment. The nasoalveolar molding appliance is made physically by methyl methacrylate polymer from the simulated model.[1] Due to growth, there are certain changes which requires frequent adjustment to eventually mold the dentoalveolar region into an approximately exact position they should ideally be placed. Extraoral taping and combined nasal stent allows a more structured orientation of the soft tissue structures such as the deformed nose and lip. With more and more development in this field, the conventional presurgical infant orthopedics has been now a days done in combination with the new approach of NAM appliance. Nasoalveolar morphology has conventionally been measured by detecting landmarks on a 2D photograph to make different measurements. In the recent times, computers have led to the rise of better and refined means of evaluation. A sur-face laser scanner was used to capture 3D denture images, and *x*, *y*, and *z* coordinates were digitized to analyze and compute the morphologies.[1,4]

CAD CAM Nasoalveolar Molding: The simulated planning of the nasoalveolarmoulding is easily attainable by the sequential production of casts and the 3D printed nasoalevolar appliances that are designed digitally, after the introduction of CAD/CAM technology in orthodontics. 3D simulated models can be manipulated with the help of CAD/CAM technology for performing and visualizing the treatment plan along with the evaluation of the outcomes of the respective treatment.[1-2,5]

Quan et al. modified the conventional nasoalveolar molding technique in cases with unilateral cleft lip and palate with the help of CAD technology. In the last 10 years, the CAD/CAM development has taken the science from a world of visual-tactile simulated protype models to a world of touch-understand-influence.[2] There was a study regarding the analysis of the anatomic changes in the cases of unilateral cleft lip in maxilla following a CAD/CAM nasoalveolar appliance. The 3D prototype model which was designed digitally was evaluated by the reverse engineering software system. The study revealed that the computer aided nasoalveolar therapy markedly decreased the alveolar cleft gap and the length of the arch. The alveolar defect width and the sagittal length of anterior region of the arch was also reduced with nasoalveolar molding. Few other studies have also cited the same results as the above. The deviation in the midline due to the cleft was also fixed with the CAD NAM. The non-affected side of the maxilla was adjusted by reducing the bulge and the rotation in the outward direction. the alveolar contour was also modified as the growth of the patient continued.[2]

Rapid NAM: The plate is frequently modified due to the changes in the maxillary bone as a result of growth. The stent is fabricated again with the modifications after the fit and retention of the plate is checked on the maxillary arch. Thus,there is frequent as well as long appointments which may lead to the apprehension that nasoalveolar molding is a long treatment procedure. Therefore, a refined version of CAD/CAM technique is developed, known as RapidNAM, which acts a semi automation of CAD/CAM NAM. The aim of the developers was to alter the already existing CAD/CAM technique for the production of molding plates. This allows a faster chairside modification of nasal stents thus lessening the time taken for the treatment procedure. This technique is a combination of the conventional and the well-known characteristics of the nasoalveolar molding with the benefit of additive fabrication (Figure 1).[3]

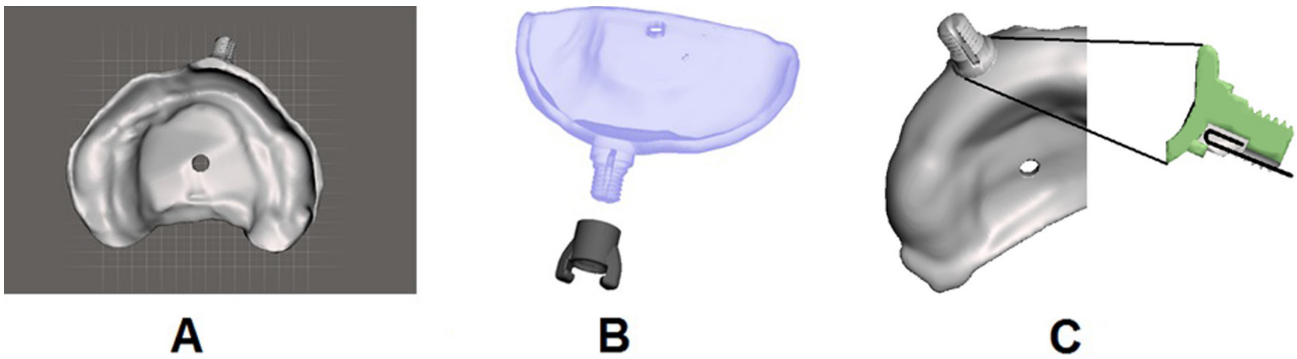

Figure 1: (A) Virtual "Rapid NAM plate" along with the retention pin and screw thread (B) Respective nut with retentions for the buccal tapings (C) Caudal view of the retention pin with the retention groove and profile view

Measurements: In a study where both the techniques were compared, the plaster models designed digitally were physically measured by using the software "Python (Python software foundation, version 2.7, Netherlands; The scientific Python development environment, Spyder developer community, version 2.3.4)" based on the landmarks selected. The following points on the nasal area were chosen by two different observers. "AB, AB' indicates alar bases, NT for nasal tip, SN for subnasal point, CA denotes the most anterior point of the columella and NT, NT' top and NB,NB' bottom of the nostril on the unaffected and cleft side, NL,NL' and NR.NR' indicates the inner rim of the both nostrils. The columella angle was denoted by the angle formed by the lines crossing through AB, AB' and Sn; CA" For a generalized evaluation of the previously known CAD/CAM-technique and Rapid NAM, plaster models of CAD/CAM-NAM-treated children were digitally evaluated again using the same reproducible landmarks in both treatment groups (Figure 2).

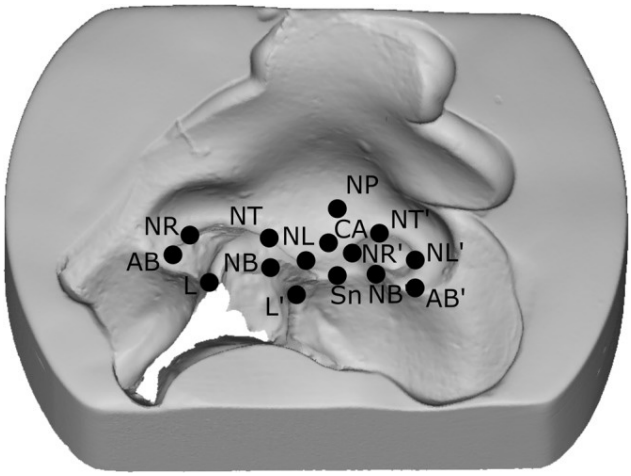

Figure 2: Selected landmarks

Still many studies and discussions are going on regarding thepost treatment outcome related to the nasal esthetics and functional improvements. Nasoalveolarmolding therapy has also showed improvement in the nasal symmetry and thus led to the reduction in the frequent surgeries. A study was done and designs oftwo nasal stents were evaluated. One stent was made by the conventional "CAD/CAM" molding plates and the other was made by semi-automated "RapidNAM" plate design. The techniques used were the result of the conventional Nasoalveolar molding with the usual wire activation, despite distinct plate and retention pin designs. The wire permits accurate positioning of nasal bulb. The outcome of study indicated that both the techniques markedly improve the nostril position on the cleft side with height increase of more than approximately 75% as compared to the non-affected side on the other nostril. The angle of the columella was significantly increased in both the groups, however the starting values varied between both the groups. The columella increased in length by 55% in the CAD/CAM group but in the RapidNAM group it was 31%. When the results were evaluated at the end in total, they were matching with the results of the other studies. The goals of NAM that are the nasal symmetry improvement, lengthening of the columella and the nostril height increase and increasing the columella angle, have all been attained. Further surgeries performed to close the lip will again correct some amount of the nasal symmetry left and few authors have suggested to do over correction in this aspect to prevent the chances of relapse (Figure 3)..[3]

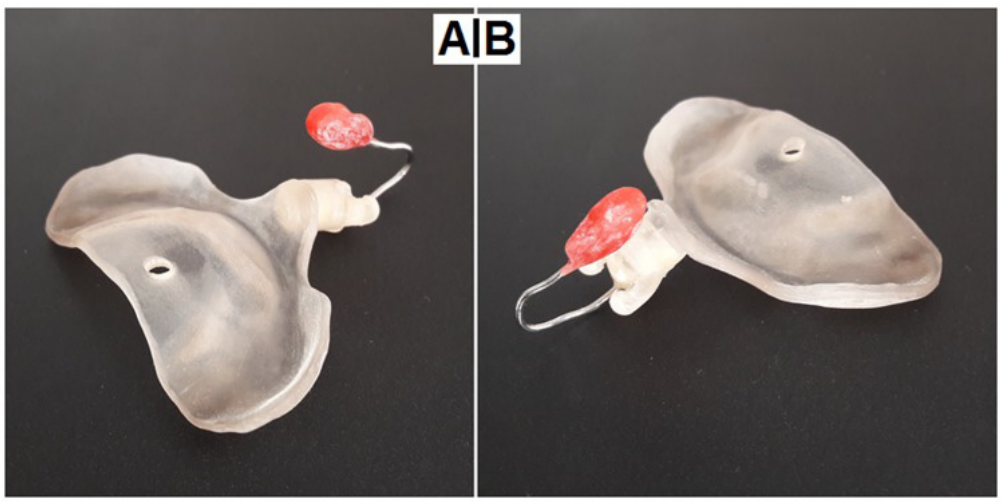

Figure 3: (A) Dorsal view of the "RapidNAM plate" with the nasal stent attached (B) Frontal view of the "RapidNAM plate" with the stent attached

The benefit of the new pin and the nasal stent design is easy modification and fabricationwhen a new plate is fabricated. This technique overcomes the traditional CAD/CAM techniques which required physical manipulation of stent parts or attachments. As the RapidNAM plates consists of a pin having same measurements, an already fitted nasal stent can be eliminated by unwinding the screw and can be relocated on to the new plate fabricated. Before the actual complete usage of the nasal stent, the wire length taken should be long enough to cause activation during the course of the treatment with no need of the stent exchange. This retention technique can be fabricated manually by experts in CAD/CAM software and thus this overcomes

the low availability of this system through the world. After the designing, the retention pin can be placed virtually upon the intraoral molding plates with a "Boolean operation". 3-dimensional photography aids in the recording of the soft tissue relationships, particularly the various movements of the face for an appropriate placement of the pin in the case where the pin is designed later. More efforts are made to place the pre-fabricated stents of various dimensions and loop angles. Based on the clinical cases, the exact size can be selected and the required modifications can be done rapidly thus saving a lot of time of both the patient and the doctor. Also, to avoid the frequent manipulation of the resin pattern, the retentive 180-degree knee will be refined.

Conclusion

The combination of the "CAD/CAM" system for the frequent NAM plate fabrication in the cleft treatment signify a distinct field with a high potential ability. This work is the first step in a case including the self-automation with a less usage of manpower for the NAM therapy in pre surgical cleft lip and palate treatment. "Geomagic studio" allows easy designing of the plates is simple. The final plate adaptation has to done intraorally in the infant. The following steps will be to combine the 3D growth factor and also for the frequent fabrication of "NAM appliances" to refine the planning of the virtual NAM treatment. This area needs further studies and research in its software and the programming steps.

Endodontic Sealers: Current Concepts of Sealers

Anshuk Ghosh[1], Sthitaprajna Lenka[2]

[1]Intern, [2]Professor, Department of Oral and Maxillofacial Surgery,
Siksha 'O' Anusandhan (Deemed to Be University), Bhubaneswar, Odisha, India

Abstract

The main objective of root canal treatment is the total removal of the microorganism the invaded the root canal system of the tooth. The three-dimensional sealing of the root canal system is achieved by the root canal sealers along with solid core material. The main part of this sealers is to adapt the rigid gutta percha to the canal walls, and to fill the voids, accessory canals. In endodontic treatment, Sealers plays a very important role in the outcome of the procedure, because of its perfect combination of sealing ability and biocompatibility with the root canal system. This article explains briefly the current concepts related with the usage and recent concept of endodontic sealers in root canal treatment, along with evaluation between different types of sealers properties.

Keywords: *Root canal treatment; three-dimensional sealing; endodontic treatment; biocompatibility.*

Introduction

The complete root canal treatment procedure depends on various phases of the treatment such as removal of microbial contaminants, cleaning and shaping of the root canals and the actual sealing of the root canal. The accomplishment or the failure of this whole procedure be contingent mostly on the accomplishment of the final phase that is the sealing of the root canal system. The main components are the solid core material and the sealers, they also consider as true implants as they are basically placed in the vital tissues of our body. The most commonly used solid core material is the gutta-percha, which occupies the majority of the canals, and the root canal sealers which fills the interface between the core material and the dentin wall, the voids and the accessory canals are also filled with the sealers and hence they provide more support and strength to the restoration[1].

The properties of an ideal sealer are to create a bond among the solid core material and the dentinal surface of the root canal, to prevent leak. It should have a nontoxic nature and can also enhance the healing procedure in the periapical lesion.

A various variation of endodontic sealers isaccessible commercially, they differ from each other in matter of composition from each other. It is recognized that the three-dimensional sealing properties of the root canal has the major clinical standing for the long-term achievement of endodontic treatment. While some of the clinical outcomes have been described with the practice of these non-bonding root canal sealers, but there is unremittingexploration for some alternate sealers or procedures that helps in better bonding of the endodontic sealers with the canal wall dentine as well as with the core materials[2,3].

Classification of Sealers: The various types of sealers that are available now commercially in markets are Zine oxide eugenol-based sealers, Epoxy resin-based sealers, Silicon based sealers, MTA based sealers, Calcium silicate phosphate-based bio ceramic sealers, Methacrylate resin-based sealers, Calcium phosphate-based sealers. These endodontic sealers are classified historically according to its eugenol content, usage, absorbance etc[4].

Recent Endodontic Sealers

Proroot Endo Sealer: It is a calcium silicate-

Corresponding Author:
Dr. Sthitaprajna Lenka
Professor, Department of Oral and Maxillofacial Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to Be University), Bhubaneswar, Odisha, India
e-mail: sthitaprajnalenka@gmail.com

based root canal sealer that is planned to be used with root filling material. Powder components–tricalcium silicate, dicalcium silicate, calcium sulphate as a setting retardant, bismuth oxide as a radio pacifier, tricalcium aluminate in small amount. Liquide components water-solublepolymer. This sealer on reaction with water also produce calcium hydroxide[5].

Herbal Sealer: Its type of a copaiferamultijuga oil resin. These trees are basically found in north America mainly in the amazon rainforest.

Nanoseal Plus Root Canal Sealer: The most shared problem in root canal treatment is the incapabilityto seal the accessary canal of the roots. One of the modern updates in the endodontic dentistry is the expansion of the first nanotechnology based endodontic sealer. This type of sealer is very useful as it seals the tiny gaps and therefore prevents infection. Its composition is basically calcium phosphate hydroxyapatite nanoparticles ranging from 40-60 nm. Its special charactersare this sealer penetrate the wall (dentinal tubules) and arrive of the accessory canals the seals the gaps effectively[6,7].

Hybrid Root Seal: It is accessible in the market in powder and liquid form, it is the fourth-generation self-adhesive dual cure sealer. It can be used with gutta percha or resilon as it is insoluble, radiopaque material.

Gutta Flow 2 Sealer: It stands the cartilage form of the original gutta flow sealer. It is the choice of sealer because of its excellent flowable nature. Later gutta flow 2 was introduced, which has a slightly better enlargement after mixing which helps in better sealing. It is available in the syringe form[8].

IROOT SP/Endosequence BC Sealer: It has the capacity to form hydroxyappetitethroughout the setting progression and produce a chemical bond amongst dentine wall and the sealer.It is expedient, ready to use, injectable white cement paste development for enduring root canal filing and sealing application. This sealer is also termed as bio ceramic sealer in general.

The Concept of Monoblock: Franklin R. Tay is the first one to defined the concepts of Monoblock in endodontics.

Primary Monoblock: It is a type of a simple, one surface bonding. Hydron sealers is another example of this concept. The main drawback of primary Monoblock is the lack of strength and stiffness that is necessary for a perfect sealing, due to this reason the development of secondary Monoblock is taken into account[9].

Secondary Monoblock: It is a type of a two-surface interface bonding material. The simple case for a secondary Monoblock is the bond between the sealer material with the canal walls and the gutta percha during obturation. In this type there is one bond between the gutta percha and sealer and another bond are between the sealer and root canal walls.

Endodontic Sealers are Compared: Orstavik has given some of the limitations that can easily evaluate the different properties of endodontic sealers[10].

Leakage: The main property that matters in an endodontic sealer is leakage it is the key factor for the failure of the root canal therapy. It provides a barricade that prevents bacterial opening from the oral cavity. Zine oxide-eugenol sealer, methacrylate-based resin sealers are found to be most effective.In bacterial leakage test of sealers Epiphany and resilon were superior to gutta percha and various other sealers, it has been reported that it provides instantaneous coronal seal[11]. Instantaneous coronal seal gives clinically advantage,since the canal can might be exposed to oral environment and can be re-contaminated to bacterial environment.Weller et al suggested the newly introduced sealer that is calcium silicate based pro root endo sealer that has a better sealing property then ZOE-based sealer[12].

Biocompatability: Its principle requirement of the endodontic sealer is it should be non-cytotoxic and immunologically well-matched with outlyingtissue. ForSelection of a sealer for dental restoration, the biocompatibility and antimicrobial property is an important factor that should be taken in consideration. Calcium hydroxide-based sealers encourage calcification but energeticallyitsnegotiations the restoration seal. Glass ionomer sealers may bond with the tooth structure perfectly but it also promotes the announcement of prostaglandins in periapical tissue[13].

Antibacterial Activity: Now a days the properties of antimicrobial activity as its primary property is not taken into account, but most of the sealers has some such properties.The new cohort sealers are also proved their antimicrobial worth of a widerrange[14].

Conclusion

The degree of endodontic success is directly proportional to a clinician's knowledge of the root canal

anatomy and the techniques selected while performing treatment. Properly performed endodontic therapy is the cornerstone of restorative and reconstructive dentistry. Three-dimensional sealing of the root canal is one of the main goals of endodontic treatment to prevent the reinfection of the canal and for preserving the health of the periapical tissues, thereby ensuring the success of root canal treatment. Thus, several types of endodontic sealers have been recommended to achieve this goal. It is important to note that not only the apical seal of the root canal but the coronal seal is of equal importance for the success of endodontic treatment. Ideally, further directions should focus on materials that penetrate the patent dentinal tubules, bind intimately to both organic and inorganic phases of dentin, neutralize or destroy microorganisms and their products, predictably induce a cemental regenerative response and strengthen the root system.

Bite Mark Analysis in Dentistry: An Emerging Probe of Criminal Investigation in Judicial System

Rashmi Kumari

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar

Abstract

Bitemark analysis is now-a-days an emerging tool used by dentists for criminal investigation purpose. In spite of a number of method used for bitemark analysis, 3-Dimentional method of analysis is the most reliable and commonly used method. Bitemark analysis process includes registration of both bitemark from the victim and the assailant's dentition, comparison of the bitemark and dentition and inspection of similarities and dissimilarities. Forensic Odontology is defined as the branch of dentistry which in intertest of justice deals with proper handling, examination and comparison of dental evidence and presentation of dental findings.

This article discusses about the highlights of importance and method of bitemark identification in judiciary system.

Keywords: *Bite Mark Analysis, Forensic Odontology, highlights of importance and method of bitemark analysis, Assailant dentition.*

Introduction

According to Mc Doland (1974) mark formed by teeth either alone orin combination with other parts of mouth like tongue[3]. By Beckstead (1979)-imprints caused by the cutting edges of teeth on an object due to closing of the mouth[4.] In cases of sexual assault bite marks are commonly seen in specific body parts as in neck, genitals and breasts. Also in cases of violent fights and child abuse bite marks can be seen on buttocks, shoulder, arms and other areas like that on thighs. Hence cross-matching of bite-marks to an potential assailants dentition may aid the judicial system by solving the criminal cases.

Thus, in order to consider bite-marks as an reliable record of identification requires analysis of a set of peculiar dental features which include[5]; Shape and size of each tooth, Missing tooth, Maxilla-mandibular relationship, Form of the dental arch, Mesiodistal measurement of tooth, Any dental anomalies like as mesidens, paramolars, diastemas, rotation, peglateral, buccoverted or linguoverted and many more.

Classification of Bite-Marks:

Based on Origin[6,7]:

1. Animal bite Marks-caused due to biting of animals.
2. Human bite marks-inflicted by humans itself.

Based on manner of causation[6,7]:

1. **Criminal-**bite-marks seen in any criminal cases of sexual assault or child abuse. They are of two types.
   a. **Offensive bite-marks-**bite-mark made upon the subject by the assailant.
   b. **Defensive bite-marks-**bite-mark made upon the assailant by the victim.
2. **Non-Criminal bitemark-bite-**marks caused by own self or others, eg. Love bites.

Based on the etiology: (by Mc Donald in 1974)[8:]

1. **Tooth Pressure Marks-**bite marks caused by the incisal edges of the anterior teeth.

Corresponding Author:
Rashmi Kumari
Intern, Institute of Dental Sciences, Siksha O Anusandhan Deemed to be University, Bhubaneswar
e-mail: rashmikumari@gmail.com

2. **Tongue Pressure Marks-**caused when ample amount of soft tissue is taken in mouth, the tongue presses it against the hard areas of mouth like the lingual aspect of tooth and the rugae.
3. **Tooth Scrape Marks-**bitemarks due to the irregularities in teeth caused due to fractures or restorations.
4. **Complex BiteMarks-**it is combination of all the above types of bite marks.

Based on the degree of indentation and borders of the bite marks (by Shashikala K in 2003)[9]:

1. **Haemorrhage:** bite marks with a small bleeding point.
2. **Abrasion:** bite marks on skin without any damaging of the overlying skin.
3. **Contusion:** Bite-mark on skin appearing as a bruise due to rupture of the blood vessels.
4. **Laceration:** almost near to damaging of the skin.
5. **Avulsion:** bite marks showing removal of the overlying skin.
6. **Artefact:** bitten off piece of the body.
7. **Clearly Defined-**bite mark resulting from the application of a small magnitude of pressure.
8. **Obviously Defined-**bite mark caused by the application of first degree of pressure.
9. **Quite Noticeable:** bite mark caused due to application of violent pressure leading to laceration of the skin.

Clinical Appearance of Bite-Marks:

Characteristically, human bite-marks appear as a round or oval mark with a central area of contusion bruise or ecchymosis caused by the mandibular and maxillary arches, where ecchymosis being the result of the tongue pressure.[10]

Common Location Sites for Bite-marks: Bite-marks can be found on any body parts with specific sites associated with specific type of assault. According to Pretty and Sweet, in feminine gender bite marks are usually found on the breasts, shoulder and lower extremeties (mostly on inner aspect of thigh) as result of any physical or sexual assault.[2]

In cases of male child abuse, bite marks are usually seen on the genital areas. But as for cases of adult male sexual assaults bite marks are commonly found on phalanges, fore arm, shoulders, as a result of fights in his defense.[11] Also self caused bite marks in adults and adolescence age group people are commonly seen on the inner aspest of Hand.[12,13]

Evidence collection in Bite-mark Analysis: Saliva swabs: A cotton swab wettened with distilled water is used. This hydrates the dried cells in the bitten region. The swab is then dried for about half an hour at normal room temperature and then kept in labelled packets and stored at a temperature of 4^0C in order to prevent DNA rupture and microbial growth.[2]

Double Swab Technique: In this technique first the bitten site is wettened using a wet cotton swab with sterile saline, then drying the bitten site using another dry swab. And both the cotton swabs are sent for the bite-mark analysis.[14]

Bite-mark Photograph: Immediate photographs of the injury sites should be taken because rapid changes occur in appearance due to healing. Both colour and black and white pictures should be taken from various angles.

2 types of photographic views which are used are[2]:

1. Orientation images: depicts the location of bite marks on the body.
2. Close-up images. Images of the bite-marks are taken using chromic photographic films and high resolution cameras.[15]

Impressions of the Bite Injury: Material of choice for impression making is Vinyl Polysiloxane.[16] *Transillumination of the excised bite*-mark in the deceased subject.[17] *Test Bites.*[16]

Method used in Bite-marks Analysis:

1. **Direct Method:** In this method, direct comparison of bite marks on the skin of the subject is done with the dental casts and images obtained from the potential assailant.[18]
2. **Overlays:** Overlays are colourless transparent acetate sheets used to transfer information from the dental cast. Overlays are then used to compare the cutting edges of the assailants bite-mark photography.[2]

3. **3-Dimensional Comparison:** this is one of the most reliable method used now-a-days for bite-mark analysis. This is done using 3-D overlays and geometric morphometric analysis. This method is completely machine controlled.[19]

Softwares in Bite-mark Analysis:

1. **Adobe-Photoshop-Software:** widely used software in bite-mark analysis.[2]
2. **Dental-Print software:** developed by the Dept. Of Forensic Medicine and Forensic Odontology; University of Granada.[20]

Concluding Statements in a Bite-mark Analysis:

By Levine and American Board Of Forensic Odontology (ABFO):[2]

Definite Biter: medical certainty+ bitemark pattern similar to assailant dentition.

Probable Biter: degree of specificity with assailant teeth > matching points

Possible Biter: non-specific match.

Not a Biter: not at all consistent.

Conclusion

Bite-mark analysis, being a newer aspect of Forensic Dentistry, needs to be established as a potent and reliable probe of investigation in the judiciary system. But due to not so advanced technologies and errors while collection of evidence and its analysis and comparison, sometimes results in wrongful accusation of the innocent leading to incorrect verdict in a criminal investigation. Hence it is the utmost need of the time that standard criterion should be developed for evidence collection and comparison of the bite marks.

Alloys Used in Fixed Prosthodontics: An Overview

Debarchita Sarangi[1], Upasana Mohapatra[2]

[1]Assistant Professor, Department of Prosthodontics and Crown & Bridge, [2]Tutor, Department of Pedodontics and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Various types of metals have been used in dentistry, since ages. The properties, manufacturing process, reaction within the oral cavity are to be studied by the clinician to decide a treatment for the patient. Alloys are made of two or more metals. The basis of mixing two metals is to obtain a product that has improved properties, ideal for utilization. Alloys are used as filling materials like amalgam. They are used for all-metal fixed partial denture casting; metal sub-structure for ceramic-veneered fixed partial denture casting;removable partial denture framework casting; in implant body, fixture, component fabrication by manufacturer. The most commonly used alloy now is cobalt-chromium-nickel alloy. This article is a short overview about some commonly used alloys and their applications such as silver-palladium, cobalt-chromium, cobalt-chromium-nickel and also titanium alloys. These are a few among the various alloys formulated. A thorough knowledge about these materials and their properties are necessary by the clinician to obtain a desired outcome. This article shall also highlight the new trends being observed in alloy selection.

Keywords: *Alloy;Casting alloys; Mechanical properties; metallic materials, dentistry, properties.*

Introduction

Alloys are used in fixed prosthodontics for crown, bridge, coping and framework fabrication. These materials are selected on the basis of their reaction in the oral cavity and their mechanical properties. Alloys are a combination of two or more metals in molten metal. Single metals are not used clinically because the properties are not conducive for the physical, chemical and mechanical challenges provided by the oral environment. According to Glossary of prosthodontic Terms, "alloy is a mixture of two or more metals or metalloids that are mutually soluble in the molten state; distinguished as binary, ternary, quaternary, etc., depending on the number of metals within the mixture; alloying elements are added to alter the hardness, strength, and toughness of a metallic element, thus obtaining properties not found in a pure metal; alloys may also be classified on the basis of their behavior when solidified."[1]

Dental service can be rendered by a team of dentists, dental assistants and dental lab technicians with the help of dental materials. Metals are indirect restorative dental materials. The primary goal of dentistry is to maintain or improve the oral health of the patient, which includes a variety of dental materials. Dental casting alloys must satisfy certain criteria, which must be a balance of factors that influence its application. It is therefore important to know the properties of dental materials, in order to understand their behavior in the oral cavity and predict the outcome of the patient's health.

Review of Literature: Metallic alloys being used in dentistry have been classified according to presence of noble metals in them. Highly noble alloys contain precious metals like Gold, Silver, Palladium, etc. and are used used for full-metal prostheses, Metal substructures for ceramic layering and also partial denture framework. These contain higher percentage of gold. Noble metal alloys such as Silver-palladium alloys contain precious metals also, but the percentage of precious metals are lower. These alloys are mostly used for substructure and full metal fixed dental prostheses. Predominantly base metal alloys including cobalt-chromium, cobalt-chromium-nickel, titanium alloys are also used for full-metal prostheses, Metal substructures for ceramic layering and also partial denture framework.

Four most common alloys have been discussed in the following:

Gold alloys: Gold is one of the oldest metals used in dentistry. Gold has been used in fabrication of inlays and onlays; post–cores; crowns and bridges; implantology also. Earlier, casting was the major process for gold fabrication. " Lost wax technique " is employed in casting. Nowadays, galvanoforming is also being utilized for gold. Mostly, gold sub-structures for ceramic layering are prepared for fixed prosthesis, utilizing electrolysis process. This method makes the gold framework or sub-structure fracture-resistant, as compared to those fabricated by traditional casting method.[2]

Silver-palladium alloys: This alloy contains precious metals other than gold. Zinc, copper, Manganese, etc. are added to improve the strength of the alloy. Castability and ceramic-binding properties are improved by adding ruthenium and indium, respectively. This material is grey in color due to its silver content.[3,4] These are used for mostly as sub-structure material.

Cobalt chromium alloys: This is a base-metal alloy. The use of Co-Cr-based alloys for metal ceramic applications was first mentioned in the 1959 Weinstein patent for dental porcelain. This alloy is very economical, though it requires technical set-up for being casted. These are used for Removable Partial denture framework casting, for metal substructure; metal prosthesis for fixed dental prosthesis. This alloy was first called " Stellite" due to its metallic luster.[4,5]

Cobalt-Chromium–Nickel alloys: These alloys have been launched in the 1950's. Their typical chemical composition is: 40% Co, 20% Cr, 15% Ni, 15.8% Fe, 7% Mo, 2% Mn, 0.16% C and 0.04% Be. They have excellent resistance to corrosion and tarnishing. Hardness, yield strength and tensile strength are the same as for stainless steel, while the ductility is higher in softened condition, but it is less after hardening. In addition, it provides the corrosion resistance and allows the elasticity and toughness to alloys. However, nickel is not completely safe for the patient's health, especially for the female population, because it can cause allergies and dermatitis.[4,5]

Titanium alloys: Titanium has been the most popular metal in dentistry for use in implants. Pure form of titanium has also been used in restorations and have been fabricated by casting procedure. A special type of ceramic is being used for the same because it requires less fusion temperature. Titanium to ceramic bond is still questionable as the bond-strength is lower than Nickel chromium bond with ceramic. But, shear strength is better than Gold-ceramic bond.[6,7,8]

Discussion

In-vitro studies on nickel-chromium and even gold alloys conclude that there have been traces of cytotoxic materials being released into the oral cavity. Pure gold is non-toxic in nature. But, gold alloy may release some harmful substances. Thus, gold should not be considered completely bio-compatible by practitioners.[9]

There are multiple options in nonprecious or basemetal alloys for prostheses fabrication, other than those used for implants. Titanium alloys and Cobalt-chromium alloys have the advantage of being corrosion-resistant in the complex oral environment. Research for new materials are being done for better materials.[6,10] Titanium is now being viewed as a versatile material and many studies are being done to prove the same.Its properties make it conducive not only for implantology, but also for use in removable and fixed dental prostheses fabrication. Among all metallic dental materials available, titanium alloys are very much preferable due to better properties and their biocompatibility.[11,12]

Conclusion

With so many materials and newer ones coming up, the dentist should have in-depth knowledge about alloys; their properties; composition of the indicated alloy. It is preferable to use materials that are backed by research and are produced by trust-worthy manufacturers. Knowledge about any allergic content or proper evaluation of patient-history should be done before prescribing a particular material for a patient. Accordingly, instruction should be given to the laboratory technician. Co-ordination of knowledge and application can bring out desired results.

Cantilever Fixed Dental Prosthesis on Periodontally Treated Abutment: A Case Report

Debarchita Sarangi[1], Mohit Das[2], Abhaya Chandra Das[3], Manoj Kumar[3], Rinkee Mohanty[4]

[1]Assistant Professor, Department of Prosthodontics and Crown & Bridge, [2]PG Student, Department of Periodontics and Implantology, [3]Reader, Department of Periodontics and Implantology, [4]Professor and Head of the Department, Department of Periodontics and Implantology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Cantilever fixed dental prosthesis is a popular choice of treatment in ideal cases with missing lateral incisors, after implants. Prosthodontic evaluation of edentulous area and abutment teeth/tooth; periodontal evaluation and endodontic evaluation of abutment teeth should precede the treatment planning. This article is a case-report of a rehabilitation of a missing lateral incisor with cantilever fixed dental prosthesis following periodontal therapy of canine which was used as abutment tooth.

Keywords: *Biomechanics, Crown-To-Root Ratio, Mobility, Periodontally Compromised Dentition.*

Introduction

According to Glossary of Prosthodontic Terms," cantilever is a projecting beam or member supported on one end cantilever bridge. Cantilever fixed dental Prosthesis is a fixed complete or partial denture in which the pontic is cantilevered and retained and supported by one or more abutments."[1] Goldfogel and Lambert described the design for cantilever fixed dental prosthesis for replacing missing maxillary lateral incisor, with canine as abutment. [2]

Various factors determine the success of these kind of prosthesis. Periodontal condition of abutment tooth is one of them. Besides, prosthodontic factors, periodontal factors should be evaluated for proper treatment planning which would lead to good prognosis of the cantilever prosthesis.

Clinical Report: A forty-two years old female patient reported in Department of Prosthodontics and Crown & Bridge, Institute of Dental Sciences, Bhubaneswar with the chief complaint of missing right lateral incisor and she wanted replacement of the same tooth. Patient also informed that she was conscious even to smile and speak because her front tooth was missing. The reason for tooth loss was trauma. Period of edentulism was for more than five years and patient was using a temporary partial denture for more than two years. There was no relevant medical history. The intra-oral examination was done. Figure 1 shows the pre-operative Ortho Pantomo Graph. There was missing maxillary right lateral incisor and presence of generalized deposition of plaque, calculus, extrinsic stains with periodontal pockets in some regions. Figure 2 shows the pre-operative photograph of the patient. Thus, she was referred for periodontic consultation.

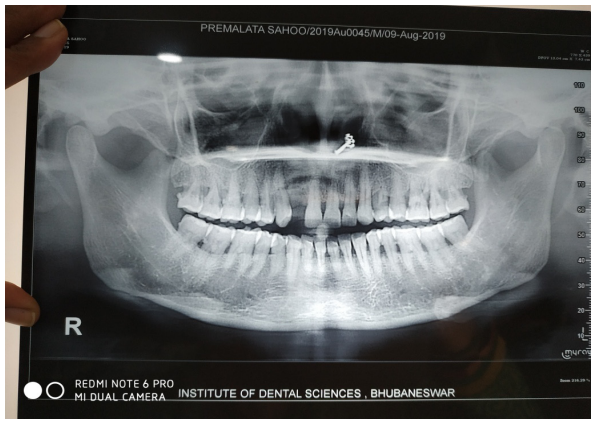

Figure 1: Pre-operative Ortho Pantomo Graph

Cooresponding Author:
Dr. Debarchita Sarangi
Assistant Professor, Department of Prosthodontics and Crown & Bridge, Institute of Dental Sciences, Bhubaneswar
e-mail: debarchitasarangi@soa.ac.in

Fig 2: Pre-operative probing depth of maxillary right canine

On examination, the patient had minimal deposits with generalized subgingival calculus in the first quadrant. Bleeding on probing was present with respect to all the teeth in the first quadrant. The upper right canine was found to be grade II mobile according to Glickmann's classification and slightly mesially drifted with a 8mm deep periodontal pocket on its distoproximal aspect. On examination of the rest of the sites of the first quadrant, generalized periodontal pockets were found. The first premolar had a pocket depth of 5mm on both the disto and mesioproximal aspects, the second premolar had a pocket depth of 5mm interproximally, first and the second molar with a pocket depth of 6 mm each interproximally. Endodontic consultation was taken to rule out any pulpal pathology. Radiographic evaluation revealed generalized horizontal bone defect extending upto the middle third of the root with generalized radiopacity in the interproximal areas suggestive of flecks of subgingival calculus. There was no medical or family history associated. Patient had no adverse habits like smoking, drinking or parafunctional habits like bruxism or tongue thrusting. Patient had a history of extraction of the lateral incisor in the first quadrant (time period). A preliminary diagnosis of generalized Stage III Grade B Periodontitis was made according to 2017 World Workshop Periodontology. Clinical pictures were taken and it was decided to begin with the phase I periodontal therapy which included scaling and root planing followed by oral hygiene instructions which included brushing technique. Once the Phase I therapy was over, patient was recalled after 4 weeks for re-evaluation of plaque, calculus and loss of attachment. On reevaluation after 4 weeks it was found that there was persistence of residual pockets and loss of attachment. However, the patient's oral hygiene was maintained with minimal plaque and calculus. Therefore, the decision to initiate phase II periodontal therapy was taken to gain attachment as the primary objective. Open flap debridement using Kirkland flap was done under local anesthesia. Osteoplasty was done to achieve proper bone contour. Then the flap was re-approximated and sutured with 4-0 Mersilk sutures. Post surgical instructions were given to the patient and medications were advised to the patient and the patient was recalled after 1 week for suture removal. The sutures were removed after a week, and the patient was placed on a maintenance and recall program, which included a recall visit every 2 weeks for first 1-month followed by every 3 weeks for 3 months postoperatively. At the end of three months 5mm of attachment gain was seen with respect to the canine with no mobility and an attachment gain of 3mm was seen with respect to the other teeth in the quadrant, as seen in figure 3.

Fig 3: Post-operative probing depth of maxillary right canine after 3 months follow-up

Patient was then referred to address the chief complaint in department of prosthodontics. All the treatment options ranging from Removable dental prosthesis, fixed dental prosthesis and also implant therapy was also explained to the patient. Occlusion was found to the canine-protected. Implant therapy option was eliminated because patient did not find it economical. Since, patient was using a removable prosthesis, she informed that she was unsatisfied with the same and wanted a fixed option. She was explained about conventional, cantilever and resin bonded bridge. A conservative approach for the treatment was followed. A canine-supported cantilever prosthesis was finalized, as canine has the longest root and the improved periodontal condition of the the canine also improved the prognosis.

The edentulous area classification had Siebert's class 2 defect. Vital tooth preparation for porcelain-fused to metal crown was done in 13 with shoulder finish line, under local anaesthesia. Alginate impression was made for provisionalization and final fixed denture prosthesis. Shade of prepared tooth structure and adjacent tooth was selected. Self-cure, tooth colored provisionals were prepared in the institute laboratory immediately. Occlusal adjustments were done with occlusal contact of the lateral incisor pontic with the opposing tooth and they were luted with Zinc-oxide eugenol cement. Patient was recalled after 7 days for the final prosthesis. The bisque trial was done. Occlusal adjustments with articulating paper was made and labial contour was checked. Then, the prosthesis was glazed and luted with Glass Ionomer Cement. Post-insertion instruction were given to the patient and she was recalled for a follow-up after 24 hours and 7 days. **Figure 4 and 5 show the post-operative pictures**. Patient had esthetic demand and was satisfied with the treatment outcome.

Fig 4: Labial view after luting of final prosthesis

Fig 5: Labial view after luting of final prosthesis

Discussion

Canine has the longest roots. This is the reason why canines are being used as abutment for cantilever prosthesis to replace missing lateral incisors.[3] The crown–root ratio represents the bio-mechanical and periodontal status of the tooth. The crown-root ratio was adequate to provide support to pontic i.e. lateral incisor which is a much smaller tooth.[4,5,6, 7,8] Cantilever FDPs usually should utilize two abutments, but in case of missing lateral incisor, canine provides adequate support.[9,10] Ovate pontic was used because of its esthetics in anterior region and for maintenance of good oral hygiene.[11,12]

Conclusion

Cantilever prosthesis is preferred over removable prosthesis, as it is more comfortable to patient and is a fixed prosthesis, in all age groups. It requires less follow-up and comparatively less patient compliance. The periodontal condition and alveolar support of abutment teeth or tooth should be properly evaluated. Vital teeth/tooth as abutment are more beneficial than non-vital ones. Though, implants are the best options to replace single missing tooth, time and financial factors play an important role. There-fore, it is upto the clinician to conduct proper intra-oral examination with ideal abutment, crown-root ratio, periodontal condition, edentulous area for a good treatment outcome of the selected prosthesis type.

Diagnosis of Impacted Canine: An Overview

Sashikant Sethi[1], Subhrajeet Narayan Sahoo[2]

[1]Tutor, Department of Public Health Dentistry, [2]Assistant Professor, Department of Orthodontics and Dentofacial Orthopaedics, Institute of Dental Sciences, Siksha' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Impaction of maxillary and mandibular canines is a frequently encountered clinical problem, the treatment of which usually requires an interdisciplinary approach. Surgical exposure of the impacted tooth and the complex orthodontic mechanisms that are applied to align the tooth into the arch may lead to varying amounts of damage to the supporting structures of the tooth, not to mention the long treatment duration and the financial burden to the patient. Hence, it seems worthwhile to focus on the means of early diagnosis and interception of this clinical situation. In the present article, an overview of the incidence and sequelae, as well as the surgical, periodontal, and orthodontic considerations in the management of impacted canines is presented.

Keywords: *Diagnosis, etiology, impacted canines, orthodontic techniques, prevention, surgical techniques.*

Introduction

The treatment of impacted teeth has caught the imagination of many in dental profession. However, the orthodontic/surgical modality has achieved the most satisfactory result in long-term. Order of teeth getting impacted: Mandibular third molar, Maxillary canine, Mandibular second premolar

Canine playing an important role in esthetics, being corner tooth of mouth and function deserves special attention for its impaction to be properly diagnosed and managed[1].

When Can A Tooth Considered To Be Impacted?: Under normal conditions, tooth erupts with a developing root and with approximately ¾ of its final root length. Hence in simple terms, a tooth can be considered impacted if its root is completed but still has not erupted. Applying this concept to maxillary and mandibular canines, they generally have their ¾ root completed by 11-12 yrs and 9-10 yrs respectively. According to Shafer, Hine and Levy, Impacted teeth are those which are prevented from erupting by some physical barrier in the eruption path[2]."

Incidence: Dachi and Howell reported that the incidence of maxillary canine impaction is 0.92%, and mandibular canine impaction is 0.35%. Asians present more of buccal canine impactions. Impactions are twice as common in females (1.17%) as in males (0.51%). Of all patients with maxillary impacted canines, it is estimated that 8% have bilateral impactions[3].

Etiology

Generalized Factors

Endocrine deficiencies,

Febrile diseases, and

Irradiation.

Localized factors

Tooth size-arch length discrepancies,

Prolonged retention or early loss of the deciduous canine,

Abnormal position of the tooth bud,

The presence of an alveolar cleft,

Ankylosis,

Cystic or Neoplastic formation,

Dilaceration of the root,

Iatrogenic origin and

Idiopathic condition with no apparent cause

Theories Put Forth for Maxillary Canine Impactions[4,5]:

1. **Long path of eruption:** This theory was believed during the early days of Broadbent in 1940. This was the most common reason been given those days. Tooth had much to travel from floor of orbit to oral cavity, hence had greater chances of "losing its way".
2. **Crowding:** Acc. to Hitchson in 1956, crowding could have been the major cause for buccal canine impaction. He stated that developmental position of lateral incisor and 1st PM is palatal to line of arch, and the canines are the last teeth to erupt. Hence due to inadequacy of space end up in being blocked.
3. **Non-Resorption Of Root Of Deciduous Teeth:** Lappin in 1951 believed that it was failure of the resorption of root of deciduous teeth which led to palatal deflection of eruption path of permanent canine which led to its impaction. Many authors have done subsequent studies supporting spontaneous eruption of previously impacted canines, following extraction of deciduous canine. Critics of this theory state a simple clinical evidence–" presence and advancing eruption of the permanent tooth provides a stimulus for resorption, and a portion of root distant from unerupted permanent tooth may be unaffected by the process."
4. **Trauma:** Acc. to Brin et al in 1993 trauma to the permanent erupting canine by following ways could lead to its impaction.
   - May cause movement of lateral incisor
   - By conduction, movement of canine bud itself
   - Shortness of lateral incisor root, whose development ceased as a result of trauma.
5. **Presence of chronic irritation:** Fearne in 1988 correlated chronic irritation in the form of inflammation associated with deciduous canines as the reason for impaction.
6. **Peg Laterals:** Becker et al in a study done in 1981 found small lateral incisors were found to be 8 times more frequent and peg laterals 9 times more frequent in palatal impacted canine cases as compared with normal population. Anomalous small and peg shaped laterals develop much later than normal laterals.
7. **Guidance Theory of Miller:** Miller in 1963 found prevalence of impacted canines to be high with congenitally missing lateral incisors. Permanent canines lack the normal guidance provided by the distal aspect of lateral incisors.
8. **Heredity:** Zilberman et al in 1990 studied familial trends in palatal canines and anomalous lateral incisors and found that prevalence of small peg shaped and missing lateral incisors, late developing dentitions and other missing teeth among close relatives were very high in addition to palatally impacted canines.This states impacted palatal canines to have a genetic cause.

Complications of Untreated Impacted Canines[6,7]

A. **Morbidity of deciduous canine:** Root of the deciduous counterpart is resorbed and small leading to eventual mobility and shedding.Deciduous canines also exhibit high susceptibility to caries.

B. **Cystic change:** Loss of vitality of deciduous canine leads to development of periapical pathology at the root apex which being in close proximity with the follicular sac of erupting permanent canine communicates with it leading to its enlargement and ultimate result being an cystic change.

C. **Permanent canine crown resorption:** Long standing impacted canine as seen in the figure may lead to degeneration of the reduced enamel epithelium (REE), which brings the enamel in direct contact with the surrounding bone which generates an osteoclastic reaction leading to replacement resorption of the permanent canine. In few years the radio opacity of bone and the impacted canine appear to be almost same and indistinguishable.

D. **Resorption of roots of adjacent teeth:** Brin et al in 1993 studied the resorption of roots of lateral incisors adjacent to impacted canines and concluded the resorption to have rapid onset and an aggressive conduct.

Diagnosis: Impacted canines can be diagnosed and localized by following a routine clinical examination[8,9]

Inspection: Following points should raise suspicions of an impacted tooth: Non-appearance of permanent canine clinically by its eruption age. Presence of antimere. Presence of anterior spacing for a long period. Persistent median diastema. Abnormal morphology of lateral incisor or presence of peg laterals. Improper angulations of adjacent teeth.

Palpation: Bulge of per. canine could be palpated buccally above the deciduous canine 2-3 yrs before its eruption. It should be palpated deep above attached gingiva in the sulcus where mucosa reflects. Deciduous canine should be checked for mobility. Palpation should be done in abnormal locations after getting clue from inspection.

Radiography: After getting clues from inspection and palpation, next step would be to localize the impacted canine in order to plan a treatment[10].

Radiographs can be classified as

Periapical view: First simplest and most informative view

Advantages

1. Root development, pattern and integrity
2. Crown resorption
3. Root resorption of adjacent tooth
4. Minimum of surrounding tissue is exposed which increase accuracy and resolution.
5. Minimal radiation exposure

Disadvantage:

1. 2D picture of 3D object
2. Cannot determine bucco-lingual posn of tooth & vertical position of impacted tooth.

Maxillary anterior occlusal: Does not show exact cross section of anterior teeth making it difficult to find bucco-lingual position of impacted teeth.

Maxillary true (vertex) occlusal: X-ray beam runs parallel to long axis of incisors. It is possible to get cross section of anteriors. It allows for exact localisation of bucco-lingual position of impacted canines.

Maxillary true (vertex) occlusal ONG'S Projection: An alternative technique was given by Ong in 1994. Extra-oral technique for vertex occlusal view was given which had advantages:

1. to increase clarity
2. reduction in exposure was found due to use of intensifying screen.

Mandibular Occlusal: To determine bucco-lingual position of the impacted tooth in 2 regions:

1. **90° to OP**–cross-section of premolar, molar region
2. **110° to OP**–cross-section of incisor region

Lateral Cephalogram: Periapical views can be misleading to determine vertical position of canine. A lateral cephalogram gives an accurate location of canine in vertical and saggittal plane.

OPG: Chaushu et al in 1999 gave a method to localize the impacted maxillary canine using single orthopantomogram. When mesio distal width of canine crown was 1.5 times larger (i.e. 15% larger) than the adjacent central incisor, then the canine is palatally placed This is only true in cases where canine should not be at a higher level.

Tube shift technique or Clarke technique (Parallax Method)[11]: It was given by CLARK in 1909. It is based on binocular principle.

Disadvantage: In cases when canine is highly placed and Periapical film shows no superimposition of canine with the roots of erupted tooth or when superimposition is only in the periapical region the result may be misleading.

Vertical Tube Shift Method: Left canine is highly placed in OPG. In IOPA left canine moves towards apical 1/3 of lateral incisor. Left canine is labially placed, as it moves in opp. direction of tube shift.

Radiographic Views at Right Angles: Similarly any two views taken at right angles can help in 3-D localisation. For e.g. lateral cephalogram & a frontal cephalogram.

2. mandibular posterior periapical film & a true occlusal film.

CT Scan: The above mentioned plain film method are inadequate in fully describing 3D location and relationship to adjacent structures particularly in B-L plane and relation to adjacent teeth roots.

These shortcomings are taken care of by CT scan and newly introduced CBCT.

Disadvantage:

1. Expensive.

2. Increased radiation exposure than any other method.

Rapid Prototyping: In 2006 Faber et al published a new tool for diagnosis and treatment planning of impacted canines which made it possible to construct 3D prototypes of the impacted tooth and allowed to fabricate customized attachments for its traction.

Classification Of Palatally Impacted Canine[12]: Based on two variables:

1. Transverse relationship of the crown of the tooth to the line of dental arch which may be

   (a) Close

   (b) Distant (nearer the midline)

2 Height of the crown of the teeth in relation to the occlusal plane which may be

   (a) High

   (b) Low

Group 1: Proximity to the line of arch–close.

Position in the maxilla–low.

Group 2: Proximity to the line of arch–close.

Position in the maxilla–forward, low & mesial to the lateral incisor root.

Group 3: Proximity to the line of arch–close.

Position in the maxilla-high.

Group 4: Proximity to the line of arch-distant.

Position in the maxilla high.

Group 5: Canine root apex mesial to that of lateral incisor or distal to that of first premolar.

Group 6: Erupting in the line of arch in place and resorbing the roots of incisors.

Conclusion

The management of the severely impacted canine is often a complex undertaking and requires the joint expertise of a number of clinicians. It is important that these clinicians communicate with each other to provide the patient with an optimal treatment plan based on scientific rational.

Cleft Lip and Cleft Palate: A Review

Shreya Kotish

Post Graduate Student, Department of Orthodontics And Dentofacial Orthopedics, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar

Abstract

Cleft Lip and Palate is one of the most common facial deformity that occurs in 1 in 1000 newborns. This congenital deformity occurs mainly due to some defects in genes or is teratogenic or occurs due to some unknown cause. However, cleft lip and palate can be detected during 3rd week on the intrauterine life. It not only effects the aesthetics, speech and impaired hearing or feeding but also effects the growth of maxilla, proper functioning of the facial muscles, eruption of teeth and the arch form of the palate.

Keywords: *Cleft Lip, Cleft Palate, Embryology.*

Introduction

The first description of cleft lip and palate dates back to several centuries where it was illustrated in the form of oil paintings, drawings and sculptures. The first time ever cleft lip was illustrated in the field of medicine was in 1564 Abroise Pare, in which he showed pin and "figure of eight" suture in the treated patients of cleft. Clefts, particularly of lip with or without involvement of palate (CLP) that are non-syndromic, Isolated Cleft Palate (ICP), are the most common facial deformity that affect newborns worldwide. The large impact of this defectare on the growth of face, various roles performed by the structures and social incorporation which makes them the major health problem worldwide[1].

The environmental factors contributing to this anomaly has been proven but the genetic factors responsible for the development of this facial deformity is still been studied.

Epidemiology of "Cleft lip and Palate": Cleft lip affects more males and cleft palate affects more female. The occurrence of cleft lip and palate have been seen highly dependent onethnicity, which occurs maximum in Asian population and Native Americans, then in Caucasians, the minimum chance of occurrence is in African American populations. Unilateral clefts accounts of more 80% when compared to bilateral that accounts for merely 20%. In Unilateral Clefts, left side are more commonly seen[2].

Aetiology of Cleft Lip and Palate

1. Heredity (Genetic predisposition).
2. Lack of nutrition or impaired nutrition supply
3. "Physiologic", "Emotional" and "Traumatic" stresses during development
4. Impaired blood supply to the affected area
5. Mechanical disturbances (Tongue size may interfere)
6. Effect of certain drugs ("Aminopterin", "Cortison", "Thalidomide", "Anticancer Drugs" etc.)
7. Alcohol consumption during pregnancy
8. Radiation exposure
9. Lack of inherent forces that are responsible for development
10. Infection
11. Smoking during pregnancy

12. Syndromes Associated with cleft lip and palate

    ("Down's Syndrome", "Wardenburg's syndrome", "Vande Woude's Syndrome", ":Orofacial digital syndrome", etc.)

Issues faced by the patients of cleft lip and palate

1. Issues with feeding: New born babies with "Cleft lip and palate" does not have the ability to form the mouth seal, so they cannot breastfeed or or use nursing bottles for feeding
2. Problems with speaking: Majorly, in the older age group with untreated "cleft palate" the words that requires the nose for pronunciation are not clearly heard. However, with speech therapy and early surgical intervention this problem is solved.
3. Problems associated with auditory canal: In "Cleft lip and Cleft palate patients" there is continuous collection and secretion of pus in the auditory canal, which results in impaired hearing abilities of the patient.
4. Orodental Problems: During the eruption of teeth in these patients, the teeth is aligned properly in the arches, due to which there is collection of food debris and plaque as the brush cannot approach such areas. This can cause periodontal problems and endodontic problems.

The best way to prevent these issues are surgical repair, regular therapies of the patient and also making the parents aware of the problems[3].

"Embryology of cleft lip and palate"

"The Cleft Lip": The 1st, 2nd and 3rd branchial arches has a contribution in the growth of the face, mouth and tongue. At 24th day of intrauterine life the" frontonasal process" can be appreciated, which is surrounded on every side by "maxillary processes". At end of 4th week there is a two-pronged oval-shaped thickening of the surface ectoderm (called as"nasal placodes") that grow on every side of the inferior part of "frontal prominence". After this, the relocation of neural crest cells into region of front-nasal and the area where the "maxillary prominences" will grow. It results in proliferation of the mesenchyme to proliferate at the margins of the nasal placodes, resulting in the formation of the horseshoe-shape "medial nasal process and lateral nasalprocesses[4]."

Now, the "maxillary process"grows medially and shortly move towards both the" medial nasal process" and "lateral nasal processes". After this, these three processes grow downward and forward but the way they interfere and harmonize is still not understood.[1.] The "maxillary prominences" now shows growth in the medial direction which pushes the medial nasal process in the direction of midline, and fuses with its matching part from the contrary side, eradicating the "fronto-nasal process", which occurs around 6th week of the intrauterine life. Along with this undergoing procedure the "medial nasal prominences" joins together and take the shape of the "inter-maxillary segment". This segment gives grows into the middle portion of the upper lip also called as "philtrum", as well as the primary palate.

When the "placodes" are placed close to the midline in an abnormal way, it could result in the formation of clefts on the face. Also when the medial nasal process and the lateralnasal process looses the ability to grow, it prevents its fusion and forms clefts in between itsderivatives.[2] In minor situations, the clefts may be restricted to the "vermillion border of the upper lip". In more major situations, the the tissue of the lip develops unilateral or bilateral cleft lip, and may sometimes engage the side of the nose (obliqueclefts)[5].

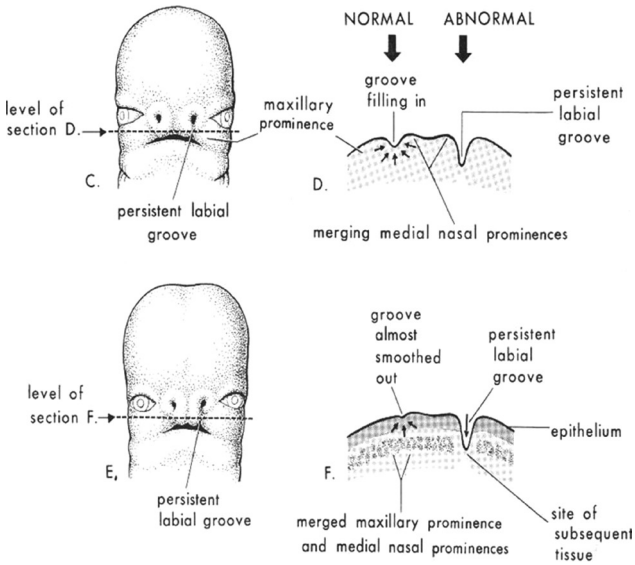

Figure 1. The development of "cleft lip"

"Cleft Palate": The initiation of development of secondary palate occurs at around 6th to 7th week of the intra-uterine life from the Secondary palate begins to develop in the sixth week from the projections of the maxillary processes, referred as the palatal shelves or lateral palatine processes. In the beginning, the shelves are positioned in the vertical direction on both the sides of the tongue that is still developing, however, with the growth of mandible in the downward direction, the

shelves acquire a horizontal position so that they can move towards each other. These shelves then fuse the with the primary palate. There are certain intrinsic forces that elevate the shelves, which are in turn are produced by the hydration of hyaluronan,[3]which are produced by the collagen fibers, the mesenchymall cellsand contractive forces within thepalate.

During the 9th week of the intra-uterine life the palate begins to fuse anteriorly, which on the 12th week of the intra-uterine life is completed with the posterior merging of the palate.During this undergoing fusion, there is epithelial apoptosis, immigration or alteration and results in mesenchymal permanence.[4.] The outer epidermal layer is shed off which occurs before there is fusion of the shelves and the basal epithelial layer is what remains behind. Shelves shows development in the direction of midline and each palatal shelf approaches towards each other and forms the midline epithelial seam, which is later on sloughed off., leading to convergence of these 2 shelves.

Alterations caused by"genes","mechanical", or "teratogenic" factors can occur at any of the step of palate development, and may result in a cleft palate[2]. The most important cause of the development of cleft palate is failure of tongue to descend and allow the "palatal shelves" to fuse. This occurs because of progressive action of "musculature", this includes, opening of the jaw and forward positioning of the tongue, and the way the lower jaw grows.

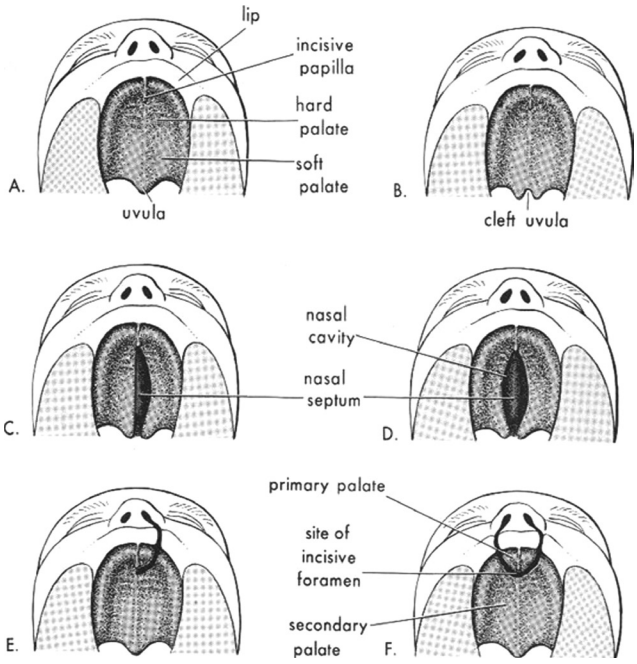

Figure 2. Development of "cleft lip and palate"

Diagnosis

Most cases of "cleft lip and cleft palate" are easily seen right after birth and doesn't need any tests for the diagnosis. However, the tests to confirm the presence of this anomaly is ultrasound before the baby is born.

Ultrasound before birth: A prenatal ultrasound is a test that uses sound waves to create pictures of the developing foetus. When we view the pictures, a doctor may observe a variations in the structures of the face."Cleft lip" may be diagnosed using ultrasound beginning around the 13th week of the pregnancy. As the foetus continues to develop, it becomes easier to diagnose the cases of Cleft Lip. However, the diagnosis of Cleft palate by the means of ultrasound is more difficult to diagnose using the ultrasound[5,6].

If prenatal ultrasound confirms the presence of cleft, your doctor may a ask you to undergo a procedurein which the sample of amniotic fluid from your uterus (amniocentesis)is taken. The fluid test may further confirm the presence of Cleft lip and cleft palate and various other inherited syndromes that can cause defects to the newborn.

Effects :f Clefting[7,8]

The Effect of Cleft Lip and Palate on the palatal arch form

There exists a stability between forces generated by the muscles of tongue and face.

a. The superficial zone of muscles, the orbicularis oris, buccinator, and superior constrictor muscles together form a ring which exhibit compressive forces on the palatal and mandibular arches as well as the teeth.

b. Tongue exerts the forces of expansion on the teeth and arches

The alignment of the teeth is determined by the above two factors.By cleft formation the ring of stability formed by orbicularis oris-buccinator-superior constrictor muscles changes the mechanism of force application which displaces the tissue masses.

Effect on Tensor Veli Palatini and Eustachian Tube: Due to clefting, the mechanism of action of tensor veli palatini muscle on the Eustachian tube (which is mostly dilatory) results in recurrent otitis media with effusion.[5.]

Effect on Teeth Eruption:

- Delay in dental development or tooth eruption
- Multiple supernumerary teeth
- The teeth that are present close to the cleft area are seen to erupt late when compared to the teeth that are resent away.

Figure 3. Cephalogram showing effect of clefting on dentition

Psycosocial Effects of Clefting: The patient of "Cleft Lip and Palate" who suffers from phycological or psycosocial problems are very difficult to identify. The surgery solves the aesthetics but the emotional damage done is very difficult to cure. The studies have been done in this field but are not so significant that can make us understand the reality behind this issue. More studies are required, in which the studies are done on the members of family and not only on the patient[9,10].

Treatment: Cleft lip and cleft palate treatment aims to improve ability of a child to eat, to speak and hear and to have a appearance of the face close to or absolutely normal.

A team of doctors and experts are required to completely treat the patients of "Cleft lip and palate", this team includes

- Surgeons: plastic surgeons or ENTs
- Oral surgeons
- Ear, nose and throat doctors (ENTs, also called otorhinolaryngologists)
- Pediatricians
- Pediatric dentists
- Orthodontists
- Nurses
- Specialists inn hearing and auditory
- Speech therapists
- Genetic counselors
- Social workers
- Psychologists

Surgery: Surgery in the correction of "Cleft lip and palate" totally depends upon the current situation of the child while he/she is undergoing surgery. After the "cleft repair" is done, the appointed doctor might recommend the patient to various following surgeries that helps in improving the speech and appearance of lips and nose[11].

The order in which the surgery occurs is as follows:

- Cleft lip repair – within the first 3 to 6 months of age
- Cleft palate repair – by the age of 12 months, or earlier if possible
- Follow-up surgeries – between age 2 and late teen years

The surgery occurs under General anaesthesia. Several various surgical procedures are available that are used to surgically repair "cleft lip and Cleft palate", to rehabilitate the areas that are affected (eg. Surgery to repair the ear tube) and also to prevent any issues that might occur after the surgery)[12].Surgery can significantly enhance aesthetics of the patient, quality of life, and ability to eat, breathe and talk.

Possible risks of surgery

Possible risks that might occur in patients after surgery. Some complications ate:

- Bleedingat the surgical site
- Infection of the treated area
- poor healing of the wound
- widening or elevation of scars
- and temporary or permanent damage to nerves, blood vessels or other

Conclusion

Orofacial clefts mainly cleft lip and palate is the second most common developmental anomaly affecting new born. For the proper treatment and restoring the normal profile of the patient, the deep study of the embryology plays very important role. Though, late treatment of it is possible but as early as possible the treatment occurs, it would serve to be the boon to the patients and family members. However, deeper study on the effect of cleft lip and palate on the psychology of patient and response of the family is required. The post surgical treatment should involve the speech therapy and the regular appointments of the patient and family members with psychiatrist for the moral upliftment. The entire team is responsible for the success of the treatment, the team includes: dentists (An orthodontist, endodontist and Oral surgeon), psychiatrist, actively participating family members and the always positive patient. The parents of the patient should keep a lot of patience, as the treatment time with proper result is long i.e. 18-19 years.

Altered Microflora in Orthodontic Patients

Sumita Mishra[1], Lipika Mali[2]

[1]Associate Professor, [2]Post-Graduate Trainee, Department of Orthodontics & Dentofacial Orthopaedics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneshwar, India

Abstract

Oral/Sub gingival micro biota is always affected by Orthodontic therapy. Presence of appliances in the mouth might be accompanied with a higher incidence to caries and might cause inflammation of the periodontal tissues. Various researches have shown that the presence of orthodontic appliances in the oral cavity can alter the basic nature of dental plaque that would increase in the microbial population, mainly Streptococcus and Lactobacillus. It has been observed that fixed appliances causes difficulty in maintaining oral hygiene, due to which the sub ginival microbiota is also affected, since presence of appliance favors bacterial plaque to hold on to the surface. This leads to bacterial colonization that is accountable for the inflammation of the gingiva and also for the destruction of the periodontium and alteration in the enamel surface. Therefore, instructions for oral hygiene maintenance are essential in all cases of orthodontic therapy.

Keywords: *Oral micro biota, fixed orthodontic appliances, altered micro biota, oral hygiene.*

Introduction

Health of the periodontium is of utmost importance in all age group and needs proper examination before beginning with the Orthodontic therapy. Maintaining the periodontiumis one amongst many goals of the Orthodontist, which has led to the introduction of specific oral hygiene maintenance protocols for those undergoing orthodontic treatment.

Various studies have found that orthodontic appliances in the oral cavity of patients alter the nature of dental plaque causing changes in its basic structure, metabolic activity and the composition. There has also been found an increase in the microbial population, mainly Streptococcus and Lactobacillus.[1]

The sub gingival microbial environment is also altered by presence of any Orthodontic appliance in the mouth allowing accumulation of plaque and deepening of the gingival sulcus.[2]

e-mail: sumita.mitali@gmail.com

Lack of adequate oral hygiene maintenance during Orthodontic therapy is followed by various consequences such as formation of dental caries and periodontal diseases. Presence of appliances in the oral cavity creates retentive sites favorable for accumulation of plaque and inflammation.

Normal Oral Micro Biota: The oral cavity comprises of various surfaces, coated with abundance of bacteria, also called as the bacterial bio film. Among all these bacteria, few of these bacteria have been detected in contribution of various oral diseases such as dental caries and periodontitis. It has been a known fact that oral bacteria colonize in various surfaces in the oral cavity because of presence of specific adhesins on the surface of bacteria that binds to the specific receptors on a given oral surface.[3]

Saliva of an adult human contains about 6 billion microorganisms per mililitre such as Streptococci, Peptostreptococci, Neisseria, Nocardia, Fusobacterium, Bacteroides, Lactobacilli, Veillonella, Corynebacterium Actinomyces, Spirochaetes, Yeasts, Protozoa, etc. Various studies indicate that saliva comprises of 47% streptococci, 21% to 55% of the facultative streptococci on the tongue, and 10% of the facultative streptococci on the cheek. S. sanguis has found to be predominantly present streptococci in early plaque form on the teeth surface. It contributes to only a minor portion of the oral

microflora in the cavity. Hence, dental plaque is not the major contributor to the salivary micro flora, but the main source appears to be the tongue.[4]

Altered Microflora During Orthodontic Therapy: There has been an increase in demand, for Orthodontic therapy in the general population along with the increasing demand in facial esthetics. There is an increase in the incidence of dental caries, gingivitis and periodontitis in presence of Orthodontic appliances in the oral cavity. The presence of appliance in the oral cavity makes it difficult in cleaning of the tooth hence allowing deposition of plaque. Along with it, there is restriction of the self-cleansing action of the tongue, cheek and lips to remove food debris from the tooth surface. Thus, food debris mostly the carbohydrate that is fermentable supports the growth of the bacteria that is cariogenic like Streptococcus mutans and Lactobacillus[5]. Mostly the bacterial growth site is seen on the gingival margin and on the edges of orthodontic bands. Presence of these attachments promotes the retention and accumulation of dental plaque that contributes to formation of white spot lesion and causes demineralization of the enamel if the oral hygiene is not well maintained.[6]

Altered Microflora with Various Brackets

Self Ligating Brackets (SLB): Various studies demonstrated an increase in bleeding on probing and worsening of the periodontal index in patients being treated with SLB. Another 2 studies exhibited an increase in gram negative bacterial colonization with or without the use of elastomeric rings with SLB. While one more study showed increased concentrations of S Mutans and Lactobacillus spp in patients undergoing treatment with SLB as compared to the control group, another showed a decreased concentration of S Mutans, 3 months after initiation of treatment.[7]

Lingual Brackets: Three out of four analytical studies have found that lingual brackets worsen the periodontal index and gingival health. 2 studies showed increased levels of S Mutans and Actinobacillus Actinomycetemcomitans at one month after initiation of treatment.[8,9]

Removable Appliances: Six analytical studies have been performed on the usage of removable appliances. 1 study showed increased S Mutans and Lactobacillus spp in patients using different interceptive appliances. Levrini et al. studied and analyzed Invisalign, revealing that at 3 months after treatment initiation, periodontal index, bleeding on probing and bacterial components had reduced. While Türköz et al. performed a study on thermoplastic retainers, showing an increase in levels of S Mutans and Lactobacillus spp., Farhadian et al. managed to cause a reduction in S Mutans levels at 7 weeks by the incorporation of silver nanoparticles.

Another study that was performed on space maintainers showed an increase in BOP, bacterial count and also increased candida levels. D'Ercole et al. performed a study on long term use of sports mouthguards showing aggravated bleeding on probing & periodontal index.

Oral Hygiene Maintenance Protocol: Orthodontic treatment aims at improving the overall function and esthetics by correcting the occlusion and mal alignment of the natural dentition. Esthetic enhancement also improves self esteem of the patients. Despite the numerous advantages, the major problem faced by the dentist and the patient is increased plaque accumulation which can further cause complications such as halitosis, gingivitis, dental caries etc. That is why a stricter hygiene maintenance protocol must be followed to prevent any complications that might compromise the treatment plan and hence the treatment.

The patients must brush for 2 minutes after every meal to avoid food and debris accumulation around the brackets. The techniques commonly advised are Ramfjord method, Modified Stillman, and Bass method. All these method reduce the plaque and gingival index.

A bi-level Orthodontic tooth brush cleans the tooth surfaces all around the bracket. But there are various studies that compare the effectiveness of a conventional toothbrush and a bi-level orthodontic brush and the results are conflicting. Various studies show that electric toothbrushes are extremely effective in plaque removal. But with the correct brushing technique, conventional toothbrushes can also be equally effective.

Another aspect of hygiene maintenance protocol is fluoridated mouth rinses, especially containing 0.05% sodium fluoride, to reduce enamel decalcification and gingivitis, both of which are very common during Orthodontic treatment.[10]

The recommended effective oral hygiene measures should include at least several of the following:[11,12]

(1) Mechanical plaque removal–tooth brushing, flossing, and regular prophylaxis (2) Fluoride therapy–

at-home (fluoridated toothpaste and mouth rinse) and in-office (topical fluoride) (3) Mechanical protection of tooth surfaces–sealants and glass ionomer cements (4) Diet–reduction in consumption of foods that increase acidity of the oral environment (5) Motivational communication–delivering and reinforcing proper oral hygiene instructions before, during and at the completion of treatment.

Discussion

Improper oral hygiene maintenance leads to incomplete plaque removal and thereby initiation of dental caries and periodontal diseases. Combined with fixed appliances, the plaque retention increases due to availability of more surfaces for adherence, thereby increasing the risk of developing the associated complications at a faster pace. Corrective orthodontics is an integral part of dentistry today. But it comes with the major problem of plaque accumulation, which, despite advances in materials and techniques, is still a lingering issue for both the dentist and the patient. Other major complication is white spot lesions due to enamel demineralisation. Removable retainers exhibit bio film formation due to interaction between bacteria, yeast, saliva and serum proteins that needs to be cleaned regularly.

Studies have shown a direct relation between levels of pathogenic flora with the duration of treatment, which can get aggravated by poor oral hygiene maintenance.[13]

Conclusion

Any form of Orthodontic treatment, be it fixed or removable, significantly affects the oral micro biota. Oral micro flora exhibits maximum change at 1 month post treatment initiation. Fixed appliances cause more severe changes to the oral environment as compared to removable ones. Oral hygiene protocols need to be more aggressively implemented by the dentist and reinforced to the patient to avoid the complications associated with Orthodontic treatment. It is the responsibility of both the treating dentist and the patient to make sure that all oral hygiene instructions are followed as advised.

Antibiotic Drug Resistance: A New Initiative

Lenali Baral[1], Sthita Prajana Lenka[2], Karishma Rajan Rathor[3], Barsha Ray[1], Lovlin Barik[1]

[1]Intern, [2]Professor, Department of Oral and Maxillofacial Surgery, [3]Tutor, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

We can call antibiotics are the" miracle drugs" that can kill the micro-organisms. Anti-microbial agents play important role and are the greatest benefaction of 20th century to therapeutic uses. For decades, a lot of different kinds of antibiotics have been used for multiple purposes like agriculture and animal husbandry. Now-a-days microbes have become resistant to common antibiotics. So, we need comprehensive efforts to minimize the increase level of resistance. The aim of this article is to discuss the emergent micro-organisms, mechanism of microorganisms and its antimicrobial agents.

Keywords: *Antibiotic, Drug Resistance, Multidrug resistant bacteria.*

Introduction

Antibiotics are substances produced by micro-organisms, which selectively suppress the growth of or kill other micro-organisms. They can suppress the synthesis of bacterial cell, protein synthesis, RNA, DNA. For inhibition of protein synthesis, anti-microbial agents can penetrate the cell wall of microbes and then bind to ribosomal sites using the energy-dependant transport mechanisms. To fight against infective diseases and micro-organisms, their significance is really blessing in the developing nations that has saved mankind[1].

Anti-bacteria drug resistance refers when the micro-organisms are unable to respond the antimicrobial agents and is similar to the phenomenon of tolerance seen in higher organisms. If antibiotics are used for long enough, at certain point of time microbes can't be killed by theses antibiotics and this is known as antibiotic resistance. Existing infective diseases are caused by bacteria resistant to some antibiotics. The existence of antibiotic resistant bacteria creates the danger of life threatening infections that don't respond to antibiotics. There are multiple reasons for the development of antibiotic resistance. Some micro-organisms are always resistant to certain anti-microbial agents because of their lack of metabolic process. Examples; gram negative bacilli are normally unaffected by penicillin G, M.tuberculosis is insensitive to tetracyclines. Resistance may be developed by mutations and gene transfer. Acquired resistance results from a mutation in the bacterial chromosomes or the acquisition of extra chromosomal DNA. Antimicrobial resistance refers to 'superbug' that means strains and species of bacteria become resistant to antimicrobial agents. One of the commonest and important causes of antibiotic resistance are overuse and misuse of antibiotics. Overuse of antibiotics, like penicillin, erythromycin, cephalosphorine, has been associated with emerging antibiotic resistance[2].

Origin of Antibiotic Resistance: Antibiotics are medicaments that fight against the growth of the bacteria to control the infectious bacterial diseases. Overuse of antibiotics lead to resistance that can select the specific organisms and scrape away its clinical benefits. Bacteria may obtain resistance by mutations or by several method of gene transfer. Mutational drug resistance may be low degree resistance, can be resistant to certain drug at a time, and is not transferable[3]. Transferable drug resistance is high degree resistance, is not prevented by use of combination of drugs. Now the origin of resistance is now being known. The verifications hold up large bacteria resistome. Resistome is gathering of all the antibiotic resistance genes and their progenitor

e-mail: sthitaprajanalenka@gmail.com

in both pathogenic and non-pathogenic microorganisms. These genes may be seen on antibiotic producers, may be found on pathogenic bacteria. These genes may be recognized on cryptic resistance gene in which these genes are submerged in the bacterial chromosomes[4].

Development of Antibiotic Resistance: Antibiotic resistance occurs when bacteria diminish the efficacy of antibiotics. So the bacteria live in the body and can multiply causing harm to the body. The occurrence of resistance process can depend on gene level mutation. Several bacterial colonies are genetically mutated that can lead existence of resistance. Now-a-days consumption of antibiotics is main factor of level and development of the resistant infections[5]. It can be occurred if the individuals don't complete their antibiotic drugs dosages. So bacteria may accumulate multiple resistances and can become resistant to various types of antimicrobial agents. Example; Existence of resistance seen in staphylococci from mutations of chromosomes and genes, infective transport aminoglycoside and enzyme modification. It's not mandatory that a specific antibiotic can only resistant to that particular drugs. It can occur with other drugs of same class too. Example; Broad-spectrum drug tetracycline can resistant to drugs of same classes like doxycycline, chlortetracycline, oxytetracycline, minocycline[6].

Mechanism of Antibiotic Resistance: Antibiotics can interrupt some crucial and necessary structures and procedures in bacteria. This can lead either to kill the bacteria or continuing the multiplication of bacteria. The role of antibiotic drug resistance is to cease the microorganisms from reaching its target. It can be possible If the membrane of bacterial cell reduces its permeability of that bacterial membrane. Destruction of antibiotic by some bacterial enzymes leads to resistance. Drug resistance occurs by modification of the target. It can be possible by alternative proteins[7].

A Worldwide Operation to Minimize the Antibiotic Resistance: Like global warming, existence of noticeable antibiotic resistance is out of control and has no apparent way out. Worldwide it is a major serious problem in public health. Over several decadesdecades, scientists, clinicians, physicians were not aware of existence of antibiotic resistance. But bacteria resistant already recognized before the discovery of first antibiotic drug penicillin. For this consequences, WHO declared and promoted antibiotic resistance as a global health problem. The World Health Organization recently published a book called " The evolving Threat of antimicrobial resistance–options for action"[8]. This book narrated the major problems of resistance seen in worldwide and how to control the use of antimicrobial agents. Due to several reason antibiotics are used unwisely such as person's fulfillment over doctor's prescription, ill-suited information about antibiotics, inappropriate diagnosis, quackery in many countries[9]. Having lack of discovery of newer antibiotics,this part of problem is quite tough to deal. So the individual should take antibiotics when prescribed by certified health care provider. If doctors don't prescribe antibiotics, patients shouldn't demand or request for antibiotics. To minimize the increasing resistance, the policy maker can improve surveillance of antimicrobial-resistant infectious diseases. Use of alternative therapies can control the infectious diseases. These therapies include biological therapy, vaccines against drugs[10].

Conclusion

Increasing antibiotic resistance is now major problem in world wide. The importance and value of antimicrobial agents are magnified and we are totally dependent on them for the treatment of infectious diseases. Use of antibiotic is increasing day by day in humans, animal and agriculture. At the same time antibiotic resistance is increasing at an alarming rate.

For internal and foreign policies we need to stop overuse and misuse of antibiotics to prevent the resistance of antimicrobial agents. So to minimize the drug resistance in infective diseases, we should know about its origin, administrations, varieties of resistance chromosomes.

Assessment of Dehiscence and Fenestration in Bilateral Cleft Lip and Palate Patients

Amrita Sahu

Post-Graduate Trainee Department of Orthodontics & Dentofacial Orthopaedics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Cleft lip and palate are breaks in continuity of tissues of upper lip, the hard and soft palate or both. It can be unilateral or bilateral. It results due to incomplete fusion of the facial structures during growth. It poses many problems to the child such as difficulty in feeding,swallowing, nasal twang to voice and chronic ear infections. Dental problems include absence or missing one or more teeth, deformation in the normal tooth morphology, and a lack of adequate amount of soft and hard tissue in the affected area. Preoperative orthodontic treatment is a must to align the teeth in the arches before any orthognathic surgery is performed to correct the underlying skeletal imbalance. It is imperative to evaluate the amount of bone level before planning any orthodontic, periodontal and surgical therapy. The amount of alveolar bone loss in an ungrafted cleft region of cleft patients has been evaluated using various radiographic method and it has been reported that there was increased amount of loss of alveolar bone in the affected site compared with controls. Very few studies have used CBCTas a method of evaluating the bone level in cleft patients. Hence this article discusses the evaluation of dehiscence's and fenestrations in bilateral cleft lip and palate patients using cone beam computed tomography.

Keywords: *Dehiscence, fenestration, cone beam computed tomography, cleft lip and palate.*

Introduction

Cleft lip and or cleft palate is one of the most common orofacial malformations that occur during the embryological growth period of a child. Clefting results due to lack of proper fusion between the facial structures at various stages of growth. They usually present as birth defects only or can also be in conjunction with many conditions or syndromes that may be inherited.[1] They can be unilateral or bilateral. (Figure 1).

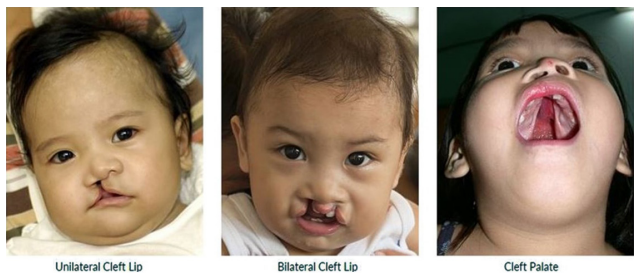

Figure 1. Types of Cleft lip & cleft palates

Incidence: Epidemiological studies show substantialvariation in orofacial clefts based on numerous factors, including the sample population and method of study.[1] Oral clefts in any form occur in about one in every 700 live births. Higher rate of incidence and prevalence has been seen in south east Asian countries (one in 500 births), whereas African-derived populations show decreased rates (one in 2,500 births). Isolated cleft palate is more commonly seen in girls when compared to boys, in a ratio of 2:1. On the other hand there is a 2:1 girl-to-boy ratio for cleft lip with or without cleft palate.[2]

Corresponding Author:
Amrita Sahu
Post-Graduate Trainee Department of Orthodontics & Dentofacial Orthopaedics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: amritasahu@gmail.com

Etiology: There is no single cause of cleft lip and cleft palate. It has a multifactorial etiology Potential causes may include medications taken by mother during pregnancy. Certain drugs like: anticonvulsant drugs, anticancer drugs, drugs used for treatment of acne and auto immune disorders. They may also occur as a result of exposure to various microorganisms or chemicals during the development stage of the foetus. In other situations, it may be associated with other medical conditions or syndromes.[3]

Features: A child affected with 'cleft lip and palate' presents with variety of features depending onnumber of factors, including the type and severity of the area involved. These individuals may face difficulties in the following (Figure 2).

- Difficulty in articulation
- Nasal voice
- Regurgitation of food and fluids during feeding and swallowing
- Dental problems like tooth malformations, ectopic eruptions, supernumerary teeth and anodontia, periodontal problems. Inability to maintain good oral hygiene.
- Skeletal imbalances of the jaws
- Recurrent ear infections
- Psychosocial Impact

Figure 2. Difficulties faced by affected children

Diagnosis: Cleft lip/cleft palate can be detected as early as 16 weeks into pregnancy in most of the cases with the help of ultrasonography. Confirmation is then done at birth with a thorough visual and physical examination. In one of rare cases when the individual has a mild cleft involving soft palate only which neither is visible in an ultrasound nor noticeable visually until the child experiences difficulty in feeding. The clinician should carry out a comprehensive examination so as to diagnose the exact nature of the problem.[4]

Treatment: The treatment of cleft lip and palate is a multi–disciplinary approach due to the numerous problems associated with it. A team of health care professionals work to design a plan to customize the treatment plan according to the patient's needs. Treatment usually begins in infancy and often continues through early adulthood.[5] This multidisciplinary team includes (Figure 3)

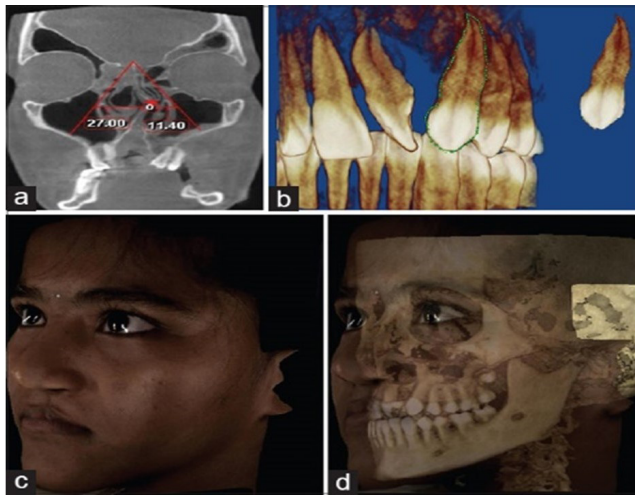

Figure 3. Treatment Protocol

- **Plastic surgeon** to carry out surgeries.
- **An ENT surgeon** to assess problems associated with hearing and its management.
- **An oral surgeon** to correct skeletal imbalances of the jaws
- **An orthodontist** to align teeth
- **A prosthodontist** to provide prosthesis for replacement of missing orofacial tissues that aims at improving the aesthetics and function.
- **A speech pathologist** to assess problems associated with speech
- **An audiologist** to assess problems associated with hearing
- **A nurse** to supervise health of the child
- **A psychologist** to provide psychological assistance to the child and his family
- **A geneticist** for genetic counselling

Multiple surgeries are required to repair the defects associated with cleft lip and palate till 18 years of age. The initial surgery for palatal repair is usually performed as early as 6 months of age. This creates a functional

palate reducing the regurgitation of fluids and food and also helps in the proper growth of the dentition and facial bones.

Once the permanent teeth are erupted, orthodontic treatment is required to correct the malocclusion. Additional surgeries may be performed to improve aesthetics. Final repairs are not done until grow this fully completed.[6]

Oral Care for Children with Cleft Lip and/or Palate: The dental treatment needs of children with clefts and non-clefts are usually the same. Since children with cleft lip and cleft palate may have numerous problems related to the dentition such as missing, deformed, or maligned teeth which requires regular follow ups and strictmonitoring[2].

- **Early dental care includes** regular oral prophylaxis, balanced diet, and fluoride treatment at appropriate intervals in order to prevent the teeth from decay.. Routine dental check-up should ideally begin at around 1 year of age.
- **Orthodontic care.** The predentate stage is the best time to consult an orthodontist as it helps in assessment of orofacial growth and development. After the permanent dentition sets in, further evaluation is needed to identify treatment needs of the child.
- **Prosthodontic care.** A prosthodontist may provide replacements for the missing teeth or fabricate appliances called "speech bulbs" or "palatal lifts" to help in normal phonation.

Problems faced during the orthodontic treatment of cleft lip and palate patients: The osseous clefts show poorly developed bone morphology and topography associated with weak supporting periodontal tissues. Such areas subjacent to the cleft are associated with delayed tooth formation and eruption, and cause problems in orthodontic movement of the involved teeth. So, it very crucial to evaluate the level and amount of bone underlying the cleft before planning any orthodontic tooth movement as weak and decreased level of hard and soft tissues can lead to anatomical defects such as dehiscence and fenestrations due to additive trauma caused during orthodontic treatment jeopardising the tooth involved[3]. According to a study conducted by Salvi et al it was concluded that patients with orofacial clefts have a greater risk of periodontal destruction progression than control sites.[4]

What is dehiscence and fenestration?: Dehiscence is defined as the reduction in the cortical bone to the level of root of a tooth, at least 4 mm apical to inter-proximal bone margins whereas "fenestration" is described as a defect where the root surface is denuded of bone. It is seen mostly at the apex or the middle third, but does not involve the alveolar margin. Fenestrations are most commonly found in the upper arch, especially in the first molar and canine region (Figure 4). Dehiscence are seen mostly in the mandibular anterior region predominantly on buccal surfaces. The bone anatomy in the maxillary first premolars is such that it becomes narrower upwards hence the maximum fenestration cases in maxilla. Since the bone density becomes less as one goes from back to the front region of jaw most of dehiscence were associated with the lower jaw. Various factors, such as the direction of tooth movement, the frequency and magnitude of orthodontic force applied and the health status of supporting tissues contribute to the occurrence of these anatomical defects[5]. Best way to avoid these issues it is important to assess the alveolar morphology before commencing orthodontic treatment through imaging.[7]

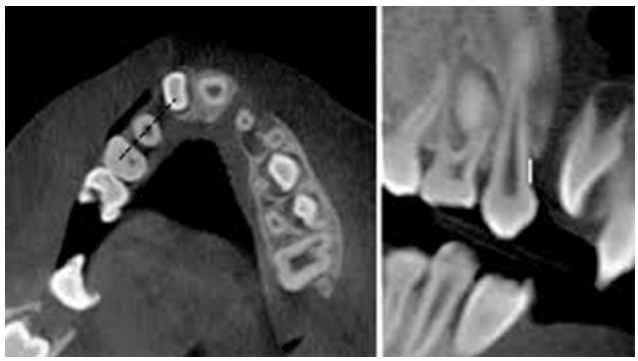

Figure 4: Fenestrations

Presence of dehiscence and fenestration can best be confirmed by CBCT[6]. The main advantage of CBCT i.e. IMAGING 3D is the ability to assess the actual anatomy without being superimposed by the neighbouring structures with increased accuracy and sensitivity. The small voxel size in the CBCT enables us to visualise images in high resolution. Also, it is more cost effective and has less radiation dose compared to conventional CT.[7] Earlier conventional radiographs were used to evaluate these anatomical defects but this has now been replaced by CBCT because of the obvious advantages.[7,8]

Studies done to assess dehiscence and fenestration in 'cleft lip and palate' patients: Previous literature shows that not many studies have been conducted to

evaluate the anatomical defects using CBCT and further studies still need to be done to confirm that dehiscence and fenestrations are more commonly seen on the cleft affected side that the non-cleft subjects."Buyuk et al"in 2015 had done a study to assess dehiscence and fenestration in unilateral CLP patients using cone-beam computed tomography (CBCT) (Figure 5) and stated that those patients showed greater prevalence on the anterior teeth of upper arch when compared with unaffected individuals[8]. Another studydone by "Mevlut Celikoglu" et al in Department of Orthodontics in Turkey in the 2017 supports the fact that cleft affected site is at a higher risk of developing these bony defects as compared to the unaffected individuals owing to decreased level and density of bone in that area.[9]

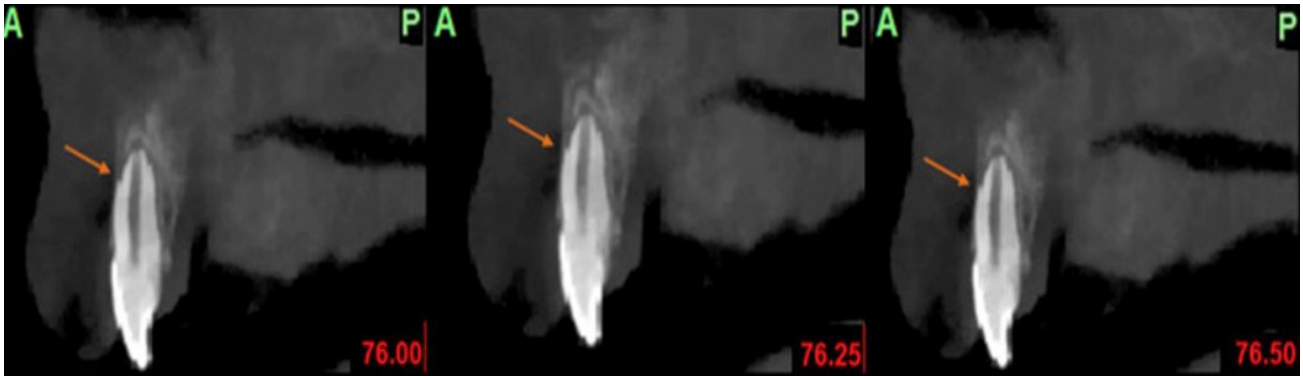

Figure 5. CLP patients using cone-beam computed tomography

In this retrospective study CBCT scans of maxilla and mandible offifty-onepatients were taken. They were categorised into 2 groups (group 1 consisting of twenty one patients affected by BCLP; with mean age; 14.62 ± 2.89 years; and group 2 consisting of thirty patients as the non-cleft control group; with mean age, 14.22 ± 1.05 years) These CBCT images were used to assess bony defects of the anterior teeth in both groups. Exclusion criteria for cleft group was no past history of orthodontic or prosthodontics treatment with the CLP repair if done should be done before the age of three years, on the other hand the exclusion criteria for the control group was no previous history of trauma, disease or any prosthodontics or orthodontic treatment. All images were obtained with CBCT machine (New Tom 5G, QR, Verona, Italy) using standard operating conditions of scanning time, 18 seconds; collimation height, 13 cm; exposure time, 3.6 seconds; slice thickness, 0.25 mm and voxel size, 0.15 mm. The assessment was done with Simplant Pro software (ver. 16.0; Materialise, Leuven, Belgium) after the images were converted to DICOM format. The sagittal and axial slices on the buccal and lingual surfaces were taken for assessment of roots of all anterior teeth of upper jaw. In areas where the height of bone was greater than 2 mm from the cement-enamel junction it was recorded as dehiscence, where as when crest of alveolar bone was unaffected, it was recorded as fenestration. All the assessment was done by an experienced orthodontist (S.K.B.), who had been trained before for the study without knowing the patients' group. Data analyses was then done using "Pearson's x2, Student's t-test" and Fischer exact test

Results

Results of the study revealed that when comparison of the BCLP subjects and controls were made it was seenthat the BCLP group had a significantly greater prevalence of these anatomical defects than did controls. BCLP group showed prevalencerate of 61.11% in the upper and 48.41% in the lower anterior teeth, whereas the rates in the control group were 7.78% and 16.67%, respectively ($P < 0.001$). Further it was seen that fenestrations were more common in the maxillary anterior teeth on the BCLP patients compared with controls, whereasno statically significant difference was seen for maxillary lateral incisors ($p>0.005$) (Figure 6)

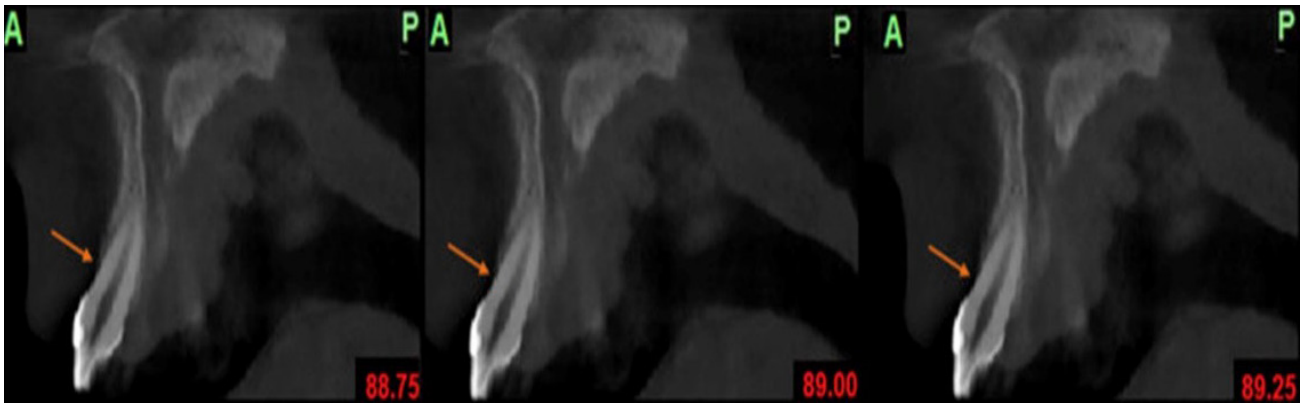

Figure 6. Comparison of the BCLP subjects

Discussion

Many studies have proved that "dehiscence and fenestration" are very commonly seen in various forms of malocclusions. And these defects can lead to decrease in the level of marginal gingiva and more amount of loss of bony architecture during orthodontic treatment,hence more chances of relapse or undesirable orthodontic treatment finishing. Since cleft patients have some form dental and skeletal imbalances, it is very crucial to diagnose these defects to carry outproper orthodontic therapy. The evaluation of these anatomical defects has long been neglected. Thus, this study was one using CBCT to present the important findings of alveolar defects in bilateral cleft lip and palate patients. Many factors contribute to the various rates of bony defects including different ethnic backgrounds, dental and skeletal problems, angulation of the teeth, crowding, cortical bone thickness, and the supporting tissues. This study shows a prevalence rate of 61.11% of dehiscence in the upper and 48.41% in the lower anterior teeth, whereas the controls had 7.78% and 16.67%, respectively[10]. Studies have shown that patients with BCLP had backwardly placedupper and lower arches, short effective jaw lengths and vertical growth patterns when compared with the controls. Hence increase in rates of both dehiscence and fenestration in BCLP patients might be due to decreased density of cortical bone in the maxillary anterior teeth at the cleft site. In contrast to the previous literature which states fenestration was more common in the upper teeth,the results of this study show it was same for both jaws of the control group. Thus, CBCT imaging is a muse prior to commencement of any orthodontic therapy. This study had severallimitations in that the periodontal status of the subjects were not assessed clinically. Moreover 0.25 mm slices were taken to study the images which is inefficient in detecting thin bone layers. Hence further studies are needed in this regard.[6-10]

Conclusion

Before commencing orthodontic treatment, the orthodontist should be aware of the morphology of theorofacial tissues of the area of interest. Most of the unwanted effects can be easily prevented by taking certain precautionary measures before,during and after the treatment. we can achieve aesthetically and functionally balanced treatment outcomes if each step starting from wise case selection, diagnosis, treatment planning, monitoring, timely intervention, and good patient cooperation,is taken into consideration.

Nicotine Replacement Therapy: A Review

Basanta Kumar Choudhury[1], K.L. Sushmita[2], Namrata Mishra[2]

[1]Senior Lecturer, [2]Post Graduate Trainee, Department of Oral Medicine & Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The products that are available in the market can be adhered to the skin if the patient is not comfortable with chewing as in transdermal patches but the patient might feel irritation on the skin. Thus, different products are produced in order to provide wide range of option to the consumer so that he/she can choose whichever way he/she likes to quit the habit. Nicotine replacement therapy (NRT)s have been so successful that they are now widely accepted.

Keywords: *Nicotine, Nicorette, Inhaler, Nicotine Vaccine.*

Introduction

A wide range of products are available in market to help tobacco cessation. In 21st century with advancing science and technology we have been benefitted in a way that we can stop the core cause of various oral cancer and pathologies. The products that are available in the market can be adhered to the skin if the patient is not comfortable with chewing as in transdermal patches but the patient might feel irritation on the skin.[1] Thus, different products are produced in order to provide wide range of option to the consumer so that he/she can choose whichever way he/she likes to quit the habit. NRTs have been so successful that they are now widely accepted. However, there are certain clinical guidelines recommend NRT as first line of treatment for de-addiction from tobacco and related products. This review aims in summarizing all the available method of NRT and its possible new approaches in future to handle tobacco products addiction.[2]

Mechanism of action: Nicotine acts by stimulating neural nicotinic acetylcholine receptors in ventral tegmental area of brain. This releases dopamine in nucleus accumbens. Dopamine leads to reduction in nicotine withdrawal symptoms in regular smokers who refrain from smoking. The coping mechanism-NRT provides coping mechanism thus making tobacco products least rewarding. It never completely eliminates the symptoms of withdrawal as none of the available nicotine delivery systems reproduce the rapid and high level of arterial nicotine achieved whenever a tobacco product is consumedsince most of the products rely on systemic venous absorption and never achieve rapid systemic arterial delivery.[3]

Available Nicotine Replacement Therapy

Transdermal patch: These are normal patches that have to adhered to the skin and it comes with glue which helps in its adherence to the body. It delivers nicotine through skin at steady rate. There are wide ranges and doses so that a higher cigarette smoker can take a patch of stronger dose and occasional cigarette smoker can take a patch of lesser dose. Such wide range of doses helps the patient to gradually taper their nicotine intake over a period of time to enable gradual adjustment of their bodies to lower level of nicotine and finally to a free from nicotine stage. Main advantage is it is simple, and it delivers nicotine at a slower rate compared to acute NRT formulations. They are available in various doses -5mg to 22mg of nicotine over 24 hours. The most frequently reported disadvantages are local skin reactions and sleep disturbances.[4]

Acute dosing nicotine products: In this the user has the control over both amount and timing of doses.

Therefore, the smoker with greater need can get a higher nicotine dose and those who are not can reduce their intake as per need. Acute dosing nicotine products include gum, lozenge, sublingual tablet, oral inhaler, and nasal spray.[5]

Nicotine gum: Ferno in 1969 started experimenting on himself with this gum and he quit smoking after one year of use. The first nicotine chewing gum was produced by AB Leo in 1971. It should never be chewed and thrown out like an ordinary chewing gum but it has to be held in oral cavity for 30 minutes so that the release of nicotine can occur. It is available in 2mg and 4mg dosage forms. The dose should be tapered gradually till it is no longer needed. Acidic drinks interfere with mucosal absorption of nicotine; thus patients should avoid acidic drinks for 20 minutes before and during chewing gum.[6]

Nicotine lozenge: Nicorette is the brand name of a number of products for nicotine replacement therapy that contain nicotine.It was developed in late 1970s in Sweden. Nicotine lozenge contains nicotine polacrilex which is a nicotine bound to an ion-exchange resin. It is available in 2mg and 4mg formulations. The method of use is similar to that of gum, but this is not chewed rather it is allowed to dissolve in mouth slowly for approximately 40 minutes with some changes across individuals. The amount of nicotine absorbed through lozenge if higher than gum.[7]

Nicotine sublingual tablet: Nicorette microtab was the commercial product produced by Nicorette company. Like the lozenge, the tablet has that advantage of not chewing the microtab is kept sublingual and since the sublingual route is faster the nicotine reaches the systemic circulation rapidly.The levels of nicotine obtained by use of lozenge and sublingual tab is similar. It has to be used at least for a period of 4 months and then tapering of dose should be followed.[8]

Nicotine oral inhaler: It comes in a similar design of asthma inhaler containing a mouthpiece and a plastic cartridge which contain nicotine. Although it is named as inhaler but majority of nicotine content goes to the oral cavity followed by oesophagus and then stomach, only a little amount reaches the lungs. Since most of the absorption occurs through the oral cavity the rate of absorption is similar to that of gum. 10mg nicotine cartridges are available and it delivers 2-4mg of nicotine pre puff.[9]

Nicotine nasal spray: It was designed for rapid delivery of nicotine. Yildiz D et al quoted "It is available as multi-dose bottle with a pump mechanism fitted to a nozzle that delivers 0.5 mg of nicotine per 50µ squirt. Each dose consists of two squirts, one to each nostril. It is the most rapid delivery system available among the all other NRT available. Patients should be started with 1 or 2 doses per hour, which may be increased up to max 40 doses per day". A single dose of nasal spray per hour for 10 hours produces average plasma concentrations of 8ng/ml.

High-dose nicotine patches: These patches of 22mg can replace half of serum nicotine and cotinine levels in smokers. Brokowski L, Chen J, Tanner S quotedin their article"A systematic review concluded that the safety and efficacy of high dose transdermal NRT for tobacco cessation have not been established in medical literature".

Rapid release gum: Niaura R, et al. quoted in there article "A rapid release gum has been formulated to provide a biphasic nicotine delivery, starting with elevated delivery in order to promote rapid craving and then levelling off to abstain overdosing. It is faster, and has high efficacy than the current nicotine gum".

Combined patch plus acute forms: Kornitzer M et al, quoted in his article "to improve the efficacy of NRT by combining nicotine delivery with other medication that permits rapid nicotine delivery. The rationale for combining NRT medications if that smokers may need both slow as well as a faster acting preparation that van be administered on demand for immediate relief of break through cravings and withdrawal symptoms. Combining the nicotine patch with an oral form of NRT has been shown to increase quit rates by 34-54 % compared to using the patch alone".

Future advances: Nicotine preloading: Lam C west quoted in his article "The use of nicotine replacement therapy before quitting smoking is called nicotine preloading". It is also known as pre-cessation or pre-quitting NRT. A review suggests that a patch use should be initiated for a brief period before making a quitting attempt, is affectively more operative than patch use initiated on the quit date itself.[10]

True pulmonary inhaler: Henning field JE quoted "It would transport nicotine to the lung in a manner more analogous to cigarette smoking. This would be predicted to deliver a dose of nicotine sufficient to

reduce background cravings and withdrawal symptoms, and would allow for more faster relief of acute cravings and morning craving. As this delivers nicotine directly into the lung it would effectively mimic the effects of smoking on a physiologic level, the smoker could eliminate the need for tobacco, and as well as taper the nicotine level over time to alleviate dependence upon nicotine together".[11]

Nicotine Vaccines: Carrera, M. R., Ashley, J. A., Hoffman, T. Z., Isomura, S., Wirsching, P., Koob, G. F.et al quoted "Nicotine vaccines represent a new approach to the treatment of nicotine dependence and is under research. As nicotine is small molecule and incomplete antigen, it can be linked to a carrier protein in order to stimulate necessary immune response. Nicotine based vaccines can prime the immune system to recognise nicotine as foreign substance and to attack it by immunologically. By doing so it decreases the amount of nicotine penetrating the brain. However, there are some drawbacks of this firstly there is difficulty in achieving sufficiently high antibody titres, the fact that vaccines are generally short lived, and significant inter-individual variation in response to the vaccine typically observed".[12]

Conclusion

With advancing research there is higher chances of more advancements in newer nicotine replacement therapy method. Even with many nicotine replacement therapy products available in market, it solely depends on the consumer whether he/she wants to quit the habit or not. Making them aware of the consequences of not quitting habit may provide a trigger to them to start taking these products. But proper counselling must be provided and benefits of using these products should be told elaborately. NRTs increase the rate of quitting by 50 to 70%.It is essential for the health professionals to know about all the available forms of NRT to be able to answer those who are willing to quit the habit.

Fibrous Dysplasia: A Rare Case Report

Basanta Kumar Choudhury[1], Smita Rani Priyadarshini[2], Rupsa Das[3], Suvranita Jena[3], Snigdha Sagar[4]

[1]Senior Lecturer, [2]Associate Professor, [3]Post-Graduate Trainee, [4]Senior Lecturer, Department of Oral Medicine and Radiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Fibrous Dysplasia (FD) is a disorder of bone that occurs rarely in which abnormal fibro-osseous tissues is replaced by normal bone. Several bones are involved including the long bones, ribs, craniofacial bone and pelvis. Out of all the FD monostotic (MFD) is found in 30% cases which involved the facial and cranial bones. It often occurs in children and stops in adulthood. FD is twice more commonly seen in maxilla than in the mandible. In most of the cases of FD it is unilateral and is commonly seen in the posterior region of jaw.

Keywords: *Fibrous Dysplasia, Maxilla, Deformity.*

Introduction

Fibrous Dysplasia (FD) is a rare bony disorder in which fibrous tissue (scar like appearance) grows in place of regular bone. This irregular bony tissue can deform the bony structure or may even lead to fracture because of weakening. In most of the patients suffering from FD the site of involvement is single but in many cases involvement in multiple site is also reported. Event thought FD is a genetic disorder in which gene mutation is seen but is not passed on from parent to the child. There is no specific cure reported to this disease. The treatment often includes symptomatic relief, which might be surgery, it focuses in improving the quality of life like relieving pain and repairing or stabilizing bones to carry on with functional uses.[1,2]

Case Report: A 23 years old male patient reported at the department of Oral Medicine and Radiology, Institute of Dental Sciences, SUM hospital, Bhubaneswar with the chief complain of swelling on the left side of the face for the past 1 year, which had been growing slowly to reach the present size. The swelling was insidious in nature, painless and was progressive resulting in the gross deformity of the face. On extra oral examination, a diffuse swelling present on the left middle 1/3rd of face measuring 8x7 cm in size, of skin colour, ill-defined margins, smooth surface and extending anteroposteriorly from lateral border of nose to imaginary line drawn from corner of mouth to the tragus, superoinferiorly infraorbital margin to left maxilla. On palpation, the swelling was bony hard in consistency, with diffuse edge and attached to the bone [Figure 1]. On intraoral examination, a bony hard swelling present in the alveolar mucosa from 24 region to 28 regions, with normal mucosa over it. It was non compressible and non-reducible in nature. Radiographic examination in an Intra oral periapical radiograph revealed obliteration of maxillary sinus, with narrowing of periodontal ligament space, distinct lamina dura, taurodontism and increased radiopacity of maxillary sinus on left side [Figure 2]. An Orthopantomograph evaluation revealed the lesion tending to blend into the surrounding structures obliterating the Floor of orbit, Zygomatic arch and Ground-Glass appearance [Figure 3]. The biopsy of the lesion was sent for histopathological examination and was confirmed to be MFD. The management of the patient was done in a conservative surgical approach and is under observation.

Discussion

Fibrous Dysplasia of bone is an uncommon congenital, non-genetic, metabolic skeletal disorder. Out of all bone tumors it is almost 2.5% and out of all benign bone tumors it is about 7%.[1] It is characterized by replacement of normal bone and marrow by fibrous tissue. The maturation of bone is arrested in the woven bone stage. It may affect single bone (monostotic) MFD, multiple bone (polyostotic) fibrous dysplasia (PFD). FD involves the facial and cranial bones in nearly 50% of PFD patients and in 10%–27% of MFD patients.[2]

Etiology: The etiology of FD is the molecular mechanism for fibrous dysplasia is a post zygotic activating mutation of the GNAS1 gene. That results constitutive activation of the adenylyl cyclase enzyme and over production of 3',5'-cyclic adenosine monophosphate. Excess cyclic adenosine monophosphate impairs the ability of stem cells to differentiate into a mature functioning osteoblast.

Clinical Features

- 70% of fibrous dysplasia (monostotic) often involves jaw
- Most common sites are ribs, femur, tibia
- Patients with jaw movement complain of unilateral facial swelling or an enlarging deformity of alveolar process.
- Polyostotic type usually found in children younger than 10 years where monostotic type found in slightly elder age group.[3]
- Pain and pathologic fractures are rare
- Pain less enlargement of the affected bone is most commonly seen
- The patient is not able to recall the onset of swelling
- Maxillary and mandibular fibrous dysplasia is associated with significant facial and palatal asymmetries present, heterogenous dental anomalies (taurodontism, enamel hypoplasia, malocclusion, displacement, high caries index seen.

Radiologic Features:

- Ground glass appearance due to superimposition of thin and poorly calcified trabeculae.
- The lesion of fibrous dysplasia is usually ill defined radiographically, they tend to blend into the adjacent bone.
- Radio-dense area obliterates maxillary sinus and involves zygoma and lower rim of the orbit.
- Involved dentition shows narrowing of pdl space with ill-defined lamina dura that blends with the abnormal bone.

Differential Diagnosis: The differential diagnosis of FD includes simple bone cyst, nonossifying fibroma, osteofibrous, dysplasia, adamantinoma, low-grade intramedullary osteosarcoma, Paget's disease.[6] The best method of diagnosis of FD id histologically proven fibrosseous lesion with poorly defined with not clearly defined margins with are then reconfirmed by radiologic evaluation.[7]

Treatment: FD treatment protocols involves the following 3 steps: Observation, Medical treatment & Surgery.

Various clinical studies have shown that the FD lesions do have any risk of pathologic fracture or related deformity. To improve various signs of FD such as pain relief, enhanced functions and to reduce the risk of fracture in certain patient's medical treatment with bisphosphonates might be beneficial.[5] Surgery can be a treatment of choice in certain cases. That might include for examination of the bone (biopsy), surgically correcting the deformity, further prevention of the fracture resulting from the pathology and/or for the eradication of symptomatic lesion.

Conclusion

Conservative supervision has been the customary of care, which involves removing the diseased bone via an intraoral approach. Cortical bone grafts are superior to cancellous bone grafts or bone-graft substitutes because of the excellent quality of the remodeled cortical bone. After a confirmatory biopsy, our case was diagnosed with symptomatic MFD. After discussion with the patient, she refused invasive surgical treatment and chose conservative management with regular recall and clinical observation. The reported prevalence of malignant transformation of FD is 0.4%–4%.

Dental Implants in Diabetic Patients

Camelia Saha

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Implants are the ideal treatment method for the Patients with missing tooth, as it is not only very much perfect aesthetically but also anchors into the bone directly and provides a strong stability. Diabetes Mellitus is classified as one of the crucial risk factors while deciding about Implant placement, as these Patients experience a delayed wound healing process, Osseointegration being very important part of Implant treatment procedure, is tremendously affected due to delayed wound healing leading to failure of Implant. But this condition may not be similar for the Patients with controlled Diabetes. Thus, we need to focus on preventive strategies as well as various selection criteria while working with Implant in Diabetic Patients.

Keywords: *Dental Implants, Diabetes, Osseointegration, Hyperglycemic.*

Introduction

These days edentulous cases are very common in dental Patients of age varying from middle age to old aged. According to modern treatment method a dentist can provide a lot of options for the replacement of an edentulous area in the dental arch depending on various factors like aesthetics and cost factors.[1] Various options for replacement of the edentulous area in the Patient are- Removable Partial Denture (RPD), Fixed Partial Denture (FPD), Complete Denture (CD), Implants, Implant supported complete Denture, Over Denture. Among all of these prosthesis Implants are more aesthetically perfect and a permanent solution but unfortunately for some Patients these Implants has some systemic disease related boundaries like it can be really risky for Patients with Diabetes Mellitus, Hypertension, Less Bone Density, Patient with acquired bleeding Tendency, Chemotherapy treated Patients.[2]

Implants: An endosteal Implant, is an alloplastic Material which is surgically inserted into a residual bony ridge, primarily as a Prosthodontic Foundation.[1]

Prefix-"Endo" meaning "within" and "osteal" meaning "bone"[2]

A dental Implant is a surgical component that Interfaces with the bone of the jaw or skull to support a dental prosthesis such as a crown, bridge, denture, facial Prosthesis or to act as an Orthodontic Anchor. Hundreds of different Type of Implant body designs are available, we can generally relate to 3 different categories: 1. Cylinder Implants, 2. Screw Implants, 3. Combination

Cylinder Implants provide Press Fit and their root form depends on a coating or surface condition to provide microscopic retention and bonding to the bone and usually are pushed or tapped into a prepared bone site. They are of different shapes like-straight, tapered, conical. This offers the advantage of ease of placement even in difficult access location.

Screw Root Form: They are threaded into the bone site, and have macroscopic retentive elements for initial Bone fixation. They can be machined, textured, or coated. 3 Basic screw thread forms are V-shaped, Buttress Thread, Power (square) thread designs that are again combined with different geometric shapes. Combination Root Form have the macroscopic features of cylinder and Screw Root forms. 3 different parts of Implant Body are: Crest Module, Implant Collar, Apex.

The Implant must the considered as the apically Extended part of the restoration. The design of the restoration should be planned and the planned design should guide the surgical placement of the Implant. This concept is known as Prosthetically Driven Implant Placement.[3] The above-mentioned theory says, Implant is nothing but the apical part of the restoration. Planning for the location of the Prosthesis placement and designing should be done earlier to the surgical procedures for the placement of the Implant.

Implants and bone loss: An Implant allows normal muscle function and it also stimulates the

bone and maintains its dimensions similar to healthy natural teeth. Crestal Bone Loss can result in increased bacterial accumulation resulting in secondary Peri-Implantitiswhich can further result in loss of bone support, which may lead to occlusal overload resulting in Implant failure.[4] Studies says marginal bone loss is very common. It is mostly seen during the 1st year of the Prosthetic Loading. So crestal Bone Preservation is one of the very important steps to be taken before the marginal method of Implant placement. As Implant failure is seen due to occlusal overload, Peri-Implantitis, loss of Bone support but also causes resorption of the marginal bone leading to unaesthetic appearance of gingival contours and loss of Interdental Papilla. The concept of "Platform Switching" says about the use of a smaller diameter abutment on a larger-diameter Implant Collar. Thus, the perimeter of the Implant-abutment junction (IAJ) is shifted a little inward towards the Central Axis (middle) of the Implant.

Diabetes: A disease in which the body's ability to produce or respond to the hormone Insulin is impaired, resulting in abnormal metabolism of carbohydrates and elevated levels of glucose in the blood. Diabetes is a disease that occurs when your blood glucose also called blood sugar is too high. Blood glucose is your main source of energy and comes from the food you eat. Insulin, a hormone made by the pancreas helps glucose from food get into your cells to be used for energy. Sometimes your body doesn't make enough-or any Insulin or doesn't use Insulin well. Glucose then stays in your blood and doesn't reach your cells. Overtime having too much glucose in your blood can cause health problems. Although Diabetes has no cure, you can take steps to manage your Diabetes and stay healthy. Diabetes Mellitus can be classified into three types: Type-1, Type-2, Gestational Diabetes, Prediabetes.

Bone healing and diabetes: Dental Implants success has been dependent on the Bone-to-Implant contact. Formation of Bone on and around dental Implant has been achieved by normal mechanism of Bone remodeling. Diabetes Mellitus affects the Metabolism of Carbohydrate, Lipid, Proteins and thus this hypoglycemic condition of the body affects the tissues of the body resulting in multiple complications of the body including micro and macro-vasculature. Thus, Lipid deposition will result in atherosclerosis, microangiopathy including Alveolar Bone and Periodontal Tissue The persistent hyperglycemic condition in a Diabetic individual results in activities of osteoblast which alters the parathyroid hormone response regulating the metabolism of Ca and P,reduces the collagen formation which is required during callus formation, including cells apoptosis of bones and progression of osteoclastic activity, as result of persistent inflammatory response. It also induces effects the bone matrix and diminishes growth and accumulation of extracellular matrix, which decreases the growth by extracellular matrix accumulation which results in reduced bone formation during healing.[5-12]

Insulin and implant treatment: The first line of treatment in the Diabetic Patients is diet. Diabetic Patients can be Insulin dependent or Non-Insulin Dependent. Insulin dependent Diabetic Patients are controlled with Regular Injections or may be with subcutaneous Insulin Infusion Pump.[13] Whereas Non-Insulin-dependent Diabetic Patients are provided with Oral Tablets, that helps in stimulating Insulin secretion, prevents glycogenolysis in the Liver, Increases Tissue sensitivity to Insulin, decrease hepatic glucgluconeogenesis, or slow the digestion and absorption of glucose from the Intestine. Insulins are also available in variety of preparation and duration of action like– It could be Long (20-30 hours), Intermediate (16-20 hours), Short (4-12 hours), Rapid action (less than 5 hours).[13]

Dentist should be familiar with the effects and side-effects due to the long duration and being not so expert, should always communicate with the Patient's Diabetologist for the best treatment plan, especially once the Implant placement is scheduled. Generally, these Implant surgeries are preferred to perform in the Late morning hours for the Diabetic Patients, just after administration of their medication and an appropriate meal, which can avoid the most common in-office Medical Emergency: Hypoglycemia, Moreover the length of the procedure would not affect the trouble of food intake. The clinician should design the treatment plan and duration of Implant Surgery according to the expected length of time a specific medication is active.[13]

Osseointegration and diabetes: Numerous studies and experiments are done on the surgical procedure of Implant to cheek the failure and success rate of Osseointegrated Implants in Hyperglycemic Patients i.e.,Diabetic Patients. The most important factors to be considered: the duration of Diabetes: The longer the duration, the higher the failure.[14] The control of Diabetes over time: The HbAIc should not exceed 7%. The Prevention of Infection: Application of antimicrobial therapy and antiseptic mouth rinses are advised for better outcome.

Success and failure of implants in diabetic patients: More failures were seen in Type-2 Diabetic Patients than Type-1 Diabetes. This is a fact which should be considered and taken seriously before designing and Planning for animplant placement in a Diabetic Patient. Most Studiessays high percentage of early Implant failure in Diabetic Patients are seen than Late Failure. Duration of Hyperglycemic effect in that particular patient significantly affects the success of the surgical procedure of placement of Dental Implant, may be due to Microvascular complications which leads to delay of healing the surrounding of the Surgical area thus early failures of Implants are more commonly seen. Few studies report failure rate seen in Type-1 Diabetes are seen more in number than Type-2 Diabetes, may be due to reduction in Insulin amount in tissues of Type-1 than in Type-2.[15-19]

In a case report, Implant was placed and intended to support an overdenture, for a patient of 65 years old Diabetic women, was retrieved after 2 months due to Prosthetically unfavourable conditions. But when histologically analysis is done, no symptoms of Implant failure recognized, with 80% bone Implant contact ratio.[20]

A Disease Mellitus Type-2 case, having Implant failure within 6 months, was reported by Park JB, and also concluded-As there was no sign and symptoms of failure before loading.[21] So Osseointegration was not affected by Diabetes Mellitus. If Plasma-glucose level were under normal range, Immediate Loading won't affect the survival of Dental Implants.[16,14,22,23] Balshi SF reported 100% success of 18 Implants after 2.5 years of placement, followed by Immediate Loading, in a 71 years old Diabetic Patient. The study suggested-For Osseointegration and Implant survival, controlled mechanical stimuli over Implant can be beneficial.[23]

Conclusion

This is a study for the restoration of Diabetic Patients with Edentulous arches in their oral cavity. It is a risk factor for placement of dental Implants in patients with Diabetes Mellitus, where the post surgical conditions are not seen as normal as in Non-Diabetic Patients and thus leads to Implant failure. But studies saypost-surgical conditions can be as normal as Non-Diabetic Patients, if the patient's Diabetes is well controlled. During surgical method the Insulin Infusion and its duration of action is another most important point of concern. Stabilization of Diabetes and preventive measures against infection can increase the success of dental Implantation in Diabetic Patients to a satisfactory rate of 85-95%.

Initial Management of Maxillofacial Trauma

Chinmayee Chidanandini Kar[1], Sthitaprajna Lenka[2], Karishma Rajan Rathor[3], Prateek Kumar Sundaray[4]

[1]Post Graduate Trainee, Department of Oral & Maxillofacial Surgery, [2]Professor, Department of Oral & Maxillofacial Surgery, [3]Tutor, Department of Public Health Dentistry, [4]Intern, Department of Oral & Maxillofacial Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Trauma create a huge bulk of the figure of lives lost, exclusively in the effective age group. Trauma related deaths acquire a trimodal circulation: First, at site or on removal due to harshness of trauma injuries. The injury could be so severe that nothing can be done to save the life of that trauma victim. Second phase of death is usually due to hypovolaemia and are often treatable and avoidable. Timely and appropriate intervention at this stage can reduce the effects of trauma and prevent morbidity secondary to the injury. The third phase includes those patients who die of complications of trauma such as infection,embolism,sepsis, ARDS, and septic shock. A well-managed second phase is likely to reduce the incidence of the third phase. A systematic approach to a victim is very necessary so that any life-threatening injury is not missed. The approach to trauma must be done in the following steps: Primary survey and resuscitation, secondary survey and definitive care. This article outlines the various steps of the various steps of the initial management of trauma.

Keywords: *Trauma, ATLS (Advanced trauma life support); GCS (Glasgow coma scale).*

Introduction

Traumaisa primary donor facing the global task of disorder. Those who struggle primary trauma keep genuine & usually different injuries combine with active probability of death or injury.[1]

Prehospital care: Any maxillofacial trauma patientscome to the hospital, it is absolutely very much essential for the trauma team to look after each and every hemodynamic parameter of the patient. If the patient arrives in golden hour of trauma the expectancy of chances of survival is more. Airway of patient has to be managed first. In a case of maxillofacial trauma, once the patient arrives in the hospital, the trauma team, neurosurgeons, accidental emergency staffs, maxillofacial surgeons & orthopaedic surgeons, the entire team has to be allotted.[1] The hospital administration has to call these health care providers so that a decision can be taken immediately regarding the treatment plan for the patients. The GCS score of the trauma patient has to be calculated so that the patient can be categorized whether to be intubated or not. If GCS score is very low then the patient is intubated and shifted to ICU. If any intra oral bleeding is there, adequate suctioning has to be done. If any foreign body present inside the mouth it should be removed.[2]

Trauma scoring (GCS): GCS was the first system to quantify the severity of head injury. The variables are-Eye opening (E): Verbal response (V); Motor response (M).

Motor response is used to assess the level of CNS function. Verbal response shows ability of CNS to integrate information. Eye opening demonstrate brainstem activity. Total score ranges from 3-15, highest score represents the increase level of consciousness. Letter T used to designate patient was intubated at the time of examination. GCS 8 or less is generally accepted

as definition of coma. At this level a monitor placed to measure intracranial pressure (ICP).Patient having moderate head injury (GCS 9-13) approximately 10%-20% will deteriorate end lapse into coma. For severe head injury (GCS 3-8) urgent management is critical. These patients are at greatest sign for mortality and morbidity. They will generally have endotracheal placed to protect their airway. Airway protection can be complicated on head injury patient because there are often can concomitant maxillofacial injuries.[2,3]

Airway: The airway is one of the most important factors in maxillofacial trauma patient. If airway is clear the survival of the patient increase, provided there is no head injury. If there is a dento-alveolar fracture or midline palatal split present, then in the emergency dentoalveolar wiring should be done, so that the bleeding can be arrested. Ahigh-volume suctioning has to be done so that if the patient is vomiting or any bleeding is present, chances of aspiration will beless. If GCS score is very low, then oral intubation should be done. A cervical collar has to be placed in all trauma patients. In that way cervical injury chances reduces. The nasotracheal intubation is avoided, if there is head injury there may be fracture of cribriform plate of ethmoid bone. Injury to ethmoid bone may cause CSF leakage. So NETI is contraindicated. If the intubation technique is difficult at that particular point of time, cricothyroidotomy can be prefer in most of the situations.[4]

Breathing: Breathing can be determined by looking at the patient's chest, the rhythm rate and depth has to be monitored. By using of the stethoscope, the entire lungs are auscultated. If saturation is getting low the operator can plan for oral intubation. An immediate chest x-ray can determine the status of the lungs. If there is any fracture present in the ribs it can also be detected and managed with the help of chest x-ray.[5]

Circulation: If a patient comes to the hospital with a hypovolemic shock or during the course of accident or trauma there is a greater amount of blood loss. The skin become pale, cool and sweaty and the patient colour of the skin looks like cyanotic. In that situation it is very difficult to administer fluid through vein flam. So, insertion of central line can save the life of the patient. The chance of deep vein thrombosis and hypovolemic shock are, more if the patient had a massive blood loss. Patient 'cross matching and blood grouping has to be done immediately. Once, the patient blood grouping has obtained immediate blood transfusion should be done. In few places, if the blood bank is not there the crystalloids and colloids plasma expenders has not given.[6]

Secondary survey: "The secondary survey is a complete re-assessment of the patient and injuries. A more complete and traditional history and physical exam is performed. Multiple sources (friends, relatives, law enforcement, and emergency services personnel) often are required to obtain a complete history. It can be learned from the mechanism of injury. The type and magnitude of the potential energy transfer provides many clues to potential injury patterns. Patients with a history of high energy transfer (e.g., high speed crashes, falls from great heights) are at higher risk for occult injury regardless of their initial clinical presentation. Single vehicle crashes, unexplained falls, or potentially self-inflicted injuries will require assessment of the patient's underlying mental state and potential for further self-harm.[7] The physical examination commences at the head of the patient and proceeds toward the toes. The experienced trauma specialist realizes that painful, distracting injuries and a less than precise examination may leave some injuries unidentified. Throughout this portion of the evaluation, the patient should be monitored with continuous cardiac rhythm with pulse oximetry, frequent blood pressure measurements, mental status exam, and clinical assessments of peripheral perfusion. End–tidal carbon dioxide monitoring can be useful also. Invasive monitoring by means of pulmonary artery catheters is rarely feasible in an ED setting. If at any time during the secondary survey the patient's clinical status deteriorates, the examiner should return to the elements of the primary survey.[8] Once the secondary survey is completed, more specific imaging and diagnostic studies can be obtained. If the patient is hemodynamically stable, and the physician has a low concern for life-threatening injury, transport to the radiology department or CT scanner for more accurate diagnostic testing is reasonable. The patient should be accompanied and monitored by a nurse at all times until the initial evaluation is complete."[9]

Tertiary survey: In tertiary survey the occult injuries, those that are not yet been detected while more life-threatening issues are managed are identified and managed properly. Other than this, the patients those are intoxicated with alcohol or other chemicals, who are unable to cooperate with the diagnosis and management of their potential injuries may require endotracheal intubation which helps to facilitate their secondary survey and diagnostic imaging.[10-12]

Conclusion

Critical responsibility authority should know the initial treatment of trauma patients. Dividing the patients into primary, secondary and tertiary groups helps in management of severely injured patients expeditiously. Primary survey includes patients having severe life-threatening complications that should be manage immediately. Secondary survey includes the remaining major injuries that required definitive treatment. The tertiary survey includes management of hidden injuries.

Antibiotic Use in Dental Practice: A Review

Debasrita Ghosh

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Antibiotics are used in the management of many dental infections since decades. Antibioticsare requisite drugs for the management of oral and maxillofacial infections. They are used for the treatment of odontogenic infections, non-odontogenic infections and as prophylaxis against local infections spreading to surrounding tissues and organs. It has been estimated that 10% of all antibiotics prescriptions are linked to dental infections, the combination Amoxicillin-clavulanate is the most preferred antibiotic amongst dentists. The concurrent prescription of non-steroidal anti-inflammatory drugs (NSAIDs) can slightly alter the bioavailability of antibiotics. Over the years various new concepts are been devised in the antibiotic usage, but there is a universal abuse of antibiotics in both medical and dental field. The ultimate indication for the use of antibiotics is bounded and distinct. Pregnancy, kidney failure and liver failure are certain situations which demands special attention on the part of the professionals while indicating antibiotics.

Keywords: *Antibiotics, Prophylaxis, Infection.*

Introduction

Antibiotics were first discovered in 1929 in the form of sulfa drugs (1935), penicillin (1941), tetracycline (1948), and erythromycin (1952).[1] Endodontics and surgical therapy in cases like odontogenic infections, antibiotics are more judiciously used. Patients who are medically compromised such as diabetic or having organ transplants also require antibiotic coverage. In case of dental infections, penicillin is the first drug of choice. For avoiding less alterations in the gastrointestinal tract, narrow spectrum antibiotics are mainly preferred. Dilemma is often noticed among the dental practitioners concerning the use of antibioticsin dental practice.[2]

Indications

Antibiotics act as an adjunct in cases of dental intervention. They are mainly indicated when clinical signs are visible. Antibiotics are majorly used in dental procedures which includes bleeding in the oral cavity. Also In immunocompromised cases and infections which are progressing rapidly antibiotics usage is vastly seen.[3]

Odontogenic Infections: In cases of odontogenic infections, penicillin is the first drug of choice. They are more susceptible to gram positive bacteria (aerobes and anaerobes) and microorganisms found in alveolar and periodontal abscess also necrosis involving the pulp.[2] Penicillin are more prone to both aerobic and anaerobic microorganisms. Infections caused by penicillinase producing staphylococcus, ampicillin like drugs are preferable. Penicillin with clavulanic acid can be preferred for infections involving staphylococci, Streptococci and pneumococci. Patients having resistance may be prescribed with clindamycin as the first choice of drug and also azithromycin and metronidazole. Since cephalosporin group falls under the broad spectrum antibiotics, it is advisable in delayed allergic reactions to penicillin where erythromycin is restricted.[4] Tetracycline are important in cases of gingivitis as they are bacteriostatic in nature and inhibits the binding of Aminoacyl-t-RNA to the ribosomal acceptor site. Ciprofloxacin is mainly used in cases of endodontic infections. Therefore penicillin followed by clindamycin is more commonly used by health professionals.[5]

Non Odontogenic Infections: Non odontogenic infections such as syphilis, tuberculosis, leprosy and other. Infections of bone which are non-specific, for them, a prolonged antibiotic coverage is required.[3] New antibiotics such as fluoroquinolones is the drug of choice for non-odontogenic infections. Fluoroquinolones are prescribed in cases of joint infections, respiratory tract infection, and urinarytract infection. They have a broad spectrum of action. Tuberculosis require a

prolonged duration of antibiotic therapy which consists of rifampicin, pyrazinamide, isoniazid, streptomycin and ethambutol. Penicillin G benzatine is used for the treatment for syphilis.[6]

Antibiotics Usage JN Infective Endocarditis: Infective endocarditis is an uncommon and serious condition which may impose certain life threatening condition. An intricate sequence of events are involved with endocarditis. The adherence of microorganisms is determined by various anatomic sites.[7] Various research has found that dental procedures sometimes lead to infective endocarditis. Similarly a poor oral hygiene with compromised periodontal health impose as a risk factor. Antibiotics therapy work by not only destroying the microorganisms but also inhibiting its adherence.[8] The first drug of choice includes high dose of amoxicillin in both children and adults, one hour prior to dental procedures. 2g of oral amoxicillin should be given to adults. In case of patients who are resistant to amoxicillin or B-lactamase, clindamycin can be given. In patients with amoxicillin and penicillin resistance, first generation cephalosporin can be given. Patients having prosthetic valves in heart, vancomycin and streptomycin is used. Negligence to administer proper antibiotics at time may lead to worst consequences for patients.

Antibiotic Prophylaxis in Case of Local Infections: Various surgical and medical conditions are routinely prescribed with antimicrobials which also includes impacted third molars, orthognathic surgeries, implants, periapical surgery, benign tumor surgery and immuno compromised patients. In case of endodontics, antibiotics should be prescribed in case of fever and signs of local infection. Researches show that post-operative pain reduce to certain extent after the usage of antibiotics in cases of removal of impacted third Molar.[9] Abu Taa et al compared the pre and post-operative antibiotics in patients undergoing periodontal surgery. Amoxicillin is the preferred choice of drug after third molar removal in a dose of 2000 mg for five days.[5] As the site of periodontal surgery is contaminated with microorganisms, it is highly recommended to use antibiotic coverage. Immuno compromised patients are a special division for dental professionals as they are more prone to bacteremia which may lead to septicemia. In such cases dental extractions, deep periodontal cleaning is to be avoided as much as possible. Also, a hematologic, oncologic, and other microbiologist should be consulted with. Other Cases include dental implant placement, surgery related to tooth apex, intra-ligamentary local anesthetic injections and subgingival placement of antibiotic fibers.[10] In case of Diabetic patients, antibiotics are also prescribed. Only when the risk factors are controlled the treatment can proceed. Dental professionals play a vital role in treatment of medically compromised patients who undergo dental treatments as early diabetes is diagnosed during the treatment period. It's the dentist's job to be involved in the health care team and help in the reduction of the diseases. Various studies have found the correlation between prosthetic joint infections and dental procedures. Cephalexin 2g given one hour prior is suggested for patients who are non-allergic to penicillin and clindamycin 600mg for them who are allergic to penicillin.[11]

Antibiotic Regimen with Precautions: Antibiotics prophylaxis should be considered in kidney, liver failure and pregnancy with caution.

Renal failure affects the hard and soft tissues of mouth. After organ transplants, consultation from the physician is strictly advised. In case of prevention of adrenal crisis, additional need of corticosteroids is required.[9] Dose is increased to 30-40mg per day. It is better to perform. Dental treatments after three months of surgery. Six months are considered best. In case of invasive dental treatment antibiotics coverage is necessary.[11] To compensate with increased plasma drug concentration dose adjustments are required in case of kidney impairment. Penicillin, clindamycin and cephalosporin are the preferred antibiotics. Periodontitis disturbs the renal function in kidney transplant patient. Patients are advised to get their dental procedures done on non-dialysis days to ensure the absence of heparin. The six months just after the kidney transplant is considered to be unfavorable to do any treatment. 25 mg of hydrocortisone administered IV reduces the risk of adrenal crisis. In case of liver failure dose of ethryomycin, clindamycin, metronidazole, and antitubercular drugs should be reduced. Zinc supplements is to be prescribed to the patients to decrease health related issues In case of hepatic encephalopathy.[12] Douglas et al in cases of liver failure have restricted the use of tetracycline and anti-tuberculosis drugs. As tetracycline and aminoglycosides have teratogenic effect on fetus it is contraindicated. Shrout et al gave importance to antibiotic prophylaxis for pregnant patients as it decreases bacterial load of periodontal pathogens.[13] Azithromycin, cephalosporin, erythromycin, penicillin with or without beta lactamase inhibitors are prescribed cautiously during pregnancy. The use of NSAIDS during early pregnancy is involved

with spontaneous abortion.[14] Risk is also involved with use of diclofenac, naproxen, celecoxib, ibuprofen and rofecoxib alone or in combination. Every pregnant women is advised to get both medical and dental treatment during the period of pregnancy. Antibiotics are mandatory and essential in both medicine and dentistry. Penicillin is mostly the drug of choice in treatment of dental infections, patients having infective endocarditis, immuno compromised patients and dental procedures which may produce bacteremia. Physician consultation is required before any dental procedure in organ transplants and pregnant patients. Thereby certain complications can be avoided at ease. The prescription should de adjunct to dental treatment.[15]

Squamous Cell Carcinoma Secondary to a Verrucous Carcinoma of Tongue and Redial Fore Arm Free Flap as a Reconstructive Option: A Case Report

Harsh Mohan Pathak[1], Sobhan Mishra[2], Subrat Kumar Padhiary[3], Kalyan Sundar Pal[4]

[1]Reader, [2]Professor & Head, [3]Professor, [4]Post Graduate Trainee, Department of Oral and Maxillofacial Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to Be University), Bhubaneswar, Odisha, India

Abstract

Verucous carcinoma is unusual variant of squamous cell carcinoma which is locally invasive and local recurrence may also common. In this type of carcinoma distance metastasis occur rarely so the prognosis is also good for them. They generally occur in the head neck region and possibility of transformation of these lesions into squamous cell carcinoma is high, for which prognosis become worst. Here in this article we discuss about a case who primarily diagnosed with verrucous carcinoma on right lateral border of tongue and undergone surgery for the same. Recovery was also uneventful but within 4 months of time again he developed a lesion on the right lateral border of the tongue. The clinical and histopathological study of the lesion suggestive of squamous cell carcinoma (early invasive). For the same we decided for aggressive treatment plan to prevent further spread of the lesion. Patient undergone right side hemiglossectomy along with SOHND on right side and reconstruction of the tongue with radial forearm free flap which proved to be functionally helpful for the patient.

Keywords: *Verrucous carcinoma (VC); squamous cell carcinoma (SCC);hemiglossectomy; free flap, reconstruction.*

Introduction

Verrucous carcinoma(VC) First described by a Ackerman (in 1948)the tumor which is comparatively uncommon variant of squamous cell carcinoma which is well differentiated, slow growing and having least metastatic possibility. Growth appears to be exophytic. Recurrence of these lesions are not uncommon. Commonest site for occurrence of these lesions are oropharyngeal region, planter aspect of foot and anogenital region and less commonly involve the other mucosal or cutaneous part.[1] Main cause of oral VC often associated with use of chewing tobacco or snuff for which it is also known as "Snuff diper's cancer". Human papilloma virus infection is also associated with the pathogenesis of this neoplasm. Other causative agents of this neoplasm are chewing of betel nut, alcohol consumption and chronic irritation or mutation in genes. Patient with verrucous carcinoma are at high risk of development of squamous cell carcinoma secondarily. Which cause poor prognosis and need aggressive treatment to prevent further spread of the malignancy. Depending upon TNM staging of planning for the treatment done. In this case we planned for right hemiglossectomy along with right side neck dissection up to the supraomohyoid level after histopatologial study of the secondary lesion suggestive of early invasive carcinaoma.[2] For reconstruction purpose we use radial forearm free flap which proved to better for the same than the other available option like antero-lateral thigh flap and jejunal free flap.[3]

Case report: A man who was in his third decade of life reported to our department complaining of overgrowth on right side of tongue since last 2 years and

the is no improvement after receiving treatment from multiple medical facility and there is no history of pain and burning sensation on taking spicy food. The lesion is gradually increasing in size with time.The patient had habit of pan chewing along with betel nut and tobacco since last 10 years. There was no relevant medical history of the patient.

On extraoral examination: No significant swelling or ulceration present extra orally. Submandibular lymph node palpable and tender on palpation on right side measuring about 0.5 cm in diameter

On intraoral examination: Exophytic lesion with papillomatous growth measuring about 3 cm*1.5 cm present on lateral border of the tongue involving anterior one third of the tongue. Multiple finger like projection present on the surface of the lesion. There is cleft like structure in between the finger like projection. Tender on palpation. The lesion appears white in color with no surface ulceration. Having problem on mastication due to the growth. Mouth opening is restricted. On radiographic examination, nothing significant was found (Figure 1).

Figure 1: Lesion of verrucous carcinoma on right lateral border of tongue.

Management

At this stage first incisional biopsy of the lesion done which suggestive of verrucous carcinoma. After obtain histopathological report wide local excision of the lesion done followed by primary closer of the defect was planned for the patient. Primarily there was difficulty in mastication and speech was not clear which was overcome by the patient within 2 months of time period. Patient was advised for follow up at regular interval (monthly) as there is a chance of recurrence of the lesion and development of squamous cell carcinoma secondarily. On follow up on 4th operative month there was small ulceroprolifarative lesion in the right lateral border of the tongue measuring about 0.5 cm * 0.3 mm in dimension. Lesion was Irregular in shape with creamy white color. Submandibular lymph node was palpable, firm, tender but not fixed. TNM staging was determined as $T_1N_1M_0$.

Primarily incisional biopsy taken from the lesion and send for histopathological study which appeared as early invasive scc. Followed by the histopathology report right hemiglossectomydone along with removal of level I level lI and level lll lymph node i.e., supraomohyoid neck dissection done. Defect created because of hemiglossectomy was reconstructed with the help of radial forearm free flap which harvested from right forearm measuring about 4cm * 2 cm and anastomosed with the with superior thyroid artery and facial vein to maintain its blood supply (Figure 2a, b, c & d). Donor site is covered with the help of split skin graft taken from left thigh region. The flap is folded and simulating the shape of the tongue. Along with other postoperative medication aspirin 150 mg given to maintain blood supply of the flap. On 6th postoperative day water started orally. On 7th day nasogastric tube removed and oral liquid diet started and discharged on 15th day (Figure 3a, b, c & d).Histopathological study reveals early invasive SCC of the right lateral border of tongue and no nodal involvement. Therefore, no planning for the chemotherapy and radiotherapy.

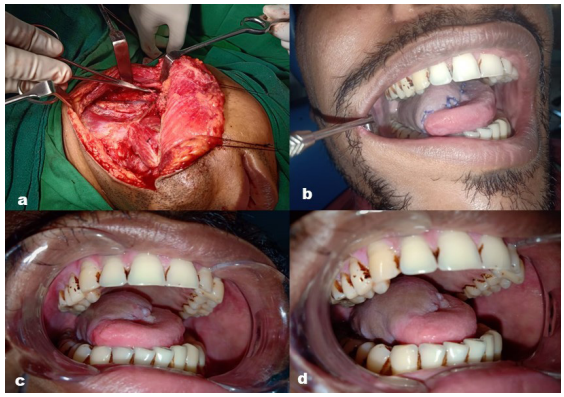

Figure 3a. Supraomohyoid Neck Dissection; 3b. Appearance of Tongue On 15th Post-Operative Day; 3c, d. Appearance of Tongue On 2 Month Review

Discussion

This type of secondary lesion is challenging for the surgeons as early detection of the lesion is needed for better outcome of the surgery and provide a better quality of life and prognosis to the patient.[4] Main goal of management of such cases is the cure the malignancy along with preservation of the normal function of different anatomical structure and provide the patient a good quality of life following surgery. Involvement of tongue made this more for the surgeon as tongue is directly involve in speech, mastication, swallowing of food.[5] Transfer of harvested free tissue with in the oral cavity for reconstruction change the total scenario of the procedure and prove to be helpful for this patient in later days. Radial free fore arm flap is chosen because it can be harvested easily by two synchronous surgical team, amount of obtained pliable skin and soft tissue and length of the flap pedicle, sensory nerve innervation potentiality and caliber of the vessles.Tongue defect is classified by Haughey et al as "hemiglossectomy, three quarter glossectomy, total oral glossectomy and base of tongue defects. They advocated the longitudinal fold technique for hemiglossectomy defects.[6] A small amount of overcorrection about (30%) is needed to allow for decrease in volume of the flap. This is the technique that was used on our patient to allow for closure of the floor of the mouth defect but at the same time simulating normal tongue appearance with a thin flap. This was evident in the acceptable appearance of the reconstructed tongue, good tongue mobility with intelligible speech and good deglutition of the patient".[7] Donor site morbidity should also be considered in this patient. A prospective study shows that there is "32% reduced radial nerve sensation, 14% cold intolerance, 14% restriction of wrist movement and 28% poor aesthetic appearance". Later it confirmed by Toschka et al. The patient shown a little restricted wrist movement except his there was no other complication. On first month follow up there was some difficulty in speech which was overcame by the patient in next 2 months duration. Therefore, radial for arm free flap can be used as suitable option for reconstruction of tongue with acceptable functionality and minimum morbidity of the donor site.[8-12.]

A Case of Orthodontic Treatment-Induced Invasive Cervical Resorption

Lora Mishra[1], Manoj Kumar[2], Shaneel Ahmed[3]

[1]Professor, Department of Conservative Dentistry & Endodontics, [2]Reader, Department of Periodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, [3]Private Practitioner, Kolkata, West Bengal, India

Abstract

A 24-year-old patient sought endodontic treatment for swelling in the upper right canine and premolar region. Surprisingly her past dental history revelled orthodontic treatment five years back. It was a non-extraction orthodontic intervention. Total orthodontic treatment time was 23 months. Twenty-seven months after debonding, a swelling appeared at the buccocervial region of the right premolar which subsides on its own after few days. It used to keep appearing and disappearing on its own since then. Radiographic evaluation on cone-beam computed tomographic scans revealed a severe case of invasive cervical resorption on premolar region. Treatment proceeded with an endodontic approach, and the invasive site reinforced with a biodentine.

Keywords: *Orthodontic Treatment, Induced Invasive Cervical Resorption;Radiographic evaluation; cone-beam computed tomographic scans.*

Introduction

A rare and aggressive form of external resorption is Invasive cervical resorption (ICR), which primarily occurs in any tooth in the permanent dentition. Because of its location and aggressive, there is loss of tooth structure in no time. Numerous factors are held to be responsible for the aetiology of ICR, 2 of which are orthodontic treatment and surgical intervention.[1] The condition is usually painless, and often teeth give no visual signs and diagnosis is usually the result of a routine or sometimes a chance radiologic examination. The process of resorption initiates below the epithelial attachment of the tooth. It progresses coronally and apically along the root dentine.[2]

The clinical features vary from a small defect at the gingival margin to a pink coronal discolouration of the tooth crown resulting in ultimate cavitation of the overlying enamel which might be painful if pulpal or periodontal infection supervenes.[2] Internal resorption could be a differential diagnosis of ICR. Radiographs are elusive in these cases. Cone-beam computed tomography is the correct approach to diagnose such cases.[2,4,5] A plethora of approaches for the treatment of ICR is present in literature. Most appropriate therapy is to expose the resorption and remove the granulomatous tissue. Glass ionomer cement, light-cured resin composite, amalgam, and mineral trioxide aggregate (MTA) is preferred restorative material to fill the defect.[6] Among the options available, a new bioactive cement, Biodentine (Septodont, St. Maur-des-Fossés, France), can also be used as a repair material for the defect.[7]

The objective of this case report is to emphasize on the management of ICR using Biodentine.

Case Presentation: A 24-year-old male patient presented to the Department of Endodontics with a complaint of painless swelling in the maxillary right premolar region. Medical history of the patient was noncontributory. The documents of clinical examination done five years ago revealed that she had undergone non-extraction orthodontic treatment with a temporary

e-mail: loramishra@soa.ac.in

anchorage device in the area of interest. Clinical examination demonstrated that the maxillary right premolar was non-sensitive to percussion and also showed swelling of attached gingiva).The periodontal probing depth was 4mm. A periapical radiograph was inconclusive. Because pulp sensability test revealed that this tooth was not vital, an Endo perio lesion was suspected. Cone beam computed tomography (CBCT) of the area revealed a V-shaped defect present on the cervical area of buccal aspect of the tooth in question (Figure 1). The diagnosis then made was of invasive cervical root resorption (ICR).

The patient was informed of the treatment plan, potential risks before giving her consent to the treatment. Followed by the administration of infiltration anaesthesia in the vestibular of maxillary right first premolar. An intrasulcular incision was made from the mesial surface of maxillary left lateral to the distal surface of maxillary right second premolar; buccally full-thickness mucoperiosteal flaps were elevated (Figure 2). Granulomatous tissue around the cervical area of the affected tooth was present. Granulomatous tissue within the defect area and from the inner aspect of the flap were cautiously eradicated by 4R/4L curette (Hu-Friedy, Chicago, IL). Because of the defect was involving the root canal and was present specific to location,the diagnosis was clinically confirmed. The root surface was carefully and completely scaled and planed with 1/2 Gracey curette (Hu-Friedy) and round bur. The surgically exposed area was then rinsed with sterile saline solution.

The access cavity was shaped with the round bur. Canal was prepared to size 25 by using K-files (Diadent, Grenoble, France). The root canal was irrigated between each file with 5% sodium Hypoclhlorite (Prevest, India), EDTA 17% (Prevest, India) and sterile saline by using a long needle alternatively. A size 25 master cone radiograph was taken, and the root canal was obturated with single cone technique. The resorption site was subsequently sealed with Biodentine (Figure 3). The flap was repositioned with nonabsorbable silk sutures. This procedure also prevented communication between Biodentin and oral environment. The access cavity was restored with a tooth colour restorative material composite (Clearfil Majesty; Kuraray, Osaka, Japan). After the surgery, the patient was prescribed amoxicillin 1 g twice a day for one week, Ibuprofen 200 mg twice daily if the pain was present and 0.2% chlorhexidine mouthwash 15 mL twice a day for two weeks. Because of the uneventful healing, the desired gingival contour was achieved; the patient was symptom-free one-weekpost-surgery, and the sutures were removed (Figure 4).

At 1-year follow-up, the periodontal status of related tooth demonstrated no mobility with normal probing depth, no gingival recession, and no loss of clinical attachment. There was reattachment between the sulcus and the Biodentin. In the radiographic examination, the related tooth and surrounding tissues showed no pathologic changes.

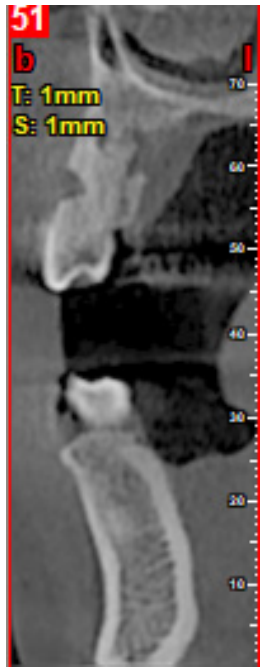

Figure 1: CBCT scan showing resorption at the cervical area of 14

Figure 2. Defect involving the root canal of 14

Figure 3. Defect site restores with Biodentin

Figure 4. Comparison of pre-operative and post-operative site

Discussion

Many predisposing factors are present to initiate ICR. Since the patient gave a history of orthodontic intervention and placement of TAD, one can suspect that both can induce ICR in the otherwise healthy tooth.[8-10] Different techniques and strategies can be adopted to treat these root lesions cause by ICR.[11] In this case, resorption lacuna was surgically explored; the root canal treatment and repair of root resorption was done simultaneously. Surgical procedures of varying degrees of invasive cervical resorption has generally involved periodontal intervention which included reflection of flap, curettage, either amalgam, composite resin, or glass ionomer cement restoration of defect, and repositioning the flap to its original position. In the case report by Yilmaz et al. there was no periodontal attachment with MTA seen.

Biodentine is a calcium silicate-based material was explicitly designed as a "dentine replacement" material. Biodentin exhibits many advantages over MTA one of them being that has better handling, which allows it easy to place in areas of resorptive defect and needsmuch less time for setting.[7] Periodontal attachment at the cervical area creates a biological seal around the reparative material, which is another crucial aspect to be considered for long term survival of the tooth.[12]

In this case, Biodentin can establish healthy periodontal attachment at the site of the defect. Biodentine also inhibits the activity of bacteria, sets in the presence of moisture and blood, and because of its hydrophilic characteristic, therefore becomes an ideal material for repairing and managing ICR cases.

Conclusion

Although this case report presents a favourable clinical outcome, further studies are necessary to provide more information about the use of Biodentin for the treatment of invasive cervical resorption.

An Alternative Treatment Method Using a Minimally Invasive Approach Employing: Ceramic Veneer to Replace Discolored Composite Veneer: A Case Report

Lora Mishra[1], Manoj Kumar[2]

[1]Professor, Department of Conservative Dentistry and Endodontics, [2]Reader, Department of Periodontontics & Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

A 26-year-old Indian female patient had a discolored tooth colored restoration in maxillary right central incisor A resin composite veneer had been placed to manage Eliis Class II fracture of 11. Her oral hygiene was excellent, and the gingival tissue was healthy. The treatment plan to manage discolored composite restoration with ceramic veneers using IPS Empress Esthetic ceramic system.

Keywords: *Discolored tooth colored restoration; Ceramic veneer; Minimally invasive approach.*

Introduction

Esthetic treatment of a single discoloured restored tooth represents a significant challenge to the dental practitioner. Due to the ageing and exposure to smoking, food, acidic beverages, temperature changes, function of the teeth, saliva and biofilm on the direct composite materials tend to degrade at a faster rate compared to indirect restorations. Direct composite veneers, therefore, require frequent replacement.[1]

Laminate veneer restorations are the treatment of choice for esthetic reasons and minimally invasive treatment concept. Ceramic Veneers provide colour stability, mechanical strength, clinical longevity, esthetic appearance and compatibility with periodontal tissues-make this material the right choice for such treatment. We present a case of restoration of a single, highly darkened anterior tooth with a feldspathic porcelain veneer. The resolution involved preparation of the dental structure guided by orientation grooves and provisional restoration using composite resin, a silicone impression and adhesive luting. Minimal invasive procedure of porcelain laminate veneers provides satisfactory esthetic outcomes and preserves sound tooth structure.[2]

This case report describes replacement of composite resin restoration with minimally invasive laminates in a patient seeking improved smile esthetics.

Case Presentation: A young woman 26 years old presented at our dental specialty clinic complaining of discolored composite resin restorations in her upper anterior teeth (Figure 1). Past dental history revealed she had a history of trauma due to fall five years back. Since then she has replaced her composite restoration twice due to color mismatch and staining. She came seeking for more permanent and esthetic restoration. Gingival and periodontal health was excellent.

Figure 1: Discolored anterior composite restoration present in relation to 11

e-mail: loramishra@soa.ac.in

Maxillary right central incisorgave a normal response to Cold test with Miracold Plus (Hager). An intraoral periapical suggested of healthy peri radicular area11. Substitution of the resin restorations by minimally invasive ceramic laminates was suggested to the patient. Initially, dental prophylaxis was performed using an ultrasonic instrument. A full mouth impression was taken with alginate (3M ESPE) for diagnostic cast and wax up. A gypsum model was obtained, and a wax-up of this model was performed. A silicon impression (Coltene Affinis) was then developed from the wax-up. The color was selected using Vita Tooth guide 3d-Master in natural light before removal of the composites to prevent dehydration of the substrate.

Figure 2: Partial Veneer with Incisal palatal butt joint preparation of 11

The initial preparation for veneer was done using depth marking diamond bur of 0.5 mm (DIATECH crown and Bridge preparation kit) on the labial aspect (Figure 3). Partial veneer with butt joint incisal overlap was prepared to the depth marked by the depth marking grooves. The preparation removed the old composite restoration as well. A silicon impression with both putty and light body (Coltene Affinis) was made after the final reparation preparation and sent for preparation of Ceramic veneers. Provisional restorations were made using bis-acryl resin (Cool Temp, Coltene). Temprorary restorations made from bis-acryl resin do not need to be cemented. However, excess gingiva must be removed. Dies were carefully made to allow for the precise development of the emergence profile. An IPS e.max press (Ivoclar Vivadent) was used to make the ceramic laminates. The cervical and proximal finish were done using stones and ceramic rubber (Shofu, Porcelain veneer Kit).

Figure 3: Veneer etched with HF

After three days, the ceramics were tried in the mouth using a try-in clear paste (Nexus™ 3, Kerr Dental Corporation, Orange, CA, USA). After receiving consent from the patient, the restorations were etched with hydrofluoric acid for 20 seconds (10% Hydroflouric Acid Angelus Dental). Each inner surface was washed for 20 seconds and dried using a triple syringe. Silane (Monobond S, Ivoclar Vivadent) was applied as the bonding agent, and 60 seconds were allowed for drying. Adhesive (Tetric N-Bond, Ivoclar) was applied, and polymerization was activated. The tooth was etched using phosphoric acid (Meta Bio-med) for 30 seconds; the surface was then washed and dried. Tetric N-Bond adhesive was also applied to the teeth and polymerization was activated. Light-curing luting composite (Ivoclar Variolink N Lc) was applied to the inner aspect of the restorations and placed in position with Optrastick (Ivoclar). The excess cement was removed using a microbrush and floss. The restoration was cured for 120 seconds using a curing light (Coltene SPEC 3 LED). All materials were applied according to the manufacturer's instructions. An incisal adjustment with ceramic rubber was prepared. The final smile in this patient is shown in Figure 4.

Figure 4: Final restoration of 11 with ceramic veneer

Discussion

Patient selection plays a pivotal role in the success of veneers. A young patient with sufficient enamel thickness, normal overjet, overbite, absence of parafunctional or unhealthy habits and lastly presence of favourable smile line make them ideal to receive ceramic veneers.[3]

Currently, porcelain veneers afford predictable and successful restoration, with relative survival of 10 years. IPS E.max is reinforced lithium disilicate ceramics which have excellent optical and mechanical properties. They provide sufficient strength and enhances esthetic appearance when compared with direct composite resins s that had initially been used in this patient. These materials are biocompatible restorative materials that are harmonious with periodontal tissues due to their surface smoothness.[4]

The only drawback of these veneers is that since their thickness is restricted to 0.3-0.5mm they can easily fracture before bonding. Therefore, they need careful handling. However, etched enamel and porcelain, combined with the bonding composite resin luting agent with a silane coupling agent, provides a long-lasting and durable restoration.[5]

The advantages of incisal overlap include masking of the otherwise noticeable incisal finish line, thicker ceramic and reinforcement of incisal edge, and positive seating of ceramic veneers.[6] Since preparation was restricted to the enamel, this favours adhesive cementation. Retention of the restoration is also helped by the use of hydrofluoric acid and by silane coupling agents. A photopolymerizable resin cement should be used for thin restorations because these are translucent. Use of this technique shortens clinical time and make the outcome more predictable.[7] After six months of clinical follow-up, the restorations in our patient proved to be adequate from both the functional and aesthetic aspect, with the maintenance of periodontal health.

Conclusion

Discolored or stained resin composites restorations can be replaced by minimally invasiveceramic laminates in a safe and esthetically pleasing manner.

Nutrition & Oral Health: An Overview

Madhusmita Sahu

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Nutrition is defined as intake and absorption of nutrients from foods and drinks. Availability of proper nutrition is essential for growth, development and maintenance of overall health. From gestational period to end of life, nutrition influences the structural and functional integrity of dentition and supporting oral tissues, directly or indirectly. If the diet taken doesn't supply enough nutrients needed to support tissues, malnutrition may develop. Poor nutritional intake affects nearly every structure of oral cavity causing further systemic disease. This article basically aims at describing importance of specific nutrients and their effects as well as results of their deficiency on oral health. Knowledge of the relationship between nutrition and oral health will help the dentists to question the patient about dietary habits, early detection of nutritional deficiencies and eventually guiding the patient to lead a healthy lifestyle.

Keywords: *Nutrition, nutrients, oral health, malnutrition.*

Introduction

Nutrition is the form of process by which an individual take and utilizes food. A well balanced, nutritious diet is important for good oral as well as general health. The food we eat supplies nutrients to body, bones, teeth, gums and also helps to fight against various infections. Hectic lifestyle, poor diet can contribute to oral diseases like Dental caries, Enamel and Dental Hypoplasia, Scurvy, Cleft lip and Cleft palate. However, poor nutrition associated with unhealthy habits can lead to progressive oral diseases such ascandidiasis, leucoplakia, squamous cell carcinoma etc.[1]

In dependent and elderly individual undernutrition are prevalent to several health problems, reduced appetite and poor quality of life. Poor oral health and Xerostomia are usually associated with reduced BMI and difficulty in mastication. Reestablishment and well maintenance of masticatory function improves nutritional status and quality of life.[2]

Effects of Nutrition on Oral Health: Notional intake influences oral health and vice versa. This interdependency promotes healthy oral tissues as of Periodontium, salivary glands, tongue, teeth, mucous membranes etc as well as overall health.[3]

Oral diseases that have strong association with national intake are:

1. Dental caries
2. Periodontitis
3. Poor development of oral cavity
4. Dental erosion
5. Oral cancer
6. Potentially malignant lesions
7. Oral candidiasis
8. Recurrent apthous stomatitis
9. Gene disease
10. Alveolar osteoporosis

1. **Dental Caries:** It is a multifactorial microbial disease, characterised by demineralisation of inorganic components and destruction of organic substances of tooth, leading to cavitation[4]

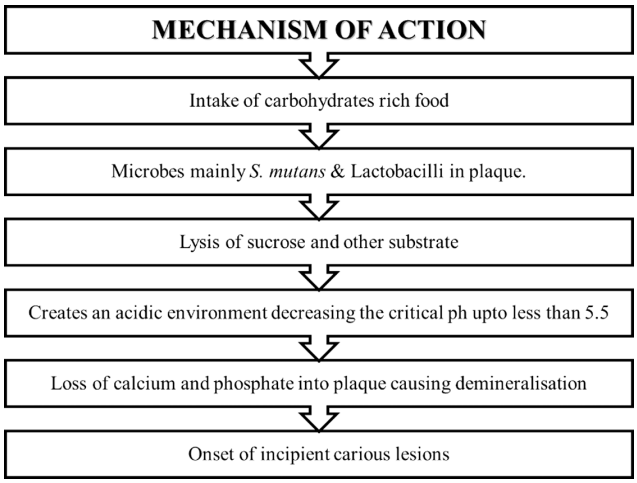

Figure 1. Mechanism of action for Dental caries

Oral Manifestation:

1. **Pre-eruptive effect:**

- Dental dysplasia causing odontoclasia in deciduous dentition
- Yellow teeth in permanent dentition
- Infantile melanodontia
- Linear hypoplasia of deciduous incisors.

2. **Post-eruptive effect:** Salivary protein deficiency can cause decrease salivation and level of Ig A level there by decreasing host defence mechanism.

Prevention

- However controlled consumption of sugary foods with proper maintenance of oral hygiene can decrease in prevalence of dental caries.
- In pre-eruptive and post-eruptive stages fluoride application can also decrease prevalence of dental caries.[5]

2. **Periodontal Disease:** Periodontal disease involves more of undernourished population. The pathology starts from gums and gradually involvesperiodontal ligament and alveolar bone.

Predisposing factors

- Poor oral hygiene associated with malocclusion
- Diabetes
- Obesity
- High carb rich diet
- Vitamin c deficiency leading to decrease collagen formation and haemorrhagic gingiva.
- Calcium and phosphorus deficiency leading to alveolar bone density and ridge resorption.

Prevention: Sufficient intake of vitamin c, vitamin B complex, calcium and phosphorus can improve the situation.[6]

3. **Poor Development of Oral Cavity:** Deficient intake of vitamin and mineral during pregnancy can influence the development of oral structure.[7]

Insufficient supply of carbs leads to

- Alternation of organogenesis
- Dental caries
- Insufficient supply of protein leads to-
- Degeneration of lingual papilla
- Alteration of dentigenisisandcemetigenesis
- Altered development of maxilla
- Malocclusion
- Hypoplastic enamel
- Insufficient lipid lead to-
- Parotid swelling
- Mucosal atrophy

4. **Dental Erosion:** It is a progressive irreversible loss of dental tissue due to chemical corrosion by acids of intrinsic and extrinsic origin.

- **Extrinsic acids**–derived from food beverages containing citric acid, Ascorbic acid and maleic acids
- **Intrinsic acid**–gastrointestinal reflux disease

Prevention

- Dietary modification. Such as increase intake of iron and calcium rich food
- Optimization of fluoride regimen with adequate oral hygiene measure.[7]

5. **Oral Cancer:** There is strong association between diet and oral cancer causing uncontrolled and uncoordinated growth of tissue.[8]

Etiology

- Consumption of carcinogenic initiators such as tobacco, alcohol etc.
- Nutritional deficiency of vitamin A, beta carotene, vitamin C, vitamin E and iron

Prevention:

- Cessation of habit
- Supplementation with iron, vitamins and antioxidant[8]

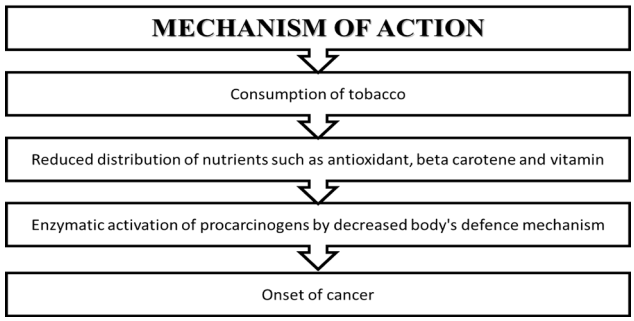

Figure 2. Mechanism of action for oral cancer after chronic tobacco consumption

6. **Potentially Malignant Lesion:** This includes a variety of lesions characterised by increased risk of malignant transformation under some favourable conditionse.g.: leucoplakia, oral lichen planus.

Etiology: Deficiency of retinol, beta carotene, vitamin B12, vitamin A, folic acid and marks onset of the lesions.[8]

Prevention: Consumption of food and vegetables rich in antioxidants and folic acid.

7. **Candidiasis:** It is the most prevalent opportunistic infection affecting oral cavity caused by *Candida albicans*.

Prevention:

- Maintenance of proper oral hygiene.
- Consumption of food stuff rich in folicacid, vitamin A, B1, B2, C and K.

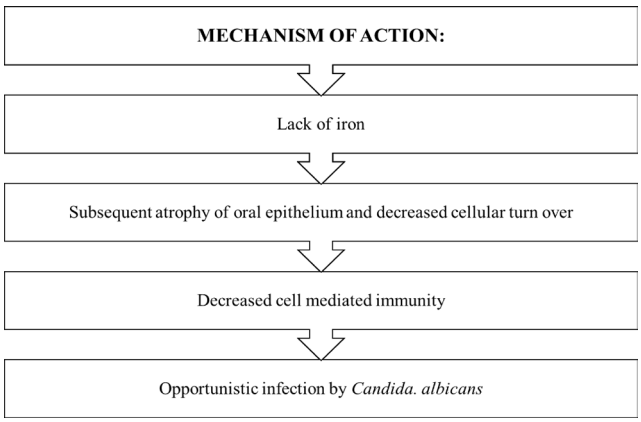

Figure 3. Mechanism of action for opportunistic infection by Candida albicans

8. **Recurrentrecurrent Apthous Stomatitis (RAS):** It is a benign painful oral mucosal disease consist of single ormultiple nonspecific ulcers.

- Predisposing factors-hematinic deficiency.
- Oral manifestation includes depapilationand atrophy of tongue.

Prevention: Consumption of diet rich in iron, folic acid and vitamin B12.[8]

9. **Geneticdisorder:** Folate deficiency during embryonic development cause defect in neural tube formation. Genetic mutation of maternal gene "MTHER" causes folate deficiency in blood which increases the risk for cleft lip and palate.[7,8]

10. **Alveolar Bone Osteoporosis:** It is anage-related condition characterized by low bone mass with consequent increase in bone fragility and fracture susceptibility.

Prevention: In elderly people, adequate amount of calcium and vitamin D, vitamin C, folic acid, iron rich food should be included.[7,8]

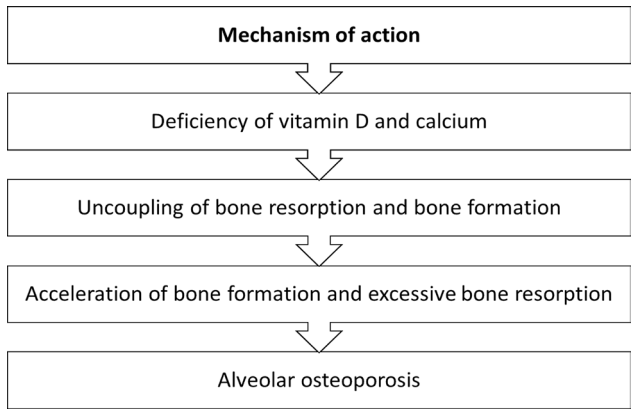

Figure 4. Mechanism of action for alveolar osteoporosis

Table 1: Oral manifestation of nutrition deficiency

Nutrient Deficiency	Clinical Manifestations
Vitamin A	Gingivitis, periodontitis Hyperplasia of gingiva
Thyamin (Vitamin B1)	Crack lips, A satin looking gingiva and tongue, Angular cheilitis, ulcerative gingivitis
Vitamin B6	Tooth & Bone decay, Periodontal disease, Anaemia, Sore tongue, Burning sensation of oral cavity
Vitamin B12	Angular Cheilitis, Halitosis, Bone loss, Detachment of periodontal fibres
Vitamin C	Bleeding gums, Delayed wound healing, mobile tooth

Balanced Diet: A balanced diet might be described as one providing each nutrient in amount needed to maintain optimum health.[9]

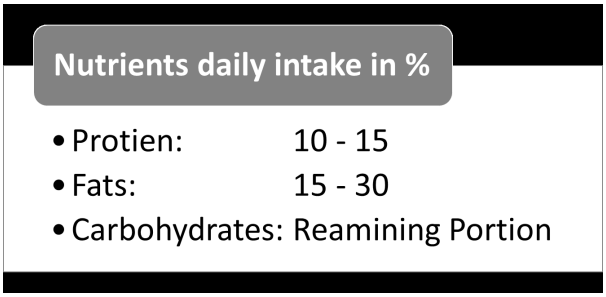

Figure 5. Daily nutrition intake

Effects of Poor Oral Health on Nutrional Absorption: Poor oral health can affect quality and quantity of dietary absorption which in fact increase susceptibility towards systemic disease.

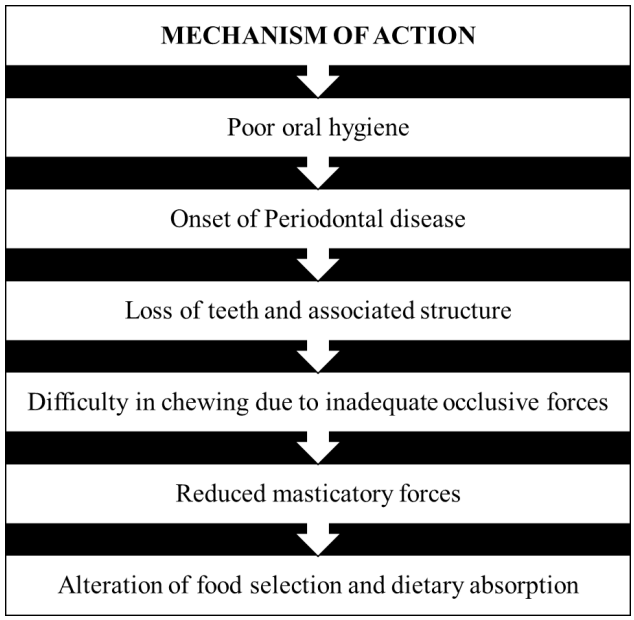

Figure 6. Mechanism of action for alteration of food selection and dietary absorption

- Studies revel people with more tooth tends to have more grinding of food, consume fewer calories including more fibres, vegetables, less saturated fat hence improved dietary quality and nutritional status.
- Loss of tooth causes decrease in masticatory ability even after use of dental prosthesis. ln elderly individuals edentulousness causes oral discomfort during chewing leading to weight loss. Iii fitting denture cause poor grinding of food leading to inadequate intake of nutrition. Edentulous or denture bearing people tend to consume more over cooked processed food containing more refined sugar, cholesterol which predispose to systemic disease.[10]

Conclusion

Nutrition is vital to human growth, development and health maintenance. Malnutrition can cause poor oral health and poor oral health can indirectly cause malnutrition. To break the interdependency dental and general health workers should reach a large number of individuals to provide clinical assessment of nutritional risk factors during regular health check-ups. Education and motivation regarding nutrition and health should be given on a regular basis. Periodic monitoring and follow ups should be included to evaluate the counselling results.

Gingival Enlargement, a Diagnostic Indicator of Leukaemia?

Manoj Kumar[1], Satya Ranjan Misra[2], Saurav Panda[3], Rupsa Das[4]

[1]Associate Professor, Department of Periodontics, [2]Professor & Head, Department of Oral Medicine & Maxillofacial Radiology, [3]Associate Professor, Department of Periodontics, [4]Post Graduate Trainee, Department of Oral Medicine & Maxillofacial Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

The mouth is considered as a mirror of the body reflecting the changes both in health and in disease. It is well known that certain systemic diseases are diagnosed due to their characteristic appearance in the oral cavity. The gingiva is enlarged due to many systemic conditions and diseases including pregnancy, hormonal variations, drugs, hypersensitivity, infections, as well haematologic malignancies. Gingival enlargement has been linked to leukaemia and that too as an early diagnostic indicator of this possibly fatal disease, which when identified early can help reducing the morbidity and mortality by referral to haemato-oncologist and initiation of chemotherapy. Leukaemia is a haematologic malignancy arising from production of anomalous haemopoietic stem cells with uncontrolled regulations, differentiation and apoptosis. We report a case of leukemic gingival enlargement in a young male patient with a brief discussion on the mechanism and clinical features.

Keywords: *Diagnostic indicator, gingival enlargement, leukaemia, systemic disease.*

Introduction

Leukaemia is a hematologic malignancy in which there is proliferation of immature leukocytes (precursor or blast cells) in the bone marrow.[1] The blast cells do not mature into leukocytes and they aggregate in the marrow spaces suppressing the hematopoietic stem cells resulting in deficient formation of all the blood cells.[2] Due to the collapse of the hematopoietic system there is pancytopenia. The abundance of the blast cells surpasses the capacity of the bone marrow and they spill into the blood as well as soft tissues, including the gingiva where it leads to gingival enlargement. [3]

The aetiopathogenesis of Leukaemia is not clear. Abnormalities in chromosomes (Philadelphia chromosome), chemicals, exposure to irradiation as well viral infections have been implicated. [2,4] The incidence of this grave disease is about 0.04% with a significantly high morbidity and mortality rate. It is said that among all the deaths due to malignancies, Leukaemia accounts for about 4%.[5] The disease is classified on the basis of its onset, types of cells lineage involved and the rate of progression. It is fatal, when left untreated.

Case Report: A 25-year-old male reported with swollen gingiva for 2 months which was associated with pain and bleeding. The past medical, dental and family histories were non-contributory.

He also reported of low-grade fever, loss of appetite and weight loss. Physical examination revealed submandibular lymphadenopathy and generalized pallor. Intraorally generalized enlargement of the gingiva was seen with pseudo pockets in both maxillary and mandibular arches, and erythema, bleeding, haemorrhagic slough in some areas. [Figure 1a] Clinical differential diagnosis of leukaemia, fibromatosis gingivae and inflammatory gingival enlargement were considered.

Panoramic radiograph did not show any alveolar

bone resorption. Peripheral blood smear revealed about 80% blast cells, faggot cells with multiple Auer rods were seen suggestive of acute promyelocytic leukaemia. [Figure 1b] Complete hemogram was performed and it was seen that the patient had anaemia, thrombocytopaenia and leucocytosis. [Figure 2a] For confirmation, flow cytometry and fluorescent in situ hybridization (FISH) assay were performed. It was seen that CD13, CD33 and CD 17 were expressed and HLA-DR and CD14 were absent, Cytogenetic or FISH analysis of acute promyelocytic leukaemia-Retinoic acid receptor alpha (PML/RARA) fusion genes was positive, confirming the diagnosis of PML. The patient was referred to the haemato-oncologist for treatment and was started on induction chemotherapeutic regimen but was lost to follow up.

Discussion

Leukaemia is a haematologic malignancy involving the leukocytes which presents as a high count of immature blast cells in the peripheral blood and their proliferation in the bone marrow at the expense of the normal erythrocytes, leukocytes and thrombocytes resulting in pancytopenia[1,2,6] Depending on the cells implicated, Leukaemia can be myeloid or lymphoid and depending on the onset, it could be classified as acute or chronic. While chronic leukaemia starts with a slower onset, runs a gradual course ranging from months to years, usually showing more differentiation of cells, acute types have characteristically loss of differentiation of the blast cells, which suddenly proliferate and are so aggressive that within a short time could lead to death if left undiagnosed/untreated. [7]

The acute myeloid series of leukaemia are attributed with the manifestations of gingival enlargement and the present case is no exception. Depending on the maturation the leukaemiais further classified into subtypes. The French-American-British classification of acute myeloid leukaemia is given in Table 1:[8]

Table 1. French-American-British classification of acute myeloid leukaemia

M0	Undifferentiated leukaemia
M1	Acute myeloblastic leukaemia
M2	Acute myeloblastic leukaemia with maturation
M3	Acute promyelocytic leukaemia
M4	Acute myelomonocytic leukaemia
M5	Acute monocytic leukaemia
M6	Acute erythroblastic leukaemia

The signs and symptoms that we encounter in the leukemic patients are due to the result of the proliferation of the malignant blast cells and their subsequent effect on the normal haematopoietic stem cells. Since erythrocytes are not formed it leads to anaemia, fatigue, breathless on exertion, mucosal pallor and generalized debility. [9,10] Due to the decrease in the leukocytes, the immunity decreases, the patients are prone to infections and are febrile. Spontaneous unprovoked bleeding especially in the gingiva, purpuric patches and clotted blood in the oral cavity are due to the decrease in platelets. [11] Besides hepato-splenomegaly, lymphadenopathy and involvement of the central nervous system are common.[12]

Oral manifestations are the most frequently encountered in the acute types and occur because of the infiltration of the blast cells in the tissues directly or indirectly due to the decrease in thrombocytes, erythrocytes and leukocytes.[13,14] Oral manifestations can lead to diagnosis of many systemic diseases, one of them is leukaemia. Oral mucosal pallor, gingival enlargement, unprovoked gingival bleeding, palatal petechiae, haemorrhagic sloughs on the gingiva and ulcerations are the hallmark of leukaemia.[15] Leukemic gingival infiltration occurs only in about 5% of cases of acute myeloblastic leukaemia (AML).[16] The antigens derived from the periodontal bacteria serve as chemo-attractants for the leukemic cells. Due to the micro-anatomy of the gingival vasculature, and expression of endothelial adhesion molecules, the infiltration of leukemic cells is further facilitated resulting in gingival enlargement.[17] [Figure 2b] It has been seen that the leukemic gingival enlargement is responsive to chemotherapy, even without any sort of periodontal treatment leading to regression in the enlargement. [18]

Dentists/oral physicians are concerned about the oral problems of the patients and are faced with a predicament whether dental treatment could worsen the leukemic situation changing the systemic status of the patient. Oral hygiene measures like oral prophylaxis will cause transient bacteraemia which would lead to considerable morbidity. However, any therapy for the disease needs removal of foci of infection, periodontal status needs to maintained and debridement may be done when warranted and even dental extraction under suitable prophylactic measures.[19,20] It may be further emphasized that all dental procedures ought to be undertaken with the supervision of the consultant haemato-oncologist and only palliative emergency dental care needs to be provided.

Conclusion

It must be emphasized that dentists and oral physicians need to differentiate between gingival enlargement seen in different conditions and recognize the oral manifestations of leukaemia aiding in their early diagnosis, ensuring prompt treatment reducing the morbidity and mortality associated with the disease.

Central Ossifying Fibroma of the Mandible: A Case Report

Mirna Garhnayak[1], Subrat Kumar Padhiary[2], Swagatika Panda[3], Sangram Panda[4]

[1]Professor, Department of Prosthodontics and Crown & Bridge, [2]Professor, Department of Oral & Maxillofacial Surgery, [3]Professor, Department of Oral Pathology & Microbiology, [4]Reader, Department of Prosthodontics and Crown & Bridge, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneshwar, Odisha, India

Abstract

Central ossifying fibroma is a benign fibro-osseous lesion of mesenchymal origin, mostly prevalent in second and third decade of life. Women are affected more with a strong predilection for the mandibular premolar and molar areas. They are usually slow growing asymptomatic tumor which treated by curettage enucleation and sometimes by enblock resection. This case report presents the central ossifying fibroma of a twenty-three-year-old female which was diagnosed, operated and rehabilitated successfully.

Keywords: *Central ossifying fibroma; fibro-osseous lesion; curettage enucleation.*

Introduction

Central ossifying fibroma (COF) is one of the most common benign fibro osseous neoplasm in oral and maxillofacial region. It is prevalent in the second and third decades of life Normally, females are affected, preferably in the mandibular premolar and molar areas.[5-7] Being a fibro osseous lesion, it looks a lot like fibrous dysplasia, cemento-osseous florid dysplasia or cemetifying periapical dysplasia. This painless lesion requires complete excision to avoid recurrence. The present case report deals with the surgical and prosthetic rehabilitation procedure of a young patient with COF of mandible.

Case report: A 20-year-old girl reported to the Department of Oral Medicine with a gradually increasing painless swelling in the right vestibular region of mandible for three months. The extra-oral examination revealed a single diffuse swelling in the right side of face about 1 cm below the angle of mouth. No lymphadenopathy was there. On intra oral examination, bicortical swelling was seen 46, 45, 44 regions, with normal overlying mucosal colour. On palpation swelling was lobulated,bony hard in consistency and was non-tender. Expansion was there both lingually and buccally, without involving lower border of mandible.

Analysis of the panoramic radiograph revealed a well-defined lesion with mixed radiopaque and radiolucent appearance. It was extending from 43 to 47 mesio-distally and from the alveolar crest to 1.5 cm above the inferior borders of the mandible supero-inferiorly. A radioopaque mass was present in relation to 45 and 44 with multiple foci of calcification throughout. It was surrounded by a radiolucent zone (Figure 1). Though roots of 46 and 45 were displaced, there were no external resorptions of any root resorption. The histopathological examination of incisional biopsy, showed mature bony trabeculae with osteoblastic rimming in a highly cellular fibrocollagenous stroma, suggestive of central ossifying fibroma (Figure 2).[1] Noperitrabecular clefting was there, which differentiate it from fibrous dysplasia.[2] Based on the above clinical findings, imaging results, and histopathologic features, a diagnosis of central ossifying fibroma (COF) was confirmed.

Figure 1: Pre-operative radiograph of patient with central ossifying fibroma

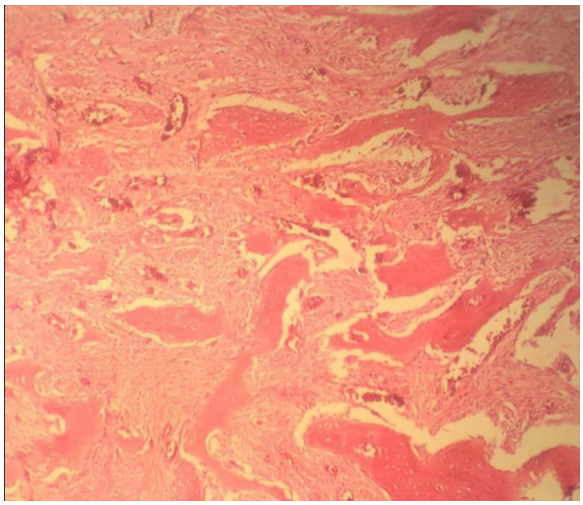

Figure 2: Histopathologic feature of central ossifying fibroma

Surgical treatment: Having a definitive diagnosis and extension of the lesion in mind, surgical excision and reconstruction with bone graft was planned. The lower border of the mandible was free from the lesion. So,a marginal mandibulectomy was planned with informed consent of the patient. With standard submandibular incision, the lesion was exposed. Marginal mandibulectomy was done from 43 to angle of the mandible. A rim of healthy bone at the lower border of the mandible was kept intact and was reinforced with 2.5 mm reconstruction plate.[3] A block of corticocancellous bone graft from the iliac crest was harvested and secured to the surgical defect on the remaining lower border of the mandible. Bone graft was fixed to the reconstruction plate with the help of soft stainless-steel wire (Figure 3a) The graft area was then covered with plasma rich fibrin(PRF) membrane and tension free closure of the flap was carried out. Post-operative instructions were given to the patient.

On her recall visit she has a good facial symmetry, mandibular contour, intact mucosa and proper occlusion. Her post-op panorex x-ray showed good graft position and size(Figure3b). The patient was followed up for a period of twelve-month. As there was no recurrence of the lesion,it was deciding to rehabilitate the case prosthetically.Post marginal mandibulectomy, a Kennedy's class II situation was created with missing teeth numbers of 48,47,46,45,44 and 43 (Figure4a).[4] Various treatment options ranging from implant supported prosthesis to cast partial denture were discussed with the patient. As the patient was not interested for a second surgery, a cast partial denture was planned for her.

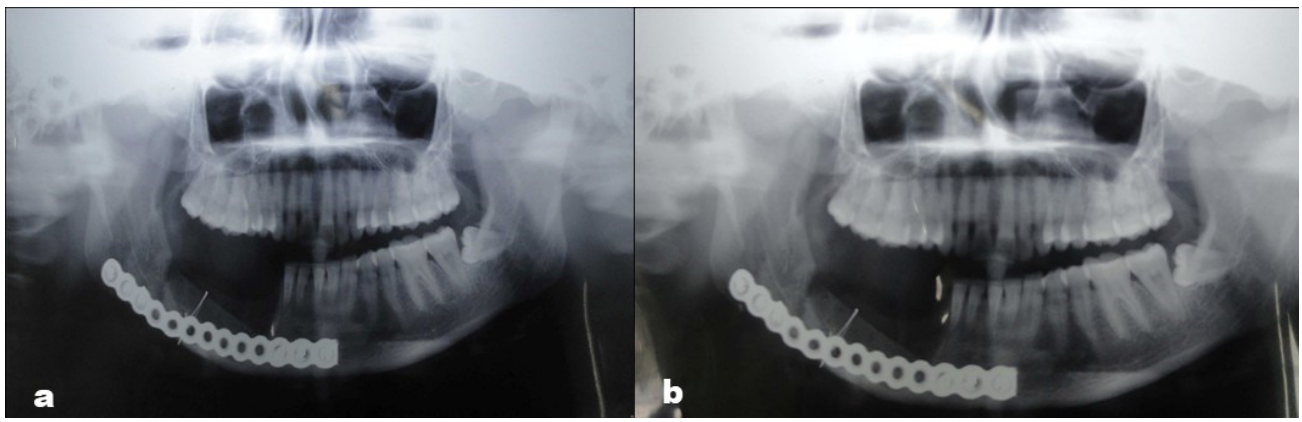

Figure 3a: Radiograph showing reconstruction of mandible with iliac crest graft and reconstruction plate; 3b: Post-operative radiograph of the patient during follow up period.

Figure 4a: Intra oral view showing Kennedy class II situation; 4b: Metal frame work Try in; 4c: Try in of waxed up prosthesis; 4d: Acrylised Prosthesis; 4e: Intra oral view of delivered Prosthesis

Initially diagnostic cast obtained from primary impression was surveyed to determine the areas of undercuts, guiding plane, aesthetics, and area of insertion and removal of prosthesis. Mouth preparation was done based on this information. It included teeth preparation of 37,36 to receive metal crown and rest seat on 34 with an extension in 33. After cementation of metal crowns, definitive impression was made with addition polyvinyl siloxane materials of medium and light body consistencies (Affinis, Coltene) on a special tray. Regular laboratory procedures were then carried out to obtain the cast framework. Embrasure clasp was given in the 37,36 and a bar clasp in 43 region for direct retention. Occlusal rest was given on 34 with a canine extension on 33 for indirect retention. The metal framework obtained after casting was then tried and adjusted in patient's mouth (Figure 4b). This was followed by jaw relation, try in and acrylization of denture to get the definitive prosthesis. The prosthesis was inserted in patient's mouth and occlusion was adjusted (Figure 4c, d & e) Proper instructions were given to the patient regarding denture care and maintenance. Routine check-up was done in every three months. Patient was satisfied with the final outcome aesthetically and functionally (Figure 5).

Figure 5: Extra oral view of delivered prosthesis

Discussion

Central ossifying fibroma (COF) is the most common benign fibro osseous neoplasm of the oral and maxillofacial region. This lesion tends to occur in the

second and third decades of life, commonly in women, and in the mandibular premolar and molar areas,which is similar to present situation.[5-7] In contrast,juvenile ossifying fibroma, though having similar features is more prevalent in age groups of 5-15 years whereas fibrous dysplasia is predominant in age group of 4th and 6th decade of life.[8] It was a painless lesion without involvement of lower border of mandible, which is the characteristic feature of COF.[9,10]

Radiographically, the lesions can be either completely radiolucent, mixed orcompletely radiopaque surrounded by a radiolucent rim depending on the amount of calcification.[11] Radiolucent ones can be misdiagnosed withfocal cement osseous dysplasia, odontogenic cyst, periapical granuloma, traumatic bone cyst, unilocular ameloblastoma, and central giant cell granuloma. But the present case is circumscribed radiolucent lesion with well-defined margins and intralesional calcification suggestive of COF.[12-14] This differentiate them from fibrous dysplasia usually appears as a diffuse, homogeneous ground-glass, radiodense region radiographically ill-defined border and located mostly in periapical region.[15] COF is also differentiated from sarcomas by presence of well-defined margins.[16]

Most COFs have a good prognosis and can be treated by conservative surgical excision through the use of curettage, enucleation, or excision.[17] A conservative marginal resection followed by immediate reconstruction of affected side mandible with iliac crest bone graft was planned. As the size of defect was more than five-centimetre, reconstruction using iliac crest graft was preferred.[18, 19] The simultaneous resection and reconstruction resulted in good anatomical and functional recovery. Moreover,as the reconstruction was done in one single surgical procedure, any distortions, deviations, atrophies and scarring inherent to secondary surgeries was avoided, making this technique much more reliable.[20,21]

It is challenging to prosthetically rehabilitate such iliac crest graft cases, as a proper stress distribution is required during chewing. In this case,it was achieved through a dual impression technique, broad coverage and clasp design.[22] Embrasure clasps was given on 37 and 36 opposite to edentulous area, as direct retainer which also helped in cross arch stabilization. Intentional undercuts were given in metal crowns of 37, 36 for direct retainer to be effective. Movement of the frame work further avoided by use of semi anatomic teeth.

Conclusion

Though not malignant, these types of cases require an early diagnosis, appropriate surgical intervention, prosthetic rehabilitation and follow-up for long term success. Rehabilitation of the post-surgical COF patient with CPD is a simple and cost-effective treatment. It is a good treatment option when precision attachment or implant prosthesis is ruled out.

Chemo Mechanical Caries Removal Technique: A Review Article on Lost and Found Approach towards Painless Dentistry

Mrinali Shukla[1], Antarmayee Panigrahi[2], Susant Mohanty[3], Sulagna Pradhan[1], Sonali Bhuyan[1]

[1]Postgraduate Student, [2]Reader & PhD Scholar, [3]Professor & Head, Department of Paediatric and Preventive Dentistry, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to Be University), Bhubaneshwar, Odisha, India

Abstract

With the advent of Minimal Invasive Dentistry in trend, chemo-mechanical caries removal technique has been a recent and unprecedented addition to it. Being non-invasive and atraumatic one, It has emerged as an unrivalled replacement of conventional technique that were instilled with an idea of unwanted drilling, extensive cavity preparation with high speed hand pieces resulting in weakened tooth structure. This review delineates the comparative evaluation of clinical efficacy of various chemo mechanical caries removal agents evolved till date.

Keywords: *Chemo mechanical caries removal, GK-101, GK-101E, Carisolv, papain,biosolv.*

Introduction

Earlier, restorative dentistry was based upon the concept of G.V. BLACK's principle of "extension for prevention" leading to extensive cavity preparation for adequate resistance and retention.

For serving this purpose, high speed hand pieceand rotary instruments came into the light. The commencement of these instruments brought the new era of operative dentistry but at the same time invasive one. The rotary intervention often led to noise, vibration, pain, unwanted drilling and loss of viable tooth structure. There by, instigating fear, absence and anxious attitude, especially in paediatric patients. Such factors were not only contrary to philosophy of minimal invasive dentistry but they eventually result in advancement of decay process that may require emergency and complex treatment in near future. However, the introduction of chemo mechanical caries removal methodology almost 3 decades ago[1]. Has surpassed the drawbacks of traditional drilling approach & simultaneously potential adverse effects of soft & hard tissues due to heat & pressure. Claimed to be one of the most efficient therapeutic alternatives, it mediates its action through chemical chlorination of decayed dentin, causing alteration in quaternary/secondary structure of collagen. Thus, smoothening the excavation process without the need of anaesthesia[2.]

Evolution of Chemo-mechanical Agents: In late 19th century, various attempts were made using the agents like EDTA, collagenase, sodium dodecyl sulphate, etc but were proven clinically inefficient due to their time-consuming process.[3-5] In last decade several amendments were made so as to improve their clinical effectiveness and are still in progress. Nowadays, with the ingression of diverse agents, CMCR has been broadly classified as1. Na-O-Cl (sodium hypochlorite) derivative;

Enzyme based derivative: Sodium Hypochlorite Derived CMCR Agents: 5% sodium hypochlorite was used as CMCR from 1972.[7]

Mechanismof action: Its proteolytic actiondisrupts H bonds of partially degraded collagen fibrils of decayed dentin resulting in its gentle removal. But because of its high instability, corrosive nature and lack of differentiation

b/w infected dentin & affected dentin, it has now been discontinued[8]. To overcome its shortcomings, the amino acids (Sorensen's solution) were added for subsequent versions. Sodium hypochlorite is further classified as–

1. GK101;
2. GK101E-Caridex;
3. Carisolv

GK-101: Introduced by Goldman & Kronman in year 1976[1.]

Composition and use: 0.05% N-monochloroglycine (NMG) & sodium hypochlorite (Na-O-Cl). It is prepared by mixing of two solutions i.e. Solution A-25ml each of 2M NaCl,2M glycine,2M NaOH. Solution B-10ml of 4-6% of Na-O-Cl. t requires a special delivery system that includes reservoir (meant for warming freshly prepared solution at 41°C) & a pump (similar to hand piece in shape) attached to needle of delivery tip of 20 gauge. Application has to be done with minimal pressure in paintbrush motion so as to avoid any patient discomfort.

Mechanism of action-Irreversible denaturation of organic structure of carious dentin by conversion of hydroxyproline (essential factor for structural stability of collagen) to pyrrole 2 carboxy-glycine.

Mean Excavation time-8.5 min:

- **Advantages-**no potential harm to pulp & other oral tissues[9.]
- **Disadvantages:** Inefficient in removal of entire carious lesion & for achieving the adequate finishing of excavated sites, use of burs become mandatory; Time consuming procedure and require great quantity of solution to achieve caries free surface[16].

GK-101 E: To overcome the limitations of GK-101, glycine was substituted by amino butyric acid. GK-101E got FDA approval in 1984 & was marketed as **'caridex'** in 1980.

Composition: It is an ethyl derivative [N monochloro-DL2 amino butyrate (NMAB)].

Mechanism of action: GK-101E acts in a similar manner to GK 101 by denaturation of collagen with additional cleavage of denaturised collagen fibrils resulting in oxidation of glycine residue.

Mean excavation time: when compared to GK-101-time duration, there was not much significant improvement except the lag period of 30-90 seconds.

Advantages: Increased specificity of solution towards infected dentin than affected dentin; Addition of urea to caridex enhanced its efficiency in caries excavation in deciduousteeth.[9]

Disadvantages: complex delivery system was still an issue; It was not still clinically superior to conventional rotary in caries removal.

Carisolv: Developed by med team Goteborg, Sweden in 1998 and later on modified by fure & lingstorm[10] in 2004, in 2013 a new carisolv system evolved as new alternative.

It is only commercially available sodium hypochlorite derived CMCR agent currently.

Composition: Original moiety was red in colour and consisted of 2 syringes–one containing carboxymethyl cellulose based gel and 3 amino acids (glycine, leucine & lysine) and another is composed of 0.25% Na-O-Cl.

Carisolv gel composition was modified (in 2004) into single all in one syringe by removal of red colouring agent and reducing the concentration of amino acid to half and subsequently increasing sodium hypochlorite solution to 0.475%.Special instrumentation is needed for its application-earlier it was with non cutting tip hand instruments that were replaced by power driven endodontic motor with non-cutting tip burs which ensured great control over tissue removal at very low sound vibration[11.].

Mechanism of action: Chemically, mono amino butyric acid was replaced by 3 differently charged amino acids that bind with different elements of carious lesion through electrostatic action. This electrostatic inter action disrupts the protienaceous structure of degraded collagen fibrils ending in further dissolution of carisolv into infected dentin. Dissolution leads to continued breakdown by chloramines softening the decayed dentin layer (Ericson et al.)

Meanexcavation time: As per the demonstration of 2 studies, original carisolv gel showed prolonged time duration of 10.4+6.1 min & 12.2+4.1min respectively[12,13] However, new carisolv gel exhibited shorter time duration in deep carious lesion 9.0+7.0 min[10] in converse of its action in moderate sized lesions. Overall mean excavation time is 5.5 min.

Advantages:

a. No requisite of either prior heating or special delivery system because of its gel form.

b. Improved handling properties due to the high viscosity of carboxymethylcellulose.

c. According to Bullet et al., it exhibits both bactericidal and haemostatic impact on exposed pulp tissue promoting its regeneration.

d. Apart from its role as CMCR, it can be utilised in other halves of dentistry as plaque removal, irrigating solution, treatment of oral ulcer.

e. Root caries can be effectively removed by this gel[10].

Disadvantages: a) proven to be less effective than rotary technique due its gradual process, customised instrument & large usage of solution (which leaves the dentin surface irregular) thus, making it cost effective; b) Patient often complaint of bad taste/odour similar to that of chlorine. [14]

Enzyme based CMCR: Even after its establishment as clinically successful CMCR to some extent, its cost effectiveness and long excavating period was still a big concern

Papacarie: Introduced in Brazil in year 2003[15]. 'Papacarie' word is derived from Portuguese literature which means 'caries eater'.

Composition: Its main ingredients are–Papain, Chloramines, Toluidine blue, Preservatives, Stabiliser, Deionised water & thickener

Papain: Also known as papaya protease I, is a cysteine protease enzyme derived from the latex of papaya (carica papaya) & mountain papaya. It belongs to a family of protein with wide range of activity i.e. both exopeptidase & end peptidase activity.

Chloramines: It is basically a monochloroamine with bactericidal & disinfectant property.

Toluidine blue: As a colouring agent, it also exhibits the property of photosensitivity towards bacterial membrane.

Mechanism of action: Papacarie has got the papain enzyme which is a proteolytic itself. This proteolytic enzyme acts on infected dentinal tissue which lacks the plasma protease inhibitor i.e. alpha-1 anti-trypsin but still précised mechanism is not clear[15].

Mean excavation time: For primary teeth-4.2 min & for permanent ones -4.17 min (S Gupta et al.)

Advantages:

a. papacarie gel is easily available on commercial basis with low cost effectively.

b. Highly effective with shorter excavation period

c. Papain, being the main constituent has got the bactericidal & anti-inflammatory properties, thus being the most biocompatible.

d. There is no requisite of either special instruments or extensive training thereby, making it user friendly.

Disadvantages:

a. the mechanism of action is still unclear.

b. It is reported that papacarie somewhat affects the mechanical properties of mineralised dentin.

Carie-care system: By Unitech pharmaceuticals (India, 2010) is another papain derived gel; its modified version Papacarie duo was released in 2011 with improved properties.

Biosolv (SFC-V & SFC-VIII, 3M-ESPE AG, Seefeld, Germany): Introduced by Clementino-Luedemann et al., is still under the wraps because of its confusing and contradictory limited data.It demands the special instrument **star V1.3** for its application.Based upon the manufacturer's information it constitutes the pepsin enzyme dissolved in phosphoric acid & sodium phosphate buffer.

Conclusion

For any treatment outcome to be successful, patient's behaviour and attitude is as necessary as performing manoeuvres. The philosophy of minimal invasive dentistry has enlightened this idealism by tissue preservation as far as possible with minimal intervention. A chemo mechanical caries removal agent {being one of the atraumatic moieties of MID concept} has substantiated its potency towards anxious, disabled & paediatric patients especially. Thus, looking at their clinical prevalence, it can be concluded that CMCR withholds the promising future of dentistry.

Abstract

This study assessed the antimicrobial potential and Minimum Inhibitory Concentration (MIC) of *Moringa oleifera* leaves and fruit extracts in contradiction to common periodontal pathogens. Agar well diffusion technique was used to evaluate the ethanol and petroleum ether extracts against *Porphyromonas gingivalis* and *Prevotella intermedia*. Analysis of Variance (ANOVA) and t-test were used for statistical analysis. All the extracts showed powerful antimicrobial action with MIC values fluctuating from 0.2-0.8 µg/ml against *P. intermedia*. Least MIC values of 0.2µg/ml against *P. intermedia* was observed in ethanol and petroleum ether fruit extracts. All extracts showed zone of inhibition that were statistically significant ($p<0.05$) at highest concentration (75 µg/ml) against *P. gingivalis*. Extracts of leaves and fruit of *Moringa oleifera* were found to be effective and contain compounds with therapeutic potential against *Porphyromonas gingivalis* and *Prevotella intermedia.*

Keywords: *Agar, plant extracts, Moringa oleifera, Porphyromonas gingivalis, Prevotella intermedia.*

Introduction

Oral infections endure to be a significant medical issue globally.[1] Dental caries and periodontal ailments are amongst the utmost vital comprehensive oral health glitches.[2] There is a significant evidence connecting deprived oral health to long-lasting conditions,[1-3] and also systemic diseases.[4] Tooth loss, caused by poor periodontal health (influencing 20% of adult population around the world) can lead to substantial illness and untimely demise.[2,3]

Despite the fact that pharmacological industries have delivered various new antibiotics over the most recent three decades, confrontation to these medications by microbes has augmented.[5] It is necessary to advance investigation to realize the transmissible schemes of resistance, and to advance with studies to develop novel reasonable medicines, either synthetic or natural. A conclusive objective is to offer reasonable and capable antimicrobial drugs to patient. As per World Health Organization (WHO) medicinal plants would be the best source to acquire an assortment of medications.[6,7]

Moringa oleifera is one of the world's most valuable trees, as virtually each portion can be utilized for nourishment or has some other positive assets. It is an

Corresponding Author:
Dr. Gayathri Ramesh
Associate Professor, Department of Dentistry,
Chamarajanagar Institute of Medical Sciences,
Chamarajanagar, Karnataka
e-mail: amug3r@gmail.com

extremely nourishing vegetable tree with an assortment of probable usages. Also, *Moringa* contains explicit plant pigments with established effective antioxidant properties making them a significant nutritional part in the body's defences against free radical damage.[8]

In developing countries, similar to India there is higher frequency of dental and periodontal disease due to neglect and lack of consciousness. Dental care services are often too expensive, rare or entirely absent, particularly in rural areas.[9,10] Periodontal disease includes two most basic microorganisms-*Porphyromonas gingivalis* and *Prevotella intermedia*. There is incredible lack of data on, antimicrobial activity of herbal extracts of plant-*Moringa oleifera*., against these microorganisms, thus the current study was undertaken to evaluate the in vitro antibacterial properties and to determine the minimum inhibitory concentration (MIC) of various extracts of *Moringa oleifera* against common periodontal pathogens.

Material and Method

Procurement of plant material: Leaves and fruit (drumsticks) of *Moringa oleifera* gathered from Agriculture University of Rajasthan, were identified and established in Department of Pharmacognosy, Pacific College of Pharmacy, Udaipur.

Extraction: Leaves and drumsticks were carefully washed, air dried at room temperature (30°C) for two days, pulverized to a fine powder utilizing a sterilized blender processor and stored in two sealed bottles, leaves and fruit independently. Two distinct solvents namely petroleum ether and ethanol were utilized for withdrawal to get a sum of four concentrates, two from leaves and two from fruit. A 10g amount of pulverized leaves were independently absorbed in 100ml of petroleum ether and ethanol for one day. Additionally, a similar sum (i.e. 10g) of pulverized fruit was submerged in 100ml of petroleum ether and ethanol for a day. Each preparation was filtered through Whatman No.1 filter paper and the sifted extract was concerted under vacuum underneath 40°C using Heidolph, VE-11 rota-evaporator. Dried out extract consequently attained was subjected to UV rays, checked for sterility and stored in a freezer at 4°C.[11]

Qualitative analysis on phytochemical constituents.[12]

Test for tannins, saponins, flavonoids, terpenoids, cardiac glycosides, alkaloids and carbohydrates were done as per the standardized laboratory procedure.

Test Microorganisms: *P. gingivalis* ATCC 33277, and *P. Intermedia* ATCC 2564 were procured from Microbial Type Culture Collection, IMTECH, Chandigarh, grown in brain heart infusion broth accomplished from HiMedia Laboratory Pvt. Ltd., Bombay and incubated anaerobically at 37°C. Documentation of complete strains was acknowledged by typical biochemical and straining procedures.

Screening for Antimicrobial Activity: Agar well diffusion technique was utilized for antimicrobial screening. Media was punched with 7mm width wells, loaded up with varying concentrations of extracts 5µg/ml, 10µg/ml, 25µg/ml, 50µg/ml and 75µg/ml and incubated at 37ºC for one day. Following incubation, Vernier callipers was used for estimating the zone of growth inhibition. Each extract was confirmed five times and recorded in millimetres.

Determination of MIC: MIC is the lowest concentration of a compound that totally impedes the development of microbes in 24h.[13] For MIC, 9 dilutions of each extract were done with brain heart infusion (BHI) broth microdilution assay. Tubes were then incubated at 37°C for 24 hours and perceived for turbidity.[14]

Statistical analysis: One-way analysis of variance (ANOVA) and t-test with a p-value ≤ 0.05 was used for statistical analysis.

Results

Antimicrobial activity of *Moringa oleifera* leaves and *Moringa oleifera* fruit extracts against P*orphyromonas gingivalis* varied greatly in different solvents (Table 1). Ethanol fruit extract showed significantly highest zone of inhibition at highest concentration of 75µg/ml (15.2±0.837, p=0.007) and also at 50µg/ml (10.2±0.837, p=0.001). Ethanol fruit extract was effective against *P. gingivalis* at all concentrations and the mean zone of inhibition significantly increased with increase in concentration (p=0.001).

Table 1: Mean zone of inhibition (mm) of all extracts of Moringa oleifera leaves and Moringa oleifera fruit (drumstick) on Porphyromonas gingivalis

Extracts	Concentrations (Mean ± SD)					P value
	75 µg/ml	50 µg/ml	25 µg/ml	10 µg/ml	5 µg/ml	
Moringa oleifera leaves						
Ethanol	10.2±0.837	8±0.707	R	R	R	0.000*
Petroleum ether	10.2±0.836	10±0.707	R	R	R	1.000
Moringa oleifera fruit						
Ethanol	15.2±0.837	10.2±0.837	10.6±0.894	9.8±0.837	10±1.00	0.001*
Petroleum ether	10.6±0.548	R	R	R	R	-
P value	0.007*	0.001*		-	-	

Test applied-ANOVA, t-test.; *P≤0.05 statistically significant

Antibacterial effect of *Moringa oleifera* leaves and *Moringa oleifera* fruit extracts presented in Table 2 showed that *Prevotella intermedia* was resistant against *Moringa oleifera* leaves extract in both solvents (petroleum ether and ethanol) while *Moringa oleifera* fruit (drumstick) extract showed zone of inhibition at higher concentrations (75µg/ml) in both solvents.

Table 2. Mean zone of inhibition (mm) of all extracts of Moringa oleifera leaves and Moringa oleifera fruit (drumstick) on Prevotella intermedia.

Extracts	Concentrations (Mean±SD)					P value
	75 µg/ml	50 µg/ml	25 µg/ml	10 µg/ml	5 µg/ml	
Moringa oleifera leaves						
Ethanol	R	R	R	R	R	-
Petroleum ether	R	R	R	R	R	-
Moringa oleifera fruit						
Ethanol	11.2±0.837	R	R	R	R	-
Petroleum ether	10.6±0.894	R	R	R	R	-
P value	0.987	-	-	-	-	

Test applied-ANOVA, t-test; *P≤0.05 statistically significant

Based on the MIC values of all extracts (Table 3) *P intermedia* were most sensitive to *Moringa oleifera* drumstick extract with both ethanol and petroleum ether solvents (MIC value: 0.2µg/ml). It was also sensitive to ethanol *Moringa oleifera* leaves extract (MIC value: 0.4µg/ml) and petroleum ether *Moringa oleifera* leaves extract (MIC value 0.8µg/ml). *P. gingivalis* was sensitive to all extracts with MIC value of > 50µg/ml.

Table 3. Minimum Inhibitory Concentration (MIC) of Moringa oleifera leaves and Moringa oleifera fruit (drumstick) extracts against periodontal pathogens on specific media for each microorganism.

Extract	P. gingivalis (µg/ml)	P. intermedia (µg/ml)
Moringa oleifera leaves		
Ethanol	50	0.4
Petroleum ether	50	0.8
Moringa oleifera fruit (drumstick)		
Ethanol	50	0.2
Petroleum ether	50	0.2

Table 4. Phytochemical analysis of Moringa oleifera extracts.

Chemical Constituent	Moringa oleifera leaves		Moringa oleifera fruit	
	Ethanol	Petroleum ether	Ethanol	Petroleum ether

Discussion

Crude plant extracts are generally a mixture of active and non-active compounds.[15] Contrasts in antimicrobial effects of plant species exists because of phytochemical properties and variances amongst species. Preliminary phytochemical examination revealed presence of secondary metabolites like tannins, steroids, cardiac glycosides, etc. in both parts of the plant (Table 4).

Our study was directed to acquire preliminary data on antimicrobial action of ethanol and petroleum ether extracts of *Moringa oleifera* leaves and fruit. Antimicrobial viability is generally determined by examining MIC, bactericidal impacts and different microbial culture techniques.[16-18] Agar well diffusion was employed as culture method which offered a few focal points such as selective quantification of microorganisms[19] however was arduous and just count microscopic organisms that can develop on agar.[16-18]

Results of current study demonstrated that at lesser concentration (5µg/ml) only ethanol *Moringa oleifera* fruit extract was found effective and produced highest zone of inhibition at highest concentration (15.2±0.837) against *P. gingivalis*, likely because of sturdier extraction capacity of ethanol which could have delivered more prominent number of active constituents liable for antimicrobial activity.[17] *P. intermedia* were most sensitive which couldn't survive even at lowest concentration (0.2µg/ml) in both ethanol and petroleum ether *Moringa oleifera* fruit extracts.

Whereas in ethanol *Moringa oleifera* leaves extract, *P. intermedia* survived upto 0.4µg/ml. Moringa oleifera fruit extracts showed higher antibacterial properties than leaves extracts. Gram-negative microorganisms are found less susceptible to plant extracts in prior investigations.[20,21] However, we observed that all extracts were active against both gram-negative bacteria tested. This may be due to its variation in phytochemical constituents like alkaloids, flavonoids, saponins, tannins, aminoacids and carbohydrates. Flavonoids, are strong antioxidants, with effective antimicrobial substances *in vitro* contrary to a varied collection of microorganisms by impeding membrane bound enzymes.[22] *Moringa oleifera* leaves likewise contain alkaloids found to have antimicrobial possessions because of their dimensions to interpolate with DNA of microorganisms.[23]

Rahman et al (2009) reported that powder from fresh leaf juice, ethanol and cold-water extracts of fresh leaves of *Moringa oleifera* were active against all the Gram-negative bacteria.[24] Lowest MICs were determined for two Gram-negative bacteria such as *S. sonnei* and *P. aeruginosa*. These results propose that *Moringa oleifera* leaves used contain bio-components whose antibacterial possibilities are exceptionally practically identical with that of antibiotic tetracycline.[25]

Currently, utmost pathogenic creatures are flattering impervious to medicines.[26] To combat this distressing issue, detection of innovative lively complexes compared to novel targets involves desperation. Antimicrobial properties of plants have been examined by various investigations worldwide and many utilized as therapeutic options due to their antimicrobial properties.[9,27-29] However, to use plant extracts for medicinal determinations, questions on safety and toxicity need to be justified.

Conclusions

P. gingivalis and *P. intermedia* both were found to be sensitive against extracts of both parts of *Moringa oleifera* i.e. leaves and fruit. On comparison, it was observed that extract of *Moringa oleifera* fruit emerged as a highly potent agent exhibiting antibacterial activity compared to that of leaves extract.

Gorlin-Goltz Syndrome: Multiple Approach to Diagnosis and Treatment

Neeta Mohanty[1], Devi Prasad Mandal[2], Snigdha Sagar[3]

[1]Professor and Head, Department of Oral & Maxillofacial Pathology & Microbiology, [2]PhD Scholar, Central Research Laboratory, [3]Senior Lecturer, Department of Oral Medicine & Radiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Gorlin-Goltz syndrome (GGS) is an autosomal dominant disorder associated with multiple systemic disorders. The incidence rate is approximately 1 in 57000 to 1 in 250000. It has a rare characteristic of multiple odontogenic keratocysts (OKCs), bifid ribs and other abnormalities. Occasionally GGS is associated with malignant lesions like rhabdomyoma, medulloblastoma, leiomyosarcoma, etc. The major and minor criteria based on the clinical and radiological findings are accessed for the diagnosis of GGS. We report a case of an 18 years old female patient, presenting with a swelling in the right side of the face which was diagnosed as GGS by correlating the clinical and histological findings. Advanced imaging tools and techniques were used for analysis. Early diagnosis and treatment have significant importance in reducing the severity of this syndrome.

Keywords: *Gorlin-Goltz syndrome, Odontogenic keratocysts, CBCT*.

Introduction

Gorlin-Goltz syndrome (GGS) is an autosomal dominant inherent disorder that has many systemic involvement presenting with variable symptoms.[1] In 1894 Jarisch and White discovered this condition while examining a patient who had multiple basal cell carcinomas, scoliosis, and learning disability. Further in 1960 Robert James Gorlin and William Goltz described the relation of these classical triads (multiple basal cell carcinoma, keratocysts in the jaws, and bifid ribs) and established the diagnosis of this syndrome.[2] According to Rayner et al. modification in 1977, cysts had to present in combination with calcification of the falx cerebri or palmar and plantar pits.[3] Later Evans et al. in 1993 elaborated the major and minor criteria for the diagnosis of GGS.[4] Kimonis et al. in 1997 stated that the diagnosis of GGS can be done only when at least two major and two minor criteria are present.[5]

The typical representative criteria for GGS are multiple odontogenic keratocysts (OKCs) (75%), BCC (50%–97%), bifid ribs (40%), palmar and plantar pits (60%–90%), and ectopic calcification of falx cerebri (37%–79%).[6] The estimated incidence rate is approximately 1 in 57000 to 1 in 250000 in normal population with 1:1 male to female ratio, and clinical symptoms arise in the 1st to 3rd decades of life.[7] GGS represents a wide spectrum of clinical defects including skin, eyes, central nervous system (CNS), endocrine system and bones.[8] It has been studied that germline mutations of the PTCH gene may lead to GGS.[9]

The early diagnosis of GGS is important to reduce the severity of the syndrome which may cause permanent maxillofacial deformities and hamper the normal functioning. In this case report, we had used new imaging modalities and radiographic techniques to emphasize our diagnosis.

Case Report: An 18 yrs. a female patient reported to our Institute of Dental Sciences, Bhubaneswar, with a

e-mail: dr.neetamohanty@gmail.com

chief complaint of swelling in her right side of face since 2–3 months and reduced mouth opening since 7–10 days. The swelling slowly progressed into the present size which caused facial asymmetry.

On general examination, the patient had an average built and all the vital signs were normal. Extraoral examination revealed there was a diffuse swelling involving the right upper and middle one-third of the face, extending from the extra-temporal region to the zygomatic region [Figure 1]. On palpation, the swelling was firm in consistency, non-tender, and there was no local rise in temperature. Restricted mouth opening was recorded at 4.8cm. On intraoral examination, there was a mild swelling noticed at the posterior 27 region with missing 28. There was no carious or infected tooth associated with the swelling. Aspiration from the swelling was blood-tinged, viscous fluid.

Figure 1: Extra oral view

Based on the clinical findings of missing 28 and reduced mouth opening, a provisional diagnosis of an infected dentigerous cyst, secondary to impacted 28 was given. Moreover, OKC and ameloblastoma were listed as a differential diagnosis.Panoramic radiograph and reformatted panoramic cone-beam computed tomography (CT) [Figure 2] image of maxilla and mandible showed multiple radiolucencies with impacted teeth. There were large multilocular radiolucencies associated with 28 and 48. 3D radiograph showed no cortical bone expansion or perforation in maxilla or mandible. Panoramic image of right maxilla showed superiorly displaced 28 with pericoronal radiolucency extending into the maxillary sinus.

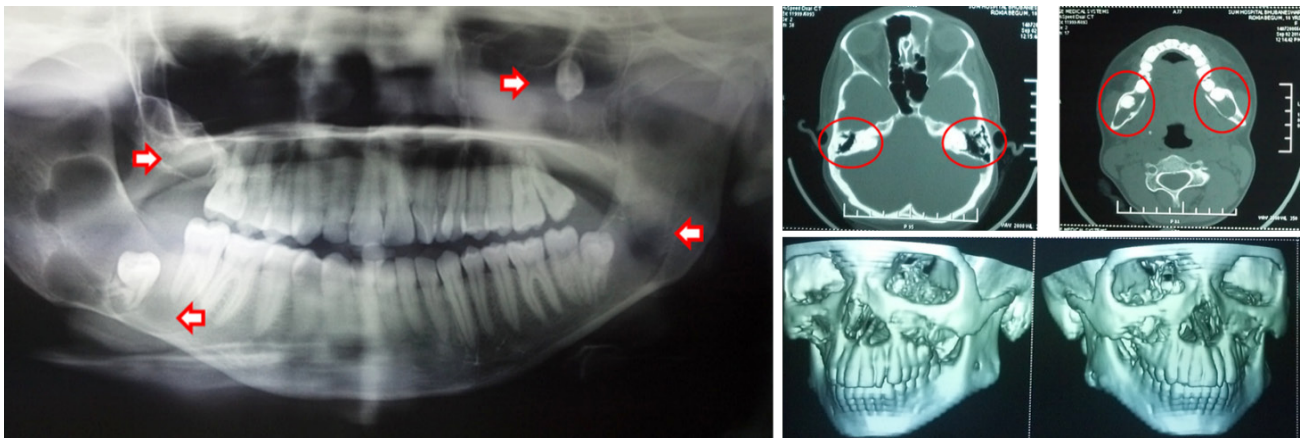

Figure 2: Panoramic radiograph, CT & 3D radiograph

As multiple jaw cysts were present, we further examined the syndromic association, hence further investigations were carried out, which revealed the presence of calcification in the falx cerebri and bifid rib [Figure 3].

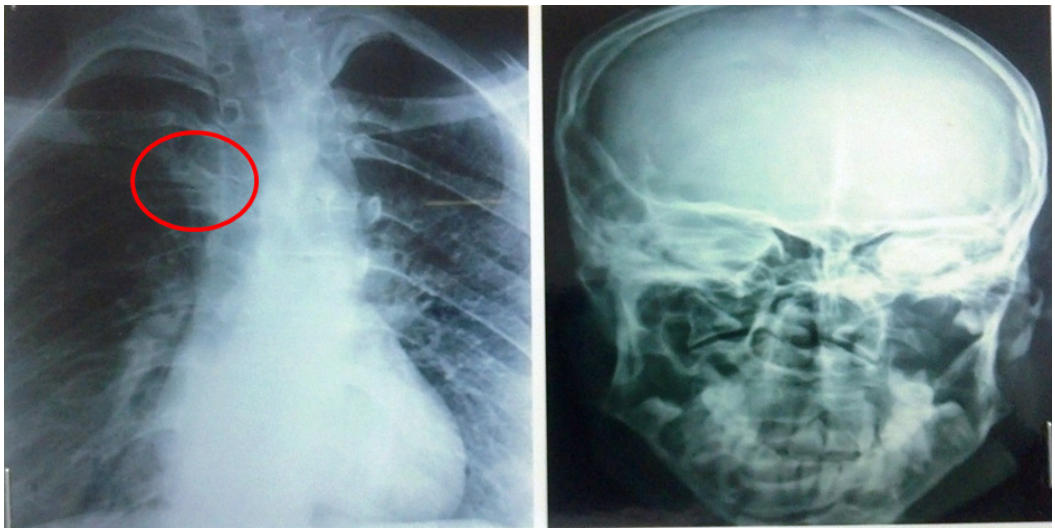

Figure 3: Bifid rib, Calcification of Falx cerebri

The enucleation of the cysts in maxillary and mandibular region was done along with the extraction of impacted third molars. Histological examination revealed para keratinised lining epithelium with surface corrugations. High power (40x) magnification revealed a uniform epithelial cell thickness of 8–10 layers. The basal cell layer showed a palisading pattern of nuclear arrangement with polarized and intensely stained nuclei [Figures 4]. All these findings revealed the presence of multiple OKC which was in accordance with our diagnosis of GGS. The patient is being followed up at 3 months interval and no recurrence has been noticed.

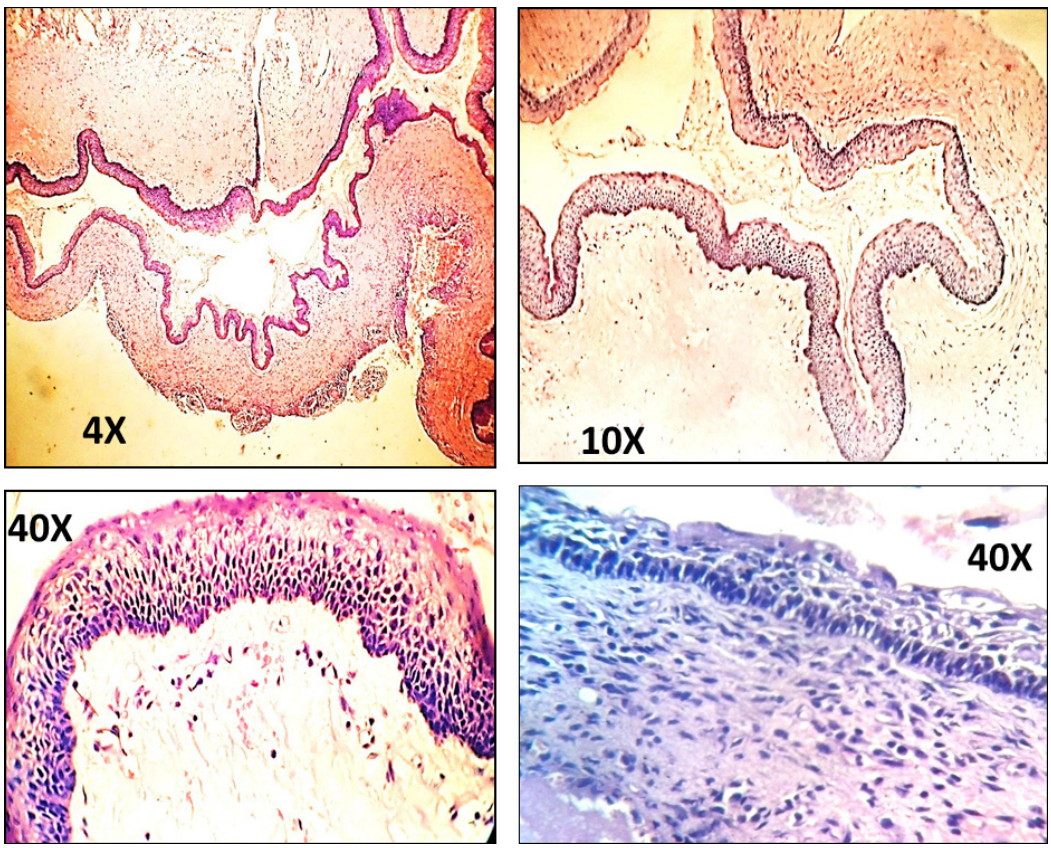

Figure 4: Histomorphograph

Discussion:

Gorlin Goltz's syndrome is also known as nevoid basal cell carcinoma syndrome (NBCCS), always associated with multi-systemic abnormalities. GGS, is an autosomal dominant disorder occurring due to mutation in the patched–1 (PTCH1) gene located on chromosome 9q23.3-q31, and encodes a transmembrane receptor for the ligand sonic hedgehog (SHH).[10] A study suggests 20%-40% of GGS occurred due to de novo mutation of PTCH1 gene.[11] The product of this PTCH1 gene has tumor suppressor activity. This reveals the ability of PTCH1 genes to alter the fundamental protocol that controls growth of normal tissues.[12]

The diagnostic criteria for GGS was given by Evans et al. in 1993 and later it was modified by Kimonis et al. in 1997.4,5 These criteria are listed in the following Tables [Table 1].[6] The diagnosis of Gorlin Goltz syndrome can be established when two major criteria are present or one major and two minor criteria are present. In our patient, there were three major criteria present that are multiple OKC, bifid rib and calcification of falx cerebri which confirm our final diagnosis as GGS.

Table 1: Diagnosis Criteria

Evans et al., 1993	
Major Criteria	• More than 2 BCCs, or One BCC in patients younger than 30 yrs. of age or more than 10 basal cell nevi • Any odontogenic keratocysts or polyosteotic bone cyst • Three or more palmar or plantar pits • Ectopic calcifications in patients younger than 20 years of age (lamellar or early falx cerebri calcification) • A positive family history of NBCC
Minor Criteria	• Congenital skeletal anomaly (bifid, splayed, fused or missing rib or bifid wedged or fused vertebra) • Occipital-frontal circumference greater than 97 percentiles, with frontal bossing • Cardiac or Ovarian fibroma • Medulloblastoma • Lymphomesentric cysts • Congenital malformation (cleft lip/palate, polydactilism or eye anomaly)
Kimonis et al. 1997	
Major Criteria	• More than 2 BCCs, or One BCC in patients younger than 20 yrs. of age • Odontogenic keratocysts of jaw • Three or more palmar or plantar pits • Bilamellar calcification falx cerebri • Bifid, fused or markedly splayed rib • A first degree relative with NBCC
Minor Criteria	• Macrocephaly • Congenital malformation (cleft lip/palate, frontal bossing, coarse faces, and moderate or severe hypertelorism) • Other skeletal anomaly (Sprengel deformity, marked pectus deformity, marked syndactyly of the digit) • Radiological anomaly (bridging of the sella turcica, vertebral anomaly, modelling defects of the hand and feet or flame shaped lucencies of the hand and feet) • Ovarian fibroma or Medulloblastoma

Odontogenic keratocyst is predominantly present in 75% of GGS cases and often is the first sign of diagnosis. The male-female ratio of OKC associated with this syndrome is 1:1 which usually developed in the second to third decades of life.[13] In younger patients, the cysts may be associated with un-erupted or impacted teeth which leads to tooth displacement and root resorption of adjoining teeth. These cysts may achieve a larger size as they grow anteroposteriorly inside the jaw bone without causing cortical expansion or perforation.[6] The major differences between OKCs associated with GGS and solitary OKCs are listed in Table [Table 2].[14]

Table 2: Difference between Solitary and Syndromic OKC

Feature	Solitary OKC	Syndromic OKC
Age	Middle or Old age	Younger age
Site	Single	Multiple in number
Recurrence rate	Low (61%)	High (82%)
Epithelium	More thickness	Less thickness
Cystic islands	Less	More frequently

Muzio in 2008 suggested the investigation protocol for GGS, these include family history-past medical and dental history; clinical examinations–oral, skin, head circumference, eyes, genitourinary system, cardiovascular system and skeletal system; radiographs–chest, anteroposterior view and lateral skull, panoramic radiograph, cervical and thoracic spine (AP and lateral), ovarian ultrasound for ovarian fibroma, and echocardiogram of children for cardiac fibroma.[15]

Two basic treatment approaches are carried out for the treatment of syndrome associated with multiple OKCs. These are conservative method, i.e. simple enucleation with or without curettage and marsupialization and aggressive method i.e. peripheral osteotomy, chemical curettage with Carnoy's solution and resection.[13]

Conclusion

The presence of three major signs (multiple OKCs, bifid rib, and calcification of falx cerebri) confirmed our patient was a case of GGS. Early diagnosis of GGS, is important to confirm conservative treatment and restore the aesthetics of the patient. Health specialists must have good knowledge of the diagnosis criteria of GGS so that the patient can be treated early and further monitored.

Flap Design in Third Molar Surgery: A Review

Pallabi Behera[1], Sthita Prajna Lenka[2], Barsha Ray[1], Abhishek Jagdish[3]

[1]Intern, [2]Professor, Department of Oral & Maxillofacial Surgery, [3]Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Amongst all the surgical procedures the third molar surgery is the most common procedure considered by the and max-facial surgeons in the world. There have been many surgical procedures involved in extraction of third molar which determines the success of the surgery. Third molars may present to be complete or partially retained and may present in mucosa, sub mucosa or completely embedded in jaw. Incision is quite technique sensitive and thus plays a very important role in surgery, hence the type of incision and the design of incision determines the wound healing.

Keywords: *Flap Design, Third Molar Surgery, Wound Healing.*

Introduction

Any tooth can be impacted in the dentoalveolar process. The accessibility influences the difficulty in removing the third molar. The exposure surgically also helps in the ease for the removal of the third molar. The article we will review various types of flap design. Impacted third molar in the lower jaw is the most commonly practised procedure and it has many complications like swelling, trismus, alveolar osteitis.[1] To reduce the number of complications surgeons across the world have investigated the various uses of flap designs in third molar extraction. The basic principle in flap designing is to receive good accessibility, adequate blood supply, adequate visibility, proper space available for instrumentation, protection of the soft tissue to reduce trauma and allowing anatomically repositioning of the flap. The incision given should always allow to elevate and reflect the tissue and without causing any harm to the adjacent tooth structure.[2]

Many factors influence the result of impacted 3rd molar extraction which also involves the mucoperiosteal flap design. In this study we are going to review an update of various flap design and their followed outcome in third molar surgery.[3]

Basic principles and Classification of flap design: The mucoperiosteal flap for the third molar surgery has a broad classification such as Envelope flap, Triangular flap, ward incision, Kruger envelope flap, Berwick tongue shape flap, Henry incision, Killy and Kay incision, Nageshwar Comma Shaped flap, Triangular flap, pedicle flap, bayonet flap, broader flap base than the free end to ensure adequate blood supply. The flap should be prepared according to the requirement of the soft tissue reflection for proper visibility. As periosteum is required for bone healing full thickness flap should be preferred. The accurate anatomical positioning of the soft tissue should be achieved at the end of the surgical procedure. The given incision must lie on the healthy bone wherever possible.[4]

Preferably long and straight incision must be done to have a good healing capacity. The incision must be placed firm through the mucosa and periosteum to the bone by a stroke which is given smoothly. While placing the incision we should use the pen grasp. The soft tissues present must have to be cut perpendicularly to the underlying bone. By using a gentle pressure, the mucoperiosteal flap should be reflected from the bone.[5]

Sequencing and comparison of flap design technique: The mucoperiosteal flaps that are used for removing of the impacted molar and are divided into triangular and envelope flap and few other variables. Howe describes a mucoperiosteal flap in which the anterior is given forward from the distobuccal corner of the crown portion of the second molar and it ends along the side of that same tooth by the distal incision and then it was extended buccally along the gingival portion to the external oblique ridge. Ward recommended a larger but similar kind of mucoperiosteal flap for improvement in access in 1956.[6]

Kruger in 1959 described envelope flap in which the first part of incision was similar to vertical incision that begins from the medial external oblique ridge and extends to distal lower angle of second molar followed by sulcular incision which was given from distofacial angle of second molar to mesio-facial angle of first molar. Barwick in 1966 described vestibular tongue shaped flap. This tongue shape flap extends to the buccal shelf of mandible with an incision line which did not lie over bony defects, that was created during removal of impacted tooth, and had its base in distolingual side of second molar to the PDL of adjacent tooth.[6] Henry in the year 1969 described the trepanation technique for excision of developing mandibular third molar and was then reported by kaj and Klein Feldt as it was having no late complications. This technique was based on the assumption after the evaluation, so that the third molar would be impacted.[7]

Killy and Kay in 1979 advocated the flap that start along the gingival crevices of second molar. Healing of the gingival crevices from this incision has been unsatisfactory. Nageshwar in the year 2002 proposed a distolingual flap, that was designed buccally in a comma shaped flap for removing the mandibular 3rd molar impacted tooth. The incision for this flap is given at a point below the 2nd molar and is curved upwards to meet the gingival crest of the 2nd molar at the distobuccal line angle, from that point it continues as a crevicular incision around the distal aspect of the second molar. Flap for this design was designed to minimize drawbacks of conventional incisions where there will be dissection of temporalis muscle tendon and flap which lies over the bony defect.[8]

Envelope flap: This incision was made starting from the medial to the external oblique ridge and was then extended up to the middle point of the distal line angle of the 2nd molar. Further sulcular incision is given from the distofacial line angle of the first molar.

Modified triangular flap: This flap design as described by Szmyd is similar in the first part of the incision to the envelope flap design. However, it is different from the original incision design as described by Szmyd.[10]

Pedicle flap: This flap was proposed by Goldsmith S, et al. in the year 2012. By a distal incision the flap is elevated which enable rotation for complete closure of the surgical wound and enable soft tissue advancement. This designing includes a pedicle flap that is the buccal envelope flap. The incision in the buccal gingival sulcus is placed from the mesiobuccal line angle of first molar to the most distal visible part of third molar. In subperiosteal plane the lingual flap is elevated while protecting the lingual nerve. The releasing incision is extended towards the external oblique ridge. The buccal soft tissue that can be incorporated along the defective region which thus allow the complete closure of wound. This flap technique prevents blood loss and the blood coagulum and minimize the bone loss.[10]

Bayonet flap designis described to place on ascending ramus following the mid portion of the third molar and then extended as sulcular incision up to the midpoint of buccal sulcus of second molar following an oblique vestibular releasing incision.[11]

Koener's flapis a modified flap incision that is placed as the distal extension, beginning from the external oblique ridge in the lateral mandible. The incision should be extended forwardly and medially towards the middle portion of the distal surface of the 2nd molar terminating at mesiobuccally line angle of the second molar.

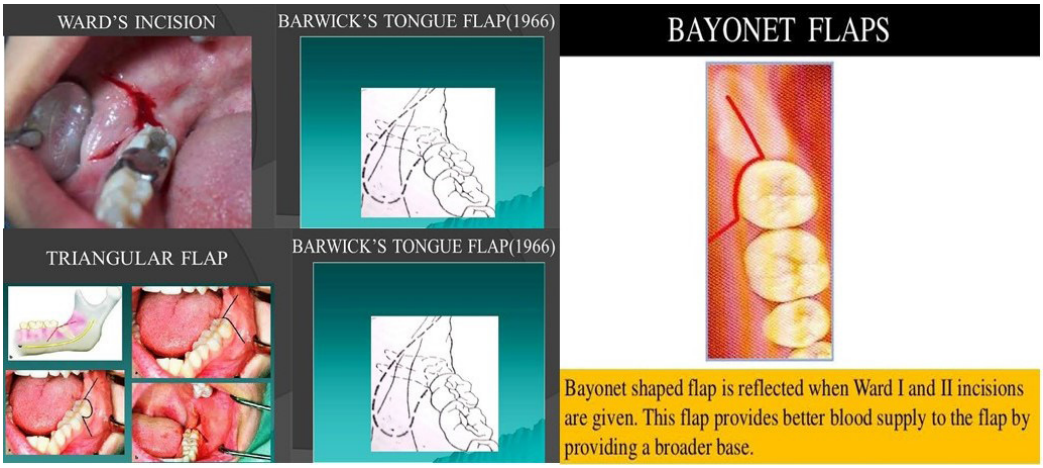

Figure 1: Types of Flap

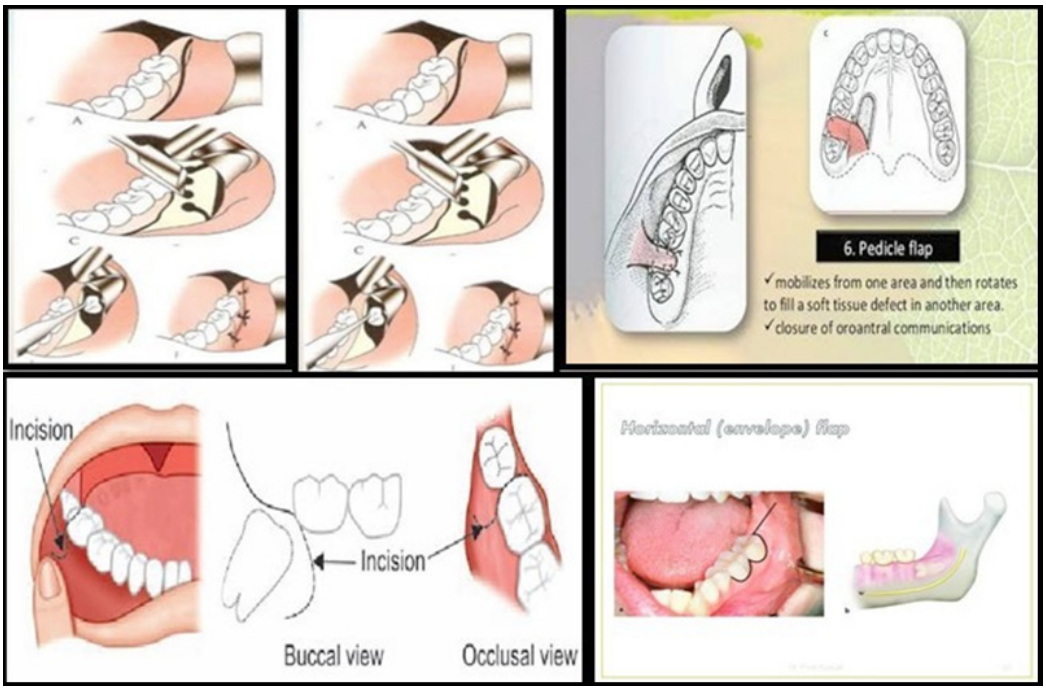

Figure 2: Flap design technique

Discussion

Depending on how good the surgeon handles the tissues, differentiate an average and an excellent surgical outcome. Handling a tissue is an essential aspect, with the implementation of proper incision and flap design techniques. The variety of proposals for describing the surgical procedure of the impacted third molars, are generally unknown but the finding of this work and tend to be disagreed by some people. Many studies lack with small number of cases and variables under further investigation could be exclusive, talks a lot for the experience of the surgeons that they have done to avoid the complications at the time of operation. However, every procedure has complications as like trismus, pain, swelling, difficulty in mouth opening.[9-11]

Conclusion

There are many proposals that tell us about the incisions of impaction of third molars, but the conclusions are accepted and these surgeries tend to be controversial and many studies lacks small number of cases and variables, hence the investigation may be done carefully and discus with the surgeons to avoid complications in the operative time. The envelope flap and triangular flap are the mostly performed technique by the surgeons in their daily clinical practice. There are

no significant differences described with respect to post-operative pain. The clinical difference that the authors have noticed is the exposure of the surgical site and damage to the flap. The surgeon who is to operate must have a thorough knowledge of the different types of flaps and should be skilled enough to decide and implement proper technique in day to day practice to execute the procedure uneventfully as each flap design has its own advantages and disadvantages.

Safeguarding the Socket: A Review of Techniques

Prachi Khuntia[1], Rashmita Nayak[2], Abhaya Chandra Das[3], Rinkee Mohanty[4], Saurav Panda[5], Sharmistha Das[6]

[1]Post Graduate Trainee, [2]Professor, [3]Reader, [4]Professor & Head, [5]Reader, [6]Post Graduate Trainee, Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

From the time of extraction till the implant placement, there are remarkable alterations in the volume of bone as well as its morphology which can make the implant reestablishment very challenging. The alveolar bone architecture is restored by the socket preservation technique and this technique also arrests the hard and soft tissue collapse, minimizing the necessity for future augmentation procedure. Therefore, in order to place implants in the extraction socket, which were thought to be compromised, distinct techniques have been invented to achieve socket preservation. Therefore, the aim of this review is to direct on several techniques for rebuilding the socket following the placement of implant.

Keywords: *Extraction socket, socket preservation, bone grafts, GTR, PRF, dental implants.*

Introduction

Due to tooth extraction,there are morphological diversification occurring in the alveolar process which includes both vertically and in the width of the residual bone.[1, 2] As far as horizontal dimension is concerned, the buccal aspect undergoes the influential rate of alveolar alteration. After the tooth loss, the tooth–dependent structure that is the buccal bone being constantly thin and composed of mainly bundle bone starts vanishing. The resorption of the alveolar wallsoccurs due to loss of tooth as a result of which the soft tissue sags into the alveolus, hence, the true aboriginal alveolar proportions are depleted. It is noticed in the first three months after the extraction of tooth that around 50% of the primary alveolar width is shrunk, although a great interindividual variability exists, and the phenomena of remodelling may sustain up to around one year afterextraction.[3]

'Socket preservation' is a surgical procedure done after extraction marked to conserve the alveolar ridge with an aimto exile the requisites for future surgical augmentation procedures for implant-prosthetic reformations. The utilization of bone or the substituted bone grafts in coalescence with or without membranes has been carried out in the socket preservation technique. Theen richment of the healing process of alveolus by utilization of biological mediators is another approach for socket preservation. There are various functions of platelets apart from the haemostatic one. The integral role in soft and hard tissue healing is played by the activated platelets released cytokines for example, platelet-derived growth factor, primary growth factors of fibroblast, fibrinogen, fibronectin, transforming growth factor β1, vascular endothelial growth factor, angiopoietin–2,as well as insulin-like growth factor-I.[3]

Greenstein (1985) with Ashman and Bruins (1985) were the first one to describe, post-extraction how to prevent the loss of alveolar bone. The term **Socket Preservation**, first coined by Cohen (1988), is a technique formulated for prosthetic maintenance of the socketalong with ridge preservation and augmentation. Basic socket preservation, although similar in all cases, varies with the method of socket closure.[1]

Indications for Socket Augmentation:

1. When instant implantation is notcommended.
2. Deficient buccal cortical plate: The presence of fenestration and dehiscence amplifies the postextractionosseous remodeling, resulting in buccal concavity in the alveolar bone. Thus, it appears foresightful to avoidalveolar socket eradication and make attempts to sustainthe ridge followed extraction.
3. Areas where esthetics is important: The most important consideration in the aesthetic zone is to preserve marginalsoft-tissue contours. In the areas with thin labial bone, extraction of tooth results in loss of labial plate and collapse of soft tissue into the extraction socket, which results in the loss of bone volume and gingival contour within the extraction socket, socket augmentation help to achieve bony fill. The preservation of vertical height of the bone helps in bracing the soft tissues at the site of extraction. This stabilized and improved soft tissue contour marginally and placement of implant is improved with an increased predictability in the aesthetic area. 4) In adolescent individuals shaping of the ridge for standard treatment with prosthesis.
5. Diminishing the requisiteto elevate the sinus floor.[9]

Different Socket Preservation Procedures:

1. Connective tissue graft (Langer and Calangar, 1980)
2. Socket seal or free gingival graft (Landsberg and Bichacho, 1994)
3. Bio-Col or resorbable hemostatic plug technique (Sklar, 1999)
4. Guided bone regeneration
    a. Nonresorbable membrane
    b. Resorbable membrane
    c. Normal restorability (4–6 weeks)
    d. Extended restorability (4–6 months)
5. Alloderm or acellular dermal graft (Misch, 1998)
6. Prosthetic “pontic” socket plug
    a. Removable (Misch, 1998; Kois and Kan, 2001)
    b. Fixed (Kois, 1998; Spear, 1999; Sklar, 1999)
7. Combination epithelialized subepithelial connective tissue graft (Stimmelmayr 2010)
8. Composite graft incorporated Modified socket seal surgery (Misch and Misch, 1999)
9. Socket Shield Technique (Hurzeler, 2010)

Materials Used in Socket Preservation

Platelet Derived Growth Factors: After injury variable growth factors from the platelets are released into the tissues. Epidermal growth factor (EGF), insulin growth factor (IGF), platelet derived growth factors (PDGF) and transdermal growth factor–β (TGF-β) are included in the seacting as differential element on the regenerating periodontal tissues. The PDGF has properties which are angiogenic and has the ability to trigger the chemotaxis and reproduction of connective tissue cells and deposition of matrix.

Platelet Rich Plasma (PRP) can be utilizedin regeneration of bone as it is a potential source of concentrated platelets. Centrifugation of a unit of freshly garnered autologous blood is done at 5.600 rpm that separates the platelet poor plasma which is eventually removed. Further centrifugation at 2400 rpm, of the specimen, is done that segregates the packed red blood cells and the PRP. The rest of the PRP containing 500 000 to 1 000 000 platelets, forms a gel after blending with a thrombin/calcium chloride (1,000 units/10%) solution. This gel can then be made use of, along with the materials of bone regeneration for example HA or DBM as a source for autogenic growth factors. Increase of the maturation rate of a bone graft in PRP is revealed to be up to 2 fold when used in amalgamation with autogenous bone. This also elevates the bone density of the graft. [6]

Bone Graft Substitutes: Since years, bone-replacement graft materials have been playing an important role in regenerative dentistry. Today’s concept in tooth extraction shall routinely consider maintenance of the existing extraction socket dimensions with some sort of bone-replacement material. This procedure has been called ridge preservation.[6]

The 3 marked properties of graft materials are: osteogenesis, osteoconduction and osteoinduction. Each property has a distinct feature in bone healing.

- The formation of a new bone by cells that are present in the graft is referred as **Osteogenesis**.
- The physical effect by which the matrix of the graft provides a scaffold favouring the cells present

outside to infiltrate into the graft and create new bone is known as **Osteoconduction**.

- A chemical process by which molecules(Bone Morphogenetic Proteins) contained in the graft converts the cells neighbouring to it into osteoblast, this in turn forms the bone, known as **Osteoinduction**.

Sources of Grafting Material

Type of bone graft	Source of the grafting material
Autogenous grafts (autografts)	Material is transferred from one position to another within the same individual. Graft may be intraoral or extraoral depending on the site of harvest.
Allografts	Material is transferred from a donor of the same species. The most common grafts are freeze-dried bone grafts, which may be mineralized or demineralized.
Xenografts	Material is transferred from a donor of another species, processed appropriately. Primarily porous deproteinized bovine bone mineral.
Alloplasts	Synthetic materials, usually inert, used as a substitute for bone grafts.

Examples

Autogenous Grafts

1. Bone from Intraoral Sites (Eg. Osseous Coagulum, Bone Blend, Cancellous Bone Marrow Transplants, Bone Swagging)
2. Bone from Extraoral Sites (Eg.Illiac Autografts)

Allografts

(Eg.Undeccalcified Freeze–Dried Bone Allograft, Decalcified Freeze-Dried Bone Allograft)

Xenografts

(Eg. Kiel bone, Anorganicbone,Calf bone)

Allografts

(Eg.Dura, Cartilage, Plastic Materials, Calcium Phosphate Biomaterials, Sclera,Bioactive Glass, Plaster Of Paris, Coral–Derived Materials). [8]

Guided Bone Regeneration: According to the Guided Tissue Regeneration (GTR) principle, which initiated in 1980s, particular type of tissue regeneration is attained when cells with such capacity are allowed to inhabit the defect during healing.

(Nyman et al. 1982; Gottlow et al. 1984).

The notion GBR treatment was based on the same theory asGTR principle. Hence, the rationale behind GBRwas to mechanically exclude the unnecessarygrowth of soft tissues into the osseous defect, hence, only osteogenic cell populations acquired from the progenitor bone is permittedto repopulate the osseous wound space (Dahlin et al. 1988; Hammerle et al. 1995).

The GBR treatment protocol allows surgical placement of a cell occlusivemembranefacing the bone surface, in order to mechanicallyplug off the bone defect site in need for regeneration (Dahlin et al. 1988). Additionally, the membrane creates as well as maintains an isolated room, hencecontributesan environment to the osteoprogenitor cells, due to whichosteoprogenitor cells are attracted and proliferates, differentiation along the osteoblastic lineage occurs and osteogenic activity is expressed.

(Linde et al. 1993; Karring et al. 1993).

In experimental and clinical studies, different non-resorable and resorbable membrane materials have been used for GBR treatment. The characteristic requisites of barrier membranes used in case of GBR therapy comprehends biocompatibility, integration, cell occlusion properties by the host tissues, clinical manageability and potential to make space.

(Karring et al,1993). [11]

Advantages, Disadvantages and Examples of Both the Membrane Categories Used in Guided Bone Regeneration Procedures Including Socket Preservation:

Membrane category	Advantages	Disadvantages	Commercial examples
Nonresorbable	• Numerous studies demonstrate their success • May be titanium reinforced • Remain intact until removal • Easily attached with titanium or resorbable tacks • Greater bone fill if membrane not exposed • Minimal tissue response if membrane not exposed	• Require a second surgery for removal • Increase patient morbidity • If exposed, must be removed • Can be technique sensitive	• ePTFE membranes, e.g., Gore-Tex (Gore Medical, Flagstaff, Ariz.) • Titanium-reinforced Gore-Tex
Resorbable	• Numerous studies demonstrate their success • Does not require surgical removal • Decreased patient morbidity • Improved soft-tissue healing • Tissue-friendly reaction to membrane exposure • Cost effective; one surgery only • Does not have to be removed if exposed	• Uncertain duration of barrier membrane function • Difficult to tack down • Slightly less bone fill than nonresorbable membranes • Inflammatory response from tissues may interfere with healing and GBR • Can be technique sensitive	• Neomem (bovine collagen matrix; Citagenix Inc., Laval, Que.) • Bio-Gide (porcine collagen matrix; Geistlich AG, Wolhusen, Switzerland) • Ossix (cross-linked collagen barrier; Implant Innovations Inc., Palm Beach Gardens, Fla.)

ePTFE = expanded polytetrafluoroethylene; GBR = guided bone regeneration

Alloderm or Acellular Dermal Graft: In several surgical procedures for example root coverage for defects in gingival recession (Minsk 2004), to increase the girth of attached gingiva (Schulman 1996), in the management of soft tissue ridge defects (Batista et al. 2001) as well as for repairing oronasal fistulae (Cole et al. 2006; Kirschner et al. 2006), an acellular dermal matrix allograft AlloDerm®has been commended for use as an alternative for autogenous connective tissue graft.[12]

Human soft tissue obtained AlloDerm®, has underwent several chemical procedureso as to remove all epidermal and dermal cells (antigenic cells) while conserving the persisting bioactive dermal matrix. The constituents of bioactive matrix are blood vessels, collagen, bioactive proteins and collagen which has the potential to support natural cell repopulation, revascularization and tissueremodeling (Biohorizons 2005). As the ultra-structural integrity of the acellular matrix is preserved, which leads to the prevention of stimulation of inflammatory reaction. (Batista et al. 2001; Minsk 2004). [12]

Preparation of Donor Tissue/Alloderm Rehydration Procedure: According to the manufacturer's instruction, preceding to the surgical procedure, the acelluar dermal matrix allograft (AlloDerm®) was rehydrated. At a temperature of 37°C, the tissue was first completely immersed and soaked in normal saline, for approximately 10 min. The paper backing was removed and the tissue was then immersed in another dish after the tissue was rehydrated.[12]

Best Socket Preservation Method for Safeguarding the Socket: Most of all of the socket preservation techniques such as bovine bone, mineralized versus demineralized allograft, autogenous bone tricalcium phosphate, membrane versus non-membrane, etc work by decreasing dimensional changes in the bone in the extraction site area. In order to find out: "Which Socket Preservation is the best?", as if now there is no one *best* way and, according to some researchers: "The scientific evidence does not provide clear guidelines in regards to the type of biomaterial, or surgical procedure."

According to othe review paper: "There is limited data regarding the effectiveness of alveolar ridge preservation therapies when compared to the control. Overall the socket intervention therapies did reduce alveolar ridge dimensional changes post-extraction, but were unable to prevent resorption. Histology did demonstrate a large proportion of residual graft material that may account for some of the difference in alveolar ridge dimensions at follow up."

The use of demineralized allograft (DFDBA) versus mineralized allograft (FDBA) accounts for more vital bone versus residual graft material present in the socket after grafting, as per the recent research. In fact, "this study provides the first histologic and clinical evidence directly comparing ridge preservation with DFDBA versus FDBA in humans and demonstrates significantly greater new bone formation with DFDBA."

Recent research shows that " There is significantly more negative results than that of the less-demanding flapless procedure, with an increased width resorption of the post-extraction site, when it comes to raising a full thickness flap."

As in dentistry, implants are trending, it is important to consider whether the patient is willing for implants or not in the future. If it is yes, then the research is transparent that there will be significant changes in the overall bony architecture surrounding the extraction site, if the preservation is not carried out. Therefore, more research and clinical studies have to be carried out, in order to find out the best protocol for socket preservation.[13]

Abstract

TMJ pain is a commonly occurring situation but not so commonly and effectively treated. A detailed and thorough knowledge of the joint diseases is a prime requisite for efficient management of the condition. It has been not yet found for TMD the main etiology. The treatment customary in such disorders are by splint given occlusally, cognitive behavioral treatment, hypnosis, acupuncture, physiotherapy, and surgery when all the other conservative type of treatment are not successful. Purpose of this article is to present a view of Temporomandibular joint pain dysfunction syndrome providing prosthodontic management of a confusing clinical problem with a simple and comprehensible approach to the diagnosis. A proper appliance selection is a need, that aimed to eliminate etiologic factors by enlightening on specific indication and use of various occlusal appliances for joint pain dysfunction syndrome cases management i.e. when and where to use it. Occlusal appliance, proved in many studies with a successful rate of 70-90% for patients with TMD this is the efficient type and commonest treatment. Occlusal appliance, being a non-penetrating and reversible appliance is an important benefit. Apart from this, dentist must check for problem if any in the muscles and that in the joints and should think of treatment available to be considered seriously, as a treatment means before the appliances to be used is decided.

Keywords: *Occlusal Appliance; Temporomandibular joint pain; Treatment & management*

Introduction

The condition is not well understood by most dental and medical practitioners, even with the popularity of the subject and relatively common occurrence as the dental literature concerning the problem of Temporomandibular joint pain dysfunction syndrome is extensive. A difficulty in obtaining its natural history and symptoms is the probable reason related to the diversity of views expressed.[1]

This article's motive is to give an outlook of the temporomandibular joint pain dysfunction syndrome which allows an easy and comprehensive way to prosthodontic management of a confusing clinical problem and diagnosis. A proper appliance selection is a need, that aimed to eliminate etiologic factors by enlightening on specific indication and use of various occlusal appliances for temporomandibular joint pain dysfunction syndrome management cases i.e. when and where to use it.[2]

Etiopathogenesis: Understanding its etiology is complex, although in the system of stomatognathic type the symptoms and signs are commonly found. The account of all the signs and symptoms of TMDs, there

Corresponding Author:
Priyanka Debta
Professor, Department of Oral & Maxillofacial Pathology & Microbiology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: debtapriyanka@gmail.com

is no single etiology; hence the following formula is suggested to simplify how TMD symptoms arise:

Function normally + an (Contributory factors) event > Tolerance physiological--→ Symptoms of TMD.

So contributing factors[3], which can initiates, the TMDS are:-Occlusal discrepancies, Emotional stress, Trauma, Parafunctional habits, Deep pain input. Different theories have been documented for initiation and progressions of TMDS are: [4]

1. Mechanical Displacement theory: Lack of molar support of functional occlusal prematurities causes direct eccentric position of the condyle in the fossa leading to pain, dysfunction and ear symptom.
2. Neuromuscular theory: In the presence of stress and tension Para-function such as grinding and clenching cause the occlusal interferences. This leads to muscle spasm and hyperactivity.
3. Psychological theory: Emotional disturbance initiating centrally induced muscular hyperactivity led to Para function and so indirectly to occlusal abnormalities.

Classification:

Currently the TMDS is divided into three major categories:

1. Myofascial pain dysfunction syndrome (MPDS)
2. Internal derangement (ID)
3. Degenerative joint disorders (DJD)

Management of Temporomandibular joint disorder syndrome (TMDS): Accurately diagnosing and treating temporomandibular joint disorders can be a difficult and confusing task. This is often true primarily because patients' systems do not always fit into one classification. In many instances several classifications seem to be appropriate because in reality the patient is suffering from more than one disorder. The interrelationship of various TM disorders always needs to be considered in the evaluation and treatment of patients. Following treatment therapies are indicated for the management of TMDS is as follows:

Definitive therapy

a. Reversible therapy: Occlusal splint, Muscle stabilizing appliance, Anterior positioning appliance, Anterior bite plate, Posterior bite plate, Soft or resilient appliance.
b. Irreversible therapy: Correction of occlusal interferences.
c. By selective grinding.

Other supportive therapies are

a. Education & motivation of patient
b. Soft diet
c. Physical modulation: Coolant therapy, Thermotherapy, Ultrasound therapy, TENS. Manual manipulation (hands-on-therapy): Soft tissue mobilization, Muscle conditioning, Passive exercises, stretching exercises, Resistance exercises
d. Pharmacological treatment
e. Psychological treatment
f. Relaxation therapy
g. Self-hypnosis
h. Meditation
i. Yoga
j. Bio-feedback therapy.

Above are the different treatment modalities for treating TMD.

Now we are in detailed discussion about the definitive therapy includes reversible therapy i.e. different types of occlusal appliances and its indication and mode of action, and in short about the irreversible therapy.

Definitive Therapy: The elimination in the other hand the factors etiologically due to this disorder are the direct aim of the definitive treatments. An accurate diagnosis is essential since it is directed towards the etiology.

Further the definitive therapy can be categories into following headings:

Reversible occlusal therapy: All the initial treatment should be conservative, reversible, and non-invasive. It alters temporarily the patients' occlusal condition along with an occlusal appliance and best accomplished.

Occlusal appliance: By many studies it is proved with successful rate of 70-90% for patients with TMD the treatment efficient and commonest is the occlusal appliance. These occlusal types of appliance have important benefits that is these appliances are

reversible and not penetrating. Occlusal appliance is used to temporarily orthopedically stable joint that encourages normal muscle function that reorganizes the neuromuscular reflex activity and the activity of reflex neuromuscular is reorganized when optimum condition is introduced occlusally.[5]

Proper appliance selection is a need that aimed to eliminate a Specific etiologic factor. The importance of through examination and diagnosis is thus emphasized.[6] Various types of occlusal appliances are available for treating the different condition of TMDS are[7]:-Muscle relaxation appliance/stabilization appliance/permissive splints (muscle deprogrammers.), Anterior repositioning appliance/orthopedic repositioning appliances since the position of the mandible is the goal to change, Anterior Bite plate, Posterior bite plate, Pivoting appliance, Soft or resilient appliance

Muscle Stabilizing Appliances: Provides the occlusal relationship considered stable along with condyle in musculoskeletally stable position and is generally fabricated in the maxillary arch, in this way the appliance of muscle stabilizing is fabricated generally (Figure 1,2)

Indicated for Myofascial pain dysfunction syndrome (MPDS) are:

1. Muscle hyperactivity,
2. Local muscle soreness or myositis,
3. Internal derangement i.e. anterior disc dislocation with reduction.

Figure 1. Muscle Stabilizing Splint

Figure 2. Intra-Oral View of Muscle Stabilizing Splint

Mechanism of Action of Muscle Stabilizing Appliances: In TMD patients the reduction in muscle activity during clenching indicates the reduction of compressive force transmitted on the temporomandibular joint. This may reflect an involuntary pain-avoidance response. In TMD patients the muscle is already in a contracted position due to presence of any pathological condition, such as occlusal interference, which interferes with the normal closure of the mandible. Hence the muscles, which regulate the mandibular movements, try to close the mandible in a least damaging pattern, thus acquiring ENGRAMS according to that condition. This is the body's protective mechanism. In this condition the muscles are in a contracted position and cannot attain the normal physiologic length. If this perimeter of muscle length is changed, the tension recorded in muscles and tendon proprioceptors is altered. These alterations in tension reflect the reduced contractile activity of the muscles in question. This may reflect an involuntary pain-avoidance response.[8]

So, the muscle stabilizing appliance, which is made 1 mm above at centric posterior contact, encompasses the occlusal interferences and it will help to eliminate the muscle Engram. As the muscle Engram eliminates the masticatory muscles attend their original physiological length i.e. minimal tonic contraction.

By photographing occlusal registrations before and after each splint adjustment visit it was shown that the stabilization of occlusal patterns as resolution progressed gave a good indication of the success of treatment in most patients.[9]

Anterior Positioning Appliances (Apa): Indications are:

1. Internal derangement i.e. anterior disc dislocation without reduction,
2. Patient with joint sound,
3. Intermittent or chronic locking of joint,
4. Inflammatory disorders retrodicitis.

APA anterior repositioning implements to provide better condyle disc position in the fossae so normal function will be reestablished which eliminates the signs and symptoms associated the disc derangement disorders and the mandible is encouraged for an alignment intercuspally rather than the alignment excess anteriorly (Figure 3,4)

Figure 3. Anterior Positioning Appliance

Figure 4. Intra-Oral View of Anterior Positioning Appliance

Directive splints i.e. APA are not indicated if correctly aligined condyle disc assembly and its maintenance during function. Aps should not be considered unless discs reduction is verified. APS is indicated if reduction of discomfort is noticied in short time of 2 to 3 weeks. Patient should be on soft diet average time of treatment is 3 months. Side effects are expense, discomfort of wearing APS splints.

The position of the mandible is not altered permanently but only to change temporarily is the goal of the treatment, to enhance adaptation of retrodiscal tissues and to eliminate the effects of neuromuscularreflex that directs the mandible to close repetitively into maximum intercuspation.[10]

Soft appliances

Soft appliances are advocated for several use commonly as a preventive means for person commonly receiving trauma to dental arches such as bruxism and clinching.

The teeth opposing with contact is simultaneously and evenly achieved which is the goal of this treatment. Though the scientific evidence supports the reduction of the symptoms related to parafunctional activities by the use of hard appliances. Soft appliances are not well documented in scientific literatures. Advantage; since the soft material equally distributed occlusal load because it was considered as "self-adjusting".[11]

Drawbacks of soft appliances are:

1. The requirements exactly of the system of neuromuscular region is not accomplished as the soft type of material does not get adjusted readily so difficult to accomplish precisely,
2. Difficult to adjust and polish,
3. Poor retention,
4. Perforations during functioning,
5. Because of flexibility patient play with appliance.

In the treatment of TMD many authors have different opinions by attention specially to the soft and hard appliances of occlusal type. The hard splint is a customary application with that of the efficacy regarding disagreements of many, based upon much research and patients suffering with disorder functionally in the system of mastication which has most successful outcome.[12-15] The condition is altered occlusally and permanently in the position of the mandible is the treatment i.e. grinding selectively is the irreversible therapy. Need irreversible

occlusal therapy is followed by the success or failure of therapy of reversible type. It is indicated for irreversible therapy, occlusally in this case successfully the patient responses to occlusal reversible therapy.

Conclusion

The need for future health care being reduced, eliminating or reducing pain, restoring the functioning of the lifestyle normally and the restoration of the function of the jaw normally are the goals of TMDS. To restore in the region of muscleto normal posture, the motion range of joint fully by exercise and length are the strategy of term which is short. The long-term strategy includes reducing the symptoms through muscle rehabilitation while helping the patient to reduce contributing factors, muscle tension and strain, and return to normal function without the need for future health care. Behavioral and psychological evaluations should be conducted on all patients who have persistent pain to determine complexity and contributing factors. Reversible therapies are often adequate and should be attempted first. Various occlusal appliances design has been recommended in the literatures, Prosthodontist must evaluate the clinical situation and must select the appropriate appliance advocated for different clinical situations.

Abstract

Depending on the meticulous surgical protocol and on understanding the concepts of occlusion there is high standards of success rates of osseointegrated implants. In osseointegrated prosthesis the concept of occlusion suitable is similar to that of gnathologic occlusion. The concept of disocclusion is generally recommended, in order to minimize the horizontal loading during the eccentric movement. So as to increase the longevity of the prostheses the anterior group function and posterior disocclusion concepts are recommended. This article presents modern gnathological concepts i.e. implant protective occlusion (IPO) for rehabilitation of patient with osseointegrated implant to enhance functional efficiency, esthetic and psychological stability.

Keywords: *Osseointegrated implants, occlusion, eccentric movement, anterior group function, concept of disocclusion, implant protective occlusion (IPO).*

Introduction

The successful completion of restorative implant Prosthodontics is dependent on the effective implementation of occlusal principles. The different physiologic conditions lie between the osseointegrated implant and natural teeth. It should be emphasized that the osseointegrated implant does not have periodontal tolerance like the natural teeth, nor does it have specific defence mechanisms against occlusal forces[1]. The high standards of success rates of osseointegrated implants depends on understanding the concepts of occlusion and also on the meticulous surgical protocol[2].

With the osseointegrated implant, the prosthesis is connected firmly to fixtures so that any occlusal stresses generated, are transmitted directly to the surrounding bone. Therefore, the prosthesis must be fabricated as accurately as possible, in order to achieve long term success. Occlusion should be a key factor to the overall success rate.

Occlusal Scheme: Same as the gnathologic occlusion is basically the concept of occlusion suitable for osseointegrated prosthesis. All the posterior teeth have contacted and all the anterior teeth have a clearance of about 30µm for occlusion in centric. If the entire arches are restored with osseointegrated prosthesis it will be easier to establish an occlusion such as fully bone anchored bridge. In the mixed dentition which is composed of natural teeth and osseointegrated bridge network, it becomes more complicated to obtain a good occlusion. On its function approximately about 30µm the natural tooth moves, axially [3]. It does not sink which is supported by only by the bone in an osseointegrated bridge. Hence in osseointegrated fixed bridge the centric

contact is needed to adjust slightly more open than the natural teeth. This can be done with the use of photo occlusion wafers, a computerised device such as the T-scan, or very tedious occlusal equilibration with the help of articulating paper of 30µm[4]. Accordingly, the opposing teeth under the short bite pressure should not contact with the osseointegrated bridge in centric. The bridge should contact the natural teeth intrudes approximately 30µm under strong bite pressure. The osseointegrated bridge begins to contact after the contact of all the natural posterior teeth. If the osseointegrated bridge is adjusted to contact at soft bite pressure, under the hard bite pressure, all the occlusal load will be born only by the bridge and will overload the bone structure. In order to avoid the overloading of the occlusal surface the osseointegrated prosthesis should not have plane-to-plane contact. Now this contact point chiefly of cusp to cusp type but long centric occlusion is preferred (freedom in centric) [5]. The concept of disocclusion is generally recommended in order to minimize horizontal loading during eccentric movement. To produce the posterior disocclusion of the anterior segment of osseointegrated prosthesis should guide the mandible. For osseointegrated prosthesis canine guided occlusion is not recommended as it generates excessive occlusal forces into the single implant fixture which is placed in the canine area[6].In order to distribute the stress over entire fixture the anterior group function is recommended.

The ideal place to bear the horizontal load is the trapezoid area, in cases of those surrounded by the osseointegrated implants. Those formed are most medially located fixture to the most distally located fixture and to form the furthest right-side fixture to the furthest left side fixture. This rule can be altered to the anterior extensions of the osseointegrated prosthesis. For example, even if anterior arch is located slightly more anterior than the most anteiorly located fixture, the load applied by the mesial extension is small because it is far away from the condyle. Therefore, it is not so destructive when the load is transmitted to the fixture on the contrary, if the prosthesis is extended distally, it is more destructive. Therefore, anterior group function and posterior disocclusion are recommended for osseointegrated prostheses[7].

It is not clearly understood in cases of osseointegrated prosthesis the specific amount of disocclusion. According to measurements of samples that have the ideal natural dentition and are free from TMJ symptoms, the disocclusion amount[8] while the condyle moves from the centric of the mandibular first molars (mesiobuccal cusp tips) this is observed, as follows:

Average amount of disclusion in protrusion is 1.1+0.6mm

- The average amount of disclusion is 1.0+0.6mm on non-working side
- The average amount of disclusion on working side is 0. 5+0.mm
- These numbers can be used to determine the amount of disocclusion necessary for osseointegrated prosthesis.

Osseointegrated Prosthesis Classification:

Classification of osseointegrated prosthesis[2] is

(I) Anchored bridge fully bone

(II) Freestanding bridges

i) Kennedy's Class I

ii) Kennedys Class II

iii) Kennedys Class III

iv) Kennedys Class IV

(III) The natural teeth are connected with bridge

(IV) Replacement of single tooth

Discussion of occlusion in each case: Fully bone anchored bridge: The fully done anchored bridge is used for edentulous cases. It is very successful for the mandibular arch because there is no anatomic limitation for placing fixture between the right and left mental foramen. Usually four to seven fixtures are installed in this area and the prosthesis is connected into these fixtures. Mandibular fully bone anchored bridges can be extended to a maximum of 15 to 20 mm posteriorly. It is not necessary to make a maxillary bone anchored bridges because there are anatomic limits made by nasal and sinus floor. Also bone structure is poor in the maxilla. The amount of bone is limited. If the maxillary bone is available, usually six to seven fixtures can be installed between the mesial of the first premolars, and a fully bone anchored bridge can be screwed on the fixture. It can be extended posteriorly a maximum of 10mm.

For a fully bone anchored bridge, the mutually protected occlusion is recommended[9]. To be in centric, it is needed for the posterior teeth to have centric stop and the anterior region to have a 30µm. The disocclusion

is applied for elimination of harmful horizontal stress. The anterior group function is functioned, to prevent the stress from localization[10]. The anterior guidance should be slightly flatter than the natural teeth to protect from the fixture getting overstressed. So, this gives rise to less quantity of disocclusion in bridges of fully bone anchored is following: 1.0 mm Protusive, the working side is 0.3mm and the non-working side is 0.8 mm.

Figure 1. Fully bone anchored prosthesis

Occlusion for Overdenture: An overdenture is often used for the maxillary edentulous case. Even though the patient has poor bone structures is the maxillary canine area, one can quit often find bone for a fixture installation. Usually it is possible to place fixtures in this area and by connecting two fixtures, it can support overdenture. The function of the overdenture makes this prostheses suitable for the maxillary arch because it gives good phonetic function, facial support, and aesthetics. In this regard, an overdenture is often recommended for maxillary arch rather than a fully bone anchored bridges. The mandibular overdenture is usually used the patient who cannot afford many fixtures or for patient who wants to have natural check support.

The fully balanced occlusion with lingualized occlusion is the occlusion for overdenture (Figure 2).[2] The osseointegrated overdenture accepts the concepts applied to regular denture. In centric small clearance is preferred in the anterior for mandibular fully bone anchored bridges case and of an edentulous maxillary overdenture. Concurrently the posterior teeth contact. The lateral movement, non-working and working side and the amount of disocclusion in protrusive is 0mm.

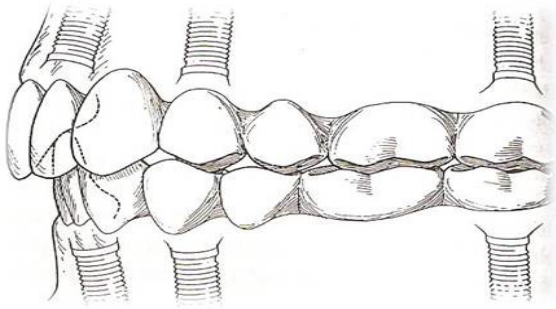

Figure 2. Fully balanced occlusion with lingualized occlusion

Occlusion for Freestanding Bridges

(i) Kennedy's class I:-bilateral cases: For Kennedy's class I situation, both side arches reinstated by osseointegrated bridges as they preserve the vertical height[12]. For determination of clearance amount given to natural anterior dentition, careful consideration should be taken. During functioning the osseointegrated prosthesis does not sink, mentioned earlier. The anterior teeth clearance should be smaller than the natural teeth. For this case the amount of disocclusion required is the same to that of natural dentition for the reason that natural dentition shows the as the contralateral side of the arch will maintain the anterior guidance (Figure 3).

Figure 3. Kennedy's class I

1.1 mm protrusive, nonworking side 1.0 mm, working side 0.5mm.

(ii) Kennedy's class II: Unilateral: The other side is restored by osseointegrated bridges as the contralateral side of the arch will maintain the ideal height and the situation ideal for osseointegrated freestanding bridges is the Kennedy's class II[13].

When in centric it includes less stress to the implant. Under strong bite pressure it begins to contact and as centric, anterior teeth should have 30µm openings while the posterior osseointegrated bridges should have 30µm open contacts. The occlusal load can be beared safely as the anterior teeth are natural teeth in situation of Kennedy's classII. The amount of disclusion in this case is same as for natural dentition (Figure 4)

Figure 4. Kennedy's class II

1.1 mm Protrusive, 1.0 mm is non-working side, 0.5 mm is working side.

iii. **Kennedy's class III:** By natural teeth the vertical height is maintained and situation ideal for implant of osseointegrated is the Kennedy's class III. Under strong bite pressure the osseointegrated bridge only contacts, in centric. The natural dentition guides the eccentric movement. The amount of disclusion in this case is same as for natural dentition (Figure 5).

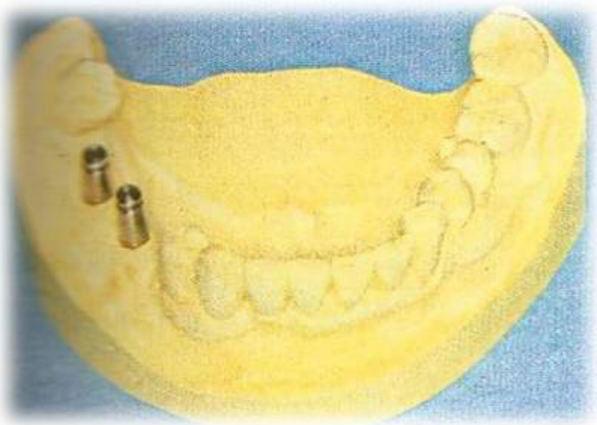

Figure 5. Kennedy's class III

1.1 mm Protrusive, 1.0 mm is non-working side, 0.5 mm is working side.

iv. **Kennedy's class IV:** The Kennedy's class IV case requires an anterior freestanding bridge, and it is another indication for the osseointegrated bridges (Figure 6). In a Kennedy's class IV, such as missing the eight teeth from first premolar regular fixed bridge is contraindicated because it produces a fulcrum. If the teeth are restored with removable partial denture, it also produce fulcrum and introduce tremendous torque to the abutment teeth. However this case is easily restored with an osseointegrated bridge. Anterior eight-unit fixed bridge can be supported by four fixtures without creating a fulcrum.

Figure 6. Kennedy's classs IV.

The osseointegrated bridges guides the posterior disclusion in a Kennedy's class IV case. The group function occlusion is preferred, introduced to the implant site in order to minimize the horizontal load. The non-working site is discluded while the horizontal load during lateral movement can withstand by the posterior teeth on working side. The posterior disclusion is produced during protrusive movement and an osseointegrated bridge will guide the mandible. During protrusive movement, in order to minimize the load the anterior guidance should be flatter than natural dentition. For this case the amount of disclusion is as follows: 0.8mm Protrusive, 0.4mm non-working, 0.0mm working.

For Natural Teeth Connection: The natural teeth as fixture must be connected to the mesial end of the bridge which prevents the loosening of the screw by rotation of the bridge and is used to restore the bridge. This osseointegrated implant is not depressed during its function but the natural teeth is as mentioned earlier. When the osseointegrated implant prosthesis and the

natural teeth are connected rigidly, under the occlusal load the implant receives majority of stress and is overloaded. This non-rigid connector is used inorder to prevent this. The female key is placed on distal end of the retainer supported by natural tooth and the key is connected to osseointegrated bridge which is engaged into the keyway. Hence the natural tooth can be depressed freely without the interference of the osseointegrated bridge.

Thus, based on long-term observation, produces gap between key and keyway by the natural tooth which are depressed permanently. The key is extruded to a visible amount in osseointegrated prosthesis along with that the retainer cemented to the natural tooth is depressed. It's not clear by the reasons when the keyway and the key are made precisely, HENRY believes that this phenomenon is caused. The natural tooth is depressed permanently, the keyway and the key are locked sometimes in cases where the natural teeth are depressed.As some suggest to prevent this phenomenon to connect the osseointegrated bridge, the telescopic crowns are used. Through a long-term observation, the natural tooth is depressed often it was found often. The outer crown to the inner crown washed out, producing plaque accumulation is the cement connecting.

The rigid connector is used presently rather than a non-rigidconnector between the natural tooth and the osseointegrated bridge. The absorption of the alveolar bone or creating resorption of the root, resulting from ankylosis of the abutment tooth. Slowly this progress. So the situation mentioned above is not preferred rather than to this. The freestanding procedure is preferred and the connection of the natural tooth is questionable.

For Single Tooth Replacement: For single tooth replacement the determined factors[14] are occlusal table width of the prosthesis, crown contour, functional surface area.

Occlusal table width: The Implant Protective Occlusion (IPO) is when the width of the implant body is related directly to the width of the occlusal table. A wider occlusal table favours offset contact (cantilever effect) as compared to narrow occlusal table during mastication or parafunction. A narrow occlusal table combined with a reduced buccal contour(in the posterior mandible) improves the axial loading and in the manner to a tooth, permits sulcular oral hygiene easier.

Crown contour: In IPO the crown contour of the prosthsis depend on the amount and position of bone. In Division A bone, in an edentulous ridge with abundant height and width and little resorption, the implant may be placed in a more ideal position for occlusion and esthetics. The most common implant placement corresponds to a central position in the residual ridges. In esthetic regions the facial aspect of maxillary implant crown should remain similar to the natural tooth. Lingual contour and cusp may be reduced to minimise offset load from opposing natural tooth. In case of mandibular posterior implant mandibular buccal cusp is reduced in width, and height. Primary contact is with maxillary lingual cusp. In Division B bone, with resorbed height and width in an edentulous ridge, implant body to be placed in lingual cusp region of the original natural tooth (in mandibular posterior). Lingual contour of the implant crown remain same but buccal cusp must be reduced in height and occlusal table is reduced from the facial region.

Functional Surface Area: An important parameter in IPO is the adequate surface area to sustain the load transmitted to the prosthesis. A greater area of bone contact at the crest occurs rather than the narrow implants (resulting from their increased circumferential bone contact area) in cases with wider diameter root forming implants. In wider implants compared with narrow ones, the mechanical stress at the crest is reduced for a given occlusal load.

As the natural dentition the occlusion required for this restoration is same. For implant prosthesis should contact only under heavy load because natural teeth depress under heavy load, it must have a clearance of 30μm for anterior teeth in centric; in the osseointegrated restoration the amount of contact to be given must be carefully designed. In order to create anterior group function, the anterior restoration should contact with the opposing teeth during eccentric movement. For implant prosthesis, the restorations should avoid lateral stress and need to disclosed during eccentric movement.

Conclusion

Basically, as the Gnathological design is, for osseointegrated prosthesis is the same in the concept of occlusion. The natural tooth sinks about 30μm during function rather than an osseointegrated bridge which is supported by the bone does not sinks. Rather than the

natural teeth in osseointegrated fixed bridge is slightly more open and it's necessary to adjust the centric contacts. The concept of disocclusion is generally recommended in order to minimize horizontal loading during eccentric movement.

Abstract

The term, Head and neck cancer comprises a heterogeneous group of malignancies spreading from the lips to the cervical oesophagus, with squamous cell carcinoma illustrating the ultimate ubiquitous histology. Treatment strategies are designed according to disease stage, sites of primary tumour, patient's age,operability conditions and performance status. Management approaches include surgery, chemotherapy, radiation therapy, brachyor external beam or combination of these therapy. The use of chemotherapy in head and neck squamous cell carcinoma has expanded considerably in past several years. This article summarizes the current evidence that guide the use of chemotherapy for advanced disease, unresectable tumour or unwilling patients to undergo surgery.

Keywords: *Chemotherapy; Head & Neck Cancer; OSCC.*

Introduction

Head neck cancer is more frequent than any other malignancy. The survival rate of approximately 5-years from these carcinomas has consequently remains the same in past 30 years and i.e. approximately 55%.[1-4] The ratio of head and neck cancer in male is more prevalent than female i.e 2:1 over decades, but it almost becomes same in sanctitude. Oral head and neck cancer are a disease of increasing age: approximately, 96%of them found in old age people. Tobacco and alcohol are the major predisposing factor of head neck cancer. Tobacco and alcohol are independently carcinogenic, and their combination has a synergistic effect rather than an addictive effect.[5,6] In India and Southeast Asia, where the use of tobacco, betel nuts, or lime to form a quid is widespread, the incidence of oral cancer is high; cancer of the oral cavity represents about 35 % of all malignant tumours.[5,7] Other identified risk factors include, exposure to various noxious fumes and chemicals also may predispose to cancer of the upper aero-digestive tract. Up to 15 percent of patients with head and neck cancer may have a viral etiology implicated in the genesis of their tumours. An association between Epstein-Barr virus (EBV) and nasopharyngeal carcinomas has been suggested by the high incidence of elevated EBV titres in patients with nasopharyngeal carcinoma. 1, 7 Many head and neck squamous cell carcinomas are preceded by various pre-cancerous lesions. Such lesions may present in the form of leucoplakia or erythroplakia. Histologically these lesions range from hyperkeratosis, parakeratosis, atypia, dysplasia, or carcinoma in situ to varying grades of frankly invasive cancer. In poorly differentiated tumours, it is sometimes difficult to determine the exact histologic nature, and electron microscopy or immunohistochemical stains may be necessary to differentiate between poorly differentiated squamous carcinoma, undifferentiated carcinoma, lymphoma, and melanoma.[4-7]

Clinical examination of the primary tumour: Many of the primary sites of head and neck carcinomas are not easily visualized and therefore, tumours do not present until quite advanced. The signs and symptoms of patients with head and neck cancer vary according to the site of the lesion and the extent of disease. Physical

examination of the oral cavity and oropharynx should include a thorough inspection and bimanual palpation of the floor of the oral cavity, tongue, gums and cheek. The nasopharynx, hypo-pharynx and larynx can be inspected with an indirect mirror examination or a flexible naso-pharyngoscope. Careful inspection of the neck is mandatory. Exophytic, endophytic, ulcerated, invasive, or infiltrative are some of the types of primary tumour.In addition, a complete head and neck examination entails careful evaluation of the scalp, skin of the face and neck, regional lymph nodes, thyroid gland, major salivary glands, and cranial nerves; and mirror or endoscopic examination of the nasal cavity, nasopharynx, hypopharynx, and larynx.[8-10]

Evaluation of cervical lymph nodes and other sites: Proper inspection of the regional lymph nodes of the neck is a major part of a complete head and neck examination. The regional lymphatics draining in head and neck region are situated in the specific anatomic locations as depicted. An adequate examination of the neck should assess the presence of palpable adenopathy; features of palpable lymph nodes; and clinical manifestations of extra capsular extension of disease.[7]

Aims of treatment: The principal aim of any malignant tumour is proper treatment that will cure it. However, there are important secondary goals such as the preservation of form and function to retain a good quality of life. There are three main method to treat cancer i.e. surgery, radiation therapy and chemotherapy. Mechanism of Chemotherapy is cessation of growth of cancer cells. It is one of the three main method used to treat cancer. W chemotherapy is very potent as it has the capability to control the metastatic cancer that has spread to different parts. So, chemotherapy plays a vital role in treatment of cancer.[11-14]

Mechanism of action of antineoplastic agents

Traditional chemotherapy drugs: Production of DNA during the S phase of the cell cycle serve as a selective template for the synthesis of specific forms of mRNA, tRNA and rRNA. The specific mRNA regulates the enzymes that will be synthesized in the cell. Function, structure, metabolism, and proliferative rate of the cells are the responsibilities of the enzymes. Mechanism of action of anti-neoplastic drugs is the inhibition of synthesis of either enzymes or substrates essential for the production of nucleic acid. Based on the mechanism of drug action, agents that are useful in HNC can be classified as follows:

1. Antimetabolites: They inhibit biosynthesis purine or pyrimidine. Methotrexate, for example, prohibitsformation of reduced folates, that is necessary for synthesis of thymidine.
2. Alkylating agents:These Drugs impede either the structure or function of the DNA molecule, such as Cyclophosphamide alter the DNA structure, and arrest cell replication. On the other hand, antibiotics such as dactinomycin and doxorubicin get embedded with the nucleotide sequences of the DNA molecule and block the synthesis of mRNA.
3. Mitotic inhibitor: Vinca alkaloids, such as Vincristine and vinblastine, and the Taxanes paclitaxel and docetaxel cease cell division by disturbing the microfilaments of the mitotic spindle.

Selection of treatment: Head neck cancer is associated with pronounced cosmetic and functional morbidities resulting from both disease and its treatment heighten its relative importance. As a result, these tumours require the multidisciplinary care and expertise of head and neck surgeons, radiation and medical oncologists, prosthodontists, speech and swallowing therapists, pathologists, radiologists, dietitians, psychiatrists, nurses, and social workers.[15]

The treatment mode should be decided on the basis of feature of the primary tumour and stage of cervical lymph nodes. Other factors that determine the treatment of choice are cost, convenience, compliance, complications.[7] The primary modality of treatment for early stage disease (AJCC stage 1 and 2) is surgery and/or radiation therapy. Combined therapy plays a major role in advanced stage of cancer. Previously, these treatment method also applied to patients with locally advanced disease (AJCC Stage 3 and 4) if it was found to be respectable.[14-16]

Patient with cancer were offered radiation therapy only, with complete response rate of less than 30%. Treatment failure commonly occurred within the first 2 years, indicating that surgery and/or radiation therapy could not solely eradicate the cancer cell. 1 Multimodality attention enhance the consequence for HNC patients. It has been recorded during the last decade that larynx preservation is possible in up to two-thirds of stage III and IV larynx and hypopharynx patients who has undergone chemotherapy earlier to radiation therapy. Chemotherapy along with radiation therapy improve the survival potency as compared with radiation therapy alone for patients with unresectable HNC.[16]

Single agent chemotherapy: At the beginning, chemotherapy was implemented in the patients with recurrent or metastatic disease. With a median survival rate of 4 months was seen in patients who are left untreated.

Combination cytotoxic chemotherapy regimens: Recurrent and metastatic cancer shows a great response with the implementation of Combination chemotherapy regimens of the head and neck in comparison with each respective single agent but have not demonstrated an enhancement in survival.

Aggregation Chemotherapy with Cisplatin/5-Fu: Several randomized clinical trials have provided conclusive evidence for the superiority of cisplatin/5-FU (PF) as the standard in this patient population. The primary method of administration for this doublet regimen is cisplatin 100 mg/rn2 on day 1 and continuous-infusion 5-FU 1 g/m on days 1 to 4 or 5.A large phase III randomized trial of combined cisplatin/5-FU versus each respective agent was initiated by Jacobs and associates; an improved overall response rate was determined for this doublet regimen at 32% (P =.035) versus cisplatin (17%) versus 5-FU (13%) in advanced head and neck cancer. (55) The median time to progression of approximately 2 months for the combination (P =.023) was minimal. The median survival in all three arms was approximately 5.7 months (P =.489).

Although the aggregation of cisplatin J5-FU was deemed to be greater in response, this was at the expense of increased vomiting (35%) in comparison with the single-agent arm of cisplatin (18%, P =.02).

A large randomized phase III trial conducted by the Southwest Oncology Group (SWOG) determined that the response rates of cisplatin/5-FU (32%) and carboplatin/5-FU (21%) exceeded that of single-agent Methotrexate (10%).

Forastiere and colleagues randomly assigned 272 patients with SCC to one of three arms:

- Cisplatin (100 mg/m2) continuous-infusion 5-FU (1000 mg/m2/day, days 1 to 4) repeated every 21 days;
- Carboplatin (300 mg/rn2) / continuous-infusion 5-FU (1000 mg/m2/day, days 1 to 4) repeated every 28 days; and
- Methotrexate (40 mg/rn2 weekly)

Although the combined chemotherapy arms clearly had an improved response when compared with Methotrexate, median survival was found to be equivalent in all 3 arms. Various method of enhancing the cytotoxicity of chemotherapy agents have been explored, including the use of interferon-a. In vitro studies of interferon-a have revealed enhanced cytotoxic effects of 5-FU when administered in combination. Based on this premise, investigators examined the combination of cisplatin/5-FU/interferon-a in a pilot trial.[12] An overall response rate of 30% was seen. A larger phase III trial of PF with randomization to interferon-a, was pursued in patients with head and neck malignancy who had a poor prognosis. After completion of the study, no statistical difference in response rate or median survival benefit could be ascertained. Increased toxicities of anorexia, fever, leukopenia, and thrombocytopenia were noted to occur in the interferon-a arm. Unfortunately, these and other phase III trials have been unable to establish an improved benefit in survival when a combined regimen is used, and increased toxicity is often noted. A critical drawback to several of the earlier studies was the consideration of response rather than overall survival in the setting of recurrent or metastatic disease as the primary endpoint. Moreover, a majority of studies failed to determine the impact of treatment on quality of life, an important consideration in patients with a poor prognosis. Clinical investigators in cancer of the head and neck have recently recognized quality of life as an important facet in the success of clinical trials, and they continue to evaluate the impact of both acute and chronic sequelae.[18-20]

Combination chemotherapy with the taxanes

Docetaxel/platinum combinations: Novel combinations incorporating the Taxanes have been initiated and continue to be evaluated. Previously, several phase II clinical trials have examined the benefits of docetaxel combined with cisplatin or 5-FU. The EORTC investigated the combination of docetaxel (100 mg/m2) Cisplatin (75 mg/rn2) every 21 days in taxane-naive patient. Forty-one patients were eligible for treatment and 31 patients were evaluated for response. The median number of chemotherapy cycles received was four in this novel combination. A favourable ORR of 53.7% was determined on an intent-to-treat analysis (14.6% complete remission [CR], 39% partial remission [PR]), with a median duration of response of 18 months and a median survival at 1 year of 50%. A majority of the adverse events noted were primarily

hematologic, resulting in anaemia (98%) and leukopenia (79%). Asthenia developed in 47% of patients with this combination regimen and is a known frequent toxicity associated with docetaxel. The favourablen response rate in this combination setting may be a result of the minority of patients (six totals) with distant metastatic disease. However, the encouraging response rate and duration of response require that this novel taxane combination be considered in the primary treatment of locally advanced disease. A Japanese study using a lower dose of docetaxel (60 mg/m2) had similar findings for the combination of docetaxel/cisplatin with an ORB of 42.4%.[21]

Paclitaxel/platinum combinations: Numerous studies have combined paclitaxel with cisplatin in the setting of recurrent cancer of the head and neck, resulting in a wide range of response rates from 30% to 70%. Both high-and low-dose paclitaxel combinations have been created to determine if a dose-response relationship exists for 24-hour infusion of paclitaxel. The myelosuppressive effects of paclitaxel often require hematologic support with granulocyte colony-stimulating factor (G-CSF) if high doses are to be administered.[22]

Current clinical approaches of induction chemotherapy: The Dana Farber Cancer Institute has recently reported the maximal tolerated dose of cisplatin when given in combination with docetaxel and 5-FU as induction chemotherapy in patients with locally advanced head and neck cancer. Patients received-three cycles of docetaxel (75 mg/m2, day 1), cisplatin (75 mg/m2 or 100 mg/m2) and continuous-infusion 5-FU (1000 mg/m2 on days 1 to 4) repeated every 21 days, followed by hyper fractionated radiotherapy and neck dissection for bulky disease. Empirical antibiotics were provided on days 5 to 15. If a PR was achieved following the completion of chemotherapy; patients underwent definitive therapy at the institution's discretion. Toxicities were similar at both dose levels, consisting of chemotherapy-induced electrolyte imbalance in 30% of patients and grade Ill/IV neutropenia in 95% of patients. Patients were considered evaluable for response if more than 2 cycles were completed. The overall clinical response rate was 94% (40% CR, 54% PR). Post-treatment biopsies were completed in 25 patients (58%). 92% of patients with a primary site CR had a negative biopsy; 54% had a pathologically confirmed PR.[22]

Intertumoral and Intra-Arterial Administration: Other method to deliver chemotherapy outside of traditional intravenous method have been explored. One example is direct intra-arterial infusion of chemotherapy for loco-regional disease to target the dominant blood supply of the targeted tumour. A phase I study by Robbins and colleagues assessed the maximum dose intensity of cisplatin by selective intra-arterial infusion. Forty-two patients received escalating doses of intra-arterial infusion of cisplatin (160 to 200 mg/m2). Approximately half of patients had been previously treated. Patients received sodium thiosulfate to neutralize the systemic toxicity of cisplatin. The maximal tolerated dose (MTD) was 150 mg/m2 weekly for 4 weeks. The ORR was 86% for previously untreated patients and 62% for patients with recurrent disease. One drawback to the intra-arterial infusion technique is the risk of subcutaneous necrosis of the surrounding tissue.

Conclusion

A multicenter clinical trial of intravenous PV7O1 has been performed in the treatment of patients with advanced or recurrent solid tumours. One CR (head and neck) and two PRs (colon and mesothelioma) were observed at higher doses, and six patients with diverse malignancies had measurable tumour reduction. The MTD was determined to be 12 biffion plaque-forming units/m2. A multi-institutional phase I study has since been initiated to determine the MTD of PV7O1 via intra-tumoral injection in patients with locally advanced HNSCC.

Osseointegration: A Comprehensive Overview

Sangram Panda

Reader, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to Be University), Bhubaneswar, Odisha, India

Abstract

Dr. Branemark developed the first concept of Osseo integration. Osseointegration is defined as,"direct structural and functional connection between the living bone and the surface of a load bearing artificial implant, typically made of Titanium." The process of Osseo integration needs the formation of new bone around the implant fixture and the process of healing of implant is somewhat same as the healing of a primary bone. The formation of bone on the surface of Titanium needs a film of oxide simultaneously with the aggregation of protein and calcium phosphate. Nevertheless, Osseointegration is the indirect bonding that is formed by an amorphous layer that includes Osteoclastin and Osteopontin that are being used as scaffolds by Osteoblasts, not any direct bond between the titanium surface and the bone. Several clinical studies show the ratio between the bone and implant contact is (40 to 60) % where the Osseo integration was successful. Many researches and studies are being performed to discover the best modification of surface of implants so as to increase the score of the implant and bone contact. Most newly the treatment of surfaces such as acid etch, glow discharge or ultra violet irradiation have been shown to be effective for the Osseointegration process. Many more changes and researches are needed to find the best method of Osseointegration and in maintaining it.

Keywords: *Osseointegration; Implants; Titanium; Dentistry*

Introduction

P.I Branemark a Swedish orthopedic surgeon with his wide ranging work finally lead to the discovery of the commercially available pure titanium, which when was located in the ideally placed in the prepared site of the bone, can result in fixation in that place because of the close bond that eventually grows between the bone and implant, a spectacle that he later called and described it as Osseo integration. These states had both the functional as well as the anatomical dimensions, as it necessitatesin cooperation a close contact between the implant and surrounding healthy bone and the ability to transmit functional loads over an extended period without deleterious effects either systemically or in the adjacent tissues. Osseo integration is not defined in terms of the extent of the bone-implant contact, provided that functional requirements are met and tissues are healthy.[1] Many of the factors that predispose to the development of OI are now known, and where these exist a successful outcome will probably follow the placing of a suitable implant. Similarly, failure is more likely where factors known to predispose to an unsuccessful outcome exist.[2] Occasionally, implants fail for no apparent reason, sometimes in group in one patient-the so called 'cluster phenomenon'. It is therefore important to advise patients that a satisfactory outcome cannot be guaranteed.[3]

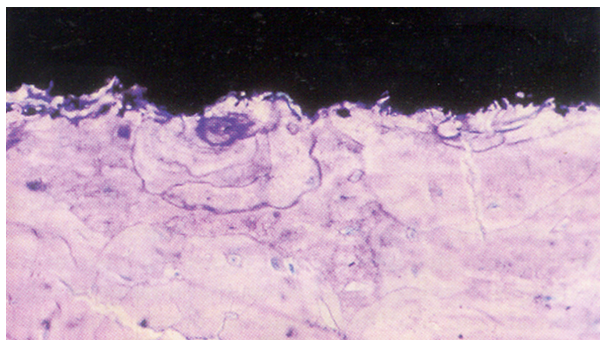

Figure 1. Close physical approximation between the surface of a dental implant and vital bone is a key structural characteristic of osseointegration, which also has important functional parameters

OI is currently viewed as the optimum implant-bone interface, without which success cannot be obtained, and great emphasis has been placed on its production and maintenance. Nevertheless, it is only one component of successful dental implant treatment from failing. While absence of OI is equated with treatment failure, its achievement does not guarantee success, which is dependent on the design and performance of the final prosthesis. This may be precluded by an inappropriately placed implant, even if it is integrated.[4] While the osseointegrated interface and associated soft tissue cuff where the implant penetrates the oral mucosa are often thought of as dental analogues, they have a number of important differences. In particular, the interface is more rigid and less displaceable than the periodontal ligament, and behaves essentially elastically as opposed to the viscoelasticity of the periodontal ligament, and behaves essentially elastically as opposed to the viscoelasticity of the periodontal ligament. The stability of the interface also precludes implant repositioning by orthodontic maneuvers, but may permit dental implants to be used as an anchorage for fixed orthodontic appliances. The osseointegrated interface is also associated with a slow rate of loss of crestal alveolar bone, typically less than 0.1 mm per annum after the first year of implantation. As a result, most implants can be expected to be functional throughout adult life.[5]

Inflammation of the tissues around an endosseous implant is sometimes observed; it is described as peri-implant mucositis when it involves only the soft tissues and peri-implantitis where loss of the bone interface occurs. While the microorganisms associated with these lesions are similar to those seen in periodontal disease, it is currently unclear whether they cause the lesion or colonize the region subsequently. [1,2]

Factors Affecting Osseointegration: A number of systemic and local factors have been identified as being associated with the production of an osseointegrated interface. Fewer systemic factors are now thought to be of significance than was once believed, and are considered below. Local factors are as follows.

Materials

Osseointegration was originally believed to be unique to high purity titanium and this material still forms the basis of the technique however, it is known that range of other materials can also form intimate bonds with bone. This included zirconium and some ceramics, particularly hydroxyapatite; however, they have not been as extensively researched as CPTi for dental implant applications.[4]

Surface composition and structure: It is thought that CPTi owes its ability to form an osseointegrated interface to the tough and relatively inert oxide layer, which forms very rapidly on its surface. This surface has been described as osseoconductive, that is, conducive to bone formation. Other substrates also have this property and may also stimulate bone formation, a property known as osseoinduction. While the initial bone implant contact with such a material can be more extensive and occur sooner than around CPTi, the long-term benefits are less evident. Nevertheless, there is a considerable clinical and research interest in modifying the composition of implant surfaces for the purpose of obtaining more rapid OI and/or a mechanically and clinically superior host/implant interface. This can take the form of surface coatings, changes in the composition of the implant material by selective surface coping with small quantities of other elements, or the local use of biochemical molecules involved naturally in mediating bone formation, such as bone morphogenic protein (BMP).[5,6]

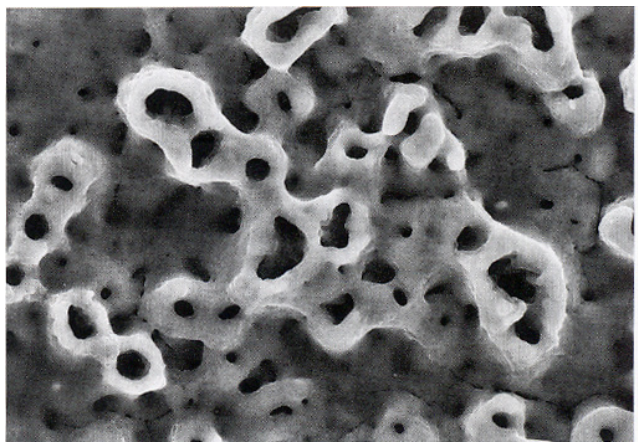

Figure 2. Manufactures have modified the surfaces of their dental implant with the intention of improving tissue responses so as to enhance osseointegration. This picture shows the TiUnite surface utilized by Nobel Biocare.

Implant surface structure is also known to influence cellular behavior, and a range of micro structured surfaces has been shown to modify cell spreading and orientation on the implant, benefitting initial anchorage in bone. The influence of these factors on OI in the long term, however is not known.[6]

Heat: Heating of bone to a temperature in excess of 47°C during implant surgery can result in cell death and denaturation of collagen. As a result, OI may not occur, instead the implant becomes surrounded by a fibrous capsule and the shear strength of the implant-host interface is significantly reduced. For these reasons great care has to be taken when preparing implant sites to control thermal trauma. This is related to drill speed, drill design, amount of bone being removed at one pass, bone density and use of coolants. In general, slow drill speeds and use of copious amounts of coolant is recommended.[7]

Contamination: Contamination of the implant site by organic and inorganic debris can prejudice the achievement of OI. Material such as necrotic tissue, bacteria, chemical reagents and debris from drills can all be harmful in this respect.[7]

Initial stability: It is known that where an implant fits tightly into its osteotomy site then OI is more likely to occur. This is often referred to as primary stability, and where an implant body has this attribute when first placed failure is less probable. This property is related to the quality of fit of the implant, its shape, and bone morphology and density.[1] Thus screw shaped implant will be more readily stable than those with little variation in their surface contour. Soft bone with large marrow spaces and sparse cortices provide a less favorable site for primary stability to be achieved. Some manufacturers produce 'oversized' and self-tapping screw design to help overcome these problems.[8]

Bone Quality: The properties of bone are well renowned by clinicians however it is more challenging to measure scientifically. Number of indices are being used to describe the bone quality and it is a function of bone density, anatomy and volume. Most widely used classifications are of lekholm and zarb and of cawood and Howell for describing bone quality and quantity. Bone quality means the thickness and density of cortical and cancellous bone, and bone quantity means the amount of bone resorption. Even though bone volume doesn't influence OI it is a relevant determinant of implant position. Where there is no bone bulk, then small implants can be used with a risk of mechanical overload and implant failure.[1,2,7]

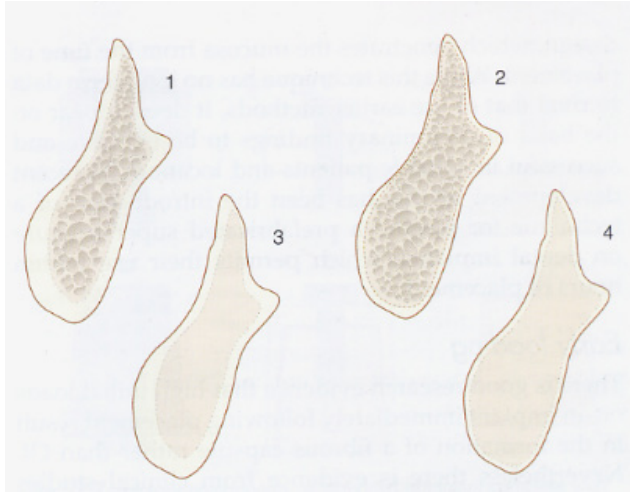

Figure 3. A scheme for classifying patterns of bone in the edentulous jaw: (1) thick cortex and plentiful cancellous bone; (2) thin cortex and plentiful concellous bone; (3) dense cortex with minimal cancellous bone; and (4) sparse cancellous bone and a thin cortex.

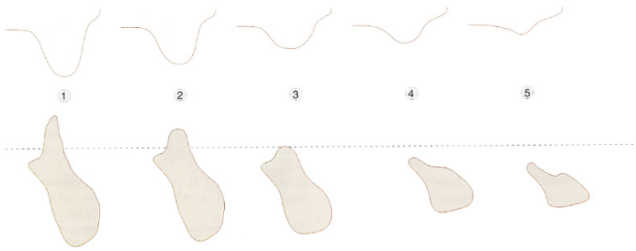

Figure 4: A scheme for classifying the extent of bone resorption in the edentulous maxilla and mandible based on the proposed by Cawood and Howell in 1988.

Epithelial downgrowth: Early implant designs were often associated with downgrowth of oral epithelium, which eventually exteriorized the device. When the newer generation of CPTi devices where introduced great care was taken to prevent this by initially covering the implant body with oral mucosa while OI occurred. The implant body was then exposed and a superstructure added, since it was known that the osseointegrated interface was resistant to epithelial downgrowth.[1] More recently, there has been a growing interest in using an implant design, which penetrates the mucosa from the time of placement. While this technique has no long-term data to rival that of the earlier method, it does appear on the basis of preliminary findings to be effective and successful in suitable patients and locations. A recent

development of this has been the introduction of a technique for placing a prefabricated superstructure on dental implants, which permits their use within hours of placement.[7]

Early loading: There is good research evidence that high initial loads on an implant immediately following placement result in the formation of a fibrous capsule rather than OI. Nevertheless, there is evidence from clinical studies that where the implant has good primary stability, early loading does not apparently preclude OI, below an ill-defined threshold.[3]

Late loading: It has been shown that excessive mechanical loads on an osseointegrated implant can result in breakdown of the interface with resultant implant failure, and it is generally considered that overload is therefore to be avoided. This could arise as a result of bruxism, in patients who habitually use high occlusal forces, and as a result of superstructure designs in which the use of excessive cantilevering causes high forces on the implants. The research evidence for a link between occlusal loads and loss of OI is, however, not extensive, and there are currently no clinical guidelines as to its determination in a particular patient other than by general principles.[4] Since bone is a strain sensitive material, the modeling and remodeling of which is influenced by deformation, it is thought that there is probably a range of strains that are associated with bone formation and could thus be of therapeutic value.[6-8]

Systemic and local factors affecting implant treatment: Implant treatment is but one of a range of procedures available to the restorative dentist to help the partially dentate or totally edentulous patient. Its use must be set within comprehensive assessment of the patient's needs and most suitable method of helping them. Treatment with dental implant does not in itself negate the need for care in patient assessment, treatment planning and provision, and cannot overcome neglect of basic principles or the use of inferior techniques. It is subject to the normal constraints on restorative and minor surgical procedures imposed by systemic conditions. In addition, there is a range of conditions that are associated with or thought to be associated with increased risk of implant failure.[9]

Systemic factors having known links with implant failure

Tobacco smoking: The use of tobacco shows an increased risk of an implant failure.

Implant failure resulting from certain associations of systemic disease:

- Active chemotherapy.
- Diphosphonate therapy.
- Ectodermal dysplasia.
- Erosive lichen planus.
- Type 2 diabetes: especially in the cases of uncontrolled DM.
- Operator has less or limited knowledge and less experience in implantology.[10]

Local factors having strong associations with implant failure:

- Resorbed maxilla implant placement
- Implant site has an history of irradiation.
- Usage of a designed implant in a press fit cylindrical design.

Matters less strongly associated with a risk of implant failure:

- In the infected sites of extraction, the implant placement.
- In the back-tooth region of maxilla use of little number of implants
- The usage implants that are short as compared to long.[11,12]

Conclusion

A major revolution that can be considered in the advancement of clinical treatment is the successful rehabilitation of edentulous area by the method of tissue integrated implants. The idea of knowing the prosthesis i.e. implants has been in a continuous process of evolution since past 4 decades starting from experimental phases to clinical practice of evidence-based dentistry.

Evaluation of Biomarker: A Review

Sashikant Sethi[1], Sourav Chandra Bidyasagar Bal[2], Radha Prasanna Dalai[3], Amit Mehta[4]

[1]Tutor, [2]Senior Lecturer, [3]Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [4]Senior Lecturer, Department of Public Health Dentistry, Santosh Dental College, Ghaziabad, Uttar Pradesh, India

Abstract

Biomarkers are frequently used for understanding the physiological processes which are changing with age or any disease which developed and closely related to age also to aging process itself. Some of the best examples' biomarkers are pathological analysis, imaging pattern lipids and protein. The biomarkers are created in our body by response to any systemic disease or by any tumour biomarkers are very useful in spectrum of disease progression. During the time of diagnosis, biomarkers can determine staging, grading, and selection of initial therapy. During treatment, they can be used tomonitor therapy, select additional therapy, or monitor recurrent diseases. Recent advances in, proteomics and molecular pathology have created lots of candidate biomarkers with highly potential clinical value. In the near future, introduction of biomarkers, identified using new advanced technologies, into medical practice will be necessary to achieve "personalization" of treatment and disease prevention.

Keywords: *Biomarkers, Evaluation of biomarker.*

Introduction

Now a days in most of the studies of human population biomarkers are frequently used for understanding the physiological processes which are changing with age or any disease which developed and closely related to age also to aging process itself. Some examples of important biomarkers are pathological analysis, imaging pattern lipids and protein. The biomarkers are created in our body by response to any systemic disease or by any tumour biomarkers are very useful in spectrum of disease progression. In disease screening process biomarker can be used before any final diagnosis of disease. Markers help in diagnosis of disease by grading, staging and gives idea about which therapy is suitable for that disease. Biomarker also select additional therapy and observe the recurrent diseases.[1]

Due to recent advancing in the technology field the close relationship or different oral diseases like cancerous and pre-cancerous lesions, dental caries periodontitis comes to our knowledge's most commonly occurring disease of oral cavity such as dental caries, periodontitis, oral cancer has some tremendous history of in their progression with evidence of bone loss attachment loss, pocket formation, enamel structure loss and various inflammatory process. Before the development of advance technology different oral disease were diagnosed by clinical examination, by using of different probes, radiograph and by asking the history of the disease. These method were time consuming or may give false negative or false positive results can not help properly for getting suitable therapeutic interpretation. Biomarker can provide early sign for development of disease or negative health output in near future. In regular routine check-up biomarkers role is essential because they can truthfully identify the mechanism of different disease progression.[2,3,4,5]

Different category of Biomarkers[6]: Inrecent year of molecular biology, biomarkers meanmolecular biomarkers they are classified in to three importantcategories:

1. Type 0 Biomarkers-their duty is to trace the disease progression in and compare with clinical measures
2. Type 1 Biomarkers their duty to check efficacy power of different drug
3. Type 2 Biomarkers-they act as surrogate end points in every clinical trial study

Some important definitions-6

Biomarker: An indicator of physiological or pathological response.

Risk marker: An attribute or event that is associated with increased probability of disease but is not necessarily a causal factor.

Risk indicator: An event that is associated with an outcome only in cross sectional studies.

Valid of biomarker-6

A biomarker is valid when allits evidence is clinically significant.

Classification of Biomarkers:

Biomarkers are classified under different ways:6

1. By their method of use
2. By their utility
3. By their the relation on clinical progression

Based on the method of use [6]

The first type of classification which is based on the method of use is further subclassified into:

1. Disease biomarkers: This is type 0 Biomarkers.
2. Diagnostic biomarker: frequently used in molecular diagnostics procedure.
3. Drug discovery Biomarker
4. Prognostic biomarkers: helps in outcome of disease.
5. Target biomarkers: Reports interaction of the drug with its target
6. Predictive biomarkers: To help in predicting disease at pre-symptomatic stage.
7. Toxicity biomarker: gives accurate idea about toxic effect of a different drug.

According to the Utility:

1. Early detection biomarker: Useful in screening procedure to detect early disease.
2. Prognosticbiomarker: Useful in assessing the survival rate.
3. Predictivebiomarker: Useful in monitoring the efficacy of treatment.
4. Targetbiomarker: Useful in detecting the molecular targets of therapy.

Different important uses of biomarker:[7]

In recent days different uses of biomarkers in medical field are

1. Biomarker as diagnostic tool.
2. Biomarker is used asstaging of disease.
3. Biomarker is used as best indicator of disease.
4. Biomarkers used as predicting and monitoring to clinical response of an intervention.

In medical science in recent year biomarkers are suitable predictors of disease occurrence and progression. These biomarkers frequently used to predict clinical responses of treatment procedure and in most of the cases they are representing the potentiality drug targets. Biomarkers can be obtained from the solid tissues and bio-fluids. Biomarker can refer to non-molecular risk like life-style information and physiological signals. Various types of biomarkers (TYPE-0,TYPE-1, TYPE-2) have been frequently used in different clinical practice to find out the progression of disease and predict clinical outcomes. At very first "Biomarker" term was popular in biomedical research but at that time it is not clear of its first use in biomedical research. The word Biomarker was collected in 1960"s but the 1st use of biomarker in a journal article title (in PubMed search) was in l980. The biomarker term is gained from biological and marker. Biomarker has a great role in describing a broad range of chemicals and physiological phenomena. [8,9]

Edwin Smith Papyri written around fifteen hundred B.C. and evidenced on the earlier work of Imhotep (27th century B.C.), details report of 48 trauma cases as well as therapeutic and prognostic coditions.[10]

The examination of all kinds of biologic specimens can also be tracked to ancient times, with reference to the qualitative and quantitative examination of urine and stools referenced in the Assyrian Book of Prognoses in six hundred fifty BC. It was not a surprising case but all the prognosticprocedure;different diagnostic findings around that time were based on purely spiritual mysticism. Hippocrates in three hundred fifty B.C. made

some advance technology forbiologic specimens in their proper diagnosis and prognosis.Ancient Greek men advocated a proper systematic approach for the diseases suffering people. the systemic approach for inspecting patients were physical examination of patients, inspection of body fluids. Greek physician employed his five senses to examine the patient's secretions and excretions to conclude the prognosis of a different types ofdisease and their treatment procedure treatment.[10]

The 19th century brought tremendous advances that allowed for the generation of huge amount of clinical data. Various types of instruments like electro cardiogram sphygmomanometer stethoscope, ophthalmoscope, laryngoscope, spirometer allowed for better qualitative physical examination and different physiologic measurement scale. In addition, the X-ray, microscope, new advanced laboratory based chemical and microbiologic techniques rapidly increased the physician's diagnostic procedure quality. This development process allowed for an unparalleled degree of specific goal oriented with respect to the assessment of biologic parameters of normal and abnormal biologic activities. As a result of which, all medical practitioner was able to build a standards and calculated deviations of human physiology.[1]

In the 20th century, all types of pathological laboratories were opened in a hugenumber of hospitals. Analysis of various types of blood culture and different urine samples made reference levels for a variety of analyses procedure, interlinked variations in disease states and gives clear-cut idea about different metabolic pathways in health and disease states. Recent advances in various analytic procedures like chromatographic separation and colorimetric sensitivity of analyses facilitated clinical tools and resulted in the ability to assess a increasing number of different biologic markers to trace the each and every changing condition of the patient. Now a days, all the practitioner became very much dependent on various chemical analysis of bodily fluids in the process of disease monitoring, final diagnosis procedure or as prognosis of different disease and follow-up the response to different interventions. By understanding of the pathophysiologic progression which is the most etiologic factor in that specific progressive nature of disease.11

From the results, biomarker have become unique in the scientific research field with considerable private and public sources now dedicated to simplify the utility of different types of biologic markers in speciallyall aspects of health sector. Novel measures of biological functions will prove critical in the research field, serving as surrogate last point indifferent types of clinical trials that promise to line-up the development of pharmacologic and non-pharmacologic therapeutic treatment.[12]

The journey of evolution of different biomarkers in recent times[6]

1. 1847: Protein cancer biomarker, Bence Jones protein in urine was discovered.
2. 1954: The measurement of transaminases in myocardial disease discovered.
3. 1960: "biomarker"term appears in the different literature and its close link with metabolites and biochemical abnormalities, connected to various diseases.
4. 1967: discovery of a qualitative test for myocardial infarction based on a suitable biomarker serum creatine phosphokinase.
5. 1971: Report of carcinoembryonic antigen (CEA) as biomarker of cancer.
6. 1987: Troponin I as a biomarker for myocardial infarction.
7. 1990: Accelerator mass spectrometry used for analysis of biological samples for biomarkers.
8. 1995: Applications of proteomics for discovery of biomarkers and use in molecular diagnostics.
9. 1999: Emergence of metabolomics for study of biomarkers
10. 2000: Sequencing of the human genome completed opening the way for discovery of gene biomarkers.
11. 2005: Discovery and application of biomarkers becomes a major activity in biotechnology and biopharmaceutical industries

Conclusion

Different Biomarkers have achieved immense scientific and highly clinical value and interest in the clinical practice of medicine. Biomarkers are truthfully essential along the whole journey of spectrum of the disease progression. Before any final diagnosis, biomarkers could be utilised for screening procedure and high-risk assessment. During the time of diagnosis, biomarkers can determine staging, grading, and selection

of initial therapy. During treatment, they can be used tomonitor therapy, select additional therapy, or monitor recurrent diseases. Recent advances in, proteomics and molecular pathology have created lots of candidate biomarkers with highly potential clinical value. In the near future, introduction of biomarkers, identified using new advanced technologies, into medical practice will be necessary to achieve „personalization‟ of treatment and disease prevention.

Non-Invasive Chairside Diagnostic Techniques: A Review

Shayari Niyogi[1], Saswati Priyadarshini[1]

[1]Post-Graduate Trainee, Department of Oral Medicine and Radiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Oral potentially malignant disorders (OPMDs) refers to a varied collection of disorders that are described by increased threat for malignancy causing Oral squamous cell carcinoma, most common being leukoplakia, erythroplakia, palatal lesions as a result of reverse smoking, oral lichen planus, oral submucous fibrosis, actinic cheilitis, and discoid lupus erythematosus. The initialdetection along withdiagnosis of these OPMDs are vital for carcinomainhibition and cure of disease. Currently, there is a budding and determined requirement for innovative non-invasive, diagnostic proceduresthat might simplify the primary recognition of oral PMDs. In this review article, we take an account on these non-invasive diagnostic procedures for easy diagnosis of oral PMDs.

Keywords: *oral potentially malignant disorders, oral cancers, light detection systems.*

Introduction

The conventional method for screening of oral PMDs are clinical inspection and palpation of the lesions. Nevertheless, elusive lesions may pass undiagnosed, and it is problematic to categorize among benign, premalignant, and malignant conditions of the oral cavity.[1] As Oral cancer is the sixth most common malignant tumor and is the prime cause of morbidity and mortality having metastatic and aggressive ability, an early detection is necessary before its advancement into oral carcinoma. [2] The stated 5-year rate of survival of the patient is around 50-63%. OSCC is usually headed by premalignant condition.[1]. The incidence is 7-17/100,000 persons every year with 75,000-80,000 fresh cases disclosed every yearly basis in India. Detecting oral cancer in its early stages radically affects survival rates rather than detecting it in later stages.[2] OPMD might procced into carcinoma in a proportion fluctuating within 5-18% of cases.[3] The frequency of oral cancer universally is nearly 500,000 new cases per year, proceeding to 3% of all carcinomas.[4]According to the risingrate of head and neck cancers, difficulties accompanying with delayed diagnosis, and the public health problems they give rise to, it seems judicious to endorse screening procedures to assess people at high risk. Initial diagnosis would permit for conservative beneficial methodologies with early recovery and better prognosis of the patients.[5].Currently, dentists have developed an oral cancer screening device that supports in prompt detection of OPMDs.[2] In the last few span of years, widespread non-invasive method have been established for revealing of oral PMDs besides the standardized techniques of biopsy.[1]

Light Operated Detection Systems: A variety of light-based discovery method have been recognized for diagnosing oral PMDs and oral carcinomas. Mucosal tissues have altered absorbance and reflectance properties because they undergo abnormal metabolic or structural changes when it comes across numerous method of light sources, permitting the credentials of the changes of oral mucosa. [1]In the pastera, light-based equipment has been improved and promoted for detection of lesions in the oral mucosa.[6]

The term bioluminescence has been documented in the year 1500. German physician, Henning Brand gave the first evidence of chemiluminescence in 1669, on

discovering phosphorus and the terminology was first devised by Eilhardt Weidemann in 1888. [7]

Classification[8]

- According to reflecting property of the tissue-Vizilite,Vizilite plus Tblue system,Orascoptic DK, Microlux
- According to autofluroscence property of the tissue–VELscope
- According to both reflecting and autofluroscence property of the tissue-Identafi 3000 ultra
- Marketed chemiluminescence kits include ViziLite, ViziLite Plus, Microlux/DL and Orascoptic DK.

VIZILITE: The terminology chemiluminescence defines the production of light on account of a chemical response. Due to the resemblances in the visual appearance of OSCC and cervical SCC, this skill has lately been modified for applicationinside the oral mucosa named as ViziLite. [6]

Components: The Vizilite kit has 1% acetic acid solution, a capsule which releases light and a retractor. The Vizilite capsule consists of an external chamber of bendable plastic cap consisting of acetyl salicylic acid andinternalbrittle glass ampoule having hydrogen peroxide.

The elements in the outer and inner compartments counter to yield bluish-white color light having wavelength between from 430 to 580 nm. The light persists for roughly 10 min. Vizilite is composed of 1% acetic acid solution having water, acetic acid, sodium benzoate, flavouring agent, propylene glycol base and alcohol whereasVizilite Plus have three swabbing constituents: 1% acetic acid dye in two swabs, including a post-dye decolorizer and a single swab containing metachromatic vital tissue dye, and toluidine blue.[7]

Patient is asked to rinse the mouth with 1% acetic acid which aids to eliminate the glycoprotein barrier, somewhatdesiccate the oral mucosa and improves theprominence of epithelial cells within the tissue. The ambient light is lowered and a turgid bluish-white chemiluminescent light is concentrated over the tissue. Normal cells absorb light under this bluish-white light, and they look bluish whereas abnormal cells causes reflection of the light and appear acetowhite having brighter followed bydiscernible borders. [8]

Vizilite Plus: It applies an alteredmethod containing Vizilite and Toluidine Blue Marking arrangement which containsestablished clearance from Food and Drug Administration for observing the oral mucosa, in the form of an adjuvant technique. Toluidine blue is an acidophilic metachromatic dye which stains the acidic components of mucosa selectively such as carboxylates, sulfates, and phosphate radicals, thus staining the cell DNA and RNA.

It also decolorizes the cells undergoing dysplasia and the anaplastic cells that have excess of nucleic acids as compared to normal mucosa. Also, the cells undergoing malignancy may enable morepermeation of the dye due to the occurrence of canals within the cells.

Following conventional examination, all the lesions are examined underVizilite. The lesion discolored using toluidine blue is undoubtedly observed even in the absence of light device and exact area for biopsy may be designated. With Vizilite Plus System, there is 100% sensitivity and the cancerare visualized by 60%. [8]

Microlux Diagnostic Light: Microlux Diagnostic Light practices light emitting diode (LED) having fiberoptic source, operated on battery whichproduces a blue-white light of low energy. Thistechnique is comparable to Vizilite and Orascoptic Dk. The benefitof it is the re-usable property. Microlux DL has the capacity to improvethe visibility of the lesion.It is poor in discerning lesions with inflammation, traumatic, or malignant lesions. [8]

Oral examinations with the help of toluidine blue (TB) was prepared by 1% acetic acid wash along with1% solution of toluidine blue rinse in a time span of 30 seconds. Additional stain was debarred by smearing 1% acetic acid for a period of 30 seconds. The oral lesions were inspected by Microlux/DL+TB to observe the extent of reserveddiscolored areas and finally explanation of the staining procedures was done. [9]

Orascoptic DK: Orascoptic DK is aadaptable, device that uses a LED light source held in hand along with three substitutable distinctive diagnostic tools such as Oral lesion screening Instrument, Trans-illuminating Instrument and Lighted Instrument with Mirror. The DK Trans-illuminating instrument aids to picturise fracture tooth and dental caries having apenetrating, focused source of light. The DK Lighted Mirror comes with a potent LED light source to lighten up the reflection obtained from the mirror thus helping inclearly visualizing the unapproachable areas within the oral cavity.[8]

The technique is comparable to Vizilite. The conventional oral scrutiny is done using an incandescent light. The oral mucosa is again examined witha Oral lesion screening instrument, upon rinsing with 1% acetic acid mouth rinse, and bluish white light is emitted. The 'acetowhite lesions' looks brighter thus helping in better visualization of lesions.[8]

Velscope:

(Visually Enhanced Lesion Scope)

VEL scope uses excitation of blue light within the range of 400 and 460 nm wavelengths to improve oral mucosal anomalies by using principle of direct tissue auto fluorescence. The normal oral mucosal layer is related with a pale green fluorescence when observed through a filter, while abnormal mucosa is related with absence of auto fluorescence (LAF) and seems darker in appearance. Though these excitation wavelengths are applied in labsto distinguishregular oral mucosa from dysplastic cells, carcinoma in situ (CIS), and carcinoma showing invasion, the makerinferred these verdicts to designate that VELscope can assist inidentifying oral mucosal anomalies invisible in white light inspection.

The VEL scope is a handheld device that produces a visible blue light which stimulates the oral mucosa and makes it fluorescence. The oral mucosa is thensurveyed as real image, improving the expert'scapability to genuinelyrecognize suspicious mucosa that may necessitate further examination. [10]

VELscope has a fairly high rate of false Positives. This proposes that VELscope differentiates poorlyamongst benign and dysplastic lesions. [11]This procedure enables to discriminate inflammatory lesions when compared to neoplasia because inflammatory lesions classicallydemonstrate totaldiascopictype of fluorescence, but not in case of neoplastic lesions. [11]

IDENTAFI 3000 Ultra: The Identafi is a type of screening methodin multispectral way involving three altered lights namely white, violet and amber green light, which are intended to be applied in order to promote intraoral inspection. Themethod work based on both reflecting and fluorescence property of the tissues.

White light is used in the beginning for conventional oral examination, followed by violet light of wavelength 405nm, which is focused on the tissues. Itassesses the auto florescence of oral tissues usingsupplementary photosensitive filters as compared to VELscope. Lastly, the green-amber light operating at 545 nm wavelength gives theimpression of light reflecting principle from tissuesto outline the blood vessels in the underlying mucosa.[11]

Photodynamic Therapy: Photodynamic therapy (PDT) is a management method that employs light to initiate photosensitizing agent (photosensitizer) using oxygen. The introduction of the photosensitizer to light effects in the development of oxygen species, and free radicals, producing localized area of photochemical damage and cell death. PDT encompasses three components: a lightsource, a photosensitizer element, and oxygen. The benefit of PDT over predictablemanagements is established on its minimal invasiveness and tumor destruction selectively, with the protection of healthy soft tissue. Some of the photosensitizers have the necessary property of concentrating in tumor cells (and in different proliferating tissue) comparative to the adjacent healthy tissue.[12]

5-aminolevulinic acid (ALA) is an efficient photosensitizer for oral PMDs and oral carcinomas, which instead of fluorescing by its own, forms protoporphyrin IX (PPIX) fluorescence in the human tissues. The oral cavity is rinsed with 0.4% ALA solution for a period of 20 min to perform PDT.

Topical use of 5-ALAin excess amount causes formation and cellular accretion internally of highly fluorescent PPIX in tissues undergoing dysplasia and malignant changes, which is agitated by brief contact to light (wavelength 405nm). Tissues appearing fluorescent are considered doubtful for malignant alteration and only biopsy can give confirmation. To increase the indicative specificity, a 5-ALA facilitated fluorescence endoscopic imaging technique viewed digitally has beenimplemented.[12]

The ratio between red-to-green and red-to-blue concentrationin cells undergoing dysplastic changes and malignancy are greater than seen in benign tissueswhen quantificationof PPIX fluorescence endoscopic images are done. When the ratio between the red-to-blue intensity in the ALA-induced PPIX fluorescence images seen under endoscope were measured, itrevealed that it could delivernobleddiscrepancyamongst benign dysplastic changes and malignancy. It was seen that oral submucous fibrosis mucosa had the lowermost ratio in the red-to-blue intensity region [1].

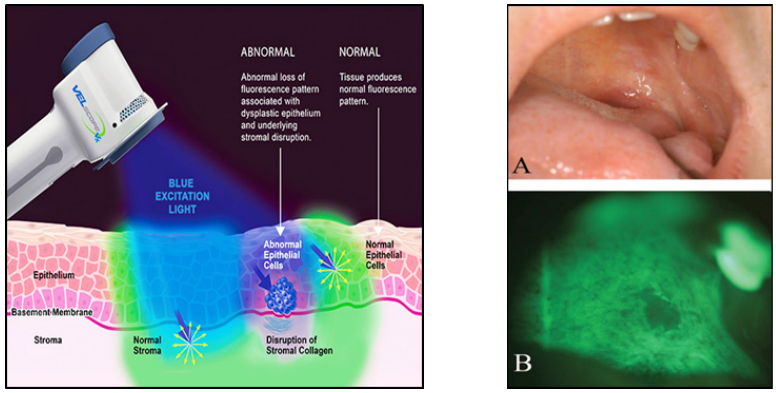

Figure 3: Velscope

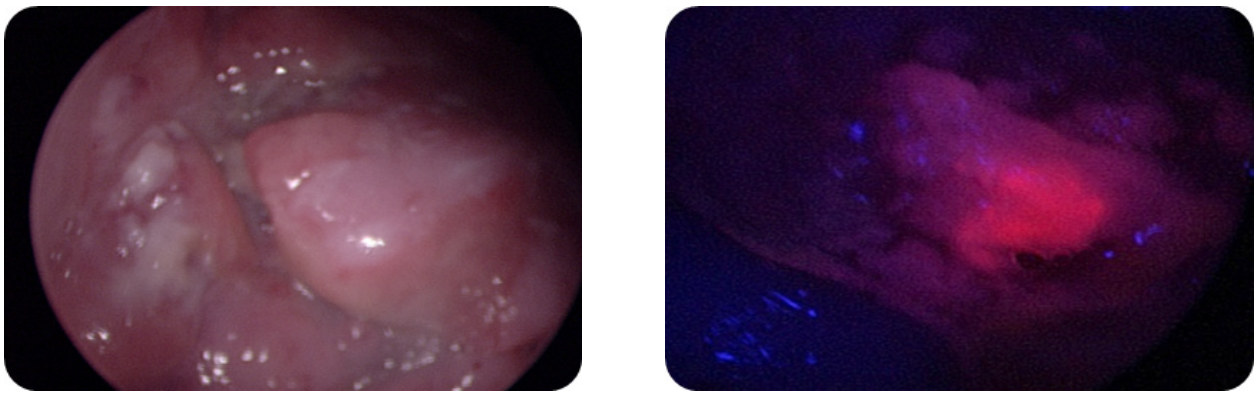

Figure 4: Photodynamic Therapy

Conclusion

Improving oral cancer detection and analysis have long been major perplexing facing both dental and medical sources in the world. Screening and early recognition in inhabitants at risk have been suggested to decrease both morbidity and mortality associated with the oral cancer. However, the subjective explanation of the inoffensive lesions by COE with the vivo examination tests significantly enhanced the diagnosis at an early stage. Many investigative procedures are tried to eradicate surgical biopsy which is the golden standard, but these tests are not the substitute for surgical biopsy rather, they can be used as an adjuvant.Maximum non-invasive diagnostic method assessed indicated great prospective for screening along with observing oral

PMDs. Furthermore, there is inadequate indication to mentioneither for or against the unrelated application of any technique inrecognizing oral PMDs.

Inappropriate Prescribing of Antibiotics by Practitioners

Shrestha Singh

Intern, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha

Abstract

Antibiotics, in this world, are very much needed in the treatment and prophylaxis of diseases in patients who can be infected by any bacterial or any other microbial disease. Over and under use of antibacterial agents is a global concern. It results in superfluous treatment costs, is a potential hazard for the development of antibiotic resistance and results in side effects. Dental practitioners frequently prescribe antibiotics to treat dental infections. Uses of systemic antibiotics in dentistry are confined since management of acute dental conditions is principally based upon extraction of teeth or extirpation of the pulp. However, the literature present evidence of inappropriate prescribing practices by practitioners, due to a number of elements from incomplete insight to social factor. To improve the standards of care, dentists need to keep themselves refurbished with the current patterns of antibiotic prescription and their use. It is thus essential to map local prescribing patterns of antibiotics in order to examine the need for improvement and to impede the consequences of their inappropriate prescription.

Keyword: *Antibiotics, prescription, resistance, practitioners, dentists.*

Introduction

Antimicrobial agents are among the most impressive example of the advances of modern medicine. Many infectious diseases once considered fatal, incurable and lethal are now responsive to treatment with a few pills.[1] An avoidable consequence of antimicrobial usage is the selection of resistant micro organism. Overuse and inappropriate use of antibiotic has fuelled a major increase in prevalence of multi drug resistant pathogen, leading some to contemplate that we are nearing the end of the antibiotic era.[2]

This growing problem has contributed significantly to the morbidity and mortality due to infectious diseases, with increasing death rate for communicable diseases. The World Health Organization (WHO) admits this global problem and declared the theme for the year 2011 as "Antibiotic resistance; No action today, No cure tomorrow".[2]

Developing country such as India has been rated as one of the biggest consumers of antibiotics in the world. And its misuse and overuse is uncontrolled. As a result, 'super bugs' that are resistant to all known types of antibiotics are starting to flourish. For some, the last line of defence is a delusion. It doesn't prevail. With both humans and the poultry/livestock industry overusing antibiotics, the window of efficiency for new anti-bacterial drugs is getting briefer.[3]

In dentistry, antibiotics are used for the prevention of life-threatening disease and to avoid postoperative infections. Amoxycillin or penicillin group is the first line of drug in managing odontogenic infections as they are sensitive to Gram-positive aerobes, intraoral anaerobes, organisms found in alveolar abscess, periodontal abscess, and necrotic pulps. Aerobic and anaerobic microorganisms are sensitive to penicillin group.[4] The prescription of antibiotics by the superiority of the dentists is vastly on empirical basis without the need for antibiotics many times just to avoid unpleasant complications and prophylactic purpose.[5]

The major reasons behind antibiotic resistance are due to the over prescription by the health care personal, improper use by patient and also due to the resistance developed by the bacteria.[2] This is backed by the evidence collected to how the significant relationship between increase of antibiotic resistance and utilization with higher resistance level in bacteria isolated from area of high antibiotic utilization.[6]

Evidence Aquisition: Computerised searches consisting of published articles received from Google, PubMed, PMC free article, Google Scholar, Science direct, Medline, EMBASS. Different keyword including antibiotic, antimicrobial agent, resistance, mechanism of resistance, health professional, practitioners, prescription, knowledge, dental care, dentists, prevention were used in the literature search. Moreover, the reference of all paper was again searched for further relevant studies.

Discussion

Antibiotics are the greatest gift of the 20th century to therapeutics. Their importance is magnified in the developing countries, where infective diseases predominate. As a class, they are one of the most frequently used as well as misused drugs.[4] Problem that arise due to overuse of antibiotic are-

- **Toxicity:**
  - Local irritancy like gastric irritation, pain and abscess formation
  - Systemic toxicity like kidney and liver toxicity, bone marrow depression, hearing loss
- **Hypersensitivity reactions:**

  Almost all antibiotic are capable of causing hypersensitivity reactions
- **Drug resistance:**
  - It is defined as the insensitivity of bacteria to a specific antibiotic.
  - It is of two types-natural and acquired. Acquired resistance occur as a consequence of a antibiotic therapy and is the result of the selection of resistant organism. Drug resistance is the main reason of failure of antibiotic and is mainly due to the overuse of antibiotic and inappropriate prescribing of them by the practitioner.[3]
- **Superinfection (Suprainfection):**

  It is defined as the presentation of a new infection as a consequence of the previous antimicrobial treatment.
- Nutritional deficiencies:

  Mainly vitamin B complex deficiency.[3]

Inflammatory diseases are the most frequently seen oral disease in India. An appreciable amount of pain of dental origin entail from acute and chronic pulpitis which require treatments like Root canal treatment or normal restorative procedure and therefore doesn't require antibiotics as such unless the periapical region is infected. The antibiotic can't penetrate the pulp of a tooth as it is enclosed in a 'closed box' surrounded by dentin and cementum and hence, antibiotics should not be prescribed in such cases. Therefore, these cases should be treated without antibiotics and emphasis should be given on use of operative procedures.[1]

A review from a survey conducted in South India showing the dentists prescribing antimicrobials for patient coming with dental pain and related symptoms in the clinical practice.[8]

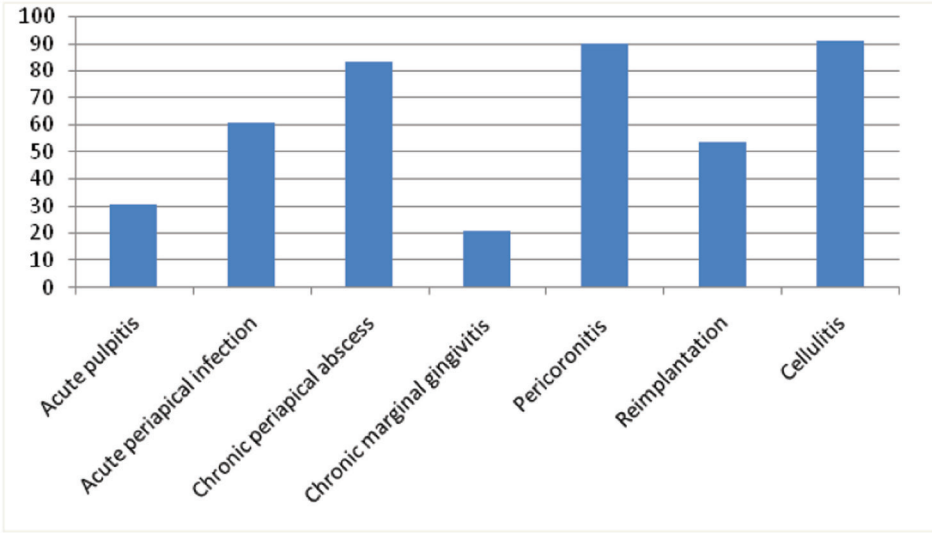

Chart 1: Percentage of dentists prescribing antimicrobials for patient coming with dental pain and related symptoms in the clinical practice[8]

The above chart represent the knowledge of some of the dentists from South India regarding the demand of prescribing antibiotic for dental pain and other symptoms in which there were no clinical sign of spread to the system. The given percentage of dentists prescribed antibiotics for above conditions where antibiotics will not work and only operative intervention will suffice. They often prescribe prophylactic antibiotics as an adjunct to the operative treatment which is mostly irrelevant.[8]

Another study from the same survey showed the various other components which affect the antibiotic prescription by the dentist which shown below in the chart 2.

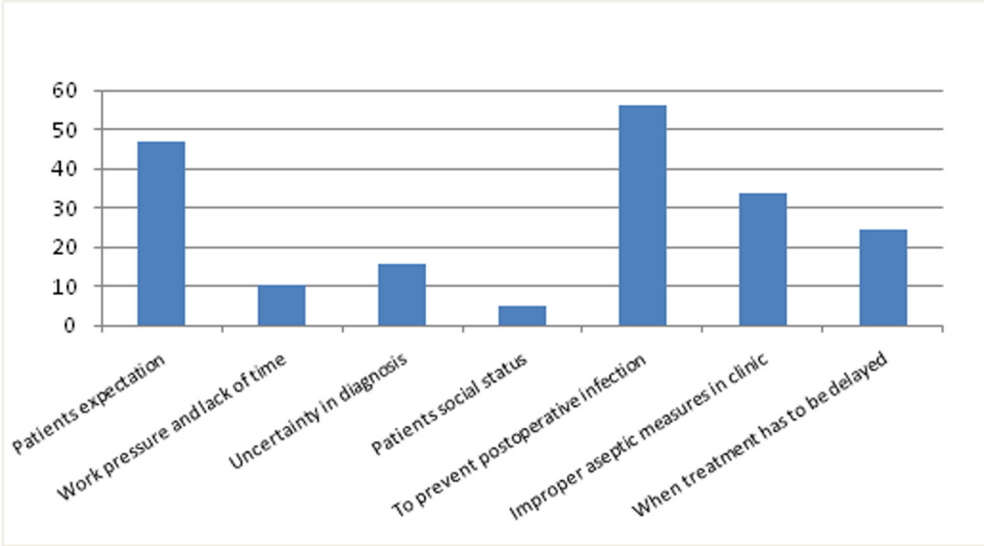

Chart 2: Percentage of various other components which affect the antibiotic prescription by the dentist[8]

Many dentists prescribed antibiotic according to the patient expectation from the treatment or due to improper aseptic measure in the clinic. More interestingly the dentists are prescribing antibiotics as a prophylactic medicine to prevent postoperative infection where it is not even required.[8]

As per the study done in Jaipur city, Rajasthan, on knowledge regarding antibiotic drug action and prescription practices among dentist, showed that the greater part of the dental practitioner utilized broad spectrum antibiotics. There is impressive assertion that the penicillin with clavulanic acid is the antibiotic agent of choice for these procedures as there are no hypersensitivity reactions or intolerances. Amoxicillin + metronidazole were recommended antibiotics for apical periodontitis by the dental practitioner.[16]

Some dentists prescribe antibiotic for abscess even though the guideline for abscess treatment clearly states simple incision and drainage or exodontia and then drainage, before the prescription of antibiotics.[10] If antimicrobials are used, they are used as a supplement with the operative management and to reduce edema and also help in reducing the spread of infection to the local areas and the body.

Antimicrobial agents are often not indicated for chronic conditions such as periodontitis; but in conditions where local or systemic spread of the infection has occurred, or where incision and drainage can't be performed, the antibiotics can be prescribed to limit the spread of infection. Submicrobial dose of doxycycline is widely used in periodontal therapy as an adjunct to mechanical therapy, although resistance is not reported if taken for a short period but there are studies which have reported doxycycline resistance if they are prescribed for prolonged periods.[1]

Self-medication is an alarming concept in a developing country like India. People often skip the consultation of a trained doctor and thrive on the medications prescribed earlier or to someone else who has had almost the same symptoms earlier.[16] The developing countries lack the basic health care centres, low income, poor financial status which leads to low awareness of the risks regarding these kinds of practising.[16]

Even practitioners teaching in hospital have a poor habit of prescribing antibiotics in irrelevant situation. Many studies have supported this and have been shown that 91% of the practitioners write irrelevant antibiotics on a daily basis.[17]

After careful evaluation and establishing the requirement of an antimicrobial agent in a patient, which can't be resolved with operative intervention alone, one has to choose the right and the most specific antibiotic from a lot of options in the market.[2] The choice depend on-

- Age may affect kinetics of many antibiotics, and certain antibiotics produce age-related effects.
- Liver and kidney failure-careful use and dosage management of antibiotics (with maximum therapeutic index) becomes extremely important when the organ responsible for the elimination of the drug is not functioning.
- Local factors-The location of the infection and the condition of that site, greatly influence the mechanism of the drug
- Drug allergy
- Impaired host defence
- Pregnancy[2]

The indiscriminate use of antibiotic, it resistance and it adverse effect can be limited by the practitioners by-

1) Avoiding the indiscriminate use by ensuring that the dosage and the time duration are appropriate.
2) Usage of antibacterial combination in appropriate circumstance
3) Continuous evaluation of resistance pattern in a hospital or community (altering the dose and duration of antibiotic used for empirical management when their resistance becomes prevalent) and relevant measures should be taken to control the spread of these resistant microbes.
4) Decreasing the antibiotic use, following the agreement between the clinician and microbiologist; resistant microbe which can proliferate following the use of that drug may require restricted usage.
5) Selection of the appropriate antibiotic is absolutely important[5]

Conclusion

With the increasing resistance of bacteria against the antibiotics and their ability to decrease the efficiency of the antimicrobial agent, it is now of absolute importance for the humans to fight against them and collect all the knowledge possible to combat antibiotic resistance. The teaching and practice in the hospitals and institutes should be carefully monitored regularly and certain CDE programmes should be conducted at regular intervals, to provide latest updates to obtain successful results from antimicrobial agents. As a lot of non-clinical factors are affecting the prescription practice among the doctors, only doctors should not be held responsible for the growing antibiotic resistance. But as a dental surgeon, it is our duty to overcome the clinical and non clinical factors, to provide quality treatment to our patients and prevent the hazard of antimicrobial resistance.

Limit injudicious use of antibiotics. Superfluous and injudicious use of antibiotics can be prevented by,

1. Using it as an adjunct and not alone as a treatment option
2. Using antibiotic sensitivity tests and using infection specific antibiotics
3. Using narrow spectrum antibiotics

Limit prophylactic antibiotic prescription. Prescribing antibiotics as prophylaxis is a subject of debate. Limiting prophylactic antibiotic prescription in healthy individuals with those having no underlying systemic diseases or no immuno compromised conditions is recommended. Knowledge and education of all the dental practitioners needs to be revised and updated to increase awareness and enhance prescribing practice to provide good patient care and avoid the occurrence of any adverse events arising as a result of erroneous drug prescription which could endanger patient's life.

Therefore, it is recommended that the local managing bodies associated with continuing dental education and dental associations organize programs to help private practitioners update their knowledge and be in sync with the ever-changing field of medicine. The programs should be easily accessible and specific to the changes occurring in prescription of antibiotic therapy. The focus should be on emphasizing the existing knowledge and updating it with modern and newer antibiotic regimen, their posology and proper use based on the clinical situation. The private dental practitioners should be

self-motivated to be a part of this continuance. This would be a step not only for the well-being of the patient but also for dentist to avoid any detrimental event just because of sheer lack of awareness.

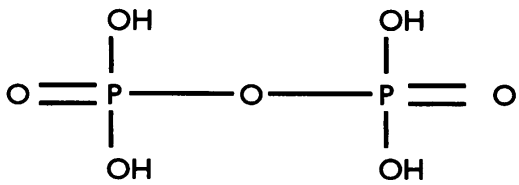
Application of Bisphosphonates in Dentistry: A Review of Literature

Sitish Nayak

Intern, *Department of Oral & Maxillofacial Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India*

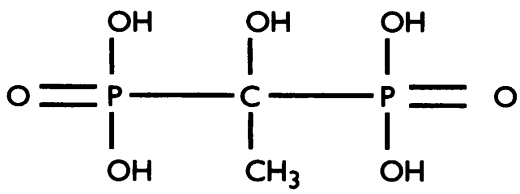
Abstract

Bisphosphonates have been of great use since many decades for their property of bone biomodulation which is very much evident. There is a lot of studies for beneficial effect of bisphosphonate across various dental treatments. Implant dentistry with Bisphosphonate coating has been shown to significantly increase retention and density in human mode. Orthodontics with application of bisphosphonates has benefits of reduced root resorption and maintaining of good anchorage. Bisphosphonate terminate osteoclast activity and their IV or oral uses have been reported to be linked with osteonecrosis of the jaw. The aim of this literature is for Application of Bisphosphonates in Dentistry.



Keywords: *Bisphosphonate, Osseointegration, IV or Oral Route, Osteonecrosis of Jaw.*

Introduction



Bisphosphonate is a group of drugs used to treat osteoporosis and prevent the loss of bone density. Bisphosphonate such as alendronate, risedronate, ibandronate and clodronate are important class of drugs. The prime categories of bisphosphonate are first generation non nitrogen (clodronate, tiludronate) and second and third generation nitrogen containing (alendronate, risedronate). Oral bisphosphonate is used for treatment such as osteoporosis and Paget's disease, whereas intravenous bisphosphonate is used to patient of breast cancer, multiple myeloma and malignant hypercalcemia.[1] A major complication in patient using oral or intravenous bisphosphonate is osteonecrosis of the jaw which is characterized by susceptible bone of the maxilla or mandible that poorly heals during 6 to 8 weeks. These facts indicate that the dental society and public are increasingly interested in the possible interaction between dental implant treatment and bisphosphonate medication.[1,2]

The Structure of Bisphosphonate: Bisphosphonates are formed by two carbon phosphorus bonds, the carbon atom replacing the pyrophosphate bond P-O-P (phosphorus-oxygen-phosphorus) and the chemical and enzymatic hydrolysis resistance bond P-C-P (phosphorus-carbon-phosphorus). Various substitutions on the carbon atom produced several different bisphosphonates, each with its own unique pharmacological properties. Etidronate was the first bisphosphonate to be used therapeutically, followed by the development of many others. Main bisphosphonates to increase the potency of antiresorptive action are etidronate, tiludronate, clodronate, pamidronate, alendronate and risendronate.[3]

Pyrophosphate

Etidronate

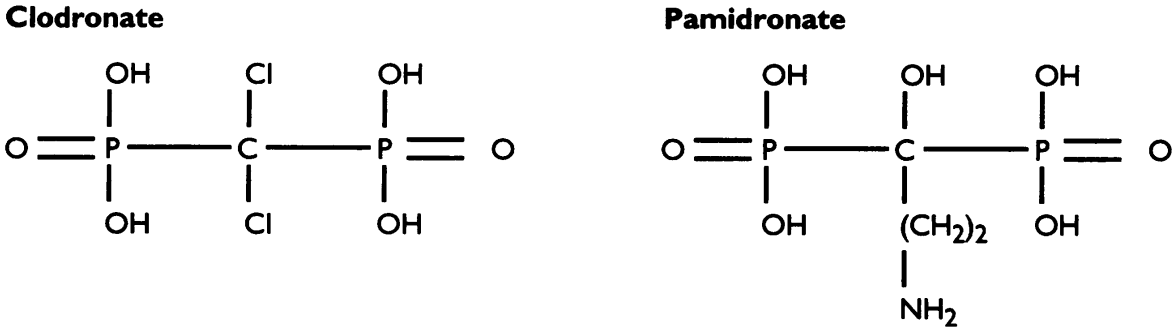


Figure 1. Chemical structure of pyrophosphate and three bisphosphonates

The Role of Bisphosphonate: Bisphosphonate is used in the management of osteoporosis where imbalances in bone remodeling lead to lower bone density and quantity. To decrease the risk of fracture, it is administered orally (e.g. daily, weekly or monthly) or intravenously (every 3 months or annually). Bisphosphonate is used in antineoplastic therapy to treat bone metastatic spread complication including: pain, hypercalcemia, and pathological fracture.[3,4]

Mechanism of Action: Bisphosphonate is usually a bone resorption inhibitor that is treated with osteoclast. Nitrogen-containing bisphosphonate such as alendronate or risedronate is bound to resorb osteoclast by hydroxyapatite on bony surfaces. During bone resorption, bisphosphonate taken up by osteoblast inhibits the farnesyl pyrophosphate synthase enzyme, a key enzyme in the mevalonate pathway. Metabolites shaped in this way are important regulatory proteins for the osteoclast function of the cell membrane.[4]

Older bisphosphonate (with no side chain nitrogen) such as etidronate and clodronate is transformed into Adenosine Triphosphate (ATP) which makes it hydrolysis-resistant. The accumulation of this non-hydrolysable adenine-containing metabolite ultimately results in osteoclast cell death. There is some evidence that they induce osteoclast precursor cell proliferation and osteoblast development of osteoprotegerin due to their direct action on osteoclasts alone. But the mechanisms of osteoblasting are not as well known.[5]

Literature review:

Implantology: Dental implant placement is a traumatic operation requiring osteotomy site bony removal and subsequent osseointegration healing. Osseointegration is characterized by a bone-implant union that, in close application to the implant surface, relies on early woven bone remodeling to shape mature bone. Records of delayed wound healing associated with oral systemic bisphosphonate are not surprising. Nevertheless, it is relevant that a systematic review of the literature found that there was no significant difference relative to control groups in the short-term survival of oral BP patients.The American Association of Oral and Maxillofacial Surgeons (2014) does not recommend a ban on the insertion of dental implants in patients receiving oral BPs, but explicitly warns doctors against a procedure involving direct bone damage in patients receiving intravenous BPs anti-angiogenic cancer therapy.[6]There is some evidence that when used as a surface coating, bisphosphonate can have a positive effect on the dental implant's osseointegration, specifically increasing early implant fixation. The reason for using BPs in implant placement is to avoid bone resorption at the osteotomy site. Changes in the dental implant surface structure (e.g. sand blasting and acid etching) and chemical composition (e.g. surface coating) by electrochemical techniques are studied as a means of assisting the formation of peri-implant bone. Hydroxyapatite, tricalcium phosphate (TCP), bioglass and more recently bisphosphonate are researched ground finishes.Bisphosphonate-coated implants are prepared by covalently binding a fibrinogenic metal-coated matrix to which BPs, specifically Panidronate and Ibandronate, are bound and absorbed. Most studies are based on animal models, but some studies are limited to human studies as well. Nevertheless, it is recognized that there is a lack of standardization of procedures and factor primary and secondary outcome measures, making it difficult to compare these studies directly.[7]

Orthodontics: Possible benefits of bisphosphonate are considered in orthodontics in the form of root resorption and safety of anchorage. Root resorption is a popular but unwanted side effect of orthodontic

treatment and it has been shown by a limited number of animal studies that bisphosphonate has a potential role to play in its prevention. A split mouth study in mice showed during fixed appliance therapy that local bisphosphonate solution injection resulted in significantly lower root resorption. This phenomenon is thought to be the outcome of bisphosphonate-induced odontoclastic apoptosis.[8]

A similar study by Liu et al. found that injection of local subperiosteal clodronate, a bisphosphonate of nitrogen, resulted in a significant reduction in root resorption at treated sites relative to rat control sites. Besides the small sample sizes used in this study, prevention of root resorption is also important in the sense of overall reduction. Current anchorage repair approaches are suboptimal based on patient adherence (e.g. head gear, elastics) and invasive procedures (e.g. mini-screw positioning of implants).Studies have suggested beneficial effects on the anchorage of bisphosphonate. Earlier study by Liu et al. found that subperiosteal injection of clodronate caused a significant decrease in movement of the tooth and a decrease in dose dependence. Bisphosphonates can also indirectly facilitate anchorage, as local zoledronate injection into implant osteotomy sites has expressed a significant improvement in the stability of mini-screw implants by promoting increased trabecular bone formation around implants. These small-scale animal studies have demonstrated several potential effects of bisphosphonate to prevent root and tooth resorption. The work is at an early stage, so it is necessary to look carefully at the potential application of this research for humans.[9]

Paget's Disease: Paget's disease is characterized by increased bone resorption due to both increased bone turnover and increased length of resorption cavity. The number and volume of osteoclasts present is significantly increased. The etiology of the disease is not established, although a viral origin has been suggested. Paget's disorder is dominant, typically affecting multiple locations of the skeleton. Bisphosphonates have become the preferred treatment for Paget's disease in term of response rate, degree and period of remission, and loss of secondary resistance in up to one-fifth of calcitonin patients.The dose-related reaction may extend the remission period by up to two years. This prolonged remission is likely to result from persistence of bone bisphosphonates after administration and subsequent low release. Post-relapse retreatment's effectiveness is close to the initial course.[5,6]

During care, the progression of the disease and its changes can be monitored biochemically using serum alkaline phosphatase and urinary hydroxyproline or bone turnover markers for deoxypyridinoline and pyridinoline. The rate of decrease in serum alkaline phosphatase activity and the degree of therapy-related suppression are positively induced and the initial incidence of the disease is inversely related to the period of remission. Failure to respond to bisphosphonates is extremely rare in Paget's disease, although it may occur. In these situations, the addition of calcitonin can lead to remission. Etidronate was most commonly used for the disease of Paget and is still the only bisphosphonate approved to treat this disorder in Britain.[7]

Nevertheless, histological changes have been reported after intermittent intravenous pamidronate, indicating reduced mineralization. No adverse health effects have been reported, but the reliability of these findings requires further study. Clodronate is available in Britain for oral and intravenous use, although the treatment of Paget's disease such as pamidronate is not approved. Effective treatment of disease results in one to six months of oral doses of 800-1600 mg daily. Conversely, equivalent medical and biochemical results emerge from a 5-day course of 300 mg daily intravenous injections.[5,6]

Periodontium: Periodontitis is an infectious disease that causes inflammation within the teeth's supporting tissues.28 Conventional treatment involves medical mechanical and antimicrobial agents used to extract plaque biofilm. Currently, due to an improved understanding of periodontal disease pathogenesis, attention has been given to an additional therapy approach with respect to modulation of the host response. Current evidence indicates an association of osteoporosis with human periodontal disease onset and progression. Numerous studies have shown that low bone mass is separately associated with alveolar crest height loss and tooth loss. Systemic loss of bone density in osteoporosis, including oral cavity, may provide an increasingly susceptible host system to infectious tissue degradation. A strong link between systemic and oral bone loss is indicated by some research to date. Research on animals has shown that systemic administration of bisphosphonate prevents bone loss.Buduneliet al11 showed that by inhibiting multiple inflammatory mediators in gingival crevicular fluid, alendronate and/or doxycycline may have beneficial effects in periodontal treatment. Many studies have shown that systemic alendronate administration

has a positive effect on the alveolar bone mass, but has no effect on the clinical parameters of gingival inflammation or plaque. The duration of treatment plays an important role in the outcome; A short duration of risedronate administration may be useful in inhibiting periodontitis bone resorption, although prolonged duration of administration may be useless. The local or topical application of bisphosphonates was also found to prevent alveolar bone loss in animal models. Similar results in human studies have been published.[5,6]

Postmenopausal women receiving oral bisphosphonates reported better clinical periodontal parameters and higher levels of alveolar bone compared to control. In a 12-month review, Lane et al demonstrated the effectiveness of oral bisphosphonates in improving outcomes of non-chirurgical periodontal therapy in patients with severe periodontitis. Some researchers found that bisphosphonate therapy improved periodontal disease clinical parameters, while others did not find such an effect. Developing bisphosphonates to slow the process of periodontal disease depends on identifying an effective dosage regime and delivery system that would reach the target site in the periodontium while limiting unwanted side effects.[1-3] Therefore, bisphosphonates may be effective not only to prevent osteoclast-mediated bone loss, but also to promote bone development under suitable conditions. Etidronate in general has been shown to reversibly inhibit bone mineralization, which would improve bone matrix formation. Once the excess matrix has been formed, etidronate discontinuation would then allow mineralization to occur, resulting in increased bone formation. Etidronate could therefore be used to promote the development of the bone matrix around titanium end osseous dental implants.Bisphosphonates may be useful not only for the treatment and prevention of periodontitis-related bone loss, but also as diagnostic and early intervention aids. Their affinity for new bone mineralization or active bone remodeling makes these drugs ideal in combination with radiolabels for the diagnosis of periodontal bone loss.[4-6]

Discussion

A research outlines recent literature that supports potential benefits from the use of bisphosphonate in numerous dental fields. There is confusion with regard to the form of bisphosphonate to be used and the correct dose and application process. There is growing evidence that, despite the association of high doses of systemic bisphosphonate with this undesirable condition, topical treatment does not cause jaw osteonecrosis. While the results of these experiments are positive, long-term human studies are not adequate and therefore should be viewed with caution. This dimension of bisphosphonates requires more study.[4]

Bisphosphonates are artificial pyrophosphate analogs that are non-biodegradable and inhibit bone resorption. For different compounds, the efficacy of their antiresorptive activity varies widely. Bisphosphonate intestinal absorption is small (< 1% to 10%) and the skeleton has a very long half-life. The main therapeutic use of bisphosphonates in diseases is characterized by improved bone turnover. These are the medication of choice for Paget's disease and hypercalcemia for malignancy.[5] Bisphosphonates also show promise in osteoporosis, especially in their prevention. Nevertheless, there was no strong evidence of beneficial effects on the incidence of fractures. The toxicity of bisphosphonate is small and varies from compound to compound. Many bisphosphonates have adverse effects on bone mineralization in doses used to inhibit bone resorption. The creation and analysis of new bisphosphonates is an important topic of research on osteoporosis. Crucial and unresolved issues include optimal (continuous v intermittent) regimens, the comparative effectiveness of different compounds and the potential for anabolic bone damage.[6]

Bisphosphonate production represents a major clinical breakthrough and is now the preferred treatment for Paget's disease and malignant hypercalcemia. In the prevention and treatment of osteoporosis, bisphosphonates do show great promise. Evaluation of osteoporosis caused by postmenopausal and corticosteroid has shown beneficial effects on bone mass, particularly in the spine, although a decrease in fracture frequency remains to be firmly established.[7]

In all of these cases, the long half-life of bisphosphonates in the bone provides a rational basis for sporadic treatment, but active regimens for Paget's disease and osteoporosis have yet to be identified; and the need for calcium supplementation in osteoporosis remains unproven. Adverse mineralization effects are a possible source of concern, at least for some bisphosphonates, and patients with long-term effects of osteoporosis on bone turnover need more detailed information. Overall, however, bisphosphonates are well tolerated and safe, and the outcome is eagerly awaited by clinical trials addressing the issue of osteoporosis fracture.[8-10]

Conclusion

It is critical for physicians to be aware of the potential threat of either oral or IV-infusion treatment of patients receiving bisphosphonate therapy. As reported on the website of the American Academy of Periodontology on bisphosphonates:'' regarding the precaution, however, periodontists are advised to decide whether a patient requires IV bisphosphonate therapy. If so, it is necessary to avoid unnecessary dental procedures, unless absolutely necessary. In comparison, if a periodontist is aware that a patient will be treated with IV bisphosphonates, any appropriate invasive dentistry should be done before such treatment is started, if possible.While this does not include oral use of bisphosphonate, this case report indicates that clinicians should be aware of the potential threat of long-term oral use of bisphosphonates as it may present some danger in certain populations of patients. There is certainly inspiration for future studies in this field.

Dentistry as a Career Option: A Gender-based Study about Scope of Dental Education

Sobhan Mishra[1], Pankaj Kumar Panda[2], Kamrakali Mishra[3], Shelly Mishra[4], Susant Mohanty[5]

[1]Professor & Head, Department of Oral & Maxillofacial Surgery, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [2]Senior Research Officer, Clinical Research Unit, Apollo Proton Cancer Centre, Chennai, India, [3]Associate Director, Analytics Evolent Health Medical Devices, Washington, USA, [4]Department of Oral & Maxillofacial Surgery, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India, [5]Professor & Head, Department Paediatrics and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Aim: To assess the opinion of dental students and interns regarding dentistry as a career option based on the course, curriculum and their future plans.

Materials and Method: A pre-piloted questionnaire was distributed among the final year undergraduate students and interns of dental institutes in Odisha, India. They were surveyed in relation to their opinion about dentistry and its scope as a career option.

Statistical Analysis Used: Age, gender and the batch to which the students belonged to were the only criteria for segregating the students. Chi-square, Fisher Exact and 2 sample T-tests tests have been used to find the significance of study parameters on categorical scale between two or more groups (gender based).

Results: 67.9% of the respondents were females which show a strong inclination among the female gender towards choosing health care as a career option. 61.2% female respondents compared to 58.8% of males preferred pursuing post-graduation after under graduation.

Conclusion: Due to the societal orientation which regards women as primarily home makers, the responsibilities for family caretaking continue to fall disproportionately on women. This study provides valuable information to the curriculum and policy makers of dental education in India which will help make dentistry a better and viable career option for many in future and in particular for the female gender to challenge these strict gender divisions.

Keywords: *Dental Education, Gender, Career, Students.*

Introduction

Dental training across the globe has witnessed a plethora of changing trends in the past century and the changing scenario could be attributed to the local geo-political demands as well as the changing mind sets of the controlling bodies. The dental students overall face a challenge to overcome the hurdles of changing patterns of dental education and thereby the need and demands of the society in general, and also want to be globally accepted with the Indian qualification. With the increasing need for highly trained dentists in India, it is imperative that the various academic institutions become more efficient in training their students based on their aptitude. Moreover, the Indian society currently is driven mainly by three factors family, economic stability and

e-mail: sobhan.surgeon@gmail.com

competitive instincts. These three factors play a major role in deciding the career aspirations of any student in India. The Indian middle class which is a male dominant society is driven by high career aspirations which would enable them to live with an affluent lifestyle. The students are from varied backgrounds with contrasting mind-sets and expectations and a curriculum is required which can satisfy the expectations of the society without compromising the students' personal ambitions and goals.

The current curriculum of dental education in India is similar to the curriculum in most of the countries with the exception of the overall expectations of the students from the dental profession which is a direct result of the factors motivating them to choose dentistry as a career in first place. India with its growing population and economy is challenged by a low dentist-to-population ratio and also the current dental education model. Moreover, given the limited number of jobs for qualified dental surgeons the competitive factor plays a major role in deciding the future plans of a dental student.

The Indian society has been a spectator to gender bias in almost all spheres. Women in India have always been considered a step behind their male counterparts. But like various other areas such as music, dance, politics, and social movements, women are making inroads in the field of dentistry too. The structure of the dental profession provides unique opportunities for both women and men to exercise a high degree of autonomy and flexibility and at the same time, enjoy the status awards associated with being a healthcare provider.[1] Worldwide, we are seeing an upward trend in women making a mark for themselves as dentists.[2] Women also represent an expanding pool of possible applicants for dental schools, who break the traditional barriers of gender discriminations and set the standards for those who followed in their path as dental professionals.[1,3] Presently, the number of women in dentistry is increasing significantly.[4,5] But once women have entered a career path, they often encounter obstacles in continuing or advancing in their careers. Those attitudes include insensitivity to gender, lack of female role models and mentors, dual family and professional responsibilities, lack of parity in rewards such as career advancement and salaries, gender discrimination and sexual harassment and special needs of minority women.[6]. There are many unique challenges that women face in achieving professional excellence beginning from choosing a career to striving and sustaining in that very career and this has been given little attention by the researchers.

In such a scenario a study which can give an insight into the mind-set of the dental students, was very essential. Understanding the students' thoughts and aspirations can, in turn, guide the academic institutions into tailoring their courses more towards the incoming students while benefiting the society as a whole.

The aim of this study is to provide the people involved in dental curriculum design with an insight into the mind-set of a subset of undergraduate dental students. This may help them in formulating a dental curriculum that doesn't fuel further gender discriminations and in turn during a period of time lead to the evolvement of a dental curriculum where females do not have to take decisions regarding dentistry as a career keeping in mind several family and social obligations.

Materials and Method

This study commenced after full review exemption from the Institutional Review Board of the university. The study was granted full review exemption as it involved not more than minimal risk to the study participants and no potential identifiers were utilized during the response collection. Strict confidentiality and anonymity were maintained throughout. Data for this study was collected using a pre-validated 7-point questionnaire which was reviewed for content validity, readability, and structure by five selected dental students who were not a part of the final study population. The questionnaire was self-explanatory with each question either having a multiple choice or binary choice answer. Data was collected from undergraduate dental students from three dental colleges in Odisha, India. The questionnaires were distributed in the lecture halls of these dental colleges among the third year, fourth year and interning students. First-and second-year dental students were excluded because their curriculum to that point was primarily didactic with little clinical exposure. The questionnaire distribution and data collection were performed by one of the co-investigators (PKP). The questionnaire also required the respondents to provide information about their age, gender and year of study. After the survey was completed, data were analyzed using Chi-Square and Fisher's Exact Test. Analyses were performed within each respondent group (males and females). For each group, the responses for the confidence and perception items were compared between males and females using Fisher's Exact Test. A p-value of <0.05 was considered statistically significant.

The explanatory variable was gender. The statistics were obtained using the IBM Corp. Released 2013. IBM SPSS Statistics for Windows, Version 22.0. Armonk, NY: IBM Corp. software and Minitab 16 software. Microsoft word 2013 and Excel 2013 have been used to generate the tables.

Results

The overall response rate was 77.4%. Sixty-eight percent of the respondents were females. The average age of both the genders was 21 years. Sixty-six percent of female respondents compared to 57. 5% male students responded that dentistry wasn't their first choice. Among students who had chosen dentistry as their first option, male students (45.9%) were more likely to have always wanted to be a dentist as compared to (26.9%) female students. Among students for whom dentistry wasn't the first career option, more than 57.9% female students and more than 64.0% male students chose dentistry because they couldn't get a seat in MBBS program.

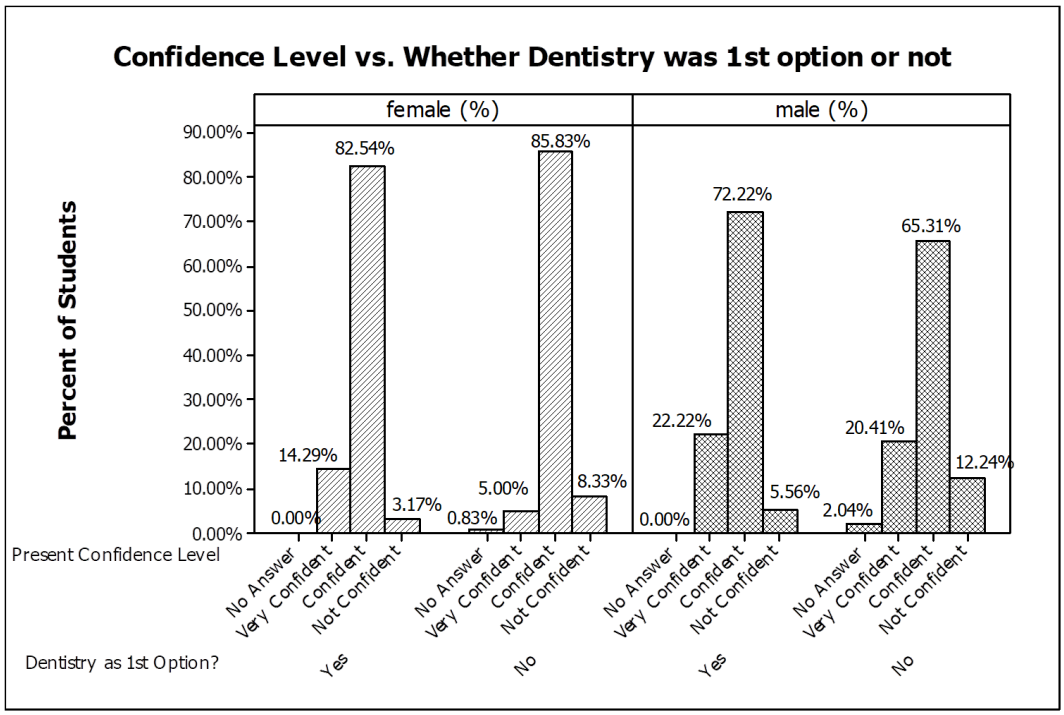

Fig.1: Bar graph showing academic confidence level of respondents compared to their choice of dentistry as a career option

Amongst students for whom dentistry was the first career option, 82.5% percent of females as compared to 72% of males were confident during the course. Amongst students for whom dentistry was not the first career choice, 86% females as compared to 65% males were confident during the course (Figure 1).

Oral Pathology was perceived to be the easiest subject amongst females while Periodontics was considered the easiest subject amongst male respondents (p-value<.005). While both the genders agreed on Prosthodontics being the most difficult subject, the second most difficult subject was Oral & Maxillofacial Surgery (10.38%) in females and it was Public Health Dentistry (12.94%) in males.

A majority of the respondents thought of pursuing higher studies (MDS) (61.2% female and 58.8% male students) or taking up clinical practice after completing their BDS (26.23% female and 32.94% male students). When asked about their preferred subject for post-graduate specialization (MDS), most students mentioned Oral & Maxillofacial Surgery, Conservative Dentistry & Endodontics or Orthodontics. The preferred subject for male respondents was Oral & Maxillofacial Surgery while that of female students was Conservative Dentistry & Endodontics.

Discussion

Out of the 271 respondents more than half of the

respondents were females which showed a strong inclination among female students towards choosing healthcare as a career option. This trend has also been reported in other parts of the world like the United States, Denmark, France, the UK. The advancement of women in academic and research careers requires global attention and strategies. The same trends are occurring amongst Indian students also. About 50 to 60% of students in all dental schools in India are female.[1-14]

While more than fifty percent of the respondents said dentistry was not their first career choice. The proportion of females was higher than males amongst this group. A large number of students chose dentistry as a career when they didn't get admission in the medicine stream. This shows the scenario of the Indian society where dentistry has always been an alternate career for those students unable to get admitted into the medicine program. Students prefer dentistry if not medicine as a career option in order to pursue their career aspirations in the healthcare sector.[1, 15-20.]

Most of the female respondents preferred subjects like oral pathology, dental materials over clinically demanding subjects like prosthodontics, which they found to be the most difficult one. On the contrary, the male respondents preferred subjects such as periodontics, conservative dentistry and endodontic which are the more clinically intensive subjects. But still found prosthodontics to be the toughest subject.[21].

A higher percentage of male respondents preferred to pursue clinical practice after graduating from their undergraduate course while more female respondents chose to go for specialization or post-graduation.[22] Among the students who chose to pursue post-graduation, conservative dentistry and endodontics was seen as the most favoured specialization among the female respondents while Oral and Maxillofacial surgery was the subject of choice for the male respondents.[23] This separation in the choice of subjects between male and female students was somewhat expected given the social expectations. Oral surgery is a clinically demanding subject which requires long hours of ward duties and night duties in hospitals. It appears that most female students take into account the long hours of clinical duties which may interfere with their other priorities such as taking care of household responsibilities and decide on a less rigorous subject. It can be said that dental institutions should keep the choices of the students and their aspirations in mind while preparing the curriculum and tailor the courses to the students. The concept of gender is rooted in societal beliefs about the appropriate roles and activities of men and women and in the behaviours and status that result from those beliefs. Gender difference is dynamic and socially constructed, and that what is considered appropriate gendered behaviour can be changed over time. Hence, the goal is not just ensuring equal numbers of men and women (gender equality), but also guaranteeing fairness and justice in the professional opportunity structure (gender equity).[24] Encouraging students especially females, to explore the challenges in each subject may change the gender gap in choice of subjects. Overall, it will require significant thought and effort on the curriculum designers and hopefully, this study will provide them with helpful insights into the dental students' minds.

On the personal front, since biological differences between males and females are unavoidable, programs such as paternity leave, childcare centres, increased involvement of father in childcare and family, extended family support along with flexible practice time, and job sharing that integrate family care with professional needs are likely to guarantee that the talent and the productivity of female dentists are not lost. To assist in overcoming barriers at the institutional level, efforts should continue to be made to identify and reduce barriers to women's advancement in science and research.[25]

Conclusion

Hence it can be said that the Indian dental education has witnessed some significant changes over the years with the focus moving to economic sustainability in the highly competitive Indian society. Therefore, the dental curriculum in India needs to be tailored to suit these varied aspirations of the dental students which would fulfil their career aspirations and, in the process, benefit the society. Even though gender inequality is on the decline in India, still some prejudices related to choices made by female students related to post-graduate specialization should be reason enough for the governing body of dental education in India and the society as a whole.

Abstract

The oral cavity has the most suitable environment for the growth of microorganisms as compared to any different body parts. Bacteria presents in dental plaque are the main causative factors of caries, gingivitis, periodontitis, and peri-implantitis, etc. Peri-implantitis is a destructive inflammatory response that leads to loss of supporting bone structure around a failing but functional implant. It is found that in 65% of disease in peri-implantitis and periodontitis there is the association of dental plaque. In this review article importance given on understanding the growth of dental plaque surrounding dental implants and their capacity to develop peri-implant diseases.

Keywords: *Dental implant; Plaques; Infections; Peri-implant diseases.*

Introduction

Biofilm is described as a relatively indefinable microbial community blended with tooth surface or any hard non-shedding material.[1] "Biofilms form on virtually all surfaces covered in physical aqueous environment, e.g., water pipes, living tissue, tooth surface, implanted medical devices such as dental implants, etc., Biofilm adhesion-mediated infections most commonly seen are on the implanted heart valves, venous catheters, vascular prosthesis, fracture fixation devices, breast implants, intraocular lenses, and dental implants.[2] Biofilms consist of one or more than one communities of microorganisms nonrandomly distributed in a glycocalyx. These biofilms allow the microorganisms to adhere and multiply on the surfaces." The interactions among the several bacterial species residing and growing in the biofilm takes place by metabolic exchange, exchange of genetic information, indicating molecule-mediated information.[3]

"Biofilms accumulated on the tooth surface are called dental plaque. Bacteria proliferating in the dental plaque from the main etiologic factors for the majority of the dental diseases, e.g., caries, gingivitis, periodontitis, and peri-implantitis. Microbial invasion has been cited as the foremost cause of the dental implant failure." Biofilms are responsible for their association of about 65% of diseases including peri-implantitis and periodontitis.[4,5]

Although bacteria are frequently noticed as being harmful to the human body causing complications such as syphilis and tuberculosis, periodontal diseases are infections that originate from indigenous bacteria. Disease occurs when the harmony between the host and the microbiota is disrupted, particularly in a susceptible host or when the microorganism is profoundly pathogenic. Peri-implant diseases comprise inflammatory reactions in the host tissues and include

peri-implant mucositis or peri-implantitis. Peri-implant mucositis also known as "ailing implant" is defined as a reversible inflammation localized to the soft tissues with no signs of supporting bone loss.[5,6,7]Peri-implant mucositis may resolve by itself or persist for an undetermined period with the possibility of developing peri-implantitis and implant failure." Periimplantitis regards to a destructive inflammatory reaction with evidence of loss of supporting bone around a failing but functional implant.[8]

"The timing at which implant failures occur describes different physiological processes. Hence, an early implant failure indicates an initial lack of osseointegration due to a failure to build an intimate bone-to-implant contact. Several factors may contribute to early implant failures such as premature loading, surgical trauma, or impaired healing response.[9,10]Late failure, on the other hand, occurs after initial integration, physiological remodeling, and loading. Causes of late failures include overloading and bacterial infection (*e.g.*, peri-implantitis) with most failures occurring after the first year of loading.[11,12,13] In fact, biofilms have been associated with infectious diseases such as periodontal and peri-implant diseases. Because the role of bacterial biofilm in peri-implant diseases has been recognized, knowledge of microbiology around dental implants is the essence of adequate diagnosis and treatment of certain diseases. This article focuses on understanding the development of oral biofilms around dental implants and their role in peri-implant diseases.[14]

After exposure of an osseointegrated implant in the oral cavity through a transmucosal abutment, an acquired pellicle is formed on the implant surface through selective adsorption of the environmental macromolecules such as alpha-amylase and serum albumin.[15] This pellicle is derived from components in the saliva, as well as bacterial and host tissue outcomes. It acts as a substrate for bacterial colonization, which occurs as early as 30 minutes after implant exposure in the oral cavity.[16] In comparison to natural teeth, the acquired pellicle on dental implants has a lower albumin adsorption capability, which contributed to the lower plaque formation around implants.[17] Biofilm describes an organized structure within which microorganisms interact metabolically as a community. Biofilm formation throughout implants occurs similarly to teeth. Next to the formation of the acquired pellicle, bacterial attachment with initial colonizers followed by cell-to-cell adhesion with secondary colonizers occurs on the implant surface.[18] Biofilms are favored for most bacteria because they facilitate the interchange of nutrients and shield the bacterial community from competing microorganisms.[19] Moreover, biofilms also contribute to the spread of antibiotic resistance.[20]

Implants with deeper probing pockets showed the presence of a minor number of coccoid and higher levels of the spirochetes. Biofilm development on dental implants and the teeth follow the alike pattern of microbial colonization.[21,22]

"Biofilm formation throughout natural teeth occurs in minutes and the specific species start colonizing as early as 2-6 hours. The reason attributed possibly lies in the fact that the clean tooth surfaces are suitable to have remnants of unattached microbiota that can immediately multiply and provide a favorable surface for the attachment of the late colonizers.[23] The pristine surfaces of the implants lack the desired indigenous microbiota and demand the early colonizers to set the stage for the complex communities to grow.[24] The pellicle starts forming on the implant surface after the implant is disclosed in the oral cavity (which is about 30 minutes of expose).[25] The acquired pellicle on the dental implants owing to their lower albumin absorption capacity causes a moderate plaque formation around implants. Early colonizers are predominantly the gram-positive cocci, rods, and actinomyces species.[26] The periodontal pathogens colonizing on the *Streptococci i.e. P. gingivalis, P. intermedia,* etc are the causative microorganisms responsible for peri-implantitis and periodontitis.[27] The osseointegration around the dental implant is largely influenced by its surface roughness.[28] Greater is the surface roughness, higher is the rate of the biofilm formation around the implant.[19] The attachment of the microorganisms to the hard surfaces, i.e., teeth and implants, besides their interactions with the surface components i.e. roughness also require certain specific characteristics of these interacting surfaces in terms of their wettability/hydrophobicity and surface free energy. In an *in vivo,* study a smooth titanium abutment and a sandblasted titanium surface was evaluated for the biofilm accumulation. The results revealed that surface roughening harbored a lower percentage of the coccoid cells (64.2%) as compared to the smooth abutments (81%)."

"A majority of the studies have pointed out comparative rates and the composition of the microbiota joined with teeth and implants in health and disease. The

microbiota in healthy peri-implant tissues is dominated with gram-positive facultative cocci and rods.[30] A typical variation in the microbial profile of the peri-implant microflora in certain in vitro studies shows the affinity of the Staphylococcus aureus for the titanium surface but it is not a common microflora around the teeth. Staphylococcus aureus has a high ability to adhesion for titanium surfaces and has been associated with bleeding on probing and suppuration. Several specific adhesins are expressed on the surface of Staphylococcus aureus that interacts with various host proteins such as fibrinogen, fibronectin, and laminin. Certain surface adhesions have been referred to as microbial surface components recognizing adhesive matrix molecules. Next to the placement of the implant, they are coated with the host plasma constituents including extra cellular matrix i.e. ECM. The outcome of the implant surface may be imagined as race for the surface involving ECM, host cells and the bacteria. The adhesion mechanism of the Staphylococcus aureus facilitates their adhesion to the biomaterials and the ECM deposited on the implant surface.[29] Transformation from health to disease (peri-implantitis) causes a shift of the microflora from predominantly gram-positive to gram-negative microorganisms. Microflora of the implant in peri-implantitis has a high prevalence of the red and orange complex species as defined by Socransky." This microflora is predominated with the red complex species as *P. gingivalis*, and *T. denticiola*, the orange complex species as *F. nucleatum, P. intermedia. Candida albicans* has been found to have increased adhesion to titanium implants in certain in vitro studies.[30]

"The success of dental implants lies in successful osseointegration. The basic principles of biofilm formation are equally applicable in context to implants as they implement positive grounds for bacterial adhesion. Researchers should have to focus on implant design surfaces that inhibit biofilm adhesion. The approach of the antimicrobial photodynamic therapy has added a new dimension in the treatment of the biofilm-related peri-implant infections. However, long-term randomized clinical and microbiological trials are required to reinforce the beneficial effects of this therapy in combating the disastrous infections caused by biofilms. Recently, an *in vitro* study was performed on the principles of electrochemistry with the hypothesis.[28,30] If it can be used as a method to disinfect the implant surface."

Conclusion

The certain conclusions for this study were in favor of a reduction in the bacterial count. Research needs to be carried out in this dimension on the animal models of peri-implantitis and improve the design of the implant.

A Rare Case Report on Temporomandibular Dislocation

Sthitaprajna Lenka[1], Santosh Subudhi[1], Stiti Pragnya[2], Aditi Ava Rath[2], Kalyan Sundar Pal[2]

[1]Professor, [2]Post Graduate Trainee, Department of Oral and Maxillofacial Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to Be University), Bhubaneswar, Odisha, India

Abstract

In Temporomandibular joint dislocation, mandibular condyle is displaced from its articulation and it require prompt medical attention due to crucial impact of airway, nutrition and communication. It may be acute, chronic recurrent or chronic persistent. Prolonged or protracted TMJ dislocation is an uncommon condition and rare. Many techniques and method are developed for its management. Acute dislocation can be managed by conservative method butlong-standing dislocation cases can be managed by surgical procedures. We presented a case of prolonged bilateral TMJ dislocation managed with midline mandibulotomy followed by bilateral condylotomy where other indirect reduction technique had not achieved the desired result.

Keywords: *TMJ joint, long standing dislocation, management,midline mandibulotomy, Condylectomy.*

Introduction

TMJ dislocation represents 3% of all reported dislocated joints. A dislocation or luxation is a condition where a joint is displaced from its articulation, due to enormous mobility of condyle beyond an articular eminence with partition of articular surface i.e. open lock. In this condition patient is unable to close his mouth after wide opening. This can be precipitated by trauma, yawning, oral intubation or endoscopy. There may be various types of TMJ dislocation in relation to glenoid fossa. Anterior dislocation is the most common type and it has also been seen that bilateral dislocation is more common than unilateral type.[1,2] If the acute dislocation is left untreated for 72 hours or more than that then it is called as chronic persistent dislocation and if the situation persists more than one month, it is called as prolonged/protracted/long standing dislocation. Lee at al explained an indirect surgical procedure where midline mandibulotomy was done, that permitted reduction of both the joint separately.[3]

Case report: A 29-year-old male patient reported in Dept. of oral and maxillofacial surgery of institute of dental science, Bhubaneswar having complain of difficulty in closing his mouth and pain while chewing food. Having history of road traffic accident 2 months back and admitted under department of neurosurgery for head injury for 15 days. Along with maxillofacial injury he had complete paralysis of right upper limb and under rehabilitation for the same. The patient is having a broad face and has a difficulty in closing his mouth properly. His speech was not transparent. There was no scar in her facial profile. On palpation, depression over preauricular region found and condyle of the TMJ palpated 2-3 cm in front of the depression. No tenderness present over TMJ and masseter muscle.

The orthopantomogram reveals bilateral condylar fracture and anterior displacement of the condyle. A clinical diagnosis of bilateral Condylar dislocation of TMJ was given and manual reduction was attempted after injecting 2% lignocaine into the glenoid fossa bilaterally. Manipulation was attempted without success and patient planned for reduction of the joint under general anesthesia. Under general anesthesia manual reduction tried first, after that one intermaxillary fixation screw placed over the ramus region through submandibular approach, wiring done and traction given to reduce the joint but this procedure appears unsuccessful. Then mandibular midline split of the mandible done through mandibular vestibular approach to reduce

the joint which was unsuccessful too and ultimately bilateral condylar shaving/condylotomy done through previous submandibular incision to achieve occlusion. After condylotomy, normal occlusion achieved and temporary intermaxillary fixation done and plating of the mandibular symphysis done. Temporary intermaxillary fixation released movement of the mandible checked and occlusion check done and mandibular vestibular approach and submandibular approach closed by means of layer by layer suturing. On 3rd postoperative day elastic given to achieve proper occlusion and after 24 hours rigid intermaxillary fixation done by means of wire for 21 days.

Discussion

There are various types of classification temporomandibular joint dislocation depending upon the head of the condyle and its relation with the glenoid fossa. If the condyle deviates it path from the articular eminence then it is called TMJ dislocation, the anterior dislocation of the condylesis most commonly found in the dislocation.[4]

Several causes may head to dislocation like habitual wide opening of oral cavity, when yawning or taking, prolonged mouth opening during minor and major surgical procedures. Some anti-psychotic drugs may cause dislocation that has been reported by various authors. Ehler Danlos syndrome, Marfan syndrome are some of the syndromes where the patients usually have a complain of joint dislocation. Whatever may be the reason, movable joint is very likely to undergo dislocation. The factors which determines the mobility of the joint are the laxity of the ligaments and the muscles surrounding the temporomandibular joint.

Several factors can cause temporomandibular joint dislocation for example seizures, during yawning and chewing hard foods, it has also been reported that the patient those are having hypermobility of the joint, flat articular eminence and weak muscle surrounding the temporomandibular joint may have TMJ dislocation.[5-7]

The TMJ dislocation can clinically be diagnosed in the first visit of the patient. Mandibular pain while opening mouth, disarranged occlusion, pre-auricular depressions, inability to chew food properly. Diagnosis of TMJ dislocation in any of the above-mentioned symptoms can immediately be confirmed through radiograph. It is obligatory that the intervention is carried out without any delay because various complications such astrismus, severe atrophy of masseter and temporalis, maycause difficulty in reducing the condyle in its proper anatomical position, so it is advisable to do the reduction of Condyle as soon as the patient reported to the hospital.[8]

On encountering long-standing TMJ dislocation, most dental surgeons try to reduce the joint using manual common Hippocratic method that usually fail, knowledge about the etiology, period of dislocation, changes which took place in the joint, and various nonsurgical and surgical techniques to treat such condition are important in the management of such cases. No standard treatment conventions or algorithms have been set down for the management of such dislocations in the literature. The choice of the technique used depends entirely on the surgeon.[9]

According to various article mostly TMJ dislocation is seen in female than in male. Various author has also suggested condylotomy, resection of lateral pterygoid usually brings back the classs-1 occlusion, but patient has to be on elastic traction for 15-20 days after condylotomy. Some authors also described eminectomy to reduce the condyle into proper anatomical position. In 1973, Laskinan intraoral surgical approach to the muscle through coronoid incision was recommended by to Performa temporalis myotomy. In 1976, Adekeya et al. described a technique to restore the occlusion by means of the inverted L-shaped osteotomy of the ramus Other authors have also recommended the use of vertical or oblique ramus osteotomy and bilateral sagittal split osteotomy for rectifying the occlusion. But it had many disadvantages like the risk of damage to the inferior alveolar bundle, less bone contact, and impingement/ impaction of the coronoid process on the condyle for which it was not accepted. [10]

Augmentation of the articular eminence can be done by autogenous bone grafts like the iliac crest or the calvarial bone. L-shaped pins, vitallium mesh implants, and mini implants are some other tomaterials usedto enhance the eminence. Silicone wedge blocks and coralline hydroxyapatite blocks have also been used by few authors. There are few drawbacks like looseness, displacement, and immune reactions for silicones.[11]

The treatment of TMJ dislocation is personalized as per the underlying cause. Autologous blood, sclerosing agents, and tarsorrhaphy are used for treatment of Hypermobility or subluxation. Acute dislocation can be managed by Manual reduction. Chronic protracted

and chronic recurrent dislocations are among the most challenging index to manage. These are treated using surgical procedures.[12] The treatment of TMJ disorders as early as possible is the best mode to avoid further complications. This boost up the success rate of treatment of TMJ disorders. If the dislocation persists more than 1 month or the patient reported to the hospital more than 45 days of dislocation then it will be difficult to reduce manually. Various author has suggested that if the dislocation persist more than 45 days, open surgical method ex: condylotomy oreminetomy to bring the patient's occlusion into normal position. Few literatures also suggested long standing after the condylotomy if the occlusion is not achieved orthognathic surgical procedures (bi lateral sagittal split osteotomy can be performed to get back the patient's occlusion into normalcy. The goal of management of TMJ dislocation should be putting the mandible into correct anatomical position, Whole range of jaw movement should be achieved. It has been reported that many cases of TMJ dislocation can be manage through manual reduction.[10-12]

Ugboko etal in their study reveals that the TMJ dislocation can be managed by MMF (Maxillo Mandibular Fixation) and manual reduction. The surgical approaches for the management of temporomandibular joint dislocation are bilateral or unilateral condylotomy/ ramus osteotomy. Other authors have also stated orthognathic surgery, injecting of sclerosing agents in the joint can also reduce the frequency of dislocation. Several reviews in the literature has stated that the use of autologous blood and injecting it in to the joint space in an interval of weekly once for one month will reduce the frequency of dislocation. Few of the authors has also inserted wires in the angle of the mandible and pulled it downward to bring the condyle to its correct position. Some authors also used midline osteotomy in the symphysis region of the mandible for treatment of temporomandibular joint dislocation. The major complication of this procedure is fracture of the root apices of the central incisor of the mandible,derangement of the occlusion, plate infections.[10-12]

Conclusion

By reviewing various literature, we concluded that most of the temporomandibular joint dislocation can be managed by manual reduction, putting the thumb in the molar areas of the mandible and pressing it downwards and backward, injecting sclerosing agent and autologous blood in the temporomandibular joint space.

Unicystic Hemangioameloblastoma: A Rare Clinical Entity

Sreepreeti Champatyray[1], Priyanka Debta[2], Shubhangi Pareek[3], Neeta Mohanty[4], Saurjya Ranjan Das[5]

[1]Assistant Professor, Department of Oral Pathology and Microbiology, Institute of Dental Sciences, [2]Professor, Department of Oral Pathology and Microbiology, Institute of Dental Sciences, [3]Post Graduate Trainee, Department of Oral Pathology and Microbiology, Institute of Dental Sciences, [4]Professor & Head, Department of Oral Pathology and Microbiology, Institute of Dental Sciences, [5]Associate Professor, Department of Anatomy, Institute of Medical Sciences, Siksha 'O' Anusandhan (Deemed to be University) Bhubaneswar, Odisha, India

Abstract

Ameloblastoma is a benign epithelial odontogenic tumour which has many histological variants. "Unicystic Hemangioamleloblastoma is a rare variant" which shows unique histopathological features varying from conventional ameloblastoma. This present case is of a 30-year-old male patient with a swelling extended in the right-side body of lesion, angle of the mandible region with egg shell crackling. It was extended anteriorly up to the corner of the mouth, posteriorly up to the ramus of the mandible and inferiorly to lower border of the mandible. It has mixed radiolucent-opacity, which on enucleation histopathologically revealed ameloblastomatous areas with extensive vascular component.

Keywords: *Ameloblastoma, haemangiomatous, vascular component.*

Introduction

Ameloblastoma is a benign epithelial tumour which arises from rest of dental lamina from developing enamel organ. It is defined as unicentric, non-functional, anatomical benign and clinical persistent. Unicystic ameloblastoma comprises approximately 6% of ameloblastomas.[1] Haemangiomatous ameloblastoma (HA) is a very rare variant which shows unique histopathological features varying from conventional ameloblastoma. More than 90% of unicystic ameloblastoma are found in the mandible usually in the posterior region 1. The lesion is often asymptomatic, painless slowing swelling of the jaw. Here we report a case on detailed below.

Case report: A male patient of around 30-years presented with a chief complaint of painless swelling on the right side of the mandible for three months to the Department of Oral Pathology and Microbiology, Institute of Dental Sciences, Bhubaneswar. Initially, it was a very small swelling which gradually grew to the present size. His medical, dental, habitual and family history was not significant. On examination it was found that the swelling is oval in shape, having well-defined margins and measuring approximately 6x6 cm in size. The colour of the lesion was similar to the normal adjacent skin. The swelling extended in the right-side body of lesion, angle of the mandible region with eggshell crackling. Inferiorly to lower border of the mandible, posteriorly up to the ramus of the mandible and anteriorly up to the corner of the mouth. No visible pus discharge was seen. On palpation, the findings were confirmed and the lesion was bony hard with the central region showing variable consistency of hard and soft areas. The lesion was not tender. On intraoral examination, firm, smooth, non-fluctuant swelling was seen extending from 41 to the anterior border of the ramus. The mandibular left first molar and second premolar have been extracted previously. The first premolar was carious.

A panoramic radiograph revealed a well-defined mixed radiopaque-lucent multilocular lesion, bone loss in the right side of body and angle region of the mandible extending from the second premolar to the

coronoid process. Few septae were arranged in tennis racquet appearance. Cytology test was done to confirm the diagnosis, cytology smear revealed brownish yellow colour fluid. A provisional diagnosis of ameloblastoma and clinical differential diagnosis of the dentigerous cyst was made. After obtaining patient's consent, enucleation was done and multiple bits of the soft tissue specimen of approximately 6cm X 6cm X 3cm were sent to the Department of Oral Pathology and microbiology. On macroscopic examination single bit of formalin-fixed tissue was received, whitish brown in colour, firm in consistency, rough surface, measuring about 0.7×1cm×0.2cm in size. On microscopic examination, the given haematoxylin and eosin section revealed multiple bits of tissue showing cystic capsule. There is the presence of tall columnar ameloblastic cell lining over which there are stellate reticula like cells and many blood-filled small vessels. The collagenous cystic capsule shows the presence of many small and large ameloblastic follicles. A mild degree of chronic inflammatory cells infiltration is present. A diagnosis of Unicystic Haemangiomatous Ameloblastoma was made.

Discussion

The most common odontogenic tumours are Ameloblastoma which is 11% of the tumours. It is categorized into three types: solid or multicystic, unicystic, and peripheral based on clinico-radiological features.[1,2] When there is a deviation from the normal process of odontogenesis it results in odontogenic cysts and tumours. In ameloblastoma, there is abnormal differentiation of enamel organ.[2,3]

Various histological variants of ameloblastoma have been described in the literature like follicular (most common), plexiform, acanthomatous, granular (most aggressive), basal cell and desmoplastic.[4] Variants like the clear cell, papilleferous, keratoameloblastoma and haemangiomatous ameloblastoma have also been reported in the literature. It has been studied that the histological variants do not differ significantly in either biological behaviour of the tumour or its prognosis after treatment. Desmoplastic and haemangiomatous ameloblastoma are exceptions with the former thought to be less aggressive than the latter due to its extreme vascular component which has complications in surgery. However, in many cases have been reported with a mixture of these patterns.[4-6]

Haemangiomatous ameloblastoma is a very rare variant of ameloblastoma. It refers to any ameloblastoma in which the stroma has spaces filled with blood or large endothelial-lined capillaries. The first case of Haemangiomatousamelobalstoma was described by Kuhn (1932) as a combination of haemangioma and adamantinoma. In Haemangiomatous Amelobalstoma the stromal component is mostly replaced by vascular component.[7]

Earlier haemangiomatous ameloblastoma was documented as ameloblastic haemangiomas, adamantino haemangiomas and haemangioma ameloblastomas.[5,6] As very few cases of haemangiomatous ameloblastoma are reported, the origin of its vascular component is still debatable and not clearly understood. Some authors consider the vascularity as hamartomatous growth and some consider it as a part of the neoplastic process or separate neoplasm. Smith did not consider haemangiomatous amelobalstoma as a separate variant of ameloblastoma but the extensive vascularity might be due to other causes.[8,9] To summarize the various theories proposed to explain the pathogenesis of the vascular component of haemangiomatous ameloblastoma are[6-10,11]

1. Angiogenesis during the development of the tumour.
2. As a separate neoplasm,
3. Hamartomatous growth,
4. Traumatic incident,
5. Secondary changes,
6. HA representing a collision tumour.

When there is an abnormal induction of blood vessels during odontogenesis, it results in their abnormal proliferation. Such proliferated vessels will turn into a component of tumour.[11] Trauma during procedures like extraction of teeth might induce the epithelial cell to proliferate and results in formation of tumour. Usually after any injury the injured tissues undergo repair to retain their original condition, so any disturbance in the repair process of damaged tissues involves excessive granulation tissue formation, which consists of proliferating endothelial cells and new capillaries.[12,13] The presence of extensive vascular component in our case might be due to stimulation and proliferation of blood vessels due to trauma created during extraction of teeth and subsequent repair phenomenon.Haemangiomas, telangiectatic osteosarcoma, angiomatoid malignant fibrous histiocytoma lesions should be included in the differential diagnosis. In telangiectatic osteosarcoma, there are large spaces filled with blood and huge areas of necrosis. Whereas, angiomatoid malignant fibrous histiocytoma contains characteristics of a fibrohistiocytic tumour and avascular tumour.[7]

Pathogenesis, clinical features, treatment modality and prognosis ofhaemangiomatous ameloblastoma until now is not completely understood as only very few cases have been reported. Few authors considered Haemangiomatous Ameloblastoma as a collision type of tumour, in which two separate tumours develop in the same area and collide, and their components blend together.[12,13] According to Lucas the vascular component in haemangiomatous ameloblastoma is purely a secondary cystic degeneration which occurs in the stroma. In plexiform ameloblastoma, and during the formation of the cyst some blood vessels persist and dilate resulting in vascular component as seen in haemangiomatous ameloblastoma.[9,12-15]

Conclusion

Haemangiomatous Amelobalstoma and other such lesions with the extensive vascular component may lead to fatality even following minor procedures. Our case clearly demonstrates the distinctive histologic pattern and should be kept in the differential diagnosis of vascular lesions large number of such cases has to be studied thoroughly to exactly know the origin, nature and behaviour of Haemangiomatous Ameloblastoma.

Birn's Hypothesis and its Implications

Subham Sekhar Parida

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Dry socket is a commons post-extraction complication developing within may 48 by of extraction very severe re reverberate pain. Most frequently occurs in the mandible 3rd molar region. Males show a lower incidence of occurrence than funds. Helotism is almost always a parent. Treatment of dry socket rinsing of the socket with Chlorhexidine or Saline Water, placement of ZOE paste or allergy above & inspirit of a home rising of the socket with chill & saline water.

Keywords: *A0, Dry socket, occurrence, Management.*

Introduction

Dry socket can be defined as the interim of the extraction socket occurring within 48 has of extraction postoperatively, characterizes by in these reverberate pain. Require of disintegrated clot & food debris in the socket & halitosis. Present with dull pain & can be moderate to severe.[1] Causes are clot has failing to form at the extracted tooth socket and Infection. Preventions are avoided excretion drawn the presence of acute intuition, aseptic preparation of the surgical site, advise the patient to stop smoking, use disposable pedicles, proper wound debridement, avoid repeated use of the same needle. Different factors have been found to be associated with an increased risk. The extraction of 3rd molars mainly imputed the lower third molar. Mandibular teeth more predilected them maxillary teeth mainly single tooth/one tooth extraction, poor oral hygiene, ulcerative gingivitis or pericoronitis, smoking, patient aged between 25 to 40 years, female predilection rather than male.[2] Wherever possible, oral hygiene measures to reduce plaque level to a minimum should be instituted and all patients should be given a 0.12% chlorh```exidine mouth rinse immediately preoperatively.

Corresponding Author:
Subham Sekhar Parida

e-mail: subhamparida@gmailcom

In case the presence of active pericoronitis or acute ulcerative gingivitis, lower third molar should be avoided. In the case of immuno compromised, appropriate antibiosis prophylaxis should be prescribed. Smoker patients should be quite the habit preoperatively for at least 15 days post-operatively while the extraction socket head. Whenever possible, for formulae patients using oral contraceptive extractions should be performed during days 23 through 28 of the menstrual cycle/tablet cycles. All extraction should be completed with the minimal amount of trauma, the maximal amount of came & as rapidly as possible commensurate with their degree of difficulty & the experience of the operator. On completion of the procedure, the operative site should be irrigated with copious amounts of sterile saline followed by 15ml of 0.12% chlordane mouth rinse for the following 7 days. Advice to all patients should be a return to the hospital/clinic if they develop increasing pain or a bad taste.[3]

In the case of established dry socket, patients should be managed along the following lines, the affected socket should be gently irrigated with wormed 0.12% chlorhexidine, and all debris dislodge and aspirated. In extremely painful cases, a local anesthesia may be required before socket irrigation can be performed. Wherever possible, regional nerve blocks should be employed. The socket should be lightly packed with a dressing that contains on obtundent for pain relief & non-irritant antiseptic bacterial a fungal growth. The dressing should prevent the completion of ford debris/ food patients & protest from irrigation to the inspire

bone. Providing antibiosis is not routinely required because there are no sins of systemic infectious, effective system analysis should be prescribed, & the patient's progress should be reviewed the following day a frequently thereafter until full healing has occurred. Krogh (1957) reported that after the removal of 6403 teeth 4403 where simple extractions and 2000, including 353 impacted teeth, were removed surgically) 138 cases of alveolar osteitis (2.17%) resulted (7 were in the upper jaw & 181 in the premolar & molar regions of the lower jaw) despite excellent post-operative care. Others have reported an incidence of 3% 4%.[4]

The cause of alveolar osteitis is variably ascribed to preexisting infections, trauma to the bone during the extraction, decreased bleeding because of the hemostatic effect of the epinephrine or other vasoconstrictor injected with the local anesthesia (leaner, 19681, infection entering the socket after the tooth has been removed, the presume of dense bone, general debilitation and loss of the clot because of revising the mouth or sucking the would none of the explanations is completely tenable. The trauma of extraction and or subsequent infection of the socket sums to offer the best explanation. Birn (1973) has suggested that trauma and infection cause inflammation of the bone marrow with the resultant release of tissue activators that convent the plasminogen in the clot to plasmin. The fibrinolytic agent then dissolves the blood clot and at the same time, releases mins from the kininogen, which is also are the clot, leading to severe pain. Birn was able to demonstrate both tissue activators and plasmin in the alveolar bone adjacent to the affected socket sockets. On the basis of his findings, he suggested that the term fibrinolytic alveolitis be used to describe the condition.[2,3]

Birn's hypothesis (1973) expands the previously popular concept that trauma damages the alveolar bone and thereby reduces its resistance to infections and that bacterial enzymes cause dissolutions of the clot. It is possible that all these factors may play varying pants in the etiology of the process. The bacteriologic examination of the cultures from alveolar osteitis generally shows a mixed infection, but the presence of a large number of fusiform bacilli and Vincent's spirochetes may point to a low-grade putrefactive process. The treatment of Alveolar Osteitis is directed primarily towards the relief of pains that can be accomplished in two ways, local thereby consists of irrigation of the socket with a warm's sterile isotonic saline solution or a dilute situation of hydrogen peroxide to remove necrotic. Material & other debris, followed by the application of either an obedient (eugenol or guaiacol) or a topical anesthetic i.e. Butacaine, Benzocaine).[4]

The drug may be applied to a piece of sterile gauze or in the form of a paste. In addition to local thereby, an antipyretic analgesic or a narcotic such as codeine sulfate (1/2gr) or meperidine 50mg every 3 to 4 hours should be prescribed for the patent. The agent of choice depends on the severity of the pain. The patient is re-examined in 29 hours. If the pain has stopped, the medication in the socket need not be replaced. If pain persists, however, the irrigation & dressing of the socket should be repeated as necessary. Curettage should never be employed in the due treatment of A.O. This procedure not only predisposes the patient to the spread of infusion but also destroys any previous attempt at normal healings. Moreover, since the socket is already infected, any new blood clot formed also will subsequently undergo lysis.[4,5]

The routine use of antibiotics in the treatment of alveolar osteitis is not recommended because the major problem is one of pain control rather than of unlimited infection. Certainly, the use of antibiotics alone is an ineffective method for the relief of the patient's pain. In the rare instance where suppuration does exist, the antibiotic should be used systemically rather than topically in the socket. Not only one topical antibiotic of little value therapeutically. But also, being acidic substances, they may actually add to the pain.[5]

Some post-extraction dressings:

1. **Alvocure:** Alvocure is a dry socket treatment and post-extraction dressing. It provides a soothing effect throughout the healing process. Its fibrous consistency allows for the easy falling off the socket. The active agents and eugenol, butamben & iodoform.[6]

2. **Alveogyl Paste:** Alveogyl paste may be used post-operatively after a difficult extraction. It relieves pain, destroys infective organisms and causes the return of blood to the socket. Indications–Dry Socket.[6]

Features & benefits: With a fibrous consistency thanks to Penghawar fiber for an early filing of the socket and good adherence to the alveolus. It provides a soothing effect on the alveolar tissues thus helping to rapidly alleviate the pain. Convenient and easy to use: Alveogyl is a one-step, self-eliminating treatment

requiring no suturing and no special attention other than observation of the healing process. May also be used as a post-extraction dressing in patients with a history of dry sockets.[7]

Prevention of Post-operative Pain: Since a great deal of post-operative pain can be prevented, every effort should be made in this direction. During surgery, tissues should be handled with the utmost lane. The periosteum and mucous membranes are well supplied with unmyelinated free never endings and are therefore extremely sensitive. Sharp instruments must be used to avoid excessive trauma. One should see that no foreign bodies such as tooth fragments, filling materials or bone chips are left in the wound. All injured bone should be removed, sharp edges, smoothed, and whenever possible, the soft tissues sulfured. Since excessive post-surgical edema and hemorrhage can produce pain by distending the tissues, pressure dressings and cold applications should be used when feasible.[8]

Analgesic drugs should be administered before the outset of pain, i.e., either before surgery is started or immediately post-operatively. The patient should be given specific instructions about how often and for how long the drug should be taken. As previously, recommended, the minimal effective also should be used at short intervals and a drug selected that is sufficiently potent to manage the amount of pain expected.

Management

As the pain serves the patient is given sedative dressings in the form of line Oxide and Oil of cloves of cotton wool or gauge is loosely tucked into the socket. This dressing is often referred to as 'Pom-Pom'.[9] The curettage of the socket to induce fresh bleeding is recommended, however, it is not advocated as the pain may get aggravated and there one chance of the infection spreading in the deeper tissue planes. Prophylactic use of antimicrobial drugs such as metronidazole and clindamycin has been shown to reduce its incidence though it is not a universal finding. The antibiotic therapy with beta-lactam group of antibiotics with metronidazole is usually adequate.

Conclusion

It must be understood that it is evident from the clinical and microbiological finding. The role of antibiotics should not be overemphasized. Empirical therapy should be primarily directed against staphylococcus (common bacteria is oral equity). Deep-seated infections require broad-spectrum antibiotics and investigation for possible surgical intervention.

Sports Dentistry: A Recent Upcoming Field in Dentistry

Sudipta Sahu[1], Kajal Kiran Sahoo[2], Sashikant Sethy[1], Nikita Sahu[1]

[1]Tutor, Department of Public Health Dentistry, [2]Tutor, Department of Prosthodontics, Institute of Dental Sciences, Siksha OAnusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Dental trauma in sports is the major linking channel between sports and dentistry. Sports dentistry deals with the prevention and management of athletics related orofacial injuries and their manifestations. Many athletes are not aware of the health implications of a traumatic injury to mouth and thus dentist can play an imperative role in informing the importance of preventing orofacial injuries in sports.

Keywords: *Dental trauma; Orofacial injuries; Sports dentistry; Prevention and management.*

Introduction

There is definite growth seen in this type of injury which is due to growing number of participants in sports and game. General dentists are seeing more dental trauma these days because patients are participating more in contact sports like football, rugby, lacrosse, ice and roller hockey, racket ball, skateboarding, cycling, basketball, wrestling, martial arts & games at very tender age.[1]

Dentistry & Sports: Jackson proposed a systemic approach for how a dental professional should interact with sports world, including opportunities for dentist in athletics. The Autor also emphasized for a "Team Dentist" from high school to professional teams.

Padilla emphasized that dentists can add sports dentistry to their practices by-

a. Making themselves available for emergency trauma care.

b. Making themselves visible and available to coaches, sports physicians, trainers, sports therapists, health clubs, youth sports league and women athletics.

Dr. Kajal Kiran Sahoo
Tutor, Department of Prosthodontics, Intern, Institute of Dental Sciences, Siksha OAnusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: dr.kajal2@gmail.com

c. Offering to speak at organization meeting, attend their games/events and developing mutual trust and credibility through community involvement.

d. Contacting trainers in school, high school or health clubs and providing brochures on injury prevention, contributing to their newsletters and explaining the need for professionally made mouth guards.[2]

Factors Playing Significant Role in Modifying Sports Injury:

They can be classified into two groups:

I. Extrinsic factors and

II. Intrinsic factors.

Extrinsic factors:

a. Improper training

b. Quality of playing surface

c. Status of equipment used/worn

d. Climatic condition e.g.: ice, rain, extreme hot etc.,

e. Quality of supervision of participants.[3]

Intrinsic factors:

a. Age: including growth & development, physical maturity, body strength, coordination & healing ability risk of injury decreases with increasing age.

b. Gender: men are more prone as there is apparent tendency for boys/men to select aggressive contact sports.

c. Body size: excessive height and weight predispose athletes to injury.

d. Central motor control: children with muscular imbalance, cerebral palsy, epilepsy and other physically handicapped children are more prone.

e. Psychological and psychosocial factors: stress, anxiety, low self confidence & performance pressure may lead to sports injury.

f. Other factors: It includes body type, nutritional status, metabolic variation and multiplicity of genetic factors.[4]

Various Sports Related Injuries:

They are classified in three categories

I. Soft–tissue injuries

II. Hard–tissue injuries/ Bone fractures

III. Dentoalveolar injuries (12%)

I. Soft–tissue injuries: They are most common maxillofacial injuries found in sports they are classified as

Injuries

- Abrasion
- Laceration
- Hematomas
- Cuts
- Burns

II. Hard–tissue injuries / Bone fractures (Figure 1).

Bone fractures	**Mandibular (56%)** Frequently seen in young persons male Frequently seen in mandibular condylar process	**Types** **1. Symphyseal** **2. Body** **3. Angle** **4. Ramal** **5. Condylar – most common** **6. coronoid**
	Zygomatic Fracture Complications include diplopia & loss of sensation in infra – orbital nerve.	
	Nasal Fracture (26%)	
	Mid facial fracture (31%)	**1. Lefort I** **2. Lefort II** **3. Lefort III**
	Frontal sinus facture Classified according to involvement of -	**Supra or bital rim** **Anterior wall** **Posterior wall** **Sinus floor**

Figure 1. Classification Hard tissue injuries / Bone factures[5]

III. Dentoalveolar injuries

- Tooth intrusion
- Tooth extrusion
- Crown and root fractures
- Tooth avulsion

These types of fractures are highly preventable by using mouthguards. Children's who are in mixed dentition period have a disadvantage with regards to dentition. When the tooth germ lies in the fracture line, the tooth can fall during healing or have delayed development that does not manifest clinically until the permanent tooth erriysts.

Prevention of Sports Related Traumatic Orofacial Injuries[6]: The use of helmet, face masks and mouthguards reduce the likelihood and severity of sports related traumatic injuries.

Helmets–They protect the scalp, brain, face etc., and prevent from direct concussions, unconsciousness, cerebral hemorrhage, brain damage, paralysis, death etc.,

Face mask: They are designed to protect eyes, nose, zygomatic arch etc., prevent from direct fractures of those bones. They are designed of different types out of which full cage mask provides greatest protection.

Mouth guards: These are appliances which aids in reducing dentoalveolar fractures, condylar fractures, neck injuries, serious CNS damage and death.[7]

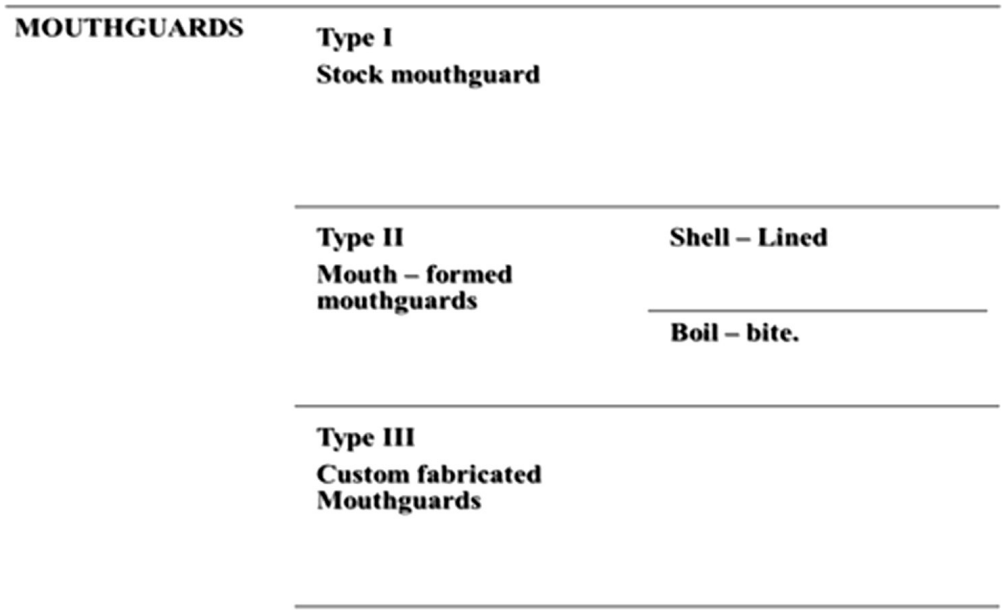

Figure 2. Types of Mouthguards

Recently academy of sports dentistry listed some 40 sports in which mouth protection will be advantageous for the participants.

- **Stock mouthguards:** They are least expensive mouthguards found in sporting goods store, and comes in different colors and styles with or without straps. They are not adapted to dentition & so held by the athlete by biting teeth together.
- **Shell–Lines mouth formed mouthguard:** They are fabricated by freshly mixed ethyl methorylate into a hard shell, which is then maxillary teeth and soft tissues, until the material sets. Though it is relatively adaptive to tooth surface but it is bulky and have unpleasant odor and taste for which it is not preferred by athletes.
- **Boil–Bite mouth formed mouthguard:** This type of mouthguard is largely used in todays world. It is fabricated by thermoplastic material placed in athletes' mouth, after softening in boiling water and molded with finger pressure as well as facial & intraoral musculature to enhance adaptive. After removal from athletes' mouth it is dipped in cold water until the shape sets firmly. It comes in wide variety of colors with or without straps.
- **Custom–fabricated mouthguards:** They are made professionally over a dental cast of athlete'sarches. They are considered superior from all types of mouthguards as they conform more closely to athletes' mouth, the material thickness can be better controlled during laboratory fabrication. They interfere least in breathing.[8-10]

Conclusion

Sports dentistry encompasses a wide range of preventive and treatment modalities of oral/facial athletic injuries and related oral diseases and their manifestations. It is the responsibility of every dentist to identify, educate and provide the athletes preventive measures e.g. mouth guards.

Abstract

Oral potentially malignant disorder is lesions with compound intraoral presentations which often obscure clinician's diagnostic skill. A missed diagnosis can subject the patient to the risk of malignant transformation as well as bring down clinician's existing reputation. This study was conducted to understand the knowledge of diagnosis and intervention of OPMDs by clinicians practicing in India through a detailed web-based questionnaire survey. Three hundred responses were collected out of three hundred fifty dental practitioners contacted. Response with respect to each question of the questionnaire was analysed. There are several aspects of diagnosis and interventions in OPMDs about which the clinicians need to update themselves so as to prevent the malignant transformations of those lesions.

Keywords: *OPMD*; *Diagnosis & Intervention; Web-Based Questionnaire Survey.*

Introduction

Oral Potentially Malignant Disorder (OPMD) are defined as morphologically altered tissue noted on clinical examination in which cancer is more likely to occur than in normal tissue.[1] It is common in south east Asian countries like India with an incidence rate reported as 0.6 to 30.2 per 1,000.[2] It is mostly attributed to tobacco. Leucoplakia, Erythroplakia, Reverse Smoker's palatal lesions, Oralsubmucous fibrosis, Lichen planus, Actinic keratosis and Discoid lupus erythematosus are few commonly encountered OPMDs. Leucoplakia, the most commonly encountered OPMD is defined as white plaque with an increasing questionable oralcancer risk after excluding other known disorders that donot increasetherisk. Lichenplanusis defined as chronic inflammatory disorder demonstrating some immunepathology chiefly characterized bywhite striae. Oral submucous fibrosis (OSMF)is defined as chronic, complex, condition of the oral cavity, characterized by progressive fibrosis of the submucosaltissues. Variants of leucoplakia and lichen planus when appropriately termed shall help in communication between clinicians and accurate prediction of the lesions. Most of the OPMDs present as white and/or red lesions which can be either innocuous or aggressive. The objective of this study is to discuss the difficulties that exist amongst clinicians during diagnosis and treatment of oral potentially malignant disorders. The present studyattempted to assess the knowledgeand awareness of a cohort of dentists inseveral states of India regarding appropriate early diagnosis and evidence-based interventions of OPMDs through conducting a web-based survey.[3]

Methodology: 350 dental practitioners were selected randomly from various parts of India. A pilot study using web-based questionnaire survey was conducted among twenty-five randomly chosen dentists. The dentists were duly contacted personally through google forms over a due course of six months. The purpose of the study

was well explained to each dental practitioner. The questionnaire was re-modified after collecting responses in the pilot study. Cronbach's alpha was estimated to be 0.85 which tested the reliability of the responses. Total 300 responses were received and results were analysed using the statistical package for the social sciences (SPSS, version 21.0, Chicago: SPSS Inc). p value <0.05 was considered as significant. A pictorial presentation of methodology is depicted in Figure number 1.

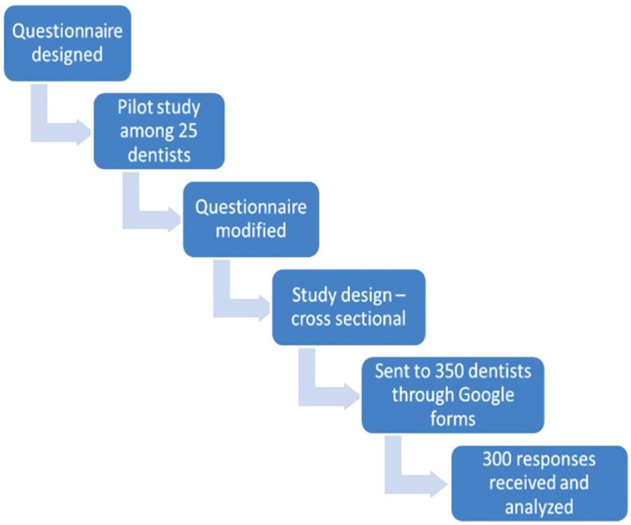

Figure 1. Methodology pictograph

Results

Three hundred responses were collected and response with respect to each question of the questionnaire was analysed and presented in table number 1. 22% of dental practitioners were ignorant of the change in terminology of oral precancer lesion and condition to oral potentially malignant disorders. While 60% of dentists get to see approximately 2-4 patients per month with OPMDs and lichen planus is the most commonly encountered OPMD followed by leucoplakia and oral submucous fibrosis.

Although leucoplakia is not a difficult diagnosis by dental practitioners however 42% of dentists were not able to diagnose proliferative verrucous leucoplakia. Furthermore, diagnosing erosive lichen planus is a difficulty for 62% dentists. 66% dentists encounter confusion in making a diagnosis between lichen planus and leucoplakia. Lichenoid reaction is not excluded by 32% dentists while attempting to diagnose lichen planus.

While determining factors to choose area of biopsy 85% dental practitioners prefer surface and consistency, duration and site were chosen by 45.7% and 33.3%. 70% of dentists do not prefer any of the chair side method to sleet biopsy area other than the visual examination only. 30 %, 20.2% and 6% of dentists chose toluidine blue, brush biopsy and light-based detection method respectively.

While almost all dentists counsel patients regarding de-addiction 74% of dentists are unaware of Tobacco Intervention Initiative programme (TII).As topical application Triamcinolone followed by vitamin A were favoured by 60% and 48% of the dental practitioners respectively whereas Antioxidants was found to be advised by 87% dentists. Diet modification was advised by only 50% of dental practitioners. Similarly, in the initial stages of oral submucous fibrosis lycopene with antioxidants and topical corticosteroid were advised by 69% and 60% of dental practitioners respectively.

Discussion

The present questionnaire-based study revealed the knowledge of Indian dental practitioners regarding diagnosis and interventions of Oral potentially malignant disorders (OPMDs).

Prevalence of oral mucosal lesions was reported to range from 16.8% to 54.18% among various Indian

populations.[4-7] This study observed a frequency of 2-4 cases of oral mucosal lesions specifically potentially malignant disorders per month. The frequency of lichen planus in this study precedes the frequency of leucoplakia and oral submucous fibrosis. While Hallikeri et alreported an prevalence of OSMF followed by leucoplakia and lichen planus, Bhatnagar et al reported highest prevalence of leucoplakia followed by OSMF and lichen planus.[4,5] The variable frequencies may be attributed to factors like population specificity, increasing stress in recent days and the ever-existing diagnostic dilemma between leucoplakia and lichen planus. There are several variants of Leucoplakia like Homogenous leucoplakia, speckled leucoplakia, Candidaleucoplakia, verrucous leucoplakia, nodular and hairy leucoplakia. Proliferative verrucous leucoplakia (PVL) is another variant which is defined as multifocal white patch characteristically present in non-habitués and females having highest potential of malignant transformation nearing about 100%.[8] The clinician should understand that the mucosa in patients with PVL has an increased propensity to develop oral precancer and cancer as because of multiple genetic abnormalities in the tissue as a whole.[9] Therefore, biopsy followed by follow up is mandatory in such patients.

Similarly, there are several variants of lichen planus like reticular, papillary, atrophic, bullous, plaque and erosive lichen planus. Erosive lichen planus has got the highest potential of malignant transformation and it should be biopsied to exclude benign mucous membrane pemphigoid, pemphigus vulgaris and OSCC. Both lichen planus and Lichenoid reaction are presented by bilateral reticular, papular and/or erythematous areas but unilateral occurrence and presence of pain differentiates lichenoid reaction from lichen planus.[10] While lichen planus is mostly stress induced lichenoid reaction is initiated by systemic medications and local allergens present in toothpaste and amalgam restorations. Immunocompetent drugs are the drug of choice in lichen planus and elimination of drugs or local allergens are the therapy of choice in lichenoid reactions.[11, 12]

The toing and froing between plaques type of lichen planus and leucoplakia is a continuous dilemma for many clinicians. Appropriate History, Bilateral presence, slightly elevated and Press with slide to see the striae are few features which help to exclude plaque form of lichen planus from leucoplakia.[13] Oral submucous fibrosis starts with marble like soft palate, faucial pillars, pharyngeal mucosa followed by shrunken uvula, blanching of buccal mucosa and retromolar region and lastly fibrosis and de-papillation of tongue and fibrosis and pigmentation of lower lip. Malignant transformation rate of OSMF ranges from 7 to 13%.

Intervention for OPMDs may include de-addiction Counselling, biopsy to rule out malignancy and pharmacologic interventions. Tobacco intervention initiative is the chief component of De-addiction Counselling. Professionally-led "call to action" programme to eradicate tobacco addiction while striving for a `tobacco free India' aiming at improving the oral health of Indians by the year 2020. Certified dental clinics where dentist offer counselling at individual, group level, behaviour therapy, self-help materials, educational CDS and books along with Nicotine Replacement Therapies (NRT). It is hereby suggested that every dental clinic may enquire a thorough habit history of patients, report that in the prescription as well as offer de-addiction counselling. In fact, patients readily accept tobacco and alcohol cessation counselling offered by the dentist.[14]

A lesion to undergo biopsy shall meet four determinants namely a non-healing ulcer, an ulcer of size more than 200 mm2, lesions with non-homogenous area, lesions in lateral border of tongue among non-habitués and females. However, this study shows that biopsy is a hard row to hoe for many dentists. The difficulty is mainly encountered during selection of appropriate site of biopsy, chair side detection method and handling of biopsied tissues. Wrong selection of biopsy site yield blunders in diagnosis and thereby increases in mortality in diseases like oral malignant neoplasms. Non homogenous areas, indurated areas and erosive areas are the appropriate sites for biopsy (reference). Biopsy from not-so-representative site may diagnose a malignant ulcer as non-specific ulcer (Figure 2). Vital staining, tissue autofluorescence and chemiluminescence are certain principles based upon which chair side screening and biopsy site determination of oral premalignant and malignant lesions is preferred. However, this study is demonstrating a high proportion of dentists (70%) not following any of the prescribed method of early detection rather they use visual examination alone for diagnosis of OPMDs. This report is supported by Kujan et alwho identified that 80% of dental practitioners strongly rely upon visual examinations alone whereas contradicted by Jaberwho identified only 24% of dental practitioners relying upon visual examinations alone.[15,16] This high percentage may have happened due to lack of knowledge in selecting the method and unavailability of cost

effective chair-side, less technique sensitive and ready to use diagnostic device. Handling of biopsied tissue is another arena where the emphasis should be given for correct diagnosis. Fixation of biopsied tissue in 10% formalin is a critical determinant of handling biopsied tissue. Oral pathologist should be given preference over general pathologist for more accurate diagnosis because of the familiarity of oral pathologist with oral lesions.[17] Histopathology report of following every biopsy especially white lesion should be carefully interpreted by dental practitioners. White lesions with presence of severe dysplasia should be excised and white lesions with mild to moderate dysplasia should be followed up in 2-4 months interval.[18] Adjunct visualization tools may be used in the follow-up of patients with dysplasia to facilitate the identification of subtle clinical changes.[18]

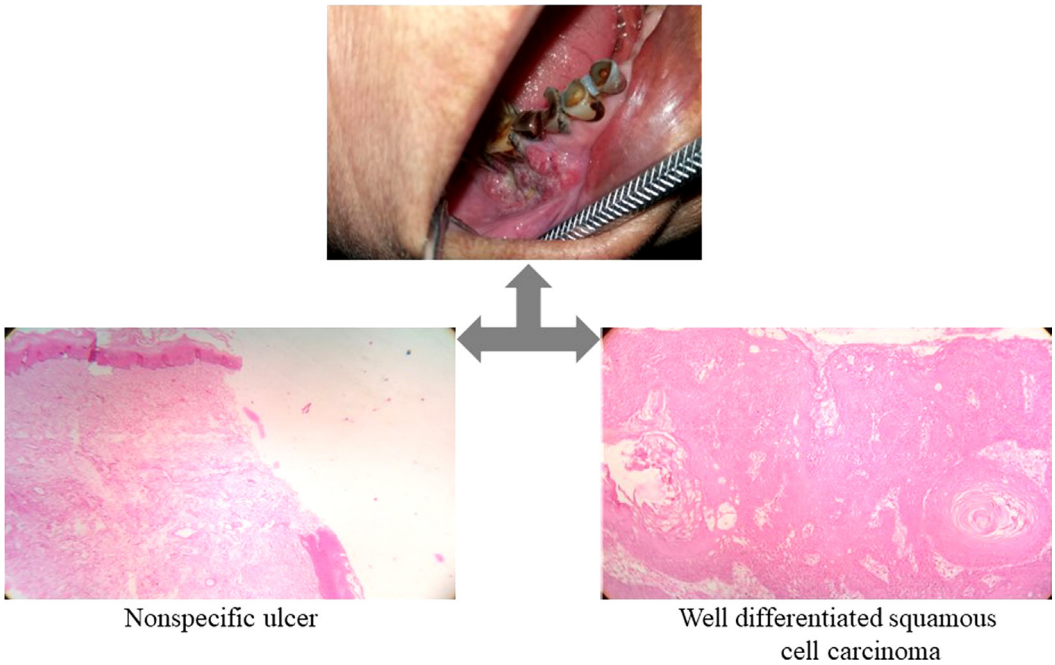

Figure 2. Importance of taking incision biopsy from appropriate site.

Triamcinolone followed by vitamin A is the choice for topical applications whereas antioxidants followed by prednisolone are the systemic medications followed by majority of dentists for the treatment of leucoplakia and lichen planus. For OSMF antioxidants followed by topical corticosteroids are the drug of choice for majority of dental practitioners. However the evidences for vitamin A in leucoplakia are low.[19] Lycopene has shown fair evidence for treating leucoplakia, lichen planus and OSMF.[20-23] Topical steroid for lichen planus and intralesional injection for betamethasone are providing fair evidence for lichen planus and OSMF respectively.[23] Although zinc is proven to be highly effective in both lichen planus(24) and OSMF the questionnaire did not include zinc which may be looked upon as a limitation of this study. There is high level of evidence for intralesional injection of dexamethasone, hyaluronidase and chymotrypsin together in treating oral submucous fibrosis.[23] Translating Evidence into Clinical Practice is the purpose of publishing quality research. This can offer the acceptable clinical care and meet the increasing awareness of the patient population. Therefore, it is better to adopt evidence-based interventions sooner rather than later. De-addiction counselling, stress management and arecanut withdrawal are first line therapy for leucoplakia, lichen planus and oral submucous fibrosis. Small size of leucoplakia requires lycopene as the drug of choice whereas large size with non-homogenous surface requires excision and lycopene as the treatment modality.[20]Follow up at regular interval is mandatory for leucoplakia irrespective of its size.[20] Anaesthetics, steroids and analgesics may be selected for topical application of lichen planus without erosive changes.[25] Tacrolimus (0.03%) once/twice a day for 6 months is In Lichen planus with ulcerations betamethasone 1mg BD for 1month followed by weekend therapy (5mg sat+ 5mg sun) as pulse therapy is the treatment of choice.[25] Intralesional injection of dexamethasone, hyaluronidase

and chymotrypsin together is the treatment of choice for oral submucous fibrosis.[23] Lycopene, diet modification along with physiotherapy only in OSMF are the adjunct therapy in leucoplakia, lichen planus and OSMF.[23]

Conclusion

Making diagnosis of potentially malignant disorders is a systematic procedure that every dental practitioner needs to understand. The process of diagnosis through careful intraoral examination is schematically presented in figure number 3. Apart from visual examination alone the clinicians are recommended to practice using various screening aids which can detect oral precancer and cancer at a very early stage thereby improving the prognosis of oral cancer and decrease the burden of mortality. There is a continuous update regarding surgical and pharmacologic interventions of OPMDs which every dental practitionerneeds to understand and implement in the clinical practice.

Occupational Hazards Associated with the Use of Mercury in Dental Office

Upasana Mohapatra[1], Susant Mohanty[2], Antarmayee Panigrahi[3], Gatha Mohanty[4]

[1]Tutor, [2]Professor & Head, [3]Reader, PhD Scholar, [4]Senior Lecturer, Department of Periodontics and Implantology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneshwar, Odisha, India

Abstract

Use of mercury in dental offices comes with a lot of disadvantages of posing threats towards both patients and the dental professionals. The clinicians are at a higher risk from the hazards of mercury. It has been found that the body fluids of the clinicians using mercury contains more amount of mercury than the clinicians of the control group.[1] The world now is approaching towards a mercury-free dentistry, where the clinicians are more inclined towards using dental materials without mercury. There are many on-going studies and researches regarding the development of ways and method to avoid mercury, i.e., Amalgam being used in the dental practice.Moreover, the proper disposal of amalgam or mercury is of utmost importance, but is being highly neglected. This article would review the proper storage, handling, disposal and recycling of mercury.

Keywords: *Mercury, Amalgam, Restorations, Disposal.*

Introduction

Dental caries, its prevention and its treatment have gained significant importance in the dental research fields. Amalgam, because of its strength and durability, has been a material of first choice by the clinicians since long.[2,3] But, because of the toxic effects of amalgam, the world health organisation has proposed "phasing down" the use of amalgam in dental office and the initiation of restorative dental materials without the involvement of mercury.[4] Because of the fact that amalgam carries the advantage of being easier to be placed in the cavity, less expensive and being durable, it still remains as the first choice for the dental professionals in the lower or middle socio-economic regions around the world.[3]

Different forms of mercury used in the dental offices: The US Department of Health and Human Services, Public Health Service, Agency for Toxic Substances and Disease Registry have stated the following:"A person can be exposed to mercury from breathing in contaminated air, from swallowing or eating contaminated water or food, or from having skin contact with mercury. Not all forms of mercury enter your body easily, even if they come in contact with it; so, it is important to know which form of mercury you have been exposed to, and by which route (air, food, or skin). When you swallow small amounts of metallic mercury, virtually none (less than 0.01%) of the mercury will enter your body through the stomach or intestines, unless they are diseased. When you breathe in mercury vapours, (from elemental mercury), however, most (about 80%) of the mercury enters your bloodstream directly from your lungs, and then rapidly goes to other parts of your body, including the brain and kidneys. Once in your body, metallic mercury can stay for weeks or months. When metallic mercury enters the brain, it is readily converted to an inorganic form and is "trapped" in the brain for a long time. Metallic mercury in the blood of a pregnant woman can enter her developing child".[5]Not only does it affect the patient, but it also affects the foetus in case of pregnant females as it crosses the placental barrier.[6]

Elemental mercury and its toxic effects: The Centre for disease control in the US, in a review

Corresponding Author:
Dr. Upasana Mohapatra

e-mail: upasanamohapatra.um@gmail.com

regarding occupational hazards in industries using elemental mercury, in 1999 (and updated in 2006) has stated that,"Short-term exposure (hours) to high levels of metallic mercury vapour in the air can damage the lining of the mouth and irritate the lungs and airways, causing tightness of the breath, a burning sensation in the lungs, and coughing. Other effects from exposure to mercury vapour include nausea, vomiting, diarrhoea, increases in blood pressure or heart rate, skin rashes, and eye irritation. Damage to the lining of the mouth and lungs can also occur from exposure to lower levels of mercury vapour over longer periods (for example, in some occupations where workers were exposed to mercury for many years). Levels of metallic mercury in workplace air are generally much greater than the levels normally encountered by the general population. Current levels of mercury in workplace air are low, due to increased awareness of mercury's toxic effects. Because of the reduction in the allowable amount of mercury in workplace air, fewer workers are expected to have symptoms of mercury toxicity".[5] This goes true as well with the field of dentistry as the same rules applies for the dental professionals regarding the storage, disposal and recycling of mercury, either elemental or in the form of amalgam.

FDA has stated that dental amalgams, in the form of restorations, are deemed safe for children above 6 years and adults because the exposure to mercury from restorations are proved to be far less than the lowest limit oh posing harm to the patients.[7] But, studies have revealed that mercury is released from the restorations on chewing food.[7,8] The harmful effects of mercury on the other systems, i.e., immune system, renal glomerular system, gastrointestinal system and on the intestinal bacteria of human beings, have also been documented.[6] It has also been proved that higher the number of dental amalgam restorations, more is the mercury levels in blood and plasma and the level rises within 3–48 hrs of amalgam removal and then drops.[9] Hence, the removal also requires a strict protocol, like hair covers, drapes, protection for eyes, rubber dam isolation and a high vacuum suctioning system.[10]

Global protocols for mercury disposal in dental offices: As published in a pamphlet by the United Nations Environment Programme (UNEP) on under the headline of "*Mercury Use In Healthcare Settings And Dentistry*", its stated that the teeth having an amalgam restoration should be considered as an amalgam waste, the wastes should be kept sealed in plastic containers and may be disposed by licenced waste disposal companies who recycle mercury and other metals, and that either placing an amalgam restoration or its removal should be avoided in pregnant ladies.[11]The American Dental Association has also published a pamphlet on the same context as "*Best Management Practices for Amalgam Waste*" in 2007.[12]Along with the disposal of mercury, its export also has seen many restrictions. The Unions in Europe, the US and Japan have banned the export of mercury since 2008.[13]The OSHA (Occupational Hazards and Health Administration) governs the environment of dental clinics regarding the safety of the patients as well as the dental officials.[6]

Requirement of informed consent from patient: In many countries, the legislation has set out rules for requirement of an informed consent from patients requiring an amalgam restoration. Countries like, Norway, Finland, Denmark in Europe have forced laws stating that the patients should be informed about the type of restorations to be placed before deciding and going ahead with the restoration. Similar laws have been enforced in few countries in the US too.[6]

Alternatives to dental Amalgam–Gallium: Because of the concerns by the public regarding the use of mercury as a restoration, dental researchers have come up with the option of using Gallium as an alternative to mercury and amalgam. They have found that when Gallium is mixed with tin and copper/nickel produces a mass which can be used as a restoration and can achieve adequate desirable properties of a restorative material.[14]

Conclusion

In spite of having the advantages of its physical properties as a restorative material, mercury use has long been tried to be avoided in dentistry. The awareness of the public regarding the toxicity of mercury also has forced the researchers to take care of the toxicity, while rendering the desired service to them. Hence, alternatives to amalgam restorations have come up and proper protocols have been followed in the storage, usage, removal and disposal of mercury in the dental offices.

Awareness, Mindset & Method Associated with Infection Control Measures in Dental Students

Karishma Rajan Rathor[1], Stithaprajna Lenka[2], Dharmashree S.[3], Sashikant Sethy[4], Radha Prasanna Dalai[5]

[1]Clinical Tutor, Department of Public Health Dentistry, [2]Professor, Department of Oral and Maxillofacial Surgery, [3]Professor, Department of Public Health Dentistry, [4]Clinical Tutor, Department of Public Health Dentistry, [5]Assistant Professor, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha O Anusandhan Deemed to be University, Bhubaneswar

Abstract

Aim: The aim of this study was to find the association between attitude and practice of infection control among 3rd, 4th and intern dental students of the College of Odisha.

Materials and Method: The study sample comprised of 625 students of the 4 different Colleges of Odisha. 15 Questionnaire was prepared related to different barrier techniques, vaccination status, infection control practices, and awareness. The sample was calculated using the statistical formula of comparison of means. The questionnaire of the CDC (Center of Contagious Diseases) was used to measure the described variables. Informed consent was taken from all the participants before the distribution of the study questionnaires.

Results: From the result of this study it was found that 62% of the students preferred to use oral rinsing agent before starting a treatment, 85.5% used the autoclave as the primary equipment to sterilize their instruments in the dental clinic, 69.8% considered that isolation is important in the control of the infection, 56.70% confirmed that hepatitis B is the most infectious disease, and only 26.51% considered it to be tuberculosis. On the other hand, it was found that the scores of knowledge, attitudes and practices were 3.74 ± 1.16, 4.59 ± 0.88, and 4.29 ± 1.73 respectively.

Conclusions: The level of knowledge was low among the students evaluated. As far as the level of practices and attitudes was considered high. The results suggest that this topic must be reinforced in the study materials so that dental students understand the importance of the risks that exist to get infected with any disease inside or outside of the dental office.

Keywords: *Infection Control Measures; Awareness; Dental Students.*

Introduction

In the medical field the high risk and chance of cross infection in dental department, in that Dentists are at high risk of exposure to blood-borne pathogens. In the dental operatory the dentist and dental assistant will be in direct contact with blood and saliva which is the important source of infection and the indirect root are contaminated instruments or environmental surfaces[1].

US Centers for Disease Control and Prevention (CDC) give the guidelines regarding the control of blood born infection and give the instructions to all the health care unit that precautions became necessary to effectively protect health-care workers, leading to the recommendations by the concerning the prevention of HIV and hepatitis B[2].

The measures for the control of infectious diseases is an important aspect for practicing dentistry as the environment where the dentist works contains many sharp instruments and involves many invasive

procedures. Various pathogens are also present in the dental office environment. Therefore, it is essential to provide better information on protection and biosecurity and to motivate everyone to comply with the infection control standards in the dental office. The identification of these risk factors is important for the creation of some sanitary strategy that prevents the control of infections in dental office[3-5].

Dental schools have the important role in the training of dental students, give them adequate knowledge regarding the biomedical waste and how maintain the infection free department to all the patients and employee working there hence, the aim of the present study was to investigate attitude and practice of infection control procedures among dental students of the 4 different College of Dentistry in Odisha, India.

Material and Method

All the individuals signed the informed consent before participating in the study. A no total of 625 undergraduate dental students were evaluated, which were evaluated in 4 different dental colleges in Odisha, May & June 2019. The sample size was calculated based on the scores obtained in the pilot test of the level of knowledge, attitudes, and practices using the mean comparison formula by software Stata 12.0, establishing a level of significanceof 0.05.

The participants were selected in strict compliance with the following criteria: Inclusion criteria: All the Undergraduate students of four dental colleges were invited to participate in the study. Students who were in good physical and mental condition and agreed to sign the informed consent were included in the study

Exclusion criteria: Students who do not want to sign the informed consent or were diagnosed with any infectious contagious disease were excluded from the study.

For the application of the instrument, the value of 0 was assigned to an incorrect answer and the value of 1 was assigned to a correct answer for each item. It was also obtained that the maximum score for knowledge was 6, for attitudes 4, and practices 5, according to the questions that were made within the questionnaire. It is worth mentioning that this methodology was repeated according to Singh et al.[6-8]

For the evaluation of quantitative variables such as the level of knowledge, attitudes, and practices, the mean and the standard deviation were obtained. For the descriptive analysis, we used the percentage (frequencies) of the qualitative. The Pearson chi-square test was used for the bivariate statistical analysis using the Stata 12.0 software.

Results

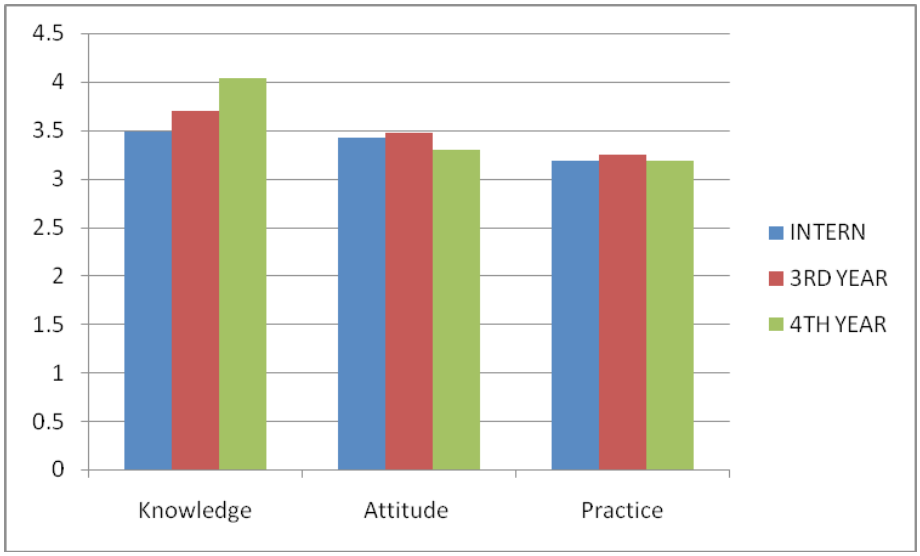
According to year of study of the students, it was found that there is statistically significant difference was found between different groups.

a) question P3 (use oral rinse before starting any procedure of a treatment) with p=0.002

b) question P6 (sterilizing the instruments in the dental clinic) with p<0.001

c) question P7 (minimum time required for autoclaving) with p<0.05

d) question P8 (temperature for autoclaving) with p=0.234



e) question P9 (highest rate of transmission through of saliva) with p<0.05

f) question P10 (immediate action taken in case of direct blood contact with a patient with HIV) with p=1.023.

Table 1. Questionnaire used in the study
Student's awareness, mindset and method in association with infection control measures

Question	Answer	3rd	4th	Intern	p*
Q1: Washing hands before and after patient examination?	Yes	249	198	124	0.327
	No	51	2	1	
Q2: what do you prefer for washing hands?	Normal soap	225	157	100	0.287
	Detergent	2	3	0	
	Medicated soap	73	40	25	

Question	Answer	3rd	4th	Intern	p*
Q3: use of mouth rinse before any procedure?	Yes	223	187	118	0.002*
	No	77	13	7	
Q4: isolation is important or not?	Yes	201	180	125	0.432
	No	99	20	0	
Q 5. Vaccinated with?	Hepatitis B	99	55	120	0.008
	Tetanus	85	86	5	
	Tuberculosis	0	0	0	
	None	116	59	0	
Q6: Method of sterilization in the dental clinic	Autoclave	296	196	125	<0.001*
	Boiling	0	4	0	
	Washing	4	0	0	
Q7. Time required for sterilization in Autoclave	5 min	10	0	0	<0.05*
	10 min	130	2	0	
	15 min	160	198	125	
Q8: what is the required Temperature for sterilization in autoclave	100° C	167	35	0	0.234
	120° C	102	140	125	
	150° C	31	25	0	
Q9: Highest rate of transmission via saliva?	Hepatitis B	99	102	120	<0.05
	AIDS	72	70	5	
	Tuberculosis	30	8	0	
	Do not know	99	10	0	
Q10: Immediate action taken in case of direct blood contact with an HIV patient?	Anti-HIV immunoglobulins	82	40	80	1.023
	Anti-HIV drugs	72	96	25	
	Blood tests	68	64	20	
	Do not know	78	0	0	
Q11: After needlestick injury, odds of HIV transmission.	0.1%–0.4%	230	45	90	
	1-4%	8	55	5	
	10%–40%	40	23	3	
	70%–90%	22	77	27	
Q12: Protective measures taken prevent yourself from injury?	Face mask and gloves	280	180	101	1.034
	Eyewear	8	0	0	
	Protective clothing	2	0	0	
	All the above	10	20	24	
Q13: Do you dispose gloves after use?	Dispose them	280	195	125	<0.05*
	Reuse them after wash	2	5	0	
	Reuse them after sterilization	18		0	
Q14: Transmission of infection from one patient to another	Yes	256	198	125	1.234
	No	10	2	0	
	Do not know	44	0	0	
Q15: Disinfection of other dental equipments is required or not?	Yes	207	200	125	2.345
	No	3	0	0	
	Do not know	90	0	0	

Graph 1: Variations showing the knowledge, attitude and practice among interns, 3rd Year and 4th year

Discussion

42% of the students are not vaccinated with the hepatitis B vaccine in our results. The knowledge level was poor among the students regarding the infection control measures. In 2010 Dental Council of India has made hepatitis B vaccination mandatory for dental students prior to admission.[9-12]

Inferable reasons could be lacking preparing for contamination control measures, deficient supply of individual defensive hardware, and heedlessness. Most understudies (94.3 percent) in our examination utilized an autoclave to sanitize instruments.[13-15] Duffy RE et al conducted a ten-year concentrate to survey frames of mind and conduct of dental understudies concerning contamination control rules.[16] In 1995, most understudies utilized an autoclave to clean instruments (83.8 percent), and this rate expanded in 2005 (95.9 percent). No understudy could depict the right weight, temperature, and sanitization time in either 1995 or 2005[17]. In any case, in our examination, 98 percent of the understudies addressed effectively about temperature and cleansing time, separately. The high level of right responses to inquiries concerning sanitization method uncovered a decent information. Method for learning, frames of mind, and practice scores were 3.75 (1.01), 3.40 (0.75) and 3.35 (1.04), separately. Staff are bound to consent to a contamination control program and presentation control plan on the off chance that they comprehend its justification. Plainly composed arrangements, techniques, and rules can help guarantee consistency, productivity, and powerful coordination of exercises.[18]

Conclusion

As per our results we find thatinadequate knowledge regarding sterilization and cross infection among the dental students and also the trainee who took part in the study. Basic sterilization protocol and how to implement it in dentistry should be taught not only to the dental students but also dental clinic staffs and paramedicos.

Dental Problems in School Children: An Overview

Shalini Mohanty

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Oral health is an important aspect of a child's overall health. Untreated oral and dental disorder can lead to severe consequences. Dental caries, pulpal and periapical lesions, trauma, Malocclusion and oral habits are most common dental problems seen in school children. Dental caries is one of the most frequent cause to seek dental care for a child. Untreated dental caries can result in pain, infection, tooth loss, difficulty in eating or speaking and poor appearance. Infection of the pulp due to dental caries result in pulp and periapical lesions. Dental trauma is extremely common in school children as they are susceptible to falling or accidentally hitting hard objects. Most common type of injury include crown fracture, luxation and avulsion. Another major problem that young children frequently engage in are oral habits. These include digit sucking, Tongue thrusting, lip biting or sucking and mouth breathing. These habits can result in various other dental problems such as gingivitis and Malocclusion. Malocclusion refers to abnormal occlusal and craniofacial relationship. In this article we will focus on these dental problems, their impact and their management and prevention.

Keywords: *Oral health, school children, dental problems.*

Introduction

Oral health is considered as the primary component of anindividuals general health. According to former US Surgeon General C. Everett Koop, "you are not healthy without good oral health". Children are more frequently affected by various dental problems. Most common dental problems seen in children include Dental Caries, Pulp and Periapical lesions, Trauma, Malocclusion and Oral habits. These dental problems can cause a severe impact on a child's social, functional and educational aspects of life[1,2].

Dental pain makes a child emotionally unstable and prevents him or her from involvement in social activities such as playing. Malocclusion reduces attractiveness and makes the child less acceptable. Traumatic dental injury especially in anterior teeth makes children anxious about others perception of them. They do not enjoy contact with other people and avoid smiling.

According to a study conducted by Jackson et al in 2008 at North Carolina, shows that poor oral health status was associated with increased parental report of low school grades. In this study low school performance was associated with school absence because of dental problems[3].

In another study conducted in 2013 dental problems were significantly associated with reduction in school performance and psychosocial well being. About 30% of children had problems in school and 80% miss at least one school day per year for illness or injury. Frequent unhappiness, feeling inferior and shyness were relatively common.

Children of all age groups are affected by various dental problems whose treatment options are expensive as well as demanding. The best option is Prevention which is acceptable and economical, especially in a country like India where there is limited man power and resources[4].

Dental caries: Dental caries is one of the most common dental disease seen in children. It is 5 times more common than asthma. About 60-90% of school children are affected by dental caries. In a survey conducted in 2004 throughout India shows prevalence of dental caries at

- 51.9%-5 years old
- 53.8%-12 years old
- 63.1%-15yeras old

It is defined as a microbial disease of the calcified tissues of the teeth characterized by demineralization of inorganic portion and destruction of organic substance of the tooth.

The most important etiologic factor for dental caries is the interrelation of the host factor;i.e, the teeth and the saliva, diet and the microflora. Saliva serves as the nutrient for the bacteria that is present in the plaque biofilm. These bacterial produce acid from the fermentable carbohydrates that is present in our diet. This acidic biofilm causes tooth decay. The critical pH for the dissolution of enamel should be 5.5. *Streptococcus mutans*is the major caries producing organism within the biofilm. Other microorganisms that cause tooth decay include *Lactobacillus acidophilus* and *Streptococcus sobrinus.* The caries susceptibility of the teeth does not only depend on carbohydrate content of the diet but also on its frequency of intake and retention of the food on tooth. Sucrose is considered the most important factor in causation ofdental caries. Other etiologic factors include socioeconomic status, presence of pits and fissures on the tooth and crowding of the teeth[5].

Pulp and Periapical lesions: Untreated dental caries and severe dental injury can lead to pulp and Periapical lesions. Microorganisms enter through these routes and cause infection of the pulp. The infection from the pulp spread into the Periapical region leading to Periapical lesions such as Periapical abscess. Dental caries is the main route of entry for the microorganismsin causation of these lesions. These lesions can affect the developing tooth buds of the succeeding permanent tooth[6].

Trauma: Trauma to the tooth is frequently seen children as they are at more risk of accidentally falling or hitting hard objects. Upper anteriorteeth are more commonly injured[7].

Classification:

By Ellis And Davey(1970)

- CLASS 1-Simple fracture involving only enamel and only little or no dentin
- CLASS 2-Extensive fracture of crown, involving considerable dentin but not pulp.
- CLASS 3-Extensive fracture of crown involving considerable dentin and exposing pulp.
- CLASS 4-Non vital tooth with or without loss of crown
- CLASS 5-Teeth lost as a trauma.
- CLASS 6-Fracture of root with or without loss of crown
- CLASS 7-Displacement of tooth without fracture of crown or root
- CLASS 8-Fracture of the crown en mass and it's replacement.

By Andreason:

- Injuries to the hard dental tissues and pulp
  - Crown infarction-an incomplete fracture of enamel without loss of tooth substance
  - Uncomplicated crown fracture–feature involving enamel and dentin but not exposing pulp.
  - Complicated crown fracture–fracture involving enamel dentin and exposing pulp
  - Uncomplicated crown root fracture–fractureinvolving enamel dentin and cementum but not exposing pulp.
  - Complicated crown root fracture–fracture involving enamel dentin cementum and exposing pulp.
  - Root fracture–fracture involving dentin cementum and pulp.
- Injuries to periodontal tissues
  - Concussion–An injury to the tooth supporting structures without abnormal loosening or displacement of tooth.
  - Subluxation–An injury to the tooth supporting structures with abnormal loosening of the tooth but without displacement of teeth.
  - Intrusive luxation–displacement of the tooth into the bone socket
  - Extrusive Luxation–displacement of the tooth partially out of the socket.
  - Lateral Luxation–displacement of the tooth in a direction other than axially.
  - Exarticulation–displacement of the tooth completely out of the socket.
- Injuries of the supporting bone
  - Comminution of alveolar socket

- Fracture of alveolar socket wall
- Fracture of the alveolar process
- Fracture of the maxilla and mandible

- Injuries to gingiva or oral mucosa
  - Laceration–a shallow or deep wound in mucosa resulting from a tear usually produced by a sharp object.
  - Contusion–a bruise usually produced by an impact from blunt objects
  - Abrasion–a superficial wound produced by rubbing or scraping of mucosa.

Severe trauma to the primary teeth can affect the germ of the developing permanent teeth. It can lead to various anomalies such as ectopic eruption, cessation of root development, dilacerations etc. Severe injuries can also lead to pulp and periapical lesions due to pulp exposure.

Therefore it is necessary to make precise diagnosis and carry out early intervention. The signs and symptoms should be recorded accurately to assess the pulp and surrounding tissues for any possible complications[8,9].

Oral habits: Young children often engage in unconscious oral habits die to some deep rooted psychological basis. These habits can create abnormalpressure on teeth and alveolar ridges leading to change in position of teeth and occlusion. These habits include[10,11].

a. Thumb sucking: Thumb sucking or digit sucking can be defined as placement of thumb or digit at various depths of mouth. Thumb sucking is considered normal till 1-2years old. If it persists beyond that it is considered abnormal and it can lead to various malocclusion.

The digit that is involved becomes reddened. The lip becomes short and hypotonic. Therefore is proclination of maxilla and retroclination of mandible which later gives rise to anterior open bite due to excessive eruption of posterior teeth. Thumb sucking causes constriction of maxillary arch due to excessive cheek pressure resulting in v shape arch.

b. Tongue thrusting: Tongue thrusting is the phenomenon in which the is placed forward and touches any tooth anterior to molars while swallowing. This results in various anomalies. Lip becomes incompetent. Proclination of maxillary anterior teeth, generalized spacing between the teeth, constriction of maxillary arch, proclination or retroclination of mandibular teeth and anterior or posterior open bite can be seen as a result of tongue thrusting.

c. Mouth breathing: It is a phenomenon in which the child has a habit of breathing through mouth instead of nose. The most common cause of mouth breathing is obstruction of nasal airway. Children with mouth breathing have an increased facial height, Adenoid facies and retroclined upper and lower anterior. Gingiva becomes inflamed and irritated because of continuous air drying.

d. Lip habit: Lip habit includes lip sucking and lip biting. The cause of lip habits may be previously present malocclusion or emotional stress. This can lead to protrusion of maxillary incisors and retrusion of mandibular incisors[12].

Malocclusion: Malocclusion is referred to the condition in which the arrangement of teeth is deviated from normal and there is abnormal occlusal and craniofacial relationship. This leads to poor esthetics and altered function. In children malocclusion can occur due to various reasons such as trauma to the developing tooth bud, oral habits such as digit sucking and tongue thrusting, various developmental anomalies like supernumerary tooth, anodontia(absence of some or all teeth), retained deciduous tooth, fusion and germination, and ectopic eruption.

During primary dentition period spacing is usually present which are called physiological spacing. The space that is present mesial to maxillary canine and distal to mandibular canine are called primate spaces. Absence of these spacing during primary dentition period can cause crowding in permanent dentition.

During mixed dentition period when the first permanent molar erupts, if the upper and lower second deciduous molars are in flush terminal plane then the permanent molars also erupt in flush or end on relationship. By the shifting of first deciduous molars to utilise the physiological space or the leeway space the permanent molars can come to class 1 relationship. If the deciduous second molars are in mesial step terminal plane then the permanent first molar erupt into class 1 relationship which later becomes class 3 if forward growth of mandible persists. If the primary second molar

is in distal step terminal plane then the permanent first molar erupt into class 2 relationship. Permanent incisors are larger than primary incisors. The difference between space that is required and that is available is called incisal liability which can be overcome by utilisation of physiologic spaces, increase in inter-canine width and change in incisor inclination. During the exchange ofdeciduous canines and molars with permanent canines and premolars some amount of space is seen known as the leeway space of Nance which is later utilized for mesial drift to attain class 1 relationship[13].

During eruption of permanent caninesthey displace the roots of the lateral incisors and central incisors mesially which results in distal divergence of their crowns. This results in midline diastema. This phenomenon is called ugly duckling stage or Broadbent's phenomenon. This condition gets corrected when the canines are erupted.

Discussion

Various preventive measures can be taken to reduce the occurrence of these dental problems. Parents should be informed about the child's oral health status and should be educated about various preventive measures. In case of dental caries pit and fissures sealant, fluoride application etc can be done. Pits and fissure sealants are used to cover the pits and grooves present on the permanent teeth to prevent accumulation of bacteria and penetration of fermentable carbohydrates as a result of which it prevents dental caries[14].

Fluoride application is very important for control and prevention of dental caries in children because of its cariostatic property. Fluoride helps in remineralisation of demineralised tooth and the remineralised tooth contains fluorohydroxyapatite crystal that are more resistant to future attack. Fluoride can be delivered in various ways. Fluoride ingestion helps in its incorporation in the enamel and dentin of unerrupted teeth which makes it resistant to caries. Communal water supply or the school water supply is the fluoridation of the water supply of the community and school. Children should always use fluoridated dentifrices. Topical fluorides can be used in form of solutions, gels, foams, varnish and mouth rinses.

Children should avoid soft foods that easily cling to the tooth and freely fermentable carbohydrates. Sugar substitutes such as aspartame, saccharine, sucralose, xylitol etc. can be used. The National Academy of science and US department of Agriculture designed a Food Guide Pyramid for school children that helps in assessing the adequacy of their diet. Prevention of dental caries can prevent the occurrence of pulp and periapical lesions. In case of infection of pulp the vital pulp can be preserved by various pulp therapy such as pulpotomy, direct pulp capping and indirect pulp capping.

In case of severe trauma parents should immediately contact a dentist after dental trauma to prevent worsening of prognosis. In case of Avulsion, parents should ask the child to keep the Avulsed tooth within the mouth below the tongue or they should store it in milk. Parents should be advised to bring there child for regular visit to the dentist to re-examine the traumatized tooth to prevent future complications.

Children involved in contact sports are more prone to dental injuries and this can be prevented by use of mouth guards. For prevention of oral habits parents counselling is most important. Parents should be asked to spend more time with the child so that they do not feel insecure. They should help the child to engage in other activities. Prolonged breast feeding and bottle feeding should be avoided. In case of thumb sucking chemicals such as cayenne pepper, quinine and asafoetida can be used over the skin. Ace bandage and thumb cap are other method of correcting the habit. Appliances that can be used for the correction of oral habits along with myofunctional exercises and speech therapy are tongue crib, vestibular screen and lip bumper

Various myofunctional appliances can be used for the correction malocclusion. Space maintainer can be used in case of early removal of deciduous teeth to prevent crowding and guide the eruption of permanent tooth, Numerous studies have been done for prevalence of these dental problems.

In a study conducted in cuttack Odisha in 2002, 1257 children of age 5, 8, 11 and 15 were examined for prevalence of dental caries. It showed increase in prevalence of dental caries from 5 to 8 years old and decreased from 11 to 15 years of age. About 63.6% children required treatment. Another study was conducted in Karnataka for prevalence of dental caries in 6-11 years of children.This showed overall caries prevalence to be 78.9% which is higher compared to other countries. In another study 333 children were examined out of which 197 children were having dental problems.

- Poor oral hygiene-41.4%
- Periodontal disease–26.72%

- Dental caries–44.4%

A study conducted on 4590 school children showed that 29.7% had habits out of which 3.1% had digit sucking, 4.6% mouth breathing, 3.2% tongue thrusting, 6.2% bruxism, 6% lip biting, 12.7% nail biting, 9.8% pencil biting and 0.09% maschistle habit. In another study 1029 children were examined out of which 57.73% had oral habits. Among them 28.8% had tongue thrusting followed by 19.5% nail biting, 12.4 % thumb sucking, 10.6% mouth breathing, 8.3% lip biting and 2.8% bruxism.

Conclusion

Establishment and maintenance of good oral health is of great importance. Good oral health can help children develop various physical and social functions. The conditions discussed in this article can help to know there impact on child's life and about there prevention and management.

Serological Investigations in Denistry

Dr. Shanta Saraswati

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

It's important for health care professionals to be aware of the medical status of their patients, so as to give them the optimal care that they can give. It helps the care giver with planning treatments and adjusting them according to the need of the patient. Serological tests are an important tool in screening the patients who are yet to be aware of their diseased state as some blood-borne pathogenic diseases like HBV, HCV etc. may remain asymptomatic. Rapid diagnostic tests can be used to get results quickly, in about 15-20 minutes, and are easy to use on site. It can further help in eliminating accidental percutaneous puncture wounds, human errors concerning safety precautions etc. which will facilitate the efforts of health-care professionals to prevent cross-contamination.

Keywords: *Health Personnel, Hepatitis B, HIV Infections, T-Lymphocytes, Helper-Inducer, Tuberculosis.*

Introduction

It's imperative for healthcare personnel, working in a dental set-up, to take appropriate safety precautions in order to avoid potential cross contamination. A set of protocols should be established by the dentist and followed strictly by the involved professionals in order to prevent transmission of communicable diseases to the patients as well as themselves. Though it's ethical for patients entering any medical set up to disclose any current or previously contracted infectious diseases, many, inadvertently or due to social stigma associated with certain diseases, are far from honest with their medical history. Many diseases like hepatic viral diseases do not show any overt signs and symptoms, therefore though infected, patients may not be aware of it. Moreover the universal safety precautions are not foolproof when variables like accidental needle-stick injuries are added to the equation[1].

Almost all dental procedures, those require the use of hand pieces and ultrasonic scalers, produce aerosols and droplets containing secretions such as oral bacteria, saliva and blood. And thus play an instrumental role in exposing a wide range of pathogenic microorganisms to the dental treatment rooms. As such, it's crucial to set a basic screening procedure for the most common communicable infectious diseases[2].

Aerosol Infection encountered in dental procedures: There is a risk of infection in every clinical setting, as patients themselves are the primary source of infection, may they be suffering from it or at convalescent stage or as healthy carriers. And the instrument used, any contacts made directly with the patients or aerosols and splatter produced by ultrasonic scalers, air-rotors etc. become the route of transmission.

Thus, the instruments play a pivotal role in exposing the clinical setup to the potential of cross contamination. Dental health-care professionals are most vulnerable to exposure from micro-organisms like mycobacterium tuberculosis, Hepatitis B (HBV), Hepatitis C (HCV), streptococci, staphylococci, herpes simplex virus type 1, HIV, mumps, influenza, and rubella[1,2].Though majority of these issues, in the occupational setting, may be mitigated through adoption of universal safety precautions, but exposure though percutaneous injuries or mucocutaneous routes (needle stick injuries, broken skin etc.) cannot be predicted.

As such, blood borne viral diseases become the

e-mail: drshanta@gmail.com

primary concern for healthcare workers and diseases like HBV, HCV and HIV, the most hazardous because of their persistent viral load in the blood.

HIV: It's a lifelong condition that has no cure till date. HIV targets the immune system by attacking a specific type of immune cells called helper T cells or the CD4 helper cells. Furthermore, it uses these cells to replicate itself, thereby causing the CD4 cells swell and burst. If left untreated the CD4 count drops below 200 per cubic millimetre and the infected person progress to more advanced stage of HIV, AIDS, within a decade (normal CD4 count in a healthy individual ranges from 500 to 1,500 per cubic millimetre). And the life expectancy of people with AIDS is about 3 years as the immune system becomes too weak to combat other opportunistic infections[3].

Prevalence: According to the India HIV estimation 2017 report, total no. of people living with HIV in India, is estimated at 21.40 lakhs (15.90 lakhs-28.39 lakhs) in 2017[4].

District-wise prevalence of HIV in Odisha: According to a report published in Odisha sun times bureau in 27th July 2015, the district of Ganjam topped the list with 35.3% of the total number of HIV infected patients[5] (Table-1).

A recent report published in The New Indian Express on 2nd December 2018 cited that total no. of HIV infected patients to be 46,264, with the district of Ganjam the most affected and Boudh the least with 59 cases[6] (Table-2).

HBV: Hepatitis B virus comes from the Hepadnaviridae family and constitutes as one of the major cause of liver disorders and later causing cancer. It's a DNA virus with some unusual retroviral characteristics. The replication of these viruses occurs through a RNA intermediate. They have the ability to integrate into the host genome and is capable of persisting in the infected cells. Immunocompetent individuals if infected have chances of recovery but in 5% to 10% cases become fatal as it progresses to liver cirrhosis or cancer. Many of the infected patients remain unaware of their infected state as acute HBV infection can be present without any symptoms indicative of the infection[7].

Prevalence: Statistics reveal that approximately one third of the world's population is infected with HBV and about 257 million being chronic carriers. Based on the prevalence surface antigen, India comes under intermediate endemicity zone. The HBsAg positivity amongst general population ranges from 1.1% to 12.2% with an average prevalence of 3-4% in India. 40-50% of hepatocellular carcinoma and 20-30% cases of cirrhosis are found amongst the chronically infected patients. Though the overall prevalence percentage remains comparatively low, India's contribution to the HBV carriers of the world ranges from 10-15% due to its huge population density[8].

HCV: Hepatitis C virus belongs to the family Flaviviridae, genus Flavivirus. They are closely related to hepatitis G, dengue and yellow fever viruses. They are said to produce atleast 10 trillion new viral particles each day. The natural targets for HCV are hepatocytes and possibly B lymphocytes. Viremia is usually accompanied by hepatic inflammation and fibrosisin case of infected patients. 50% of hepatocytes may get infected with HCV in patients suffering from chronic Hepatitis C.

Patients infected with acute HCV infection or chronic HCV infection do not show any symptoms, so patients or health care providers are unable to detect these conditions. As the initial symptoms of HCV infection are extrahepatic, astute observation for these symptoms is necessary[9].

Prevalence: In 2015, an estimated 71 million people are living with chronic HCV infection. In India, alone the anti-hepatitis C virus anti-body prevalence is estimated to be between 0.09-15% that accounts to about 6-12 million people. Among the patients suffering from chronic HCV infection, 12-32% suffers from Hepatocellular Carcinoma and cirrhosis in India[8].

Even if the primary route of transmission of HBV and HCV is through percutaneous injuries or mucocutaneous route, the virus present in the nasopharyngeal secretions spreads to the environment of the clinical set-up through aerosol or splatter produced during dental procedures[10]. HBV and HCV are found on the exposed surfaces and devices that are primarily contaminated with blood, as hepatitis B virus can survive on dried blood at room temperature for about a week, with survival up to 6 weeks on dry surfaces. Thus it becomes essential for health-care professionals to disinfect the environmental surfaces as well as properly package and heat sterilize the infected instruments[11].

Screening Method

HIV:

Three primary types of test for HIV:

1. Antibody tests
2. RNA (viral load) tests
3. Combinations tests that determines both antibodies and viral protein (P24)

No test is perfect, as such, test results may be false positive, false negative or impossible to interpret.

1. **HIV antibody tests:** when someone is infected with HIV, their body produces antibodies in order to neutralize the pathogens or the unique protein of HIV. The presence of these antibodies serves as a marker to detect if someone is infected with HIV. An enzyme-linked assay called ELISA or EIA is used on the blood sample for antibody testing.
2. **Rapid HIV testing kit:** Generally used in a health-care professional's office or points of care. Most kits require blood if not all but it can also be done using a finger stick, in some cases.
3. **HIV RNA tests:** This test has been developed to calculate the amount of HIV in the blood or the HIV viral load as the HIV RNA is different from all human RNA. These uses PCR or polymerase chain reaction technique and are helpful in screening new-borns of HIV positive mothers as it may be possible for maternal antibodies to cross the placenta and be present in the newborn. And can be used to detect HIV infection in the first four weeks after exposure, before the development of antibodies. It's not possible to perform this test routinely for screening purposes as they are costly.
4. **HIV antibody-antigen test:** It's an important test as it allows for earlier detection of HIV infection, even before the production of antibodies after initial infection. A reaction known as "chemiluminescence" is used to detect antibodies and p24 protein antigen. This test is also used to detect the type of infection, HIV-1 or HIV-2[12].

HBV: Three screening tests are done to detect three types of antibodies produced in response to three antigens present in HBV, surface, core and e. Hepatitis B surface antigen tests determines the current state of infection in the patient. Hepatitis B core antibody tests determine if the patient has ever been affected. Hepatitis B surface antibody tests determines if the persons has cleared the virus after infection or has been vaccinated and is now immune to future infection[13].

HCV: After a person is infected with HCV infections, it generally takes at least 6-8 weeks for the body to develop sufficient antibodies to be measured in screening tests. It can takes even longer for people who have suppressed immune system (e.g. HIV infected patients), and the presence of antibodies detected can't always be taken as an indication for the infected state. A positive HCV antibody test can be found in a person who is chronic carrier of HCV, or in a person who was infected but the infection has resolved, or in an acutely infected persons.

Rapid antibody test for HCV is used for individuals 15 years old or older showing hepatitis symptoms or for individuals at risk. It uses a test strip that provides results in approximately 20 minutes[13].

Table 1: District-wise prevalence of HIV in Odisha

Name of the district	No. of patients
Ganjam	12,511
Cuttack	4,696
Angul	1,234
Balesore	1,119
Khurda	1,705
Koraput	1,927
Sambalpur	1,856
Boudh	34

Table 2: Total No. of HIV Infected Patients in Different District

Name of the District	Number of Patients
Ganjam	15,034
Cuttack	6,264
Sambalpur	2,745
Khurdha	2,523
Koraput	2,356
Angul	1,652
Balasore	1,460
Balangir	1,334

Conclusion

Not every universal safety precautions are fool proof. When barrier protection like masks, gloves etc. are considered, leakage cannot be avoided when masks are not well-fitted, and masks only filter out 60-90%

of aerosols. Aerosol cloud remains in the operatory 30 minutes after the procedure has been carried out, so the masks cannot protect after its removal. Operators generally do not use two disposable gloves on each hand, which is necessary to avoid accidental needle-stick injuries. According to studies conducted, double-gloving or wearing two disposable gloves on each hand can reduce exposure to blood by upto 87%.

If the infected state of the patient is known beforehand, then the operators as well the concerned professionals can be more prepared and try their utmost to avoid any accidental errors or injuries. It will be easier to initiate appropriate post-exposure prophylaxis in case of exposure to blood-borne pathogens. Moreover, the treatment procedures may need to be adjusted according to the viral load in the blood. In case of HIV infected patients, their CD4 counts should monitored at regular intervals and contact with the patient's primary care giver should be established so as to adjust the treatments accordingly.

Various Surgical Managements of Oroantral Fistula

Shritashriya Misra[1], Sthitaprajna Lenka[2], Karishma R. Rathor[3]

[1]Intern, [2]Professor, Oral and Maxillofacial Syrgery, [3]Clinical Tutor, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha O Anusandhan Deemed to be University, Bhubaneswar

Abstract

An epitheliazed, morbid, unnatural connection connecting the oral fissure to the maxillary sinus is called as oroantral fistula, which is formed by the accident of face, surgical procedures of tumours or syphilis. For closure of this fistula there are various surgical procedures like buccal flap advancement operation, intranasal antrostomy, ashley's operation, combination of buccal and palatal flap.It require immediate attention without delay. It should be treated to avoid further complications.

Keywords: *Oroantralfistula, Buccal, palatal, flap, management.*

Introduction

Oroantral fistula evolves upon the failure of the closure of the connection. It is still remained obvious and epithelisation is also occurred. Themaxillary sinus was first described by Nathaniel Highmore in 1651. So maxillary sinus is also called as antrum of high more. These are two in numbers,one on the either side of maxilla. They are the largest paranasal air sinuses. Through the lateral wall of the nose this sinuscommunicates with other paranasal sinuses. They may be identical or asymmetrical in size and shape. Approximately the average dimension of sinus is 3.2 in height * 2.5 cm in width * 3.5 in anteroposterior (according to turner 1902). The density of the maxillary sinus is 15-30 ml. The ostium which is 3-6 mm in diameter opens into the middle meatus of the ear. One can describe it as a pyramidal shape which consists of base, an apex and four sides. The maxillary sinus base is created by the lateral wall of the nose. The apex of maxillary sinus projects laterally into zygomatic process of maxilla and it may extend into the zygomatic bone when the sinus is very large. The four walls of the maxillary sinus which looks like pyramid shaped are created by the roof of antrum which is also called as orbital floor the anterior, and infratemporal surface of the body of the maxilla and the alveolar process of maxilla which is also called as the floor of the maxillary sinus. The roof of the maxillary sinus is formed by the thin orbital plate, separating it from the orbital contents.[1-4]

The infraorbital canal, containing the blood vessels and the nerves, runs down along the roof. The maxillary sinus floor is created by the lateral hard palate, alveolar process of the maxilla carrying the roots of the premolars and the molars. The posterior wall separates the maxillary sinus from infratemporal and pterygoid palatine fossa. It is pierced by the posterior superior alveolar nerves which travel to the maxillary molar teeth. The anterior wall of the maxillary sinus is the facial surface of the maxilla.[5]

Oroantral fistula can result from several causes like extraction of teeth, Destruction of the portion of the floor of sinus by periapical lesion, perforation of the floor of sinus and sinus membrane with injudicious use of instruments, forcing a tooth or a root into the sinus during attempted removal,extensive trauma of face,surgery of maxillary sinus, removal of large cystic lesions encroaching on the sinus cavity, chronic infection of maxillary sinus such as osteomyelitis, Infected maxillary implant dentures, teratomatous destruction of maxilla such as gummainvoving palate, malignant disease such as malignant granuloma etc. Clinically in early stage patient may experience escape of fluid, epistaxis, escape of air, enhanced column of air, excruciating pain and in late stage patient may experience postnasal drip,

Dr. Shritashriya Misra
Intern, Institute of Dental Sciences, Siksha O Anusandhan Deemed to be University, Bhubaneswar
e-mail: shritishriya@gmail.com

popping out of an antral polyp, persistent purulent or mucopurulent foul unilateral nasal discharge, possible sequelae of general systemic toxaemic condition.[6,7]

Review of Literature: Closure of Oroantral fistula is a majorpredicament regarding unwanted cost of infection in sinus closure of Oroantral fistula should be performed to protect sinus from oral microbial flora,to prevent escape of fluids to eliminate existing antral pathology to establish drainage through inferior meatus. Various surgical procedures includes 1)local soft tissue flaps which have A) buccal flaps like rehrmann flap,buccal advanced flap,buccal fat pad flap, pedical buccal fat pad, buccal flap combined with displacement of the buccal fat pad. B) Palatal flaps like palatal rotation advancement flap,palatal pedicled flap, anteriorly based palatal flap,palatal hinged flap,palatal mucoperiosteal rotation flap, palatal straight advancement flap, palatal pedicled island flap, modified submucosal connective tissue flap, submucosal connective tissue pedicle flap, submucosal island flap, random palatal flap etc. C) Grafts like free mucous graft, subepithelial connective tissue graft. 2) Autogenous distant flap which have tongue flap,auricular cartilage,septal cartilage, temporalis muscle flap. 3) Autogenous bone graft–extraoral and intraoral 4) Autogenous fibrin [platelet rich fibrin]5) Allogenous–fibrin glue, dura 6) Xenografts–collagen, gelatin film, bio guide/bio oss7)Tooth transplantation 8) GTR [guided tissue regeneration], 9) Interseptalalveolotomy 10) splint 11) Biostimulation with laser light[8]

Axhausen is a professor and chair person of the transport. He was a german oral and maxillofacial surgeon who narrates the buccal flaps as a slim layer of baccinator muscular fibres which are responsible for closing of oroantral fistula. Berger advocated a procedure which is called as baccal sliding flap technique in which the closing of small to medium sized fistulas(size of less than 1 c.m) occurs. The fistulas are certainly situated laterally or centre of alveolar process. Two vertical cut are given for creating a flap with adequate dimensionfor closing of oroantral fistula after removing the epithelial margins. It is also needed to remove the epithelial covering of the palatal mucosa which usually lies behind the connection. This flap, which is trapezoidal in shape containing of both the epithelium and connective tissue, then the flap is placed over the oroantral site and sutured by using horizontal mattress sutures which is from buccal mucosa to palatal mucosa. The benefits of this buccal flap technique are that, this procedure is indicated in case of when the height of the alveolar ridge is low and in case of mesially situated fistula but, the main disadvantage is that the loss of the depth of the vestibule which needs an extra procedure which is also called as vestibuloplasty in patients with partial dentures which is usually removable.[8,9]

Egeyadi and Hao, represents that the BFP flap which is called as Buccal Fat Pad is an acceptable procedure in which the closure of the oroantral fistula takes place. The particular characteristic feature of the buccal fat pad stack is that an cut is done in posterior mucosa in the zygomatic buttress part, later that the periosteal cut is made to the affected area after that the incision of fascia which contains buccal fat pad, takes place. A fine curved artery forcep is used during the procedure of a gentle dissection for exposing the yellowish colour buccal fat. The benefits of these procedures consisting of batter and proper epithelialisation and increase the rate of achievement but decreases the vestibular height. Ashley described a palatal flap operation in which the fistula is covered with palatal flap. Therefore, the landmarks of suturing will be placed on the firm bones at the buccal aspect of orifice.[10]

Palatal tissue is denser than the buccal tissue, although it is less flexible than the buccal tissue. The sufficient supplement of blood in the area of palatal tissue structures enhanced better healing. The height of the buccal vestibule is not affected by the technique which includes the palatal flaps. Palatal rotation advancement flap enhances sufficient mobility and tissue density to the respected flap, but movement of the huge quantity of palatal tissue is needed and sometimes it leaves the scars followed by the movement of the flap which leads to venous congestion. Kruger narrated that the folding of the flap is decreased by the v shaped exclusion of the minor angulations of the flap.[7-9]

Intranasal antrostomy: It is performed to facilitate the drainage at the conclusion of an operation performed. (1) to close an oroantral fistula, or (2) to remove a tooth or a root from a sinus.An aim for the closure of major defects by the contained flaps which results failures. This procedure is called as the combination of buccal and palatal flaps. A two layered closing develops the sturdiness of the flaps and minimizes the shrinking and possibilities of infection.

A procedure, in which accessing into maxillary sinus through the canine fossa including nasal antrostomy is called as Caldwell-Luc procedure. It is given by George

Coldwell in 1893. After that Henry Luc also informed the similar technique in 1897. The indnications are: 1) open reduction for removing of pieces of roots, 2) for treatment in case of chronic maxillary sinusitis with lining of hyperplasia and polypoid deterioration of lining mucosal layer.

Another access for the closing of oroantral fistula: Ziemba reported a two layered flap procedure for closing of the fistula. According to ziemba, the benefits of using the two flaps on one flap are the procedure in which the superior surface and inferior surface of the restored area were covered by the steady covering of epithelium. These two flap techniques decreases the events ofthe contractilityand it also decreases the infection. The probability of collapsing the wound is also decreased by this two flap technique which also results the defect to be occurred ever again.[11]

Batra et al described a method for the closure of the oroantralfistula. According to him a double layer flap closure method can be used for the closure of the oroantralfistula. In this double layer flap closure method, the defect with the covering closure which includes a layer of BMF (buccal mucosal flap) is covered by BFP(buccal fat pad).[12]

The free end of the flap should have an adequate blood supply. The buccal flap is so designed, that the base should be wider than the apex; to ensure adequate vascularisation at the apex. The palatal flap should be so designed that the greater palatine vessels are incorporated in the transposed tissues and should be long enough to swing across the fistulous opening without tension or twisting at the base.Suture line is well supported by sound bone.Mobilization of either buccal or palatal flap should be done in such a manner that there is no tension on the suture line.Antibiotics,analgesics,anti-inflammatory drugs should be given for 5 days patient is instructed not to blow the nose,have soft diet and no vigorous gargling.[10-12]

Conclusion

If the oroantral fistula is identified at the correct period of occurance or at the early period, it; oroantral fistula, the alveolar ridge height, the depth of vestibule, the tenacity of defects, the inflammatory condition or infection of sinus and normal health condition of a patient etc. are contemplated as a different criteria for the different surgical procedures for it. We can close a small fistula of a size less than 5 mm in diameter immediately and by using stitching procedure, it can be effectively doneby stitching the gum with a 8 shaped stitch.

A flap technique is recommended if it doesn't enhances enough and adequate closure. Small openings can heal eventually. For closing of small and medium fistuals, buccal flap combined with buccal advancement is acceptable and in case of large oroantral fistulas palatal rotational flap is acceptable. For the defect which is placed in the 2nd and 3rd molar site, the combination of the buccal flap and the buccal fat pad is suitable. There are some widely used grafts using in current years, such as Free Mucosal Grafts(FMG) or Connective Tissue Graft (CTG). The treatment procedure for the closing of oroantral fistula must be done according to the indications and the experience of dental surgeon.**:**

Effect of Hormonal Imbalance on Jaw Growth

Subhrajeet Narayan Sahoo

Assistant Professor, Department of Orthodontics and Dentofacial Orthopaedics, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Endocrine system is an important regulator of growth and development. In childhood, it determines the longitudinal bone growth, skeletal maturation, and acquisition of bone mass. In adulthood, it is necessary to maintain bone mass throughout life. Although an association between craniofacial and somatic development has been clearly established, craniofacial growth involves complex interactions of genes, hormones and environment. Moreover, as an anabolic hormone seems to have an important role in the regulation of bone remodeling, muscle enhancement, jaw and tooth development. In this paper the influence of hormonal imbalance on jaw growth is discussed.

Keywords: *Growth hormone deficiency; Growth hormone replacement therapy; Craniofacial skeleton; Maxillary length; Ramus height; Upper facial height.*

Introduction

The activities of various organs in our body are controlled by two systems namely, nervous system and endocrine system. Most of the functions of nervous system are executed by hormonal substances. And most of the endocrine functions are controlled by nervous system. The endocrine system constitutes endocrine glands which are situated in different part of body. The functions of these glands are mediated by chemical substances which are called chemical messengers or chemical mediators or first messengers or hormones. The endocrine glands are also called as ductless glands because the hormones secreted by them are directly release into blood[1].

Hormones secreted by major endocrine glands

A. Anterior pituitary

a. Growth hormone (GH)

b. Thyroid stimulating hormone (TSH)

c. Adrenocotricotropic hormone (ACTH)

d. Follicle stimulating hormone (FSH)

e. Luteinizing hormone (LH)

f. Prolactin

B. Posterior pituitary

a. Antidiuretic hormone (ADH)

b. Oxytocin

C. Thyroid gland

a. Thyroxine (T_4)

b. Triiodothyronine (T_3)

c. Calcitonin

D. Parathyroid gland

a. Parathormone

E. Pancreas

a. Insulin

b. Somatostatin

c. Pancreatic polypeptide

d. Glucagon

F. Adrenal cortex

a. Mineralocorticoids

The Pituitary Group of Hormones[2,3]

Hypopituitarism: Decreased secretion of pituitary gland causes a condition called hypopituitarism. Decrease secretion of growth hormone may cause a condition known as pituitary dwarfism.

Clinical features:

1. Deficiency in early childhood causes stunted sphenoid bone especially spheno-occipital suture, naso-orbital configuration.
2. The nose is short, root of nose is depressed and the nasal bridge broad and flat.
3. Ossification of the cartilaginous centers is delayed and fontanels may persist to the time of adolescence.
4. In Lorain type hypopituitarism–teeth size is small.
5. In Mongolism–facial and cranial anomalies present, especially underdevelopment in the anteroposterior dimension. There is a progressive mandibular prognathism with a comparatively large tongue, cross bite and open bite.
6. Thyropituitarism–is a combined deficiency of thyroid and anterior lobe of pituitary gland. The calcification of teeth is retarded and retardation of general as well as jaw growth. The teeth are irregular and eruption is delayed.
7. The dental arch is smaller than normal and therefore cannot accommodate all the teeth so that a malocclusion develops.
8. The roots the teeth are smaller than normal.
9. Hypopituitarism in adults is usually due to an infarction of the pituitary called simond's disease, in which lips become thin and an immobile expression. No specific dental changes have been described.
10. The osseous development of the maxilla is not as retarded as that of the mandible.

Hyperpituitarism[4]: An increase in number of granules in the acidophilic cells or an adenoma of anterior lobe of pituitary is associated with hyperpituitarism. If the increase occurs before the epiphyses of the long bones are closed, gigantism results. If the increase occurs later in life, i.e. after epiphyseal closure, acromegaly develops.

Clinical features: Gigantism is characterized by a general symmetric over growth of the body, attaining a height of over 8 feet. The teeth in gigantism are proportional to the size of the jaws. The roots may be longer than normal. Acromegaly is a relatively rare disease in which lips become thick and Negroid. The tongue also becomes enlarged and shows indentations on the sides from pressure against the teeth[5].

The mandible, because of accelerated condylar growth, becomes large. The resulting prognathism may be extreme, giving the head a typical acromegalic appearance. The teeth in mandible tipped to the buccal or labial side, owing to the enlargement of the tongue.

Thyroid hormone: Thyroid is an endocrine gland situated at the root of the neck on either side of trachea. It is larger in female than in male. Its function is slightly increased during pregnancy and lactation and is decreased during menopause. Diseases of thyroid gland are more common in females than in males[6].

Thyroid gland secretes 3 hormones

1. T_3
2. T_4
3. Calcitonin

Functions of thyroid hormone

A. To increase the overall metabolic rate in the body.

B. To stimulate growth in children.

Hypothyroidism: A failure of thyrotropic function on the part of pituitary or an atrophy or destruction of the thyroid gland leads to an inability of the thyroid to produce sufficient hormone to meet the requirements of the body[7]; Cretinism, Juvenile myxedema, Myxedema

Clinical features

- Stunting of growth
- Infantile skeletal proportions and naso-orbital configurations.
- Delayed and defective tooth development.
- Epiphyseal dysgenesis.

Congenital hypothyroidism affects

1. Bone of cartilaginous origin.
2. Bone of intra membranous origin.
    - The cranial base which is of endochondral origin is disturbed and arrested in growth.
    - Length of the cranial base is shortened.
    - Retardation in normal rate of deposition of calcium in the bones and in the development of the tooth buds in the fetus.
    - In the thyroid cretinism patient has a large head and face which dull and infant facial expression.
    - Dental retardation in hypothyroidism parallels endochondral ossifications, which is extremely delayed.
    - Delayed ossification of tooth bud.

Hypothyroidism after age 6 years and before puberty can manifest itself as a juvenile myxedema. It is characterized by decrease in rate of maturation which shown itself as follow[8]:

1. Retardation in normal rate of deposition of calcium in bones and in tooth buds.
2. Disharmonies in the eruption of the teeth.
3. In adequate development of maxilla.
4. Prolonged retention of the deciduous teeth.
5. Permanent teeth are slow to erupt.
6. Mesio or disto-occlusion and crowding of teeth.
7. Malposed maxillary and mandibular incisors and canine with loss of proximal contact.
8. Openbite due to tongue enlargement.
9. Abnormal dental calcification and root resorption.
10. Alveolar bone become osteoporotic.
11. Dentoalveolar prognathism.

Hyperthyroidism: In this case there is increase in rate of maturation increase in BMR and exopthalmic goiter. Premature eruption of disturbed resorption of the roots of the deciduous teeth with early eruption of permanent teeth. Bones become fragile and secretion of saliva is increased. Acceleration of skeletal ossification. Hyperthyroidism is rare in children but when it does occur eruption of teeth accelerated; occasionally some of teeth may be present at birth. Acceleration of eruption of teeth permanent by as much as 2 years or more ahead of their normal time. Teeth may show bluish white colouring. Osteoporosis may be present. This would contraindicate orthodontic treatment[9].

Parathyroid hormone: The function of parathyroid is to maintain a normal level of diffuse calcium and phosphorus in the blood plasma and to keep constant the ratio of these minerals to each other. The act as a check on the thyroid gland parathyroids are important organs in ca metabolism and play a leading role in calcification of teeth. However, once the teeth are formed, there is no evidence found of ca withdrawal from teeth due to parathyroid disturbances. The parathyroids are important in regulating blood ca level, but have little or no direct effect on growth or tooth eruption[10].

Hypoparathyroidism: In this case Blood ca may fall to as low as 7mg/100ml (10mg/100ml is normal)**.** It Causes delay in tooth eruption and can affect morphology of teeth. Enamel defects are seen. Teeth have white appearance but later turn brown through staining. They are brittle, pitted with opaque areas and fractured easily because of poor calcification. Irregularities in occlusion of permanent teeth. In neonatal hypoparathyroidism– enamel aplasia or hypoplasia present[11].

Hyperparathyroidism: There is Increase in shifting of Ca from bones to blood stream and to excretion. Demineralization of bone occurs. Early distortion of trabecular patterns demineralization and disappearance of lamina dura may seen. In growing children there may be interrupted tooth development. Formation of osteodentin and osteocementum also may occur. The tooth may become loose as a result of loss of cortical bone resorption of the alveolar process[12].

Adrenal hormones: The hypofunction of adrenal gland has no as such effect on jaw bone and teeth. The adrenocortic hyperfunction brings about decrease in bony matrix into which calcium is deposited when bone is formed, interfering with bone formation. Height age, bone age and tooth eruption are accelerated.

Thymus: With overgrowth of thymus, general bodily growth is accelerated. Hypertrophy of the thymus may result in delayed eruption of the deciduous teeth and poor tooth calcification. The teeth may appear of bluish white colour and of uneven size.

Clinical consideration: Growth hormone and its mediators–

Mode of action on different varieties of cartilage.

1. The growth of epiphyseal cartilage of the long bones, cartilage of spheno occipital synchondrosis, lateral cartilaginous masses of the ethmoid and cartilage between the body and greater wings of the sphenoid is subject to general extrinsic factors and more specifically to GH and somatomedin. In this case orthopedic devices can modulate the direction but not the amount of growth.
2. The growth of condylar cartilage, coronoid and angular cartilage of the mandibular cartilage in some cranial sutures and cartilage in post fracture callus is subject to local extrinsic factors as well as growth hormone and somatomedin. In this case appropriate orthopedic devices may modulate both direction and amount of growth.

Growth hormone and somatomedin as well as testosterone and estrogen are seen to play a primary role in extrinsic control of postnatal growth of upper jaw. There effect is direct and indirect.

Direct effect: In represents almost the entire influence of GH and somatomedin on growth of the s-o synchondrosis and nasal septal cartilage, lateral mass of ethmoid bone and between body and greater wing of sphenoid.

Indirect effect: Indirect effect of GH somatomedin occurs through a number of intermediators.

1. Forward growth of septal cartilage
   a. Thrust effect
   b. Septomaxillary ligament traction effect.
   c. Labionarinary muscle traction effect
2. Outward growth effect of Frankel lateral vestibular–shields on widening of upper jaw.

Control of mandibular growth: Any research investigation on the control mechanism of craniofacial growth should take into account not only local and regional extrinsic factors but also general factors.

Growth in mandible is due to

1. Postural hyperpropulsor

   Function appl–Lat pterygoid muscle activity–increase in rate and amount of condylar cartilage.
2. Class II elastics
3. Herren–type activator

Conclusion

Anomalies of endocrine gland origin manifest themselves dentofacially as follows Characteristic changes in facial appearance due to retardation or acceleration of the growth of face. Changes in rate of eruption, order of alignment and relationship to each other or individual and groups of teeth in the same jaw or in the opposite jaw.

Abstract-

From that of the operator to that of the patient research continues in both dentistry and medicine with the goal to improve experience of all areas of the local anaesthetic, as local anaesthesia remains the backbone of pain control in dentistry. Much of this research is focusing on advancement in the area of local anaesthesia safer syringes and needles; articaine hydrochloride and oraqix like newer drugs; reversing local anaesthetic like phentolamine mesylate; Intraosseous anaesthesia; electronic dental anaesthesia (EDA), transcutaneous electrical nerve stimulation (TENS) and computer-controlled local anaesthetic delivery (C-CLAD) systems; clonidine as an adjuvant to local anaesthetics for peripheral nerve blocks; vibrotactile devices like vibraject and jet injections like syrijet. These devices and drugs are part of the mainstream for control of pain in the various parts of the world in recent days. The article reviews the up to day advancements in the agents and techniques for local anaesthesia, depicting the most mandatory aspect of today's dentistry and enlightening some of the advancement of the same.

Keyword: *Local Anaesthesia, Lingual Nerve, Pain Management, Paresthesia.*

Introduction-

Since the early 19th century local anaesthesia has proved its vital role for the subsidence of pain related to invasive procedures in the clinical dentistry especially proving its importance in oral and maxillofacial field. Adequate amount of anaesthesia of the working field must be achieved in order to increase patient's cooperation as well as comfort. Local anaesthesia has proved its designation as one of the most important drugs in dentistry. Pain control has remained the building block of all the dental procedures. Thus we are putting forward a bird's eye view over the advanced anaesthetic techniques that have came into existence till date. "Local anaesthesia has been defined as loss of sensation in a circumscribed area of the body caused by depression of excitation in nerve endings or inhibition of the conduction process in peripheral nerves".[1]

Articaine: In the month of April 2000, the Food and Drug Administration (FDA) approved articaine as a newest addition to the local anaesthesia. 1:100,000 or 1:200,000 epinephrine in the strength of 4% is the available amount of for Articaine hydrochloride(HCL). As liked that of other local anaesthetics agents the amide structure of the articainesuch as low systemic toxicity along with its wide therapeutic range. Diffusion of it is superior through bone and soft tissue than other various local anaesthetics. 60% to 80%of the articaine HCl approximately being bonded tog-globulins and serum albumin, thereby helps in getting expeditiously plasma is having the similar structure on a contradiction that it is not having a benzene ring rather contains a thiophene ring and an extra ester group, thereby permitting articaine to be subjected to biotransformation in the plasma (hydrolysis with the help of plasma esterase) along with in the liver (with the help of hepatic microsomal enzymes). For meeting the purpose to be used in clinical dentistry simultaneously satisfying the clinical needs for most importantly pain management in the maximum of the patients undergoing dental procedures[1,2].

Rather than other amide type local anaesthetics the properties of carboxyes terase to its primary metabolite–articainic acid–that being an inactive metabolite being secreted by the kidneys, 20 minutes being the half life of the elimination. Of about approximately 2 hours for nerve block and up to 1 hour for infiltrations of

the complete anaesthesia simultaneously within 1 to 9 minutes after injections the onset of the anaesthesia occurs. 2 ml of Articainehydrocloride boosts the extraction of teeth in maxillary arch (without any palatal injection) to the buccal vestibule of the tooth as comparison to the lidocaine, due to the articaine's better soft tissue and bone diffusion and penetration property. For the production of adequate anaesthesia in mandibular premolars and mandibular anterior teeth with the help of localized field blocks(infiltrations) without administration of mandibular blocks,Articaine has received a lot of popularities in such cases[3].

A randomized prospective, double blind cross over study looked at lidocaine andarticainebuccal infiltration anaesthesia in mandible, and the study depicted that "mandibular buccal infiltration is more effective with 4% articaine with epinephrine than with 2% lidocaine with epinephrine in achieving pulpal anaesthesia. Both injections were associated with mild discomfort. When articaine was compared with mepivacaine 2%, the results indicated that 4% articaine was superior to 2% mepivacaine in depth of anaesthesia, mainly over the first 60 minutes." With the application of articaine HCl paresthesia of the tongue, oral tissue and lips have been reported which is persistent, with slow, incomplete or no recovery. This adverse event is reported mostly following inferior alveolar nerve block and seems to involve most oftenly the lingual nerve.[4]

The articaine's metabolism appeared of being age-independent in those of the healthy male volunteers, thus there is no requirements in changing the dosage of the elderly patients, on a note of contradiction patients with having history of heart blocks should be handled cautiously, aswellas in patients at the time of or after the administration of potent general anaesthetic agents, as because such conditions may lead to cardiac arrhythmias. Many cases have been reported of having systemic allergic conditions due to the administration of Artcaine. Under the Pregnancy Category C,the Articaine is classified and is only prescribed during pregnancy on the basis of the condition that the benefit is anticipated for justifying the risk to the fetus"[5].

Oraqix (Lidocaine & Prilocaine Periodontal Gel 2.5%/2.5%)[6]: In 2004, a topical anaesthetic agent was introduced which was basically designed to be used by dental hygienists,namely Oraqix (Dentsply Pharmaceutical, York, PA, USA). The Oraqix had been approved by the FDA especially for the periodontal applications. It is designed basically for those who necessitate localized anaesthesia in the periodontal pockets during root-planing and/or scaling procedures and is basically a needle free subgingival anaesthetic.[7]

In order to facillitate easy application into the periodontal pockets that demand scaling and root planing, Oraqix is available as oil in the room temperature. It is solidified into an elastic gel at body temperature, facillitating it to stay in proper position while the anaesthetics take effect, once the application procedure is over[8].

By the use of a blunt Oraqix applicator, it is applied onto the margin of gingival of the chosen tooth. After 30 seconds of the application procedure, scaling and root planning may be started and the effect of anaesthesia remains for a duration of around 20 minutes[9].

Reversing Local Anesthesia: At the time of the follow up appointments, many individuals having comparatively less invasive procedures like restorations have complaint to their operator regarding the difficulty and displeasure of unable to drink, eat, or speak normally after their dental session for many hours after the treatment, due to the fact that tongue and/or lip of the patients being numb. The fact of a patient leaving the dental office with continuing soft tissue anaesthesia persisting for several hours is quite not acceptable as because most of the dental treatments are not at all invasive to such extent[10]. The reversal of the local anaesthesia must be followed for the patients having minimal invasive procedures along with those of the pediatric patients, so that they can be satisfied.

Thus for reversal of the anaesthesia of soft tissue and the associated functional deficiency which originates from a local anaesthetic agent, the FDA approved OraVerse (phentolamine mesylate) in May 2009. OraVerse is accepted for usingin both children and adults; however, for the children not older than 6 years or weighing not more than 15 kg, it is highly contraindicated to use.[2]

"OraVerse is an assemblance of phentolamine, which is basically a-adrenergic antagonist. The hypothesis for the mechanism of action is that phentolamine acts as a vasodilator, resulting in faster diffusion of the local anaesthetic into the vascular system and away from the site, thereby reducing the unwanted side effects of lingering lip and tongue numbness".[2]

Buffering Local Anaesthetic in Dentistry: The prefilled local anaesthetic cartridge is the primary problem(as related to buffering) in dentistry. It is practically not desirable for the manufacturer of a local anaesthetic to introduce buffered cartridges due to the reason that the addition of NaHCO3 must be occurred within minutes of injection. By defenestrating a volume of local anaesthetic from the cartridge and interchanging it with the same volume of NaHCO3, thus dentists make an effort to buffer the local anaesthetics. This in turn leads to buffering led to originate results at variance[11].

A means of routinely buffering cartridges of local anaesthetic along with a pH range is between 7.35 to 7.5 is being provided by a newly introduced product(February 2011).[1]

Electronic Dental Anesthesia (EDA): The Gate Control theory is proposed by Melzack and Wall in the year of 1965 explain the mechanism of EDA by which acute pain in the course of any dental or surgical procedure is prevented. EDA is used at a higher frequency (> 120 Hz). At this frequency, a special sensation is experienced by the patient is caused by EDA. The sensations of pressure, touch and temperature is transmitted by larger diameter nerves (A fibers), which is stimulated by EDA.

If a minimum threshold intensity of a fiber stimulation is maintained by the patient; then impulse of the pain induced by the surgical or dental apparatus like blade, curette or high speed drill that is more slowly transmitted to central nervous system through the smaller C and A-δ fibers, will come on a close gate. Hence, it will not be able to get in the brain, where physical pain is translated by it. Thus, central transmission of overall effects of small fiber input is inhibited by the large fiber input. The sensation of the pain does not arise because the impulse of pain fails to reach the brain.[12] The pleasant recovery postoperatively from local anaesthesia is provided bythe application of EDA at a low frequency setting for 30 to 60 minutes at the completion of operation.

Transcutaneous Electrical Nerve Stimulation (TENS): In order to shorten the duration of residual soft tissue anaesthesia in the year of 1980 this technique named TENS(Transcutaneous electrical nerve stimulation) became successful. In order to rehabilitate from the injury related to the soft tissue as wellas for the medicines to be used for sports, TENS is used.

Anelectrical current of low frequency deliver to the area once after the electrodes are placed at the site of the injury. The patient in benefitted in two ways after the low frequency (2.5Hz) electrical current is applied to the site of the recently injured area. i.e. perfusion of the tissue produced by arteriolar and capillary dilation is increased by its action and along with the contraction of skeletal muscle is stimulated. The area of application of the current is a cyclic process of pumping actions which is the resulting effect of these two above mentioned processes. Thus in order to reduce oedema (skeletal muscle stimulating effect) a treatment of 1hour duration is given at a low frequency therapeutically, and thereby increasing the perfusion and skeletal muscle stimulation thus portraying for “cleansing” of the injury breakdown products of the tissue area.[13]

Computer-Controlled Local Anaesthetic Delivery (C-CLAD): It is invented in the year of 1997. Primitively it is called the WAND and later renamed as the Compu Dentis the first local anaesthetic delivery system which is controlled by computer.

With the help of C CLAD devices practitioners can precisely supervise the rate of delivery of the local anaesthetic solution. In addition, a concept of disposable handpiece weighing not more than 10 gis introduced by C CLAD which facilities clinician to grasp it in a pen-like fashion, so tactile control is increased and dexterity during injection is improved. C-CLAD devices represent a significant improvement for injection which is given subcutaneously and have markedly give better results and also involvements for so many of patients over the last 10 years, helping toreduce the “fear factor” which is become so intimately associated to the dental visits.

In 2001, Hochman and colleagues advanced the science and understanding of subcutaneous injection fluid dynamics by identifying a predictable method for measuring the precise value of fluid exit-pressure in situ (at the tip of the needle) during drug administration. This led to the next significant improvement in C-CLAD technology–the development of an instrument for medical and dental injections capable of controlling all variables of a subcutaneous injection event. This instrument was initially named the Compu Flo (Milestone Scientific). This approach to fluid injection dynamics is called dynamic pressure-sensing (DPS) technology, which was developed for the delivery and aspiration of medicaments.[1]

Clonidine as an Adjuvant to Local Anaesthetics for Peripheral Nerve and Plexus Blocks:

Clonidine, an α_2 adrenergic agonist, was initially used for its antihypertensive properties. For blocking peripheral nerve and plexus it may be a fruitful ancillary to local anaesthesia. The anaesthetic duration and blockage of sensation is lengthened by about 2 hours. However, risk of arterial hypotension, bradycardia, fainting and sedation are enhanced by clonidine, and also span of the motor block islengthened by it.[4]

For dental extraction by infiltration anaesthesia in maxillary arch adrenaline at 10 μg/ml and clonidine at 15 μg/ml can use as add-on with the lignocaine harmlessly; an equal profit over use of only lignocaine can be achieved with inclusion of any of these two drugs; in terms of prolonging the span of anaesthesia and lowering the blood loss but, with no momentous hemodynamic changes and with no disparity in the onset of anaesthesia.[5]

Vibrotactile Devices: Relieving pain with the help of vibrotactile stimuli is a renowned aspect; dentists use vibrations to reduce the pain which arise from infiltration anaesthesia in maxillary arch for numerous years. To divert the brain from the disquiet of the anaesthetic injection by pinching and shaking the cheek is extensively employed with enormous profit. The sense of pain from thrust of the anaesthetic solution entering to the tissue is reduced as a result of the cerebral cortex of brain is concentrated on the vibration.[2]

Recently 4 devices are marketed in the United States that tries to decrease pain at the site of injection by depending on vibrations. Examples like Vibra Ject, Dental Vibe & Accupal.

Jet Injections: The principle of Jet-injection technology is utilizing a mechanical source of energy to builda release of pressure adequate to push the liquid medication through anorifice which is very small, developing a thin fluid column with sufficient force that it can pass through soft tissue without a needle into the subcutaneous tissue.[2]

Advantages of jet-injectors over classical needle injections are it is easy and fast to use, deliver less pain, less trauma to tissue,from injection site drug absorption is faster. Chances of infection are also less because of needle free injectors which can occur from a procedure using needle. Jet-injection used exclusively for topical anaesthesia (not pulpal anaesthesia) because of its major drawback in dentistry is that only sufficient amount of anaesthesia can express to anaesthetise the soft tissue. Examples: Syrijet, Med-Jet.

Intraosseous Injection: Local anaesthetic is less efficacious in patients having pain of irreversible acute periradicular inflammation or pulpitis. In this technique local anaesthesia is deposited into cancellous bone directly alongside to the tooth is indicated to anaesthetise and mostly used for endodontic purpose. Example: Stabident, X-Tip, IntraFlow.

Conclusion

This article thus deals with inkling the newer anaesthetic techniques together with its aspects dealing with the safety, efficacy, and simultaneously dealing with the negligible soft tissue infuriation.

Bisphosphonates Related Osteonecrosis of Jaws

Suchismita Kundu[1], Smita Rani Priyadarshini[2]

[1]Intern, Institute of Dental Sciences, [2]Associate Professor, Department of Oral Medicine and Radiology, Institute of Dental Sciences, Siksha O Anusandhan Deemed to be University, Bhubaneswar

Abstract

Bisphosphonates are the resorptive drugs prescribed for treatment of osteoporosis. Bisphosphonates related Osteonecrosis of Jaws is an adverse effect of bisphosphonate therapy. There are some associated risk factors like dentoalveolar surgery, duration of therapy and immunosuppressant therapy. This can be treated conservatively or surgically but prevention of this condition is preferred. This paper briefly reviews osteonecrosis associated with bisphosphonate therapy.

Keywords: *Bisphosphonates, Osteonecrosis, Osteoporosis.*

Introduction

Bisphosphonates are drugs used for treatment of post-menopausal and glucocorticoid induced osteoporosis, Paget's disease, osteolytic and osteoblastic bone metastases, Fibrous dysplasia, heterotrophic ossification, myositis ossificans and also used with radioactive technetium for bone imaging.[1,2] Osteoporosis is the most common resorptive disease worldwide which has increased the use of antiresorptive drugs including bisphosphonates.[3] Bisphosphonates suppress osteoclasts and decrease remodelling of bone thus raising bone density. Bisphosphonates are used as first line drugs for treatment of osteoporosis as they show decreased risk of fracture and are widely used.[4]

Although it is the most commonly used drug and has many benefits, Bisphosphonates Related Osteonecrosis of Jaws (BRONJ) is a severe side effect of bisphosphonate.[5-8] The first article on BRONJ was published in 2003.[5] After that many cases were reported[9-12]

Definition: The American Society for Bone and Mineral Research defined BRONJ to discriminate it from other conditions as:[13]

Corresponding Author:
Dr. Suchismita Kundu
Intern, Institute of Dental Sciences, Siksha O Anusandhan Deemed to be University, Bhubaneswar
e-mail: suchismitakundu@gmail.com

a. History of treatment or undergoing treatment with a bisphosphonate;
b. Bone in the maxillofacial region that has been exposed and has persisted for >8 weeks
c. No radiation therapy to jaws

But, in stage 0 BRONJ the bone is not exposed so the definition was updated to "exposed or otherwise necrotic bone."[4]

Pathogenesis: Bisphosphonates cause inhibition of osteoclasts and decrease remodelling of bone, but remodelling is necessary for healing.[1] Invitro, they produce toxic effect on the soft tissue of oral cavity during oral administration but in vivo it is not clear if it attains toxic levels to effect soft tissues.[1] Bisphosphonates have antiangiogenic property i.e. suppress angiogenesis, regeneration of capillaries and epithelial growth factor.[5] Osteonecrosis due to bisphosphonates is due to high turnover of jaw to outside environment through teeth and periodontal ligament.[2,6]

Epidemiology: BRONJ was found to be 0.7/100,000 persons/year of exposure.[7] In a study in Australia it was found that patients treated weekly with Alandronate showed a frequency of 0.01-0.04%.[8] In long-term oral bisphosphonate recipients prevalence of BRONJ was found to be 0.06% whereas for Alandronate it is approximately 4%(9 out of 208 patients).[1] By first report from Asia, prevalence of oral BRONJ was noted as 0.05-0.07%.[1,9]

470 cases of BRONJ were assessed in a multicentric

study from Europe and 37 were due to oral use(7.8%). According to AAOMS mostly those cases were not having any risk factors for BRONJ. BRONJ occurs more with IV use than oral use.[10,11]

Risk Factors

By AAOMS:

I. Drug related:

a. Bisphosphonate potency: Zolendronate is mostly used as intravenous drug for treatment as it is more potent than bisphosphonates and intravenous bisphosphonates cause more Osteonecrosis. Bisphosphonates are of two types

- Nitrogen Containing: Alendromate, Risedronate, Ibandronate. Have higher risk of BRONJ.
- Non Nitrogen Containing: Etidronate, Tiludronate, Clodronate. Have lesser risk of BRONJ.

According to a study by Deniz-Freitas et al, Alandronate was mostly prescribed compared to Ibandronate which explained higher cases of Osteonecrosis due to Alandronate or it can be due to the dose, potency and half-life and factors related to absorption of drug.[12]

b. Duration of therapy: Bioavailability of oral bisphosphonates is lower than intravenous so used for longer duration but treatment for >2 years has higher risk of BRONJ. Due to higher and faster accumulation of oral bisphosphonates in bones there are more cases of BRONJ[13]

II. Local risk factors: Surgical procedures like periapical surgery, extractions, implants and periodontal surgery, poor oral hygiene are other risk factors.[1] Injury due to ill-fitting dentures may cause BRONJ as bisphosphonates decrease proliferation of keratinocytes.[1] According to researchers, patients with infections in mouth and receiving bisphosphonate therapy have more chances of developing BRONJ.[14] Trauma to the bone cause BRONJ as bisphosphonates reduce remodelling of bone.[1] It is mostly seen in mandible and thin mucosa over bony prominences.[15]

III. Demographic and systemic factors: Elderly patients (>65 years) are more commonly effected as post-menopausal women mostly have osteoporosis and are given bisphosphonates.[22] Diabetes, kidney diseases, immunosuppressant therapy, smoking, decreased haemoglobin, rheumatoid arthritis are systemic risk factors. Prednisone and methotrexate also cause BRONJ due to further decrease in remodelling in cases of bisphosphonate therapy.[16,17,18]

IV. Genetic factors: BRONJ may be caused by single nucleotide polymorphism in cytochrome P450 and IGF-1 genes[1]

V. Preventive factors: Risk of BRONJ can be reduced by regular dental checkups and treating other oral diseases before starting bisphosphonates (as recommended by AAOMS Taskforce on BRONJ)[17]

Clinical features and other findings: Patients may or may not show symptoms. Exposed alveolar bone may be found during routine dental checkup. There may be pain or other infections. It may be due to some dental prosthesis or other dental treatment but at times no obvious factors may be detected.[16] Detection of BRONJ can be done by panoramic radiographs, dental cone beam or spiral computed tomography. But panoramic radiographs and computed tomography are not very useful in detecting early stages of BRONJ. Scintigraphy, MRI or PET scan can detect BRONJ even there is no clinically exposed bone. Risk of BRONJ may be detected by the marker serum C-Telopeptide crosslink of Type 1 collagen(CTX) but its role is controversial.[19,20]

Management: Preventing infection of necrotic bone and reducing symptoms is the aim of BRONJ management. No treatment is required for patients at risk but patient education regarding symptoms and clinical manifestations is important.

Stage 0-Patients can be given analgesics when indicated.

Stage 1-When there is no sign of inflammation, the patient should be advised antimicrobial mouth rinses to prevent infection of exposed bone and evaluation should be recalled and re-evaluated every 3 months.

Stage 2 and 3-Oral antibiotics and mouth rinses are indicated. Surgical procedures may be required for removing necrotic bone. To reduce soft tissue irritation superficial debridement should be done. If systemic conditions allow, bisphosphonate therapy may be modified or stopped. Aggressive surgery is controversial as bisphosphonates affect remodelling of bone but for

large area of necrotic bone or pathological fractures, radical surgeries like resection may be done to mitigate infection and pain.[21,22]

Hyperbaric oxygen, platelet-rich plasma, lasers and parathormone may be used.[23,24] Hyperbaric oxygen increase tissue repair, angiogenesis and kills micro-organisms and reduce edema. It also ameliorates wound healing.[25] Parathormone increases bone remodelling and healing capacity. But in patients with metastatic cancers it should be avoided as it may cause skeletal metastases.[26,27]

Prevention: Risk of BRONJ can be reduced by prevention strategies. Oral hygiene of the patient should be improved before starting bisphosphonate therapy. Risk of developing BRONJ is seen in therapy for >3 years. So, for surgery, adjustments should be made based on the duration of bisphosphonate therapy. For patients on therapy for <3 years or with no clinical risk factors no modifications are required before surgery and CTX levels may not be evaluated. Regular follow-up is required for patients with implants. Drug should be stopped at least 3 months before surgery if a patient is on corticosteroid and bisphosphonate therapy for <3 years with existing systemic conditions.[1,17] According to Marx et al if CTX value is >150pg/ml or higher surgical procedures can be performed on a patient without any risk of osteonecrosis but if it is <150pg/ml then the surgery should be delayed or drug should be stopped.[22,27] It is to be resumed only after healing.[1]

As the bone turnover markers are inhibited even after years of cessation of bisphosphonates, the exact period of pathological effects of the drug are not clear.[1,20]The American Dental Association disapproves the use of CTX as a resorption marker and support the idea of cessation of bisphosphonates if there are potential risks of fractures and decreased bone density, not because of the risk of development of BRONJ.[28,29,30,31]

Prognosis: The consequences and clinical course of BRONJ is dependent on the preceding factors and the concomitant status. It was found in a study consisting of 30 patients that patients with BRONJ healed in 8 months but in patients with extracted tooth and BRONJ healed after 18 months and those with concomitant conditions took a longer time to heal(20 months).[29]

Table 1.: As suggested by Ruggiero et al at American Association of Oral and Maxillofacial Surgeons (AAOMS) in 2009. Clinical staging of BRONJ [1, 17, 21]

At risk category	No evident necrotic bone seen in patients who were treated with either oral or IV bisphosphonates
Stage 0	No clinical evidence of necrotic bone but non-specific clinical findings and symptoms
Stage 1	Exposed/necrotic bone in patients without symptoms and without manifestation of infection
Stage 2	Exposed/necrotic bone with accompanying infection indicateded by pain and erythema in the area of the exposed bone with or without pus discharge
Stage 3	Exposed/necrotic bone in patients experiencing pain, infection and one or more of the following:, Fistula present extra-orally, Pathological fracture or osteolysis upto the inferior border

Conclusion

Bisphosphonates are one of the most prescribed anti-resorptive drugs used for treatment of osteoporosis. The chances of BRONJ is very rare but it should not be disregarded. Patients who do not undergo regular dental check-up or have associated risk factors like poor oral hygiene, immunosuppressant therapy, cancer are required to go through thorough dental check-up before or after beginning of therapy. Quitting smoking and drinking, regular dental checkups and educating the patients regarding initial symptoms of BRONJ is required. Early detection and management brings favourable outcomes. Wherever possible, invasive surgeries should be circumvented in cases with bisphosphonate therapy and associated risk factors.

Endocrinologists, physiatrists, rheumatologists are the physicians who prescribe bisphosphonates for osteoporosis, should be acquainted with the risk of development of BRONJ and should work in line with dentists.

Distraction Osteogenesis for Correction of Mandibular Deficiency and Disorder: An Overview

Sthitaprajna Lenka[1], Aditi Ava Rath[2], Loknath Sahoo[3], Karishma Rathor[4]

[1]Professor, Department of Oral & Maxillofacial Surgery, [2]Post Graduate Trainee, Department of Oral & Maxillofacial Surgery, [3]Senior Resident, Department of ENT & Head and Neck Surgery, IMS & Sum Hospital, [4]Tutor, Department of Public Health Dentistry, SSR Raghu Ram, Intern, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Distraction osteogenesis is a worldwide accepted recent approach in the field of surgery. As on date the craniofacial surgeons, across the globe, prefer the distraction osteogenesis technique over conventional reconstructive surgery by bone graft. This paper attempts to review a brief knowledge of the mandibular distraction osteogenesis and the latest developments in the field.

Keywords: *Distraction, Osteogenesis, Correction, Mandibular Deficiency, Disorder.*

Introduction

Distraction osteogenesis (DO) is a modern alternative to many of the traditional orthopaedics surgery. It is the biological process for de novo formation of new bone and adjacent soft tissue between surgically osteomised bone segments, gradually separated by traction force with the help of various distraction devices (DD). The forces exerted by the distractor not only forms callus and its mineralisation but also stimulates the surrounding soft tissue which is termed distraction histogenesis. Application of DO in craniofacial surgery created a new era for facial malformed bone reconstruction and rectification over traditional orthognathic surgery. Mandibular deficiency and disorder may be congenital or acquired[1]. The mandible is reported to be the most susceptible bone for growth anomalies than any other osseous structure in the human skeleton. DO being the versatile and promising technique is gaining momentum for surgeon's choice to rectify the mandibular deficiency and reconstruction[2]. The present review is aimed to give an overview of the principle, devises and mechanism, distraction histogenesis of DO in general and mandibular distraction osteogenesis (MDO) in particular through review of pertaining literatures.

Principle and mechanism of DO: The mechanical devises as the distractors and biological principles of DO together enhance the healing process and success in the mandibular reconstruction. DO is a process of new bone formation through a reconstructive surgical sequence. Osteogenesis is initiated at the osteotomy site when haematoma is formed surrounding the osteomised bone segments and promote the formation soft callus. The callus is stretched by some DD in the principle of "tension–stress"[3]. Thus, a new dynamic microenvironment leads the cellular proses of osteogenesis. The sequential process of DO can be described under two major sub headings viz. presurgical phase and operative phase

i. **Presurgical or preparatory phase:** This is a planning phase where the radiodiagnosis helps the planer to assess the magnitudes of mandibular deficiency or disorder for distraction, selection of DD, vectors (direction and amplitude) and adequate mandibular bone stock for placement of the distractor[4]. Sometimes presurgicalorthodontic preparation also helps to guide the distraction for occlusal correction. In this phase the approach for exposure (intraoral or extra oral) and length of invasion are also decided.

ii. **Operative phase:** The targeted mandible is accessed

with minimal invasion and adequate bone stock is exposed for fixation of the DD. The alignment of device and screw holes is made on the mandibular site. The distractor is then temporarily fixed in the appropriate position. Osteotomy line is drawn on the bone and the distractor are removed. The distraction protocol further carried out in four more phases viz. a) Osteotomy, b) Latency, c) Distraction, and d) Consolidation.

a. Osteotomy: This is the phase where osteotomised bone segments are formed by a suitable osteotome. The osteotomy may be complete or limited to the corticotomy. Complete mobilisation of bone segment is not always mandatory because distraction process progressively prompt the osteotomy. After osteotomy, repositioning of the DD is done on the bone fragments. Before the closure of soft tissue, a trail operation is essential to ensure the correctness of the distractor movement. Generally, at the end of osteotomy a gap of 1.0 mm is created.

b. Latency: During this period a lot of histogenesis activities are triggered for initiation of the fracture healing process. Initially a haematoma is formed which in turn is converted to a clot leading to formation of inflammatory cells and fibroblasts. This become more fibrous due to formation of adequate collagen, in addition the mesenchymal stem cells from bone medulla and periosteum are also differentiated.[5]Thus, the fracture site slowly turns to the soft callus. Generally, a latency period of 5-7 days is recommended with exception for some case specific distraction.

c. Distraction: Once the traction force is applied it continued with a recommended magnitude and frequency or rhythm for the entire period of distraction. The tension–tress exerted by the DD in rhythm stretches the soft callus along the distraction axis. On the progress of distraction, a central fibrous interzone is formed in the callus which becomes rich in chondrocyte-like cell, fibroblast and many other histogenic elements. The newly recruited osteoblast at this site contributes osteoid along collagen bundles and subsequently mineral crystallisation occurs. The recommended duration of this phase is about 1-2 weeks and the recommended rate of distraction may be 1 mm/day with single or multiple rhythm of splited increment. Due to distraction force the instant fracture healing process is delayed and bone lengthen process is augmented.

d. Consolidation: At the end of the distraction period when desirable bone lengthening is achieved, distractor is ceased keeping the distraction device in position with a rigid fixation device. This rigid fixation device keeps the distractor undisturbed throughout the consolidation period. During this period mineralisation and corticolization of compensatory bony structure completes its process. The recommended period for this phase generally varies from 8-12 weeks. Finally, the distraction devices are removed with supported retainer if required. However, for all these successes, a suitable DD plays the pivotal role.

Discussion

There has been a hand full of review articles on the age as a factor for successful mandibular reconstruction by distraction osteogenesis. A common consensus has been drawn that MDO is not wise to be performed in the age group under two years unless the aetiology is life threatening. It is suggested to undertake MDO after the patient is achieved the skeletal maturity. Some neonates and infants as their congenital disorders develop glossoptosis leading to upper airways obstruction. Nasopharyngeal intubation or tracheostomy is the immediate temporary arrangement to restore the respiration. In the recent past MDO has been proved to be an important tool for treatments of such neonates and infants. Among the pioneers, Sidman et al. [6] reported success in MDS and treated 11 children for airways obstruction. Scott *et al.*[7]described MDO in 19 patients under the age of 12 weeks (ranged from 5–85 days) as the most secured surgical intervention for elevating the upper airways obstruction to overcome morbidity and mortality. In this study all these patients were micrognathic and upper air ways obstruction was due to glossoptosis. They claimed that the airways obstructing tongue base could be brought forward by mandibular advancement and supraglottic airways made free.

Thus, it prevents the tracheostomy and, in some cases, prompted for decannulation. Similar observation was made by Hong and Benzulhy[8] in a recent review. Ow and Cheung[9]reported that bilateral MDO could prevent tracheostomy successfully in 90% out of 646 cases. Although MDO technique in infants is a lifesaving option of treatment, there is every possibility of tooth bud injury during osteotomy and distractor placement. Besides, there are possibilities of teeth migration in course of distraction process. Sever loss of tooth follicle and nonappearance of molar tooth were also reported in 13 children of MDO treatment out of 17 cases [10]. However, in a case study of ten children at primary dentition age, Hong *et al.*[11]recorded no remarkable complication for primary molar tooth development. They claimed this success was due to their planning for inverted 'L' shape osteotomy based on preoperative radio-imaging study to save tooth buds.

TMJ Ankylosis may be congenital or acquired by trauma and infectious and inflammatory diseases. Intervention such as gap arthroplasty, interposition arthroplasty, and correction of malocclusion are some of the traditional treatment procedures [12,13]. Sometimes facial symmetry is deviated more due to loss of ramus condylar height [14,15] Application of MDO has currently adopted to achieve better perfection of mandibular reconstruction and reduction of TMJ ankylosis[16,17]. Sharma et al.[18] obtained 30 mm mean incisal opening in five cases of gap arthroplasty with ipsilateral and contralateral coronoidectomy. After a constant follow up for one year those patients underwent DO with vertical 'L' shape cut to create a transport disc directed towards glenoid fossa by suitable intraoral distractor. Thus, they claimed the neocondyle distraction is a successful intervention for mandibular reconstruction. A step ahead, gap arthroplasty and intraoral distraction could be done simultaneously. Sharma et al. and Debal et al. and Rao et al. respectively [15,19,20] could show the gap arthroplasty and intraoral distraction osteotomy as a single step treatment for TMJ ankylosis and mandibular correction. Recently Khan *et al.*[21] described one-stage DO and interpositional gap arthroplasty in 5 patients and could increase the length of both corpus and ramus with angular osteotomy and oblique placement of distractor.

As the recent advances MDO not only overcome the donor site morbidity but also reduces the prolong anaesthetic use and graft related complicacy. However, MDO has its own limitation and complicacy which has been reviewed to educate and to enhance the skill of surgeons [22,23,24]. Balaji[21] described the limitations under three categories viz. intra-operative, intra-distraction and post-distraction complicacies. Improper and unstable device fixation, problem faced during distractor activation, inadequate device dimension, unforeseen decision on force and vector etc. are some of the mistakes came across by surgeons. Nørholt et al.[22] reported some instances of incomplete osteotomy where persistent pain was experienced during activation of the DD. They found the risk of neural injury more in the patients who underwent bilateral sagittal split osteotomy and distraction. In a different study 57 % of complication was reported on apraxia of inferior alveolar nerve (IAN) due to surgical injury of IAN of different grades by Wijbenga*et al.*[24].The risk of injury to the tooth buds by improper osteotomy and screw pin placement in children and infants have also been discussed at length by few reviewers[22].

The Ilizarov philosophy of 'Tension stress' not only effect the osteosynthesis of mandibular but also trigger the distraction histogenesis of gingiva. Ever since the first application of Ilizarov the principle in mandibular reconstruction a few fundamental researches have been revealed the scientific basis present behind the principle [25,26]. Further the focus of MDO is concentrated on the biological stimulation of osteogenic and soft tissue regeneration which could reduce the treatment period to minimize the morbidity and to improve the comfort of the patients. Various modern technique of treatment such as application of low intensity pulsed ultra sound (LIPUS), electrical simulation, hyperbaric oxygen therapy (HBOT), incorporation of several growth factors and stem cells, intermittent administration of parathyroid hormone etc. have been reported for prompt tissue regeneration and easy recovery [25]. Bashardoust*et al.* while reviewing some of the human clinical trials of LIPUS application found the statistically significant early cortical bridging in fresh fracture[27]. Some of the current reviews on the subject contradict the above finding and reported that there is no statistically significant impact of LIPUS application on distraction osteogenesis[28, 29]. In a clinical study the effect of DC electrical stimulation on MDS was evaluated and found to be a factor for new bone formation and promote the healing process of the soft tissue as well[30]. Hyperbaric oxygen therapy (HBOT) is a principle of treatment based on enhanced oxygen concentration to improve the diffusion ingredient and promote the oxygen supply even to the dipper tissue. Re *et al*[31] in a recent study are hopeful for application of HBOT in mandibular reconstruction surgery.

Conclusion

MDO has several advantages over traditional craniofacial surgery. As it is the novel science and practice of last two decades, it needs further streamlined protocols, skill development and incorporation new technology of wound healing process for easy recovery and patient comfort.There is immense scope for further development of osteodistraction of the craniofacial skeleton. The areas where further study is needed may include: Modification of the osteotomy; Design of the distraction device; Enhancement of regenerate maturation with pharmacological agents such as growth factor and cytokines; Development of new techniques to monitor distraction regenerative formation and remodelling.

Current Status and Call for Action: Regenerative Endodontics

Sumit Dash[1], Debkant Jena[1], Siba Prasad Jena[2]

[1]Professor, [2]Senior Lecturer, Department of Conservative Dentistry & Endodontics, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

From past few years, Endodontic therapy shows high rate of success to prevent diseased tooth. It help to decrease the pain and swelling, and after completion of endodontic therapy. In children are more prone to caries due to high carbohydrate diet and bed food habits. So in early case we have plan for regenerative endodontic procedures which help in replace the damaged tissue including dentin and root structures. Sir Dr. B.W. Hermann was first ever clinician to carry regenerative endodontic procedure in a patients. In his case report, he used calcium hydroxide paste in vital pulp amputation which shows great results after 21 days. In this review article we focus on current aspect of Regenerative endodontic procedures.

Keywords: *Endodontic therapy, Regenerative endodontic procedures, Cell based and gene based therapies.*

Introduction

The main goal of the regenerative endodontic procedures to establish the normal function of damaged cells or tissue. There are two treatment approaches cell based and gene based therapies which help to restore the lost structure. In the era 2000 the main focus of all the clinicians and researchers are to restore the lost tissue or part of the tooth by various method, these method are applies the concept of tissue engineering to repair the lost part of dental tissues. These method includes scaffold of implant, gene therapy, the process of revscularization and many more new advancement.[1]

The aim of this article is to review the prospects of endodontic regeneration.Future clinical research would likely focus on translating basic research findings into improved regenerative procedures, such as formation of cementum-like material on the dentinal walls that might lead to studies evaluating benefits of revascularization procedures for overall tooth resistance to fracture. Controlled differentiation into odontoblasts is an important area of research and amenable to tissue engineering concepts. The development of the delivery systems might permit structural reinforcement of the cervical area that might provide clinical opportunities to regenerate lost tooth structure, thereby permitting natural teeth to be retained. Clinical significance: Expanding the scope of regenerative medicine, researchers have also developed and applied regenerative procedures in oral soft and hard tissues.[2]

Regenerative Endodontic Therapy: Objectives arerevascularization, tissue regeneration and continued root development. Protocol given by American Academy of Endodontists for RETonly minimum instrumentation was done on dentinal wall needed to remove the smear layer.[2]

First visit: After local anesthesia given to the patient, rubber dam placement was done with respected tooth. Round bur was used to make access opening during the biomechanical preparation 1.5% sodium hypochlorite (NaOCl) then irrigated for 5 minutes with 20 ml of ethylenediaminetetraacetic acid (EDTA) or saline, safe irrigation was done to prevent periapical extrusion of the chemical, which may lead to severe pain and swelling in site after proper irrigation final irrigation was done with saline liquid, then drying of the canal with paper point. CH or double/triple antibiotic paste was placed into the canals sealed with the temporary restoration.

Corresponding Author:
Prof. Sumit Dash
Professor, Department of Conservative Dentistry & Endodontics, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: sumitdash@soa.ac.in

Second visit: Patient recalled after 21 to 30 days, if there is no pain and infection in peri-apical, local anesthetic without vasoconstrictor is administered and the canals gently irrigated with 20 ml of 17% EDTA before being dried. The periapical tissue is briefly over-instrumented 2 mm beyond the open apex to cause bleeding and to produce a blood clot extending in the canals up to the CEJ. A resorbable matrix may be placed over the clot before placing MTA/tricalcium silicate cement/bioceramic over it, and then a restorative material. (Figure 1) Reassessment is recommended every 6 months for 2 years to evaluate bony healing, ideally with no symptoms, and continued root development.

Biologic Mechanism to Explain RET[3-5]:

1. Overinstumention in periapical area cause blood clot formation in that area.
2. RET act as scaffold and matrix containing undifferentiated cells
3. Stem cells + HERS= responsible for root development
4. Low concentration of Naocl was used to decrease the cytotoxic effects and EDTA increase viability of stem cells
5. HERS cells are able to promote differentiation of pulp stem cells and thereby dentin repair

Clinical Outcomes[5-7]: In the review process we found the significant results were found that in a apexification process using CH or an MTA barrier technique. In found the RET have 98.9% success rate as compare to apexification of 88.6%, respectively. No significant differences were found in bone density, and continued root development following RET varied.

Adverse events associated with RET[8]: In various clinical trials we found that after successful treatment of 3-4 months in post operative radiograph root resorption, apical periodontitis and tooth discoloration seen in almost patients.

Discussion

Revascularization has change the treatment aspect to save the disease tooth;the rationale behind this procedure is that it has now been shown that tissue in the periapical region of a nonvital tooth has the potential to regenerate and that the host's own pulpal cells can be utilized to achieve apex closure.[9]

Calcium hydroxide was the first choice in fractured traumatic tooth during apexification. It's help in thickening of the root walls and help increased root length. In other words, it allows normal root maturation to take place as opposed to just the formation of a calcific barrier induced by apexification with calcium hydroxide.[10]

Conclusions

New approaches to regenerative endodontics continue to be evaluated. Future research into specific signaling molecules that could promote pulpal regeneration has been recommended, as well as the development of improved scaffolds. The clinicians are doing research to preserve non vital teeth which can be a boon in the field of regenerative endodontics.

Ceramic Veneers: Technique Overview with a Case Report

Gunjan Srivastava[1], Sreeprada Dash[2], Manoj Kumar[3], Lora Mishra[4], Subrat Kumar Padhiary[5]

[1]Professor, Department of Prosthodontics, [2]Post Graduate Trainee, Department of Prosthodontics, [3]Reader, Department of Periodontics and Oral Implantology, [4]Professor, Department of Conservative Dentistry and Endodontics, [5]Professor, Department of Oral and Maxillofacial Surgery, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Ceramic veneers are layer of tooth colored material used to restore esthetic. The main objective of this article is to provide an overview on the techniques to be followed at all steps of restoration with a ceramic veneer. Careful treatment plan and appropriate selection of case provides a good treatment option with the use of veneers. This report describes the case of a young female patient with generalized diastema in the anterior teeth region. Ceramicveneers were fabricated for six maxillary anterior teeth for the patient to improve the esthetics.

Keywords: *Ceramic veneers, dental ceramics, esthetics.*

Introduction

A veneer is a layer of tooth-colored material that is applied to a tooth to restore localized or generalized defect and intrinsic discolorations. Veneers are made directly by applying composite, or could be fabricated indirectly by composite, porcelain or ceramic. The veneer is a conservative option to full crown for improving the esthetic of an anterior tooth. To improve the tooth size, shape and colour, veneers are the least invasive aesthetic treatment options. Ceramic veneers in absolute indications and comprehensive planning provide excellent result. They show biocompatibility with the periodontal tissues and can be handled in low thicknesses.(1)

Indications:

1. Discoloration of tooth due to tetracycline,fluorosis, advance in age,non-vital teeth
2. Diastema present between the central incisors.
3. Enamel hypoplasia, small cracks in the enamel gradually due to age.
4. Peg laterals and rotated teeth
5. Multiple Diastemas
6. Mesial Angle Fractures

Contraindication:

1. Full coverage crown prosthesis should be given when little or no enamel is present
2. In Patients with parafunctional habits such as bruxism, forceful clenching, pencil chewing, nail biting
3. Severe crowding of teeth.
4. Class III & edge to edge bite occlusion.

The esthetic smile design should be conducted with a proper treatment planning. The amount of enamel reduction to be done and the remaining dental structure plays significant role in determining effects of load on to the tooth structure that could lead to failure of ceramic veneers.(2) The treatment planning helps to assist the cosmetic intervention and develop esthetic smile. Therefore, a proper set of guidelines should be followed by the clinician to achieve desired goal. The efficacy of ceramic veneer is improved through the appropriate cementation procedure and understanding the nature of the ceramic used. (3)This paper aims to describe the

Professor, Department of Prosthodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: gunjansrivastava@soa.ac.in

protocols and steps that should be followed to achieve minimum thickness ceramic laminate veneers and create esthetically beautiful smile.

Techniques: The tooth preparation greatly influences the durability and shade of the veneer, since the amount of reduction will decide the intaglio surface contour and ceramic thickness. This stage is determined by evaluating the condition of the teeth and the ceramic material chosen for the restoration (feldspathic or glass ceramic).[4]

Earlier concepts proposed minimal or no tooth preparation for the ceramic veneers in order to protect the underlying tooth, but the current concept advocates removing varying amount of tooth structure so that sufficient bulk of ceramic can be provided for the restoration and also this shall prevent fracture of the veneers and simultaneously it should allow for the proper marginal adaptation.[5] Care should be taken to confine the preparation completely in the enamel to achieve anoptimum bond with the ceramic veneer. Newest generation dentin bonding systems show optimal bonding with dentinestill the bond strength of porcelain to enamel is found better than the bond strength of porcelain to dentin.[6,7]

The difference in preparation is only at the incisal part of the tooth. The margin preparation of the veneer is equigingivalor slightly subgingival for the anterior teeth with a chamfer finish line. To maintain adequate depth while conserving intact enamellayer is difficult, therefore the reduction depth should be approximately 0.3 mm. At themiddle third, the depth should be approximately 0.5–0.8 mm. At the incisal third, the preparation differs which can be categorised in to three types. (Figure. 1)

First type is the "window" preparation, the most conservative and maintains enamel in incisal third, but the disadvantage with this design is discernible line between enamel and ceramic veneer layer, furthermore the remaining tooth structure becomes more prone to fracture upon load.

Second type is **"feather"** preparation, which covers the incisal of the tooth and ends lingually. The difficulty in this preparation is the technique sensitivity while positioning the ceramic restoration during cementation of the veneer and in matching the optical properties of the remaining incisal tooth surface to that of the veneer. In order to obtain optimalcolour properties and translucency at the incisal third of the ceramic veneers, the preparation should provide a thickness of 1.5–2.0 mmceramic, and this can be obtained with the **"overlap"** type of preparation. And at the proximalregion, the preparationshould follow the papilla and extenduntil interproximal contact. [8,9]

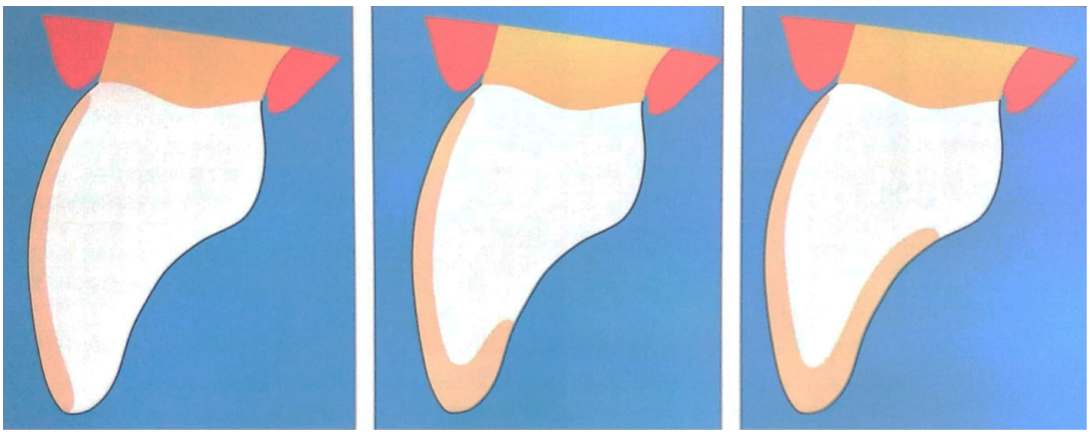

Figure 1. Different preparation design for Veneers(a)window (b) feather (c)overlap

Impression Procedure: A custom tray with perforations should be fabricated to make the impression of the prepared tooth. Before the impression procedure, gingival retraction is necessary in order to obtain accurate margin details in the impression. Preparation sites are cleaned using a disinfectant surface tension reducer. Tray adhesive should be applied on the tray, andthen high viscosity of either polyether or polyvinyl siloxane impression material has to be loadedon to the custom tray,and light body impression material is applied on the tooth. Hydrophilic polyvinyl siloxane is material of choice for excellent accuracy, detail reproductionand

dimensional stability. Putty consistency should not be used as it displaces light body material. The loaded tray is then placed on the acrylic block, and a single-step impression (dual-viscosity impression technique) is made as it provides easy access to all margins. Wash impression technique is not recommended for the ceramic veneer preparation. All the impressions were then poured in type-IV die stone material.

Clinical Procedure for Bonding Laminate Veneers: The longevity of the ceramic veneer is mainly dependant on the strength and toughness of the bond formed between the three different layers of the bonded veneer complex: the tooth surface, the porcelain veneer, and the adhesive cement. Bonding to teeth depend on the adequate preparation and conditioning of the involved surfaces, the ceramics and dental tissues.

Tooth/enamel surface treatment: The conditioning of the enamel surface should be done with 37% phosphoric acid. This step leads to an increase in the surface area of the prepared tooth, which results in perfect wetting of the tooth surface to bond with the tooth structure. At this stage, use of rubber dam isolation can reduce contamination with moisture and saliva.

Ceramic surface treatment: Alteration of the surface structure through etching will lead to the change in the surface area of the porcelain veneer and enhance its wetting properties. This is done in order to create undercuts that increases the bond strength of the resin luting cement. The ceramic veneers are conditioned with hydrofluoric acid and silane coupling agent. Acid conditioning with 2-10 % hydrofluoric acid helps to remove the superficial micro cracks and round off surface flaws thus decreasing stress concentrations. It is done for glass ceramics or silica-based ceramics only. Silanization of ceramic with a bifunctional coupling agent offers a chemical link between the resin based luting agent and ceramic. It is done for the alumina or zirconia ceramics.

Luting cement: Intrinsic brittle nature of ceramics compels to use adhesive cementation to increase fracture resistance by going deep into flaws and irregularities on internal surfaces, diminishing crack propagation, and resulting in a more effective stress transfer from the restorative part to supporting tooth structure.

Cementation of ceramic veneers warrants the use of a light-curing luting composite. Light-curing luting permits a longer working time as compared to dual cure or chemically cured luting agents. Removal of excess composite becomes easier for the dentist prior to curing and significantly shortens the time required for finishing these restorations. Color stability of light cured material is better than dual-cured or chemically cured systems.

First a primer is painted on the tooth and the ceramic veneer, followed by resin bond; lastly the luting resin is applied on the ceramic veneer. The veneer is placed onto tooth by a specific instrument (Accu-placer) or with a plastic handle with mounted wax ball to hold the veneer. Curing is done on all surfaces of the tooth for complete polymerization of the luting composite.

Case Report: A 19-year-old female patient reported to Department of Prosthodontics with the chief complaint of generalized spacing in her maxillary anterior teeth region. Radiographic and clinical examination were done. The patient was initially counselled for the orthodontic treatment for the correction of diastema but she refused to undergo the orthodontic therapy due to the longer time frame for the treatment and she wanted immediate results. So, correction of multiple diastema with ceramic veneers was opted as the treatment plan. Clinically, the amount of spacing and discrepancies present between the incisors and canines was observed. (Figure 2) The gingival zeniths were at different levels in all the anterior teeth. Gingivectomy was performed to correct the zeniths. (Figure 3 A and B) Diagnostic casts were obtained and wax mock-up was done to define shape and form of the teeth that will assist in the treatment planning as well as for the fabrication of the ceramic veneers. (Figure. 4a) Putty index was prepared from wax mock up. Forth is case, ceramic veneers of minimum thickness were indicated for the six maxillary anterior teeth.

Figure 2. Pre-Operative

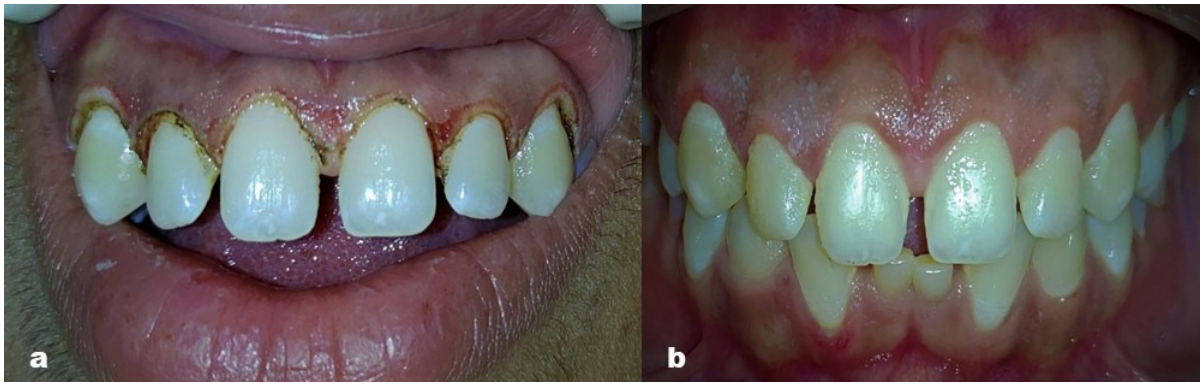

Figure. 3A After Gingival Surgery to correct the Zenith; 3B. After healing post gingival surgery

Tooth preparation comprised of feather reduction i.e. covering the incisal edges of the incisors and canine and extending the preparation palatally with a diamond bur.(Figure 4b) Followed by 0.3 mm tooth reduction at the cervical portion and 0.5mm reduction at the middle third of the teeth. A chamfer finish line was placed at the level of gingival crest. Proximally the preparation followed the papilla and extended till the interproximal contact area.

Provisionalisation was done with the help of putty index. Shade selection was done and impression was made using retraction cords. The impression was made using a poly vinyl siloxane rubber base material (Affinis, Coltene, India). The heavy-bodyconsistency was loaded onto the tray andlight-bodyconsistency was applied on the maxillary anterior teeth. The impression along with wax mock-up was send to the lab for the fabrication of the ceramic veneers. Ceramicveeners were fabricated with a lithium disilicate reinforced glass ceramic material (IPS emax Press, Ivoclar–Vivadent, Liechtenstein), using heat press technique. A layer of ceramic was added at the incisal edges of the veneers to improve the translucency thereby providing a natural appearance to the restorations and enhancing the esthetics.

On subsequent appointment after 1 week,etching of internal surfaces of veneers was done with hydrofluoric acid for 20 seconds. (Figure.4c) Bondingagent was applied and light-cured. The tooth was conditioned with 37% phosphoric acid (Figure 4d) The veneers were cemented with a light-cured resin cement. The polymerization was completed using LED-curing unit for 30 s from all aspects of each tooth. Presence of any occlusal interferences was evaluated and removed. Final finishing and polishing at the marginal area of the restoration was done. The patient was highly satisfied with the treatment and the esthetics of the anterior tooth. (Figure.5) The patient was followed up at an interval of 7 days, 1 month and 6 months and 1 year.

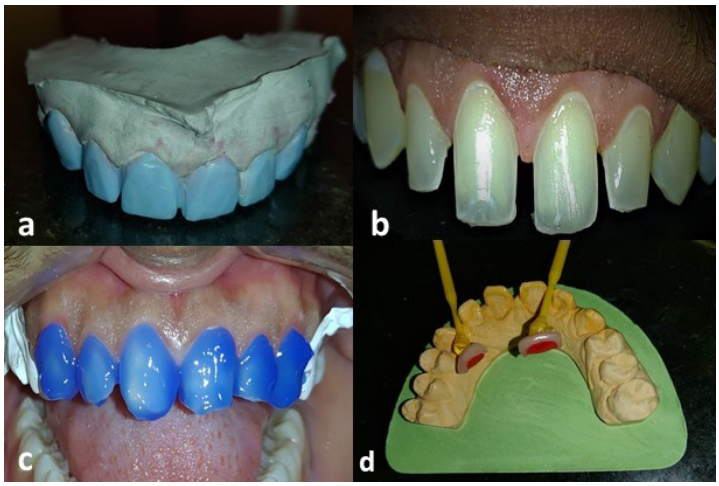

Figure. 4a Wax up on diagnostic cast; 4b, Tooth Preparation; Figure 4c. Acid etching, 4d. Etching of Ceramic veneers with Hydrofluoric Acid

Figure. 5 After cementation of Ceramic Veneers

Conclusion

The success criteria for ceramic veneers are absolute indication for the patient and the proper use of the restorative materials and suitable techniques available for it. This report described the case of esthetic restoration in a young female patient. The patient was satisfied with the esthetic outcome.

Diagnostic AIDS for Detection of Oral Precancerous Condition

Tariq Soyab

Post Graduate Trainee, Department of Oral Pathology and Microbiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

In this Modern–world, the world of Medicine and its technologies is growingrapidlyin a Phenomenal Manner.Today it is very easy toexamine the oral cavityof a personto know the hazardous factorsfor the oral–cancer. There is a hugeopportunity to enhance patient'soutcomesthroughproper examination plus proper evaluation along with accurate treatmentto reduce thepremalignant lesions before the development of Invasive oral-carcinoma. The advancement in the field of medical sciences are extremely important to improve the Penurious & life-threatening outcomesassociated with oral cancer due to our lack of ability to diagnose andtreat this disease at an early, preventablestage.

Keywords: *Precancerous condition, neoplasia, biopsy, OSCC.*

Introduction

Cancer has a major Impact on Society across the world. According to the statistics in 2018 an estimated 1,735, 350 new cases of cancer is been diagnosed in the United Statesand 609,640 people die from this disease. The world which is challenged by this Impactful disease, the incidence of oral cancer is growing tremendously. Incidence rates for oral–cancer vary in men from 1 to 10 cases per 100000 population in many countries.[1]In South Central Asia, cancer of the oral cavity stands amongthe three most common types of cancer. In India, the age standardized incidence rate of oral canceris 12.6 per100 000 population. Oral cancerrates are significantly higher for males than for females. The incidence of oral–cancer has increased from past few decades and is usually diagnosed when the condition is worst and at anend stage.[2] The over-all 5-year prognosis for oral cancer have remained very less at around 50% for the past fewdecades and have remained among one of the top causes of death rates, considerably lower than that for colorectal, cervix and breast origin. This is due to lack of knowledge & skill to diagnose the disease by health professionals at an early stage. The aim of this article is to outline the different diagnostic technique which is provided and marketed to the health–professional for early diagnosis of potential cancerous lesion.

Clinical Sign and Symptoms of oral cancer: Oral cancer refers to cancer that occur in any part of the mouth which includes gums, tongue, lips, soft palate, inner lining of the cheeks, hard palate, and floor of the mouth. Mouth cancer is one of the several types of cancers group in a category called head and neck cancers. The signs and symptoms may comprise a mouth uncomfortable that doesn't cure,a white or reddish patch inside the mouth¸ loose teeth, anextra growth or long inside the mouth, mouth pain, ear pain and difficult or throbbingswallowing.[3]

Risk factors contributing to oral neoplasia: The factors that can enhance themenace of oral tumor:

- Tobacco use of any kindscontaining Cigarettes, pipes, khaini, snuff, cigars, etc.
- Heavy liquor use.
- Extremesun exposure to our lips.
- A sexually spreadvirus called human papillomavirus (HPV).
- A weekend immune system.

Screening: Recognition and diagnosis of oral neoplasia has conventionally relied comprehensively on the clinical skill of the examiner and his or her ability to identifyoften subtle morphological changes. However, some early malignant lesions are clinicallyvague from benign lesions, and some patients develop carcinoma in the absence of clinically identifiable OPLS. Moreover, it can be difficult even for health providerto determine which OPLS are at greaterrisk to develop into invasive carcinoma. Therefore, an exact, independent and non-invasive procedure that aid to identify pre-malignant lesions and to differentiate those at a risk of malignant conversion is needed.[4]

Diagnostic Aids: Oral–cancer is the sixth most common cancer in the world and in India oral cancer ranks in the top 3 of all cancers. Amongst all oral cancers, more than 90% are squamous cells carcinomas (OSCC) while the remaining 10% of the cases are mainly melanomas, sarcomas, minor salivarygland carcinomas and metastatic cancers. Several technologies are used to detect and diagnosis of oral cancer which includes.[5]

Biopsy and cytology: These are three ways to take a biopsy to detect for oral cancer[6]

- **Exfoliative cytology:** The doctors will scrap some cells from the suspicious lesion and will put them in the slide. This technique can be performed in a doctor's office.
- **Incisional-Biopsy:** The doctor will cut out a small sample of tissue. In the suspicious area is easy to reach then your doctor can numb your mouth and do this in his / her office. If the area is deeper in the mouth or throat, this is done in the operating or laboratory room.
- **Fine-Needle Aspiration:** The physician may noticea lump in your neck. If so, then he or she uses a thin needle to remove a small sample of tissue. This can be performed in a doctor's office. Once the biopsy is completed, the pathologist examines the tissue samples in a lab. A biopsy is the only sure way to tell it the patient have cancer or not and if it persists then what type of cancer it is.

Non-Invasive tools for earlydetection: These are the new and advance technology towards detecting the oral cancer, the following new techniques have recognized the world of cancer which includes:

- **Toluidine Blue:** The test aims in detecting various types of malignant and pre-malignant lesions in early stage. The sensitivity of toluidine blue in detecting pre-malignant or malignant lesions was found to be 97.8% and overall specificity was found to be 100%. It is a basic thiamine metachromaticwith high affinity with acidic tissue components, there by staining tissues rich in DNA and RNA.[7]
- **Fluorescence Imaging Techniques:** Oral cancer is a challenging health problem in through out of the world. Most of the oral cancer patients are diagnosed at a late stage, when treatment is less successful with treatment associated mobility is more severe and complicated. In particular, autofluorescenceimaging has emerged as a promising adjunctive method to improve early detection at oral pre-malignant lesions. Direct visual inspecting of tissue autofluorescence has shown encouraging results in high prevalence, populations but the technique requires subjective interpretation and depends on the visual reorganization skills of the examiner. High resolution fluorescence imaging is a new modality that can be used in conjunction with wild filled imaging to improve specificity by imaging sub cellular detail of neoplastic tissues.[8]
- **Saliva as a Diagnostic tool:** Saliva from patients is been used in a peculiar way to provide molecular biomarkers for oral cancer detection. The wide spectrum of molecules present in saliva provides valuable information for clinical diagnostic applications. Molecular markers for the diagnosis of oral squamous cell carcinoma can be identified in three levels. 1) Changes in cellular DNA, 2) Altered rnRNA transcripts, 3) Altered protein levels. Hence in future the salivary diagnosis test can replace the serum diagnostic procedure.[7]
- **Identify 3000:** Theidentari ®uses the identari multi spectral feuroscenesand reflectance technology to enhance visualization of mucosal abnormalities such as oral cancer or pre-malignant dysplasia that may not be apparent to the naked eye. The identari uses white, violate and amber wave length of light to excite oral tissue in distinct and Unique ways. As a result, biochemical changes can be monitor with feuroscenes, while morphological changes can be monitored with reflectance. The combine system of feuroscenes and reflectance uses the body's natural tissue properties as an adjunctive tool for oral

mucosal examination. Conventional examination of tissue is performed using a highly concentrated white light.[9]

Role of histological slides (Aids a way for Detection): Now a days the oral pathologist in dental and medical colleges and in laboratories preparing the histological slides for detecting the oral precancerous lesion and different types of cyst and tumors. A vital role which is played by oral pathologist for detecting this impactful disease has a high rate of accuracy in detecting any kind (Benign & Malignant) type of cancer.[10]

Procedure:

1. **Tissue Fixation**: The slide preparation starts with fixation of the tissue specimen. There are many types of fixative agents are used in which 10% neutral buffered formalin is used maximally. Formalin containers should be capped properly and it should be leaked proof with proper labelling.
2. **Specimen transmission to cassettes**: After fixation specimens are trimmed using a scalpel to enable them to fit into an appropriately tissue cassette. Specimen should not be big as they can fit into the cassette ideally, they should be less than 4 mm otherwise they risk being waffled when the cassette lead is closed.
3. **Tissue Processing**: It is done using a paraffin block usually. The steps as follows:
    i. Dehydration
    ii. Clearing
    iii. Embedding: Which is the final stage where specimen are infiltrated using embedding agent usually Paraffin wax.
    iv. Sectioning: In this step the wax is removed from the surface of the block to expose the tissue. The blocks are chilled on a refrigerator plate or ice try for minutes before sectioning.
    v. Staining: The histochemical stains typically Hematoxylin & Eosin are further used to provide contrast to tissue sections making tissue structures more visible and easier to evaluate.

Conclusion and Ensuing Directions: The modern tools and its techniques which has brought a lot of change in this medical scenario of the world, the dentist and technicians should have proper skill, knowledge and education in detecting oral cancer at its pre-cancerous phase which is the key to prevent its progression to the later stages. A depth of knowledge and its proper utilization can bring a drastic change in treating this dangerous outcome. The survival rate from oral cancer better than 90% at 5 years, whereas late-stage dieses survival rate is only 30% and this method of diagnostic-aids can change a scenario of the survival–rate, if it is used in its up to the mark. In a developingcountry like India, where large account of population is not well educated and are not aware of any health complication, cancerspecially plays an important role for death among population. Among cancers, oral cancer is very common in society and the commonest to be neglected. The dentist or physician should create a proper awareness among the public regarding the oral health and its consequence and the govt. should be taking part in it to encourage this mission. Government must take strict action against that factory. That manufactures products that are responsible for cancer.Product labelling must showsaturator warning so that people can understand it and avoid using such life-threatening disease-causingproducts. In primary health care level, there must some awareness program camps to be organized so that people will be aware about these hazardous product & avoid using such products. With the help of mass education lot of people can be benefitted and at the same time educated about these things. With the combine effect of govt. Plus people and us (the medical specialists) lets beat cancer.

Radiographic Differential Diagnosis of Ossifying Fibromas of the Jaws. A Case Series

Abhishek Ranjan Pati[1], Rajat Panigrahi[1], Smita Priyadarshini[1], Basanta Choudhury[2], Sayari Niyogi[3], Swastik Mishra[4]

[1]Reader, [2]Senior Lecturer, [3]Former Post Graduate Trainee, [4]Intern, Department of Oral Medicine and Radiology, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Ossifying fibromas are bony tumors, which derived from the cells of the periodontal ligament. They behave like, a benign bone neoplasm. In a recent WHO classification (2005), "the term 'cemento-ossifying fibroma' was replaced with 'ossifying fibroma'." These lesions usually grow slowly and are painless. These lesions are more common in girls and women rather than men and these lesions are seen during third and fourth decade of life. This bone tumour entails highly cellular, fibrous tissue which comprises of aggregates of calcified tissue similar tocementum,bones or both of them. We have reported a few cases of ossifying fibroma of maxilla and mandible and their clinic-radiological presentation.

Keywords: *Ossifying fibroma; Clinicoradiological presentation; Radiographic differential diagnosis.*

Introduction

Ossifying fibroma (OF) is usually well thought-out to be a type of fibro-osseous lesion (FOL) and which usually affects both maxilla and mandible, and usually more frequent in the mandible. The bone tumour contains, "highly cellular,fibrous tissue that comprises of variable amounts of calcified tissue similar tocementum, bone or both".[1]In a recent WHO classification (2005), the term, " 'cemento-ossifying fibroma' was replaced with 'ossifying fibroma'. "These lesions are more common in girls and women rather than men and these lesions are seen during 3rd and 4th era of life.[2] COF very closely look like lesions such as "fibrous dysplasia, cementifyingperiapical dysplasia or cemento-osseous florid dysplasia."Central ossifying fibroma is believed to instigate from the periodontal membrane.[2] This neoplasm occurs in patients of a varied range of age, but the most of cases are seen during the 3rd and 4th decades of the life. Occurrence is usually high among females with a ratio of 5:1. The most common site where COF occurs is mandibular premolar area.[4-6] When viewed radiographically, COF displaysaamount of patterns depending on the degree of mineralization of the lesion.

Case Study: In our case study, the radiographic features of COF have 2 types: mixed density lesions and cyst like appearance. The radiographic appearance is concentric, with equal expansion in all sides. The outer cortex is displaced and perforated in giant tumours thinned, restsin one piece, particularly in those giant tumours. The lesion has mixed density in nature and the core structure may be a concoction of radiolucent and radiopaque tissues. As the tumour expands displacement of the inferior alveolar canal or the teeth can take place. "Lamina dura"generallyabsent in those involved teeth and root resorption may occur in these affected teeth. Some lesions show increase in expansion. Some juvenile ossifying fibroma can involve the complete jaw .Cancellate dense lines with medium-density mass are often seen in these pattern of lesions. However,"Ossifying Fibroma"might present as irregular in shape, mainly when the tumour recurs or grows quickly in a small period of time. In such cases, "the tumors always nurture along jaws, sometimes involving the complete jaw." These phenomenons put forward

e-mail: abhishekranjanpati@soa.ac.in

that "Ossifying Fibroma"canexpressdestructive local growth.[1]

"Hansen and Buchner"observed that the mineralized tissues in peripheral ossifying fibroma can be of 3 basic types.

- The structure of bone can be trabecular lamellar, or woven,at times enclosed by osteoid tissue.
- It can be "Cementum"-like material that are seen as spherical bodies or oval eosinophilic bodies which coalesce to form islands.
- Areas of Dystrophic calcification.[5]

The periodontal membraneis believed to be the origin of Central Ossifying Fibroma, which are alayer of "fibrous connective tissue"neighbouring all tooth roots. The periodontal membrane'sconnective tissue harbours the potential for elaboration of both cementum andbone. Thompsonand Bernier speculated that infection that resulted in the fibrosis andinflammation of the peri-apical area might arouse the periodontal membrane. Subsequentlyafter a traumatic event such as exodontia and road traffic accident, the enduring periodontal tissue may aid as the origin of Central Ossifying Fibromawhich are attached to the wall of the "alveolus".[6]

Another type of benign lesion is JOF, which is analogous to Ossifying Fibroma but is early on onset and is more aggressive. The case proposes that Ossifying Fibroma, usually in children (below fifteen years of age), can show rapid growth and erosion or incursionto adjacent tissue. In this type of distinct case, it is unfortunate that the tumour became too big for surgical excision. As quickly as possible it is necessaryto resect the tumour. Treatment of choice for Ossifying Fibroma usually involves radical surgery because it has a propensityto reoccur and has a risk of malignant transformation.[1]

Recurrence of Ossifying Fibroma was experienced in all those patients whounderwent complete or particular resection. It can reoccur and it isall the time unpredictable, extending from 6 months to 7 years after the surgery in the reports done by us. So, the follow-up period should be long enough of at least 10 years. Presence of 3 different radiological appearances: Unicystic;Multicystic.

Radiopaque mass; were noted during these follow-ups. The differential diagnosis of Central Ossifying Fibromaconsists of other lesionsthat comprise of radiopacities within a distinct radiolucentmass. These lesions are: "Fibrous Dysplasia, Chondrosarcoma, Squamous Cell Carcinoma, Odontogenic cysts, Osteosarcoma; Gorlin's cyst, Pindborgtumour". The distinctborders of Central Ossifying Fibroma help it to differentiate from aggressive carcinomas and sarcomashas atypical ground glass appearance is seen in Fibrous dysplasia. Grolin cysts and Pindborgtumours are very tough to discriminate and can only be found onhistologic examination.

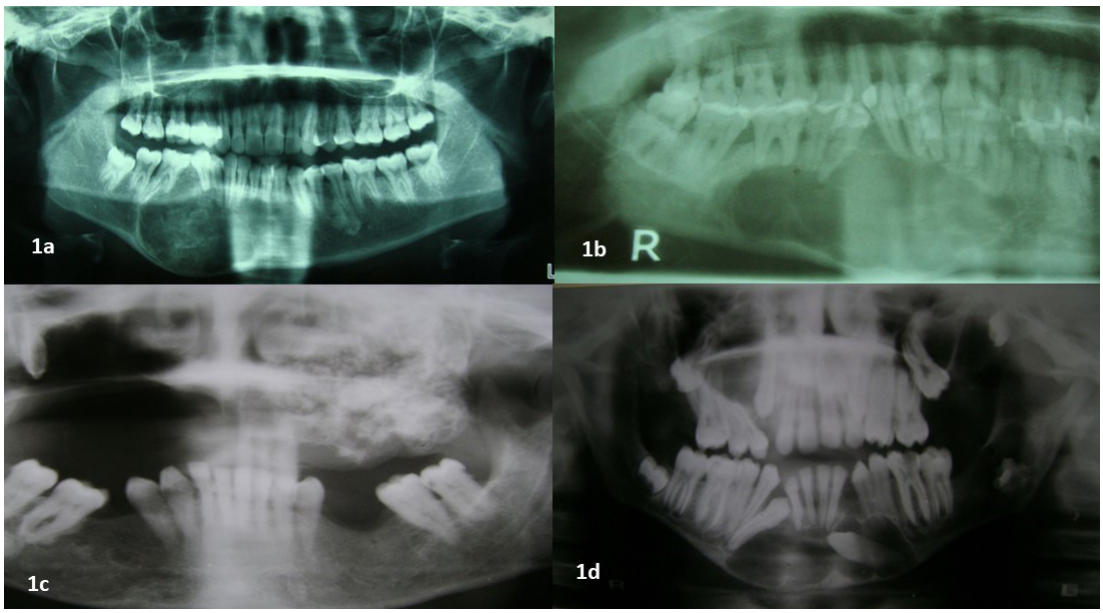

Figure 1. Radiographic Images

Figure 2. Radiographic Images

Table 1: Description of radiographic images

Figure No.	Location	Appearance	Border	Internal Structure	Cortical Expansion	Impacted Tooth	Root resorption	Tooth Displacement	Inferior Border of Mandible
1a	Anterior and right body of mandible	Mixed radiolucency and radiopacity	Well-corticated opacity	Diffuse opacity in radiolucency	present	absent	present	present	Expanded but intact
1b	Anterior and right body of mandible	Mixed radiolucency and radiopacity	Well-corticated opacity	Diffuse opacity in radiolucency	present	absent	absent	present	Expanded but intact
1c	Left posterior maxillary region	Mixed radiolucency and radiopacity	Ill-defined border	Dense radiopacity	present	absent	Absent due to edentulous area	Absent due to edentulous area	present
1d	Anterior mandible	radiolucency	Well-corticated opacity	Radiolucency present	Absent	present	absent	present	Intact
2a	Left posterior body of mandible	Mixed radiolucency and radiopacity	Well-corticated opacity	Diffuse radiopacity in radiolucency	Not appreciable	present	absent	absent	Expanded but intact
2b	Left posterior body of mandible	Mixed radiolucency and radiopacity	Well-corticated radiopaque border	Diffuse opacity in radiolucency	present	absent	absent	absent	Expanded but intact
2c	Right posterior body of mandible	Mixed radiolucency and radiopacity	Diffuse border	Mixed opacity and radiolucency	present	absent	absent	absent	Expanded with perforation of inferior border

Table 2. Clinical features of cases

Case Numbers	Chief Complaint	Clinical Features
1	swelling on the right side of the lower jaw for 3 years	no history of tooth ache, trauma, discharge, fever associated with the swelling
2	swelling in his lower jaw 1 ½ years back	history of trauma, with no associated discharge from swelling
3	Swelling in the left upper jaw for 2 years	No history of trauma, edentulous patient with palatal perforation
4	Swelling with respect to upper and lower jaw	Multiple impacted teeth present with swelling in the right side of the lower jaw
5	Swelling in the left lower jaw	Swelling in the left lower jaw with impacted molar teeth
6	Swelling in the left lower jaw	Swelling in the left side lower jaw with grade II mobility
7	Pain in the right side of the lower jaw	Tenderness with respect right side lower molar teeth

Discussion

The term ‘‘ossifying fibroma’’ was first used in 1927, and since 1968 tumors showing cementum were grouped together. During 1971, the “World Health Organization (WHO)” classified 4 types of cementum-containing lesions which were “fibrous dysplasia”, “Ossifying fibroma”, “Cemento-ossifying fibroma” and “Cementifying fibroma.” Conferring to the 2nd WHO classification, in the oral and maxillofacial region benign fibro-osseous lesions were classified into two categories, non-neoplastic bone lesions and osteogenic neoplasm. COF belonged to the category of osteogenic neoplasm. But later ‘‘cementifying ossifying fibroma’’ was again renamed in a WHO classification during 2005 as Ossifying Fibroma.[1] Some Ossifying fibromas contain prevalent cementum-like calcifications and while bone-like material is seen in others, but in few lesions’ combination of both cementum and bone-like materials has been studied.[2]

Ossifying fibromas are formed from pluripotent mesenchymal cells that are usually get originated from the periodontal ligament. Bone tissues and cement are formed from these cells. “There is a school of thought that previous exodontia or localized periodontitis might provoke a spur,[3,12] or that the formation of “ossifying fibromas” might be a commotion of bone maturation of congenital origin.”[3] In 1872,” Yih et al. and Sciubba et al. accredited the 1st description of this disorder to Menzel.” At 1927, Montgomery first coined the term ossifying fibroma, by which the lesion is now recognized. Other authors have also used this name simultaneously. Up to 1948, it was thought that fibrous dysplasia and ossifying fibroma were both one of the “similar entity” or variations of a similar lesion.[4]In that same year, Sherman and Sternberg issued a detailed depiction of the histological, pathological, radiologicaland clinical characteristics of ossifyingfibroma, and after that most researchers correspond in considering the 2 lesions to diverse clinical entities.[4]Though it can befall at any age, numerous authors have confirmed that Ossifying fibroma of the mouth inclines to ensue mostly in the middle-aged patients. Ossifying fibroma of the jaw bone shows female predilection as compared to males. The females were more affected than males in our case.Central Ossifying Fibroma mostly affects the craniofacial bones and hardly encompasses the long bones. In the maxillofacial region, Ossifying fibroma most commonly occurs in the mandible, usually inferior to molars and pre-molars.[1]

Conclusion:

“Ossifying fibromas” represents a plethora of radiopaque radiolucent benign lesions manifested in the maxilla and mandible ranging from slow growing benign lesions to aggressive juvenile ossifying fibromas, one needs to be thorough with the various radiographic appearances, growth pattern, areas of involvement and clinical manifestations for proper diagnosis and treatment planning.

Revolution of Graphene in Dentistry

Sudipta Sahu[1], Debasruti Naik[2], Kajal Kiran Sahoo[3], Nikita Sahu[4], Sashikant Sethi[5]

[1]Tutor, Department of Public Health Dentistry, [2]Former Post Graduate Trainee, Department of Public Health Dentistry, [3]Tutor, Department of Prosthodontics, [4]Tutor, Department of Public Health Dentistry, [5]Tutor, Department of Public Health Dentistry, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Graphene has been discovered to have unique properties that could revolutionize the world. The reason graphene is such a beneficial material is due to its 2D like nature and short/strong bonds. Biomedical researchers have begun to make use of the properties of graphene. Its derived substances open a completely new research path in tissue engineering as well as regenerative dentistry and medicine. This paper aims to review and present the useful properties of graphene and its revolution in the era of modern dentistry.

Keywords: *Graphene; regenerative dentistry; medicine; biomedical research.*

Introduction

The material graphene consists forms of allotrope of carbon as a single layer of atoms in a 2D hexagonal lattice where one atom forms each different vertex honeycomb sheet of carbon atoms.[1] It contains all the basic structural element of different allotrope which includes graphite, carbo nanotubes, charcoals and fullerenes. Its striking physical, electronic, and mechanical properties originate from the two-dimensional (2D) electron confinement within a one-atom-thick layer.[1,2]

Graphene was discovered in 2004 by Andre Geim and Konstantin Novoselov at the University of Manchester.[3,4] Their discovery gave them Nobel Prize in 2010. Novoselov stick a crumble of graphite to a scotch strip and after that exfoliated it to split the graphite layers and repeated this process several times to reduce the thickness of graphite until few layers of Graphene sheet was inaccessible.[2] The word graphene material was latersuggested by the lUPAC commission to re-establish the old term "graphite layers" that was suitable in the research of single carbon single layer structure, since a three-dimensional configuration is identified as graphite.[1]

Graphene sheets are building blocks for other graphitic material: a) stacked on top of each other they make graphitemm thick graphite contains about 3 million layers of graphene); b) rolled up they make a carbon nanotube(cut and folded into a spherical shape they make a fullerene)

Graphene forms: Graphene nanoplates; Graphene nanoflakes; Graphene powder; Graphene thin sheets; Graphene foam

The discovery of graphene's extraordinary properties has led to a stampede in research and development and a patent land rush with 31,000 patents and hundreds of thousands of scientific papers. [5]

Properties of graphene [6]

1. **Atomic width:**Single atom thick ("two-dimensional"), about 0.335 nanometers
2. **Electron mobility:**Maximum electron mobility with theoretical limit of200,000 cm 2/(V•s) (>100x higher than silicon)
3. **Strength:**Monolayer graphene is the strongest material ever tested with a strength of 42 N/m.
4. **Toughness and Stretchability:** Comparatively brittle, it can be stretched by up to25%–highly relevant for flexible electronics.

Corresponding Author:
Dr. Sudipta Sahu
Tutor, Department of Public Health Dentistry, Siksha O Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India
e-mail: sudiptasahu@soa.ac.in

5. **Stiffness:**Same as diamond.
6. **Impermeability:**Even the minimum atom(helium atom) cannot pass through a sheet of graphene
7. **Electrical resistivity:**1x10-8Ω•m among the lowest of any known material at room temperature (~35% less than copper)

There are well over 100 graphene producers worldwide and growing. The estimated market value for graphene: €100 million in 2020; €150-550 million in 2025 [5]

Applications in General: Super capacitors, Energy storage, Wireless power, Super sensitive touch screen, Ultra-thin batteries, Instant de-icing of aircraft, Nano-scale transistors, Thermo conductive lubricants, Water filtration & desalinization

Applications in Biomedical field

a. **Medical applications:** Graphene based biosensors are used for detection of small biomolecules (dopamine, glucose, etc) proteins and DNA. They are also used in bio-imaging, photo thermal therapy, drug delivery, gene delivery, tissue engineering. Some of the reliable ultrafast biosensing platforms are fluorochrome based nano-optical biophonic detection system such as FRET/CRET.[7]

   1. **DNA Detection:** Graphene has been widely used[8]

      a. to detect aromatic molecules as well as single stranded DNA through pi-pi stack interactions.

      b. can incandesce a wide range of wave-length (from near infrared to ultraviolet)and can efficientlyput out the fluorescent dyes.

      c. useful material in fabricating fluorescence resonance energy transfer (FRET) sensors.

      d. By combining the optical properties of graphene oxide along with its interaction with nucleic acid, target DNA will be able to be identified and quantified.

   2. Drug delivery: Graphene oxide and its derivatives exhibits properties used to carry DNA, proteins and antibodies.[6] High surface area of graphene allows high drug loading capacity that can be compared to other nanomaterials. But due to poor rigidity cell penetration, the success of grapheme based drug delivery tool is dependent on three factors such as, a) constructing optimal loading capacity, b) to confirm degree of toxicity and c) designing a system which will be able to release drugs in a controlled manner at the required site(tumour) for successful therapy.[8]

b. **Dental application:** Dental diseases like caries, periodontal problemsare closely associated with microorganisms such as *Streptococcus mutans*, *Fusobacteriumnucleatum* tend *Porphyromonasgingivalis*. Zisheng.[8]

Detection of Bacteria: Sensors and interfacing electronic devices with biomaterials are gaining interest for decades. But such device designs involve either mechanical mounting of components by clamps or other additive or implantation of electrodes into the tissue surface. Specialization have been made to identify the specific type of organism.[7]

1. **In Restorative Dentistry:** Natural tooth surfaces are subjected to stresses and wear repeatedly due to forces applied over to the tooth while chewing and masticating. Those surfaces which undergo wear develop caries or produces sensitivity in later period which require restorations as a treatment approach. The commonly used materials like silver amalgam, glass ionomers, composites and ceramics can also undergo wear over a long period of time. Graphene fillers supplementaryinto restorative materials maximizes the strength and durability of the restoration. Though ceramics are the best material for indirect restorations their use is limited because of low fracture toughness, poor creep, brittleness. Presence of impurities, pores and cracks can cause pure ceramic extremely brittle. They if integrated as fillers in ceramics can also get better fracture hardinessas well as other mechanical properties.[9]
2. **Bone tissue engineering:** Major bone rebuilding is a worldwide health crisis and represents a great challenge. Materials such as polycaprolactone (PCL). But these polymers lack cell adhesion sites and may require chemical modification for stem cell adhesion. Also, their byproducts on degradation can trigger immune response. Because of the differential and significant properties of graphene has as a show's potential material for stem cell research. They allow stem cell adhesion, growth along with they also improve osteogenic segregation.[10]

3. **Periodontal tissue regeneration:** Chemical vapour deposition (CVD) is a reliable processto make high definition qualityof graphene in huge scale that can be shifted to a variety ofother substances. CVD grown graphene is hydrophobic along with is a non-cytotoxic substance that permit stem cell connection and proliferation. The substance is competentenough to maintain the induced pluripotent stem cells (iPSC) in the undeferential state as well as also to induce stem cell differentiation into specific lineages.[10-12]

4. **Cancer Therapy:** Cancer stem cues (CSC) or tumour stimulating cells are resistant to predictable therapeutic approaches. Drug resistant CSC can cause in unfavourable chemical outcomes. Studies suggest that GO can also be directly used as a beneficial agent for targeting CSC as a differential agent. GO execute its belongings on CSC by inhibiting numerous key signal transduction pathways. GO can be delivered as a therapeutic agent that will depend on the site of tumour, GO flakes can also be utilized as a lavage solution during surgery,with the aim of preventing tumour recurrence and distant metastasis.[12]

5. **Coating for implants:** Graphene strips acts as an anti-bacterial, anti-biofilm, anti-adherence activity of GR coated tooth surface over the implants which can inhibit *S. mutans* biofilm formation. Graphene strips also stimulates osteogenesis aswell as bone regeneration thereby preventing peri-implantitis.[13]

6. **Antibacterial activity of Graphene:** Graphene oxide destroys bacterial cells through ceU-wrapping, on the other side reduced graphene strips stops bacterial cells through cell-trapping.[14,15]

Advantages.[6,8]

a. It is the thinnestyet the strongest

b. It is a good conductor of heat and electricity

c. It is both pliable and transparent

d. Used in production of high-speed electronic devices

e. Enhance differentiation of stem cells

f. Biocompatible

Disadvantages[16]

a. Graphene is prone to oxidative environments in the form of catalyst.

b. Through its jagged edge graphene penetrate cell membrane as well as distrupts normal function

c. Super expensive

Conclusion

Graphene has been discovered to have unique properties that could revolutionize the world. The reason graphene is such a beneficial material is due to its 2D like nature and short/strong bonds. It is the strongest material ever discovered;however, its brittle nature cannot be used structurally but only used to reinforce other materials. It is found to have various applications in medical field, further research is needed to ensure its usage in dentistry.

Antioxidants and its Role in Periodontal Health

Someswar Chakraborty[1], Manoj Kumar[2]

[1]Intern, Institute of Dental Sciences, [2]Reader, Department of Periodontics & Oral Implantology, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Periodontitis is a chronic inflammatory disease of the periodontium resulting from the pathogenic bacteria which are present in the plaque biofilm. Excessive reactive oxygen species plays an important role in the pathogenesis of periodontal disease. Increased polymorphonuclear count and activity is a reason for high rate of REACTIVE OXYGEN SPECIES(ROS) release which in turn leads to oxidative stress in periodontal tissues. Antioxidants(AO's) are the substance present at low concentrations which retards the oxidative stress.As Reactive oxygen species and Antioxidants are in active harmony so any disturbance in one would cause change in the latter. This review will be solely focused on the role of ROS, AO's and oxidative stress in causing periodontitis.

Keywords: *Periodontitis; Reactive Oxygen Species; Antioxidants.*

Introduction

Periodontitis is a chronic inflammatory disease of the periodontal tissues as a result of noxious bacteria present in the dental plaque which results in periodontal loss of attachment and subsequent exfoliation of the tooth.In recent years, reactive oxygen species (ROS) have gained special attention due to their special role in inflammatory disease progression.[1]

These ROS are a product of regular cellular pathways and are located within all tissues. Antioxidants (AO' s) are another category of substances present in cells which works by efficiently delaying or inhibiting "ROS-induced oxidative stress" which in turn presents ROS-mediated tissue damage[1]

The aim of this review article is to highlight the role of ROS and AO defense system in the pathophysiology of periodontitis.

Corresponding Author:
Dr. Manoj Kumar

Effects of Reactive Oxygen Species on Periodontal Tissue: The reactive oxygen species affects periodontal tissues by following mechanisms

- Degeneration of the Ground substance
- Direct or indirect collagenolysis due to oxidation of proteases.
- Enhanced proinflammatory cytokine release by NK-KB activation
- PG-E_2 production via lipid peroxidation of superoxide release both of which have been linked with bone resorption[2].
- In a cell there is harmony between development and obliteration of free radicals. The harmonical balance takes a radical turn by excessive generation of free radicals due to low levels of antioxidants.[2]

Mechanisms for Periodontal Tissue Degradation by Reactive Oxygen Species: Although ROS have very short acting half-lives (10^{-9} to 10^{-6} s), they are capable of causing considerable tissue destruction by starting free radical chain reactions.

Different pathways mediating tissue destruction are:

- DNA Damage
- Lipid peroxidation (by activation of "cyclo-oxygenases" & lipo-oxygenases)

- Protein damage of gingival hyaluronic acid and proteoglycans.
- Oxidation of certain enzymes eg."anti-proteases"like α_1-antitrypsin.

Recent studies have also shown that ROS are produced by osteoclastic activity and it has a hand in resorption.[3] Moreover ROS like superoxide and Hydrogen peroxide have been linked with activation of osteoclasts and on the other hand, Nitrous oxide(NO) is believed to curb bone resorption.

Antioxidants:

- Antioxidant is a substrate which in low concentrations than its oxidizable counterpart prevents or delays of that substrate.
- Several biologically important compounds have antioxidant properties. These include "vitamin-C" (ascorbic acid),"vitamin E" (α-tocopherol), "vitamin A" (retinol) "β-carotene", NADPH, Adenosine co-enzyme Q10, cysteine. taurine,methionineetc.

A functional classification of antioxidant system based on the way they act (Nikki1996) feels most important.[4]

Table I: A functional classification of Antioxidants.

Types of defense systems	Mode of Action	Examples
Preventive anti-oxidants	Subdues the formation of free radicals; nonradical decomposition of lipid hydroperoxide and hydrogen peroxide. Sequestration of metal by chelation.	Catalase, GPX' serum-transferase
Radical scavenging antioxidants	Quenching of active oxygen. Scavenge radicals to inhibit chain initiation and break chain propagation.	Superoxide dismutase, carotenoids, lipophilic vitamins e.g. Vit A and Vit E
Repair and de novo enzymes	Repair the damage and reconstitutes the membrane	DNA repair enzyme, proteases, transferases, lipases

Table II: Classification based on their origin.[5]

Exogenous	Synthetic	Endogenous
Carotenoids Ascorbic acid Tocopherols Polyphenols Folic acid Cysteine	N-Acetyl cysteine Penicillamine Tetracyclines	Catalases Superoxide dismutase Ceruloplasmin Transferrin Ferritin Proteases

Effects of Antioxidants on Periodontal Health:

- Antioxidants are those molecules that inhibits oxidation. It works by terminating the chain reaction caused by free radicals and thus inhibits cell damage or death.

  Major rich sources of antioxidants in diet includes:

  - Broccoli
  - Berries
  - Beans
  - Avocados
  - Red wine
  - Kiwi
  - Dark chocolate
- Panjamurthy (2005) reported that there were increased levels of antioxidant enzymes but the level of Vitamin-C, Vitamin-E and GSH were decreased in periodontalsubjectsin spite of accommodating the protein levels which he ascribed as a protective mechanism to oxidative stress.[6]
- Battino et al (2005) described the antioxidant activity of toothpaste and established the antioxidant activity of sodium ascorbyl phosphate in vitro. The antioxidant property of zinc chloride and sodium fluoride were due to the ability of Zn+2 ions to shield thiol groups and prevent formation of Hydrogen peroxide and Superoxide dismutase which formed due to reaction with transition metals and capability of Fluoride to form complex divalent iron ion.[4]

Conclusion

Current scenario clearly depicts a strong connection between oxidative stress and periodontal disease. The

balance between antioxidant mechanism and Reactive oxygen species is of utmost importance for improved periodontal health. Increased Reactive oxygen species activity or decreased antioxidant mechanism can cause huge impact over the equilibrium in periodontal tissues resulting in periodontitis. For avoiding periodontal diseases daily adequate consumption of natural antioxidants,omega fatty acids,Vitamin D and calcium are of utmost importance. There is increasing evidence showing higher the intake of antioxidants lowers the risk of Oxidative stress and simultaneously lower the risk of lipid peroxidation and finally leading to a good overall periodontal health.

Botox and Dermal Fillers: Expanding the Horizon of Dentistry

Tulya Shubh

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

BOTOX and DERMA FILLERS are coveted twin-faces in the world of facial esthetics as well as cosmetic dentistry. Botox is a neurolysin derived from the bacteria Clostridium botulinum which freezes or reduces the tonicity of the muscles after being injected while Dermal fillers contain injectable ingredients such as hyaluronic acid (Juvéderm, Restylane) and calcium hydroxyapatite fillers (Radiesse), that act as plumpers and add fullness to areas that have thinned due to aging. There is no doubt that Botox (since 2002) and dermal fillers (since 1981) are well known for their esthetic results in terms of smooth, wrinkle free skin and enhancing or replacing lost volume in the face by soft tissue augmentation, especially in the oral and perioral areas. Though in recent years, they have paved their path into Dental practice for both dental esthetics as well as therapeutic uses. In this article, we will focus on the mechanisms of their actions, their therapeutic uses in dentistry as well as other body parts, side effects and contraindications in maxillofacial areas along with their future implications in the world of dentistry.

Keywords: *Botox, Dermal fillers;Dental Esthetics; Therapeutics.*

Introduction

It's a general thinking that Botox and Dermal fillers are primarily used for cosmetic purposes regarding fine lines and wrinkles on the face, but they both have a golden history of various therapeutic uses as Strabismus, Blepharospasm, Axillary hyperhidrosis, Crow's feet etc. Both furnish most noteworthy, least invasive procedure at affordable cost with limited to negligible recovery time. Today Botox and Dermal fillers both go hand in hand for rejuvenative, cosmetic as well as therapeutic procedures. The Dental Quality Assurance Commission (DQAC) of Washington has given an elucidate statement effective July 26, 2013, which now ratify the ability of general dental practitioner to use Botox and dermal fillers when "used to treat functional or aesthetic dental conditions and their direct aesthetic consequences and the treating dentist has appropriate, verifiable training and experience." Similarly, Michigan board of dentistry and New Jersey state board also affirms the use of Botox and dermal fillers by general dental practitioners.[1,2]

Botulinum Toxin or Botox: Botulinum neurotoxin, famously known as BTX or BoNT is derived from a gram positive anaerobic, spore forming bacillus, *Clostridium botulinum.* BoNT is divided into 7 different neurotoxins,categorized as type A, B, C [C1, C2], D, E, F and G which are serologically and antigenically vivid but structurally identical. Among these neurotoxins, three forms of BTX type A (Botox, disport and xeomin) and one form of BTX type B (MyoBloc) are available commercially for multiple esthetic, cosmetic and medical procedures. Although BoNT may lead to botulism, a serious life-threatening condition in humans and animals, still it can be used as an effective and potential medication in required terms.[3]

Mechanism of Action of Botulinum:

- Administration of BoNT type A in muscles
- Inhibition of exocytosis of Ach on nerve endings
- Prevention of attachment of Ach containing vesicles to the neurotransmitter prone sites
- Blockage of release of Ach by neurons
- Decreased muscle activity or partial paralysis of muscles (for around 3 to 4 months)

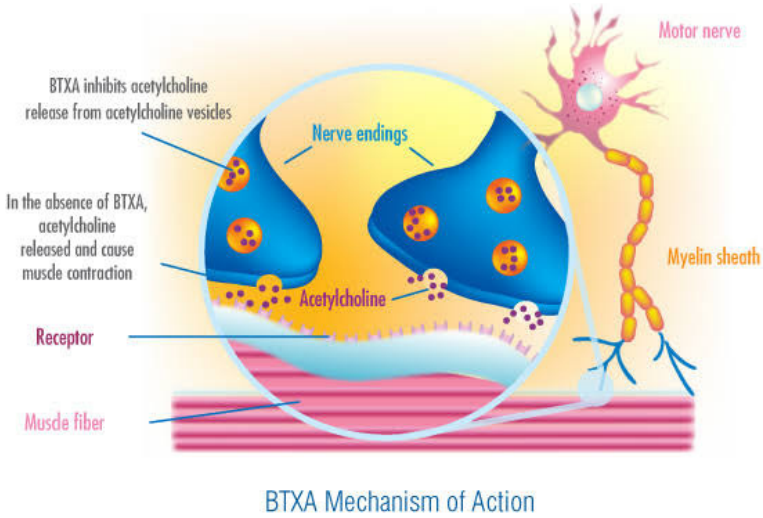

Figure 1: BTXA Mechanism of action

Botulinum as Dental Therapeutic:

Temporomandibular joint disorders or syndrome: This includes all the conditions that affect the synovial joint between mandible and temporal bone (jaw joint), as well as related neurological and vascular integrant, leading to pain and impaired movements of the joint and the surrounding associated muscles as well.

It commonly includes TMDS i.e. Temporomandibular joint Dysfunction Syndrome and MPDS i.e. Myofascial Pain Dysfunction Syndrome.

Aetiology: The preponderance of TMJ disorders include a myogenic factor as,Hyperactive muscular activity; Repetitive subconscious jaw movement associated with bruxism and clenching; Inflammatory disorders; Stress (external); Ankylosis; Neoplasia

Signs and Symptoms: Pain in jaw movement; Trismus or Reduced mouth opening; Deviated mandible on opening; Clicking or popping sound on opening of jaw; Facial pain; Headache (generally at temples); Indistinct Toothache.[4]

How BoNT can be used to treat TMDs?: Generally, there are trigger points in muscles associated with TMD cases. On palpation, pain emerges from these points which instantly get transmitted along associated muscles or neuronal tracks. Interruption of these trigger points may cause relief, either for short-term or long-term.

Certain agents as sterile Saline and Local Anaesthetics together have been injected directly into these trigger points, but their effect does not last very long i.e. from few minutes to a few days, so have limited benefits. On the contrary, the use of BoNT can reduce the strength of muscle contraction with the effect lasting for around 3 to 4 months, thus are surprisingly beneficial in painful TMD cases. [5]

Bruxism: Bruxism is an oral parafunctional activity characterized by excessive grinding of teeth or clenching of jaw or gnashing. It can be **Nocturnal** i.e. Occurs while in sleep and **Awake** i.e. Occurs while wakefulness. Bruxism leads to hypersensitive teeth with wear facets, aching muscles of jaws, headache, facial pain, along with aggravation of periodontal diseases.

Treatment: Bilateral administration of neurotoxin in masseteric as well as temporalis muscles, even if only one side of the face is affected. The proper and accurate amount of BoNT (5 to 6 injections) will not only diminish the strength of contraction of muscles of mastication by partially paralyzing them and reducing their ability to clench and grind the jaw forcefully, but also improve the ability for masticating and talking. This effect may be noticeable by the next day and usually lasts for about 3 to 4 months with occurrence of disuse.[6]

Masseteric hypertrophy: This condition is usually seen in patients who are chronic jaw clenchers and is characterized by unilateral or bilateral enlargement of masseter muscles. Symptoms include facial disfigurement, trismus, protrusion and bruxism. Pain may also occur but most frequently patients consult clinicians for cosmetic purposes.

Treatment: Initially, surgical reduction of the jaw muscles was done which resulted in substantial contracture of the muscles. But in recent years, Botox has gained quite remarkable status regarding treatment of hyperactive muscles. Administration of right amount of BoNT in both sides of the masseter results in sustained reduction of muscle's hyperactivity as well as concurrent reduction in overall size of masseter over time. For pain relief, muscle relaxants can be used. [7]

Removable prosthesis: Overactive muscles can affect the retention, stability and support of removable dentures. Lack of these can hamper mastication, speech as well as esthetics which can cause psychological issues to the patients. BOTOX can provide an excellent relief in such cases as it will decrease the tonicity of overactive muscles, thus neutralising the force responsible for denture instability and so will aid in retention of the removable prosthesis.

Post-orthodontics Therapy: BOTOX can also be used to prevent relapses of orthodontic treatment in case of patients having stronger muscle activity as that of hyperactive mentalis muscle. Hyperactive mentalis muscle can often cause disruption in the alignment of teeth as well as muscle spasm leading to pain. Botox can reduce the strength of muscle contraction without hampering its normal functional activities. But this therapy should be done prior to any major irrevocable dental procedure for better results. [8]

Oro-mandibular Dystonia: It is a rare, focal neuro-dystonia characterized by strong and assertive contractions of muscles of face, jaw with or without involvement of tongue, thus causing distressed opening and closing of mouth in lateral, vertical and protrusive directions. It can lead to several dysfunctions as impaired mastication, dysphagia, dysphonia, TMD and many others.

Treatment: BOTOX acts as a promising therapy for treating OMD as it inhibits the release of Ach by neurons at presynaptic levels, thus causing transitory chemical denervation of skeletal muscles.

Sialorrhea: Sialorrhea or Ptyalism is nothing but excess salivation or inability to hold saliva in mouth. It is usually witnessed in ALS patients, Parkinsonism, Frey's Syndrome, Bell's palsy etc.

Treatment: BOTOX can be used to treat sialorrhea as it inhibits the release of Ach by neurons at cholinergic synapses of ANS, thus can block cholinergic parasympathetic secretomotor fibers of salivary glands leading to diminished salivation. But while administration of the toxin, care must be taken as too much of BoNT can cause impaired mastication, dysphagia and dry mouth.

Trigeminal Neuralgia: It is a neurological disorder affecting trigeminal nerve (Vth Cranial nerve) and its branches and is characterized by chronic, unilateral, episodic and transitory, lancinating type of pain and is usually associated with trigger zones.

Treatment: BOTOX can be used as an adjunct for treating this disorder. Administration of 25 to 75 unit of BoNT in pericranial muscles can provide symptomatic relief from headache, facial pain etc. It relaxes the associated hyperactive muscles by inhibiting the nerve impulses that trigger contractions.[9]

Gummy smile: It is excessive exposure of gums of maxilla (generally) while smiling. It is an issue of both oral hygiene as well as cosmetic concerns.

Treatment: Botox is a non-surgical and least intrusive treatment alternative for rectification of gingival smile. It is advisable when the gummy smile is because of over functional upper lip elevator muscles. Administration of BoNT in overactive elevator muscles of lip blocks it's immoderate contraction and thus deter the lip from being wrenched too far up while smiling.

Contraindications:

- In mentally challenged patients.
- Patients having neuromuscular disorders as Myasthenia Gravis.
- Patients being hypersensitive to any component of the formulation.
- In pregnant or lactating women.

Dermal fillers: Dermal fillers are kind of magical stuffs that are administered underneath the skin for soft tissue augmentation, smoothening the perioral wrinkles and folds and plumping out the areas of reduced volume. In addition to prevent the process of ageing and for other cosmetic issues, dermal fillers can also be used as a promising dental therapeutic agent.

Ideal properties: It should be, safe, economical, ready to use, painless while administration, hypoallergenic, operator as well as patient friendly,

long lasting with reliable results and low possibility of complications. [10]

Classification of Dermal Fillers:[11-12]

A. On the basis of longevity:

1. Temporary or non-permanent fillers

   It is biodegradable and degrade in less than 1 year.

Types:

- Bovine collagen
- Human tissue derived collagen
- Synthetic fillers as Hyaluronic acid-based fillers

2. Semi-permanent fillers

   It is also biodegradable and degrade in 1 to 2 years.

3. Permanent fillers

   It is called as non-biodegradable and degrade in more than 2 years.

B. On the basis of placement site:

1. Dermal fillers
2. Sub-dermal fillers
3. Supraperiosteal fillers

C. On the basis of origin of filler material:

1. Autografts
2. Allografts
3. Heterografts
4. Synthetic materials

Indications:[11-12]

- Facial wrinkles and folds
- Enhancement of lips
- For facial disfigurement or imperfections
- Deep scars as **Traumatic, Post-surgical** or **due to acne and other diseases.**
- Soft tissue augmentation as for Breasts, buttocks.
- In case of periorbital melanosis or hyperpigmentation
- Sunken eyes
- Dermatological disorders as **Scleroderma, AIDS induced lipoatrophia.**

Contraindications:

- Patients having autoimmune diseases
- Hypersensitive patients
- Psychologically unstable patients
- Patients having tendency of secondary healing, leading to keloid formation
- Pregnant and lactating women

Dental therapeutic uses:[11-12]

1. For construction of esthetic dental lines and smile lines as an auxiliary to crown elongation, gingivectomy and veneers.
2. For augmentation of lips and perioral volume for better retention of removable prosthesis.
3. For eradication of dental embrasures i.e. 'Black triangles' form in between teeth after periodontal and implant surgery.
4. For treatment of angular cheilitis.
5. Soft tissue augmentation of lips for better phonetics.
6. For abolishment of gummy smile.

Conclusion

In recent years, Botox and Dermal fillers have created their own identity in dentistry for therapeutic purposes as well as cosmetic concerns. Since these are minimally invasive substitutes for surgically treating cases, they have gained popularity in quite some time. Nevertheless, much more is yet to be discovered before their daily use in dental practice for several different purposes. There is no dubiety that they both have expanded the horizon of dentistry and are prevailing dental practitioners to avail them in day to day practice.

Different forms of Tobacco and its Bad Effects on Our Health and Society

Sourav Chandra Bidyasagar Bal[1], Radha Prasanna Dalai[2], Sashikant Sethi[3], Varun Darshan[4]

[1]Senior Lecturer, Department of Public Health Dentistry, [2]Senior Lecturer, Department of Public Health Dentistry, [3]Tutor, Department of Public Health Dentistry, [4]Senior Lecturer, Department of Paediatrics & Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneshwar, Odisha India

Abstract

Better health is achieved by good nutritive food. Different constituents reside in the food have their individual role in betterment of our health. But there is certain harm full product like (different forms of tobacco chewing and non-chewing tobacco) which has very dangerous effect directly on our systemic health and oral heal. In other hands it also affects environment economic status of that country. Due to heavy use of different kinds of harm full tobacco product most of the people develops non communicable diseases like oral cancer, lung cancer, chronic obstructive pulmonary diseases, chronic heart disease. After the development of these non-communicable fatal diseases they have to spend a huge amount of money for the management of these diseases. Ithas direct impact on the productive capacity of that individual and that community also.

Keyword: *Tobacco; Effects of tobacco; Healthcare; Society; Awareness.*

Introduction

"Tobacco habit appears to be the Hydra of our modern society" *Kenneth JR*

Use of tobacco is most popular habits among every community worldwide now days. Any form of tobacco use weather Smoke or smokeless is one of the top most risk factors of chronic diseases or non-communicable diseases, including cancer, lung diseases, and cardiovascular diseasesalso high etiologic factor responsible for various oral mucosal lesions and periodontal diseases.[1]

Four hundred year back Portuguese introduce tobacco in India. Rapidly tobacco became an integral part of different socio-cultural in various communities.[2] In the process of tobacco production and tobacco use India is the second largest tobacco after republic China.[2,3] Every form of tobacco products made entirely or partly from leaf of tobacco as raw material and then these are used as smoked and smokeless tobacco. These tobaccoscontain highly addictive psychoactive constituent named–Nicotine. This nicotine makes every tobacco user addicted to different form of tobacco and making it very difficult for the habituated tobacco users to quit the tobacco habit. Highly dependence of tobacco is a chronic condition for every tobacco user and it requires high dedication constant effort to overcome.[4]

It has been seen some countries throughout the world, children from low socio-economic status family are frequently engaged in tobacco cultivation to support their family income. These children are in high risk group for exposure to **"Green Tobacco Sickness."**[2]

The vast use of tobacco is one of the dangerous threats to global health. Consumption of tobacco is the most important factor in the growth of non-communicable diseases in developing countries as well as developed country.[4]

Now a days wide use of tobacco in every society and the growing burden on heavy tobacco use and its health output. Tobacco use in any form is the the major

public health problems and top most cause of death in the world today.

As wide use of tobacco is the main causes of changes in the role and economic stage of a person in the society and that change affects directly to the change in social, cultural, and economic factors. Aggressive and seductive advertise with the idea of independence, sex appeal, slimness, glamour, and beauty of tobacco, targeted to people who are the triggering factors behind increase in tobacco use.[5]

All countries high-income (HICs), low-income and middle-income (LMICs) have experience of bad negative effects related to various types of smokeless and smoked tobacco production, their destructive impact differs heavily between HICs and LMICs. Now a days it has been seen a stable shifting of tobacco production from HICs to LMICs, which enhancing the economic and environmental impacts of tobacco production in LMICs is now a important consideration.[6]

Impact on Environmental: During the late 1970s, growing concerns have been expressed about the "energy" or "fuel wood" crisis caused by tobacco production, with emphasis being placed on deforestation caused by the outstanding rate of soil nutrient depletion and considerable usage of wood. The tobacco production has direct negative impact on the public health and to the environment in long term and in other hand substantially outweigh to the benefits of employment, huge income and foreign currency exchange.The huge amount of tobacco production directly affects the socio-economy status of the population those who are engaged in that field. The huge tobacco production affects the agriculture production rate.A report from Bellagio on different forms of tobacco and sustainable development concluded that, in the growing world, "tobacco is a major challenge, not to the health, but also tothe environmental sustainability." An organisation of united nation (FAO Food and Agriculture Organization), has noticed the deforestation created by excess amount of tobacco production in the form of fuel wood shortages among those people residing in rural area in the developing world.[7,8,910,11]

From the data of population statistics, wood consumption and forest density it is cleared that those area where tobacco production is more in developing countries those people are facing severe wood deficit condition. It also implies that the increasing deforestation is going to create loss of land sources, biodiversity and also can create food insecurity.[7]

It is estimated that two lakh hectares of woodlands are removed by tobacco cultivation every year. Tobacco–related deforestation is a serious emerging threat to our environment, mainly in Southern Africa, Middle East countries, South and east Asian country, South America and in the Caribbean countries. [7]

In another hand, tobacco cultivation may be linked with lowering of ground water resources, sedimentation of rivers, irrigation and also in changing of climate. It directly affects to habitat and overexploitation.[8] Its directly also have narrative effects on every human health and livelihoods.

Economic impact: The use of different form of tobacco and various health problems including systemic as well as oral heal has known to each and every population throughout the world. Tobacco use directly affects the economic system of every individual. Tobacco and poverty have very close connection. It has found from various studies conducted throughout the world that in low socio-economic class families ten percentage of total house hold expenditure money spends on tobacco use so for that reason expenditure for the basic item like food, education and on health care became less. Tobacco is another main cause for mal nutrition. Higher illiteracy rate is due to high tobacco consumption because lots of money spends on tobacco use instead of education. [10,11]

The economic costs of tobacco use are equally devastating. Apart from economy loss of family different forms of tobacco causesdifferent kinds of systemic and fatal oral diseases, tobacco kills people at their developing stage of their productivity, depriving families of breadwinners and nations of a healthy workforce. Tobacco consumers productive capacity is less as compared to non-tobacco consumers they are just alive due to increased sickness.[10]

The World health organisation Framework Convention on Tobacco Control has also taken steps on protection of the environment from the adverse effects of tobacco farming and the health of each individual who are employed in tobacco farming. Throughout the glove it is estimated from each and every tobacco industry thirty-three million population attached to tobacco farming most of them are part time worker in tobacco production in addition to other work. From the

thirty-three million workers half of that member works at different areas throughout the world on tobacco product manufacture, distribution and retailing. Except these people another ten million are employed in supplier industries, providing materials and services to the different tobacco industry throughout the glove.[12,13,14,15]

India ranked 9th globally in the exporter of different form of tobacco product and tobacco. After Brazil and China, India stood third in rank for production of more than ten percent of world's raw tobacco in the year 2003 and 2004. Expenditure in health problem after using of tobacco product is a serious burden to annual budgets of every country mostly developing countries like India. It is estimated from an estimate India spent approximately 6.2 million us dollar in the year 2003 and 2004 for the treatment of various diseases and ill health caused by heavy tobacco consumption.[15]

Tobacco industry and market in India: India has become third most country after Brazil and Chna in tobacco production and consumption. India has the biggest bidi production industry in the glove. In the year nine teen ninety-eight, 858 billion beedi were consumed by bidi user in India and this number touches to 1031 by the year 2007. Pan masala and gutkha user are more in India in young population. These gutkha and pan masala are available in different packet in the market with very low price. Some of the top most tobacco companies of India are now facing competition withunorganized bidi production company.[16]

Costs of tobacco use: For the management of tobacco related different kind of systemic diseases and oral diseases, especially the three main diseases-lung cancer, coronary artery disease (CAD) and chronic obstructive lung disease, oral diseases like squamous cell carcinoma of different intra oral structure like tongue, buccal mucosa etc. throughout the glove widely. A lot of studies in these aspects proved that there is some close connection between morbidity rate, mortality rate and tobacco use, which affects to the financial condition of the country [17]

Rath,Chaudhary. in 1999 took astep to estimate the total national costs spent on the three major tobacco-related diseases. [17]

For the improvement of public health control of different forms of tobacco use is very much essential now a day. Many organisation, professional and different government of different countries are working in this field. But it is very difficult task to fight against the tobacco use and achieve the results. Each and every small steps and big steps are huge successes for our health and quality of life of every community in the world.[18]

Though the rate of use of different tobacco product in United States lowered, but death rate due to tobacco use is approximately 6 million every year. The fatal rate due to tobacco use is eighty per cent in low-and middle-income countries. Most of the developed countries like US achieve success in control of tobacco use by increasing the tax on tobacco product creating tobacco free areas. Some other countries have created some policies like tobacco promotion on TV, radio, higher the taxes on tobacco product, graphical warning on different tobacco product for creating awareness among different communities. [19]

Tobacco Control Programs evaluation: The government of each country should regularly monitor the progression and implementation of tobacco control policies by tracing the development of the ordinances, rules and laws. The area under tobacco farming, annual different tobacco production, major category of tobacco product and regular annual export of tobacco, tax return from tobacco and different diseases developed from tobacco use should thoroughly studied as national indicators. Minimum ten per cent of the budget of every local project should spend on tobacco control for better health and quality of life.[20]

Conclusion

Well organised tobacco control is dependents on good implementation of demand and supply reduction policies by the Government and inter-sectorial approach which involvesstakeholder departments and ministries. The implementation of the well organised Government policies, synergized with tobacco control initiatives by each community are pivotal in reducing prevalence of different forms of tobacco use in the country which also reduce the fatality rate of that country and increase the productive capacity of community and economy of the countries.

Toxic Effects of Amalgam on Body

Sushma Swaraj

Intern, Institute of Dental Sciences, Siksha 'O' Anusandhan (Deemed to be University), Bhubaneswar, Odisha, India

Abstract

Amalgam is constantly used in dentistry for its durability, strength and low cost. It has been under use for more than hundred fifty years as of now, in dentistry. If patient does not care about aesthetics, then it can be used in individuals of all ages. It is long-lasting and needs very less techniques from the operator. But with all that is good with amalgam; there is also a bad side to the use of amalgam, lately there has been a rising concern among people that amalgam is the reason for mercury toxicity. Mercury is present in our environment all around us, so everyone is exposed to measurable but small amount of mercury in urine and blood, although these amounts are raised by dental amalgam restorations. It is the mercury from removal or placement of dental amalgam from tooth that exposes the body to mercury toxicity. Amalgam canproduce hyper sensitivity reactions in some people,if proper mercury hygiene procedures are not followed the risk of bad health effects grows extraordinarily. This study sheds a light on the day to day use of amalgam in dentistry and how mercury toxicity affects the patient and the practitioner.

Keywords: *Amalgam, mercury toxicity in dental office, prevention and safety measures, substitutes, conclusion.*

Introduction

Amalgam can be defined as an alloy of mercury. It is a greatdental material used for restorations. It has beenused in dentistry for hundred fifty years. Its low cost, ease of application, durability has given amalgam its reputation as one of the most used restorative materials in dentistry. However, it is being used less and less due to the rising concerns about its adverse health effects, environmental pollutions and aesthetics. Natural white colour of teeth does not go with metal colour of amalgam aesthetically,so many patients and also dentists themselves prefer restorative materials that resembles the tooth colour. amalgam consists of amix of copper, silver, zinc and tin mixed with mercury. These particles form a matrix containing gamma-1 (Ag_2Hg_3) and gamma-2 phases. ($Sn_{7-8}Hg$). Early breakage and failure of amalgam restorations is caused by gamma-2 phase, so copper was added to avoid gamma-2 phase, replacing the tin mercury phase with a copper tin phase (Cu_5Sn_5).[1] Louis Regnart, is called the father of amalgam, he improved on boiled mineral cement. He added mercury which extraordinarily reduced the high temperature originally required to pour the cement on a tooth. In 1890s, GV Black gave us a clinically acceptable formula, which also gives good performance and it wasn't changed of at least 70 years. In 1959, Dr. Wilmer Eames raised low mercury to alloy mixing ratio. As a result,the mercury to amalgam ratio which was 8:5 was brought down to 1:1. The modern amalgams are created from encapsulated alloy containing of 45% mercury by weight.[2] These are easy to use and gives us some degree of certainty that the material has not been contaminated before use. But today various research papers around the world proves that amalgam restorations release mercury into the body.[3]

Mercury toxicity in dentistry: Mercury is a known toxin. It is a bio accumulative material. Dental amalgam restorations are a major carrier of mercury into the body. Brain, nervous system, kidney etc are affected by the mercury release. The silver filling used in dentistry

e-mail: sushmasuraj@gmail..com

aremade up of a metal amalgam which contains mostly 50%of elemental mercury and 50% other metals which is basicallycopper and tin.[4] The Amalgam we use in our day to day practice in dentistry contains mercury and it affects the safety and health of the patient. Amalgam releases tiny amounts of mercury vapour through time and patient unknowingly ingests and inhales the vapour. As a vapour metallic mercury is more harmful as it would be inhaled and absorbed by the alveoli of the lungs at an alarming rate of 80% efficiency.[5] It is the main entry of mercury to our body. Also while removing the amalgam by bur the friction of bur on the amalgam surface creates a mercury cloud and more than 65% of the particles in this cloud are less than one micron in size which are absorbed by the body and mercury breaks down to systemically affect the body in the course of few days. Toxic effects of mercury depend upon the amount of accumulated mercury, amount of expose and length of expose. Mercury exposure in dental office can occur while amalgam is being stored, in use, during trituration. Exposure can occur during finishing and polishing.[6]

Signs and symptoms of mercury toxicity: Symptoms of mercury poisoning can occur either rapidly or over long periods of time. The symptoms of elemental and vaporised mercury poisoning are mood swings, insomnia, headache, tremors, weakness and decreased cognitive functions.[7]

In oral cavity, mercury causes bleeding gum, loosening of teeth, alveolar bone loss, excessive salivation, metallic taste in mouth are seen. It also causes GIT problems like inflamed colons, cramps and diarrhoea. Mercury causes CVS problems like weak pulse, increased BP, chest pain. Respiratory problems and neurological problems like headache, vertigo and twitching in various areas of the body. In pregnant women, the effects of toxicity on their children was studied and importantly the foetal brain was shown to be very sensitive to methyl mercury.[8]

Diagnosis and prevention: Exposure to elemental organic and inorganic forms of mercury causes toxicity. Various diagnostic tests or method are there to diagnose the level of mercury inhuman body which includes the test for blood, urine, saliva. By using atomic fluorescence spectrophotometry, we can detect fast and trust worthy results of mercury toxicity in blood and urine**.** A thorough physical exam alerts the physician to the potential for mercury poisoning. Mercury poisoning can be detected by mercury levels in blood. A normal mercury level is less than 10µg/L and less than 20 µg/ Lin urine. We can also do complete blood count to detect mercury poisoning.[9] We can use encapsulated alloys which eliminates the possibility of a bulk mercury spill. We can use amalgamator fitted with cover. We can also remove the remaining amalgam from the mouth by the use of high-volume suction or high-volume evacuation after a restorative procedure. We can use masks; we can dispose the mercury contaminated items in sealed bags according to applicable regulations.[10]

Amalgam Substitutes: Composites, GIC (glass ionomer cements) and many hybrid structures are emerging as very convenient replacement of amalgam restorations. Amalgam possess greater lifespan than composites, but this disadvantage is disappearing by the constant changes that are brought in the field of Dentistry by constant research to produce a superior composite resin. Amalgam is slightly forbearing to the presence of moisture during restoration.[11] On the contrary composite restoration needs high skill and sensitive techniques to perform. More and more research are needed to make composite better for the day to day and widespread use of composites. Good research and an abundance of follow up to successful cases is needed for this change from a grass root level. Amalgam use is decreasing day by day but to make it a day practice among dental practitioners is still a long way to go.[12]

Conclusion

If the required mercury hygiene procedure is followed, the risks and bad health effects in dental office could be minimised. The complete and definitive replacement of amalgam is yet to see its success in a large scale. The dentists of every country, whether a private practitioner or an undergraduate student has to take initiative in replacing amalgam with other suitable restorative materials in their day to day practise which can benefit both the dentist's and the patient's overall health.

Peripheral Odontogenic Fibroma: A Case Report

Manoj Kumar[1], Lora Mishra[2]

[1]Reader, Department of Periodontics & Oral Implantology, [2]Professor, Department of Conservative Dentistry & Endodontics, Institute of Dental Sciences, Siksha 'O' Anusandhan Deemed to be University, Bhubaneswar, India

Abstract

The tumors of odontogenic origin generally present as swellings present within the bone, but they may be seen superficial to the bone on the gingival tissues which are known as peripheral odontogenic tumors (POTs). These are not seen commonly but the most common of these is Peripheral odontogenic fibroma which is a slowly progressing benign enlargement of the periodontium. This type of enlargement generally has a substantial chance of recurrence, but the exact figure is unknown. This paper presents a case report of "Peripheral Odontogenic fibroma" with the clinical and histological findings.

Keywords: *Peripheral Odontogenic Fibroma, Odontogenic Tumors, Histological Findings; Benign Enlargement.*

Introduction

The oral mucous membrane is constantly subjected to various types of stimuli resulting in a wide variety of diseases. One of the most common findings is gingival enlargement which can be caused by a multitude of factors. It was proposed by Cook that all gingival enlargements are basically "Epulis" which commonly present itself in the maxillary anterior region.[1] They are generally seen in the interdental gingiva region due to irritation from dental calculus, faulty restorations or dental caries. "Odontogenic fibroma" is a benign tumor arising from the ectomesenchyme which has fully developed collagenous tissue and differential quantity of odontogenic epithelium. There is a slight female predilection for the same as has been reviewed by Daley et al.[2]

The World Health Organization defines it as "benign odontogenic neoplasm of fibroblastic origin characterized by relatively mature collagenous fibrous tissue and varying amounts of odontogenic epithelium with potential to occur in either a central or an extra osseous location. The extra osseous counterpart is designated as peripheral odontogenic fibroma".[3]

Case Report: A 21-year young female patient reported to the Department of Periodontics and Oral Implantology, Institute of Dental Sciences, Bhubaneswar with the chief complains of a slowly enlarging painless swelling in the upper front teeth region for 6 months. On enquiring about the history of the swelling, she mentioned that she was apparently alright 6 months back and noticed a small gum swelling in her maxillary front teeth region. It was not associated with any other symptoms and it gradually increased to its present size. On physical examination, she appeared to be moderately built and nourished and cooperative in nature. On enquiring about her medical and family history, nothing was contributory. We specifically enquired about her diabetic status as it has been reported to alter wound healing[4] and she gave a negative history for the same. She gave a history of oral prophylaxis which was done 2 years back. She had no adverse or deleterious habits and used to brush once daily with a medium bristle toothbrush and a fluoridated toothpaste. Intraoral examination revealed presence of twenty-eight teeth with all the third molars missing. There was no abnormality seen in the buccal and palatal mucosa, tongue, lips as well as the hard and soft palate. There was no gross facial asymmetry seen, profile was convex,

no abnormality detected in the temporo-mandibular joint and the patient had competent lips. She had a fair oral hygiene with mild stains and calculus predominantly in the maxillary and mandibular anterior region.

Moving to the area of chief complain, there was a diffuse gingival swelling present in the interdental area of upper right central and lateral incisor. It was slightly erythematous, pedunculated and measuring about 10mm x 8mm in size. (Fig.1) There were no symptoms associated with it except for occasional bleeding while brushing or physical irritation. It was firm in consistency with no sign of induration. Diascopy was negative ruling out the possibility of vascular lesion. Radiograph of the particular area was also noncontributory with no abnormal findings seen on the intraoral periapical radiograph. Based on the complaint, oral and radiologic findings, a provisional diagnosis of inflammatory gingival hyperplasia was given. Differential diagnosis included Irritational fibroma, pyogenic granuloma and peripheral ossifying fibroma.

Figure 1. Pre-operative stage

The patient was explained about the condition and it was decided to do an excisional biopsy of the lesion with subsequent histopathologic examination. A written informed consent was taken from the patient explaining the procedure in detail along with the complications associated with the surgical procedure. A detailed blood investigation was carried out prior to the procedure and all the values were well within the normal range. On the day of the surgical procedure, external facial disinfection was done with povidone iodine and sterile drape was used for the patient. Under aseptic conditions, local anesthesia was administered to the patient (Lignocaine hydrochloride with 1:80000 adrenaline as a vasoconstrictor). After confirming for the objective signs and symptoms, we decided to go ahead with the procedure. An excisional biopsy was performed with a no 15 bard parker blade and handle and the entire tissue was removed in toto. After that a mucoperiosteal flap was raised and the root surface was thoroughly debrided to remove any surface irritant and was copiously irrigated with a disinfecting solution. Upon satisfactory debrided, interdental ligation was performed with direct loop sutures by using sterile silk sutures. The entire enlarged tissue was immediately stored in formalin and sent for histopathological examination. The surgical site was debrided and coe pak was applied to prevent the surgical site from mechanical and thermal injury. (Figs. 2 & 3)

Figure 2: Excised Growth

Figure 3: Periodontal Dressing

The hematoxylin and eosin stained section showed a stratified squamous epithelium overlying a cellular fibro collagenous stroma. There were islands and strands of odontogenic epithelial cells seen in the stroma along with presence of diffusely arranged minimal chronic inflammatory cells. (Fig.4) Based on this, a final diagnosis of "Peripheral Odontogenic Fibroma" was made.

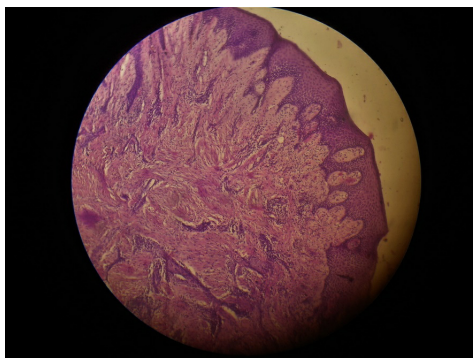

Figure 4: Histopathologic slide

Discussion

In 1982, Gardner mentioned about the peripheral odontogenic fibroma and described it as the superficial equivalent of the central odontogenic fibroma.[5] Itwas showed by Siar and Ng in 2000 that peripheral odontogenic fibroma accounts for 1.2% of all cysts and tumors of odontogenic origin.[6] It is generally seen as a diffuse enlargement mainly in the maxillary anterior and premolar region, it can be sessile or pedunculated, generally pinkish in color which may or may not be ulcerated. It generally needs to be diagnosed properly to separate it from other lesions like peripheral giant cell granuloma, peripheral ossifying fibroma and pyogenic granuloma due to its different course of progression.[7]

WHO has described peripheral odontogenic fibroma as a very uncommon benign neoplasm of odontogenic origin.[8] It was studies extensively by Daley and Wysocki[2] and they found out that peripheral odontogenic fibroma was the third most prevalent neoplasm of odontogenic origin and the most prevalent peripheral odontogenic tumor (POTs). Peripheral odontogenic fibroma is believed to be having a high chance of reappearing even after excision with as high percentage of 38.9%.[9] It was seen mostly in cases of non-calcification type.

Peripheral odontogenic fibroma generally does not cause displacement of the tooth which was seen in this case as well. It has to be kept in mind that esthetic issues are not encountered after excision of this growth and happens only if the lesion encroaches upon the attached gingiva which is quite rare.[10] Periodontal plastic surgical procedures can be employed if it is involved, though in this case it was not.

Due to its similarity with other lesions of the gingiva, it should be differentiated with pyogenic granuloma, peripheral giant cell granuloma and ossifying fibromas as well.

Conclusion

The peripheral odontogenic fibroma is an extremely uncommon enlargement of the gingiva which can be easily confused with other inflammatory hyperplastic lesions due to the clinical similarity. It should be diagnosed properly with the clear cut clinical and histologic features and monitored closely due to high chances of recurrence.

Abstract

Purpose: To obtain the correlation between Down syndrome and a delayed eruption of permanent teeth according to the chronologic age of the individual.

Method: 80 children within the mixed dentition period of 6–12 years were included in the study. 30 among them were children with Down syndrome and 50 healthy ones. The clinical examinations and radiographic evaluations were carried out in order to differentiate between the chronologic and dental age of the individual.

Results: The Down syndrome was found to influence the delayed eruption of teeth ($p<0.001$) in children, as compared to healthy children with a weighted average of delay at 1.20 years.

Conclusion: The children with Down syndrome should be evaluated regularly to provide for a good health and a high standard of life.

Keywords: *Children, chronological age, Down syndrome, dental eruption, mixed dentition.*

Introduction

Down syndrome is an autosomal disorder caused by trisomy 21.[1] With an incidence of 1/700, it is amongst the most prevalent forms of intellectual disability.[2] The first description of a child with Down syndrome was provided in the year 1838.[3] The risk of occurrence is related to the mother's age and represents an etiological factor for various medical conditions.[4]

A child having Down syndrome has a typical physical appearance. The craniofacial features involved include–Brachycephaly, flattened facial appearance, short neck, flat occiput, generous nuchal skin, neuromuscular hypotonia, a low nasal bridge over a small nose, hypotonic maxilla, small anteverted nares, flat nasal bridge, upward-slanting palpebral fissures, and hypertrophy of papilla. The lobes may be hypoplastic or absent, smaller ears, hearing difficulties, and epicanthal folds present[5], along with a markedly decreased brain volume, temporal lobe, parietal cortex and impaired neural development. These typical features result in a mental retardation.[6] Computerized anthropometry is used for quantitative examination of the facial characteristics of Down syndrome.

The oral complications routinely associated with this syndrome in children includes–mouth breathing, macroglossia, open-bite, hypodontia, microdontia, angular stomatitis, fissured tongue and lips, malocclusion, delay in the eruption of primary and permanent dentitions, incidence of dental caries etc.[7] Eruption, determined using clinical examination and radiographs forms the most important aspect of morphological development. In children with Down syndrome, there will be a delay in the eruption timing for both deciduous

and permanent teeth. The least affected ones, however, are the central and lateral incisors and the first molars. Asymmetry, commonly affecting the canines are more frequent between 10–14 years, while between 7–9 years they are less common.[8]

The delayed eruption of teeth in children having Down syndrome could be influenced by decreased peripheral blood circulation, delay in the growth of the maxilla and mandible.[9] Other local causes could be– caries, periapical lesions of the deciduous teeth, trauma etc. This study aims to evaluate the association of Down syndrome and delay in the eruption of permanent teeth in relation to chronological age in children.

Method

80 children, between 6–12 years of age, having mixed dentition were considered for this study. 30 among them were children with Down syndrome, whereas 50 children were healthy. The eruption sequence of permanent teeth, and eruption disorders, if any, were evaluated in all the quadrants using clinical examination and radiological techniques. Data were obtained concerning family history, dental history, growth indices and state of dentition for each patient, and they were then recorded in the dental examination sheets.

The consents for the examination were taken from the parents and the university. The study was subsequently conducted between 2016 and 2017.The dental age was determined by clinically examining for the presence, absence, and the number of the permanent teeth. A statistical calculus of correlations and regressions were considered to establish the relationship between Down syndrome and delay in the age of tooth eruption. The software used for this purpose is the SPSS software. A test was carried out on variation Inflation Factor (VIF) to eliminate multicollinearity with the maximum acceptable limit below 10 that allows acceptance. Also, a simple and ordinary least squares regression was done to evaluate the significance of the adopted model which was set at $p < 0.05$.

Results

On examination both clinically and radiographically, 10 children demonstrated concordance between the dental and chronological ages. 8 children each had a difference of 2 years and 3 years respectively between the two ages. 4 children presented with the greatest discrepancy of 4 years between the two ages.

Among the 50 children in the control group, 45 presented with a correspondence between the chronological and dental age or a difference of within 1 year, whereas 5 children demonstrated a 2-year delay. Thus, overall 25 children with Down syndrome (75%) presented with delayed eruption as against only 10 children (17%) from the control group. This difference is statistically significant. The correlation coefficient between presence of Down syndrome and delay in tooth eruption was found to be 0.609. This can be considered as between average and high-resolution value between the two variables. The statistical calculus of regression value came at 0.37 with a 99% level of significance. A positive correlation coefficient, at the level of 99% ($p < 0.001$) was found between presence of Down syndrome in children and delay in tooth eruption. The weighted average value of discrepancy in the study group was 1.20 years (Figure 1).

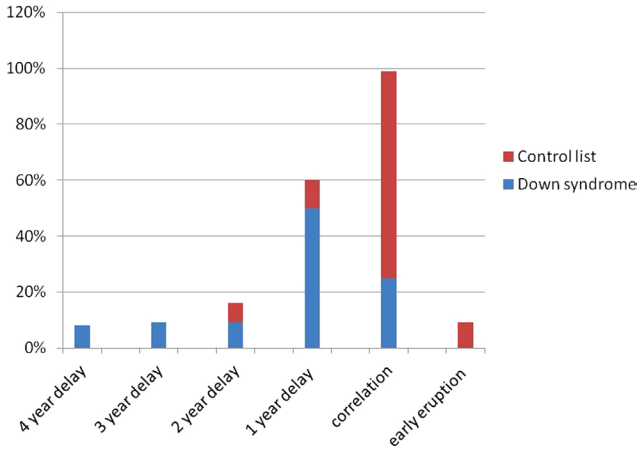

Figure 1. Average value of discrepancy in the study group

Discussion

From a statistical viewpoint, the results of this study, significantly correlate with other studies. Authors in a study on 41 children with Down syndrome between 6–10 years of age, have obtained a statistically significant correlation with a delayed tooth eruption ($p<0.004$).[10] Bagherpour et al 2010, Hedge et al 2002, Baghdadi et al 2012 have described the Demirjian's method to be accurate, whereas, Nik-Hussein et al 2011, Cruz Landeira et al 2010 had mentioned of its various drawbacks.[11,12,13,14,15]

Diz and Limeres carried out a study to assess the discrepancy between chronological age and dental age in children having Down syndrome, cerebral palsy and Intellectual disability respectively. 37 patients

between 3–17 years of age formed the group with Down syndrome. Out of them, 30% presented a delay of 2 years, 2.5 years and 3 years respectively, with a p value of 0.02 at 95% level of confidence. However, since only female patients had shown statistically significant results, the results remained inconclusive.[16] Ogodescu, in his study, demonstrated an increased dental age in girls and an advanced chronological age in boys between 5.5 to 14.4 years.[17] When the results from our study were compared with previous studies conducted on Caucasian and Black samples, most of them suggested the chronological age to be more advanced than the dental age. Karatas et al in 2012, conducted a study on Turkish children from the Anatolia region with a delayed dental age of 0.48 years in boys and 0.38 years overall.[18]Leurs in his study on a Dutch sample, revealed the dental age to be lower than the chronological age by–0.6 years in girls and 0.4 years in boys.[19]Studies in India by Serene Koshy and Hedge also reported similar results. Rizig in a sample of Sudanese children also found the dental age to be lower than the chronological age for both boys and girls.[20]

In the Nordic countries, studies revealed the dental age to be more advanced than the chronological age. According to a study by Mornstad, the difference varied between 0.4–1.8 years in boys and 0.5–1.8 years in girls.[21] The difference was by 0.2 years in boys and 0.3 years in girls when Nykanen performed the study on a population in Norway.[22] Nystrom, in 1986, found the difference to be 0.7 years in boys and 0.9 years in girls when he carried out the study in a Finnish population.[23] Similar results were again observed by Rozylo-Kalinowska et al in 2008 on a population of French children.[24] Rizig in 2013 and Hedge et al in 2002 stated that the differences of sample structure in terms of its age, sex, size, nationality, ethnicity, socio-economic status, diet and the statistical analysis led to a discrepancy between the chronologic age and dental ages when measured by Demirjian's method.

The interval of delay in the eruption can be due to–different study group structure, regional/ local and general factors. Estimations on the stage of development of the Dentofacial complex is significant for the orthodontist as well as the maxillofacial surgeobn, in determining the perfect time to initiate the treatment. This also helps the surgeon to decide on the extraction of the deciduous teeth. A precise diagnosis is always essential to decide on the correct treatment plan.

Conclusion

The presence of Down syndrome in children strongly influences the delayed eruption of teeth as against children who do not have this syndrome. Thus, the children with Down syndrome should be regularly monitored to identify abnormalities in their dental eruption, and in turn provide a good health and quality of life.

Storage Media to Preserve the Avulsed Tooth

Susant Mohanty[1], Antarmayee Panigrahi[2]

[1]Professor & Head, [2]Reader, Ph.D. Scholar, Department of Pedodontics and Preventive Dentistry, Institute of Dental Sciences, Siksha O Anusandhan (Deemed to be University), Bhubaneshwar, Odisha, India

Abstract

Complete loss or exarticulation of tooth out of the socket resulting from trauma and mutilation of periodontal ligament. Immediate reimplantation is the most preferred treatment but is not always practically possible. So, the only option is to have interim storage media to transport the avulsed tooth in least possible time for the best possible outcome. Ideal medium is expected to have pH and osmolality conducive to retain viability of periodontal cells during the extra-alveolar time period. This review focuses on all the available storage mediums and also the medium which are newly proposed and needs further research.

Keywords: *Avulsion, Interim Storage Media, Emdogain.*

Introduction

Advances in dentistry over past decade have progressed and aimed at preserving the natural teeth in every possible. Dental and oral pathology. Complete loss or displacement of tooth out of its socket in the alveolar bone due to trauma is known as dental avulsion and has been categorized as Ellis Class V fracture.This has diverse complications and more importantly in children affecting their growth as well as psychosomatic development. Tooth is normally held in the socket by means of periodontal ligament which gets stretches and splits resulting in loss of teeth. Earlier time the only line of management was to discard the teeth, but now there has been extended research in storage and transport media which assures the vitality of cells and tooth can be successfully reimplanted. The most important criteria are the time and media for storage.[1,2]

Permanent incisors are the most commonly injured teeth and there has been sufficient literature supporting the reimplantation. Also there has been scanty reports about reimplantation of deciduous teeth as well as few cases of delayed reimplantation. Unanimously all studies have shown that if the teeth are stored in ideal media and reimplanted within 15 min reimplantation shows good prognosis. This review focuses on the available storage media as well as on newly developed medias which are on horizon.[2]

Storage Media is a physiological medium which closely simulates the oral environment and preserve the viability of cells of periodontal ligament. Its osmolarity and pH matches with physiological environment and thus sustaining the cells of pdl.[3]

Tap water: Easily available but least desirable and most unacceptable storage media because of it is hypotonic, has pH 7.4-7.9 and osmolality not conducive for pdl cells along with higher chances of bacterial contamination. This causes fastened destruction of pdl cells which is almost similar to storing it dry condition. [4]

Normal Saline:0.09% w/v solution of sodium chloride with osmolality 280 mosm/kg, even though it is found to be compatible to the cells of periodontal ligament but it lacks nutrients which are necessary for the metabolism of cells. Pileggi et al did the study and concluded that viability of cells was reduced to 55% after 4hrs of storage and 20% mortality after 45 min of placement.[5,6]

Saliva: Owing to its easy availability and pH of 7.4-7.9 this can be used safely for storage shorter period of

time. It causes swelling and membrane damage of cells and enhances the chances of replacement resorption. The only advantage is its easy availability but it can be stored only for shorter period of time 2-3hrs.[7]

Milk: It is considered as one of the most acceptable transport medium especially cold milk.

Various studies have conducted to evaluate its efficacy for extended period of time up to 6 hours and have proven to be satisfactory. Marino et al in their study concluded that low fat milk and chilled milk showed better results for longer periods of time. The main drawback is that the presence of antigen in the milk may interfere with the reattachment process.[8,9]

HBSS (Hanks Balanced Salt Solution) introduced by Hanks in 1975 for tissue culture preservation. This is considered as the gold standard and used as comparison criteria to assess the efficacy of medias. This is accepted by American Academy of Endodontics because of its ability to maintain the cells and its capacity to proliferate up to 48 hours. This is composed of sodium chloride, potassium and calcium chloride, anhydrous magnesium sulfate and D-glucose. Its pH and osmolality favor the cells and tissue viability until 24hrs. It is marked as Save–A-Tooth, but its knowledge and use in India is limited and not even readily available.[10,11]

Quest for search of ideal storage and transport media continued leading to trial of various commonly and naturally available and chemically feasible options such as coconut water, aloevera, pomegranate juice, mulberry, propolis, ascorbic acid, growth factors,emdogain, powdered milk etc.

Propolis is plant-based product derived from buds of conifer trees. It is a sticky resin with antibacterial and anti-septic properties. Mori et al evaluated its efficacy and deduced the cell maintainaceuntil 6hrs. Also being immunomodulatory did not interfere in reimplantation. 10% and 50% propolis showed no significant difference in effect on cells of periodontal ligament and the outcome.[12,13]

Coconut Water is natural pure and sterile solution rich in minerals, vitamins, and minerals. Along with it possess regenerative and antioxidant properties so it can be more effective in preserving the periodontal cells. The activity is however dependent on concentration and can be used to store avulsed tooth for longer period of time up to 45 minutes. Thomas et al concluded efficacy of coconut water and HBSS to be equivalent. Silva et al studied the cytotoxic activity of coconut water in comparison to HBSS and found both to be least toxic. Thus, owing to its superior properties and natural easy availability this has been recommended as one of the preferred storage media.[14-16]

Green Tea Extract contains polyphenols which attribute to its health benefits and it is easily commercially available and thus has been tested for being used as storage media. The major polyphenol known as epigallocatechin 3-gallate provide its antioxidant, anticariogenic, and antiseptic property. Hwang et al and Jung et al reported excellent results with almost 90% of cell viability for almost 24 hours similar to HBSS.[17,18]

Aloe Vera belong to Liliaceae family. Inner part is gel like material which can be used but it should be for at least time as possible. Various concentration of aloe vera (10%,30%,50%) was studied by Badakhsh et al and proved to be supplemental culture media up to 9hrs and cell viability was found to be 90% thus aloe Vera can be recommended as suitable media for storing avulsed teeth.[19,20]

Pomegranate Juice have antioxidant, anti-inflammatory and anticarcinogenic property and thus an extraordinary fruit with medicinal power. At concentration of 1% and 2.5% it showed profound proliferative effect at 1hour. It also shows enhanced cell attachment. Pomegranate juice like HBSS produces spindle like morphology of periodontal fibers in 24 hours of storage. However further research is needed to design recommendation.[21]

Egg White has increased protein content, water, vitamins, lesser chances of microbial contamination and can be easily obtained at the site of trauma. In comparison to milk egg white showed better cell viability and fastened healing. With pH of 8.6-9.3 and osmolality of 258 mosmol/kg this can be a suitable media as in comparison to milk. Few researchers have also advocated its use in cases of teeth requiring delayed replantation and avulsed teeth can be stored up to 10 hrs.[3]

Ascorbic Acid being known to stimulate the type I collagen production and also enhances the expression of specific marker for osteoblastic activity such as alkaline phosphate and osteocalcin, this has been proposed to enhance outcome of reimplantation of avulsed teeth. For successful attachment of periodontal fibers to the

socket ascorbic acid plays crucial role and thus serve as prospective storage media.[22]

Growth Factor mediates and regulates numerous activities of the wound healing and also has been proven to promote healing of periodontal fiber regeneration and attachment. Platelet derived growth factor and insulin-like growth factor enhance the formation of periodontal apparatus almost up to 5-10-fold especially during the initial phase of wound healing.[23]

Emdogain (Enamel Matrix Derivatives, EMD) extracted from enamel of porcine origin and contains exceptional matrix proteins. Various researchers have concluded that the matrix proteins influence the attachment of periodontal ligament, proliferative and biosynthetic activity of PDL cells. However, these are among the mediums on the horizon to be further evaluated and compared.[24]

Conclusion

Reimplantation of avulsed tooth is established treatment line to preserve the natural teeth. However, it is influenced by various factors such as growth stage of the tooth, extra-oral time, storage media to maintain viability of PDL cells and delicate handling of the tooth. With so many options available, still there is need to further exploration to have storage media which suits all the criteria and should be easily available and cost effective.

Hypothesising the Research Question

Swati Patnaik[1], Shakti Swaroop[2]

[1]Senior Lecturer, Department of Public Health Dentistry, Institute of Dental Sciences, Siksha O Anusandhan Deemed to be University, Bhubaneswar, [2]Senior Resident, Department of Orthopedics, AIIMS Bhubaneswar

Abstract

With an increase demand in the field of research, it is crucial to have good knowledge about the fundamentals of research. Some of the major setbacks in research can be attributed to a faulty research question, unsatisfactory hypothesis and impractical research objectives. The afore mentioned form the founding stone of a good research paper. Hence, a thorough knowledge about writing a research question, hypothesis and objectives is quintessential. This review provides a simple outlook on penning down a research question.

Keywords: *Research question, hypothesis, objectives.*

Introduction

"Your manuscript is both good and original; but the part that is good is not original, and the part that is original is not good."

Samuel Johnson: After deciding on the research topic, the investigators have to think carefully about the desired outcome of the research and to do so, a research statement or question or hypothesis is essential. This forms the quintessential base of the research. Careful and meticulous reasoning is required to frame an appurtenant research question or hypothesis. A well composed research question with clear objectives helps in the development of a precise study design and hence can produce an outcome which would be authentic and valid.[1,2] This paper aims to help the readers in overcoming the hurdles of framing a research question, with suitable hypothesis and objectives.

Research question: In order to develop the research design, the research topic often has to be changed to a research question, and the research question should be *defined* and *refined* so that it can be answered with precision. The research question defines the "area of interest" but it is not a declarative statement like a hypothesis.[1,3]

While framing a research question one should follow a funnel approach i.e. go from the general focus of the study to the more specific focus areas. A research question should be answerable. The research question should be *right* for the concerned research topic. It should be important, unambiguous, justified for the research topic.[4,5] Apart from delving into the vast knowledge of medical literature, research question designing can be made simpler by following guidelines given by Hulley et al in 2007.[6]

The criteria of the FINER highlight useful points that may increase the chances of developing a successful research project. A good research issue should specify the population of interest, be of interest to the scientific community and beneficial to the public, have relevance, significance and add on to the existing literature.[6]

Table 1: FINER criteria for a good research question[6]

F	Feasible	**Adequate Number of subjects:** • Preliminary sample size • Estimate No of subjects available • No. of subjects who would be excluded or refuse • No. of subjects that would be lost to follow up • Conduct a pilot study whenever necessary **Technical Expertise:** • Subject recruitment • Measurement of variables • Data analysis **Cost:** • Estimate early • Modify design / discard question **Scope** • Don't attempt to accomplish too much • Avoid multiple research questions • Narrow the goal and focus on important question
I	Interesting	• Getting the answer intrigues investigator and community • Benefit for the researcher
N	Novel	• Confirms, refutes or extends previous findings • Old research can be modified based on study populations, variable under study or can add on to the previous findings
E	Ethical	• Amenable to a study that institutional review board will approve • Confirms confidentiality • Follows the helsiki declaration
R	Relevant	• To scientific knowledge • To clinical and health policy • To future research

Whereas the FINER criteria outline the important aspects of the question in general, a useful format to use in the development of a specific research question is the PICO format.[6]

Table 2: PICOT criteria[7]

P	Population (patients)	• What specific patient population are you interested in?
I	Intervention (for intervention studies only)	• What is your investigational intervention?
C	Comparison group	• What is the main alternative to compare with the intervention?
O	Outcome of interest	• What do you intend to accomplish, measure, improve or affect?
T	Time	• What is the appropriate follow-up time to assess outcome

PICOT helps the researcher streamline the study towards specific focus area which can in turn, narrow down the population, cutting costs in carrying out the research. If required, a pilot study can be conducted to further strengthen or modify the research question. Few more things to consider early in designing a research question is to involve a biostatistician as early as possible. They can help in designing a good methodology by selecting an appropriate study design and give an accurate sample estimation.[5,7]

Generating the research hypothesis: Hypothesis: an idea or theory that is not proven but that leads to further study or discussion. It is a tentative and formal prediction about the relationship between two or more variables in the population being studied, and the hypothesis translates the research question into a prediction of expected outcomes. Hypotheses are designed to express relationships between variables. If this is the nature of your question, a hypothesis can add to your research. If your question is more descriptive or explorative, generating a hypothesis may not be appropriate.[6,8]

The experimental or medical hypothesis is formulated on the basis of the research question and is summed up to provide a framework for experiments, statistical and eventually clinical relevance–testing method, intervention (if applicable), correlation and outcome parameters. A research question should be based on the hypothesis rather than the available data. Hence to formulate a good hypothesis one needs to look at variables under study, target population and the relationship between the variables.[6,8,9]

Following the conception of a research question, a researcher also should be able to formulate and alternative hypothesis. The criteria for the research issue in the form of a null hypothesis and an alternative hypothesis should be indicated as the relationship between two or more variables. The null hypothesis and alternative hypothesis should have clear implications for the testing and identification of the relationship. It is essential to refine the research question to design a good and valid research. Finetuning the research question often leads to elimination of ambiguity.

Hypothesis are broadly classified under two categories, namely the 'null hypothesis' and 'alternative hypothesis'. Null hypothesis generally states that there is no relationship between a given set of variables, it can also be called as a statistical hypothesis while alternative

hypothesis states that there is a relationship between a given set of variables. Alternative hypothesis can sometimes be called as working hypothesis or research hypothesis.[9,10]

The design of a research hypothesis is supported by a good research question and will influence the type of research design for the study. The study can then proceed confidently with the development of the research objective based on the principles of appropriate hypotheses.[10]

Research objectives: Research objectives help in making the expected outcomes clearer and specific. A good set of research objectives help in planning a good research design, with minimum flaws and maximum output. A guideline proposed by National Institute of Health in 2016 helps in effective designing of an objective.[11]

S = Specific

M = Measurable

A = Attainable/Achievable

R = Realistic

T = Time Bound

Specific: A specific goal is far more likely to be accomplished than a general purpose. Provide sufficient detail so that it is not undecided what precisely needs to be done. Specific objectives need to focus on the "what" rather than the "why". To successfully design an objective we need to know the nature of the problem or situation we are dealing with.

Measurable: Choose an objective that can be calculated, so that one can see the improvements as they take place. A tangible goal has a quantifiable and evaluable result. Not just the outcome, an objective should also be able to measure the magnitude of the problem.

Attainable/Achievable: An acceptable objective is a realistic outcome, given the current resources and time available to the individual, whether personal, economic or cultural. If the outcome is difficult to begin with, the goal achievement may be improbable. The objective can try to achieve the outcome step by step instead of trying to get everything in one shot.

Realistic: The objective should be relevant and realistic for the particular research question and the study population. The objective should do justice to the need of the population as well as need of the researchers.

Time Bound: A time bound objective is essential to the study as without a time frame, the resources including an investigators time will not be effectively utilized. A time frame can aid in effective evaluation of an ongoing research and can provide adequate leeway for any necessary modification.

Conclusion

A successful research question needs a thorough review of the literature and a deep insight into the particular area to be investigated. The research question needs to be focused and basic with a base of a good hypothesis. Work that is motivated by such a problem can have a wider impact in the field of social and health research by contributing to the current knowledge and simultaneously opening new research prospects.

Comparing the Anti-Plaque and Anti-Gingival Effectiveness of Punica Granatum and Chlorhexidine Containing Mouthwash: A Single Blinded Randomized Clinical Trial

A. Ashwatha Pratha[1], Jayashri Prabakar[2]

[1]Graduate Student, [2]Senior Lecturer, Department of Public Health Dentistry, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India

Abstract

Objective: The objective of this current research is to compare the anti-plaque and anti-gingival effectiveness of Punicagranatum and chlorhexidine containing mouthwash.

Materials and Method: A single blind randomized controlled trial was conducted among 20 healthy individuals. The participants were randomly allocated into two groups: Group I (Experimental group-Punicagranatum), GroupII (Controlled group-Chlorexidine). Before conducting the trial, the study design was explained to the qualifying participant and informed consent was obtained from the voluntary patients who were willing to participate in the study. Erythrosin disclosing solution was used to disclose the plaque. The plaque index and gingival index was recorded at baseline and 7th day. Wilcoxon signed Rank test used to compare the mean differences before and after treatment within each group for Plaque and Gingival index score. Mann-Whitney 'U' test to estimate differences between the mean Plaque and Gingival index score between the groups.

Results: A statistically significant reduction in mean Plaque and Gingival Index score was observed in both Group I and Group II at baseline and 7th day follow up. But there was no statistically significant difference was observed between the groups at 7th day of follow up.

Conclusion: To conclude, there was no statistically significant difference was observed in mean plaque index and gingival index between group I and group IIat 7th day of follow up. Hence, PunicaGranatum mouthwash can be used as an effective antimicrobial oral hygiene measure against plaque and gingival diseases.

Keywords: *Dental plaque, mouthwash, gingivitis, oral hygiene, Index.*

Introduction

Dental plaque is defined clinically as a structured,resilient substance composed of bacteria in a matrix of salivary glycoprotein and extracellular polysaccharides that adheres to intra-oral hard surfaces[1]. The unimpeded accumulation of dental plaque on gingival margin triggers inflammatory effects. The widely recognized factor in the initiation and progression of many oral diseases is dental plaque[2-4].

The principle means of preventing the progression of dental plaque is through mechanical removal by tooth brushing[5]. But for the people who are mentally and physically challenged and as well as those people who lack that skill and motivation,mouthwashes aids in preventing the plaque accumulation[6]. It is the duty of dental professionals to recommend effective oral hygiene to control dental plaque and accumulated inflammatory

Senior Lecturer, Department of Public Health Dentistry, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences, Saveetha University, Chennai, India
e-mail: jayashriprabakar@yahoo.com

components to maintain optimal oral health[2]. The mouthwash has various therapeutic uses which includes reducing inflammation,halitosis and deliver fluoride for caries prevention[7]. However mouthwash should only be used as conjunction with mechanical measures[8].

Chlorhexidine mouthwash is found to possess the most superior anti-plaque property and is considered to be the gold standard among chemical plaque control measures. Its use began as a disinfectant which has a wide anti-microbial spectrum.But there is existence of some side effects which include brownish discolouration of teeth and long term use of this mouthwash may impair taste sensation[9,10]. Thus many alternative herbal mouthwashes has been introduced on daily basis to maintain the oral hygiene and to treat plaque induced gingival diseases as effectively as chlorhexidine[11].One among them is Punicagranatum mouthwash.

Punicagranatum or pomegranate belongs to the Punicaceae family and is the major source of bioactive compounds such as polyphenols,flavonoids,tannins,min erals and vitamins[12]. It acts as astringent, hemostatic agent and as well as drug for diabetic control[13]. It also has various actions like it acts like an anti-oxidant including radical scavenging ability,ferrous ion chelating and ferric ion reducing anti-oxidant power.But nowadays it has been used in dentistry[14]. Pomegranate rinsing significantly decrease the salivary activity of enzyme aspartate.Lowered saliva activities of alpha-glucosidase,an enzyme that breaks down sucrose,it increased the activities of ceruloplasmin,an antioxidant[15]. As it acts as antioxidant it attacks the causes of tooth decay at biochemical level. According to several studies,there is positive clinical result on pomegranate and suppression of oral bacteria[16]. It also has anti-plaque and anti-gingival activity.Thus this study is designed to evaluate and compare the anti-plaque and anti-gingival effectiveness of chlorhexidine and Punicagranatummouthwash.

Materials and Method

Study Design: It is a singleblinded, parallel group, randomized controlled clinical trial.

Study Population: Final year dental students and Interns of saveetha dental college and hospital, chennai were recruited for a double blinded, parallel group, randomized controlled clinical trial.

Eligibility Criteria

Inclusion Criteria:

(a) Apparently Healthy patients without any known history of systemic illness above 18-25yrs of age.

(b) Dental students with Good to Fair Plaque index score.

(c) Dental students with mild to moderate gingivitis.

(d) Dental students with habit of tooth brushing twice daily

Exclusion criteria:

(a) Dental students with positive history of usage of anti-microbial therapy and routine use of oral antiseptics in the previous 3 months

(b) Dental students with history of allergic and idiosyncratic reactions to product ingredients.

(c) Dental students undergoing orthodontic treatment.

(d) Dental studentswith presence of systemic diseases that could alter the production or composition of plaque and saliva.

Sample Size Determination: Sample size was calculated based on study by FarinKiany et al. (2016)[16] using *a priori* by G*Power 3.1.2 software. The minimum sample size of each group was calculated, following these input conditions: power of 0.95 and $P \leq 0.05$ and sample size arrived were 10 per group.

Ethical clearance: Prior to the start of the study, ethical clearance was obtained from the institutional ethics committee, Saveethauniversity.

Randomization

Sequence Generation: Computer generated block randomization with a block size of five were used to generate the assignment schedule well in advance by a third person who was not related to the study. The investigator was blinded to the sequencing of the block and allocation of the groups.

Allocation Concealment: SNOSE (sequentially numbered, opaque, sealed envelopes) method was implemented for allocation concealment which conceals the sequence until interventions were assigned. Patients were assigned their study numbers as they sequentially entered the study.Based on the group assigned, respective treatment was carried out as described in the procedure.

Blinding: Investigator was unaware about the treatment groups. Therefore the investigator was blinded in this study.

Study Procedure

Step 1: Obtaining preoperative details and informed consent from study participants-Prior to the treatment, a careful medical and dental history was taken. Preoperative data for each participant was recorded in the predesigned proforma which includes age, gender and address. The study design was explained to the qualifying participant and informed consent was obtained from the voluntary patients who were willing to participate in the study.

Step 2: Application of disclosing solution- Disclosing solution was generously applied to the surfaces of the teeth with the help of applicator brush (Refer fig 1). The study participants were instructed to rinse the mouth.

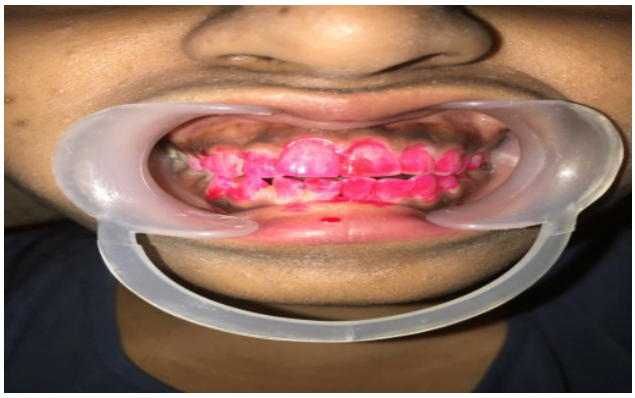

Fig 1: Application of Disclosing agent

Step 3: Scores and Criteria for recording Plaque (Silness and Loe) and Gingival index (Loe and Silness): Plaque index was recorded for the indexed teeth.The mean score of plaque and gingival index is recorded in the pre structured proforma

Step 4: Oral hygiene instructions and tooth brushing technique and Use of mouthwash: A standardized toothbrush and the toothpastes were allocated according to the group. Oral hygiene instructions withan emphasize on the appropriate brushing technique were given.

Direction of use for the Group I and Group II mouthwash (Refer fig 2): Fill cap to the "fill line" (15 mL). Swish in mouth undiluted for 30 seconds, then spit out. Use after breakfast and before bedtime. Or, use as prescribed. NOTE: To minimize medicinal taste, do not rinse with water immediately after use.

Fig 2: Study Groups

Group I-Punicagranatum mouthwash

Group II-Chlorhexidine mouthwash

Step 5: Follow up at 7th day: The above mentioned steps were repeated at 7th day of follow up.

Outcome Measure: The investigator recorded the mean score of plaque and gingival index after the use of tested products at baseline and 7th day.

Statistical Analysis:

- Data was entered in Microsoft excel spread sheet and analysed using SPSS software (version 17).
- Numerical data were presented as mean and standard deviation values.
- For test, a p value of <0.05 is to be considered statistically significant.
- **Wilcoxon signed Rank test** used to compare the mean differences before and after treatment within each group for Plaque and Gingival index score.
- **Mann-Whitney 'U' test** to estimate differences between the mean Plaque and Gingival index score between the groups.

Results

Fig 3 depicts changing trends of Mean Plaque Index score of Group I, II at baseline and 7th day. A significant reduction was observed in mean plaque Index score of Group I from baseline value of 0.52 to 0.37 at 7th day of follow up and in Group II, Plaque Index score dropped

from 0.53 to 0.37. Fig 4 shows the Changing trends of Mean Gingival Index score of Group I, II at baseline and 7th day. A significant reduction was observed in mean Gingival Index score of Group I from baseline value of 0.31 to 0.21 at 7th day of follow up and in Group II, Gingival Index score dropped from 0.28 to 0.19 respectively. Table2: Comparison of Mean Plaque and Gingival Index scores at Baseline, and 7th day time points of Group I and II. A statistically significant difference was observed in mean Plaque Index and Gingival Index score at Baseline and 7th day of follow up using Wilcoxon signed rank test. Table 3 depicts comparison of Mean Plaque and Gingival Index scores of Group I and II at Baseline and 7th day. There was no statistically significant difference was observed in mean Mean Plaque and Gingival Index between the Groups using Mann-whitney U test.

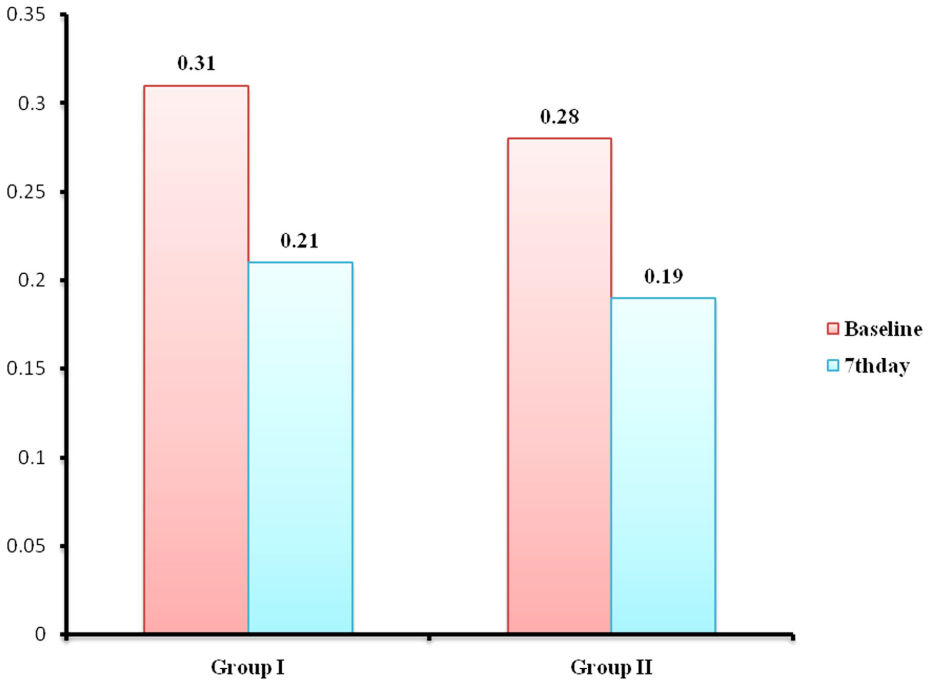

Fig 4: Changing trends of Mean Gingival Index score of Group I, II at baseline and 7th day

Table 1: Comparison of Mean Plaque and Gingival Index scores at Baseline, and 7th day time points of Group I and II

Index	Groups	Time Points (Mean±SD)		Wilcoxon signed Rank test
		Baseline	7th day	P value
Mean Plaque Index	Group I	0.52±0.16	0.37±0.11	0.04*
	Group II	0.53±0.16	0.30±0.12	0.05*
Mean Gingival Index	Group I	0.31±0.09	0.21±0.05	0.03*
	Group II	0.28±0.06	0.19±0.06	0.04*

Wilcoxon signed Rank test (P<0.05)

Table 2: Comparison of Mean Plaque and Gingival Index scores of Group I and II at Baseline and 7th day

Index	Time Points	Groups		Mann Whitney U test
		Group I	Group II	P value
Mean Plaque Index	Baseline	0.52±0.16	0.53±0.16	1.00
	7th day	0.37±0.11	0.30±0.12	0.42
Mean Gingival Index	Baseline	0.31±0.09	0.28±0.06	0.54
	7th day	0.21±0.05	0.19±0.06	0.39

Mann Whitney U test (P<0.05)

Discussion

In the present study, a statistically significant reduction in mean plaque index and gingival index scores was observed in both the groups at baseline and 7th day using Wilcoxon signed Rank test. Eventhough there was no significant difference in mean plaque index and mean gingival index was observed between the groups at 7th day of follow up, but Group II showed an higher reduction when compared to Group I. Our results were found to be controversial when compared with the study done by Ahuja et al., where pomegranate mouth rinse was found to be more effective. This can be due to the smaller sample size and lesser follow up period. According to a study done by Danubia Robertade Medeiros Nobrega, there was a reduction in the mean values of the PI index between the first and the 7th day of assessment in both groups (Chlorhexidinegluconate and Punicagranatum). However, no variation was observed between the 7th day and the 14th day of assessment. There was a reduction in the mean values of the gingival index in both groups. Nevertheless, this reduction was statistically significant only in the control group using 0.12% chlorhexidinedigluconate[17]. According to a study, the zone of inhibition against S.mutans by chlorhexidine mouthwash was found to be 19mm[18]. Our study is in contrast with a study done by Batista ALA et al., where there effective reduction of gingival index of the subjects using Punicagranatum mouthwash for 15 days[19]. A similar study done by SakshiAhuja showed significantly more reduction in plaque score seen in chlorhexidine group as compared with pomegranate and Mean ± SD for pomegranate group has decreased from 3.941 ± 0.257 at baseline to 3.498 ± 0.4206 at 7 days and 3.069 ± 0.4577 at 15 days with% reduction of 11.24% and 22.13%, respectively (P<0.05).Also significantly greater reduction was seen in chlorhexidine group, i.e., from 3.882 ± 0.42918 at baseline to 3.26 ± 0.4356 at 7 days and 2.667 ± 0.6360 at 15 days with% reduction of 16.02% and 31.3%, respectively (P<0.05).But in this study, there is significant reduction in bleeding on probing in subjects using Punicagranatum mouthwash as compared with chlorhexidine [20]. P. granatum was used in other forms, different from mouthwash, or in combination with other herbal medications.It was shown that mouth rinsing with pomegranate mouthwash resulted in lowering of total protein content in saliva in relation to placebo. Total saliva protein is normally higher among people with gingivitis and may correlate with plaque-forming bacterial content. Pomegranate-treated participants also experienced significant decreases in the salivary activity of the enzyme aspartate aminotransferase that is considered a reliable indicator of cell injury and is elevated among patients with periodontitis[16]. Pomegranate peel (Punica granatum) is a nutritive-rich byproduct [21]. It is rich in antioxidants, has antibacterial activity, and has been found effective in treating dental diseases [22]. Therefore, Traditional plants and natural phytochemicals can treat bacterial infections and are considered to be a good alternative to synthetic chemicals [23].

Conclusion

To Conclude, there was no statistically significant difference was observed in mean plaque index and gingival index between groupIand group II at 7th day of follow up,but group II (Chlorhexidine mouthwash) showed higher reduction than group I. In an urge of looking for better antiplaque and antigingivitis mouthwash with limited side effects compared with chlorhexidine, various herbal mouthwashes have

been tried with positive results. Punicagranatum is a recent herbal product used in field of dentistry. More clinical trials are required to know the effectiveness of *Punicagranatum* and its advantage over chlorhexidine, which is still a gold standard for reduction of dental plaque.

Adherence of Hypertension Drugs among 30 Years and above Age Group Urban Population of Eluru, India

Ratna Balaraju[1], K. Chandra Sekhar[2], Shatrughna Bhayya[3]

[1]Assistant Professor, at Kamineni Institute of Medical Sciences, Narketpally, Telangana, [2]Currently working as Professor at Saudi Board Family Medicine Program, Buraidah, Qassim Region, Saudi Arabia.Earlier worked as Professor at Alluri Sita Ramaraju Academy of Medical Sciences, Eluru, [3]Professor & HOD Community Medicine at Kamineni Institute of Medical Sciences, Narketpally, Telangana.

Abstract:

Background: Hypertension is a chronic condition and has got significant role in the development of coronary heart disease, stroke and other vascular complications. To prevent some of the complications of hypertension regular intake of the prescribed treatment in the form of medicines (pills) is essential.

Objectives: 1. To find the adherence status among hypertension individuals. 2. To find the source of diagnosis of hypertension in study population.

Materials and Method: The present community based cross sectional study was conducted at urban area of Eluru, Andhra Pradesh, during the period from June 2013 to June 2014. A total of 533 individuals were selected randomly from the urban field practice area of AlluriSitaRamaraju Academy of Medical Sciences. Results were analyzed and necessary statistical tests were applied.

Results: In the present study overall prevalence of hypertension wasfound to be 24.9%.Majorityof the hypertensive had diagnosed incidentally that was 48.8%, less percentage 17.3% were got diagnosed by the health care providers visit to patient.majority(64.6%) were using beta blockers as anti hypertensive drugs and very less proportion of people were using combination of drugs that is 4.5%.Among 133 hypertension individuals who were on treatment, among them 42.1% were found to have adherence to drugs (taking regularly 6/7 days) and 57.9% were taking drugs less than 6/7 days.

Conclusions: based on the above study results, compliance of hypertensive drugs was poor as study population was taking drugs six days out of 7 days in a week. But majority taking 5 days or 4 days regularly out of seven days in a week due to ignorance and other factors. Good compliance of anti hypertensive drugs reduces the incidence of hypertension associated mortality and morbidity.

Introduction

Uncontrolled hypertension will lead to cardiovascular complications such as myocardial infarction, heart failure, peripheral arterial diseases and aortic aneurysm. It may lead to renal complications like chronic renal failure, end stage kidney diseases etc and neurological complications like cerebrovascular accidents such as stroke. Most of these complications will occur without obvious signs and symptoms. Hence this disease, hypertension is called as "silent killer"[1].

Globally cardiovascular disease accounts for approximately 17 million deaths in a year, nearlyone third of the total deaths. of these, complications of hypertension account for 9.4 million deaths worldwide

every year. Hypertension is responsible for at least 45% of deaths due to heart disease and 51% of deaths due to stroke[2].

Epidemiological studies shows that there is significant geographical difference in the occurrence of hypertension and its complications both between and within the countries: this is considered to be influenced by the interaction of nutritional and environmental factors with the subjects genetic predisposition/susceptibility to hypertension[3,4,5].

The WHO definition of adherence is "the extent to which a person's behaviour taking medication, following a diet, and/or executing lifestyle changes, corresponds with agreed recommendations from a health care provider[7-9].Detection of hypertension is not sufficient for the reduction of health problem in the society and also one must take care about regular treatment at least 6 days of treatment out of 7 days treatment means 85% adherence would bring the disease control as well as complications reduction in terms of mortality and morbidity. Many studies taken adherence criteria as 6/7 days of treatment in a week.Hypertension is an iceberg disease and the many studies were conducted on hypertension prevalence in many urban areas mainly in metro cities. Still some data is lacking, as such as in small towns like Eluru regarding hypertension prevalence and adherence of hypertension drugs status. Earlier many studies found that hypertension was observed in above 40 years of age group. As per my knowledge there is no much studies conducted in and around Eluru city regarding adherence of hypertension more than 30 years age group. Early onset of hypertension leads to decreasing life expectancy and also leads to pre mature deaths and disability. Hence, I have taken this particular study to find out adherence of hypertension drugs among 30 years and above age group and how factors associated with hypertension.

Objectives:

1. To find the adherence status among hypertension individuals.
2. To find the source of diagnosis of hypertension in study population.

Materials and Method

This was a community based cross-sectional study conducted among the adult individuals (aged ≥ 30 years) residing in the urban field practice area of a Alluri Sita Ramaraju Academy of Medical Sciences, Eluru. It would also serve the purpose of providing base line data of Hypertension in the target population of the Urban Health Training Centre, for future follow up and studies. The study has been conducted from June 2013 to June 2014 (including 6 months of field work) individuals above 30 years of age residing in the field practicearea of AlluriSitaRamaraju Academy of Medical Scienceswas included in the study. Systematic random sampling method was used for collecting the data. Based on JNC VII [6]criteria, a person was considered hypertensive if Systolic Blood Pressure ≥140 and/or Diastolic Blood Pressure ≥90 mmHg and Persons already on anti-hypertensive treatment. Data was collected by listing all the areas which comes under urban field practice area. As there were no prevalence studies in this area above 30 years age group, for calculating required sample size for the study, a pilot study was undertaken by considering 50 subjects above 30 years of age in one of the urban field practice area and the prevalence of hypertension was found to be 25% and as per the global statistical report 2010 the prevalence of hypertension in urban area was also 25%. So, by taking the mean prevalence of Hypertension in this age group was 25%. Fixing the allowable error to be 15% the minimum required sample size was calculated by using the formula n = 4 pq/L2. Hence sample size was arrived 533 and response rate in the study was 91%. Compliance criteria in our study was those who taken medicines regularly 6 days out of 7 days in a week.

Statistical Analysis: Necessary statistical tests like simple proportions were used with 95% confidence intervals.

Table No. 1: Age and sex wisedistribution of study population

Age in yrs	Male	Female	Total
30-40	138 (52.5%)	125 (47.5%)	263 (100%)
41-50	76 (53.1%)	67(46.9%)	143 (100%)
51-60	37(52.8%)	33 (47.2%)	70 (100%)
>60	26 (45.6%)	31(54.4%)	57 (100%)
Total	278 (52.1%)	255 (47.9%)	533 (100%)

In the present study, out of 533 sample 52.1% were males and 47.9% were females. 49.3% (263/533) of the study population in the age group of 30-40 years remaining 50.7% were in 40 years and above age group.

Table 2: Hypertension status among study population

Status	Hypertension individuals	Percentage
Diagnosed	83	15.6%
Newly diagnosed	50	9.3%
Total	133	24.9%

Table 2 shown out of 533 study population, 133 individuals were having hypertension. of which total of 133 hypertensives, 15.6% were already diagnosed hypertension and 9.3% were newly diagnosed during the study.

Table 3: Source of diagnosis of hypertension among hypertension population

Source of diagnosis	Hypertension
Incidental	65 (48.8%)
Periodical health check up	45 (33.9%)
Health care providers visit to patient	23 (17.3%)
Total	133 (100%)

Table 3 depicts thatthe hypertension among the study population were diagnosed. Majority of the hypertensive had got diagnosed incidentally that was 48.8%, less percentage 17.3% were got diagnosed by the health care providers visit to patient.

Table 4: Type of drug usage among hypertension population

Type of drugs	Hypertensive individuals
Beta blockers	86 (64.6%)
Calcium channel blockers	15 (11.2%)
Diuretics	5 (3.7%)
Alpha blockers	14 (10.5%)
ACE inhibitors & receptor blockers	7 (5.2%)
Combination	6 (4.5%)
Total	133 (100%)

Table 4 shown that among 133 hypertensive individuals majority (64.6%) were using beta blockers as anti hypertensive drugs very less proportion of people were using combination of drugs that is 4.5%

Table 5: Adherence to drugs in hypertension population

Adherence	Number of people	Percentage
Present	56	42.1%
Absent	77	57.9%
Total	133	100%

Table 6 shown that among 133 hypertension individuals who were on treatment, among them 42.1% were found to have adherence to drugs and 57.9% were not found be non adherence to drugs among study population.

Table 6: Reasons for non adherence in the study population

Reasons	Number of people	Percentage
Cost	31	40.3%
Distance	24	31.2%
No idea	10	13%
No family support	8	10.3%
Other factors	4	5.2%
Total	77	100%

In the hypertension population, about 40.3% were giving reason for non adherent was cost of the medicine and about 31.2% were giving reason as distance to house for getting the medication.

Discussion

The present study was conducted to study the Adherence of hypertension in urban field practice area of AlluriSitaRamaraju Academy of Medical sciences, Eluruand to study the factors associated with hypertension.A total of 533 study subjects were selected comprising of 278 males and 255 females. Most of the study population belonged to age group 30-40years.

In our study the overall prevalence of hypertension was found to be 24.9% These results were comparable to the rates obtained by shymalkumar etal [15] in his study titled ‘prevalence of hypertension in urban population of west Bengal, representing eastern India, where the prevalence of hypertension has been reported to be 24.9 in urban adults and also similar rate was obtained by Renu rani etal[16] among adults in urban area of Jammu in 30 years and above age group.

In the present study, among 133 hypertensive individuals majority were using beta blockers as anti hypertensive drugs very less proportion of people were using combination of drugs that is 4.5%. Among 133 hypertension individuals, who were on treatment, among them 42.1% were found to have adherence to drugs and 57.9% were not found as adherence to drugs among study population.About 40.3% were giving reason for non adherent was cost of the medicine and about 31.2% were giving reason as distance to house for

getting the medication.An Open access peer reviewed E-Journal research article on Antihypertensive Drug Compliance across Clinic and Community Settings[18], in Thiruvananthapuram, South India found it difficult to purchase medicines from commercial outlets on a long-term basis. A similar finding was reported from Sudan where 36.8% of the patients cited lack of money to purchase anti hypertensive drugs as the reason for non-compliance[17].

In the current study the prevalence of poor adherence to their anti-hypertensive treatment was found to be 42.1% which was quite similar to the findings of the studies done in Kasturba Hospital, Manipal by Sheilini M et al.[10] and in Mangalore by Kumar N et. al[11] where prevalence were 49.2% and 45.8% respectively. In the study by Khanam M A et al[12]among people of rural Bangladesh the prevalence of non adherence to treatment hypertension was 26.2% in the study population (25 years and above) which was low in comparison to this study. This wide difference in the prevalence of non adherence compared to our study could be because the study participants were aged 25 years above and in our study the age of the participants was 30 years andabove. Our study findings are similar to studies from China[13] and Malaysia[14] where overall 52% and 53.4% of the participants were found to be adherent to their anti-hypertensive medication respectively.Noncompliance to antihypertensive drug treatment is a complex issue, which needs to be corrected by the implementation of multifactorial strategies. The recognition and proper understanding of these complexities are expected to facilitate the development of effective solutions. Just detection of prevalence of hypertension does not give solution to the community and also researchers must focus on adherence to treatment and problems for poor adherence and multi dimensional strategies to be implemented in terms of education, diet and drugs and facilities etc.

Conclusions

Based on the study results, The adherence of hypertension treatment in the study population was little low comparatively other studies. All factors need to be synchronized so that adequate compliance, reasons for poor adherence to the treatment and blood pressure control is to be achieved in the affected population, thereby reducing the morbidity and mortality associated with hypertension.

Acknowledgements: My sincere thanks to all my study population who spared their time for successful completion of the study.

A Study on Attitude of Female Teachers Towards Inclusive Educationwth Special Reference to Schools in Chennai District

K. Kalaiselvi[1], M. Vetrivel[1]

[1]Assistant Professor, Department of Commerce, School of Management Studies & Commerce, VELS University, Chennai

Abstract

The study was carried out to find the attitude of teachers towards inclusive education and the factors affecting it. A total of 60 teachers as respondents were involved in this study. The researchers conducted the research using the Descriptive Research Design. Descriptive Research is a scientific method which involves opening and describing of an individual without influencing the individual in any way. The tools used for data collection from the sampling were questionnaire. This questionnaire was prepared after a considerable and deep understanding of the research problem, discussion with experienced researchers, extensive study of pertinent literature and contextual imagination. The tentatively formed questionnaire was pre-tested with few samples to detect the shortcomings. The questionnaire used in this study included a scale which was derived from various other scales used to study the attitude of teachers towards inclusive education. The researchers used convenient sampling as sampling design to select the schools and teachers for gathering information. The researchers used convenient sampling due to many schools unavailability and used convenient sampling to select teachers due to unavailability of a proper list of teachers to select randomly. The respondents in this study are primarily having a positive attitude towards inculcating inclusive education in their respective schools, but are widely influenced by the type of disability that the children have when inclusion is decided upon.It can be found that most of the respondents are aware about what inclusive education is, its advantages as well as the difficulties it brings but still have a positive attitude towards inclusive education.

Keywords: *Inclusive education, attitude, teachers, Descriptive.*

Indroduction

The attitudes of teachers are shaped through a variety of factors which are both internal as well as external and which play a major role in determining whether the attitude reinforced is positive or negative. Teachers' past experiences as learners are powerful in shaping conceptions and expectations about teaching students, and form beliefs about the process of teaching during their pre-service training, and once a belief has been held for a long time it becomes difficult to change.[1] In India, a majority of children with special needs don not receive any formal education, in spite of the practice of inclusive education is some schools. This is because children with disabilities and learning deficiencies are segregated from mainstream schools and other regular routines and social activities of normal children. Inclusive education is more in tune with the social model of disability which sees the system as the problem.[2] The teachers and the education system as a whole are enabled to change in order to meet the individual needs of all learners. Teacher development has to be the heart of initiatives for developing inclusive practices in schools. There is need for strengthening knowledge, competence, skills and attitudes of teachers for creating inclusive ethos and learning environment in schools.[3]

Meaning Of Inclusive Education: Inclusive education means that all students attend and are welcome by their neighbourhood schools in age-appropriate, regular classes and are supported to learn, contribute and participate in all aspects of the life of

the school.Inclusive education in Chennai as the same could prove to be helpful in findings the solution to the problem besetting inclusive education and make improvements is considered as one of the primary goals behind creating sustainable communities for the future.[4] Inclusive education is defined as a process in which all school systems welcome all learners despite their background, disability or other personal characteristics. Inclusive education helps in not only shaping the lives of the differently-abled into that of normal ones but also in exposing the minds of young normal children to the various disabilities and developing a welcoming attitude. Inclusion is not an experiment to be tested but a value to be followed. All the children whether they are disabled or not have the right to education as they are the future citizens of the country. At the "World Conference on Special Needs Education: Access and Quality" (Salamanca, Spain 1994), the principle of inclusive education was adopted and it was also restated at the World Education Forum (Dakar, Senegal 2000).[5]

Objective of the Study:

- To study about the demographic characteristics of teachers
- To know the type of attitude the teachers have towards inclusive education
- To study the influence of different types of disability in children on attitude of teachers

Sampling: All the regular schools in Chennai (Tambaram and surrounding areas) and their teachers. 5 regular schools and 50 schools teachers (10 teachers from every school). Convenient Sampling for selecting schools: Convenience sampling is a non-probability sampling technique where subjects are selected because of their convenient accessibility and proximity to the researchers. Any 5 regular schools are chosen to fulfil the research process. Convenient Sampling for selecting teachers: Almost all schools have more than thirty teachers. The researchers couldn't get an appropriate list of all the teachers present in that particular school and hence could only choose the teachers according to their availability and the researchers' convenience.

Tools Data Collections: A questionnaire was used to collect data for the study. A questionnaire is a research instrument consisting of questions or other types of prompts for the purpose of gathering information from the respondents.

Age of the Respondents: This table was studied to find out the age of the respondents

Table 1: Age of the Respondents

Age	Frequency	Percentage (%)
29 and Below	13	26
30-39	27	54
40 and Above	10	20
Total	**50**	**100**

Source: primary data

Table 1 shows that among 50 respondents, 54 per cent of the respondents are in the age group of 30-39 years, 26 per cent of the respondents are in the age group 29 and below and 20 per cent of the respondents are in the age group 40 and above. From the above data, it can be inferred that the highest frequency of age of most of the teachers falls under the 30-39 years category and that is usually the average age of an experienced teacher in schools. It can also be observed that there are very less percentage of teachers in the 40 and above age group indicating that schools prefer middle-aged teachers more than elderly ones.

Gender of the Respondents: This table was studied to find out the gender of the respondents

Tabel 2: Gender of the Respondents

Gender	Frequency	Percentage (%)
Male	13	26
Female	37	74
Total	**50**	**100**

Source: primary data

Table 2 shows that among the 50 respondents, 74 per cent of the respondents are female teachers and 36 per cent of the respondents are male teachers. From the above data, it can be inferred that the majority of the respondents are female and male teachers are very less in number. This may be due to the fact that most of the teachers being employed nowadays are female. It can also be that teaching in schools has traditionally been considered a profession for the women due to their ability to take care of children and also male teachers' reluctance to take care of children in schools.

Table 3: Teaching Class Of Respondents

Respondent	Frequency	Percentage (%)
Elementary	8	16
Primary	12	24
Middle	6	12
High	24	48
Total	**50**	**100**

Source: primary data

Table 3 shows that 48 per cent of the respondents are teaching in high school, 24 per cent of the respondents are teaching in primary school, 16 per cent of the respondents are teaching in elementary school and 12 per cent of the respondents are teaching in middle school.

It can be inferred from the above data that that most of the teachers are from the high school and also a small percentage of the majority are from the primary school and hence most of the data collected is based upon the attitude of teachers towards inclusive education in high schools. It can also be observed that due to the lottery method more number of high school teachers was selected which is indicative of presence of more high school teachers in a school.

Significant Levels of Interaction with Person with Disabilities: The table is used to study the significant level of interaction the respondents have had with children with disabilities.

Table 4: Significant Level Of Interaction

Interaction	Frequency	Percentage (%)
Yes	21	42
No	29	58
Total	**50**	**100**

Source: primary data

The data shows that 58 per cent of the respondents haven't had significant interaction with persons with disabilities and 42 per cent of the respondents have had significant interaction with persons with disabilities. It can be inferred from the above data that more than half the respondents haven't had significant interaction with persons with disabilities and it shows the lack of opportunities and interest most teachers have when interacting with children with disabilities. But due to the percentage being less skewered, we can also conclude that there is a positive intent among teachers to interact with children with disabilities. It also shows that due to half of them having less or very less interaction with persons with disabilities, their very few experiences may be determining their attitude towards children with disabilities.

Knowledge of Local Legislation Policy Regarding Disability: This table is used to study about the respondents' knowledge of local legislation policies regarding disabilities.

Table 5: Knowledge of Local Legislation Policy Regarding Disability

Knowledge level	Frequency	Percentage (%)
Very good	1	2
Good	13	26
Average	26	52
Poor	2	4
None	8	16
Total	**50**	**100**

Source: primary data

The above data shows that 52 per cent of the respondents have an average level of knowledge regarding local legislations, 26 per cent of the respondents have a good level of knowledge, 16 per cent of the respondents are not aware of any legislations, 4 per cent of the respondents have a very poor knowledge level and 2 per cent of the respondents have a very good knowledge level.

It can be inferred from the above data that most of the respondents have some level of knowledge regarding the legislations for disabilities. The data also shows that most of the teachers have either something or the other knowledge about the local legislation policy due to increased awareness campaigns and more socially aware public in general.

Level of Confidence in Teaching a Student with Disability: This table is used to study about the level of confidence of respondents in teaching a student with disability.

Table 6: Level of Confidence in Teaching a Student with Disability

Level of confidence	Frequency	Percentage (%)
Very high	5	10
High	23	46
Average	20	40
Low	2	4
Very low	0	0
Total	**50**	**100**

Source: primary data

The above data shows that 46 per cent of the respondents have a high level of confidence in teaching student with disability, 40 per cent of the respondents have an average level of confidence, 10 per cent of the respondents have very high level of confidence and no respondent has very low level of confidence in teaching children with disabilities.

It can be inferred from the above data that most of the respondents have average to high level of confidence in teaching children with disabilities. It shows most of the teachers are confident or confident enough to teach children with disabilities even though they are not qualified or trained enough. This is due to the inherent ability and confidence of teachers which they possess to deal with any kinds of problems they face.

Major Finding:

- The study found that majority of the respondents have a positive outlook towards inclusive education and have an attitude which would progress the implementation of inclusive education in regular schools at a faster rate
- According to the study, the demographic factors played a major role in influencing the attitude of teachers towards inclusive education. It is due to reasons such as previous experience, gender and continuous exposure to disability and students with disability which shape their thoughts and prejudices.
- The study also found out that the attitude of teachers are vastly influenced by the type of disability which curtails a student among other factors and this was observed in the respective interpretation when the respondents were divided upon the type of attitude which they have towards inclusive education when it pertains to various disabilities.

Suggestions: Inclusive education is one of the most trending topics in modern education system and inclusion is the norm in today's world of bigoted, racist and cattiest people. Segregating normal children from children with disabilities in the name of special schools and special attention in another form of marginalization and division and it denies both groups the chance of getting to know each other and in the process getting to know themselves. One powerful group which can put an end to this are the educators and the teachers who are the driving force behind the education system in this country.

Teachersshould try to be more aware and gain knowledge about disability and try to be more ready to handle children with disabilities when the time of inclusion comes. Experiential learning should be a must for all newly appointed teachers who need to be appointed based on their expertise in dealing with all types of children. Inclusion is natural; teachers need to embrace it as their own.

Conclusion

The study has been completed successfully with the help of various people who have helped at various times during the research process. Inclusion is very essential in bringing in the marginalised communities in our society along with normal people and this is the way humans are intended to be, together and with unity in diversity.[6] Such diversity must be celebrated from a very young age and inclusive education plays a major role in it. There is a generally positive attitude among teachers for inclusive education and most of them seem ready if given the task of being an inclusive educator. The research was successful in determining the various aspects of inclusive education which influence the attitude of teachers towards inclusive education.

Conflict of Interest: Completed.

A Descriptive Study to Assess the knowledge on Fertility and Infertility among Adolescent Girls in a Selected College at Kanchipuram District Tamil Nadu, India

R. Renuga[1], R. Vaishnavi[1], S. Saritha[1], K.Vanitha[2]

[1]Nursing Students, [2]Assistant Professor, Chettinad College of Nursing, Chettinad Academy of Research and Education, Kelambakkam, Kanchipuram, Tamil Nadu

Abstract

A descriptive study to assess the knowledge on fertility and infertility among adolescent girls in a selected college at kanchipuram District TamilNadu. The objectives were to assess the knowledge on fertility among adolescent girls in a selected college at Kanchipuram District,Tamil Nadu, India., To assess the knowledge on infertility among adolescent girls in a selected college at Kanchipuram District Tamil Nadu, India, To compare the knowledge on fertility and infertility among adolescent girls in a selected college at Kanchipuram District,Tamil Nadu,India, To associate demographic variables With the knowledge on fertility and infertility among adolescent girls in a selected college at Kanchipuram District,Tamil Nadu, India.Hypothesis of the study were 1. There is no significant co relation between the knowledge on fertility and infertility among adolescent girls in a selected college at Kanchipuram District,Tamil Nadu, India,2. There is no significant association between the selected demographic variables with the knowledge among adolescent girls in a selected college at KanchipuramDistrict,Tamil Nadu, India. The convenience sampling was used to select 78 samples. The data collection tools were validated and reliability was established. The data were collected by self-administered questionnaire. The collected data tabulated and analyzed. Descriptive and inferential statistic were used. The study showed that 60 adolescent girls had poor knowledge on fertility where as 4 had adequate knowledge on fertility, 39 adolescents had poor knowledge where as 9 had adequate knowledge on infertility.There is a weak positive correlation between knowledge on fertility and infertility among adolescent girls were r=4.586.There is no significant association between the knowledge on fertility and infertility among adolescent girls with the selected demographic variables.

Keywords: *Fertility, Infertility, Adolescent Girls.*

Introduction

This is a list of the states and union territories of India of ranked in order of number of children born for each woman. Recent surveys show that majority of Indian states fertility rate has fallen well below the replacement level of 2.1 and the country is fast approaching the replacement level itself. The total fertility rate of India stands at 2.2 as of 2017. In seven years Indians will cross the 1.44 billion mark and the nation will go on to have a bigger population then china, according to a U.N.report [7]

The world population prospects :The 2017 revision report released on June 21,2017 recorded two other dramatic facts :The fertility rate of Indians have more then halved over the last 40 years to 2.3 and Indians have added almost a decade to their life expectancy in the past 25 years which is now nearly 69 years. [7]

Materials and Method

Research Approach: In this study, researchers assessed the level of knowledge on fertility and infertility among adolescent girls by using **Quantitative approach**

Research Design: Descriptive research design was used for the present study.

Research Setting: The study was conducted in Tagore College of Nursing at Kanchipuram District, TamilNadu, India.

Population: The entire set of individuals or objects having some common characteristic(s) selected for a research study; sometimes referred to as the universe of the research study.

Target Population: The entire population in which the researchers are interested and to which they would like to generalize the research findings

Accessible Population: The population of the present study comprises of all the adolescent girls in a selected college who were all available during the period of data collection in selected College, at Kanchipuram District, Tamil Nadu.

Sample: Adolescent girls in the course of first year B.Sc Nursing in Tagore College of Nursing at Kanchipuram District, TamilNadu, India.

Sample Criteria

Inclusion Criteria

- Girls who are in age group of 17 and 18 years
- Girls who are in the course of first year B.Sc Nursing
- Those who are willing to participate
- Who are able to understand English

Exclusion Criteria

- Girls who are not available at the time of study.

Sampling Technique: Non Probability-convenience sampling technique was adopted for this study.

Sample Size: The sample size=79

Description of the Tool

Data Collection Tool: A self-administered questionnaire was used as a tool for data collection. It was consisted the following parts.

Part-A: A description of the demographic characteristics of the sample like Age, Educational status of the father,Educational status of the mother, Occupational status of father, Occupational status of mother.

Part-B: Question to assess the knowledge regarding fertility among adolescent girls which contains10 questions Each sample has taken 10 minutes to fill up.

Part-C: Question to assess the knowledge regarding infertility among adolescent girls which contain 10 question Each sample has taken 10 minutes to fill up.

Score And Interpretation

Total number of knowledge question-20. Each correct answer was given 1 mark.

Score	Level of Knowledge
Above 76%	Adequate knowledge
51-75%	Moderate knowledge
Below 50%	Inadequate knowledge

Analysis of data: Data was analyzed using Descriptive and Inferential statistics.Data were analyzed using computer software MS Excel,The sample's characteristics were reported as percentages. The association was reported by using chisquare. The comparison was done by using correlation coefficient.

Results and Discussion

The study showed that 60 adolescent girls had poor knowledge on fertility whereas 4 had adequate knowledge on fertility, 39 adolescents had poor knowledge whereas 9 had adequate knowledge on infertility

Table 1: Frequency and Percentage of knowledge level on fertility

Grade	Frequency	Percentageof Sample
Adequate knowledge (76-100%)	04	5.127%
Moderate knowledge (51-75%)	14	17.94%
Poor knowledge (50%)	60	76.92%
Total	**78**	**100%**

Table 2: Frequency and Percentage of knowledge level on infertility.

Grade	Frequency	Percentageof Samples
Adequate knowledge	09	11.53%
Moderate knowledge	30	38.46%
Poor knowledge	39	50%
Total	**78**	**100%**

There is a weak positive correlation between knowledge on fertility and infertility among adolescent girls were r=4.586.

There is no significant association between the knowledge on fertility and infertility among adolescent girls with the selected demographic variables.

Findings of the study were presented under the following headings based on the study objectives

The findings of the present study reveals that

60 (76.92%)of adolescent girls where had poor knowledge on fertility where has only 39(50%) of adolescent girls had poor knowledge on infertility, above table shows that the adolescent girls need to be educated on fertility and the association with demographic variables revealed that There was no significant association between the age and the level of knowledge on fertility and infertility among adolescent girls x^2 =3.5093,p<(0.05),There was no significant association between educational status of the father and the level of knowledge on fertility and infertility among adolescent girls x^2 =5.3082,p<(0.05),There was no significant association between occupational status father and level of knowledge on fertility and infertility among adolescent girls x^2=6.7008.p<(0.005),There was no significant association between occupational status of mother and level of knowledge on fertility and infertility among adolescent girls x^2=5.0879,p<(0.005)

Conclusion

As our study state that adolescent girls had poor knowledge on fertility and infertility which is alarming. So researchers were given health talk to the adolescent girls on fertility and infertility

Conflict of Interest: No

Source of Funding: Nil

Ethical Clarence: In this study the researchers have got prior permission to conduct the study and got informed consent from each participant. we ensured that no physical harm to the samples. Confidentiality maintained

A Descriptive Study on Practice of Self Medication in Urban Field Practice Area of Perambalur Municipality, Tamil Nadu, India

Karthikeyan K.[1], Tamilarasan M.[2], Rock Britto[3]

[1]Associate Professor, [2]Assistant Professor, [3]Assistant Professor, Department of Community Medicine, Dhanalakshmi Srinivasan Medical College and Hospital (DSMCH), Perambalur, Tamilnadu

Abstract

Introduction: Allopathic medicines in India are available through pharmacies and a doctor prescription is essential for procuring any allopathic drug. There are few medicines that are available over the counter (OTC) without doctors prescription. However in India, medicines are available without doctors prescription.

Objective:

1. To study the profile and practice of self medication among the urban residents of Perambalur district in India.
2. To understand the various factors influencing self medication among the study participants.

Materials and Method: Its a questionnaire based cross sectional study conducted in the urban field practice area of a medical college involving 150 participants.The study subjects were interviewed after they purchased medications from pharmacy.The study was intended to study the profile of practice of self medication rather than trying to estimate the prevalence.The study was conducted for a period of 6 months from Jan 2018 to August 2018.The study data was analysed using microsoft office excel.

Results: Fever was the most common condition (72%) closely followed by headache (67%) for which pharmacy was approached for self medicaton followed by Respiratory infections (55%), general body pain (40%), diarrhoeal problem (8%) and lack of sleep (8%).

Conclusion: The practice of self medication was found to be deeply inculcated in the minds of the participants and the participants did not feel that prescription by pharmacist without consultation of a doctor is going to be dangerous for their long term health. The knowledge regarding the medications and its side effects was negligible among the study participants. There is an urgent need from the health system planners to address this issue in a comprehensive manner before this burden goes out of control.

Keywords: *Self Medication, Over the Counter drugs, Prescription.*

Introduction

Medicines are important for treating diseases, and they are responsible for improving the population's life quality. However, indiscriminate use of medicines might cause health risks. Self-medication is defined as obtaining and consuming drugs without the advice of a physician either for diagnosis, prescription or surveillance of treatment.[1]The practice of self-medication is worrisome because of the easy access to medicines.There is a bewildering variety of medicines available without prescription in various parts of the world.They include paracetamol, nonsteroidal anti-inflammatory drugs (NSAIDs) as aspirin and ibuprofen, and opioids (usually codeine), as well as numerous 'complementary therapies' and 'herbal' products.[2,2–6]

Corresponding Author:

e-mail: karthikspm@gmail.com

They may be available in different formulations, such as standard tablets, fast acting tablets, effervescent powders, or liquids. Packaging and branding can make it difficult to identify similar products or to compare them[7]. Patients often have limited knowledge of the properties of OTC drugs and how to use them appropriately. [3,8,9] Increased availability of OTC drugs has previously been suggested to lead to more relaxed attitudes towards the use of these drugs. There is evidence that patients are unaware of the adverse risks associated with concurrent use of OTC drugs with other drugs and agents [5,6,]and the long-term use of certain OTC drugs in general.[6,7,] The Practice of Self medication is a global problem and its extent of practice in developing countries like India is not fully explored. The availability of medicines without prescription is largely unregulated in India and hence this study was conducted to analyse the extent of self prescription practices in India.

Objective:

1. To study the profile and practice of self medication among the urban residents of Perambalur district in India.
2. To understand the various factors influencing self medication among the study participants.

Methodology

Study Design: Descriptive Crosssectional study

Study setting: Urban residents of Perambalur Municipality, Perambalur district, Tamilnadu.

Study Period and Duration: From May 15, 2018 to July 15, 2018

Sample Size: Assuming the prevalence of selfmedication practices as 50% and taking allowable error of 15% with 95% confidence levelusing the formula 4p (1−p)/d^2, the minimum sample size was calculated to be 142.68 which was rounded off to 150.

Sampling technique: Non probability convenience sampling.The people who bought the medications from the urban area pharmacy was interviewed after they purchased the medications from the pharmacy.This was done to ensure that the participants purchased some form of mediation and the possibility of bias is minimized.

Inclusion criteria:

1. Persons who were 18 years of age and who were able to read and write the local language (Tamil or English) were included in the study after informed consent explaining the purpose of study.

Exclusion criteria:

1. Participants belonging to medical, paramedical and pharmacology fields were excluded from the study survey to avoid selection bias as they are well aware with potential side effects of self medication and expected to have lower self medication rates.
2. Participants with intellectual, psychiatric and emotional disturbances that could affect the reliability of their responses were excluded from the study.

Data Collection: A pilot study was conducted initially to test the questionnaire on 20 subjects who fulfilled the inclusion criteria of our study in the same setting. In the light of responses obtained, ambiguities from questionnaire were removed before its implementation in the final study.The data from pilot study was not included in the final results.

Data were collected by interview using semi-structured pretested questionnaire which was administered to the participants. Prior written informed consent was obtained from the study subjects. The data was collected from the field practice area of urban health centre in Perambalur.

Data collection tool: We used paper based questionnaire which was divided into 2 parts for data collection. Each section was preceded by the statement to elaborate the type of question that would follow, for the better understanding of participants. The first part assessed the demographical features of the subject followed by second part which dealt with the prevalence and practice of self medication. The entire tool used consists of close ended questions only.

Data Analysis: The prevalence of self-medication was reported in percentages. Various determinants of self-medication use were analyzed using either Chi-square test or Fisher's exact test using Epi Info. The $P < 0.05$ was be taken as statistically significant.

Results

The average age of study population was around 44.6 yrs. Among the study participants majority of the participants were male (86%). Education plays a major role in practices such as self medication. Hence the education and occupation was assessed and it was

found that all most all of the population who participated in this study were literate barring only 4% rest 96% were literate. It was found that about 56% of the study population were involved in semi skilled occupation mainly farming. (Table 1).

Table 1: Socio Economic Characteristics of the Study Population

Variable	Frequency	Percentage
Age	44.6±3.8	
Gender		
Male	129	86
Female	21	14
Education		
Illiterate	6	4
Literate	144	96
Occupation		
Skilled	48	32
Semi skilled	84	56
Unskilled	18	12

It is expected that the population which is economically superior might be less interested in obtaining medicines from pharmacy without prescription. As expected it was found that about 47% of the lower socio economic strata of people were the majority who were indulged in self mediation practices. (Table 2).

Table 2: Distribution of subjects according to the socio economic status

Socio Economic Class	Frequency	Percentage
Upper	27	17.6
Middle	51	33.3
Lower	72	47.1
Total	150	100

Table 3 shows that there could be various clinical conditions for approaching a pharmacy. Hence the analysis was done to find out the common clinical conditions for which pharmacy was approached and it was found that fever was the most common condition (72%) closely followed by headache (67%). The other conditions for which a pharmacy was approached are Respiratory infections (55%), general body pain (40%), diarrhoeal problem (8%) and lack of sleep (8%). In India over the counter dispensing of medications is so unregulated such that even sleeping pills are available over the counter for general population without restriction.

Table 3: Frequency distribution according to the various clinical conditions & medications

Clinical conditions	Frequency (%)	Medications	Frequency (%)	Form of medicines	Frequency (%)
Headache	99 (67)	Paracetamol	105 (70)	Tablets	141 (94)
Fever	108 (72)	Cetrizine	12 (8)	Syrup	60 (40)
Respiratory infection	84 (55)	Analgesic	6(4)	Ointment	9 (6)
Body Pain	60 (40)	Doesn't know	96 (64)	Injections	42 (28)
Diarrhoeal infection	12 (8)				
Lack of sleep	12 (8)				

Coming to the knowledge of medications consumed over the counter among the participants it was found that paracetamol was the most common known medication (70%) among the participants. However knowledge regarding other medications are very minimal. In fact most of the study participants did not have any knowledge about the medication prescribed by the pharmacist.

Among the medications obtained from the pharmacy it was found that 94% of the particpants obtained medicines in the form of tablet followed by Syrup (40%) and Injections (28%). This is another feature of Indian health care scenario wherein even injections are given by the pharmacist.

Further we analysed who is the key person behind determing what medicine to be given to the participants and it was found that in 56% of the cases it is the pharmacist who decides what medicine should be given and in 32% of the cases the participants themselves decide about the medicine to be purchased. Friends and relatives also seem to play a role in prescribing the medicines for purchase (14%). Also we wanted to understand whether the location of health centre has any influence on self medication practice. It was found that in 76% of the cases, a pharmacy is located near their place of residence while in 24% of the participants, hospital was located near their place of residence.

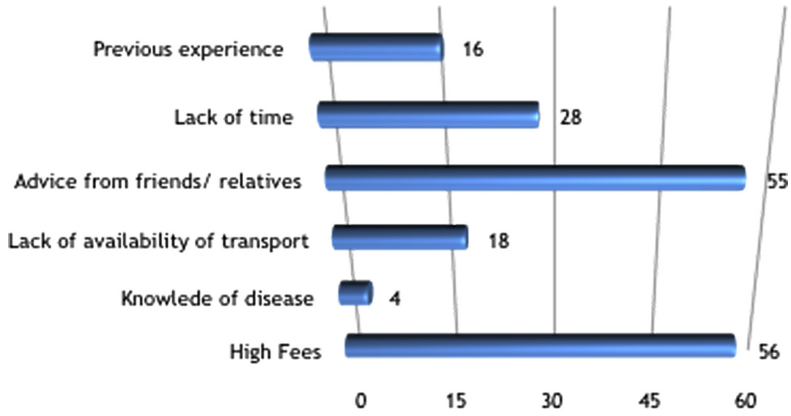

Figure 1: Percent Distribution of various reasons for self medicationpractice among the participants

The important component of this study is to analyse the various reasons responsible for self medication among the study participants and it was found that High fees charged by the doctors. Other reason for self medication were high fees, lack of time for consulation with the doctor(28%), previous experience with the disease (16%) and knowledge about the particular disease conditions (4%).

Table 5: Various other factors pertaining to self medication practice among the participants

Factors	Frequency of positive responses (%)
Suggestion of Medications to others	84 (56)
Any known person taking self medications	111 (74)
Is the Self medication effective	135 (90)
Any side effects with Self medications	33 (22)
Knowledge about side effect of Self medications	3 (2)

In Table 5 it was found that the knowledge about the side effects of self medication was very minimal (2%) among our study participants. About 90% of the participants responded that the medication was effective. However 22% of the respondednt said that they had some side effects with self medication and they consulted the doctor for the same. Further about 56% of the respondents was found to be willing to suggest self medication for others.

Discussion

The present study was conducted among the participants who used self medication. This study analyses the various practice profiles ofself medication among the urban population of Perambalur town. In our study the mean age of study population was found to be around 44.6 yrs. Other studies done in India also shows that younger population below 45 years are more likely to use self medication than the old [4,13,14]

However the male preponderence among self medication users in our study is similar to another study done in Nepal where male sex was more likely to get involved in self medication practices than females. [13]

It was found that about 53% of the upper and middle socio economic strata of people were the majority who were indulged in self mediation practices and almost 47% of the lower socio economic class of people were also involved in self medication practices. The upper socio economic strata of people might prefer self medication because of various reasons such as knowledge regarding the disease and medication, previous experience with the illness, advice from the friends & relatives and nearby location of the pharmacy and confidence over the chemist.The lack of regulation among the pharmacies is a major factor contributing to this harmful health care scenario. The findings were similar to other studies done with respect to these factors.[15–20] Fever was the most common condition (72%) closely followed by headache (67%). Similar findings were found among other studies which showed higher percentage of visit to pharmacies was for fever and painful body conditions.[13,15,15,21] The other conditions for which a pharmacy was approached are Respiratory infections (55%), general body pain (40%), diarrhoeal problem (8%) and lack of sleep (8%). In India over the counter dispensing of medications is so unregulated such that even sleeping pills are available over the counter for general population without restriction. Such unregulated practice indirectly promotes various social evils in the society such as crime and suicide. However majority of the participantsdidnt

have any knowledge about the drugs and they simply procured from the pharmacies. So the drugs that they use are the discretion of pharmacist who is formally unqualified for drug prescription. Pharmacist role is only drug dispensing but this rule is frequently overruled and the scenario is the pharmacist take up the role of doctor and in due course of time becomes a doctor himself. Tablets and syrup were the most commonly dispensed drugs for self medication.However about 28% of the respondents said they receive injections from the pharmacy.Injections have to be given only after proper training and injections by untrained personnel can lead on to complication varying from abscess to dangerous complications such as axillary and sciatic nerve palsy. However it is seen that without understanding the risk involved the participants are approaching the pharmacy for injections.Most of the participants are of the opinion that pharmacist prescriptions are very effective and they dont have any knowledge about the side effects of these medications. Thus its imperative enough that urgent intervention is needed with respect to self medication practices in India.

Conclusion

The practice of self medication was found to be deeply inculcated in the minds of the participants and the participants did not feel that prescription by pharmacist without consultation of a doctor is going to be dangerous for their long term health. The knowledge regarding the medications and its side effects was negligible among the study participants. There is an urgent need from the health system planners to address this issue in a comprehensive manner before this burden goes out of control.

Prevalence and Determinants of Depression among the Elderly in Rural Field Practice Area of a Medical College in Perambalur District, Tamil Nadu: A Cross-Sectional Study

Karthikeyan K.[1], Sriandaal V[2], Tamilarasan M.[3]

[1]Associate Professor, [2]Post Graduate, [3]Assistant Professor Department of Community Medicine, Dhanalakshmi Srinivasan Medical College and Hospital (DSMCH), Perambalur, Tamilnadu

Abstract

Introduction: Depression is one of the most common psychiatric disorders worldwide, with the elderly population being the most vulnerable group. As a result of changing lifestyle & increase in nuclear families, elderly people lose their support & importance in their own family. They are often neglected, leading to loneliness & depression. It is commonly seen in the rural population.

Objective: To estimate the prevalence of depression among elderly in the rural field practice area of DSMCH and to assess the socio-economic factors influencing the depression among the study population.

Materials and Method: A community based cross-sectional study was conducted among 400 elderly people aged 60 years and above in the rural field practice area of Dhanalakshmi Srinivasan medical college and hospital, Perambalur district, Tamilnadu. The study subjects were contacted through household visits for data collection. The study was conducted for a period of 3 months (April 2017 to July 2017) using a pretested semi-structured proforma. The collected data was analyzed using SPSS software trial version. A p-value of <0.05 was considered statistically significant.

Result: The prevalence of depression among the study subjects was 56%. A statistically significant association was found between the prevalence of depression and the elderly who were aged ≥70 years (p value = 0.0015), females (p value = 0.0048), illiterates (p value = 0.0071), class V socio economic status (p value <0.0001), living alone (p value = 0.0205), widows & separated family (p value = 0.0117%), economically dependent (p value <0.0001), neglected & just taken care by family members (p value <0.0001).

Conclusion: The prevalence of depression was found to be higher in our rural population and many socio-economic factors influence the depression among them. Health policy makers should take necessary steps to include a mental health programme for the elderly within the purview of the primary health care.

Keywords: *Geriatric, Depression, Psychiatric disorders.*

Introduction

Aging is a usual physiological processthat is associated with the decreased physical activity[(1)]. Worldwide the proportion of aged population is projected to increase to a greater extent. Globally the proportion of aged more than 60 years in 1950 was 13.7%, in 2017 it was 23.2% and in Asia it was 11.0% in 1950 and 21.8% in 2017. In India in 1950 it was 8.9% and in 2017 it was 16.3% and in 2030 it is projected to increase to 22.3% and in 2050 to 35.1%[(2)]. Mental and neurological disorders among older adults account for 6.6% of the total disability for this age group. Approximately 15% of adults aged 60 and over suffer from a mental disorder[(3)]. According to the WHO global burden of disease report 2004, depression was the leading cause of burden of

Corresponding Author:
Dr. Karthikeyan K.
Associate Professor (Community Medicine),
Dhanalakshmi Srinivasan Medical College, Perambalur
e-mail: karthikspm@gmail.com

disease during 2000-2002, ranked as third worldwide[4]. In olden days elders are given priority in their family, their blessing and decision are frequently sought[5] but as a result of changing lifestyle & increase in nuclear families elderly people lose their support & importance in their own family[6]. They are often neglected, leading to loneliness & depression. Depression is a disorder that is characterized by sadness, changes in appetite, altered sleep patterns, feelings of dejection or hopelessness and sometimes suicidal tendencies[7] but studies to assess the depression among the elderly population has hardly been done in this part of the country and very few in the rural community. So this study would help in understanding the magnitude of depression among geriatrics in a rural area of south India which would further help in the planning and assessment of geriatric welfares programmes and measures.

Objectives:

1. To estimates the prevalence of depression among elderly in the rural field practice area of DSMCH.
2. To assess the socioeconomic factors influencing the depression among the study population.

Material and Method

A community-based cross-sectional study was done among elderly more than 60 years from April 2017 to July 2017 in the field practice area of the rural health training center, Dhanalakshmi Srinivasan medical college and hospital, Perambalur district, Tamilnadu**.** Assuming the prevalence (p) of depression among the elderly as 55% from various studies and taking the 5% allowable error (*l*) with a 95% confidence level, the sample size was calculated to be 400 by using the formula $\{\frac{4pq}{d^2}\}$. By **simple random sampling**, 6 villages were chosen from 18 villages in the rural field practice area of DSMCH, Perambalur. The number of samples required from 6 villages was calculated by population **proportional to the size** of villages. 200 male subjects and 200 female subjects were selected.

Method of Data collection: Ethical approval was obtained from the Institutional ethics committee on human subjects, DSMCH. The study subjects were contacted through household visits in the study ward for data collection. The door to door survey was carried out. In each household, the head of the family or any other responsible adult was contacted and the nature & purpose of the study were explained to him/her. Written and informed consent was obtained

Inquiries regarding the old age persons of that particular family were made i.e. a Total number of old age persons present in that house, their age, and sex. Information regarding the age was cross-checked by asking children's age, relating to major events, verifying with the records like ration card, etc. if present. Where the subject was living alone or living with his/her spouse i.e. Nuclear family, the nature and the purpose of the study was explained to the study subjects themselves. Informed consent was obtained before the study.

Study Tool: The randomly selected elderly under this study was interviewed personally using a questionnaire which was developed to achieve the statistical objectives. This questionnaire was validated by experts and field tested in a pilot study among 10% of the study population before being used in the main study.

The pre-designed, pre-tested, semi-structured questionnaire consisted of two parts: The first part of the questionnaire contained questions relating to personal, family and socio-demographic characteristics (age, sex, level of education, marital status, occupation, income, living status etc). The second part of the questionnaire was regarding depression, Jerome a Yesavage geriatric depression scale(short version)[8] was used since this scale was used in most[9]of studies. Socio-economic status of the study subject was assessed using the Modified Kuppuswamy classification. While assessing the socio-economic status, the family was taken as the unit instead of the individual i.e. the study subjects of the same family/house was given the same scoring.

Analysis of data: The data was entered and compiled in a Microsoft Excel sheet. The analysis was done using SPSS software 16th version. All qualitative variables are presented as frequencies and percentages. The prevalence rates are given in percentages. Pearson Chi-square test of significance was used to find the association between variables. P-value of < 0.05 was taken asstatistically significant

Results

Table 1: Frequency distribution of the study population according to socio-demographic profile

S.no	Variables		Frequency N = 400	Percentage (%)
1	Age	60-70	276	69
		71-80	95	23.75
		> 81	29	7.25
4	Literacy status	Illiterate	194	48.5
		Primary education	124	31
		Secondary education	77	19.25
		Higher secondary & above	5	1.25
5	Marital status	Married	238	59.5
		Separated & widowed	162	40.5
6	Occupation	Not doing any work	201	50.25
		Unskilled worker	30	7.5
		Semi-skilled worker	147	36.75
		Skilled worker	22	5.5
7	Living arrangement	Living alone	80	20
		With spouse	159	39.75
		With children	66	16.5
		With spouse & children	88	22
		With siblings	7	1.75
10	Socio-economic status	Other classes	114	28.5
		Class 5	286	71.5
11	Economic dependency	Independent	163	40.75
		Partially dependent	153	38.25
		Totally dependent	84	21
12	Status in the family	Neglected	24	6
		Just looked after	279	69.75
		Looked after well	64	16
		Respected and consulted	33	8.25

The study was conducted among 400 elderly populations in rural field practice area of DSMCH. The mean age of the study population was 71.28±7.85. The table 1 shows that 69% of the study subjects were in the age group of 60 to 70 years and 31% belonged to ≥70 years of age.200 Male and 200 Female subjects were selected equally for the study. Nearly half of the study participants were a widow or separated. Half of the elderly (50.25%) were not doing any work. About 48.5% of the geriatric population was illiterates. It was observed that 71.5% belonged to the lower class according to Modified Kuppuswamy socio-economic status Classification. In this study, 80.75%% of the elderly population was living with Family members. It was observed that nearly three fourth (75.75%) was neglected by their family or just looked after. Male was respected and consulted more than female in our study population.

Table 2: Prevelance of depression in association with socio demographic variables (n=400)

S.no	Socio demographic character		Depression Present (%)	Depression absent (%)	χ^2 value	P value
1.	Age	>70 years	84(67.74)	40(32.26)	10.06	0.0015*
		60-70 years	140(50.72)	136(49.28)		
2.	Sex	Female	126(63)	74(37)	7.955	0.0048*
		Male	98(49)	102(51)		
3.	Literacy status	Illiterate	122(62.89)	72(37.11)	7.250	0.0071*
		Literate	102(49.51)	104(50.49)		
4	Occupation	Not working	117(58.21)	84(41.79)	0.8001	0.3711
		Working	107(53.77)	92(46.23)		

5	Socio economic	Class 5	202(70.63)	84(29.37)	87.16	<0.0001*
	Status	ther class	22(19.30)	92(80.70)		
6.	Economic	Dependent	155(65.40)	82(34.60)	20.86	<0.001*
	Dependency	Independent	69(42.33)	94(57.67)		
7.	Marital status	Widow	103(63.58)	59(36.42)	6.349	0.0117*
		Married	121(50.48)	117(49.16)		
8.	Living	Alone	54(67.50)	26(32.5)	5.367	0.0205*
	Arrangement	With family	170(53.13)	150(46.88)		
9.	Status in family	Neglected & just cared	197(65.02)	106(34.98)	41.23	<0.0001*
		Taken care well	27(27.84)	70(72.16)		

In table 2 the Chi-square test of significance was used to test the association between socio-demographic factors and depression. The prevalence of depression was found to be higher among subjects aged more than 70 years of age (67.74%) as compared to another age group (50.72%). It is found to be statistically significant (p-value 0.0015). Nearly 63% of depression was observed among females and 49% among males. It is statistically significant (p-value 0.0048). Nearly 62.89% of depression was observed among illiterates and 49.51% among literates. Association between literacy status and depression was found to be statistically significant (p-value 0.0071).Nearly 63.58% of depression was observed among widowed and 50.84% among the married elderly population. Marital status was found to be statistically significant (p-value 0.0117). The prevalence of depression was found to be more among the elderly population living alone (67.50%) than the elderly living with family. It is statistically significant (p-value 0.0205). Depression was found to be higher in economically dependent (65.40%) than independent group and statistically significant (p-value <0.001). It was observed that those who were either neglected or just taken care of by their family members (65.02%) were more depressed as compared to elderly who were taken care well and respected by their families (27.84%). A significant association between depression and status in the family was found in this study (p-value <0.0001). It was found that depression was higher among the geriatric population who were not doing any work (58.21%) as compared to elderly who were working (53.77%). But there was no significant association found between depression and occupation in this study (p-value 0.3711). It was observed that depression was higher among those whobelonged to class v according to modified BG Prasad classification (70.63%) as compared to other class groups (19.30%) and found to be statistically significant (p-value <0.0001).

Discussion

The prevalence of depression among the elderly was found to 56% which was similar to the study done by vafaei et al (50.3%) in Isfahan[10] and higher than the study by Gadit M et al in Pakistan (45.98%)[11], Sau A et al in Kolkata (45.7%)[12] and in Europethe prevalence of depression varies from 8.8%-23.6%[13]. The difference in rate of prevalence might be due to different study setting and geographic variation across countries and the reason for increased prevalence in our study might be due to various social factors like sudden loss of respect in family after retirement and increased rate of dependency. In our study more than 70 years of age group were more depressed, which is similar to Dasgupta A et al study in West Bengal and their prevalence was 58.8%[14].In comparison between the gender, we found that females are more depressed than males which is similar to Javed s study in Pakistan[15] and the reason might be due to the feeling of dejection and fear of death is more among rural women. According to Maulik'sstudy[6] illiterateare more depressed which is corresponding to our study and the reason might be due to the reduced self esteem among the study participants. In our study widowed subjects were more depressed similar to the study done by RadhakrishnanS et al[2] inSalem.This might be due to a feeling of loneliness and feeling of no one to share at the end stage of life. Unemployment was a major risk factor which is similar to Suganthan S et al [16] study done in Porur, Chennai. The reason could be due to the lack of source of income and dependency upon others for their basic needs. The depression was more among persons who live alone.Similar findings were observed by Ramachandran V etal[17] in Chennai and by Chong M et al, in Taiwan[18]. In our study significant association between depression and economicalldependence was found which is similar to the findings by ChuiP et al, Hong Kong[19] and comparatively lower in astudy

done by Swarnalatha et al in Chittoor district[9]. The variation might be due to poorer status of living and fear of fulfilling for daily needs. In a review by Grover et al [20]in India the socio-demographic factors related to depression in elderly are widowed elderly, residing in rural locality, being illiterate, increasing age, lower socioeconomic status, and being unemployed and the psychosocial factors includes loneliness, poor family support, isolation, dependency, lack of family care, and affection which are similar to our study findings.

Conclusion

The prevalence of depression was observed to be quite high in this rural population.Depression was found to be positively associated with increasing age, female and economic dependency. The prevalence of depression was inversely proportional to education and socio-economic status. The burden of depression among the geriatric population of developing countries needs to be addressed as a priority before it becomes a public health menace. With increasing number of old people and with a radical change of social structure even in the rural area, it is high time that health policymakers take steps to include mental health programme for the elderly within the purview of the primary health care. Regular counselling, supply of effective and affordable drugs in the PHC, regular training programmes for primary care providers on geriatric care, research on preventive and promotional aspects of depression preventive measures and aggressive education-awareness campaigns to fight depression at individual,community and national level are some of the recommended measures to reduce the prevalence of geriatric depression.

CT Guided Radiofrequency Ablation of Osteoid Osteoma

Murugesh E.[1], Devimeenal J.[2], Krishna Prasanth B.[3], Pavan Kumar N.[4]

[1]Radiographer,Government Medical College, Omandurar Government Estate, [2]Professor & Head, Department of Radio diagnosis, Government Kilpauk Medical College & Hospital, [3]Assistant Professor, Department of Epidemiology, Sree Balaji Dental College & Hospital, Chennai, Bharath Institute of Higher Education & Research, [4]Post graduate, Department of Radio diagnosis, Sree Balaji Medical College & Hospital, Chennai, Bharath Institute of Higher Education & Research, Chennai

Abstract

Aim: To evaluate the therapeutic efficacy of CT Guided Radio Frequency ablation of benign bone tumour-Osteoid osteoma.

Materials and Method:

1. **Study group:** *Patients who presented with typical history and were clinically diagnosed as Osteoid osteoma were subjected to radiological evaluation. The patients graded their pain at day and night on a visual analogue scale between Grade 0-No pain and Grade 10-Unbearable pain. We evaluated 16 patients of Osteoid osteoma in whom Radio Frequency Ablation (RFA) was performed between November 2015 and October 2016. The lesions were located in the femur (n = 10), tibia (n = 5) and fibula (n=1).*
2. **Study design:** *Prospective Interventional study*
3. **Method:** *MDCT guided RFA procedure was performed using a STAR med VIVA RF Generator and cooled tip probe standard technique under spinal anesthesia.*

Results: Significant pain relief was observed in 15 out of 16 patients on first week post-operative visual analog scale. Immediate complications included a case of minor thermal skin burns in 3 patients, which healed on its own. There were no delayed complications. The average follow-up period was 2-3 months. One patient (6.25%) had persistent pain even after one month, following ablation which was due to residual lesion. Complete pain relief was achieved after a second ablation in that case. Thus, our primary and secondary clinical success rates were 93.8% and 100%, respectively.

Conclusion: RFA is a safe, quick, minimally invasive, and extremely effective method for the management of Osteoid osteomas.

Keywords: *Osteoid osteoma, Radio Frequency Ablation and Visual analog scale.*

Introduction:

Bone neoplasms have been routinely treated by either chemotherapy or radiotherapy/surgery. Current practice in the treatment of benign neoplasms like Osteoid osteoma is inclining towards minimally invasive procedures like chemo or thermoablation[1]. In ablative procedures, neoplastic cells are subjected to temperatures over 60°C and destroyed completely. This can be achieved by radiofrequency (RF) energy, microwaves or laser therapy. Cryotherapy is also a form of ablation technique in which neoplastic cells are destroyed by freezing to temperature less than-20°C[1]. MR guided focused ultrasound is an advanced non-invasive, radiation-free modality. where sharp focus of ultrasound waves targeted towards lesions eventually lead to thermo-ablation (> 57°C). Benign bone tumours like

Osteoid osteoma and Osteoblastoma can be completely cured using RFA. It is also effective in alleviating pain in malignant lesions like metastasis[2].Our study is focused on evaluating the technical and therapeutic efficacy of radiofrequency ablation in the management of Osteoid osteoma and to assess the technical limitations and post procedural complications.

Materials and Method

Patients attending the OPD of Orthopaedics department of Govt. Kilpauk Medical College, presenting with typical history and clinical diagnosis of Osteoid osteoma were included in this study. They were later subjected to radiological evaluation after obtaining informed consent.

The study was carried out as a prospective interventional study for a period of 1 year (From November 2015 to October 2016) which included 16 patients with age group from 8 to 28 years(mean age-16 years), which includes 14 male patients and 2 female patients.

Criteria for diagnosis of Osteoid osteoma:

- **Clinical criteria:** Patients presenting with pain getting worse at night, relieved by taking aspirin and with visual analog scale grade above 6.
- **Radiological criteria:** Radiolucent nidus of less than 1.5 cm with adjacent bony osteosclerosis and cortical thickening on thin slice CT (1 to 3 mm).

Inclusion Criteria:

- Patients who met clinical and radiological criteria.

Exclusion Criteria:

- Patients who are symptomatically silent.
- Patients with lesions close to neuro vascular bundles (within 2cm).
- Non-consenting patients.

Methodology: All patients included in the study, were radiologically confirmed cases of Osteoid osteoma and posted for radiofrequency ablation. Day time & night time pain intensity of 16 patients were noted using visual analog scale (Grade 0-No pain and Grade 10-unbearable pain). The procedure and its alternatives were thoroughly explained to the patients & informed written consent was obtained in all cases. Before the procedure, Hemoglobin, clotting time, bleeding time, prothrombin time and INR were confirmed as normal. All the patients obtained anesthesia fitness and were planned to RFA under spinal anesthesia. Prophylactic antibiotics were administered, prior to the procedure. Radiofrequency ablation machine and all anesthesia equipments were shifted to the CT scanner room. Radiofrequency ablation was done under spinal anesthesia (conscious sedation). Dispersive grounding pads were applied on either side of patient's thighs, in correct alignment with each other and with appropriate skin contact; both of them were kept at almost equal distance from the place of ablation.

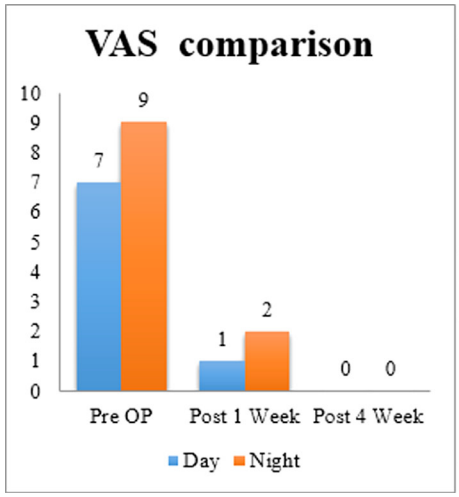
The RFA equipment (figure 1) comprised of STAR med VIVA RF generator (**S**olutions for **T**hermo **A**blation with **R**F medical technologies, South Korea), STAR RF cooled tip electrode with tip exposure 5-10mm, 13G COOK bone biopsy needle, a K-wire and a driller.

Lesion localization: The lesions were targeted with the help of a 16 slice MDCT scanner (Toshiba medical systems, Tokyo, Japan) with multi-planar evaluation to assess accurate needle position within the lesion.

Procedure: Skin preparation and proper sterilization was done. Small skin incision was made using 11' blade.13-guage bone biopsy needle was introduced into the lesion under CT guidance. And, in patients where there is marked peri-lesional sclerosis, the tumor was reached through a drill advanced over an appropriate Kirchner guidewire. Biopsy was taken and sent for HPE in formalin. Under aseptic precautions, a 350 mm long, 15-gauge single cooled tip electrode with exposure tip of 5-15 mm length was then introduced into the centre of Osteoid osteoma nidus (Figure 2).The electrode was connected to the RF generator and coolant pump with cool saline so that it reduces impedance and favour ablation without over "burning" the lesion area. RF machine settings changed to continuance mode and kept at 20 watts for 6 minutes. The RF output is generated continuously with the setting value. Finally a small compressive dressing was applied at the percutaneous puncture site.

Follow-up: Post procedure, day and night time pain intensity was measured at 1 week and 4 weeks using visual analog scale. Follow up CT/MRI was taken at 4 weeks (Figure 1). HPE reports were collected within a week.

Criteria for assessment of success of the procedure: Technically, success was considered when the tip of the electrode was rightly placed into the nidus



and was heated for the appropriate time, at correct parameters. Clinically, success was considered when patients get complete relief from pain and getting back to normal activities.

Figure 1: Axial section of Thigh CT of a 17 year female patient showing left neck of femur Osteoid osteoma with RF probe noted within the nidus. Follow up MR Axial STIR and Coronal T1 MR images at 4 weeks shows no evidence of nidus. No marrow edema was noted.

Statistical Analysis and Results: The collected data were analysed with IBM, SPSS statistics software version 20.Descriptive variables were expressed in terms of frequency. Categorical variables were expressed as percentage and continuous variables were expressed in terms of mean and standard deviation.For the multivariate analysis in the repeated measures (Pre, 1 week & 4 weeks) the Friedman test was used. To find the significance in categorical data Chi-Square test was used. In all the above statistical tools the probability value 0.05 was considered as significant level.

In our study, the mean age was 16 years with mean nidus size of 6.6 mm and most common bone involved was femur (n = 10), followed by tibia (n = 5) and fibula (n = 1). Commonest location in bone was cortical (n=13), sub-periosteal (n =2) and intramedullary (n= 1).

Figure 2:Comparison of pre-procedure day & night VAS with post procedure day & night VAS at 1 week and 4 weeks

Multivariate analysis using Friedman test, revealed statistically significant p values (< 0.05) between day Pre op VAS, day Post op VAS at 1 week and at 4 weeks. Similar values were obtained for night VAS multivariate analysis too.

We experienced residual lesion in a 22 year old patient and treatment was completed successfully after second RFA procedure. We had 3 patients with mild skin burns which got healed by its own with no major complications.

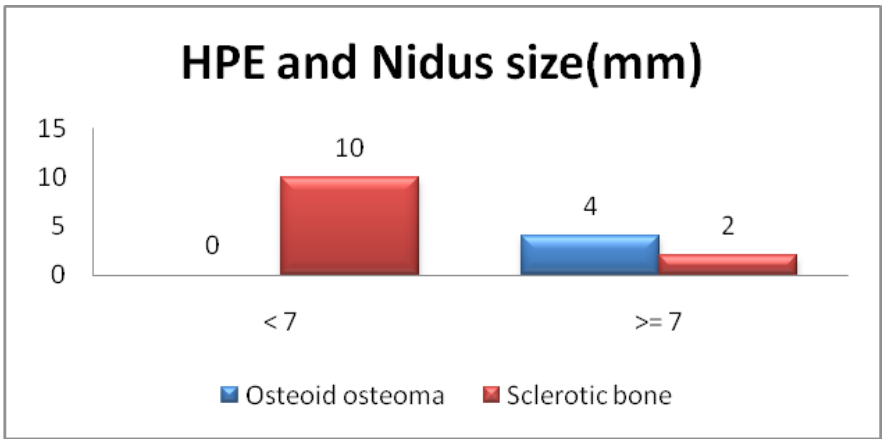

Figure 3: Comparison between nidus size and histopathological report

Six patients had nidus size of more than or equal to 7 mm, of which 4 patient's HPE turned positive for Osteoid osteoma. Rest of 10 patients had nidus size of less than 7mm and their HPE reports came as sclerotic bone. This was statistically significant with P value < 0.05 using fisher's exact test.

Discussion

In our study with 16 patients, day time pre-treatment median VAS was 7 and post-treatment median VAS at one week was 1. Night time pre-treatment median VAS was 9 and post treatment median VAS at one week was 1. The VAS reduction for both day and night time was statistically significant. Several supportive studies to our results include De Palma et al., who reported in their study of 20 patients that night time pre-treatment mean VAS was 8.5 and post-treatment VAS was 0.5 and day time mean VAS as 5.95 pre and 0.9 post-treatment[3,4]. Karagoz E. et al., reported in their study of 18 patients that night time median VAS as 9 pre and 0 post-treatment and day time median VAS as 7 pre and 0 post-treatment[3]. Morassi et al., in 2014 evaluated 11

patients and they observed the significant reduction in visual analog score in pre and post procedure evaluation from 8.6 to 0. And, our study too revealed significant reduction in visual analog score from 8 to 1[5].

Patients getting complete pain relief following treatment ranged between 1 day and 2 weeks. A study by Vanderschueren et al., in 2002 which included 54 patients reveals 87% patients got completely relieved from pain on day 1 and 13% patients recovered at two weeks[6]. Another study in 2001 by Lindner et al., reported that complete pain relief was obtained at the end of 1 week[7]. Whereas, Karagoz et al.,[3] reported pain relief between 3 to 10 days post ablation. In our study except one patient with residual lesion, all were relieved of pain by around 8 to 9 days.

In our study with 16 patients, 15 (93.8%) patients achieved technical and clinical success after one sitting of RFA and remaining one patient achieved technical and clinical success after second sitting of RFA. The problem we encountered in that one case was high impedance probably, because of large size drill compared to electrode size which did not allow adequate ablation, that was needed to cook the nidus[8].However, the success rates of our study were comparable with several other studies like Cantwell CP et al., in 2004. Yang et al., in 2007 observed technical success of near 100%, clinical success of 76 to 100% and after second Radio Frequency ablation the success rate was near 100%[9,10].A study by Rehintz et al., in 2013 which included 72 patients showed 99% primary clinical success rate and 100% secondary clinical success rate[11]. Another similar result i.e., 100% technical success, 94% Primary success and 100% secondary success rate was obtained in study by Karagoz et al., in 2016[3].

In our study, we had 3 patients with mild skin burns with no major complications. All three had lesions in mid tibial shaft and distance between lesions and skin was less than 1 cm. Skin burns might have occurred due to some transient contact between electrode tip and skin while ablating. However, all three skin burns healed after topical application. None of the patients had any other complications.

In a study by Jankhariaet al., in 2009[8] out of 40 patients, one patient had skin burn of around 6 mm near probe insertion site in mid arm i.e., diaphysis of humerus and the nidus was 1.7cm deep to skin surface. They also experienced one more complication, a small bony chip fracture occurred in entry site. Since, it was a sclerotic bone it can be negligible and patient was advised rest for few weeks. Rosenthal et al., in 2003[12] and Lindner et al., in 2001[7]observed neural injury as complications of RF Ablation when the lesions are close to nerves i.e., within 1 cm, particularly while ablating spinal and hand Osteoid osteomas.

In our study, we found that the lesions with nidus size of less than 7mm (in 10 patients) HPE revealed only sclerotic bone. Whereas, if nidus size exceeds 7mm HPE came as Osteoid osteoma (in 4 out of 6 patients) which possibly explains that the smaller nidus might have been destroyed while drilling itself.

Limitations of the study: Smaller sample size. RFA treatment assessment is not done in other less common sites of Osteoid osteoma like spine, ribs, hands and feet. Hence the success rates in those sites are not assessed. Average follow up period in our study is only 2 to 3 months which is not adequate as most of the recurrences occur in between 3 to 6 months only.

Conclusion

Radio Frequency Ablation is a safe, quick, minimally invasive and extremely effective method in Osteoid osteoma management. We have been able to achieve a high technical and clinical success rate with less morbidity & complications.

Ethical Clearence: This study was duly accepted by the ethics committee of Govt. Kilpauk Medical College, Chennai-10, Protocol ID no: 04/2015 dated 02.11.2015.

[1]Postgraduate Student, Department of Public Health dentistry, Ragas Dental College and Hospital, Uthandi, Tamilnadu-119, [2]Senior Lecturer, Department of Public Health Dentistry, Saveetha Dental College and Hospital, Ponamallee, Chennai, [3]Reader, Department of Public Health Dentistry, Ragas Dental College and Hospital, Uthandi, Tamilnadu-119, [4]Professor and Head, Department of Public Health Dentistry, Ragas Dental College and Hospital, Uthandi, Tamilnadu

Abstract

Objective: This study explores the association between the sociodemographic factors of the urban slum dwellers with unmet dental needs and dental service utilization pattern.

Method: A cross sectional study conducted among 430 slum dwellers of Chennai city.. Using a structured proforma socioeconomic data was collected. DMFT, TI(Treatment Index) and TNI (Treatment Need Index) were recorded.

Results: About 59.9% of them had never utilised dental services. Income was found to have a direct relation with Treatment need index. Education and occupation had a moderating effect.

Conclusion: From the present study we can conclude that overall utilisation of dental services is low among slum dwellers. However income is the main detrimental sociodemographic factor in the minds of the people living in slum areas.

Keywords: *Socioeconomic status, slum dwellers, DMFT, dental services, Utilisation, Unmet needs.*

Introduction

Inequalities in oral health are profound worldwide, affecting the overall health and quality of life of millions. These inequalities are seen most often in association with racial and ethnic minorities, lower socioeconomic levels, in groups defined by gender or differences in environment and cultural factors, and patterns of utilization of care[1]. When this scenario is applied to India context, millions of people are affected due to lack of socio economic equality [2]. Studies have documented disparities in oral health services among urban, suburban and rural regions of India. Residents of rural and suburban regions have increased unmet dental needs compared to people living in urban areas[3]. This can be further substantiated by the inverse care law which states that availability of good medical care tends to vary inversely with the need for it in the population served, which implies decreased utilisation of health services among the slum dwellers[4].

United Nations Human Settlement Program (UN-HABITAT) defines slum as residential areas that are physically and socially deteriorated and in which satisfactory family life is impossible[5].These people also lack durable housing of permanent nature, sufficient living space, access to safe water, inadequate sanitation in form of toilets and insecure tenure, hence have compromised general health status.

Evidences are suggesting that socio-demographic factors, such as place of residence, age, gender, family income and education and individual factors in terms of

e-mail: lakshmi.krish24@gmail.com

oral health behaviors directly or indirectly influence oral health outcomes[6].Therefore; there is a need to explore the influence of social factors on oral health and its utilisation.

There are reports that suggest dental patients only visit the dentist when in pain and never bother to return for follow-up in most cases[7]. Epidemiological studies have shown underutilization of dental care services among the people with low socioeconomic status[8].

But,there are very few published studies that have investigated the unmet dental needs and dental service utilisation rate among slum dwellers making it difficult to understand the pattern of oral health status in this marginalized community. Also, there is not much data on the oral health status of people residing in slums in India. Therefore, this study explores the association between the sociodemographic factors of the urban slum dwellers with unmet dental needs and dental service utilization pattern.

Method

This is a cross sectional,study done in a slum dwelling regions of Chennai city. This study was carried out as there is sparse literature about oral health status among marginalised population. The study proposal was approved by the Institutional Review Board ofour college.The research was carried out in compliance with Helsinki declaration.A verbal informed consent was obtained from the participants as per the suggestions provided by the Ethical Board.

Study Site And Population: The study was carried out in the slum dwelling regions of Chennai city. Though definition of slums varies from nation to nation, in India according to the Slums Areas Improvement and Clearance Act 1956, they are defined as places unfit for human habitation due poor health and sanitation**.**

Study Sample: A convenience sampling technique was used. Sample size was calculated by keeping the medium effect size as 0.08, alpha error as 0.05 and power as 95%. Based on these, the total sample size was estimated to be 425.To attain this sample randomly 71 participants from each region-Tondaiyarpet, Manali, (North) Sholinganallur, Perungudi,(Central)Parry's corner and Ambattur (South) were taken into the study. Participants between the age group of 21 to 60 years, who did not suffer from any systemic diseases and those who gave consent to participate were included in the study.

Data Collection

Questionnaire administration: A questionnaire was structured in the regional language (Tamil) which included information about age, gender, family income, family size, occupation,education and utilization of dental services was used to record the responses of the participants**.** All variables recorded were categorized for further analysis**.**The data was collected from October 2017 to February 2018.

Clinical examination: Two calibrated dentist examined all the subjects and the inter rater reliability was found to 0.9.Oral health status of the participant was recorded in terms of DMFT index[9].All the subjects were examined under adequate illumination and general oral examination was carried out to check the caries experience using DMFT criteria 1997 [9]. The examination was conducted with a mouth mirror and probe by the calibrated dentist based on WHO level 3 examination.

Variables of interest: The dependent variables of this study were unmet needs of the participants, utilisation rate, treatment Needs Index [TNI], Treatment Index [TI]. We hypothesized a mediation analysis to be carried out between TI and TNI with income and education occupation as mediators. For this study purpose, utilisation of dental services was calculated by asking the question "Whether the person had visited the dentist before?".Treatment Need Index calculated the causal relationship between untreated decay teeth and teeth treated with restorations or extractions [due to caries], and was calculated as follows:

$$TNI = \frac{\text{Decayed}}{\text{Filled} + \text{Missing}}$$

Treatment Index predicts the proportion of teeth that had received treatment and was calculated as follows:

$$TI = \frac{\text{Missing} + \text{Filled}}{\text{DMF}}$$

Data Management: Data obtained from questionnaire and clinical examination were entered into Microsoft excel Sheet (Version 2007) and were analyzed using SPSS software (Version 20).

Statistical Analysis: Descriptive statistics were done to determine the distribution of the study variables in the population. Pearson Chi-square test was done

to compare the association between unmet needs, and utilization of dental services with the sociodemographic variables like age, income, education, occupation and family size. Independent t test was performed to check for the relation between TI, TNI with the predictor variables.The statistical significance was kept at $p \leq 0.05$, significant variables were later subjected to linear regression (backward model). Poisson regression was run for the Independent variables and DMFT.

Results

A total sample of 430 participants comprising of 227 males(57.2%) and 204 females (47.3%) were included for the study. The mean age of the study population was 39.4 ± 4.6 years. Table 1 represents the study characteristics of the population.

Gender, Income, occupation, education and utilisation of dental services of the respondents were significantly ($p < 0.05$) associated with decay component of DMFT as well as with the utilisation of dental services, (table 1) while other factors like age and family size did not show any significant association with utilisation and Decay component of DMFT. Poisson regression was computed for all independent variables and DMFT, and it was found that only gender were significant with DMFT. (Table 2).

The results of the linear regression analysis of the predictor factors for Treatment Index and Treatment need Index are shown in Table 3. A backward model was performed for income, education, occupationwith TNI, TI.Since education and occupation are interdependent to income and was found to be significantwith TI and TNI,all the three variables were added to the models. Model 1included income education and occupation, income showed a significance with standardised β coefficient value of 0.199 and 0.155 with TI and TNI respectively.In model 2education and income were added, and a decrease in standardised β coefficient value for income was seen as 0.198 and 0.148.In this model 3income was included as predictor variables for TNI and TI, and good decrease in standardised β coefficient value of 0.195 was seen with TI and a slightdecrease in value of standardised β coefficient of 0.146 was seen with TNI. The models developed had a R^2 value of 38% and 23% respectively which was found to be acceptable.The change in β coefficient value for income alone indicated that education and occupation had a moderating effect over the outcome, as these two variables were found to be statistically insignificant with TNI and TI in regression model.

Table 1: Distribution of Sociodemographic characteristics, comparison of mean distribution of DMF components and association of the independent variables with DMF and utilisation of dental services among the study population.

Discussion

Equity in health reflects an apprehension to reduce disparate opportunities to be healthy associated with affiliation in marginalized groups, such as poor people, tribal population and slum resident. Social exclusion is perhaps one of the biggest factors which influence all the wider determinants of health[10]. Several challenges are faced by the marginalised population in accessing the oral health services due to poor accessibility, affordability and limited availability[11]. So the present study was

designed to evaluate the impact of the socioeconomic factors on unmet needs and utilisation of dental services among the slum dwellers of Chennai city.

In the present study, it was observed that there was almost equal gender distribution among the participants, and most of the respondents were living in a joint family. Similar results from other studies have shown illiterate patients (70%) belonged to low income group (50%)[11].

In the current study, the mean tooth decay was found to be higher among females (4.56 ± 3.16) than males (3.79 ± 2.95). Our present study also presented a incidence rate ratio of 1.14, was seen among females than male in relation to DMFT, which was in unison with the findings of Heaton et al(2004)[12] which reported an value of 1.12 among females than male.

The mean tooth decay was highest among the illiterates (7.36 ± 3.36)and lowest among the graduates(3.00 ± 2.63) which is similar to that reported by Jairo et al (2011)[13]; also about 59.9% of the respondents never utilised the available dental services in their area. This could be explained by the fact that higher education provides increased awareness about oral health importance hence a better utilization of dental services leading to decreased decay status among the graduates[14].

Similar to the present study, Poudyal et al (2006)[14] showed 44% of the patients never visited dental clinics for their oral problems whereas the study done by Varene et al (2006)[15] showed only 27.7% used oral health services which was far less than the present study findings. This non utilisation of dental services can also be substantiated by the fact that education, occupation and income were negatively correlated to utilisation of dental services which is in concurrence with reports of Kertz et al(2014)[16], who mentioned similar results.

Among those utilized (46.6%) majority of them had tooth extraction followed by restoration of decayed tooth, which was similar to findings of Poudyal et al(2006)[14]. This difference in treatment choice could be explained by the bivariate regression analysis which revealed Income to be a significant predictor value for TI and TNI. Since occupational status, education and income share a commonality under socioeconomic status and serve as a measure for each other[17], three models were developed for multiple linear analysis using income, education and occupation for TI and TNI which showed a direct relation with income and a moderating effect by education and occupation. Therefore it can be stated that socioeconomic factors play a major role in his/her willingness towards dental care services which in turn plays a pivotal role in oral health status of the person.

Conclusion

From the present study we can conclude that overall dental attendance is low among slum dwellers and income is the main determinant which influences their utilisation of dental services. Also, illiterate people showed higher unmet dental needs than the educated ones. Hence, it can be concluded that the socioeconomic factors play a pivotal role in determining the dental service utilization pattern among the urban slum dwellers of Chennai city.

Alteration of Serum Vitamin D in Patients of Myocardial Infarction and Ischemic Heart Diseases

Lata Mullur[1], Kusal K. Das[2] , M.S. Biradar[3]

[1]Associate Professor, Laboratory of Vascular Physiology and Medicine Department of Physiology, [2]Professor, Laboratory of Vascular Physiology and Medicine, Department of Physiology, [3]Professor,Department of Medicine, Shri B.M. Patil Medical College, Hospital and Research Centre, BLDE (Deemed to be University), Vijayapura, Karnataka, India

Abstract

Background: Cardiovascular disease (CVD) is the one of the major cause of morbidity and mortality. Experimental studies have demonstrated physiological functions of vitamin D metabolites on cardiomyocytes and endothelial and vascular smooth muscle cells. In view of a complex scenario to understand cardiac disorders linking with vitamin D the currentstudywasundertaken oncardiac patients of MI and IHD.

Methodology: The cross sectional study was conducted on patients who were suffering fromcardiovascular disease (CVD). Study included 150 CVD patients (age 18 to 79 years)who wereadmitted in ICCU of a tertiary care hospital.). Patients were divided in to two groups namely myocardial infarction(MI) group 1(n=75) and ischemic heart disease (IHD) group 2 (n=75).Anthropometric, physiological and biochemical parameters were measured using standard techniques. Data was expressed as mean ± Standard Deviation (mean ± SD). The level of statistical significance was observed at $P<0.05$, $P<0.01$ using SPSS software 16.0.

Results: There is increase in the blood pressure mainly mean arterial pressure in both MI and IHD patients. Biochemical parameters which shows normal levels of serum sodium, potassium and creatinine, higher levels of CPK-MB and reduction in serum calcium and vitamin D of both MI and IHD patients compared to normal recommendedvalues although these values are not statistically significant between MI and IHD patients.

Conclusion: The significant role of vitamin D for calcium homeostasis may be considered as important marker for assessment of severity and morbidity of MI and IHD.

Keywords: *Cardiovascular disease, serum calcium, vitamin D.*

Introduction

Cardiovascular disease (CVD) is the one of the major cause of morbidity and mortality. It is also the number-one cause of death globally. People with CVD, or those who are at high CVD risk, need early detection and management of their condition, through either counseling or medication.[1] In recent years, deficiency of vitamin D has been associated with clinical atherosclerosis in coronary calcification as well as with cardiovascular events such as myocardial infarction, stroke, and congestive heart failure.[2] Experimental studies have demonstrated physiological functions of vitamin D metabolites on cardiomyocytes and endothelial and vascular smooth muscle cells. Low vitamin D levels are associated with left ventricular hypertrophy, vascular dysfunction, and renin-angiotensin system (RAS) activation.vitamin D deficiency is prevalent in 30% to 50% of adults in developed countries.[3] Molecular, animal and human studies have established

that both calcium and vitamin D are associated with cardiovascular diseases (CVD).[4]

In view of a complex scenario to understand cardiac disorders linking with vitamin D dependent alteration of calcium homeostasis, the current study has been undertaken oncardiac patients of myocardial infarction(MI) and ischemic heart disease(IHD)in a tertiary hospital of Vijayapura, Karnataka,India

Materials and Method

The cross sectional study was conducted on patients who were suffering fromcardiovascular disease (CVD). Study included 150 CVD patients (age 18 to 79 years) who wereadmitted in ICCU of a tertiary care hospital of Vijayapur (Karnataka). Patients were divided in to two groups namely myocardial infarction(MI) group 1(n=75) and ischemic heart disease (IHD) group 2 (n=75).Patients suffering from hyperthyroidism, chronic kidney disease, metabolic andmalignant bonediseases whichaffect calcium homeostasis, and patients who is with supplementation of calcium, vitamin D, calcium containing antacids were excluded from the study. Written informed consent was obtained from all patients and were subjected to detailed history.Anthropometric parameters like height in centimetres (cms), weight in kilograms (kg), body mass index (BMI) in kilograms per square meter (kg/m^2) and body surface area (BSA) in square meter (m2) and physiological parameters like heart rate (HR) in (beats/minute), systolic blood pressure (SBP) in millimetre of mercury (mmHg), diastolic blood pressure (DBP)(mmHg), pulse pressure (PP) (mmHg) and mean arterial pressure (MAP) (mmHg) were recorded by using standard procedures. All the recordings were done in the morning between 9-10 am at room temperature. Blood sample was collected from antecubital vein by means of dry disposable syringeto estimate biochemical parameters like serum electrolyte such as $Na^+$and K^+[by Ion Selective Electrode (ISE)method],serumcreatinine,CPKMB,serum calcium(byCresolthelinemethod), vitamin D kitmethod)in all patients. The study protocol was approved by the Institutional Ethics Committee(IEC Ref No-251/2017-18 dated March 20, 2018) as per the ICMR guidelines 2006.

Statistical analysis: Data was expressed as mean±Standard Deviation (mean±SD). The data have been expressed in the form of tables and diagrams. Differences between mean values of parameters between MI and IHD were evaluated by one-way ANOVA followed by Post-Hoc test (Least significant difference). The level of statistical significance was observed at $P<0.05$, $P<0.01$ using SPSS software 16.0.

Results

Table 1 showsweight, height, BMI, BSA, HR and BPof both MI and OHD patients.There is no significant difference in between the observed groups but there is increase in the blood pressure mainly mean arterial pressure in both MI and IHD patientsfrom normal recommended range.

Table 1: Physical anthropometryand physiological parameters in MI and IHD patients

Parameters	Myocardial infarction (n=75)	Ischemic heart disease (n=75)	p-value
Age (yrs)	54.92±9.96	58.9± 14.5	0.214

Vitamin D **(20-50 ng/ml)**	**12.8±2.30**	**12.83±1.93**	0.760

Discussion

Results of our study shows lower calcium and vitamin D in MI and IHD patients which is indicative of altered calcium homeostasis in both MI and IHD patients. Possibly vitamin D might have played a significant role to control calcium homeostasis in case of cardiovascular disorders including MI and IHD.Emerging studies show that vitamin D deficiency is a highly prevalent condition and is independently associated with most CVD risk factors and to CVD morbidity and mortality.[5]Vitamin D and calcium deficiency is associated with ischemic heart disease and myocardial infarction[6]. Vitamin D and calcium status is prognostic for major post infarctionadverse events, such as heart failure, recurrent acute myocardial infarction, death [7-8]. Some case reports of patients suffering from heart failure support our hypothesis that low serum levels of vitamin D metabolites might be an important cause of the reduced serum Ca^{2+} level and of cardiac dysfunction.[9-11]Many recent studies have demonstrated a strong association between low levels of vitamin D and hypertension [12-14]Results also indicate that lower vitamin D levels irrespective of MI or IHD are suggestive of a relationship between vitamin D and cardiovascular health.

New findings reinforce that vitamin D deficiency is an important public health problem. Future studies are still required to establish clinical guidelines for vitamin D supplementation required to achieve adequate vitamin D levels in people who are at risk for CVD.

Conclusion

The significant role of vitamin D for calcium homeostasis may be considered as important marker for assessment of severity and morbidity of MI and IHD.

Abstract

A Descriptive study was conducted to assess the level of knowledge on water borne disease among adult in selected village at Kanchipuram district, Tamilnadu, India. The objectives of the study were to assess the level of knowledge on water borne diseases among adults in selected village, Kanchipuram district, Tamilnadu and to associate the knowledge on water borne disease with selected demographic variables. The review of literature was done and organized under various aspects on studies related to water borne disease. The research approach used for the study was quantitative approach and the design selected was Non experimental-Descriptive research.70 samples were participated in the study by using Simple random technique. Demographic variables were assessed by using the statistical measurement. The level of significance selected was $p<0.05$ level. Data was analyzed by inferential statistics and presented through tables and figures. Findings revealed that variable like monthly income was found to be significant and variables like age, sex, types of family, education, occupation. The numbers of adults having moderate knowledge were 29(41%), inadequate knowledge were 39(56%) and adequate knowledge were 2(3%). The Mean value and 23.3 and standard deviation (SD) was 15.62.

Keywords: *Assess, knowledge, water borne disease, adults.*

Introduction

Water borne diseases are the diseases which are all supported, carried or transmitted by water. Water borne diseases are viral, bacterial and parasitic diseases which use water as a common means of transmission. Some pathogens spend most of their lives in the water environment and only coincidentally encounter a host(1). Water borne diseases spread by the contamination drinking water systems with the urine and faeces of infected animals or peoples[12]. In worldwide water borne diseases represent a major burden on human health. Water borne diseases are simple to explain but very complex to understand.In developing countries four fifths of all the illnesses are caused by water borne diseases [11]. In rural areas, there are no proper water supply and sewage systems so water contamination can be attributed to infiltration, leaching, and surface run-off through pastures, lacing and leakage of sewerage disposal systems in villages. Poor water quality is responsible for disease outbreaks in many parts of the developing world [8].

Methodology: Research approach used for the study is Quantitative non-experimental evaluative approach. The research design is non-experimental descriptive research design was adopted for conducting the present study. The study was conducted at selected village Kanchipuram district, Tamil nadu with the population of Adults are available among the age group of 19-59 years and the sample size is 70. Simple random technique was used to select the adults for conducting the study.

Description of Tool

Part 1: Demographic variable: It consists of demographic variables of adults such as Age, sex, education, occupation, monthly income, previous knowledge about water borne disease, source of drinking water, how do you stored drinking water, toilet facility.

Part 2: Structured interview schedule on knowledge regarding water borne diseases: It consists of 20 objective type questions. Each question consists of 4 options. This was framed to assess the level of knowledge on water borne diseases among adults.

Study Findings: The majority 25(36%) of the adults belongs to the age group of 14-28 years, the majority 38(46%) of them are female, the majority of the adults 35(50%) of them belongs to nuclear family, the majority of the adults 28(40%) have high school and higher secondary education, the majority of the adults 24(34%) has own business and the majority of the adults22 (32%) monthly income is of Rs.7, 001-10,000.The findings shows that there was no significant association between demographic variables like age, sex, types of family, education, occupation and there was significant association between demographic variable like monthly income. Overall mean in knowledge aspects of adults with water borne disease was found to be 23.3 and with SD of15.62. The maximum score for the knowledge were adequate knowledge 2(3%).

Percentage distribution of knowledge on water borne disease N=70

Discussion

Findings of the study are presented based on the objectives:

1. To assess the level of knowledge on water borne disease among adult.
2. To associate the level of knowledge on water borne disease among adult with demographic data.

Distribution of demographic characteristics of adults: Majority of the adults 25(36%) with in the age group of 19-28Years, Majority of adults 38(54%) are female, Majority of adults 35(50%) are belongs to nuclear family, Majority of adults 28(40%) are belongs to high school and higher secondary education, Majority of adults 24(34%) are doing business andMajority of adults 22(32%) are belongs to monthly income of Rs.7001-10000

Hence it is stated that there is significant association between the levels of knowledge on water borne disease with selected demographic variable of adult like monthly income. With regard to the hypothesis H_1 is accepted.

The major finding of the study was discussed under the objectives:

Objective-1: To assess the level of knowledge of water borne disease among adult 56% had inadequate knowledge, 41% had moderate knowledge and 3% had adequate knowledge. Overall mean and SD of mothers with related to knowledge aspects.

From the above discussion, it is seen from the results that the highest mean score noticed is 23.3.

Objectives II: To associate the level of knowledge on water borne disease among adults with selected demographic variables.

The findings shows that there was no significant association between demographic variables like age, sex, types of family, education, occupation and there was significant association between demographic variable like monthly income.

Mean and standard deviation of knowledge aspects of adults with water borne disease: Overall mean in knowledge aspects of adults with water borne disease was found to be 23.3 and with SD of15.62. The maximum score for the knowledge were adequate knowledge 2(3%).

Conclusion

The numbers of adults having moderate knowledge were 29(41%), inadequate knowledge were 39(56%) and adequate knowledge were 2(3%) and overall mean in knowledge aspects of adults with water borne disease was found to be 23.3 and with SD of15.62. The maximum score for the knowledge were adequate knowledge 2(3%).Hence the administrators should

initiate health education programme on water borne disease in community by utilizing the trained staff and encouraging them in such activities and facilitate to implementation of various health education programme on water borne disease among adults to improve their knowledge level on water borne disease.

Working Capital Management and Ratio Analysis of Paper Mills

C. Ganesan[1], M. Nirmal Dev[2]

[1]Associate Professor, [2]Assistant Professor, Department of Commerce, VELS Institute of Science Technology and Advanced Studies, Pallavaram,Chennai

Abstract

The working capital management has a significant contribution for firm's profitability as well as to maintain liquidity powers. The motive of this study is to find out working capital adequacy and its impact on profitability [1]; to investigate the relationship between profitability and liquidity of firms. The amount invested in working capital is often high in proportion to the total assets employed and so it is vital that these amounts are used in an efficient way.

Working capital management main aims at maintaining a balance between liquidity and profitability while conducting the day to day operations of business concern. Improper working capital management not only decreases the profitability of business but also ultimately lead to financial problems, Chowdhury and Amin (2007). The study aims to provide empirical evidence about the effects of in current assets and current liabilities of JK Paper Mills Limited and Emami Paper Mills Limited.

Keywords: *Working Capital, Liquidity Ratio, Short Term Liquidity Position, Current Ratio, Acid Test Ratio, Cash Ratio, Current Liabilities and Current Assets.*

Introduction

Today, most of the management is wants to know their financial ability to make best of availability of resources to the maximum extent and able to sort out its weaknesses to promote and implement suitable actions to improve its industrial operations in terms of profitability, efficiency. The management can use various techniques like, trend analysis, common size statements, comparative statements, schedule of changes in working capital, fund flow statements, cash flow statements, cost-volume-profit analysis and ratio analysis for its financial position and performance. It is a process of establishing and interprets the quantitative relationship between individual figures and group of figures. If ratios are properly analyzed and interpreted the management can strengthen its solvency position, enhance its efficiency and growth in profits. Taking this as central idea, a research work on comparative analysis was undertaken on JK Paper Mills Ltd., and Emami Paper Ltd., at micro level to examine and evaluate its current financial areas in terms of solvency, liquidity, efficiency and profitability by adopting Ratio Analysis. An attempt has been made to analyze the financial results basing on the financial statements from 1st April 2008 to 31st March 2017.

The main aim of this article is to find out the impact of Working Capital Management on solvency of the Paper mills. This is performed by developing a unique empirical framework first used by Shinand Soenen (1998) and the subsequent work of Deloof (2003). The study is exclusively on the Paper mills limited. The data reported in this paper were collected for a period of 2008 to 2017. As a part of study used to examine solvency and working capital management from financial area. And the primary data was collected by in person to the production unit and having personal interviews with the employees concerned and the secondary data collected through audited financial statements, broachers, bulletins, statistical returns and company profiles.

Review of Literature: Many researchers have studied working capital from different views and in different environments. The following study were very interesting and useful for our research: According to Eljelly, 2004, working capital management requires planning and controlling current assets and current

liabilities in such a way that eradicate the threat of inability to meet short term t short term liabilities and evade excessive investment in these assets[2].

Amit, Mallik, Debashish and Debdas (2005) in their study regarding the relationship between working capital and profitability of Indian pharmaceutical industry found and concluded that no definite relationship could be established between liquidity and profitability. Vishanani and Shah (2007) studied the impact of working capital management policies on corporate performance of Indian consumer electronic industry by implemented simple correlation and regression models.They found that no established relationship between liquidity and profitability exist for the industry as a whole; but various companies of the industry depicted different types of relationship between liquidity and profitability, although majority of the companies revealed positive association between liquidity and profitability.

Reheman and Naser (2007) found in their study negative relationship between profitability and liquidity of firms and also Ganesan (2007) studied working capital management efficiency in Telecommunication equipment industry and the study revealed significant statistical evidence and negative relationship between profitability and liquidity[3]. Bhunia (2007) studied liquidity management of public sector Iron and Steel enterprise in India. He has found that the actual values of working capital lower than the estimated value of working capital for both companies under study and poor liquidity position in case of both companies.

Objectives of the Study

The objectives of the study are:

- To study the concept and importance of working capital and the concept of ratio, utility of ratio analysis, and compiling of ratios.
- To examine the financial performance through Ratio Analysis of JK Paper Mills Ltd., and Emami Paper Ltd., on comparative basis in terms of short term.
- To interpret the summary of findings in form of conclusions and suggestions for effective functioning of JK Paper Mills Ltd., and Emami Paper Ltd.,

Plan of Analysis: The primary data collected through general discussions and the secondary data collected from various published sources have been taken in find with the objectives of the study and relevant tables were equipped. In the analysis of data usual statistical techniques like percentages and averages have been used.

Field Study: The period for the study is April 2008 to 31st March 2017. The field study was conducted from 1st April 2016 to June 2016. The personal interview method was used. In this regard, impulsive help has been received from executives. However, there were few problems in the gathering of information, owing to the tendency of people to keep the facts in privacy, fear about tax assessment, poor memory and reluctance of respondents. These problems were partially finished by prompting information through discussions.

Scope of the Study: The current comparative study was mostly confined to JK Paper Mills Ltd., and Emami Paper Ltd., This is an effort to have a micro level imperial analysis in the financial progress and performance of paper mills. The findings and suggestions throw light on the directions for future policy formulation and implementation for the active functioning of paper mills in other districts of the state and the country also

Limitations of the Study: The ratios have been designed, analyses and interpreted for the period under study i.e. from 1st April 2008 to 31st March 2017. Ratios are calculated on the basis of historical financial statements[4]. Henceforth, future performance of the industrial units not reflected. The financial declarations are subject to window dressing.

Ratio Analysis: The short term creditors of a firm are primarily involved in knowing the company's capacity to understand its present or short-term duties as and when these become due. This paper contracts with a dangerous evaluation and analytical interpretation of the financial performance of JK Paper Mills Ltd and Emami Paper Ltd as a comparative study relating to short-term solvency for the study period from 2008 to 2017.

Short Term Liquidity Position

Current Ratio (Working Capital Ratio): This ratio dealings the liquidity position in short term by creating relationship between current assets and current liabilities [5]. The formula to calculate current ratio is as follows.

Current Ratio = Current Assets/Current Liabilities

The statistical data involving to calculation of current ratio was calculated over the financial statements mentioned in their respective annual reports of JK and Emami paper Ltd for the study period from 2008-09 to 2016-17 are signified in the below table.

Table 1: Assets and Current Liabilities of JK and Emami paper Ltd 2008 to 2017 (Rs. in Lakhs)

Year Ending 31st March	JK paper Ltd			Emami paper Ltd		
	Current Assets	Current Liabilities	Ratio	Current Assets	Current Liabilities	Ratio
2008-09	13866	7983	1.74:1	14192	7879	1.80:1
2009-10	15234	8112	1.88:1	15171	10492	1.45:1
2010-11	15300	8771	1.74:1	17250	12229	1.41:1
2011-12	15602	14487	1.08:1	17919	12703	1.41:1
2012-13	18165	12562	1.45:1	21512	14010	1.54:1
2013-14	22010	13344	1.65:1	23535	16631	1.42:1
2014-15	23901	15975	1.50:1	21246	11819	1.80:1
2015-16	24835	12840	1.93:1	22709	10584	2.15:1
2016-17	28986	14455	2.00:1	36715	11022	3.33:1

Source: Annual Reports

Interpretation: As a conservative rule, a current ratio of 2:1 is measured satisfactory. This rule of thumb should not recklessly be followed because, low current ratio specifies that the unit may not be having satisfactory funds to pay off liabilities or it may be trading beyond its ability. cash and bank balances may be untruthful idle because of insufficient investment opportunities. This ratio is below the accepted standard norm both in JKPL and EMAMI PL in the entire study period, except 2010-11 in JKPL, 2009-10 and 2010-11 in EMAMI PL. It clearly specifies, the usual general accepted solvency to meet their current obligations in time is not acceptable during 2002-2009. This ratio just reached at standard in 2010-11 in JKPL compared with previous years. In both companies the current ratio is stable with effect from 2009-10 which designates the short term financial position is quite satisfactory. However, the management of JKPL must initiate essential steps to employ its idle cash and bank balances in good-looking investments or to pay back its short term liabilities.

Quick Ratio (Acid Test Ratio): Quick ratio is harder test of liquidity than current ratio. It founds the relationship between quick or liquid assets and quick liabilities [6]. The formula to compute quick ratio is as follows.

Quick Ratio = Quick Assets/Current Liabilities [7]

The statistical data relating to calculation of quick ratio found through the financial statements mentioned in their own annual reports of JKPL and EMAMI PL for the study period from 2008-09 to 2016-17 and are showed in the below table.

Table 2: Quick Assets and Current Liabilities of JKPL & EMAMI PL 2002 to 2011 (Rs. in Lakhs)

Year Ending 31st March	JK paper Ltd			Emami paper Ltd		
	Quick Assets	Current Liabilities	Ratio	Quick Assets	Current Liabilities	Ratio
2008-09	5888	7983	0.74:1	11393	7879	1.45:1
2009-10	6530	8111	0.80:1	10829	10491	1.03:1
2010-11	6675	8771	0.76:1	12556	12230	1.03:1
2011-12	7509	14487	0.52:1	12924	12703	1.02:1
2012-13	9218	12562	0.73:1	16016	14011	1.14:1
2013-14	11529	13344	0.86:1	16482	16631	0.99:1
2014-15	10376	15975	0.65:1	14041	11818	1.22:1
2015-16	13248	12841	1.03:1	17928	10583	1.69:1
2016-17	16879	14486	1.17:1	32227	11021	2.92:1

Source: Annual Reports

Interpretation: A quick ratio of 1:1 is measured to represent a acceptable current financial condition. A quick ratio of 1:1 does not unavoidably mean suitable liquidity position, if all debtors cannot be understood and cash is needed directly to meet current obligations. A low quick ratio does not unavoidably mean a bad liquidity position as inventories are not a completely non-liquid. It is detected from the above data the quick ratio is less than the accepted norm in JKPL from 2008-09 to 2016-017, whereas it is just above the standard in EMAMI PL Further the quick ratio is above the standard in JKPL from 2015-16 to 2016-17.In EMAMI PL this ratio is at standard from2010-11 to 2011-12 with a slight fall in 2013-14. Thereafter it is increasing increasingly. It is noticed in the arrangement of current assets; the percentage of inventory in total assets is high in amount in JKPL compared to EMAMI PL seeing other current assets like debtors, loans, advances, cash and bank balances. Therefore, quick ratio is more satisfactory in EMAMI PL with JKPL in the total study period.

Cash Ratio (Absolute Liquid Ratio): Cash is the greatest liquid asset. The association between cash including cash at bank and short term marketable retreats with current liabilities is examined to know the instant solvency [8]. While receivables, debtors and bills receivable are generally more liquid than inventories, yet there may be fears regarding their understanding into cash immediately or in given time. The formula to compute the cash ratio is,

Cash Ratio = Cash in hand and at bank + Marketable Securities/Current Liabilities[9].

The statistical data relating to computation of cash ratio got through the financial statements referred in their respective annual reports of JKPL and EMAMI PL for the study period from 2008-09 to 2016-017 and are depicted in table 3 with its graphical representation.

Table 3: Cash +Marketable Securities and Current Liabilities of JKPL & EMAMI PL 2008-09 to 2016-017 (Rs. in Lakhs)

Year Ending 31st March	JK paper Ltd			Emami paper Ltd		
	Cash and Bank Balance	Current Liabilities	Ratio	Cash and Bank Balance	Current Liabilities	Ratio
2008-09	564	7983	0.07:1	4603	7879	0.58:1
2009-10	795	8112	0.10:1	4789	10492	0.46:1
2010-11	612	8771	0.07:1	5957	12230	0.49:1
2011-12	777	14487	0.05:1	6189	12703	0.49:1
2012-13	972	12563	0.08:1	7210	14011	0.51:1
2013-14	1329	13345	0.10:1	8045	16631	0.48:1
2014-15	807	15975	0.05:1	6441	11818	0.54:1
2015-16	1376	12841	0.11:1	9168	10583	0.87:1
2016-17	2068	14456	0.14:1	2884	11021	0.26:1

Source: Annual Reports

Interpretation: The perfect cash ratio is 1:2 or 0.5 or 50 percent. This ratio in APPML is less than the standard and not hopeful for the whole study period i.e. 2008-09 to 2016-17. The cash ratio is above the standard in SSPBL in 2008-09 and a quick decrease up to 2010-11, thereafter solidly increased to 87 percent in 2009-10. But then it has fall to 26 percent in 2010-11, which is less than the standard. The percentage of cash and bank balances in total assets in APPML was 1.27 in 2008-09, reduced to 0.90 percent in 2010-11 and subsequently with increasing trend reached to 1.71 percent in 2010-11. Hence, cash ratio is not satisfactory mainly in JKPL as compared with SSPBL. It needs the concentration of the management to introduce sufficient effective actions for proper maintenance of working capital needs by utilize available cash and cash at bank balances.

Net Working Capital Ratio: Working capital is very much requisite sufficiently for any association for effective performance of its operation successfully[10]. Usually, working capital is directly related to sales. Net working capital is as the difference between current

assets and current liabilities. This ratio can be considered by using the following equation.

Net Working Capital Ratio = Net Working Capital/ Net Assets.

The statistical data involving to net working capital ratio obtain through the financial statements referred in their particular annual reports of JKPL and EMAMI PL for the study period from 2002-03 to 2010-11 and are depicted in the table.

Table 4: Net Working Capital and Net Assets of JKPL and EMAMI PL 2008 to 2017 (Rs. in Lakhs)

Year Ending 31st March	JK paper Ltd			Emami paper Ltd		
	Net Working Capital	Net Assets	Ratio	Net Working Capital	Net Assets	Ratio
2008-09	5882	43471	0.14:1	6313	35952	0.19:1
2009-10	7122	44236	0.16:1	4679	34381	0.14:1
2010-11	6528	48118	0.14:1	5021	40549	0.12:1
2011-12	1115	45748	0.01:1	5218	41100	0.13:1

Source: Annual Reports

Interpretation: The net working capital ratio in JKPL was solid during 2008-09 to 2016-17 It was augmented to 54 percent in 2006-07 which was ever maximum due to irregular increase in current liabilities in the applicable period. Thereafter, this ratio vary from 8 percent to 12 percent from 2014-15 to 2014-16. This ratio was between 12 percent to 19 percent in EMAMI PL between 2008-09 to 2016-17 and presently decreases to 9 percent in 2007-08. Thereafter, it was steady between 13 percent to 29 percent during 2012-13 to 2014-15. The percentage of current assets in total assets was 31.35 in JKPL in 2002-03 reduced to 17.45 percent in 2006-07 and registered a reasonable increase up to 24.12 percent in 2010-11. It was observed that the percentage of the investment was at 8.25 in JKPL in 2008-09 decline to 1.39 percent in 2016-17 as against 2.19 percent in 2008-09 in EMAMI PL reach to 2.66 percent in 2016-17.

Conclusions

From the above study we can investigate that, the management of JKPL must begin essential steps to utilize its idle cash and bank balances in attractive investments or to pay back in short term liabilities. (Current ratio). The low quick ratio may also have liquidity position, if it has fast moving inventories and is more acceptable in EMAMI PL with JKPL. Cash ratio is not acceptable in JKPL as compared to EMAMI PL and it needs the notice of the management to encourage effective utilization of cash and bank balances.

A Study on Farmers' Opinion Towards Marketing of Agricultural Seeds: An Analysis

M. Vetrivel[1], K. Indira[1]

[1]*Assistant Professor, Department of Commerce Department of Commerce, School of Management Studies & Commerce School of Management Studies & Commerce, VELS University, Chennai*

Abstract

This research paper presents the farmers' opinions towards marketing of agricultural seeds-an analysis. Agriculture sector is an important sector in development of economy in our country. It provides direct employment to more than two third populations in our country. Marketing of agricultural seeds can be made effective if it is looked from the collective and integrative efforts from various quarters by addressing to farmers, middlemen, researchers and administrators. It is high time we brought out significant strategies in agricultural marketing with innovative and creative approaches to bring fruits of labour to the farmers. In this backdrop it is necessary to marketing of agricultural seed and quality management in Cuddalore district.

Keywords: *Farmer, Agricultural Seeds, Agricultural Marketing, Problems of Farmers.*

Introduction

In a country like ours agricultural sector is a dominant one. The agricultural production is depending upon various factors like the fertility of the land, availability of water or the irrigation system, the technology adopted and the quality of the seed. of these factors the seed quality alone is affecting the output by 15 to 20%.Realising the fact that the seed is the pivotal in the enhancement of the agricultural production in the country, the government of India has implemented. "National Seed Project phase-I" in 1977-78, phase-II in 1978-79 and phase-III in 1990-91 Also the government has pronounced New Seed Development Policy in 1988-89.[1]

The Indian seed industry is occupied by both the governmental agencies and private seed traders in the Indian agricultural sector. A major portion of agriculturists are either using their own seeds or they procure from the local agriculturists who are having surplus seeds The green revolution during the 70's enabled the private commercial traders to enter into the Indian Seed Industry.[2] The economic liberalization made it possible to import seed from abroad and thereby the entry of foreign companies to market genetically improved varietiesof seeds. Apart from these players in the Indian Seed Industry, State Seed Corporation is also playing a vital role in the production and marketing of seeds.[3]

Agricultural Marketing: The National Commission on Agriculture defined agricultural marketing as a process which starts with a decision to produce a saleable farm commodity and it involves all aspects of market structure of system, both functional and institutional, based on technical and economic considerations and includes pre and post-harvest operations, assembling, grading, storage, transportation and distribution.[4] In the olden days selling of agricultural produce was easy as it was direct between the producer to the consumer either for money or for barter. As it is well known more the number of mediatory more will be the costs as each transaction incurs expenses and invites profits. Ultimately when it comes to the producer the cost of the produce goes up steep. In the entire process of marketing the producer gets the lowest price and the ultimate consumer pays the highest as the involvement of more middlemen in the entire distribution process.[5]

Statement of the Problem: There has been spiraling demand for quality seed in India, despite the implementation of seed certification and the enactment of the Indian Seed Act, 1966. The entry of private companies in the Indian Seed Industries and establishment of State Seed Corporations has not resolved these problems entirely. There has been a vast gap between the demand and supply of seeds. In the state of Tamilnadu the actual requirement of seed was 2.79 lakhs tonnes but supply has been 1.05 lakhs tonnes. In India the seed production has been steadily increasing. The total production of seeds was 1.0396 tonnes during 2002-2003 and it was spurred up to 2.5035 million tonnes, during 2008-2009 (Seed Division of DAC) Even then, the demand for seed has not been fully met. The seed certification has not improved the quality of seed available to the Indian farmers as a major portion of them are using locally available seeds. Hence, a study ofthis nature is considered timely and urgent for assessing the quantity available of selected seeds and the quality of the seeds used by the farmers. Unfortunately, our agricultural seeds sector is really suffocating due to a variety of problems. Generally, the price of a commodity must be either cost based or demand based. The present study is an attempt to look into these aspects for the purpose of gathering more information for improving marketing of agricultural seed in Cuddalore district.

Objectives of the Study: To analyze of problems faced by agricultural seeds cultivators in Cuddalore district

Research Methodology: The study is primarily aims at assessing the availability of quality seeds in Cuddalore district. For the nature of this study, survey method is found suitable. Hence, it is proposed to undertake this study by following survey method. Samples are going to be selected by stratification. It is also proposed toadminister two schedules, one to the sample agricultural farmers and another to the sample seed marketing traders.

Hypotheses

Ho1: There is no significant difference between problems faced by farmers relating to agricultural seeds and demographic profile.

Sampling Struture: Purposive sampling method was adopted for the collection of data from the sample respondents for the study. Sample data were collected from agricultural farmers and seed marketing (firms) traders. The study is confined to only Cuddalore district. 60 samples were selected from each taluk and farmers who have been engaging actively in the cultivation of paddy, black gram, and green gram were chosen as samples for the study. So the total sample size of the study was 480 and it was considered adequate for the main objective of the study.

Statistical Tools: The collected data will be subjected to different statistical analysis such as percentage analysis, mean, standard deviation, co-efficient of variation, correlation analysis, regression analysis, chi-square test, 'T' test, ANOVA, factor analysis, reliability test, Friedman Kandall's "W" Test and descriptive statistics using SPSS package for 20.0.

Age of the Respondents: Age is an important determinant in marketing of agricultural seeds. Generally young farmers have more capacity to assess each and every part of the quality management, cultivation of seeds, problems relating to the marketing of agricultural seed. But the older peoples' advice and their suggestions are important to strengthen of agricultural activities

Table 1: Age of the Respondents

Age	No of respondents	Percentage
20-30	16	3.33
31-40	23	4.79
41-50	129	26.88
51-60	159	33.13
Above 60	153	31.88
Total	**480**	**100**

Source: Primary data

It is evident from the Table 1 that majority of the respondent farmers 159 (33.13 per cent) belong to the age group of 51-60. Out of total 480 respondents 31.88 per cent in above 60 years and 26.88 per cent in 41-50 years. It is evident that 92 per cent of the respondents have an age of above 40 years, of which 31.88 per cent are above 60 years. From this, it is obvious that the aged borrowers dominate the sample population and only 8.12 per cent respondents are up to 40 years of age. This is an indication of the reluctance of the youngsters in agriculture activities.

Sex of the Respondents: One of the important profiles is the sex of farmers. Since the sex has its own influence on the awareness, understanding and availing of the existing benefits in the cultivation of seed, it is included as one of the variables.

Table 2: Gender of the Respondents

Gender	No of respondents	Percentage
Male	421	87.71
Female	59	12.29
Total	**480**	**100**

Source: Primary data

The Table 2 shows that among 480 sample farmers, 412 (87.71 per cent) are male and 59 (12.29 per cent) are females. Agriculture as business or livelihood is carried on more by men by women. Yet women are engaged as labourers for major agricultural activities like cropping, weeding, and harvesting.

Occupation of the Respondents: Occupation is a widely accepted and probably the best documented measure of social class, because it implies occupational status. The importance of occupation as a social-class indicator is dramatized by the frequency which people ask others when they meet for the first time, what do you do for a living.

Table 3: Occupation of the Respondents

Occupations	No of respondents	Percentage
Government employees	32	6.67
Semi government employees	28	5.83
Private employees	57	11.88
Agriculture	356	74.17
Others	07	1.46
Total	480	100

Source: Primary data

The Table 3 shows that majority of the 356 (74.17 per cent) respondents are doing agriculture as a main occupation. Among the sample respondents about 32 (6.67 per cent) are working as a government employee. Likewise 28 (5.83 per cent), 57 (11.88) and 7 (1.46) of respondents are working as a Semi-Government Employee, private employee and others. But all the employees are doing agriculture as partly.

Own Agriculture Land: The Own Agriculture land of the respondents has been included in marketing of agricultural seed with respect to quality management.

Table 4: Own Agriculture Land of the Respondents

Agricultural land	No of respondents	Percentage
Yes	453	94.38
No	27	5.63
Total	**480**	**100**

Source: Primary data

The Table 4 shows that the majority of the respondents 453 out of 480 are having own land which is 94.38 per cent and remaining 27 are not having own land which forms 5.63 per cent of the sample respondents.

Testing of Hypotheses (Problems in Seed Cultivation and Marketing): This section is to testing the significant difference between farmers' annual income, how many years are cultivating lands, how many years are engaged in agriculture and type of land cultivated with respect to problems in seed cultivation and marketing towards quality management in Cuddalore district.Testing the significant difference between problems in seed cultivation and marketing on the basis of the annual income (demographic profile) one way ANOVA was applied to ascertain if there were any significant difference between problems in seed cultivation and marketing on the basis of the annual income and the following null hypotheses has been framed:

Ho1: There is no significant difference between problems in seed cultivation and marketing on the basis of the annual income.

Table 5: Anova for Problems in Seed Cultivation and Marketing on the Basis of the Annual Income

Variables	Annual Income	N	Mean	SD	F-value	P Value
Financial Problems	Below 25,000	34	32.71	4.707	1.868	0.134 (NS) Accepted
	25,001-50,000	85	34.06	4.734		
	50,001-75,000	149	34.65	4.493		
	Above 75,000	212	34.41	4.310		
	Total	**480**	**34.30**	**4.484**		

Variables	Annual Income	N	Mean	SD	F-value	P Value
Maintenance Problems	Below 25,000	34	20.47	3.535	1.052	0.369 (NS) Accepted
	25,001-50,000	85	21.12	3.992

	Total	480	24.04	3.656		
Problems faced by the Farmers towards Agricultural Seeds	Below 25,000	34	58.65	8.521	4.308	0.005 (S) Rejected
	25,001-50,000	85	61.58	7.122		
	50,001-75,000	149	62.94	7.223		
	Above 75,000	212	60.49	8.302		
	Total	480	61.31	7.875		

Source: Computed From Primary data, NS-Not Significant

The Table 5 inferred the F-value of financial problems on the basis of their annual income. The calculated F-value (1.868) is not significant. Hence, the stated hypothesis is accepted. Therefore Rs.50, 001-Rs.75, 000 annual income groups of respondents has highly face financial problems than the other groups.

The F-value of maintenance problems on the basis of their annual income, the calculated F-value (6.599) is not significant. Hence, the stated hypothesis is accepted. Therefore Rs.25, 001-Rs.50, 000 annual income groups of respondents has highly face maintenance problems than the other groups.

The F-value of low yield in Agricultural Seeds problems on the basis of their annual income, the calculated F-value (1.868) is significant. Hence, the stated hypothesis is rejected. Therefore Rs 25, 001-Rs.50, 000 annual income groups of respondents has highly face low yield in agricultural seeds problems than the other groups.

The F-value of labour problems on the basis of their annual income, the calculated F-value (4.032) is significant. Hence, the stated hypothesis isrejected. Therefore below Rs.25, 000 annual income groups of respondents have highly face labour problems than the other groups.

Problems Faced by the Farmers towards Agricultural Seeds: The analysis of problems in seed cultivation and marketing namely financial, maintenance, low yield in agricultural seed cultivation, labourproblems and problems relating to the crop cultivation and also problems faced by the farmers problems faced by the farmers in agricultural seeds cultivation, these challenges making the agricultural farmers

Table 6: Problems Faced By the Farmers Towards Agricultural Seeds

SNo	Variables	N	Mean	SD	Rank
1	Water scarcity, drought	480	4.00	1.187	1
2	Crops were lost due to the heavy rainfall and floods	480	3.86	1.093	7
3	Cyclone	480	3.69	1.136	14
4	Pest and diseases	480	3.74	1.125	11
5	Irrigation problems	480	3.67	1.438	15

SNo	Variables	N	Mean	SD	Rank
6	Non availability of inputs (seeds, fertilizers and pesticides)	480	3.98	1.127	3
7	Low price of the products	480	3.89	1.249	5
8	Power problems	480	3.70	1.464	12
9	High price of inputs	480	3.81	1.469	8
10	Canals overflowed due to heavy rainfall	480	3.87	1.152	6
11	Collapse of Irrigation System	480	3.70	1.313	13
12	Heat Wave and Cold Wave	480	3.75	1.250	10
13	Change in Production/ Climate Change	480	3.99	1.141	2
14	Spurious seeds	480	3.76	1.360	9
15	Poor fertility of land	480	3.96	1.151	4
16	Crop loss due to Livestock/Others	480	3.91	1.344	4

Source: Computed from Primary data

It is noted from the Table 6 shows that problems faced by the farmers towards water scarcity, drought first rank the mean value=4.00 and standard deviation value = 1.187 followed by Change in production/climate change of mean value=3.99 and standard deviation value = 1.141, Non availability of inputs of mean value=3.98 and standard deviation value = 1.127, Crop loss due to livestock of mean value=3.91 and standard deviation value = 1.344, Low price of the products of mean value=3.89 and standard deviation value = 1.249, Canals overflowed due to heavy rainfall of mean value=3.87 and standard deviation value = 1.152, Crops were lost due to the heavy rainfall and floods of mean value=3.86 and standard deviation value = 1.093, High price of inputs of mean value=3.81 and standard deviation value = 1.469, Spurious seeds of mean value=3.76 and standard deviation value = 1.360, Heat Wave and Cold Wave of mean value=3.75 and standard deviation value = 1.250, Pest and diseases of mean value=3.74 and standard deviation value = 1.125, Collapse of Irrigation System of mean value=3.70 and standard deviation value = 1.313, Cyclone of mean value=3.69 and standard deviation value = 1.136 and finally Irrigation problems of mean value=3.67 and standard deviation value = 1.438. Hence, it is concluded that problems faced by the farmers towards water scarcity drought the first rank, the mean value=4.00 and standard deviation value = 1.187 followed by Irrigation problems last and fifteenth rank, the mean value=3.67 and standard deviation value = 1.438.

Suggestions:

- Improved verities and high quality seeds are basic requirements for productive agriculture, which is the basis of sustainable economic development in developing countries.
- The number of new verities increased after the introducing of plant variety protection.
- Currently in developing countries there is not an adequate seed quality assurance infrastructure with respect to seed testing and this is required to increase crop productivity and provide enhanced food security.
- The evolution of seed quality determination has not reached an end point and there are interesting developments in the pipeline that take account of the changing needs of the market.
- In the seed technology area transparency in and scientific exchange of the latest results remain of crucial importance for continued progress.

Conclusion

The present study concluded that, the necessary reforms coupled with proper price discovery mechanism through regulated market system will help streamline and strengthen agricultural marketing. In order to avoid isolation of small-scale farmers from the benefits of agricultural produce they need to be integrated and informed with the market knowledge like fluctuations, demand and supply concepts which are the core of economy.[6] Marketing of agricultural seeds can be made effective if it is looked from the collective and integrative efforts from various quarters by addressing to farmers, middlemen, researchers and administrators. It is high time we brought out significant strategies in agricultural marketing with innovative and creative approaches to bring fruits of labour to the farmers.[7]

A Study on Consumer Behaviour Towards Durable and Non-Durable Goods in Cuddalore District

R.V. Suganya[1], M. Vetrivel[1], R. Lakshmi[2]

[1]Assistant Professor, [2]Associate Professor, Department of commerce, School of Management Studies and Commerce, VELS University, Chennai

Abstract

The purchasing is done by keeping all these factors in mind. Today, price is not the only consideration as it was a few years back when prices played a major role in purchasing. The automobile industry in general and two wheeler industries in particular have shown a tremendous growth over the recent years. Tomorrow's consumer will focus more on technology and credit purchase. To become a successful producer of milk products, they should think about price, quality and health consciousness of those products. Offers, gifts, price discount etc, can be given to attract more customers. This article paper highlights the consumer behaviour on durable and non-durable goods.

Keywords: *Consumer behaviour, Durable goods, Non-durable goods, Automobile industry.*

Introduction

The India consumers today are highly aware about the product, price, quality and the options available with them. The purchasing is done by keeping all these factors in mind. Today, price is not the only consideration as it was a few years back when prices played a major role in purchasing.[1] The automobile industry in general and two wheeler industries in particular have shown a tremendous growth over the recent years. Tomorrow's consumer will focus more on technology and credit purchase. Number of nuclear families will increase. Health care will become very important in the coming years. Talking of the two wheeler industry, the names that effortlessly come to us is Bajaj Auto, Hero Honda, TVS motor, Yamaha Motor, kinetic and others.[2] The two wheeler segment has played an important role in giving a push to the automobile industry in India. In fact, the production, sales and export of the Two Wheeler is a fair indication of the growing importance that it enjoys in this country's manufacturing economy.[3] The total sale of Two Wheeler in India has touched the figure of 7.86 million units by March 2007 up 11.42% from the previous fiscal figures of 7.05 million. Production during the period reached 8.63 million units.

The production of Two Wheeler in India is expected to reach a staggering 17.85 million units by 2010-11, double than the current production level. The two-wheeler production capacity is to reach 22.31 million units in 2011-12, compared with 10.78 million in 2006-07.[4]

Consumer Behaviour: Consumers behaviour is a composition of four aspects viz., consumer preference, information search purchase decision and post purchase behaviour or satisfaction. These aspects are explained in detail in the following pages. Define consumer behaviour as "those acts of individuals directly involved in obtaining, using, and disposing of economic goods and services, including the decision processes that precede and determine acts.

Importance of the Study: Today the company's image is built and made know by its customers. Thus the success of a firm is determined by how effective it has been in meeting the diverse consumer needs, by treating each customer as unique. Consumer is the king and it is the consumer who determines what a business is. Therefore, a sound marketing programme should start

Corresponding Author:
Dr. R.V. Suganya
Assistant Professor, Department of Commerce, School of Management Studies & Commerce, VELS University, Chennai
e-mail: sugan9979@gmail.com

with a careful analysis of the habit, attitude, motives and needs of consumers.[5]

Need of the Study: India consumers are increasingly becoming aware of the importance of health and hygienic. Hence companies are making products to suit their health like low calorie, low fat food etc., they acquire knowledge about the product by collecting information through different medias, friends and relatives. Similarly they are buying milk products by undertaking their health as one of the important factor in their minds. Milk products are perceived differently at various types of purchasing places.[6] The most important variable explaining individual differences in consumer behaviour regarding purchase of milk products are trust, quality, origin, price of product, fat contents, and doctor's suggestions and so on.

Scope of the Study: The study aims at analysing consumer behaviour relating to Two Wheeler and Milk products. The scope of the study has been limited to certain buying behavioural aspects of purchase decision process namely information search, product awareness, interest, product evaluation process, brand preference, factors of motivation, price and quality consciousness, purchase and post purchase behaviour. The study broadly aims at examining perceptions of the consumer mainly in terms of the information gathered, sources of information, location where the purchase is made and the ultimate purchase decision.

Objectives of the Study

1. To identify and comparatively evaluate their article evaluation process, information search for the products.
2. To examine the association between demographic variables and elements of consumer behaviour.

METHODOLOGY

The sources of data are primary as well as secondary. The data collected from the consumer's survey primary and information gathered through books, journals, magazines, reports, dailies consist of secondary data. The data collected from both the sources are scrutinized, edited and tabulated. The data are analysed using SPSS (statistical package for social sciences) computer packages. The primary data is obtained through a well framed questionnaire as research instrument. The perception of consumers of two-wheelers and milk products are considered as main source of study.

Sample Size: Sample selected for the study covers different areas of Cuddalore district. Totally, 400 consumers of Two Wheeler and milk products are considered for research. They are selected on a simple random sampling method.

Review of Literature: The previous discussion of the literature identified significant gaps that will be explored in the thesis. Most of the studies in the area of consumer behaviour are limited for comparing with respect to Two Wheeler and non-Two Wheeler products neglecting the various elements of the behaviour. These issues are examined from the perspective of that behaviour and rarely take note of the dealer's opinion.

Perspectives on Consumer Research

The Rational Perspective: The economists were the first to dominate model building, in the area of buying behaviour. The early economic view considered consumer behaviour in terms of a single act of purchase itself, and post-purchase reactions. Economic theory holds that purchasing decisions are the result of largely "rational" and conscious calculations. Thus, the individual buyer seeks to spend his income on those goods that will deliver the most utility (satisfaction) according to his tastes and relative prices.

The Behavioural Perspective: As mentioned above, in contrast to the economic view which underscores the importance of internal mental processes in consumer decision making, the behavioural perspective emphasizes the role of external environmental factors in the process of learning, which it is argued causes behaviour. Thus, the behaviourists approach the consumer, as a "black box" and thereby assume that consumer behaviour is a conditioned response to external events.

The Cognitive Perspective: In contrast to behavioural theories of learning, the cognitive perspective stresses the role of information processing in consumer decision making. This perspective views people as problem solvers who actively use information from the world around them to master their environment. However, much debate surrounds the issue of whether or when people are actually aware of these learning processes. On the owned hand, there is some evidence for the existence of unconscious procedural knowledge.[7]

Analysis of Consumer Behaviour

Gender: Gender plays a vital role in determining behavioural aspects of consumers. In fact most of the

behavioural studies have identified the significant differences between the male and female consumers. In in this study the sample units execute the following frequency distribution of the gender.

Table 1: Gender Wise Respondents

Gender	Frequency	Percentage
Male	226	56.5
Female	174	43.5
Total	**400**	**100**

Sorce : primary data

From the above table it is ascertained that in the sample unit, a maximum of 56.5 per cent are male consumers and 43.5 per cent are female consumers. So it can be deduced that the sample unit comprises of more male consumers and reasonable number of female consumers of Two Wheelers and milk products.

Age: Age being one of the demographic characteristics of consumers influences the buying behaviour of consumers to a greater extent. The following table shows the distribution of respondents belonging to the different age groups.

Table 2: Age Wise Respondents

Gender	Frequency	Percentage
Below 20	06	1.5
20-30	115	28.5
30-40	132	33.0
40-50	127	32.0
Above 50	20	5.0
Total	**400**	**100**

Sorce : primary data

From the table 2 it is known that 33 per cent of respondents are between the age group of 30 to 40, 32. per cent are under the age group of 40-50, and 28.5 per cent are under the age group of 20-30. Negligible percentages i.e. (1.5 per cent) are belonging to the age group of below 20. Therefore it is understood that the respondents selected for the study are more or less evenly distributed.

Marital Status: The table given below depicts the marital status of the respondents selected for the study.

Table 3: Marital Status Wise Respondents

Gender	Frequency	Percentage
Married	286	71.5
Single	114	28.5
Total	**400**	**100**

Sorce : primary data

The table 3 shows that 71.5 per cent of the total consumers selected for the study are married and the remaining 28.5 per cent are single.

Present Status: While studying about the buying behaviour of the consumers, it is necessary to take into account the status of the consumers as the status also influences the behaviour. The distributions of status of the consumers are tabled below;3

Table 4: Present Status Wise Respondents

Gender	Frequency	Percentage
Salaried	275	68.75
Self-employed	16	4.0
Housewife	31	7.75
Student	40	10.0
Professional	38	9.5
Total	**400**	**100**

Sorce : primary data

The above table clarities the level of income of the consumers selected for the study. 36 per cent of the respondents belong to the income level of below Rs.10,000. 28.75 per cent of the consumers are under the category of above Rs.40,000. From the above it is understood that the respondents selected are evenly distributed to all categories of income.

Income: The level of income influences the purchase decisions of the consumers. The income distribution of the respondents is given in the following table;

Table 5: Income Level Wise Respondents

Gender	Frequency	Percentage
Beloe 10,000	144	36.0
10.001-25,000	78	19.5
25,001-40,000	63	15.75
Above 40,000	115	28.75
Total	**400**	**100**

Sorce : Primary data

The above table clarities the level of income of the consumers selected for the study. 36 per cent of the respondents belong to the income level of below Rs.10,000. 28.75 per cent of the consumers are under the category of above Rs.40,000. From the above it is understood that the respondents selected are evenly distributed to all categories of income.

Educational Qualifications: The data regarding the educational qualification of the consumers are also collected as it affects the buying behaviour of the consumers to greater extents. This is given in the following table;

Table 6: Educational Level Wise Respondents

Gender	Frequency	Percentage
School Level	19	4.75
Graduate	79	19.75
Post Graduate	222	55.5
Professional	82	20.0
Total	**400**	**100**

Sorce : primary data

The table indicates the educational qualification of the respondents. 55.5 per cent of the respondents belong to the category of PG level education. 20 per cent are professionally qualified category, 19.75 per cent belong to graduate level and the negligible level of just 4.75 per cent belongs to the school level education.

Suggestions: Since brand consciousness is predominant among two wheeler customers in Cuddalore district, the two wheeler marketers should concentrate on their brands to increase their characteristic features and innovative technology to attract maximum customers. Innovation in case of model, technology, pollution free vehicle will definitely help to increase the market share of that particular product.[8] To become a successful producer of milk products, they should think about price, quality and health consciousness of those products. Offers, gifts, price discount etc, can be given to attract more customers.

Conclusion

From this article concluded that the promotional offers for milk products entirely depend on offers and attractive schemes. It is concluded that there is significant association between cluster classification and size of the family, cluster classification and gender, clusters of milk products and status, clusters of buyers of milk products and income and clusters of buyers of milk products and their educational qualifications. The consumers treat shopping as an enjoyable activity while buying their two wheelers whereas they treat it as a waste of time while buying their milk products. The consumers often buy their milk products from the same store each time. They purchase their favourite brands in case of two wheelers.[9] The buyers buy their two wheelers on cash, credit card and instalment basis whereas they often buy milk products on cash basis rather than on their basis.

Magnetic Resonance Imaging Evaluation of Normal Ocular Anterior-Posterior Diameter and Interzygomatic Length in Healthy Adult and Pediatric Eastern Indian Population: A Retrospective Study

Manoranjan Mohapatra[1], Ranjan Kumar Sahoo[1], Saroj Ranjan Sahoo, Manoj Kumar G.[2]

[1]Associate Professor, [2]Post Graduate Resident, Department of Radiology, Kalinga Institute of Medical Science, KIIT University, Bhubaneswar, Odisha, India

Abstract

Purpose: To determine the anterior-posterior diameter of both eye balls by use of magnetic resonance imaging (MRI) and to find out possible association between the ocular anterior-posterior diameter with inter-zygomatic length, age and sex of healthy individuals.

Material andMethod: Retrospective study of ocular APD and inter zygomatic length (IZL) was carried out in Department of Radiology. About 403 cases with normal MRI findings of brain and orbit were retrospectively analyzed by two senior radiologists independently keeping in view of inter observer variability. Study includes T2 weighted axial imaging of brain and orbit from January 2017 to Jan 2019. Data were analyzed using SPSS software version 22.0 for Microsoft Windows 10.

Results: The normal anterior-posterior diameter of the right and left globe of male person were 22.97 ± 0.946 mm and 22.94± 0.928 respectively. The normal anterior-posterior diameter of the right and left globe of female person were 22.48 ± 0.919 mm and 22.42± 0.921 respectively. The IZL was 97.6±4.297 and 94.05±4.277 in male and female individual respectively. Male individuals had higher ocular APD and IZL than female individuals ($P < 0.001$).

Conclusions: The normal ocular APD will help the clinicians, ophthalmologists and radiologist to quantitatively evaluate patients with abnormal ocular size and/or refractive errors.

Keywords: *Ocular, axial, eye,zygoma,magnetic resonance imaging.*

Introduction

The anterior-posterior diameter (APD) of eye ball is an important parameter than other ocular biometry as it helps in calculation of lens power before cataract surgery and predicts the risk of retinal detachment.[1,2] APD is measured in magnetic resonance imaging at the level of inter-zygomatic line and lens level objectively form anterior to posterior ocular pole. The inter-zygomatic line (IZL) joins the anterior margins of the zygomas.[3,4] Previous studies in rural population of central India suggest the average length of eye ball to be 22.6±0.91 mm in normal healthy adult.[5] Race, ethnicity, and genetics can influence the axial ocular length.[6] The ocular APD increases with age upto adult after which the APD remain unchanged. The average APD in newborn and adults were about 16 mm and 19.5 respectively.[7] The APD is an important dimension of eye than other diameters and is larger in myopia and smaller in hypermetropia.[8] Anterior chamber depth, lens thickness, crystalline lens refractive power, and variations in APD affect the refractive error in older aged people especially 50 years

e-mail: saroj.sahoo1@kims.ac.in

or older.[9] The variation of ocular APD is associated with refractive errors and few retinal diseases like age-related macular degeneration, and glaucoma.[10] The sonographic evaluation of eye is operator dependant. Computed tomographic evaluation of eye involved ionizing radiation. However MRI of orbit is safer alternative for ocular biometry and it can give additional information about optic nerve, intraocular and orbital pathology. MRI of orbits provides accurate anterior-posterior diameter as compared to A-scan ultrasonography. APD measurements with MRI match reliably with that measured by A-scan ultrasonography.[11] Present study will provide useful ocular biometric information from retrospective analysis of MRI study of head and orbit of healthy individuals.

Materials and Method

This study was based on retrospective analysis of 403 brain and orbital magnetic resonance imaging (MRI) examinations without contrast enhancement in our institution between January 2017 to January 2019. The study was conducted in 1.5 T MRI (GE) systems with head coil for the acquisition of the images. The study population was aged 10-80 years (average age was 48.2), there were 230 male and 173 female. Cases with history of orbital/head trauma, metabolic or systemic diseases, glaucoma or other ophthalmologic diseases such as microphthalmus, staphyloma, buphthalmos, and macrophthalmous were excluded from the study. The images showing movement artifacts, asymmetry sections of eye balls, eye with intraocular lens and lateral deviation were also excluded from the study. All the MRI reports stated no significant abnormality, so the study population was considered as representative of general Asian race population. T2-weighted axial images of brain/orbit were used for all ocular measurements at lens level. The IZL was drawn with electronic calliper and used as a reference line. The APD of the eyes was obtained with the aid of electronic calipers at lens level from posterior aspect of corneal apex to posterior globe wall-fat interface (Fig. 1).

Statistical Analysis: Statistical analysis was done inSPSS software version 22.0 for Microsoft Window. Values were expressed in terms of the mean and standard deviation (SD). The difference in APD between male and female was analyzed using the independent t test. The differences of the estimated APD obtained by right and left sides were compared using paired t test. Correlation between different parameters was tested by Pearson correlation test. The $P < 0.05$ was considered statistically significant. The ethical committee approval was not needed as this is a retrospective and non-interventional study. However institutional research committee was informed about the study.

Results

Total 806 globes of 403 individuals were studied. The mean age of individuals was 48.5± 18.83 years. Two hundred thirty (57%) of the cases were males while one hundred seventy three (43%) were females. The right and left globes paired samples correlation and paired samples test showed no statistically significant differences between right and left globes (Table 1). Age wise distribution of APD of right and left eye ball is shown in Table 2. There was no statistical significant correlation between age, right and left eye ball anterior-posterior diameter. However, IZL is more in elder individuals which is statistically significant (Table 3). The mean APD of the right globe is 22.76 ± 0.905 mm, while that of the left is 22.73 ± 0.915. There is no significant difference of APD between right and left eye ball. (P =0.22). The male individuals had more APD of eye ball and inter zygomatic length than female individual (Table 4). The IZL shows weak positive correlation with right and left eye ball anterior-posterior diameter (Table 5).

Table 1 Difference in the right anterior-posterior diameter (RAPD) and left anterior-posterior diameter (LAPD)

Parameters	RAPD	LAPD	Mean Occular APD	P-VALUE	IZL

Discussion

The APD of the globe is defined as the distance from the corneal apex to an interference peak corresponding to the retinal pigment epithelium/Bruch's membrane.[12] The IZL represents the size of face and its mean length in our entire study was 96.06 ± 4.6 mm. IZL is higher in male than female in our study (P < 0.001). The mean value in males and females are 97.6±4.297and 94.05±4.277 mm respectively. Our observation is consistent with the larger male head size than female head and with the findings of other authors.[13,14,15] Ozgen et al. and Jong Soo Lee et al. found larger IZL in male individual than female by use of MRI and CT imaging respectively.[14,15]Among adult populations in eastern India, the mean ocular APD in our study was found to be 22.73 ± 0.911 mm (Table 1). Nangia V et al.[16] studied the APD of globe by use of ultrasonic biometric method in rural Central India with mean age 49.4± 13.4 years and found the mean APD as 22.6 ± 0.91 mm which is similar to our study. George et al.[17] also showed similar mean APD value (22.28 ± 0.8 mm) as obtained in our study. However He M et al.[18] and Wickremasinghe et al.[19] conducted study in South China and Rural Mongolia respectively and found the APD value as 23.11 and 23.1 mm which are larger than our study. Beaver Dam Eye Study by Lee et al.[20] and Epic EPIC-Norfalk eye study by Foster et al.[21] study in England show the mean APD as 23.69 and 23.80 respectively. Huang Q et al. carried out ocular biometry in western china by partial coherence laser interferometry in patient with 50 and

above age with cataract and shows the average APD as 24.32±2.42 mm.[29] Bikbov MM et al. conducted study in Russian population and shows the average APD of eye ball is similar to Beijing and Singaporean population.[30] The difference of APD measurement in all above studies could be due to racial variation and environment influence.[22] Ozgen et al.[14], Jong et al.[15]and Detorakis et al.[23] did not find any statistically significant difference between data for the right and left globes. Salaam et al. reported no significant difference of APD between globes in their sonographic evaluation of eyes in Nigeria population.[24] There is no significant difference in right and left eye ball APD in our study. The APD of the male eyes has higher values than that of female. The APD of the right globe in males was 22.97±0.946 mm while that of the females was 22.48±0.919 mm($P < 0.001$), and the mean APD of the left globe among males was 22.94±0.928 mm compared to 22.42 ± 0.921 mm for females ($P < 0.001$). Tanjong-Pagar and Angeles Latino Eye studies[25, 26] had similar sexual dimorphism. Study conducted by Albashir SI, Saleem M et al. shows statistically significant higher axial eye ball length in male than female.[28]

In our study, there was no positive correlation between participants' age and the ocular APD. This differs from the observations of some authors. [16,19,25,27] The studies conducted by Lee et al.[20] (Beaver Dam Eye Study) and Wong et al.[25] (Tanjong-Pagar study) showed that the APD decreased with increasing age while a central Indian Eye and Medical Study by Nangia et al.[16] showed that the APD increased with increasing age. Similar observation was also noted by Guo et al.[27]and Wickremasinghe et al.[19] The contrast observed between our findings and that of these authors may be due to racial variations, environmental influences and/or technique employed in the studies. Weak statistical correlation is seen between IZL and APD of globe in our study.

Limitations of the study: The sample size is relatively smaller. A large prospective study after ruling out ocular abnormality/refractive error by ophthalmologist is advised for further study.

Conclusion

Sexual dimorphism is seen in APD of globe with males having higher values. The mean APD obtained in this study is matching with the study of central India and differs from the values obtained in China and Britain which further confirms that racial variation and environmental influences affect the APD of the globe as supported by other studies also. This normative data will help the ophthalmologist, clinician and radiologists for better quantitative evaluation of ocular and refractive abnormality such as small eye, large eye and refractive errors.

Conflict of Interest: All authors declare no conflict of interest.

Assessment of Quality and Safety Aspects of Home Healthcare Services Provided by Tertiary Care Hospital

Meenal Kulkarni[1], Ankita Tyagi[2], Radhika Raut[2]

[1]Assistant Professor, [2]Students, MBA (Hospital & Healthcare Management), Symbiosis Institute of Health Sciences, Symbiosis International (Deemed University), Pune, India

Abstract

The present study is based on Home Healthcare service provided by Tertiary Care Hospitals in Mumbai. These tertiary care hospitals provide services like Nursing Care, Physiotherapy Care, Home Sample Collection and providing the reports and X-ray at patient's home environment. The purpose of this study was to determine the quality and safety of the Home Healthcare services.

The questionnaires were prepared by taking under consideration the JCI guidelines for Home Healthcare Patient Safety 2016 for all the four services viz. Nursing Care, Physiotherapy Care, Home Sample Collection and X-ray. The patients 'data was collected for the period of five months through telephonic medium which was further compiled and analysed. The study revealed satisfaction percentage which were above 95% for nursing care and home x-ray services, physiotherapy and home sample collection need improvement where percentage was between 80% to 90%. Further gap analysis was done where mean score of service dimensions like reliability, responsiveness, assurance and empathy were calculated.The highest gap observed for empathy dimension (0.24) followed by responsiveness (0.15) and assurance (0.12). Home Healthcare service is an emerging field in today's world;hence, this research will help the hospitals in understanding the gaps in home healthcare services, which will in turn enhance the quality and safety of health care services at patient's home environment.

Keywords: *Home Healthcare Service, Quality, Safety, Gaps.*

Introduction

It was a common practice of caring for someone medically at home before modern medicine era set in. Hospitalization was rare phenomenon. People believed in traditional way of giving treatment and comfort to the ailing person. Today, with a growing trend toward reduced hospital stays, home healthcare is gaining in popularity. While caregivers of the past were generally family members or friends, home healthcare today usually consists of a professional healthcare team working toward a common goal[1]. Home healthcare is defined by the National Clinical Homecare Association (2011) as "the provision of medical supplies and/or clinical services directly to patients in the community[2].

Home healthcare services aims at helping individuals to improve health and live with greater independence. It aids in promoting the client's optimal level of well-being; and assist the patient to remain at home, avoiding hospitalization or admission to long-term care institutions. Consultants may refer patients for home health care services, or family members or patients themselves may request the services[3] [4].Home health care is a system of care provided by skilled practitioners to patients in their homes under the direction of a physician. Home health care services include nursing care; physical, occupational, and speech-language therapy; and medical social services[5].

The home healthcare market is expected to reach USD 349.8 Billion by 2020 from USD 227.5 Billion in 2015, growing at a CAGR of 9.0% from 2015 to 2020. Major factors driving the growth of this market include rising aging population, increasing incidences of chronic diseases, growing demand for affordable healthcare delivery systems due to the increasing healthcare costs, technological advancements, and government initiatives to promote home healthcare[6]. Health care is a big concern in India, the land of nearly 1.12 billion people 4 and the second most populous country in the world. It is estimated that lifestyle diseases will account for a whopping 74% of total deaths by 2030 (compared with 56% in 2008) with Cardiovascular, Cancer and Diabetes accounting for a majority. Home-based healthcare is an initiative to reach to such households beyond the boundaries of traditional hospital infrastructure [6]. With growing geriatric population, where India stands second, it is essential that such services are promptly promoted and utilized.Home Healthcare is a need of the today's world. With increase in number of chronic diseases and increase in need of convenience, the Home Healthcare sector is emerging day by day. In such services, it is very important to maintain and quality and safety of the service as home healthcare services are provided at patient's home, which is completely different from hospital setting[7].

Thus, a study was planned by the tertiary care hospitals, to find out satisfaction among the patients who have received such care services in the comfortable environment of home and also to find out the gaps and suggest recommendation the to reduce the same.

Various aspects of quality and safety were studied; these aspects include Appointment Booking Procedure, Punctuality of the Home Health staff, behavior of Home Healthcare staff towards patient and reporting Facility. In addition to this patient's safety aspect such as asking for doctor's prescription before doing any procedure, educating the patients regarding the procedure carried out, taking the blood sample in one prick were also taken under consideration.

Methodology

This cross-sectional study done for the home healthcare services provided by the tertiary care hospital in the city of Mumbai. Data was obtained from the patient who had availed these services in the year 2016. The study period was for five months, i.e. from January to May 2016.

For the purpose of data collection, four types of services were chosen namely:

- Home Nursing Care
- For Home Physiotherapy
- For Home X-ray Service
- For the Home sample, collection

Sample Size Obtained:

- Home Nursing Care: 144
- Home Physiotherapy Care: 11
- Home X-Ray Service: 24
- Home Sample Collection Service: 459

Thus, the total patients surveyed were-638

The feedback was taken from the patients using the patient satisfaction questionnaire prepared for each of the four departments under home healthcare of tertiary hospital about their satisfaction level with respect to:

- Appointment booking procedure.
- Patient Identification
- Punctuality
- Patient safety precautions

Results and Discussions

Home Nursing Care: Nursing care provided by hospital is for routine and specialized care. The nurse attendants re well-qualified registered nurses, who are on roll of employment with the hospital. The nursing staff is also trained in basic life support by American heart Association making them well qualified and equipped for the job. This as seen in the percentage of satisfaction in table 1, which is above 95% in all parameters. Patient safety is of upmost importance in home healthcare services. Criteria like asking for doctor's prescription before the procedure, educating the patient regarding the procedure and making patient comfortable ***during*** the procedure were taken under consideration, which scored high in terms of satisfaction

Table 1: Satisfaction Percentage on parameters related to home healthcare services

Services	Parameters-Satisfaction Percentage			
	Appointment booking procedure	Patient Identification	Punctuality & Reporting	Patient safety precautions
Home Nursing Care (n= 144)	98.5%	100%	97%	95.5%
Home Physiotherapy Care (n=11)	100%	81%	90.9%	94.9%
Home X-Ray Service(n=24)	94.4%	100%	97.2%	95.8%
Home Sample Collection Service(n=459)	94.10%	94.7%	98.55%	86.6%

Home Physiotherapy Care: The physiotherapy care provided is mainly for orthopedic patients and post operatives cases. The aim is to help patient regain strength, movement and function. The physiotherapist are also well qualified with bachelors of physiotherapy and adequate experience. Usually electrotherapy like Ultrasound, IFT, TENS along with manual therapy like mobilization and soft tissue techniques like Myofascial release and Trigger point therapy is carried out for patients with periodic re-evaluation and follow up. The no. of patients availing the service is gradually going up. With respect to patient safety. However, measures needs to be taken for patient identification where satisfaction percentage is 81% other parameters score high as compared to this one.It is important to ask patient/ family members regarding the medication history of the patient before giving the physiotherapy treatment, risk assessment of the patient's home environment and make patient comfortable during the physiotherapy treatment. Here the percentage is 94.9% as depicted in tale 1, which can be worked on where ample care should be taken to follow all the procedures and protocols before administering the treatment along with punctuality and reporting.

Home X-Ray Service: This service is mainly targeted for senior citizens who find it difficult to come to hospitals for getting their X-ray done. Thus, a team of medical assistants is sent along with portable X-ray machine to provide simplified and stress free experience. With appointment procedure, 94.4% patients were satisfied. For patient safety aspects such as confirmation of name and prescription of the patient, not allowing family members inside the house during X-Ray procedure and taking X-Ray in one attempt etc. re included to which 95.8% patients were satisfied as per table 1. As this facility is brought to the comfort of the home, people have to pay little above the regular price, thus making this aspect where 84.3% are satisfied with the cost of X-Ray.

Home Sample Collection Service: This is the widely used service of the hospital, for which they have employed trained technicians who are good communicators as well. As per table 1, 94.10% are satisfied with appointment procedure, rest they feel it takes little longer for them to take appointment when they call. It is also suggested that there should be on line system for ease of taking appointment. With punctuality of phlebotomist, staff 94.7% patients are satisfied. Patient Identification scores 98.55% for satisfaction. Patient Safety which include 3 aspects such as washing hands before procedure, wearing gloves, and taking sample in single prick, this aspect has 86.6% satisfied which needs improvement tremendously as it may lead to certain hazards which can be harmful for patients and end up earning bad reputation for the hospital.

Moreover, with more competitors operating in the market. It becomes even more imperative to take care of these parameters for sustaining the patient base.

Table 2: Gap Analysis between Patient Expectation and perception of care providers of various Service Dimensions

Service Dimensions	Mean Score (Customer Satisfaction)	Mean Score (Perception of care providers)	Gap between customer expectation and employee perception
Reliability	3.77	3.99	-0.23
Responsiveness	4.03	3.99	0.15
Assurance	3.89	3.775	0.12
Empathy	3.99	3.8	0.24

Table 2 shows the gap analysis between patient expectation & employee perception of various service dimensions. The highest gap is observed for empathy dimension (0.24) followed by responsiveness (0.15) and

assurance (0.12). Positive gaps indicate where hospital should focus more and should make improvement on above dimensions of services so that gaps can be filled. In case of reliability (-0.23) is negative which shows customers are satisfied with what services are offered by the hospital to them.

Conclusion

Home Healthcare service is majorly provided to the patients who are in need of convenience or for patients who find difficulty in travelling all the way to the hospital for availing medical services.

The Home Healthcare service is a one of the best option for the patients because they have the trust of getting quality care from this hospital. It was revealed from the study that certain parameters score above 90% in satisfaction where as there are only few parameters where attention and focus needs to be given in order to enhance patient experience. It is important for the home healthcare service to provider to maintain the quality and safety of the services because the care is given outside the hospital setting. Hence, the home healthcare staff should follow a proper protocol so that the patient feel satisfied after receiving the services, a continuous improvement-training program is also necessary. There is a great need to increase the patient base hence proper implementation of strategies should be done to reach out to large number of patients. Home healthcare service is a necessity of today's world because of increasing geriatric population and chronic diseases with acute shortage of hospital beds, patients want alternative sources. Hence, Home Healthcare is the best option to consider catering to the healthcare needs of the population.

Recommendations

For quality improvement

- A proper protocol should be maintained so that uniform care is provided to all the patients.
- Home healthcare staff can be given refreshment training on patient safety protocol.
- Regular monitoring of most common systemic diseases like Diabetes, hypertension and thyroid problems.
- Phlebotomist should be certified and diploma holder with proper training.
- An Online Appointment Booking can be started to ease the appointment booking procedure and reduce the time required for booking the appointment on Call.
- Psychological counseling of geriatric patients should be done on regular basis by healthcare staff.
- Report Facility of sample collection service needs lot of attention. A system can be developed where a patient can track his/her report or patient can be informed via SMS or Call about the report when it is ready for delivery.
- A confirmation from patients can also be taken after the report is delivered to them.
- Training can be given to the staff regarding identifying the patient correctly using Name, Address or Contact Number.
- The patient's and test information barcodes can be stuck on the sample as soon as sample is collected from the patient as this will reduce the risk of misplacing sample or performance of wrong test and can give assurance to patient that the sample is labelled correctly.
- As per the patients' feedback, the cost of X-Ray service is expensive, hence it needs to be revised and competitive pricing can be done.
- Online Mode of payment can be introduce for home healthcare services offered.
- Each call has to be recorded by the Home Healthcare department to know exact calls being converted into successful appointment.

To reach out to more number of patients:

- Need to track the discharged patients from the IPD and patient need to be informed about the home healthcare service of the hospital.
- The Advertisements films can be shown on the television in the OPD/Visitors lounge areas.
- The Live Chat can be introduced on the website to clarify the doubts of the patient visiting the website, as this can also help to reach more number of patients.
- Need to prepare more informative website portal for Home Healthcare Service of the Hospital.

Myocardial Bridging and Coronary Artery Dominance: A Cadaveric Study

Mohandas G.V.[1], Shanta kumari B.[2], Sitansu ku.Panda[2]

[1]Department of Anatomy, Maharajas institute of Medical Sciences, Vizianagaram, [2]Department of Anatomy, IMS & SUM Hospital, Bhubaneswar, Odisha, India

Abstract

Background: In the left coronary artery dominant people the total left ventricle is purely supplied by left coronary artery. Left coronary dominant people has an poor prognosis in acute coronary syndrome when compared with the right coronary dominance. Left coronary dominant with myocardial bridged may be an additional risk to the coronary artery disease.

Objectives: To evaluate the incidence of myocardial bridging and cardiac dominance pattern in myocardial bridged hearts in cadavers.

Material and Method: As this is a cadaveric study 100 heart specimens were obtained from routine dissection conducted for undergraduate students in the department of Anatomy, Maharajas institute of medical sciences, Vizianagaram and department of Anatomy IMS & SUM Hospital Bhubaneswar. After simple dissecting procedure myocardial bridges and coronary dominance pattern were observed.

Results: Myocardial bridging was seen in 41(41%) specimen with major involvement of mid-segment of left anterior descending artery (LAD). Out of 41 myocardial bridged herats right coronary dominance is present in 35 (85.37%) hearts and left coronary dominance present in 6(14.63%) hearts.

Conclusion: The dominance pattern of heart had great role in coronary heart disease. The left dominant heart was found to have significantly higher mortality than the right dominant heart and mixed type. In addition to the left dominance if the single and multiple myocardial bridges are present over the epicardial coronary artery there may be increased frequency of myocardial ischemia.

Keywords: *Left anterior descendind artery (LAD), Myocardial bridging (MB) Coronary dominance.*

Introduction

A myocardial bridge exists when one of the coronary arteries tunnels through the myocardium rather than resting on the epicardium. Usually, the coronary arteries branch out from the ascending aorta and rest on the surface of the heart muscle and feed blood down into smaller vessels that populate throughout the myocardium. But if the muscle grows around one of the larger arteries, then a myocardial bridge is formed. During systole as the heart contracts, the muscle exerts pressure across the bridge and constricts these arteries. This is a congenital defect and may manifest with signs of angina.

Epicardial coronary arteries usually pass over the interventricular and atrioventricular grooves. Myocardial Bridge (MB) can be defined as a band of myocardium which crosses the coronary artery during its course[(1)] Due to the MB, a segment of the epicardial coronary artery lies deep to the myocardium during its course thus termed as tunnelled artery[(1)]. The myocardial bridge (MB) is an anatomical variant that is often seen on the left

e-mail: gvm.das@gmail.com

anterior descending coronary artery (LAD) and located commonly over the middle segment of the LAD[2]. Myocardial bridging usually has a benign character but in some cases is associated with myocardial ischemia, infarction, coronary spasm, arrhythmias and even sudden death has been reported.[3] Anomalous origin and distribution of the coronary arteries were shown to be a cause of sudden death in young and adult patients during exertion [3]. The word "Coronary Dominance" was coined to show which coronary artery supplies the heart's diaphragmatic surface, based on the origin of the posterior interventricular artery (PIVA). Origin of the PIVA from the right coronary artery(RCA) was termed 'right dominance'; from the circumflex artery was called 'left dominance'. Origin from both the RCA and the circumflex artery was known as balanced pattern.[4] Left dominance and balance type was associated with higher mortality due to acute infarction and a higher incidence of atherosclerosis[5]. MB was itself sometimes considered to be one of the risk factor for coronary artery diseases (CAD) and if MB is associated with left dominance then risk for CAD will be increased. So this study was undertaken to correlate coronary dominance in MB with CAD.

Materials and Method

The sample size used for this study is 100 heart specimens. The specimens of hearts used for this study were obtained from routine dissection conducted for undergraduate students from the Department of Anatomy Maharajas institute of medical sciences, Vizianagaram and Department of Anatomy, IMS & SUM Hospital Bhubaneswar. Institutional ethical committee clearance was taken. The hearts were preserved in 10% Formalin and dissected. Visceral pericardium and subepicardial fat were removed. A total of 41 myocardial bridged hearts were identified. The coronary arteries and its branches were carefully dissected and traced unto their termination. The PIVA running in the posterior interventricular sulcus was identified and reviewed along its course up to its termination and its origin and course was noted. Photographs were taken and data analyzed statistically.

Results

The present study was done on a total 100 heart specimens, out of which 41 had myocardial bridges. Majority of bridges were seen in mid segment of left anterior descending artery (LAD). Single myocardial bridge(MB) were present in 36 cadaveric hearts, double myocardial bridges were present in 4 cadaveric hearts and triple myocardial bridges were present in only one cadaveric heart. PIVA originated from RCA in 35 hearts and from left circumflex artery in 6 hearts. Right coronary dominance is present in 35 cases and left coronary dominance present in 6 cases. Balance type of coronary dominance was 0.

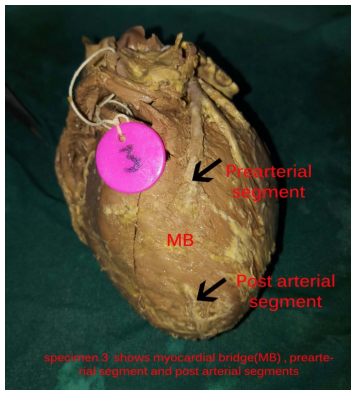

Figure 1: Specimen no. 3 showing the presence of myocardial bridge over the left anterior descending artery (LAD).

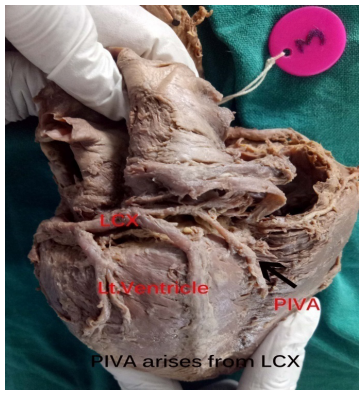

Figure 2: Showing the Posterior interventricular artery (PIVA) arise from the left circumflex artery (LCX).

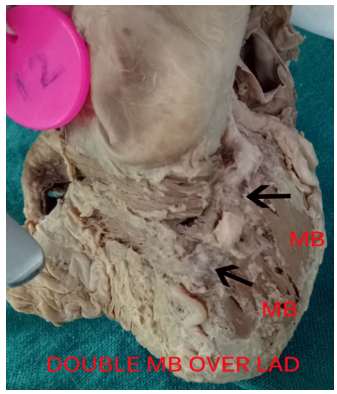

Figure 3: Showing the double myocardial bridge (MB) LAD = Left anterior descending artery

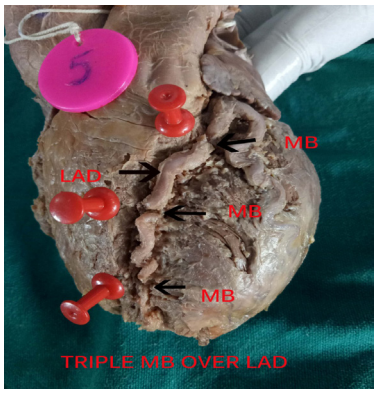

Figure 4: Showing the triple myocardial bridge (MB) LAD = Left anterior descending artery

Discussion

The dominance pattern of heart had great role in coronary heart disease. The left dominant heart was found to have significantly higher mortality than the right dominant heart and mixed type[6].It was found that left circumflex artery(LCX) length will be more and supplies the major part of myocardium in left dominant people but in right dominant people posterior intervententricular artery which is a branch of right coronary artery supplies only the diaphragmatic surface of the heart. So in lesions of LAD and LCX in left dominant people most of the myocardium will be damaged leading to heart failure.[7] It was found that in left dominance anterior wall, lateral wall and most of the diaphragmatic surface of the heart will be affected and in right dominance Sinuatrial (SA) node and Atrioventricular (AV) node. In inferior wall myocardial infarction the arterial supply to SA node and AV node will be cut off and so heart blocks can occur. [8]Myocardial bridge (MB) present in the heart causes compression of the epicardial coronary artery during systole and may be responsible for ischemia.[9]

The Right dominance, left dominance and codominant or balance type of classification was first introduced by Banchi in 1904.[10] Schlesinger described that if the right coronary artery runs beyond the crux point of the heart and projects its branches to the posterior wall of the left ventricle,there is always dominance of the right coronary artery. He classified as mixed type to only those cases where each ventricle is supplied with blood from the relevant artery, i.e. right from the right and left from the left. The dominance of the left coronary artery was appropriate only for those cases when the circumflex branch ran over the crux cordis, forming the posterior interventricular branch and supplying the entire posterior part of the ventricular septum.[11]

Autopsy and intravascular ultrasound studies have shown that the intramural and distal segments of bridged vessels remain free from atherosclerotic disease while the proximal segment of the vessel is prone to developing atherosclerosis.. Clearly, complex and dynamic biomechanical factors influence the blood flow within and at the exit of the bridge that in aggregate appear to attenuate the proatherosclerotic stimulus of low WSS observed distal to the bridge. These data suggest that both systolic and diastolic flow impairment contribute to myocardial supply-demand mismatch in patients with myocardial bridging.

Table 1: Distribution of origin of Posterior interventricular artery from RCA and LCA (n=41)

PIVA Origin	Number	Percentage
RCA	35	85.36%
LCA	6	14.64%
TOTAL	41	100.00%

Table 2: Dominance pattern compared with other studies

Author	Rt. dominnce (in%)	Lt. Dominance in (%)	Balanced in (%)
Harika Das (2010)	70%	18.57%	11.43%
Puli Darmender (2014)	83.11%	16.88%	0%
Caroline E.Veltman (2014)	86%	9%	5%
Jaisree H (2015)	83%	14.5%	2.5%
Madhushree Pal (2016)	70%	22%	8%
Present study	85.37%	14.63%	0%

Most of the authors have reported higher incidence of right dominance and even in the present study 85.37% of right dominance was observed. Balance type of dominance is 0% in present study which is similar to found by some authors [12]. The difference between the present study and tabulated authors is, in the present study dominance pattern was observed in the myocardial bridged hearts where as in other studies dominance pattern was observed in nonmyocardial bridged hearts.

Statistical analysis done by using Chi-square test to distribution of origin of posterior interventricular artery from RCA or LCA and distribution of hearts according to number of myocardial bridges (MB) over left anterior descending artery. p value is $p<0.0001$ and shows that right dominance is statistically significant followed by left dominance and balance pattern is insignificant in distribution.

Conclusion

In addition to the left dominance if the multiple myocardial bridges are present over the epicardial coronary artery there may be increased frequency of myocardial ischemia. Thus coronary artery disease proportion increases in presence of myocardial bridges.

Patients with myocardial bridging are commonly encountered clinically and may present with exertional symptoms of myocardial ischemia, syncope, and even sudden death. An array of noninvasive and invasive diagnostic modalities that have shed light on the pathophysiology of myocardial bridging can be deployed to evaluate symptomatic patients. Medical therapy with beta-blockers and calcium channel blockers remain the mainstay of treatment. For select patients refractory to intensified medical therapy, surgical intervention, or less preferably PCI with DES, can be considered. Larger registries and randomized clinical trials are warranted to shed light on optimal strategies for patients with myocardial bridging refractory to medical therapy.

Somatotype Characteristics of School Going Children with Visual Disabilities

Mohd Arshad Bari[1], Hussein Ali Hasan Alghazal[2], Haq Nawaz Mir[2] , Muzaffar Husain[2]

[1]Assistant Professor, [2]Research Scholars, Department of Physical Education, Aligarh Muslim University, Aligarh India

Abstract

Objectives: The main objective of this study was to describe the somatotype characteristics of school-going children with visual disabilities and to establish a somato profile chart for visually disabled children.

Method: A total of 25 (twenty-five) male school-going children with visual disabilities participated in this study. The ages of the participants were between 12-18 years. Selected 10 (Ten) anthropometrical dimension were examined to calculate somatotype characteristics of visually disabled persons: stretch stature, body mass, four skinfolds (triceps, subscapular, supraspinal, medial calf), two bone breadths (bi-epicondylar humerus and femur), and two limb girths (arm flexed and tensed, calf).[27] developed a computer program somatotype is used to calculate somatotypes.

Results: Results of the study shown that the range of the age of 12 to 18 years of the visually challenged persons were 80% ectomesomorphic. However, from the youngest to the oldest age group considered, the mean values of all the three components change gradually. Among the three components of somatotype (endomorphy, mesomorphy, and ectomorphy), mean values for mesomorphy dominate, while that of endomorphy remain lowest as mean values of mesomorphy 7.61 ± 1.73, ectomorphy 3.74 ± 1.80 and endomorphy 0.66 ± 0.20 respectively. On the whole, the visually disabled person physique could be described as showing a high musculoskeletal development with relatively least fat.

Keywords: *Somatotype, Morphology, Visual Challenged, Anthropometry, Visual Disability.*

Introduction

Somatometry is a fundamental scientific process of measurement of bodily size and proportions in living individuals in anthropology. They are used in different field of sports, physical education, health care, fitness industry, education, rehabilitation, industry, etc [4]. somatotype is usually used to expressed in three numbers-rating where each of them represents one of the three basic components endomorphy, mesomorphy, and ectomorphy of body composition [1]. Heath and Carter empirically define the body composition based on the percentage of fatness, musculoskeletal structure and the body linearity [7].

Assistant Professor, Department of Physical Education, Aligarh Muslim University, Aligarh, India-202002

The majority of the national or international studies reported that the physical growth and development significant influence with different endogenous and exogenous factors. The endogenous factors are gender, heredity and hormonal state, and gender, while exogenous factors are a lifestyle, disability, disease, diet, social and economic status and physical activity [9]. However, when talking about the visual disability of school-going children, we can see that studies were dealing with a visual disability, somatotype and physical activity, though rare and less include both endogenous and exogenous factors, especially physical activity. It was noted that the visual disability of children influences on motor abilities and function, including overall body functionality [5, 6].

The participation in physical activity of the visually disabled person are more restricted due to visual disabilities, have a lower level of physical fitness and have higher levels of obesity than their peers without

visual disabilities[3]. The fear of injury is one of the key reasons for visually challenged person lack of participation in physical activity. In active life style leads to different kind of bodily changes as compared with their peer without disability[2]. The main aim of the study is to find out the somatotype characteristics of the visually disabled person and compare with the peer without disabilities. This study also helps to understand the impact of visual disability on physical activity and body characteristics.

Methodology

Participants of the Study: This study mainly focused on somatotype characteristics of visually challenged school going children. Twenty Five (n-25) visually challenged school going children (male) without any multiple disabilities from Ahmadi School for the Visually Challenged, Aligarh Muslim University, Aligarh were selected as subjects of the study.

The ages of the participants were between 12-18 years. Each subject was somatotyped by the Heath-Carter Anthropometric Method[1].

Measurement Techniques: Selected Ten (n-10) anthropometrical dimension were selected to calculate somatotype characteristics of visual disabled person: body mass, stretch stature, four skinfolds (subscapular, medial calf, triceps, supraspinale), two bone breadths (femur and biepicondylarhumerus), and two limb girths (flexed arm and calf tens). Height was calculate with a standard stadiometer to nerest 0.1 mm. Body mass was measured using Actofit digital weighing machine. Skinfold variable were measured using a standard caliper. Three measurements were taken and intermediate score were recorded. Flex arm was a largest variable under maximum voluntary contraction and calf measurements were recorded by using non stretchable tape. The femur and humerus diameters were recorded with a Mitutoyo pachymeter [12].

Procedures to Prepare Somatochart: Developed a computer program SOMATOTYPE[27] (Computer Programs for Somatotype Analysis) was used to calculate somatotypes, descriptive and comparative statistics and plotting somatocharts (http://www.somatotype.org/2012).

Results

Analysis of Project Report on the Basis of Collected Data on Somatotype in Visually Disabled Persons.

Following table presents descriptive statistics of 10 anthropometric data were recorded for the assessment of anthropometric somatotype. Mean value of height was 162.96 cm (SD 7.56 cm) and of weight was 52.50 kg (SD 11.19 kg) respectively. Descriptive statistics of other skin folds, breadths and girths measurements are shown in Table 01.

Discussions

The present study was undertaken to report the somatotypes of visually disabled persons. One of the objectives of the study was to explore the changes with visual disabilities in mean somatotypes. It is clear from table No. 4 that the ranges of the age 12 to 18 years of the visual challenged person were 80% ecto-mesomorphic. However, from the youngest to the oldest age group considered, the mean values of all the three components change gradually. Among the three components of somatotype (endomorphy, mesomorphy, and ectomorphy), mean values for mesomorphy dominate, while that of endomorphy remain lowest as mean values of mesomorphy 7.61 ± 1.73, ectomorphy 3.74 ± 1.80 and endomorphy 0.66 ± 0.20 respectively. On the whole, the visually disabled person physique could be described as showing a high musculoskeletal development with relatively least fat.

Somatotype Categories: Twenty five (n-25) visually challenged persons were found to be distributed among 05 out of 13 somatotypes categories. The visually challenged person fall under endomorphic-mesomorph, balance mesomorph, ectomorphic-mesomorph, mesomorph-ectomorph and mesomorphic-ectomorph. However, at least 80% of the boys with visual disabilities fall under the category of ectomorphic-mesomorph, 08% fall under the category of balance mesomorph and 04% equally distributed under the category of endomorphic-mesomorph, mesomorph-ectomorph and mesomorphic-ectomorph.

Differences: In order to evaluate population similarities/differences, one of the objectives of the present study was to understand the present findings with other such studies. Therefore, the somatotypes of visually disabled persons were compared with boys of comparable ages from other populations of the Indian region. Majority of the studies were found to compare selected somatotype parameters with the same age group from North India. But no studies were found till date to compare selected somatotype parameter of the disabled person. Most of these studies have followed the Heath Carter method of somatotype which was most significant with our study. However, so many studies were compared in which few of the studies were reported present mean somatotypes at age groups similar to the present study (i.e., 12 to 18 years).

The comparisons of the present study with a normal population of Indian context helps us to understand the relationship of visual disability with somatotype. Visually challenged populations were highest on mesomorphy, lowest on ectomorphy, and very low on endomorphy in comparison with the normal population of North-India.

Visually challenged persons of the present study were closest to Tibetan (J & K) in endomorphy. Endomorphy rating of visually challenged person is significantly less as compared to the studies [16, 17, 18, 19, 20]. The present studies show that Mesomorphic and Ectomorphic rating of visually the disabled person was highest as compare with the normal population as reported previous studies i.e. [18, 20, 21, 22].

Carter divided somatochart into 13 various sectors [23]. According to sector division of visually disabled persons were placed in ectomorphic-mesomorph 80% of the total population, 08% of balance mesomorph, endomorphic-mesomorph, mesomorph-ectomorph and mesomorph-ectomorph 04% respectively. Ectomorphic-mesomorph sector along significant high with Tibetan, Bodh, and Baltis of Jammu and Kashmir, and GaddiRaj put of Himachal Pradesh but by visually disabled persons show a somatotype (balanced mesomorph 08% of the total population) which was quite different from that of the other populations compared.

Studies were reported change in component dominance during adolescence [24, 25]. Tanner had reported that there were not many changes in somatotype ratings during the course of growth of normal population [11]. Almost all studies show some change in the component ratings as the children. From the comparisons presented above it becomes clear that though at the ages 12 the somatotype of visually challenged person may have some similarity to the somatotypes of some other populations, but by the age of 18 years the visually challenged show a somatotype (balanced mesomorph) which was quite different from that of the other populations compared.

One of the aims of the present study was to make some suggestions in the light of the findings of the present study.-In an earlier study [26] it was suggested that one of the major applications of somatotype is to explore changes with disability in the physique. The findings of the present study reveal that on the whole visually disabled person ecto-mesomorphic higher in rating, though average values of all the three components register changes with disability. Among the three components, mesomorphy dominates, while endomorphy was at the lowest. In other words, the physique of visually disabled persons may be described as showing a high musculoskeletal development with relatively less fat. The present study of somatotypes shows a tendency to move away from the upper axis of endomorphy towards the upper axis of mesomorphy. Considering the total sample of 25 visual disabled persons, a majority (88%) fall in two categories, i.e., ectomorphic-mesomorph and balanced mesomorph.

The Effects of Exercise on the Sympathovagal Regulation of Heart and Functional Capacity in Patients Following Coronary Artery Bypass Grafting

N. Venkatesh[1], T. Senthil Kumar[2], R. Yogeswari[3], S. Sridevi[2]

[1]Professor and Course chairman, [2]Assistant Professor, [3]Tutor, Faculty of Physiotherapy, Sri Ramachandra Institute of Higher Education and Research (Deemed to be University), Porur, Chennai, Tamil Nadu, India

Abstract

The autonomic dysfunction of heart and persistent tachycardiais seen with reduced functional capacity following surgical revascularization. Evidence on the role of exercise training is limited in sympathovagal dysfunctions. This Randomized controlled trail included stable post coronary bypass surgery patients in control (13) and study group (12). The study group received thrice/week training for 12 weeks after discharge and the control group received a routine care. The R-R Interval Variabilityand the functional capacity (6-minute walk test)assessed before and after 12 weeks of the training. The study group had increase in functional capacity and a positive correlation between the RRIV analysis and functional capacity after training ($p<0.05$).Phase II exercise training after coronary bypass surgery had a significant improvement of the functional capacity. There was a significant positive correlation between R-R interval variability and the functional capacity in the training group.

Keywords: *R-R Interval, CABG, functional capacity, heart regulation.*

Introduction

Coronary Artery disease (CAD) is one of the leading causes of non-communicable disease increasing mortality in India. The Indian prevalence of Coronary Artery disease is about 7-13% in urban and 2-7% in rural population and is on increase.[1] Coronary Artery Bypass Grafting (CABG) have become the standard and reliable method of management for CAD. Imbalance in the autonomic function is seen after the CABG especially after the sixth day of CABG and is expected to be restored at the 3rd month after surgery.[2,3] The autonomic dysfunction happening after CABG could increase the risk of ventricular arrhythmias and sudden cardiac death results. The autonomic dysfunction also would cause early attainment of maximal heart rate which reduces the exercise capacity of the patient, thus delaying the recovery time and also result in premature functional capacity ceiling. The phase-II Cardiac Rehabilitation exercise training program results in an increase in R-R interval due to improvement in the parasympathetic/vagal dominance. This improvement in the parasympathetic dominance could cause reduction in the mortality rate and can also improve the functional capacity of the patients following phase II cardiac rehab. Hence individualised supervised exercise training is recommended for all the patients who undergo CABG surgery. It has been proved that there is improvement in maximum oxygen consumption, maximal heart rate and the resting heart rate following supervised exercise training.[4-8] The research finding on such analysis in Indian subset is sparsely available. Owing to differences in the exercise participation rate, socio-cultural variations and rehabilitation facilities and attributes in India, it's worth exploring the utility of autonomic function effects on functional capacity analysis in Indian population before generalising the other study results to this population.

Methodology: This study was conducted in a multi-specialty hospital after getting clearance from the Institutional Ethical Committee (IEC No. CSP/13/MAR/27/59). This is a Randomized control trail design with sample size estimated to be 25 based on the power analysis with 80% power at 95% Confidence Interval. Assuming attrition rate of 25-30% for this study the sample size was estimated to be 40. The sampling design was restricted randomized sampling method. The patients at low risk as per American Heart Association (AHA) guidelines and patients without any neurological impairment or musculoskeletal diseases or injury affecting the mobility and patients with uncomplicated clinical course during hospitalization were included for the study. The patients with moderate and high risk as per AHA guidelines, uncontrolled arrhythmias, post-cardiac arrest survivor, recent Myocardial Infarction, co-existing pulmonary disease were excluded for the study. In this study 66 patients who had undergone CABG were screened, 40 were randomly assigned to control and experimental group. 25 patients were analysed for the study. Patients in both the groups were subjected to low level exercise testing i.e. 6MWT prior to and after 12 weeks of discharge. The supervised group exercise training in the physiotherapy department thrice a week for about 12 weeks was done.

Exercise Training protocol: The exercise training for both the groups includes the warm-up, training session and cool-down period. The warm up session included the breathing exercises, active movement to the limbs and the large group muscle flexibility. The training session was advised twice a day lasted for 20-30 minutes each with warm up and cool down for about 5-10 min each and training session for about 20 minutes. The training session included the strength and endurance training in alternative days, and walking session. The strength training was given based on one repetition maximum and the progression was done based on their exercise tolerance. The walking was done twice a day as tolerated by the patient without any symptoms.

Control group (Unsupervised training group): Patients were counselled regarding exercises and to be done in a self-paced manner with telephonic reviews and guidance once a week for 3 months. Experimental group (Supervised training group): The patients in this group attended a low intensity phase II cardiac rehabilitation program training session thrice a week for about 12 weeks. The exercise training includes the following. Before starting the exercise session patients were checked for their vitals i.e. heart rate and saturation using the pulse oximetry, Pulse rate, and respiratory rate. Then warm up exercises were given for about 10 min, exercise session of about 20 min and cool down for about 10 min. After the exercise session again the patient was monitored for their heart rate and saturation using pulse oximetry and pulse rate and respiratory rate. If the exercise response is satisfactory they were instructed to continue the same exercise in the home for 1 week. If they had any doubts regarding the exercise they were cleared through telephone conversation or by face to face clarification. Progression in the intensity and duration of exercise was done based on the patient's response to the exercise tolerance. The R-R Interval Variability was assessed by using the NIHON KOHDEN-NCS/EMG/EP equipment, by an independent assessor who was blinded to the study details, after three months for all the patients. The interpretation is taken up for the statistical analysis. The statistical analysis was performed using the SPSS version 15.1. The normally distributed data were expressed as mean and standard deviation. The Kendal taub test was used to analysis the relation with the R-R interval variation (RRIV) dysfunction and RRIV normal with that of the SMWD. The paired t-test was used to find out the difference between the control and the experimental group.

Results

Totally 66 subjects were screened for the study, out of which 49 were selected, 9 patients were not willing for the study and other 40 were randomly assigned in to control and experimental group. In the control group 1 was expired, 5 did not turn for follow up and 2 patients migrated to other place. In the experimental group 1 was expired, 3 did not turn for follow up 2 patients had travelling problem and 1 had migrated to other place. Other 25 patients were analysed for the study. Both the groups were received the education about the secondary prevention measures based on their condition. The baseline characteristics are expressed in table 1. The age, BMI and sex distribution are more similar and not of much difference. The present study results shows that there is no relation of the RRIV analysis function with the SMWD ($p>0.05$). The results shows that the pre mean values of both the control and the experimental group (212.91 ± 63.85, 201.15 ± 73.20) respectively has increased at the end of the training session (416 ± 49.78, 490 ± 50.62) but the experimental group had statistically significant increase in the post SMWD following training ($p<0.00$). The study also shows that there is significant

correlation between the RRIV analysis measurements and functional capacity after post 5 min, and post 10 min in the Post SMWD ($p<0.05$).

Table 1: Characteristics of the sample

Baseline Characteristics	Study Group	Control Group
Male, Female (%)	92,8	92, 8
Age (Years)	59.46 ± 5.58	57.5 ± 4.81
Body Mass Index (Kg/m^2)	24.86 ± 3.32	23.79 ±3.54
Hypertension (%)	23	41
Diabetes (%)	61.5	50
Heart Rate Variability (%)	15.3	33
Smoking Status (%)	38	41

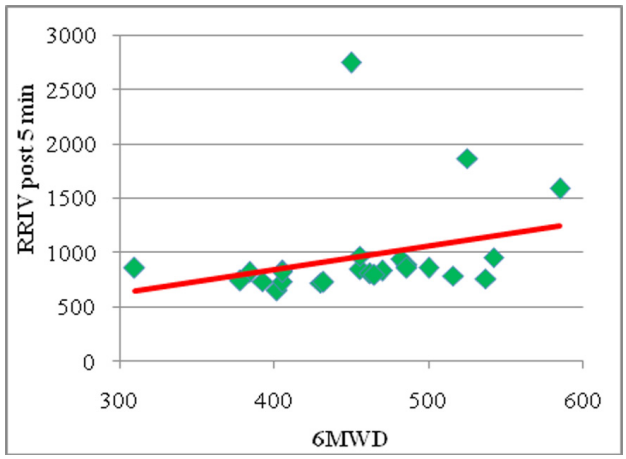

Figure2: Correlation of SMWD and RRIV parameters

Discussion

This study results shows that there is autonomic dysfunction with both the training group after the training session. Following CABG immediately there is autonomic dysfunction of the heart[3,4] with further recovery after 2 months. In this study while comparing

within 2 groups the dysfunction is more in the control group than the study group. These effects could be due to the supervised training. The same has been replicated in the previous studies.[5,6,10,11] They have concluded that Phase II CR exercise training has a significant improvement in the autonomic activity of the heart. The autonomic activity of the heart acts as the independent predictor for the mortality,[12] also increase in the sympathetic activity of the heart can cause early attainment of the target heart rate, thus it reduces the functional capacity of the subject. Following exercise training improvement in the autonomic activity can improve the functional capacity.[9]

This study shows that there is improvement in the SMWD for both the groups but the supervised training group showed a statistically significant improvement compared to the control group. Another study also had showed in his study that there is a significant change in the haemodynamic parameters that has caused improvement in the functional capacity for the experimental group.[8] Also, other studies,[4,10] have concluded that following supervised exercise training there is significant improvement in the Vo2 max. Previous studyhas concluded that following exercise training there is significant increase in the 6MWD for the women population.[13]But one Indian study has showed that the unsupervised exercise training with regular follow up has shown increase in the 6MWD for both the rural and urban population.[14]This study shows that there is relationship between the autonomic function and the functional capacity. The same has been concluded in previous study that the Heart Rate Variability (HRV) is independent of 6MWD and peak Vo2 max.[11]This study also reveals that there is significant correlation with the SMWD and RRIV parameters at post 5 and 10 minutes ($p<0.05$). This study suggests that the supervised exercise training has shown to be more effective in improving the autonomic activity and the functional capacity following CABG. Thus supervised exercise training can be advised for the patients following CABG and thus improve their hemodynamic status and functional status.

Conclusion

This study concludes that there is significant improvement of the functional capacity in the experimental group than the control group. Also there is significant positive correlation between R-R interval variability and the functional capacity in the training groups.

Assessing the Awareness of Anti-Tobacco Laws among Adults in Chennai-Need for Strengthening Legal Actions

Naziya K. Babu[1], Meignana Arumugham Indiran[2], Pradeep Kumar Rathinavelu[3], Sakthi Doraikannan[3]

[1]Post Graduation, [2]Professor, Department of Public Health Dentistry, [3]Reader, Department of Public Health Dentistry, Saveetha Dental College, Saveetha Institute of Medical and Technical Sciences

Abstract

Introduction: Tobacco use is a serious public health challenge in several regions of the world. Current trends show that more than 8 million deaths will be associated with tobacco use worldwide by 2030. According to the world health organization (WHO), tobacco is the single greatest cause of preventable death globally.

Aim and objective: To assess the awareness and attitudes towards tobacco control measures developed by COTPA.

Materials and method: The cross-sectional study was designed to assess the awareness and attitudes towards tobacco control measures developed by COTPA.. Following convenience sampling, equal representations from all 4 zones were taken. Questionnaires were distributed to the individuals and data was collected. Data was analyzed using SPSS software (Version 20.0).

Results: There is association between awareness, age and education. As the age increases the awareness about anti-tobacco laws also increase. As the education increase the awareness about anti-tobacco laws also increase. There is no significance between gender and awareness.

Conclusion: In this community based study to see the awareness and attitude towards COTPA, good awareness was reported by 44% and positive attitude by 92% of the population.

Keywords: *Tobacco, oral cancer, anti-tobacco law, COTPA, FCTC.*

Introduction

Tobacco use is a serious public health challenge in several regions of the world. According to the 2008 World Health organization report on the global tobacco epidemic, currently 1.3 billion persons use tobacco in the world out of which 5.4 million people die every year[1].

According to Global Adult Tobacco Survey, 34.6% adults of which 47.9% males and 20.3% of females use some form of tobacco in India. Among 13-15 year old school-going children, the current use of any tobacco product varies from 3.3% in Goa to 62.8% in Nagaland[2].

Among minors (age 15-17), 9.6% consumed tobacco in some form and most of them were able to purchase tobacco products. About five in ten adults (52.5%) were exposed to second-hand smoke at home and 29% at public places (mainly in public transport and restaurants). Three in five current tobacco users (61.1%) noticed the health warning on tobacco packages and one in three current tobacco users (31.5%) thought of quitting tobacco because of the warning label[3].

In India, more than 40 percent of cancer cases are due to tobacco use. Tobacco contains more than 2500 chemical constituents, many of which are known human carcinogens, of which at least 250 chemicals known to be toxic or carcinogenic[4]. World is heading towards various types of non communicable diseases, which are

also known as modern epidemics. Among these modern epidemics cancer is the second commonest cause of mortality in developed countries[5] A serious need was felt for framing a comprehensive national legislation on tobacco control, which would ensure uniform and effective enforcement of measures to achieve desired results.

The relationship between oral cancer and tobacco can be assessed from the WHO estimates according to which 91 percent of oral cancers in South-East Asia are directly attributable to the use of tobacco[6]. India has been a forerunner in the fight against the tobacco epidemic. In order to curb this epidemic, India has enacted comprehensive tobacco control legislation.

The Framework convention on Tobacco control (FCTC) is the first international treaty negotiated under the auspices of the WHO aimed at curbing tobacco related deaths and diseases. The WHO FCTC, a multilateral treaty with more than 150 parties, was the first step in the global fight against the tobacco epidemic[7].

Large amount of information was provided by the report on tobacco control in India by Reddy KS and Gupta PC on behalf of Ministry of Health and Family Welfare, Government of India[8]. Accordingly, the tobacco control act, 2003 was introduced. As an impact of the act, public smoking is banned by legislation.

There is an immediate need to curb this much publicized evil of our society[9]. In India, the extent of public support and public opinion on COTPA remains largely unknown. No study has been done in Tamil nadu to see the awareness and attitude of the people toward the act. From the public perspective, such information may be of great importance with respect to understanding the degree to which public support and opinion may have on the successful implementation of the tobacco control policies and legislation.

Therefore, this study is designed to gather baseline information from the adult population of Chennai, Tamil nadu about awareness and attitudes towards four key tobacco control measures developed by COTPA.

Aim:

- To assess the awareness and attitudes towards tobacco control measures developed by COTPA.

Objectives:

- To assess the knowledge of adult population of Chennai city towards Cigarette and Other Tobacco Products Act (COTPA).
- To assess the attitude of adult population of Chennai city towards Cigarette and Other Tobacco Products Act (COTPA).

Materials and Method

The cross-sectional study was designed to assess the awareness and attitudes towards tobacco control measures developed by COTPA. The study population consisted of selected individuals of 18 years and above under the juridisction of Chennai corporation.

Inclusion Criteria: Individuals of 18 years and above and willing to participate.

Exclusion Criteria:

- Individuals who were below 18 years.
- Individuals who were not willing to participate.

Prior to the start of the study, ethical clearance was obtained from the Institutional Ethics Committee, Saveetha University.Data collection was scheduled for the period of September 2017 to October 2017.

Sample Size: N=201(95%power @5%alpha based on a study done by Indrani Sharma et al10 in 2010)

The city of Chennai has been divided into 4 zones namely North, South, Central and West zone. Following convenience sampling, equal representations from all 4 zones were taken.During the research period, all the individuals of 18 years and above were eligible for the study. Following convenience sampling, samples were selected. Data was collected during interview by using a data collection form.

A pre-tested structured and self administered questionnaire was adapted from the questionnaires used previously by Indrani Sharma et al[10]. After a brief introduction on the purpose and intent of the study with the help of information sheet, questionnaires were distributed to the individuals and data was collected. Data was entered in Microsoft Excel spreadsheet and analyzed using SPSS software (Version 20.0).

Results

Table 1: Socio-demographic characteristics of the sample population

Variable	Frequency (%) N=201
Gender	
Male Female	135(65.5) 66 (32)
Education	
<=10 years of schooling >10 years of schooling	65 (34) 136(66)
Occupation	
Currently Not Employed Currently Employed	43(20.9) 153(79.1)
Marital status	
Currently married Single	133 (64.6) 68 (33.4)
SES (Rs)	
<=6221 6222-19465 >19465	82(40.8) 102 (51.0) 17 (8.2)

Table 1 shows the Socio-demographic characteristics of the sample population. About 65.5% of the population were males and 32% were females respectively. About 34% had less than 10 years of schooling and about 79.1% were currently employed. About 40.8% were of low socio-economic status and only about 8% were of high socio-economic status.

Table 2: Tobacco use practices among the Sample population

	Negative Attitude* (%)	Positive Attitude* (%)	Total N=201	χ^2 P-value
Awareness of the Act				
Poor awareness*	13 (6.5)	101(50.2)	114	< 0.015
Good awareness*	2 (1)	85(42.3)	87	

Table 2 shows the Tobacco use practices among the Sample population.. Only about 27.2 were current users of tobacco. About 19.9% use smoke type of tobacco and about 25.7% have family members used to tobacco.

Table 3: Association of awareness of COTPA with the attitude towards COTPA.

Variables	Frequency (%)
Current Use	
Yes	56(27.2)
No	145(70.4)
Type of tobacco	
Smoke	41 (19.9)
Smokeless	11 (5.3)
Anyone in family use tobacco	
Yes	53(25.7)
No	148(74.3)

*Chi-square test. Significance p<0.05

Table 3 shows the Association of awareness of COTPA with the attitude towards COTPA. It shows that the awareness and attitude were significant. As the awareness about anti-tobacco laws increases, the attitude towards it also increase

Table 4: Association of socio-demographic factors with Awareness of COTPA

Poor Awareness (%)		Good Awareness (%)	Total	χ^2 P-value
Age (N=201)				
18-35 years	97 (48.3)	64(31.8)	161	0.001
36-50 years	0	29 (14.4)	29	
50+ years	0	11 (5.5)	11	
Education				
<=10 Years of schooling	65(32.3)	32(15.9)	65	0.000
>10 Years of schooling	0	104(51.7)	136	
Gender				
Female	36(48.3)	30(14.9)	66	0.212
Male	61(30.3)	74(36.8)	135	

* Chi-square test. Significance p<0.05

Table 4 shows the Association of socio-demographic factors with Awareness of COTPA. It shows that there is association between awareness, age and education. As the age increases the awareness about anti-tobacco laws also increase. As the education increase the awareness about anti-tobacco laws also increase. There is no significance between gender and awareness.

Table 5: Association of socio-demographic factors with attitude towards COTPA.

Poor Attitude (%)		Good Attitude (%)	Total	χ^2 P-value
Age (N=201)				
18-35 years	8 (4)	153(76.1))	161	0.026
36-50 years	5(2.5)	24(11.9)	29	
50+ years	2(1)	19(4.5)	11	
Education				
<=10 years of schooling	15(7.5)	0	15	**0.000**
>10 years of schooling	50(24.9)	136(67.7)	186	
Gender				
Female	3(1.5)	63(31.3)	66	0.211
Male	12(6)	123(61.2)	135	

*Chi-square test. Significance p<0.05

Table 5 shows the Association of socio-demographic factors with attitude towards COTPA. As the age increases the attitude about anti-tobacco laws also increase. As the education increase the attitude about anti-tobacco laws also increases. There is no statistical difference between gender.

Discussion

Cigarettes and Other Tobacco Products Act (COTPA) intended to protect and improve public health, encompasses various measures to reduce tobacco consumption. Less awareness and negative attitude towards the Act may lead to non implementation or poor implementation of the Act which will result in increase tobacco use in the population. Oral cancer is one of the serious and growing health problems worldwide[11].This is a matter of great public concern.

In this study almost everyone 84 percent was aware that tobacco causes health problem unlike the study in Kolkata where 20 percent of the cases and control had no idea about the adverse effects of tobacco use[12]. This is a positive aspect because if people are aware of the health problems caused by tobacco with a little more effort to implement the Act, we can expect the population to accept the Act and support it.

The awareness on harm caused by second hand smoke was quite high (79 percent) which was contrary to other studies done in Wellington and Sydney[13,14], but is comparable to a study in China where half of the Chinese urban smokers and 4 in 5 non-smokers believed that second-hand smoke (SHS) is harmful[15]. Steps should be taken to encourage the vast majority of non smokers, to recognize their right to life and health.

About 84% of the population was aware of any tobacco control law in India contrary to the study in Kerala and Azerbaijan where most respondents had low levels of awareness about existing national tobacco control laws and the FCTC[16]. In this study there was good awareness about ban on smoking in public places and specified health warnings on all tobacco products. This may be due to the recent enforcement of both the provisions of the Act. Chandigarh is the first city in Southeast Asia and India to be declared as a smoke free city from 15th July 2007.This was possible because the law was strictly enforced following all the norms and the Government as well as the enforcement officials in Chandigarh considered tobacco to be a very serious issue[17].

People in the study were not much aware about the ban on sale to minors and prohibiting sale of tobacco within 100 yards of educational institutions. All the enforcement officials including the staff of the school should be empowered to take actions against violations[18,19]. In this study about 60.7 percent of the population was aware of the ban on advertisement of tobacco products. Cigarette companies have developed sophisticated campaigns targeting men, women, and children in different socioeconomic groups. Understanding these marketing strategies is critical to minimise the exploitation of loopholes in tobacco control legislation[20]. As age increases the attitude towards COTPA increases significantly. This could be because the elderly people do not want the younger generation to become addicted to tobacco. Smokeless tobacco proved to be highly associated with oral cancer[21,22]. They must have seen and experienced the harmful effects of tobacco and thus they don't want the younger generation to suffer. As education improves the attitude towards COTPA also improves similar to the study in China[23].

As age increases the good awareness of COTPA increases significantly. This may be due to the exposure of the older people to anti tobacco advertisements on television or radio. Most of the older people in this study were retired, so they stay at home and they pass their time by watching television or listening to the radio. Anti tobacco messages are delivered in those medias. Education campaigns are needed to raise public awareness about oral cancer and its links with tobacco

and alcohol consumption[24], This could be one reason why the awareness is high among them.

Conclusion

In this community based study to see the awareness and attitude towards COTPA, good awareness was reported by 44% and positive attitude by 92% of the population. Efforts should be made to increase the awareness about the Act focussing on younger population, less educated, and those belonging to the low Socio-economic status. Educational campaigns should also focus on effects of second hand smoke.

Understanding the population's attitudes and behaviours before implementing policies that will affect them will likely increase their effectiveness. Violations should be reported to the concerned authorities and followed up to check for the actions taken. All the enforcement officials should be notified about the law and they should be empowered to take actions. Proper training should be provided to the enforcement officials.

Ethical Clearance: Taken from Saveetha institutional committee.

Personal Mastery Model on the Ability to Self Care in the Primary Hypertension

Abdillah Fatkhul Wahab[1], Nursalam[1], Oedojo Soedirham[1], Noer Saudah[2]

[1]Faculty of Public Health, Postgraduate of Airlangga University, [2]Department of Nursing Bina Sehat PPNI Institute of Health Science, India

Abstract

Elderly was someone who has reached 60 years and over. One of the factors that affect the physical condition of the elderly is the cardiovascular problem that most suffered by the elderly. As a result of the aging process the blood vessels become stiff and cause the left ventricular wall to decrease its elasticity, resulting in a progressive increase in pressure progressively. Increased peripheral vascular resistance due to vasoconstriction or constriction of blood vessels is a factor in the occurrence of hypertension. Physically someone who has entered the old age all the function of the organs will decrease, so it will affect the daily activities of the elderly. A person who enters the elderly and suffers from hypertension will experience a decrease in physical function so that it will disturb the elderly in meeting their daily needs (Activity Daily Living). The purpose of this research was to develop the elderly Personal Mastery approach model on the ability of elderly self care with primary hypertension. This type of research uses a cross sectional approach. This research was conducted in community health center of Jember Regency in 2017. This research uses rule of thumb, so it needs sample of 100-155 respondents or 5-10 times indicators (observed variables) in the model used is 150 elderly. Instrument collected data with questioner. Analized data used PLS.The result of this research showed that elderly factor, nurse factor, family factor, Integrated Coaching Post service factor, personal mastery, self efficacy, self care agency have an effect on the improvement of self-care ability in Elderly with Primary Hypertension.

Keywords: *Personal Mastery, Self Care, Ability, Elderly.*

Introduction

Aging according to Law No. 13 of 1998 is someone who has reached 60 years and over. In 2050 it is predicted that the elderly will amount to 434 million people. Data from the Central Bureau of Statistics shows that the elderly population in Indonesia in 2000 was 14,439,967 (7.18%), in 2010 it increased to 23,992,553 people (9.77%). Physically someone who has entered the old age all the function of the organs will decrease, so it will affect the daily activities of the elderly [1]. One of the factors that affect the physical condition of the elderly is the cardiovascular problem that most suffered by the elderly. As a result of the aging process the blood vessels become stiff and cause the left ventricular wall to decrease its elasticity, resulting in a progressive increase in pressure progressively[2]. Increased peripheral vascular resistance due to vasoconstriction or constriction of blood vessels is a factor in the occurrence of hypertension. A person who enters the elderly and suffers from hypertension will experience a decrease in physical function so that it will disturb the elderly in meeting their daily needs (Activity Daily Living) [3]. The problem that arises in the elderly with hypertension is a discrepancy between expectations and reality, namely the physical condition that occurs due to weakness due to hypertension[4]. Then the elderly are required to choose between healed or still suffering from hypertension. Hypertension in the elderly tends to increase at the age of 55-64 years reaching 45.9%, aged 65-74 years reaching 57.6% and in the age group > 75 years reaching 63.8%[5].

Indonesia ranks fourth in the world with 24 million elderly people at 4.24%. Jember Regency was ranked 2nd with the highest number of elderly population at 308,792, after Malang Regency was ranked first. In the theory of Personal Mastery emphasizes how the elderly continue to strive in improving the quality of health by way of determining personal vision, self-awareness, empathy and communication. So that the elderly can improve the Self Efficacy they have that aims to fulfill Activity Daily Living (ADL) with the help of the Self-Care Agency owned by the elderly[6].

Method

The type of this research approach is cross sectional. The first stage in this study collected data about the factors of elderly, nurse factors, family factors, Integrated Counseling Post service factor, interpersonal factor elderly and self-care fulfillment in elderly primary hypertension. This research was conducted at community health center of Jember Regency 2017. This research uses rule of thumb, so that the number of samples at least 100-155 respondents or 5-10 times indicators (observed variables) in the model used is 150 elderly. Results from the analysis using PLS which is a variance-based Structural Equation Analysis. Simultaneously this method can do model testing. Structural model testing in PLS is done with the help of Smart PLS software version 2 for windows.

Results

Table 1: Hypothesis Test on the Model

No	Influence	Koef Orginal	(Bootstrap n = 1000)			Information
			Koef.	T Statistik	T Table	
1	Factors of the elderly → Personal Mastery	0,001	-0,001	1.367	1,96	Not significant
2	Nurse factor → Personal Mastery	0,023	0,016	1,416	1,96	Not significant
3	Family factor → Personal Mastery	0,244	0,309	4,087	1,96	Significant
4	Integrated post coaching service factor → Personal Mastery	0,426	0,373	3,804	1,96	Significant
5	Personal Mastery →Self care agency	0,103	0,126	4.267	1,96	Significant
6	Personal Mastery → Self efficacy	0,512	0,511	1,583	1,96	Significant
7	Self Efficacy → Self care agency	0,372	0,364	5,643	1,96	Significant
8	Self care agency → Self care activity daily living	0,316	0,312	5,096	1,96	Significant

After to do validity and reliability tests on all valid and reliable latent variables, the bootstrap sample test B = 1000 gives significant results, then continued in the model analysis with the diagram form presented as follows on table 1 shows that:

1. Factors of the elderly have no effect on personal mastery. This can be seen from the value of Statistics T of 1.241 which is smaller than T-table = 1.96. There is no relationship between elderly and personal mastery.
2. The nurse factor does not affect the personal mastery. This can be seen from the Statistics T value of 0.989 which is smaller than T-table = 1.96. The nurse factor has nothing to do with the personal mastery. This means that the nurse factor does not significantly influence the personal mastery
3. Family factors have a significant and significant influence on Personal mastery. This can be seen from the path coefficient that has a positive sign of 0.244 with a statistical value of T of 3.290 which is greater than T-table = 1.96. Family factors directly affect the personal mastery of 3,290, which means that any increase in family factors will increase personal mastery of 3,290. This means that family factors significantly influence the personal mastery.
4. Integrated coaching post service factors have a significant and significant personal mastery. This can be seen from the path coefficient which is positively marked by 0.426 with a statistical value of T of 9.078 which is greater than the T-table = 1.96. Integrated Coaching Post service factor directly affects the personal mastery of 0.426, which means that if there is an increase in the Integrated Coaching Post service factor, it will increase the personal mastery by 0.426. This means that the Integrated Coaching Post service factor significantly influence the personal mastery.

5. Elderly factors have an effect on and significance to self efficacy. This can be seen from the path coefficient which is positively marked by 0.041 with the value of Statistics T of 2.026 which is greater than T-table = 1.96. There is a relationship between elderly factors and self efficacy.

6. Factor nurses have an effect on and significance to self efficacy. This can be seen from the value of Statistic T of 5,519 which is bigger than T-table = 1.96. The nurse factor is not related to personal mastery. This means that the nurse factor has a significant effect on self efficacy.

7. Positive and significant family factors for self efficacy. It can be seen from the coefficient of positive sign of 0,512 with the value of Statistic T equal to 5,839 which is bigger than T-table = 1,96. Family factors are effective on self efficacy of 0.512, which means that there is an increase in family factors, it will increase self efficacy by 0.512. That is, the factors of significance to self efficacy.

8. Positive counseling postal service factor and significant self efficacy. This is evident from the coefficient of the path marked positive by 0.372 with the value of Statistics T of 5.845 is greater than T-table = 1.98. Integrated counseling service post directly on self efficacy of 0.372, which means there are some integrated coaching post service factor then it will raise the self efficacy of 0.372. Factors that positively affect self efficacy.

9. Self efficacy, positive and significant towards personal mastery. This is evident from the coefficient of the path marked positive by 0.363 with the value of Statistic T of 3.371 is greater than T-table = 1.98. Direct self efficacy on personal mastery is 0.316 which means that every self efficacy will increase personal mastery by 0.316. This means that self efficacy has a significant effect on personal mastery.

10. Personal mastery has a positive and significant effect on daily self-care activities. This can be seen from the path coefficient which is positively marked by 0.803 with the value of Statistics T of 5.576 which is greater than T-table = 1.98. Personal mastery directly on the daily self-care activities of 0.803, which means any increase in personal mastery will increase the daily self-care activities by 0.803. This means that personal mastery significantly influence the ability of self-care fulfillment.

Discussion

Model simulation is done in an effort to solve problems by providing intervention in the form of knowledge in the form of counseling and group discussion involving elderly and family as well as health workers. When elderly difficult to meet the needs of self care then the action to be done is with the level of elderly personal mastery and self-afficacy that will increase the ability of elderly to do self care agency to meet the self care activity daily living[7].

Nursing care for the elderly with a personal mastery and self afficacy approach helps the elderly in fulfilling self care activity daily living which includes food diet, stress coping and activities. Elderly with high personal mastery will be easier to do self care. Elderly and family will be assisted with a structured module that aims to make the elderly know and understand the importance of improving personal mastery 8. And in the module there are also materials that can be a guide in maintaining the self care activity daily living. In addition, health workers will continue to work so that the elderly continue to be actively present in integrated coaching post activities, because Integrated Coaching Post is one of the means to do positive activities and control blood pressure routinely. Hypertension is one of the blood vessel disease, known as Silent Killer, because it often does not cause symptoms. The majority of hypertensive patients in Indonesia are not detected, generally unaware of the condition of the disease and only a small proportion are treated regularly 9. By 2025 around 29% of adults worldwide will suffer from hypertension. Cardiovascular disease ranks 4th or 15% of causes of death[10]. Therefore need serious attention to reduce the number of elderly hypertension. The theory explains that the occurrence of hypertension is caused by several factors that influence each other, where the main factors that play a role in pathophysiology are genetic factors and at least three environmental factors, namely salt intake, stress, and obesity[11]. In general, people with hypertension are people-people aged over 40 years, but currently does not close the possibility suffered by young people. Most primary hypertension occurs at the age of 25-45 years and only in 20% occurs below the age of 20 years and over 50 years.

The result of this study is that the variable self-care agency has a positive effect on self care activity daily living. Although the activity indicator is still in the less category. But the whole contains significant value. The

ability of the elderly to do self care is shown by the ability of the elderly to maintain and choose good for the body, the elderly are also able to control emotions when there are problems, and the elderly are able to do light activities that are very beneficial for the body and keep blood pressure stable. Therefore, modules that have been prepared can be used in implementing nursing care, so the target of nursing care is easy to reach

Findings: Integrated Coaching Post service factor, personal mastery, self efficacy, self care agency have an effect on the improvement of self-care ability in Elderly with Primary Hypertension.

Conclusion

Based on the results of research and discussion that has been done can be concluded that:

a. Family support factors consisting of instrumental support, informational support, assessment support, and emotional support have an effect on increasing elderly hypertension personal mastery.

b. The role of integrated coaching post service is very helpful in improving elderly personal mastery which includes facilities, financial officer, nurse communication.

c. Personal mastery is the main basis in improving the ability of the elderly in the process of self care activity daily living. Personal mastery is the main focus in helping elderly people to do self care.

d. Self care agency is one component in nursing theory. The self care agency focuses on the ability of the elderly formed from the knowledge and motivation of the elderly.

e. Daily living self care activities become the main target in this study which includes food diets which means that the elderly are able to maintain and choose foods that are not at risk for increased blood pressure. Mild exercise is one solution besides being able to maintain stable blood pressure can also help bone health

Suggestion: Elderly with good personal mastery will always learn to achieve life goals in this case the elderly can recover from high blood pressure. Self awareness, knowledge and motivation become the main capital in improving self-care abilities. This is what attracts researchers to take personal mastery in elderly hypertension. The theoretical review states that the central role of personal mastery is to achieve a personal vision by continuing to learn from a life. The application of personal mastery is expected to be applied anywhere and in any condition.

Ethics approval and consent to participate: The experimental procedures on responden were approved by institutional ethics committee of Publict Health Faculty, Airlangga University Indonesia.

Informed Consent: Informed consent was given to the respondent along with the explanation that the research included anonymity and confidentially

Conflict of Interest: The authors declare that they have no competing interests. We have no conflicts of interest to disclose. It as nil

A Study to Assess the Effect of Community based Educational Programme Regarding Prevention of Anxiety Related to Child Birth among Primi Gravida Women in Selected Rural Community of Pune District

Prachi Shete[1], S.G. Joshi[2], Mangesh Jabade[3]

[1]Second Year MSC Nursing, [2]H.O.D. Research and Statistics, [3]Tutor, Symbiosis College of Nursing, Symbiosis International (Deemed University), Pune

Abstract

Introduction: Childbirth is one of the greatest events in every woman's life, especially among primi gravida mothers. Having had fantasies about pregnancy and motherhood when confronted with the reality many of them doubt their ability to cope with this great event in their lives. Many of the mothers do not know about what changes takes place and their role in the presence of childbirth. At this time, the mother to be needs lot of help for the realization and acceptance of childbirth as a normal physiological phenomenon[1].

Objectives: To assess the anxiety regarding child birth process among Primi gravida women, To compare the effectiveness of community based education on anxiety related to child birth among Primi Gravida women, To determine the association between the selected demographic variables with post assessment level of anxiety among Primi Gravida women.

Materials and Method: Pre Experimental, One group pre-test-post-test design was usedon 60 women of primigravida in selectedrural area. Non probability purposive sampling technique was used for data collection. Modified Zunkself-rating scalewas used. Community based education was given.

Result: Paired t-test was used to assess the effectiveness of community based education on anxiety related to child birth. Average anxiety score in pre-test was 49.4 which reduced to 39.9 in post-test. Corresponding p value was 0.000, which is small (less than 0.05), the null hypothesis is rejected.

Conclusion: This study concludes that, through community based education anxiety related child birth was reducing among primigravida mothers.

Keywords: *Anxiety; community based education; Primi Gravida.*

Introduction

A woman's ability to adapt to the changes and challenges of pregnancy is unique and the level of the stress she experiences affects the outcome of pregnancy. Most studies reported varied prevalence rate from different parts of the world and majority of them explored general anxiety than pregnancy-specific anxiety. Prevalence of high anxiety disorders in pregnant women was found to be undiagnosed and untreated[2].

Childbirth has an intense event and strong emotions, both positive and negative, can be brought to the surface. Abnormal and persistent fear of childbirth is known as tokophobia[3].

Need of study: Each year, complications from pregnancy and childbirth result in about 500,000 maternal deaths, 7 million women have serious long term problems, and 50 million women have health negative outcomes following delivery. Most of these occur in the developing world[4].

In 2015 there were about 135 million births globally. In that 15 million were born before 37 weeks of gestation[5].

Hypothesis: H_{0}_There is no significant effect of community based education on anxiety regarding child birth in Primi parous women.

Material and Method: Quantitative approach Pre Experimental One group pretest post-test design was used. The sample was chosen for this study was 60 primigravida women by using purposive sampling technique which filled the inclusion criteria and were selected from rural community of Pune district. The tool used for this study was demographic data (age in years, antenatal visit, L.M.P., education, occupation, current living status, injection TT, family income per month).

Inclusion Criteria: Women who is giving first time birth to the child. Women in the third trimester.

Exclusion criteria: Women who are not willing to participate in the study. Primi gravida women who has diagnosed as high risk pregnancy. The women who are going for a prenatal classes. Women who has taken a fertility treatment.

Data Collection: A formal letter seeking approval to conduct the main study was taken. The data collection was carried out from 20/2/2018 to 29/3/2018. A systematic plan was prepared for the study and efforts were to made to stick to the planned scheduled.

Findings: The data and findings have been organized and presented under the following sections:

Section I: Analysis of data related to demographic data in terms of frequency and percentage.

Table No. 1: Distribution of demographic variables (N= 60)

Characteristics	Category	Frequency	Percentage
Age	below 20	29	48.2
	21-30	31	51.6
	31-40	0	0
	above 40	0	0
Antenatal visit	first visit	0	0
	second visit	13	21.6
	third visit	47	78.3
Education	Graduates and above	3	5
	Post high school diploma.	27	45
	High school certificate.	20	33.33
	Primary school certificate.	11	18.3
Occupation	Profession	3	5
	Farmer	16	26.6
	skilled worker	5	8.33
	unskilled worker	13	21.6
	house wife	23	38.3
Current living status	mothers house	10	16.6
	In laws house	26	43.3
	Independent	24	40
injection TT	first dose	0	0
	second dose	60	100
family income per month	>41430	0	0
	20715-41429	3	5
	15536-20714	11	18.3
	10357-15535	26	43.3
	6214-10356	15	25
	2092-6213	5	8.3
	<2091	0	0

Section II-level of anxiety among primigravida mothers.

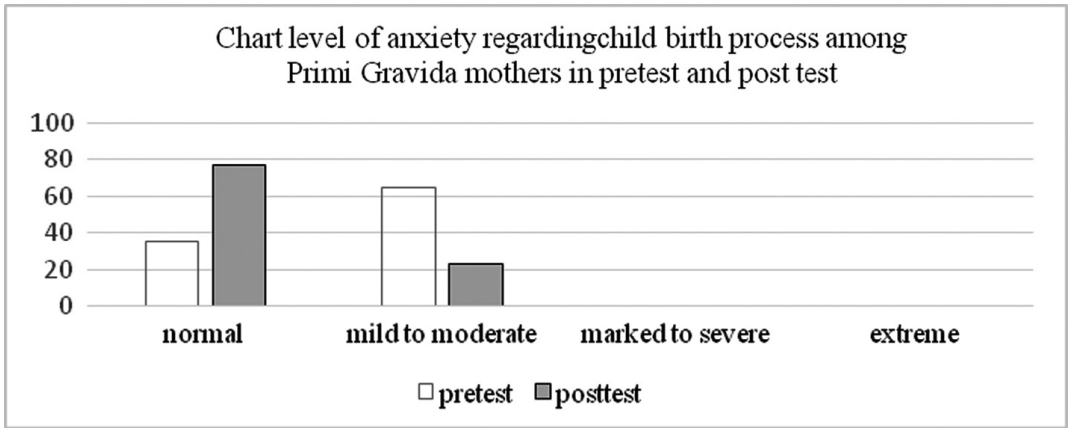

Fig. No. 1: Level of anxiety among primigravida mothers (pre-test and post-test). N=60

Fig. 1 Shows that, in pre-test, 35% of the primi gravida mothers had normal anxiety and 65% of them had mild to moderate anxiety. In post-test, 76.7% of the primi gravida mothers had normal anxiety and 23.3% of them had mild to moderate anxiety. This indicates that the anxiety related to child birth among Primi Gravida women reduced remarkably after community-based education.

Section III: Analysis of data related to the effectiveness of community-based education on anxiety related to child birth among Primi Gravida women.

Table no. 2: Paired t-test for effectiveness of community-based education on anxiety related to child birth among Primi Gravida women N=60

	Mean	SD	T	df	p-value
Pre-test	49.4	5.7	20.6	59	0.000
Post-test	39.9	4.1			

Table 2 shows that paired t-test used for effectiveness of community-based education on anxiety related to child birth among Primi Gravida women. Average anxiety score in pre-test was 49.4 which reduced to 39.9 in post-test. T-value for this test was 20.6 with 59 degrees of freedom. Corresponding p-value was 0.000, which is small (less than 0.05), the null hypothesis is rejected. It is evident thatthe anxiety related to child birth among Primi Gravida women reduced significantly after community-based education i.e. community-based education is significantly effective in reducing the anxiety among primi gravida mothers.

Section IV: Analysis of data related to association between the selected demographic variables with level of anxiety among Primi Gravida women

Table 3: Fisher's exact test for association between the selected demographic variables with post assessment level of anxiety among Primi Gravida women N=60

Demographic variable		Mild to moderate	Normal	p-value
Age	21-30	20	11	1.000
	Below 20	19	10	
Antenatal visit	Second visit	11	2	0.114
	Third visit	28	19	
Education	Graduate and postgraduate	3	0	0.542
	High school certificate	12	8	
	Intermediate or post high school diploma	18	8	
	Primary school certificate	6	5	

Demographic variable		Mild to moderate	Normal	p-value
Occupation	Farmer	12	4	0.186
	Housewife	16	7	
	Profession	3	0	
	Skilled worker	3	2	
	Unskilled worker	5	8	
Current living status	In laws house	16	10	0.215
	Independent	14	10	
	Mothers house	9	1	
Family income per month	Rs. 10357-15535	16	10	0.548
	Rs. 15536-20714	7	4	
	Rs. 20715-41429	3	0	
	Rs. 2092-6213	2	3	
	Rs. 6214-10356	11	4	

Since Antenatal visit, Occupation and Current living status, p-values are less (smaller than 0.5), so this demographic variable was found to have significant association with the level of anxiety among primi gravida mothers.

Discussion

This findings are supported by the study which was conducted by Rut Khaikin, Yehudit Marcus, Shoshana Kelishek, Chaya Balik, on "The effect of childbirth preparation courses on anxiety and self-efficacy in coping with childbirth", shows that After completing the preparation courses the anxiety level dropped significantly in the long and short course groups (p =.04 and p =.01, respectively). The anxiety in both groups was significantly related to the self-efficacy for coping with childbirth (r =-0.26, p =.03 and r =-0.48, p =.001, respectively)[6]

Megha Kadam Dr. S. G. Joshi, conducted a study on "Effect of Prenatal Teaching on Pregnancy Wellbeing" and they found the almost complications occurred because of lack of knowledge regarding prenatal care and health facility in low-resource settings, and most could have been prevented. Findings revealed that pre-test knowledge score was less. After prenatal teaching 42(70%) of them possess good knowledge and 18 (30%) under average score. It was observed that there is significant difference between pre-test and post-test knowledge score. The findings suggest that increases in knowledge level after prenatal teaching and it helps to create awareness in community[7].

Conclusion

One of the major roles that nurse play is educating the client and community regarding various health related facts. Community based education given to the group and it found effective in reducing anxiety related to child birth. This study help to know the level of anxiety and also the effect of education on that anxiety among the rural women.

Customer Perception Towards Organic Products: An Exploratory Study

Prakash N.[1], S. Gurusamy[2]

[1]Research Scholar, [2]Professor and Head, Department of Commerce, University of Madras, Chennai

Abstract

Organic products are obtained by processes which are friendly to the environment, by crop techniques that consider both the attributes of final product and production method. The consumption of organic food has increased in recent years as a result of its direct impact on consumer health, lifestyle and social convenience, as well as on the environment and sustainable development. The demand for organic products in India has been growing significantly during the last five years. Consumers are willing to pay more for organic products. This article investigates the customers' perception and attitude towards organic products. The data was collected from 200 respondents using questionnaire and analyzed by descriptive and inferential statistics. The findings revealed that the willingness of consumers to buy organic products is influenced by limited and erratic supply, higher price of products and very limited access and information.

Keywords: *Consumer Behavior, Organic Produce, Environmental Sustainability.*

Introduction

The rapid growth in industrial development along with the population explosion is increasing the pressure on agricultural production method to improve crop yield. Many studies have raised concerns about the Increase levels of chemical fertilizer use to increase the yield of food production. Awareness about the harmful effects of these highly polluting food products is growing among the consumers. As an alternative to these, more people are turning to organic food products. Organic foods are part of agricultural food products that are not treated with chemical fertilizers, pesticides, herbicides and other synthetic chemicals during their production, processing and storage. In addition, organic food products they do not contain genetically modified materials, with the aim of achieving a sustainable agriculture system. In Cattle breeding, organic method does not use growth hormones, antibiotics and other chemicals to improve the increase. The growth and consumption of organic food products have increased dramatically in recent years due to the increase of health consciousness. Before a product can be labeled as "organic," a Government-approved certifier inspects the farm where the food is grown to make sure the farmer is following all the rules necessary to meet US Department of Agriculture (USDA) organic standards before it is certified.

Organic food market in India–Current Scenario: Organic farming is an ancient concept in India in terms of the extensive agriculture that takes place in the country. The organic food market is worth USD 129.3 million and shows great potential for growth in the future. The growing export market and government support, has boosted the market. An analysis of the drivers explains the factors for the growth of the industry including the huge export market, the improved organized retail distribution network, government initiatives and the increase of health awareness among consumers. The main challenges identified include the high prices of organic food, the lack of an integrated supply chain and the difficulties for farmers, the barriers to certification. The competition section provides an overview of the competitive landscape, including brief profiles of key national producers and promoters of organic food products. The key development sections provide an overview of the developments related to the last year. Under current government policy, it takes approximately three years for a conversion farm to be certified as organic, and the costs are hefty for the small farmer.

Scope And Importance of the Study: With rising concern of health issues and food safety, many consumers have turned their site to organic products. The increased consumers' interest in organic has been

attributed among others to the growing demand for food free from pesticides and chemical residues. This study attempted to gain knowledge about consumer motivators towards organic product consumption,consumer's perception towards organic products, willingness to pay for organic product and intention to purchase organic will be the main agenda of this study.

Objectives of the Study

- To investigate the motivators and inhibitors for the purchase and use of organic products.
- To study the consumers' consumption pattern of organic products with demographic variables.

Literature Review: Actual purchasing patterns, seeking to quantify the extent of purchase of organic food and the consumer′s commitment Davies *et al*. (1995)[1]. Estimation of the influence of consumers' views of specific food aspects (attributes) and personal attributes on demand for organic foods Onyango *et al.* (2007)[2]. (2009)[4]. U.S. consumer attitudes toward organic foods in order to demonstrate that multiple and meaningful segments can be identified based on attitudes and beliefs rather than demographics and that a more targeted marketing strategy could likely create a better fit with consumer wants and needs Stanton*et al*. (2010)[5]. Determine the factors influencing consumer behavior towards organic food Paul*et al*. (2012)[6]. The demographic differences between the with respect to Swedish consumers' attitudes towards organic foods (milk, meat, potatoes, and bread), purchase frequency, purchase criteria, perceived availability, and beliefs about organic foods Magnusson *et al.* (2001)[7]. Respondents are willing to pay a premium if they have already purchased organic products, have good health, strong ethical and environmental concerns, think that organic products provide greater quality and health benefits, and reside in the city Sriwaranun *et al*. (2015)[8]. Insight into the purchase of organic food products by consumers and to explore the main factors driving this process Xie*et al.* (2015)[9].

Methodology

In order to identify the perceptions and attitude of Indian consumers about organic products, the researchers used descriptive research design. Convenience sampling method was employed for the study. Information's were gathered by both primary and secondary data sources. For the purpose of primary data structured questionnaire was used and for the secondary sources books, journals, and research papers are used by the researchers. Self administered questionnaires were distributed to 200 individuals in order to elicit the organic consumers' perception and attitude towards organic products and the factors that positively contributed for the formation, change and maintenance of these attitudes. The data collected were coded, computed, and analyzed using the Statistical Package for Social Sciences (SPSS) version 21 software.

Limitations

- The study focuses only on the Consumers' attitude towards organic products.
- The study conducted for the short period of time with 200 samples.
- The study has been conducted in the Chennai city only.

Data Analysis & Discussion

Table 1

S.No.	Variables	Frequency	Percentage
1	**Gender:**		
	Male	93	46.5
	Female	107	53.5
2	**Age:**		
	18-25	180	90.0
	26-35	20	10.0
	36-45	0	0
	Above 45	0	0
3	**Education:**		
	Higher Secondary	9	4.5
	U.G	19	6.5
	P.G	176	88.0
	Others	2	1.0
4	**Occupation:**		
	Student	189	94.5
	Employee	7	3.5
	Businessmen	4	2.0
	Housewife	0	0
5	**House Hold Monthly Income:**		
	UPTO Rs 20,000	85	42.5
	Rs 20,001-Rs 50,000	77	38.5
	Rs 50,001-Rs 1,00,000	23	11.5
	Above Rs 1,00,000	15	7.5

Demographic Profile: It can be observed that of the total respondents, majority are female respondents. 90% of the respondents are in the age group of 18-25 years. The distributions of the respondents based on their educational qualification reveals that post graduates constitute 88.0% of the sample unit. It can be deduced that student constitute a maximum of 94.5%. Respondents with household income of up to Rs.20,000 and between Rs.20,001-Rs.50,000 constitute a maximum of 42.5% and 38.5% of the sample unit respectively.

Table 2: Gender wise opinion of consumer preference on organic products

Products	Male		Female	
	Frequency	Percentage	Frequency	Percentage
Produce	11	11.8	12	11.2
Processed foods (Cereal etc)	23	24.7	20	18.6
Meat, Egg, Poultry	32	34.4	19	17.7
Vegetables	27	29.1	56	52.5
Total	**93**	**100**	**107**	**100**

The above table reveals that female respondents (52.5%) are majority when compare to male in preferring organic vegetables, whereby male respondents are showing most of the preference to meat, egg, Poultry (34.4%), processed foods (24.7%), Produce (11.2). It is inferred that most of the male respondents are preferring varieties of organic products and female respondents prefer only vegetables.

To identify the respondents' opinion on Environmental concerns and Eco-friendly products, t test was used to analyze the data and the results are presented below.

Table 3: Independent t-test on Attitudes

Groups						
Statements	**Variable**	**N**	**Mean**	**Std. Deviation**	**T-Value**	**Significance**
Experience major ecological disaster	Male	93	4.24	.107	3.946	0.000
	Female	107	3.98	.911		
Agreement to change the current standard of living	Male	93	3.88	.750	4.924	0.000
	Female	107	3.88	.844		
Exaggeration on environment problems	Male	93	3.82	.073	6.980	0.000
	Female	107	3.75	.870		
Consumers power to remove polluted products in the market	Male	93	3.97	.814	12. 903	0.000
	Female	107	3.98	.879		
Organic products not different from conventional products	Male	93	2.78	.160	14.792	0.000
	Female	107	3.44	.933		
Preparedness to buy organic products though expensive	Male	93	3.67	.036	26.442	0.000
	Female	107	3.93	.669		

T test was applied to identify the Gender wise attitudes of the respondents on environmental concerns and eco-friendly products. The results show that there is significance at 5% level in the opinion of the respondents. The study reveals the following.

- With regard to the opinion on the effect of environmental degradation male respondents agree to a great extent that environmental degradation will lead to environmental disasters.
- With regard to the opinion on compromising the

current living standard to protect the environment, there are differences in the opinion of male and female respondents.

- Male respondents optimistically agree that the current claims that environmental problems are changing the earth's climate are exaggerated.
- Regarding the power of the consumers to avoid the products that pollute the market the opinion of the female respondents are better than the male respondents.
- Majority of the female respondents are of the opinion that organic products are not different from conventional products.
- Majority of the respondents agree that people should be prepared to buy organic product though it is expensive.

To test the significant difference among demographic variables with respect to Environmental concerns and Eco-friendly products ANOVA was used.

H_0–There is no significant difference between demographic variables and opinion on eco-friendly products.

H_1–There is significant difference between demographic variables and opinion on eco-friendly products.

Table-4

Anova					
Variables	**Sum of Squares**	**Df**	**Mean Square**	**F**	**Sig.**
Age	4.448	14	.342	4.696	0.000
	13.552	186	.073		
	18.000	200			
Education	6.457	14	.497	1.720	0.060
	53.698	186	.289		
	60.155	200			
Occupation	8.061	14	.620	3.481	0.000
	33.134	186	.178		
	41.195	200			
Monthly Income	14.737	14	1.134	1.423	0.152
	148.143	186	.796		
	162.880	200			

While analyzing the significant difference on the demographic variables and respondents' opinion on attitudes toward eco-friendly products, the above table reveals that the results are statistically significant for two demographic variables namely gender and age. Thus the null hypothesis is rejected and alternative hypothesis is accepted. For the variables on education (0.60) and monthly income (.152) the P values are not statistically significant at 5% level.Since the P values are greater than.050 the null hypothesis is accepted. Therefore it can be inferred that there is significant difference in the opinion of the respondents on organic products with reference to environmental degradation, cost of organic products, willingness to buy organic products, and on the difference between organic and conventional products. But based on education and income there is no significant difference in the opinion on organic products.

Findings & Conclusion

Demographic profile of the respondents

- Majority (53.5%)* of the respondents are the female.
- Majority (90%)* of the respondents are in the age group of 18-25 years.
- Majority (88%)* of the respondents are post graduates.
- Most (42.5%)* of the respondents have monthly income of Up to Rs 20000. Majority (94.5%)* of the respondents are students.

*(for the above result refer table 1)

Motivators and Deterrents of Consumers' Purchasing Organic Products: T test was applied to identify the Gender wise attitudes of the respondents on

environmental concerns and eco-friendly products. The results show that there is significance at 5% level in the opinion of the respondents.

*(for the above result refer table 3)

The results are statistically significant for two demographic variables namely gender and age. Thus the null hypothesis is rejected and alternative hypothesis is accepted. For the variables on education and monthly income the values are not statistically significant at 5% level. Hence the null hypothesis is accepted. There is significant difference in the opinion of the respondents on organic products with reference to environmental degradation, cost of organic products, willingness to buy organic products, and on the difference between organic and conventional products. But based on education and income there is no significant difference in the opinion on organic products.

*(for the above result refer table 4)

Consumers' Consumption Pattern of Organic Products: Majority of the female respondents (52.5%)* are preferring organic vegetables when compare to male, whereby male respondents are showing most of the preference to meat, egg, Poultry (34.4%)*, processed foods (24.7%)*, Produce (11.2)*. It is inferred that most of the male respondents are preferring varieties of organic products and female respondents prefer only vegetables.

*(for the above result refer table 2)

Conclusion

Consumer behavior plays a major role in Organic products segment. The marketers of organic products need to be innovative and dynamic in order to complete with the changing purchase behavior in the Organic food products market among consumers. The importance of organic food products was ignored for quite a long period. As a result of environmental sustainability, importance is shifted towards Organic food products rather than conventional farming. The study brought out the fact that the people were aware of organic products, but not entirely converted in to organic. Knowledge and awareness about organic products could affect attitudes and perceptions about the product and, ultimately, buying decisions of the consumers. Vegetables followed by Meat, Eggs are the most preferred and highly demanded commodities at present. So we conclude that Consumers' willingness to purchase organic products is influenced by limited and erratic supply, higher price of the products and very limited access and information.

Assessing the Knowledge of Post Natal Mothers Regarding Danger Signs of Neonates at Various Health Facilities in Bihar: A Survey

Preysi Chauhan[1], Abhinandan Anand[2], Poonam Joshi[3]

[1]Assistant Professor, Ved Nursing College, Panipat, [2]District Technical Officer-Out reach and Nutrition, Care India, Bihar, [3]Lecturer, College of Nursing AIIMS, New Delhi

Abstract

Introduction: India accounts for 25% of the mortality around the world. According to the National Family Health Survey (NFHS-4) report and data shown by Niti Ayog in 2013, the neonatal mortality rate (NMR) in India is 28 per 1,000 live births, which accounts for more than half of the under-five child deaths (50/1000). The majority of the new-born deaths occur at home where a few families recognize signs of newborn illness. Delay in recognizing the signs of neonatal illnesses contributes to the death of a neonate.

Aim: To assess the knowledge of post natal mothers regarding danger signs of neonates at various primary health centres in Bihar, India

Methodology: A descriptive cross sectional survey was conducted at 54 health facilities of 16 districts in Bihar in the month January, 2017 using self developed, pretested and validated structured questionnaire. Tools were validated and reliability was tested ($\rho = 0.74$). Data collected from 277 post natal mothers were analysed. Knowledge of mothers was classified into three categories, poor knowledge (score 1-5), average knowledge (score 6-10) and good knowledge (score 11-15).

Result: More than one third (35.7%) mothers were third to fifth gravida. Most of the mothers (41.2%) attended two antenatal visits. Around half (50.6%) of the mother responded that they are aware of any danger in neonate. More than one third (45.5%) of the mothers were aware of fever as neonatal danger sign. Most of the mothers (39.7%) had poor knowledge regarding danger signs.

Conclusion: The finding of the study showed at health facilities post natal mothers had poor knowledge regarding danger signs of neonate. This alarms the need of continuous monitoring of post natal educational services and it also depicts the enhancement of educational efforts for effective education of mothers regarding early recognition of danger signs of neonate.

Keywords: *Knowledge, post-natal mothers, danger signs, neonates.*

Introduction

There are 25 million babies born every year in India, of which, one million die in one year. This accounts for 25% of the mortality around the world. Child health is the important indicator of health for a country. Therefore, eight millennium development goals (MDG) were set by United Nations in the year 2000. Out of 8 MDGs, MDG 4 was aimed to reduce child mortality rate by two third till the end of year 2015. Now the sustainable development goal (SDG, 2015) also aims towards good health and well being for all.[1,2]

According to the National Family Health Survey (NFHS-4) report and data shown by Niti Ayog in 2013, the current neonatal mortality rate (NMR) in India is 28 per 1,000 live births, which accounts for nearly 68% of all the infant deaths (41/1000) and more than half of the under-five child deaths (50/1000).In India, the neonatal mortality rate varies widely among the different states, ranging from 6 per 1000 live births in Kerala to 37 per thousand live births in Odisha. According to a report,the four big states namely Uttar Pradesh, Madhya Pradesh, Bihar and Rajasthan account for 46% of all births and

57% of India's neonatal deaths. Odisha, Chattisgarh contribute tohigh neonatal deaths in India.[3,4 5]

A recent systematic analysis suggests that around 44% of the under-5 mortality occurs during neonatal period, thereby emphasizing the importance of neonatal period for improving child health indicator[1].The primary causes of neonatal deaths are sepsis (52%), birth asphyxia (20%), prematurity (15%) and otherscause (13%).[6,7]There is slow progress of illness in neonates and hence they are often present with non-specific signs and symptoms of severe illness[8]. Even the single sign of feeding difficulty can be indicative of severe sickness in neonates. The majority of the new-born deaths occur at home where a few families recognize signs of newborn illness. Delay in recognizing the signs of neonatal illnesses contribute to the death of a neonate therefore, early recognition of these signs and seeking prompt medical care is necessary for improvement of health indicators of children[6, 9].

There are several studies conducted in southern and northern parts of the India to assess the knowledge of mother regarding danger sign of newborn but no study has been conducted yet in Bihar to assess the knowledge of post natal mothers regarding danger signs Therefore, the present study was undertaken to find out the postnatal mothers' knowledge regarding danger signs of neonates at various health facilities in Bihar. Findings of the present study would help us in planning some interventions for the postnatal mothers in future.

Material and Method

A descriptive study aimed to assess the knowledge of post natal mothers regarding danger signs of neonatesat various primary health centres in Bihar, India.

Setting: Current study was conducted in Bihar, the 12th largest state of India. Bihar is located in the eastern part of the country (between 83°-30' to 88°-00' longitude). Bihar is the state with 38 districts in it, total 534 blocks in it. It contributes to the huge population of India that is 10,38,04,637 (Census 2011)[10.]

For improvement in maternal and child health indicators CARE India with the collaboration of government of Bihar launched a mentoring programme named as AMANAT (apatkalin matritva evam navajat tatparta karyakram) in year 2013. The programme was launched in 4 phases in different districts of Bihar in order to cover the maximum health facilities of Bihar. Current study was conducted in 54 health facilities of 20 districts where the Phase IV AMANAT programme was going on. Out of 20 districts, pilot study was conducted in 4 districts named as Vaishali, Nawada, Gaya and Supaul districts on 30 sample and study was found feasible. The distribution of the districts where data was collected for study is given below in the map:

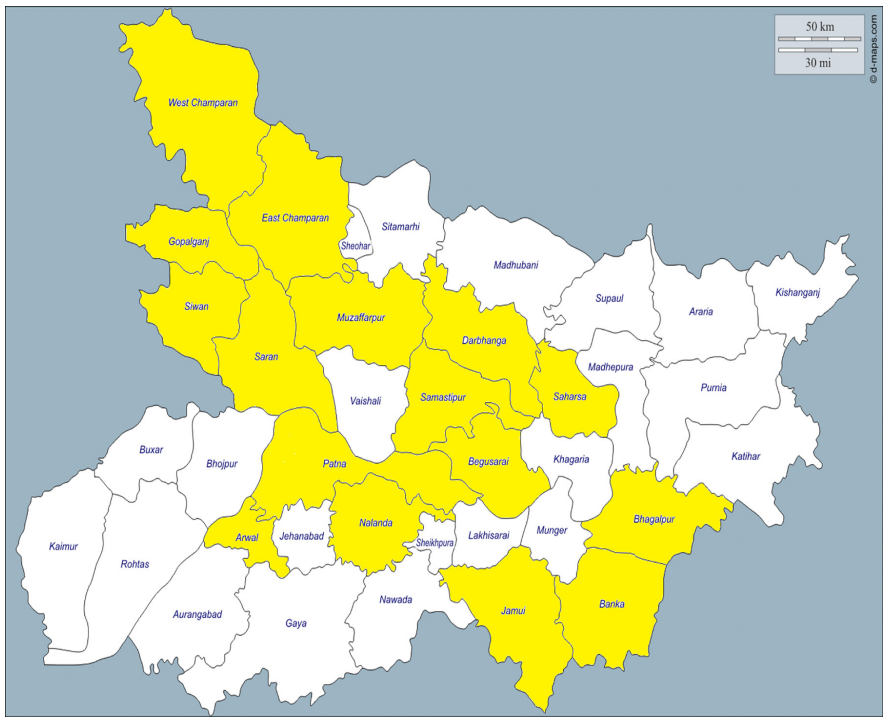

Figure 1: Represents the map of Bihar. Area indicates the districts selected for data collection.

Sampling and Data collection: The present cross sectional survey was conducted at various health facilities of Bihar in the month January, 2017 using self developed, pretested and validated structured questionnaire. Tools were validated by five experts. Reliability was tested by split half method and cronbach's alpha was found to be 0.74. WHO's neonatal danger signs were included in the tool. Convenient sampling method was used. Mothers who responded yes for having knowledge of neonatal danger signs were asked for the signs they know and for each correct response score given was 1 and for incorrect response 0 score was given. Knowledge of mothers was classified into three categories, poor knowledge (score 1-5), average knowledge (score 6-10)and good knowledge (score 11-15). Based on the previous studies the calculated sample size was 310. Out of 310, data from 33 sample was lost during storage. Therefore, data from 277 mothers were finally analysed.All mothers who delivered in facility and stayed for more than 2 hours after delivery and agreed to participate in the study were enrolled. Each participating women was explained the purpose of study. Confidentiality and anonymity was ensured. Written informed consent was obtained from participating mothers; those who were illiterate were asked to give left thumb impression on a consent form that was read to her before data collection.

Results

Table 1: Socio-demographic profile of mothers n=277

Variables	Frequency (f)	Percentage (%)
Location of residence		
Rural	254	91.7
Semi-urban	19	6.9
Urban	4	1.4
Religion		
Hindu	240	86.6
Muslim	36	13
Christian	01	0.4
Caste		
General	63	22.7
Other backward caste	135	48.7
Schedule caste	64	23.1
Schedule tribe	15	5.4
Level of education		
Illiterate	102	36.8
Primary education	35	12.6
Matriculation	100	36.1
Intermediate	24	8.7
Graduation and above	16	5.8
Occupation		
House wife	264	95.3
Labour	7	2.5
Farmer	2	0.7
Service/job	4	1.5
Monthly family income (in Rs.)		
Less than 5000	149	53.8
5000-10000	99	35.7
More than 10,000	29	10.5
Parity		
Primigravida	91	32.9
Secondgravida	80	28.9
Third–fifth gravida	99	35.7
Equal to or more than 6	7	2.5
No. of Antenal visits attended		
No visit	31	11.2
One visit	59	21.3
Two visits	114	41.2
Three or more than three	73	26.4
Facility opted for ANC visits (if attended)		
Anganwadi	156	63.4
Subcentre	22	8.9
Primary health centre	54	21.9
Subdivisional/ district hospital	12	4.8
Private clinic/ private hospital	2	0.8

Mean age of mothers were 24.04 with standard deviation of 3.43. Majority (91.7%) of mothers were residing in rural area. Majority (86.6%) belonged to Hindu religion. Most (48.7%) of the mothers were from other backward caste. More than one third (36.8%) of the mothers were illiterate and 36.1% were educated up to matriculation. Majority (95.3%) of the mothers were housewives. Monthly family income of more than half of the mothers (53.8%) was less than Rs. 5000/-. More than one third (35.7%) mothers were third to fifth gravida and 32.9% were primigravida. Most of the mothers (41.2%) attended two antenatal visits. Out of those who attended antenatal visits, most (63.4%) mothers opted anganwadi for antenatal check up.

Table 2: Response of mothers regarding awareness of danger signs of neonates n= 277

Variables	Frequency (f)	Percentage (%)
Do you know any danger sign in neonate		
Yes	140	50.6
No	137	49.4

Around half (50.6%) of the mother responded that they were aware of any danger in neonate.

Table 3: Knowledge of mothers regarding danger signs of neonates n= 140

Variables	Frequency (f)	Percentage (%)
Not feeding well	71	25.6
Convulsion	14	5.1
Drowsy or unconscious	28	10.1
Movement only when stimulated or no movement at all	14	5.1
Fast breathing	49	17.7
Neonate is producing sound during breathing	14	5.1
Severe Chest indrawing	13	4.7
Fever	126	45.5
Baby cold to touch	92	33.2
Bluish coloured baby	12	4.3
Yellow palms and soles	16	5.8
Umbilicus red or draining pus	16	5.8
Skin boils	26	9.4
Eyes draining pus	9	3.2
Diarrhoea	65	23.5

More than one third (45.5%) of the mothers were aware of fever as neonatal danger sign. Out of 140 mothers who responded yes about One third (33.2%) of the mothers were aware that baby cold to touch is neonatal danger sign. Not feeding well and diarrhoea were known neonatal danger signs by 25.6% and 23.5% of the mothers respectively.

Table 4: Knowledge score of mothers regarding danger sign n= 140

Category	Frequency	Percentage
Poor knowledge	110	78.6
Average knowledge	27	19.3
Good knowledge	3	2.1

Most of the mothers (39.7%) had poor knowledge regarding danger signs. Very less 2.1% of mothers had good knowledge and 19.3% of mothers had average knowledge regarding danger sign.

Discussion

Mother is primary care taker for a child. Study have shown that unawareness regarding danger signs increases in the delay in seeking medical care, ultimately leads to high neonatal mortality rate. At facility level various efforts has been taken by the Bihar government to counsel the post natal mothers regarding post natal care of mothers as well as of baby. The present study was conducted at various facilities in Bihar to assess the knowledge of post natal mothers regarding danger signs of neonates delivered at facility. In the present study the knowledge of mother regarding danger sign was poor. Most of the neonatal were found having deficient knowledge regarding danger signs the result is in line with the study Uchenna Ekwochi et al[11] which also showed that mother were not aware regarding WHO danger signs. The resultsare also in line with study done by Jacob Sandberg[12]which also showed that mothers had poor knowledge regarding danger signs. In the present study fever (45.5%), baby cold to touch (33.2%), not feeding well (25.6%), and diarrhoea (23.5%) were known danger signs by post natal mothers. Most of the mothers identified fever as danger sign. In the study done by Shally Awasthy in U.P. also showed that majority of mothers are aware of fever as danger sign. The study results shows that danger signs which are specific to respiratory distress were not known to mothers. The umbilical area pus discharge which shows sepsis was not noticed by the mothers as danger sign. The present study showed that only few post natal mothers had good knowledge regarding danger sign, A study conducted by Solomon Gedlu Nigatualso showed that very less number of mothers had good knowledge regarding danger sign.

Limitation of the Study: Data was lost during the study so this study could not be produced on large sample size.

Recommendation: The present study was conducted in post natal mothers the similar study can be conducted in all mothers whose babies are neonates and those who are residing in community.

Conclusion

The finding of the study showed at health facilities post natal mothers had poor knowledge regarding danger

signs of neonate. This alarms the need of continuous monitoring of post natal educational services and it also depicts the enhancement of educational efforts for effective education of mothers regarding early recognition of danger signs of neonate.

Abstract

Background: Urinary tract infection is the second most commonly seen bacterial infection in the health care sector Each year, more than 8 million people were diagnosed with UTI. According to the National ambulatory medical survey, urinary tract infection accounted for nearly 7 million outpatient visits and 1 million emergency room visits, resulting in 1,00,00 hospitalizations.[4] Patients with type 2 diabetes mellitus are at increased risk of infections, with the urinary tract being the most frequent infection site.

Aims: The objectives were to assess the knowledge on prevention of UTI and to find out the association between the knowledge on prevention of UTI and selected demographic variables.

Materials and Method: This was a pre experimental one group pretest and post test design used over a period of 4 months. The sampling technique was simple random sampling technique with the sample size 32 women with type 2 diabetes mellitus and structured questionnaires was used to assess the knowledge on prevention of UTI. Seven days interval was kept between pretest and post test after the implementation of STP on prevention of UTI. Ethical clearance was obtained. The collected data was tabulated and analyzed. Descriptive and inferential statistical were used.

Result: The study result reveals that Pretest level of knowledge on prevention of Urinary Tract infection mean score was 4.62 and the Post test level of knowledge mean score was 9.37 which projects 't' value of 10.68 which was statistically significant at $p<0.05$ level. The post test knowledge score is greater than the pre test knowledge score. The Mean difference was 4.75. This indicates the structured teaching programme on prevention of urinary tract infection is effective in increasing the knowledge level, thereby it may reduce the frequency of UTI among type 2 Diabetic women.

Keywords: *Urinary tract infection (UTI), Structured Teaching Programme (STP), Type 2 Diabetes mellitus.*

Introduction

The prevalence of diabetes mellitus has increased over the past decades and it is now approaching epidemic proportions.Worldwide, 371 million people have diabetes and it is estimated that by 2030 this number will reach 552 millions,with larger increases in the developing than in the developed world. Changes in lifestyle,aging of the population and the increasing prevalence of obesity are responsible for this dramatic situation. Urinary tract infection are more common, more severe, and carry worse outcomes in patient with Type 2 diabetes mellitus. UTI more often caused by resistant pathogens. Various impairments in the immune system, poor metabolic control, and incomplete bladder emptying due to autonomic neuropathy may all contribute to the enhanced risk of urinary tract infection in these patients. The new anti-diabetic sodium glucose co-transporter 2 inhibitors have been found to significantly increase the risk of symptomatic urinary tract infection. Symptoms of urinary tract infection are similar to patients without

diabetes, though some patients with diabetic neuropathy may have altered clinical signs.

As per the WHO statement the urinary tract infection is most common among Type 2 diabetes women. All types of UTI are more frequent in patients with type 2 diabetes. Various studies have reported the overall incidence of UTI among these patients. A meta-analysis of 22 studies, published in 2011, found a point prevalence of 12.2% of ASB among diabetic patients versus 4.5% in healthy control subjects.[6] In a recent study from Europe, asymptomatic bacteriuria was more prevalent among women with diabetes (26%) than in women without diabetes (6%).Diabetic patients are at a high risk of development of UTIs, so it is recommended that special attention is paid to them, especially for the management of bacterial UTIs. Various risk factors such as sexual intercourse, age, duration of diabetes, glycemic control, and complications of diabetes are associated with UTI.[9] A cohort study of over 6,000 patients enrolled in ten clinical trials found an incidence rate of 91.5 per 1,000 person-years in women and 28 per 1,000 person-years in men, and a cumulative incidence of 2% during 6 months. An American database study during 2014 found that a UTI diagnosis was more common in subjects with diabetes compared to those without diabetes (9.4% vs 5.7%, respectively)[5]. Another study done in America with over 70,000 patients with DM type II found that 8.2% were diagnosed with UTI in 1 year (12.9% of female and 3.9% of male, with increasing incidence with age [7]. A Canadian study demonstrated that diabetic females were 6–15 times more frequently hospitalized for acute pyelonephritis than non-diabetic females, and diabetic males were hospitalized 3.4–17 times more than non-diabetic males. Asymptomatic bacteriurea was reported to have an increased prevalence in diabetics by about 8% to 25%, and was also found to have amplified occurrence with in patients with longer duration of diabetes [10].
